Session 1A FIAP: Industrial Physics Forum: History, Current Status, Future Prospects Ballroom C1

1:00PM 1A.00001 Room-Temperature Superconductivity: Prospects but Challenges[1] J.C. SEAMUS DAVIS, Brookhaven National Laboratory, Cornell University and St. Andrews University — Why do we not have ambient temperature superconductivity and all the benefits it would bring? If the challenge were less than profound, our celebrated industrial research/development approach should have succeeded in achieving this objective already. In fact, however, the unknowns we face with this issue are believed to involve entangled-many-body quantum mechanics beyond the limits of present understanding. We shall review these issues.

[1]This work was supported by the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Basic Energy Sciences.

1:40PM 1A.00002 Confirmation of BCS Theory and Its Impact on Applications Past and Future , MALCOLM BEASLEY, Stanford University — The experimental confirmation of BCS theory established it as the correct microscopic theory of superconductivity. It also led to applications of superconductivity distinct from those based on the Josephson effect and the magnetic properties of superconductors. The most prominent of these are SIS mixers for astronomy and high-Q filters for the cellular phone industry. In this talk we trace these historical developments and consider where today's more novel (beyond simple BCS) superconductors might be useful looking forward.

2:20PM 1A.00003 From BCS to Vortices: A 40 Year Personal Journey through Superconductivity from Basic Research to Power Applications , PAUL M. GRANT, IBM Research Staff Member Emeritus, San Jose, CA 95120 USA — A century has passed since the discovery of superconductivity in Leiden followed 75 years later by the Great Leap Forward in Zuerich.[1] This talk will chronicle the author's trajectory through the science and technology of superconductivity first taking off with his IBM career in fundamental research on organic and layered copper oxide perovskite superconductors to a final landing at EPRI to explore applications of the latter to the electric power industry. Although many fundamental mysteries remain with respect to the copper and iron compounds, especially regarding the BCS pairing mechanism, nonetheless a significant number of successful demonstrations of cables, rotating machinery, storage and power conditioning equipment employing both low-and high-T_C superconducting materials[2] have been undertaken worldwide since the decade of the 1960s to the present. However, massive application to the power industry has yet to take place or be inserted into utility long-range planning cycles.[3] Although there will certainly be a relatively small number of opportunistic deployments in those situations where superconductivity has a compelling advantage over conventional technology, its time will more likely await a future revolution in energy and electricity infrastructure such as a symbiosis[4] of nuclear and hydrogen with superconductivity. Perhaps the distant future will even deliver the dream[5] of a room temperature superconductor.

Sunday, March 20, 2011 3:30PM - 5:30PM –

Session 1B FIAP: Industrial Physics Forum: Large-Scale Applications Ballroom C1

3:30PM 1B.00001 Superconducting Materials, Magnets and Electric Power Applications , GEORGE CRABTREE, Argonne National Laboratory and University of Illinois at Chicago — The surprising discovery of superconductivity a century ago launched a chain of convention-shattering innovations and discoveries in superconducting materials and applications that continues to this day. The range of large-scale applications grows with new materials discoveries - low temperature NbTi and Nb_3Sn for liquid helium cooled superconducting magnets, intermediate temperature MgB_2 for inexpensive cryocooled applications including MRI magnets, and high temperature YBCO and BSSCO for high current applications cooled with inexpensive liquid nitrogen. Applications based on YBCO address critical emerging challenges for the electricity grid, including high capacity superconducting cables to distribute power in urban areas; transmission of renewable electricity over long distances from source to load; high capacity DC interconnections among the three US grids; fast, self-healing fault current limiters to increase reliability; low-weight, high capacity generators enabling off-shore wind turbines; and superconducting magnetic energy storage for smoothing the variability of renewable sources. In addition to these grid applications, coated conductors based on YBCO deposited on strong Hastelloy substrates enable a new generation of all superconducting high field magnets capable of producing fields above 30 T, approximately 50% higher than the existing all superconducting limit based on Nb_3Sn. The high fields, low power cost and the quiet electromagnetic and mechanical operation of such magnets could change the character of high field basic research on materials, enable a new generation of high-energy colliding beam experiments and extend the reach of high density superconducting magnetic energy storage.

4:10PM 1B.00002 High Temperature Superconductors for the Electric Power Grid , ALEXIS P. MALOZEMOFF, American Superconductor Corp. — High Temperature Superconductor power equipment is positioned to play a key role in addressing our national and global energy challenges. While the most obvious benefit is efficiency by using the superconductor's lossless current flow to cut the 10% power lost in the grid, other benefits are likely to be even more impactful. These benefits arise from the high current density of superconductor wire which enables design of highly power-dense and compact equipment including high capacity cables and rotating machinery – generators and motors. Vast and dense urban areas are becoming home to an increasingly large proportion of world population, and high capacity ac superconductor cables offer a non-interfering and easily installed solution to increasing urban power needs. Longer term, the ultra-low loss of long-distance dc superconductor cables offers strengthened links and power sharing across wide geographical areas. Compact superconductor generators are the key to high power off-shore wind turbines, a major source of renewable energy. Some of these applications have reached a sophisticated level of demonstration, initiating commercial use.

4:50PM 1B.00003 Industrial Large Scale Applications of Superconductivity – Current and Future Trends , KATHLEEN AMM, GE Global Research — Since the initial development of NbTi and Nb3Sn superconducting wires in the early 1960's, superconductivity has developed a broad range of industrial applications in research, medicine and energy. Superconductivity has been used extensively in NMR low field and high field spectrometers and MRI systems, and has been demonstrated in many power applications, including power cables, transformers, fault current limiters, and motors and generators. To date, the most commercially successful application for superconductivity has been the high field magnets required for magnetic resonance imaging (MRI), with a global market well in excess of $4 billion excluding the service industry. The unique ability of superconductors to carry large currents with no losses enabled high field MRI and its unique clinical capabilities in imaging soft tissue. The rapid adoption of high field MRI with superconducting magnets was because superconductivity was a key enabler for high field magnets with their high field uniformity and image quality. With over 30 years of developing MRI systems and applications, MRI has become a robust clinical tool that is ever expanding into new and developing markets. Continued innovation in system design is continuing to address these market needs. One of the key questions that innovators in industrial superconducting magnet design must consider today is what application of superconductivity may lead to a market on the scale of MRI? What are the key considerations for where superconductivity can provide a unique solution as it did in the case of MRI? Many companies in the superconducting industry today are investigating possible technologies that may be the next large market like MRI.

Monday, March 21, 2011 8:00AM - 11:00AM –

Session A1 DCMP: Silicon Qubits Ballroom A1

8:00AM A1.00001 Coherent control of donor states in Si[1] , THORNTON GREENLAND, London Centre for Nanotechnology and Department of Physics and Astronomy, University College London, WC1H 0AH, England — The spin degrees of freedom of group V donors in Si satisfy many of the criteria required for qubits [1,2]. The orbital Rydberg states of group V donors can also be used to control these spins coherently [3,4]. Critical to such schemes are the population (T_1) and dephasing (T_2) lifetimes of these Rydberg states. We describe the use the free electron laser FELIX [5] to perform pump-probe experiments to measure T_1 [6] and photon echo experiments to measure T_2 [7]. The lifetimes we obtain from a theoretical analysis of the experiments are $\sim$ 200 ps, which is long enough for orbital excitation to be a practical control mechanism for 2-qubit quantum gates. The experimental and theoretical analysis of these gates is also described.

8:36AM A1.00002 Single-shot readout and microwave control of an electron spin in silicon , ANDREA MORELLO, Centre for Quantum Computation and Communication Technology, University of New South Wales — The electron spin of a donor in silicon is an excellent candidate for a solid-state qubit. It is known to have very long coherence and relaxation times in bulk [1], and several architectures have been proposed to integrate donor spin qubits with classical silicon microelectronics [2]. Here we show the first experimental proof of single-shot readout of an electron spin in silicon. The device consists of implanted phosphorus donors, tunnel-coupled to a silicon Single-Electron Transistor (SET), where the SET island is used as a reservoir for spin-to-charge conversion [3]. The large charge transfer signals allow readout fidelity $> 90\%$ with 3 μs response time. By measuring the occurrence of excited spin states as a function of wait time, we find spin lifetimes (T_1) up to $\sim$ 6 s at $B = 1.5$ T, and a magnetic-field dependence $T_1^{-1} \propto B^5$ consistent with that of phosphorus donors in silicon [4]. In a subsequent experiment we have integrated the single-shot spin readout device with an on-chip microwave transmission line for coherent control of the electron spin. We have detected the spin resonance of a single electron, and observed two hyperfine-split resonance lines, consistent with Stark-shifted coupling to the ^{31}P nuclear spin. Further experiments are underway to demonstrate coherent spin control and observe Rabi oscillations. This demonstrates the microwave control of a single spin, combined – for the first time in the same experiment – with electrically detected single-shot spin readout.

9:12AM A1.00003 Integrated Quantum Photonics , JEREMY O'BRIEN, University of Bristol — Of the various approaches to quantum computing [1], photons are particularly appealing for their low-noise properties and ease of manipulation at the single qubit level [2]. Encoding quantum information in photons is also an appealing approach to quantum communication, metrology (eg. [3]), measurement (eg. [4]) and other quantum technologies [5]. However, the implementation of optical quantum circuits with bulk optics has reached practical limits. We have developed an integrated waveguide approach to photonic quantum circuits for high performance, miniaturisation and scalability [6]. Here we report high-fidelity silica-on-silicon integrated optical realisations of key quantum photonic circuits, including two-photon quantum interference and a controlled-NOT logic gate [7]. We have demonstrated controlled manipulation of up to four photons on-chip, including high-fidelity single qubit operations, using a lithographically patterned resistive phase shifter [8]. We have used this architecture to implement a small-scale compiled version of Shor's quantum factoring algorithm [9] and demonstrated heralded generation of tuneable four photon entangled states from a six photon input [10]. We have combined waveguide photonic circuits with superconducting single photon detectors [11]. Finally, we describe complex quantum interference behaviour in multi-mode inter- ference devices with up to eight inputs and outputs [12], and quantumwalks of correlated particles in arrays of coupled waveguides [13].

Monday, March 21, 2011 8:00AM - 11:00AM –

Session A2 DCMP: Compressibility and Transport in Bilayer Graphene Ballroom A2

8:00AM A2.00001 Electronic compressibility of bilayer graphene , ERIK HENRIKSEN, Caltech — We have recently measured the electronic compressibility of bilayer graphene [1], allowing exploration of the thermodynamic density of states as a function of applied electric and magnetic fields. Utilizing dual-gated field-effect devices, we can independently vary both the carrier density and the size of the tunable band gap. An oscillating voltage applied to a back gate generates corresponding signals in the top gate via electric fields lines which penetrate the graphene, thereby allowing a direct measurement of the inverse compressibility, K^{-1}, of the bilayer [2]. We have mapped K^{-1}, which is proportional to the inverse density of states, as a function of the top and back gate voltages in zero and finite magnetic field. A sharp increase in K^{-1} near zero density is observed with increasing electric field strength, signaling the controlled opening of a band gap. At high magnetic fields, broad Landau level (LL) oscillations are observed, directly revealing the doubled degeneracy of the lowest LL and allowing for a determination of the disorder broadening of the levels. We compare our results to tight-binding calculations of the bilayer band structure, and to recent theoretical studies of the compressibility of bilayer graphene. Together, these clearly illustrate the unusual hyperbolic nature of the low energy band structure, reveal a sizeable electron-hole asymmetry, and suggest that many-body interactions play only a small role in bilayer-on-substrate devices. This work is a collaboration with J. P. Eisenstein of Caltech, and is supported by the NSF under Grant No. DMR-0552270 and the DOE under Grant No. DE-FG03-99ER45766.

8:36AM A2.00002 Electronic Structure and Carrier Transport in Graphene Bilayers[1] , SHAFFIQUE ADAM, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, Gaithersburg, MD 20899 — Graphene bilayers come in different varieties ranging from the micro-mechanically exfoliated Bernal stacked sheets where the strongly coupled layers act like a single electronic material, to the essentially decoupled turbostratic graphene bilayers observed in both epitaxial and CVD grown graphene. In this talk I will first review the experimental evidence and early theoretical understanding for the band structure of bilayer graphene. I will then discuss electrical transport measurements and present the semi-classical theory for carrier transport in bilayer graphene. I will show that close to the Dirac point, the co-existence of electron and hole carriers gives rise to an interesting interplay between disorder and temperature [1-3]. For example, we predict that knowing the strength of the disorder potential from low temperature conductivity measurements completely determines the temperature dependence of the conductivity. Detailed comparison with recent experiments highlights both the successes and the shortcomings of this theoretical model. Finally, I will examine the different factors influencing the transport in twisted graphene bilayers. For example, the breaking of inversion symmetry results in a charge imbalance between the two layers giving rise to unexpected features in magneto-transport.

9:12AM A2.00003 Probing layer imbalance in bilayer graphene with electrostatic capacitance measurements , ANDREA YOUNG, Columbia University — In bilayer graphene, application of an external electric field modulates both the charge carrier density and the band structure itself. In particular, application of an electric field perpendicular to the sample plane opens up a band gap in the bilayer graphene energy spectrum, leading to insulating behavior at charge neutrality. Using capacitance measurements, we extract the electronic compressibility as a function of density, applied bias, and temperature. We find that the compressibility remains high even in the region in which a gap is expected, confirming that the insulating behavior observed in transport is due to transport via localized states. Temperature dependent capacitance measurements allow us to estimate the gap in the spectrum, which we find to be in qualitative agreement with that measured by optics. Away from charge neutrality, the density dependence of the compressibility is consistent with hyperbolic electronic bands. Features identified with the $1/\sqrt{\epsilon}$ van Hove singularity—expected for the nearly quartic dispersion of gapped bilayer graphene—are observed near the band edge. These features show a polarization dependent asymmetry, appearing only where the near layer is at lower energy layer for the corresponding carrier type. Using a model of bilayer graphene that incorporates the finite interlayer separation, we show that capacitance measurements in bilayer graphene are sensitive to *layer indexed* compressibilities, in addition to the total charge compressibility. This allows an unambiguous determination of the layer polarization of the ground state, a particularly useful tool in the study of the broken symmetry states observed at high magnetic field.

9:48AM A2.00004 Compressibility of bilayer graphene: the role of disorder , DAVID ABERGEL, University of Maryland — We discuss the role of disorder caused by charged impurities on the compressibility of bilayer graphene. In doing so, we take into account the full hyperbolic dispersion relation and the presence of a gap between the valence and conduction bands to produce an exact calculation of $\frac{d\mu}{dn}$ for the non-disordered case. We then introduce two methods for including the disorder in a statistical way and evaluate the effectiveness of each by comparing their predictions with recent experiments. We find that averaging is best done at the level of the observable quantity: in this case the compressibility. This work is done in collaboration with Sankar Das Sarma and Euyheon Hwang, and supported by US-ONR, NRI-SWAN, and UMD-CNAM.

10:24AM A2.00005 Local Compressibility Measurements of Correlated States in Suspended Bilayer Graphene[1] , JENS MARTIN, Harvard University — Bilayer graphene has attracted considerable interest due to the important role played by many-body effects, particularly at low energies. The exceptional quality of suspended devices has enabled the observation of interaction-driven broken-symmetry states and the fractional quantum Hall effect. Here we report local compressibility measurements of a suspended graphene bilayer. We find that the energy gaps at filling factors +/- 4 do not vanish at low fields, but instead merge into an incompressible region near the charge neutrality point at zero electric and magnetic field. These results indicate the existence of a zero-field ordered state and are consistent with the formation of either an anomalous quantum Hall state or a nematic phase with broken rotational symmetry. At higher fields, we measure the intrinsic energy gaps of broken-symmetry states at filling factor 0, +/- 1 and +/-2, and find that they scale linearly with magnetic field, yet another manifestation of the strong Coulomb interactions in bilayers.

Monday, March 21, 2011 8:00AM - 11:00AM –
Session A3 DCMP: Experimental Studies of 5/2 Fractional Quantum Hall Effect Ballroom A3

8:00AM A3.00001 Observation of neutral modes via shot noise measurements , MOTY HEIBLUM, Weizmann Institute of Science — Current propagates in the quantum Hall regime along the edges of a two-dimensional-electron gas via chiral edge modes, with chirality dictated by the applied magnetic field. In the fractional regime, for some fractional states - the so called "holes-conjugate" states – e.g., between filling factor 1/2 and 1 - early predictions suggested the presence of counter propagating edge modes: a "downstream" mode with the expected chirality and an "upstream" mode with an opposite chirality. Since experiments in the ubiquitous 2/3 state did not find upstream propagating edge modes, it had suggested that in the presence of interactions and disorder edge reconstruction may take place with a resultant downstream charge mode accompanied by upstream neutral mode - with the latter carrying only energy - thus explaining why the upstream modes were not detected thus far. Moreover, a neutral upstream Majorana mode is also expected for selected wavefunctions proposed for the even denominator state 5/2. I will review some of our observations of neutral modes in selected quantum Hall states. Neutral mode detection was performed by allowing a chiral mode to impinge on a quantum point contact (QPC) constriction. The partitioning of the neutral mode led to current fluctuations propagating in the downstream chirality. The main following effects that were observed were: (a) Current noise, being proportional to the applied voltage on the injecting contact, without net current; (b) Similarly, partitioning charge current in a QPC led to generation of an upstream neutral mode; (c) The neutral mode decays fast with length and temperature; (d) Having a neutral mode impinge simultaneously with a charge mode affects strongly the Fano factor and the temperature of the partitioned charged quasiparticles; (e) For the 5/2 fractional state, our observation of an upstream neutral mode is likely to single out the proposed reconstructed Pfafian or anti-Pfafian wavefunctions for non-abelian quasiparticles.

8:36AM A3.00002 Competing Phases of 2D Electrons at $\nu = 5/2$ and $7/3$[1] , JING XIA, California Institute of Technology — The N=1 Landau level (LL) exhibits collective electronic phenomena characteristic of both fractional quantum Hall (FQHE) states seen in the lowest LL and anisotropic nematic states in the higher LLs. A modest in-plane magnetic field $B_{||}$ is sufficient to destroy the fractional quantized Hall states at $\nu = 5/2$ (and 7/2) and replace them with anisotropic compressible nematic phases, revealing the close competition between the two. We find that at larger $B_{||}$ these anisotropic phases $\nu = 5/2$ can themselves be replaced by a new isotropic state, dubbed re-entrant isotropic compressible (RIC) phase. We present strong evidence that this transition is a consequence of the mixing of Landau levels from different electric subbands in the confinement potential. In addition, we find that with $B_{||}$, the normally isotropic $\nu = 7/3$ FQHE state can transform into an anisotropic phase with an accurately quantized Hall plateau but an anisotropic longitudinal resistivities. As temperature is lowered towards zero, ρ_{xx} diminishes while ρ_{yy} tends to diverge, reminiscent of the anisotropic nematic states, while surprisingly ρ_{xy} and ρ_{yx} remain quantized at $3h/7e^2$, indicating a completely new quantum phase.

9:12AM A3.00003 Luminescence experiments measuring spin at 5/2 , ISRAEL BAR-JOSEPH, Wiezmann Institute — This abstract not available.

9:48AM A3.00004 Electrostatic Measurements of Fractional Charge in the Second Landau Level , VIVEK VENKATACHALAM, Harvard University — The fractional quantum Hall state at filling factor 5/2 is predicted to result from a BCS pairing instability in a Fermi sea of composite fermions. The resulting p-wave paired state would have the lucrative property of supporting non-Abelian braiding statistics which can be leveraged for decoherence-free quantum computation. A robust prediction of any theory involving pairing at half-integer filling in the quantum Hall regime is that quasiparticles should have charge e/4. Local compressibility measurements allow us to compare how quasiparticles charge disorder puddles at 7/3 and 5/2. From this comparison, we can extract the ratio of quasiparticle charges for these states. The value we obtain, 4/3, suggests a local charge of e/4 at 5/2 (assuming e/3 at 7/3). We additionally show that these e/4 quasiparticles can be pinned by disorder, a prerequisite for the interferometry measurements that may demonstrate non-Abelian braiding statistics.

10:24AM A3.00005 "Looking" at Competing Quantum Phases of the Second Landau Level[1] , ARON PINCZUK — Partially populated higher Landau levels of 2D electron systems support striking collective states in which quantum Hall phases overlap and compete with alternate phases emergent from remarkable interplays between fundamental interactions and quantization of 2D states in a magnetic field. Optical studies by light scattering methods are revealing previously unexpected roles of the spin degree of freedom in quantum phases of the second (N=1) Landau level [1,2]. Inelastic light scattering experiments uncover the collapse of the long wavelength ferromagnetic spin wave for filling factors that are below nu=3. This discovery, interpreted as loss of spin polarization in the N=1 Landau level, is made more intriguing by findings that a sharp spin wave does not recover at filling factors nu=8/3 and 5/2 that support well-known fractional quantum Hall states. Simultaneous resonant elastic (Rayleigh) scattering measurements indicate that below nu=3 the collective states of quasiparticles in the partially populated N=1 Landau level break into sub-micron size domains of fluid that seem to lack full spin polarization and that persist to temperatures that are above 1K. The determination of spin polarization in the quantum Hall state at nu=5/2 requires further consideration. While coexisting with spin unpolarized domains, quasiparticle condensation at nu=5/2 may still result in an incompressible fluid that has spin polarization. This work is in collaboration with T. D. Rhone, U. Wurstbauer, Y. Gallais, J. Yan, L.N. Pfeiffer and K.W. West.

9:48AM A4.00004 Interfacial Aspects of Polymer Based Photovoltaic Structures[1] , THOMAS RUSSELL, University of Massachusetts Amherst — Controlling thin film morphology is key in optimizing the efficiency of polymer-based photovoltaic (PV) devices. Poly(3-hexylthiophene) and [6,6]-penyl-C61 butyric acid methyl ester (P3HT:PCBM) based solar cell performance is dictated by nanostructure of the active layer, the interfaces between the active layer and the electrodes, and the P3HT chain orientation in the thin film. The above parameters were systematically studied by scanning transmission electron microscopy, scanning force microscopy, optical microscopy, grazing incident angle x- ray diffraction., dynamic secondary ion mass spectroscopy and near edge x-ray absorption fine structure analysis. The influence of thermal annealing on the morphology, interfaces and crystal structure was investigated in films that were either initially confined by two electrodes or confined by only one electrode. While the bulk morphology in these films were identical, significant differences in the concentration of components at the electrode interfaces were found, giving rise to a marked difference in performance. In addition, a model was established, based on the crystallization of the P3HTand the diffusion of the PCBM to describe the origins of the nanoscale morphology found in the active layer. The device performance parameters were quantitatively studied.

[1]In collaboration with D. Chen, H. Liu, Y. Gu and F. Lu at UMass Amherst , A. Nakahara at Kuraray Co., D. Wei at Carl Zeiss NTS LLC, D. Nordlund at SSRL and supported by the DOE-supported EFRC at the UMass Amherst (DE-PS02-08ER15944).

10:24AM A4.00005 Morphology control in printable solar cells , JOACHIM LOOS, School of Physics and Astronomy, University of Glasgow Glasgow G12 8QQ, Scotland, United Kingdom — Nanostructured polymer-based solar cells (PSCs) have emerged as a promising low-cost alternative to conventional inorganic photovoltaic devices and are now a subject of intensive research both in academia and industry. For PSCs to become practical efficient devices, several issues should still be addressed, including further understanding of their operation and stability, which in turn are largely determined by the morphological organization in the photoactive layer. The latter is typically a few hundred nanometers thick film and is a blend composed of two materials: the bulk heterojunction consisting of the electron donor and the electron acceptor. The main requirements for morphology of efficient photoactive layers are nanoscale phase segregation for a high donor/acceptor interface area and hence efficient exciton dissociation, short and continuous percolation pathways of both components leading through the layer thickness to the corresponding electrodes for efficient charge transport and collection, and high crystallinity of both donor and acceptor materials for high charge mobility. In this contribution we review recent progress of our understanding on how the efficiency of a bulk-heterojunction PSC largely dependents on the local nanoscale volume organization of the photoactive layer.

Monday, March 21, 2011 8:00AM - 11:00AM –
Session A5 FIAP: Industrial Physics Forum: Small-Scale Applications Ballroom C1

8:00AM A5.00001 Prospects of superconducting qubits for quantum computation , MICHEL DEVORET, Yale University — Superconducting qubits are solid state electrical circuits fabricated using techniques adapted from those of conventional integrated microprocessor fabrication. They are based on the Josephson tunnel junction, the only non-dissipative, strongly non-linear circuit element compatible with low temperature operation. In contrast to microscopic entities such as spins, atoms or ions, superconducting qubits can be well coupled to each other, an appealing feature for 2-qubit gate implementation. Very recently, new circuit architectures have greatly improved the isolation of qubits from unwanted noise, yielding coherence quality factors well in excess of 100,000. Entanglement, the key property that distinguishes a quantum processor from a classical one, has been produced and measured for up to 3 qubits.[1,2] Current experiments are addressing the problem of whether the Preskill criterion of 10,000 coherent 1- and 2-qubit gate operations can be met to enable quantum error correction.

[1]DiCarlo, L. et al. Nature 467, 574-578 (2010);

8:36AM A5.00002 Superconductor Digital Electronics: – Current Status, Future Prospects , OLEG MUKHANOV, HYPRES — Two major applications of superconductor electronics: communications and supercomputing will be presented. These areas hold a significant promise of a large impact on electronics state-of-the-art for the defense and commercial markets stemming from the fundamental advantages of superconductivity: simultaneous high speed and low power, lossless interconnect, natural quantization, and high sensitivity. The availability of relatively small cryocoolers lowered the foremost market barrier for cryogenically-cooled superconductor electronic systems. These fundamental advantages enabled a novel Digital-RF architecture - a disruptive technological approach changing wireless communications, radar, and surveillance system architectures dramatically. Practical results were achieved for Digital-RF systems in which wide-band, multi-band radio frequency signals are directly digitized and digital domain is expanded throughout the entire system. Digital-RF systems combine digital and mixed signal integrated circuits based on Rapid Single Flux Quantum (RSFQ) technology, superconductor analog filter circuits, and semiconductor post-processing circuits. The demonstrated cryocooled Digital-RF systems are the world's first and fastest directly digitizing receivers operating with live satellite signals, enabling multi-net data links, and performing signal acquisition from HF to L-band with 30 GHz clock frequencies. In supercomputing, superconductivity leads to the highest energy efficiencies per operation. Superconductor technology based on manipulation and ballistic transfer of magnetic flux quanta provides a superior low-power alternative to CMOS and other charge-transfer based device technologies. The fundamental energy consumption in SFQ circuits defined by flux quanta energy $2x10^{-19}$ J. Recently, a novel energy-efficient zero-static-power SFQ technology, eSFQ/ERSFQ was invented, which retains all advantages of standard RSFQ circuits: high-speed, dc power, internal memory. The voltage bias regulation, determined by SFQ clock, enables the *zero-power at zero-activity regimes*, indispensable for sensor and quantum bit readout.

9:12AM A5.00003 Superconducting Receivers for Millimeter and Submillimeter Astrophysics , PAUL L. RICHARDS, Department of Physics, U. C. Berkeley — Important information about the structure and evolution of the Universe can be obtained from astrophysical measurements at millimeter and submillimeter wavelengths. The noise in receiver systems used for such measurements should approach as closely as possible the fundamental limits such as photon noise and quantum fluctuations. Narrow line emissions are measured by such major projects as the recently launched 1.5B$HerschelSpacetelescopeandthe1B$ International Alma project, which is now under construction. These projects are enabled by heterodyne receivers with superconducting hot electron bolometer (HEB) mixers and Quasiparticle (SIS) mixers. The temperature and polarization of broad band thermal sources such as the Cosmic Microwave Background and dust emission are being measured from a variety of high altitude telescopes in Chile and at the South Pole using large format arrays of transition edge sensor (TES) bolomters. The status of international efforts in this field will be described with special reference to the rapidly developing technology of very large format arrays of TES bolometers with SQUID-based output multiplexers.

9:48AM A5.00004 The Ubiquitous SQUID: From Axions to Cancer[1] , JOHN CLARKE, UC Berkeley and LBNL — I briefly review the principles, practical implementation and applications of the dc SQUID (Superconducting QUantum Interference Device), an ultrasensitive detector of magnetic flux. Cosmological observations show that a major constituent of the universe is cold dark matter (CDM). A candidate particle for CDM is the axion which, in the presence of a magnetic field, is predicted to decay into a photon with energy given by the axion mass, ranging from 0.001 to 1 meV. The axion detector constructed at LLNL consists of a cooled, tunable cavity surrounded by a 7-T superconducting magnet. Photons from the axion decay would be detected by a cooled semiconductor amplifier. To search for the axion over an octave of frequency, however, would take two centuries. Now at the University of Washington, Seattle the axion detector will be upgraded by cooling it to 50 mK and installing a near-quantum limited SQUID amplifier. The scan time will be reduced by three orders of magnitude to a few months. In medical physics, we use an ultralow-field magnetic resonance imaging (ULFMRI) system with SQUID detection to obtain images in a magnetic field of 0.132 mT, four orders of magnitude lower than in conventional MRI. An advantage of low fields is that different types of tissue exhibit much greater contrast in the relaxation time T1 than in high fields. We have measured T1 in ex vivo specimens of surgically removed healthy and malignant prostate tissue. The percentage of tumor in each specimen is determined with pathology. The MRI contrast between two specimens from a given patient scales with the difference in the percentage of tumor; in healthy tissue T1 is typically 50 percent higher than in a tumor. These results suggest that ULFMRI with T1-weighted contrast may have clinical applications to imaging prostate cancer and potentially other types of cancer.

10:24AM A5.00005 Semiconductor Circuit Diagnostics By Magnetic Field Imaging , T. VENKATESAN, National University of Singapore and Neocera — At the forefront of IC technology development are 3D circuit technologies such as system-in-package (SiP), wafer-level-packaging (WLP), through-silicon-vias (TSV), stacked die approaches, flex packages, etc. They integrate multiple devices, many times stacking them in layers with complex, intricate and very long interconnections in significantly reduced area, in addition to an ever-increasing number of opaque layers. We could very well say that the near future looks like the perfect nightmare for the Failure Analysis (FA) engineer with localization of defects becoming a major challenge. Magnetic field imaging (MFI) allows the fields generated by the circuit currents to go through various packaging layers and be imaged. I will describe in this talk Magma, a scanning magnetic field imaging system based on a high temperature superconducting SQUID device based on YBa2Cu3O7-δ. The HTS SQUIDs used have a noise level of $\sim$ 20pT/$\sqrt{}$(Hz) and for typical scanning conditions, a field sensitivity of about 0.7 nT. While current shorts are imaged with spatial resolution, up to 3 micron (with peak localization) resistive opens can also be imaged and currently different strategies are being adapted for imaging opens with large working distances of 50-100s of microns. Higher spatial resolution ($\sim$250nm) is obtained by the use of magneto-resistive devices as sensors though the working distance requirement is sever

Session A6 DCOMP: Great Advances in Computational Physics: Past, Present and Future

Ballroom C2

8:00AM A6.00001 The path integral picture of quantum systems , DAVID CEPERLEY, University of Illinois — The imaginary time path integral "formalism" was introduced in 1953 by Feynman to understand the superfluid transition in liquid helium. The equilibrium properties of quantum many body systems is isomorphic to the classical statistical mechanics of cross-linking polymer-like objects. With the Markov Chain Monte Carlo method, invented by Metropolis et al., also in 1953, a potential way of calculating properties of correlated quantum systems was in place. But calculations for many-body quantum systems did not become routine until computers and algorithms had become sufficiently powerful three decades later. Once such simulations could happen, it was realized that simulations provided a deeper insight into boson superfluids, in particular the relation of bose condensation to the polymer end-to-end distance, and the superfluid density to the polymer "winding number." Some recent developments and applications to supersolids, and helium droplets will be given. Finally, limitations of the methodology e.g. to fermion systems are discussed.

8:36AM A6.00002 Advances in Monte Carlo computer simulation , ROBERT H. SWENDSEN, Carnegie Mellon University — Since the invention of the Metropolis method in 1953, Monte Carlo methods have been shown to provide an efficient, practical approach to the calculation of physical properties in a wide variety of systems. In this talk, I will discuss some of the advances in the MC simulation of thermodynamics systems, with an emphasis on optimization to obtain a maximum of useful information.

9:12AM A6.00003 Computational Physics and Drug Discovery for Infectious Diseases[1] , J. ANDREW MCCAMMON, HHMI/UCSD — This lecture will provide a general introduction to some of the ways that modern computational physics is contributing to the discovery of new pharmaceuticals, with special emphasis on drugs for infectious diseases. The basic sciences and computing technologies involved have advanced to the point that physics-based simulations of drug targets are now yielding truly valuable suggestions for new compounds.

[1]Supported in part by NSF, NIH, HHMI, CTBP, NBCR, and SDSC.

9:48AM A6.00004 The need and potential for building a integrated knowledge-base of the Earth-Human system , CLIFFORD JACOBS[1], National Science Foundation — The pursuit of scientific understanding is increasingly based on interdisciplinary research. To understand more deeply the planet and its interactions requires a progressively more holistic approach, exploring knowledge coming from all scientific and engineering disciplines including but not limited to, biology, chemistry, computer sciences, geosciences, material sciences, mathematics, physics, cyberinfrastucture, and social sciences. Nowhere is such an approach more critical than in the study of global climate change in which one of the major challenges is the development of next-generation Earth System Models that include coupled and interactive representations of ecosystems, agricultural working lands and forests, urban environments, biogeochemistry, atmospheric chemistry, ocean and atmospheric currents, the water cycle, land ice, and human activities.

[1]In collaboration with Tim Killeen, National Science Foundation

10:24AM A6.00005 Simulating the First Cosmic Structures , EDMUND BERTSCHINGER, Massachusetts Institute of Technology — Understanding how the first stars and galaxies formed is one of the forefront challenges of modern astrophysics and cosmology. During the last three decades numerical simulations have proven to be a powerful tool in the development and testing of galaxy formation theories. The raw ingredients are the atomic and dark matter that comprise galaxies combined with a well-tested cosmological framework of small-amplitude seed perturbations generated in the early universe. This talk will briefly review progress in galaxy formation simulations and will highlight outstanding issues and prospects for the future.

Monday, March 21, 2011 8:00AM - 11:00AM –

Session A7 DBP DPOLY DCMP: Prize Session: Single Molecule Biophysics I: Recent Advancements in Technology and Applications Ballroom C3

8:00AM A7.00001 Single Fluorescent Molecules as Nano-Illuminators for Biological Structure and Function , W.E. MOERNER, Stanford University — Since the first optical detection and spectroscopy of a single molecule in a solid (Phys. Rev. Lett. **62**, 2535 (1989)), much has been learned about the ability of single molecules to probe local nanoenvironments and individual behavior in biological and nonbiological materials in the absence of ensemble averaging that can obscure heterogeneity. Because each single fluorophore acts a light source roughly 1 nm in size, microscopic imaging of individual fluorophores leads naturally to superlocalization, or determination of the position of the molecule with precision beyond the optical diffraction limit, simply by digitization of the point-spread function from the single emitter. For example, the shape of single filaments in a living cell can be extracted simply by allowing a single molecule to move through the filament (PNAS **103**, 10929 (2006)). The addition of photoinduced control of single-molecule emission allows imaging beyond the diffraction limit (super-resolution) and a new array of acronyms (PALM, STORM, F-PALM etc.) and advances have appeared. We have used the native blinking and switching of a common yellow-emitting variant of green fluorescent protein (EYFP) reported more than a decade ago (Nature **388**, 355 (1997)) to achieve sub-40 nm super-resolution imaging of several protein structures in the bacterium *Caulobacter crescentus*: the quasi-helix of the actin-like protein MreB (Nat. Meth. **5**, 947 (2008)), the cellular distribution of the DNA binding protein HU (submitted), and the recently discovered division spindle composed of ParA filaments (Nat. Cell Biol. **12**, 791 (2010)). Even with these advances, better emitters would provide more photons and improved resolution, and a new photoactivatable small-molecule emitter has recently been synthesized and targeted to specific structures in living cells to provide super-resolution images (JACS **132**, 15099 (2010)). Finally, a new optical method for extracting three-dimensional position information based on a double-helix point spread function enables quantitative tracking of single mRNA particles in living yeast cells with 15 ms time resolution and 25-50 nm spatial precision (PNAS **107**, 17864 (2010)). These examples illustrate the power of single-molecule optical imaging in extracting new structural and functional information in living cells.

8:36AM A7.00002 Multiple Pathways of Single-Stranded DNA Stretching Observed Using Single-Molecule Manipulation[1] , CHING-HWA KIANG, Rice University — DNA has a double helix structure and contains the genetic code of life. When the information needed to be read, the DNA double helix has to be opened up to allow access to the bases that make up the DNA. During the reading process the DNA adopt a different conformation, and the energetics and mechanics of the dynamic process is important in gene regulation. We used an atomic force microscope to pull single DNA molecules and measured the force associated with the conformational changes of poly(dA), a single-stranded DNA composed of uniform A bases. We found that the DNA can be stretched in two different ways, and the DNA can hop between these two conformations. These results suggest that poly(dA) has a novel conformation when highly stretched, and the unique conformation makes poly(dA) more stable at large extensions. The unique property of poly(dA) may play a role in biological processes such as gene expression. Moreover, single molecule force measurement allows us to quantify the elastic and thermodynamic properties of single biological molecules, and may ultimately be developed into a tool for drug screening.

9:12AM A7.00003 Max Delbruck Prize in Biological Physics Talk: Zoom into life at the nanoscale with STORM , XIAOWEI ZHUANG, Howard Hughes Medical Institute, Harvard University — Powered by its molecule-specific contrast and live-cell compatibility, fluorescence microscopy is one of the most widely used imaging methods in biological research. The resolution of fluorescence microscopy is classically limited by the diffraction of light to several hundred nanometers. This resolution limit is substantially larger than the typical molecular length scales in cells, preventing detailed characterization of most sub-cellular structures. Here, I describe a new imaging method, stochastic optical reconstruction microscopy (STORM), which breaks the diffraction limit and allows for super-resolution imaging. STORM uses single-molecule imaging and photo-switchable fluorescent probes to temporally separate the spatially overlapping images of individual molecules, thereby allowing each molecule to be localized with high precision and a super-resolution image to be reconstructed from the numerous measured positions of the molecules. Using this approach, we have imaged cellular structures with nanometer-scale resolution. In this talk, I will discuss the general concept, recent technical advances, and various biological applications of STORM.

9:48AM A7.00004 DNA overstretching transition and the biophysical properties of S-DNA , JIE YAN, National University of Singapore — DNA double helix undergoes an "overstretching" transition in a narrow tensile force range slightly above 60 pN. Overstretched DNA is about 1.7 times longer than B-DNA. Despite numerous studies the basic question of whether the strands are separated or not remains controversial. Our recent experiments show that two distinct transitions are involved in DNA overstretching: a slow hysteretic strand-unpeeling transition to strand separation from free DNA ends or nicks, and a fast, non-hysteretic B-to-S transition to an elongated double helix called "S-DNA". We find that the relative fraction of these two overstretched forms is sensitive to factors that affect DNA base pair stability. Under conditions when S-DNA is stable, we characterize its force-extension curve and compare it with that of single-stranded DNA. We find that the S-DNA is 0.01 - 0.02 nm/bp shorter than that of a nucleotide of single-stranded DNA in the force range 75 - 110 pN. Under conditions when S-DNA is less stable than single-stranded DNA, a slow force increase leads to direct strand separation from B-DNA, while a quick force jump to greater than 70 pN leads to a quick formation of the S-DNA first, followed by a slow secondary transition which is a strand separation from S-DNA. From the secondary transition, the extension difference between S-DNA and single-stranded DNA can be directly calculated, which is found in perfect agreement with that computed from the force-extension curves. Finally, we show that DNA in between a pair of small GC-rich segments is biased toward B-to-S transition. This result also demonstrates that in the absence of nicks and free ends, torsion-unconstrained DNA still undergoes the overstretching transition but only through the B-S transition pathway.

10:24AM A7.00005 Ultra-high resolution optical trap with single fluorophore sensitivity , YANN CHEMLA, University of Illinois, Urbana-Champaign — We present a new single-molecule instrument that combines ultra- high resolution optical tweezers with single-fluorophore fluorescence microscopy. The new instrument will enable the simultaneous measurement of angstrom-scale mechanical motion of individual DNA-binding proteins (e.g., single base-pair stepping of DNA translocases) along with the detection of fluorescently labeled protein properties (e.g., internal configuration). The optical tweezers portion of the instrument is based on a timeshared dual optical trap design and is interlaced with a confocal fluorescence microscope. In a demonstration experiment, individual single-fluorophore labeled DNA oligonucleotides can be observed to bind and unbind to complementary DNA suspended between two trapped beads. Simultaneous with the single-fluorophore detection, coincident angstrom-scale changes in tether extension can be clearly observed.

Monday, March 21, 2011 8:00AM - 11:00AM –

Session A8 DCMP GSNP: APS/GSNP/DCMP Prize Session: Heineman, Onsager, IUPAP/C10

Ballroom C4

8:00AM A8.00001 Dannie Heineman Prize for Mathematical Physics Talk: Shape fluctuations of growing droplets and random matrix theory , HERBERT SPOHN, TU Munchen — In 1986 Kardar, Parisi, and Zhang (KPZ) proposed a stochastic evolution equation for growing interfaces, thereby triggering an intense study of growth processes with local growth rules. Specifically we have in mind the recent spectacular experiment of Takeuchi and Sano [1] on droplet growth in a thin film of turbulent liquid crystal. Over the last ten years one has studied universal probability density functions on the basis of simplified lattice growth models. Surprisingly enough the one-point shape fluctuations are governed by the same statistical laws as the largest eigenvalue of a random matrix, Gaussian Unitary Ensemble (GUE) in case of a curved front and Gaussian Orthogonal Ensemble (GOE) for a flat front. Recently we obtained the first exact solution of the KPZ equation for initial conditions corresponding to droplet growth, thereby providing the probability density function for the height at any time [2]. For long times we recover the universal statistical properties as computed from lattice growth models.

8:36AM A8.00002 Lars Onsager Prize Talk I , ALEXANDER BELAVIN, A.D. Landau Institute for Theoretical Physics — This abstract not available.

9:12AM A8.00003 Lars Onsager Prize Talk II , ALEXANDER POLYAKOV, Princeton University — This abstract not available.

9:48AM A8.00004 ABSTRACT WITHDRAWN –

10:24AM A8.00005 IUPAP C10 2011 Young Scientist Prize in the Structure and Dynamics of Condensed Matter Talk: Breakdown of thermalization in finite one-dimensional systems[1] , MARCOS RIGOL, Georgetown University — Little more than fifty years ago, Fermi, Pasta, and Ulam set up a numerical experiment to prove the ergodic hypothesis for a one-dimensional lattice of harmonic oscillators when nonlinear couplings were added. Much to their surprise, the system exhibited long-time periodic dynamics with no signals of ergodic behavior. Those results motivated intense research, which ultimately gave rise to the modern chaos theory and to a better understanding of the basic principles of classical statistical mechanics. More recently, experiments with ultracold gases in one-dimensional geometries have challenged our understanding of the quantum domain. After bringing a nearly isolated system out of equilibrium, no signals of relaxation to the expected thermal equilibrium distribution were observed. Some of those results can be understood in the framework of integrable quantum systems, but then it remains the question of why thermalization did not occur even when the system was supposed to be far from integrability. In the latter regime, thermalization is expected to occur and can be understood on the basis of the eigenstate thermalization hypothesis. In this talk, we utilize quantum quenches to study how thermalization breaks down in finite one-dimensional lattices as one approaches an integrable point. We establish a direct connection between the presence or absence of thermalization and the validity or failure of the eigenstate thermalization hypothesis, respectively. **References:**

Monday, March 21, 2011 8:00AM - 11:00AM –
Session A9 DFD: Micro-fluidics D220

8:00AM A9.00001 Hydrodynamic resistance of confined cells in rectangular microchannels , ZEINA S. KHAN, SIVA A. VANAPALLI, Texas Tech University, Department of Chemical Engineering — Several microfluidic approaches have been developed to screen suspended cells mechanically in microchannels by exploiting characteristics that are linked to their individual mechanical properties. Typically changes in cell shape due to shear-induced deformation and transit times are reported; while these measurements are qualitative compared to more precise techniques such as atomic force microscopy and micropipette aspiration their advantage lies in throughput, with the ability to screen hundreds to thousands of cells in a minute. We study the potential of a microfluidic cell squeezer to characterize the hydrodynamic resistance of LNCaP prostate cancer cells by measuring dynamical pressure-drop variations along a micrometer-sized channel. The hydrodynamic resistance of the cell introduces an excess pressure drop in the narrow channel which depends on the mechanical stiffness of the cell. We additionally visualize the cell size and assess the influence of cell size on the hydrodynamic resistance of each cell, demonstrating the capability of the microfluidic cell squeezer to yield the hydrodynamic resistance as a mechanical fingerprint of cells.

8:12AM A9.00002 Bio-inspired artificial iriodphores based on capillary origami , SUPONE MANAKASETTHARN, J. ASHLEY TAYLOR, TOM KRUPENKIN, University of Wisconsin - Madison — Many marine organisms have evolved complex optical mechanisms of dynamic skin color control that allow them to drastically change their visual appearance. In particular, cephalopods have developed especially effective dynamic color control mechanism based on the mechanical actuation of the micro-scale optical structures, which produce either variable degrees of area coverage by a given color (chromatophores) or variations in spatial orientation of the reflective and diffractive surfaces (iridophores). In this work we describe bio-inspired artificial iridophores based on electrowetting-controlled capillary origami. We describe the developed microfabrication approach, characterize mechanical and optical properties of the obtained microstructures and discuss their electrowetting-based actuation. The obtained experimental results are in good agreement with a simple theoretical model based on electrocapillarity and elasticity theory. The results of the work can enable a broad range of novel optical devices.

8:24AM A9.00003 Micropipette as Coulter counter for submicron particles[1] , YAUHENI RUDZEVICH, TONY ORDONEZ, GRANT EVANS, LEE CHOW, University of Central Florida — Coulter counter based on micropipette has been around for several decades. Typical commercial Coulter counter has a pore size of 20 μm, and is designed to detect micron-size blood cells. In recent years, there are a lot of interests in using nanometer pore size Coulter counter to detect single molecule and to sequence DNA. Here we describe a simple nanoparticle counter based on pulled micropipettes with a diameter of 50 – 500 nm. Borosilicate micropipettes with an initial outer diameter of 1.00 mm and inner diameter of 0.5 mm are used. After pulling, the micropipettes are fire polished and ultrasound cleaned. Chlorinated Ag/AgCl electrodes and 0.1 M of KCl solution are used. The ionic currents are measured using an Axopatch 200B amplifier in the voltage-clamp mode. Several types and sizes of nanoparticles are measured, including plain silica and polystyrene nanospheres. The results will be discussed in terms of pH values of the solution and concentrations of the nanoparticles.

8:36AM A9.00004 ABSTRACT WITHDRAWN –

8:48AM A9.00005 On demand fusion and triggering of confined chemical reactions in femtoliter volume aqueous droplets controlled by interfacial tension , PAT COLLIER, SEUNG-YONG JUNG, SCOTT RETTERER, ORNL — Droplet-based microfluidic platforms offer many opportunities to confine chemical and biochemical reactants in discrete ultrasmall reaction volumes, and investigate the effects of increased confinement on reaction dynamics. Current state-of-the-art microfluidic sampling strategies for creating ultrasmall reaction volumes are predominately steady-state approaches, which result in difficulty in trapping reacting species with a well-defined time-zero for initiation of biochemical reactions in the confined space. This talk describes stepwise, on-demand generation and fusion of femtoliter aqueous droplets based on interfacial tension. Sub-millisecond reaction times from droplet fusion were demonstrated, as well as a reversible chemical toggle switch based on alternating fusion of droplets containing acidic or basic solution, monitored with the pH-dependent emission of fluorescein.

9:00AM A9.00006 Acoustic actuation and sorting of droplets and cells at ultrahigh rates in microfluidics , THOMAS FRANKE, Harvard University/University of Augsburg, LOTHAR SCHMID, SUSANNE BRAUNMUELLER, ACHIM WIXFORTH, University of Augsburg, DAVID A. WEITZ, Harvard University, FRANKE TEAM, FRANKE/WEITZ TEAM — We direct the motion of droplets in microfluidic channels using a surface acoustic wave device. This method allows individual drops to be directed along separate microchannel paths at high volume flow rates, which is useful for droplet sorting. The same principle can be applied for biological cell sorting which operates in continuous flow at high sorting rates. The device is based on a surface acoustic wave cell-sorting scheme and combines many advantages of fluorescence activated cell sorting (FACS) and fluorescence activated droplet sorting (FADS) in microfluidic channels. It is fully integrated on a PDMS device, and allows fast electronic control of cell diversion. We direct cells (HaCaT, MV3 melanoma, fibroblasts) by acoustic streaming excited by a surface acoustic wave. The device underlying principle works without additional enhancement of the sorting by prior labeling of the cells with responsive markers such as magnetic or polarizable beads. We have combined the acoustic device successfully with a laser based fluorescence detection system and demonstrate sorting of fluorescent labeled drops at rates of several kHz without any false sorting.

9:12AM A9.00007 Microfluidic mixing using an array of superparamagnetic beads , WENBIN MAO, ZHENGCHUN PENG, PETER J. HESKETH, ALEXANDER ALEXEEV, Georgia Institute of Technology — We present a combined numerical and experimental study on the dynamics of superparamagnetic beads in a microfluidic channel, wall of which is decorated with an array of stationary magnetic disks. When exposed to a rotating magnetic field, the beads circulate around the magnetic disks. We conduct experiments with micrometer-sized supeparamagnetic beads and use a numerical method that is based on the lattice Boltzmann model to examine the dynamics of this microfluidic system. We isolate the conditions in which beads exhibit stable periodical motion around magnetic disks and probe the effect of microchannel flow on the bead dynamics. We demonstrate that the fluid circulations created by rotating beads can be exploited for microfluidic mixing, thereby offering a new approach for designing highly-efficient active microfluidic mixers.

9:24AM A9.00008 Separating Magnetically Labeled and Unlabeled Biological Cells within Microfluidic Channels , TOM BYVANK, GREG VIEIRA, The Ohio State University Department of Physics, BRANDON MILLER, BO YU, JEFFREY CHALMERS, L. JAMES LEE, The Ohio State University William G. Lowrie Department of Chemical and Biomolecular Engineering, R. SOORYAKUMAR, The Ohio State University Department of Physics — The transport of microscopic objects that rely on magnetic forces have numerous advantages including flexibility of controlling many design parameters and the long range magnetic interactions generally do not adversely affect biological or chemical interactions. We present results on the use of magnetic micro-arrays imprinted within polydimethylsiloxane (PDMS) microfluidic channels that benefit from these features and the ability to rapidly reprogram the magnetic energy landscape for cell manipulation and sorting applications. A central enabling feature is the very large, tunable, magnetic field gradients ($> 10^4$ T/m) that can be designed within the microfluidic architecture. Through use of antibody-conjugated magnetic microspheres to label biological cells, results on the transport and sorting of heterogeneous cell populations are presented. The effects of micro-array and fluid channel design parameters, competition between magnetic forces and hydrodynamic drag forces, and cell-labeling efficiency on cell separation are discussed.

9:36AM A9.00009 Coating microchannels to improve Field-Flow Fractionation , TYLER N. SHENDRUK, GARY W. SLATER, University of Ottawa — We propose a selective-steric-mode Field-Flow Fractionation (ssFFF) technique for size separation of particles. Grafting a dense polymer brush onto the accumulation wall of a microchannel adds two novel effects to FFF: the particles must pay an entropic cost to enter the brush and the brush has a hydrodynamic thickness that shifts the no-slip condition. For small particles, the brush acts as a low-velocity region, leading to chromatographic-like retention. We present an analytical retention theory for small but finite-sized particles in a microchannel with a dense Alexander brush coating that possesses a well-defined hydrodynamic thickness. This theory is compared to a numerical solution for the retention ratio given by a flow approximated by the Brinkman equation and particle-brush interaction that is both osmotic and compressional. Large performance improvements are predicted in several regimes. Multi-Particle Collision simulations of the system assess the impact of factors neglected by the theory such as the dynamics of particle impingement on the brush subject to a flow.

9:48AM A9.00010 Digital Flow Control of Electroosmotic Pump: Onsager Coefficients and Interfacial Parameters Determination , ZULI XU, Department of Physics, the Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong (PR China), JIANYING MIAO, Nano and Advanced Materials Institute Limited, Hong Kong (PR China), NING WANG, PING SHENG, Department of Physics, the Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong (PR China) — Electroosmosis (EO) and streaming potential (SP) are two complementary electrokinetic processes related by the Onsager relation. In particular, electroosmotic pump (EOP) is potentially useful for a variety of engineering and bio-related applications. By fabricating samples consisting of dry-etched cylindrical pores (50 μm in length and 3.5 μm in diameter) on silicon wafers, we demonstrate that the use of digital control via voltage pulses can resolve the flow regulation and stability issues associated with the EOP, so that the intrinsic characteristics of the porous sample medium may be revealed. Through the consistency of the measured electroosmosis and the streaming potential coefficients as required by the Onsager relation, we deduce the zeta potential and the surface conductivity, both physical parameters pertaining to the liquid-solid interface.

10:00AM A9.00011 AC electrophoretic effect in inhomogeneous electrical field: potentials for single molecule trapping[1] , WEIHUA GUAN, Department of Electrical Engineering, Yale University, JAE HYUN PARK, PREDRAG KRSTIC, Physics Division, Oak Ridge National Laboratory, MARK REED, Department of Electrical Engineering, Yale University — In micro-fabricated fluidic devices, we have experimentally observed trapping of objects in the supposed unallowed positive dielectrophoresis (pDEP) region. This 'anomalous' trapping behavior motivates us to investigate the missing contributions in the trapping dynamics. We present here a study on overlooked aspects of alternating current (AC) electrokinetics-AC electrophoretic (ACEP) phenomena. The dynamics of a particle with both polarizability and net charges in an *inhomogeneous* AC electric trapping field are investigated. It is found that either electrophoretic (EP) or dielectrophoretic (DEP) effects can dominate the trapping dynamics, depending on experimental conditions. A dimensionless parameter is developed to predict the relative strength of EP and DEP effect. Contrary to conventional thought, an ACEP trap is feasible for charged particles in 'salt-free' or low salt concentration solutions. In contrast to DEP traps, an ACEP trap favors the down scaling of particle size. We anticipate that this feature will allow the confinement of single nanometer-sized objects or macromolecules.

10:12AM A9.00012 Making robust electrowetting processes: dielectric breakdown and satellite droplets , GREG RANDALL, BRENT BLUE, General Atomics — For over ten years, charge-related wetting phenomena such as electrowetting or dielectrophoresis have been used to manipulate individual liquid droplets on grids of patterned electrodes. Many proof-of-principle droplet actuations have been shown, however some physics-based problems are complicating this technology's move to industry. These problems include: breakdown of a device's dielectric coating at field strengths lower than anticipated and generation of satellite droplets from the primary droplet's surface. We use atomic layer deposition (ALD) to fabricate high-quality dielectric layers required for robust droplet electrowetting and generate operating plots for several dielectric materials. Using scanning electron microscopy and X-ray spectroscopy, we study damage and ionic penetration into the device's dielectric layer. Using video and current measurements, we examine the physics of satellite droplet generation. We apply these findings to engineer a microfluidic process to mass produce inertial fusion energy targets.

10:24AM A9.00013 Introducing the Hybrid Free Surface Microfluidics for Gas Sensing , MEYSAM BARMI, CARL MEINHART, Department of Mechanical Engineering, University of California Santa Barbara — Free-Surface MicroFluidics (FSMF) have recently received much attention for their applications especially their ability for airborne chemical detection [Piorek, PNAS 2007]. Due to their sensitivity to the ambient condition and possibility of contamination, hybrid configuration is introduced to perform the measurement more accurately. The hybrid free surface microfluidics are combination of free surface and closed surface microfluidics. The gas is absorbed by the working fluid through a small opening on the microchannel and transported to the closed surface reaction chamber to carry out the measurements. The working fluid is transported by surface tension and regulated by temperature-controlled evaporator at the outlet. The microchannels are fabricated on Silicon substrates with built-in Ti/Pt electrodes to measure the conductivity of the working fluid before and after the gas absorption to find the concentration of the absorbed gas. It proves that the hybrid free surface microfluidics are appropriate for gas sensing and the minimum exposing time and required opening size are calculated. Numerical simulations are carried out by COMSOL multiphysics. Navier-Stokes equations along with the mass transport with reaction are solved simultaneously to find the correlation between vapor pressure of the surrounding gas and concentration of the absorbed gas.

10:36AM A9.00014 Motion-Reversal Transitions in Self-Assembled Colloidal Walkers , STEPHANIE MORAN, CHARLES SING, ALFREDO ALEXANDER-KATZ, MIT — Nature has created a variety of designs in order to move fluids and transport objects within living organisms. At microscopic scales (in the region of micrometers) two motifs are common: flagella and cilia. Within the cell, however, molecular motors with nanometer dimensions transport small sized vesicles. Here, we describe a novel approach that combines properties from two systems: cilia and molecular motors, to create self-assembled colloidal walkers. These walkers are assembled by superparamagnetic beads in the presence of a rotating homogeneous magnetic field, and are able move in a given direction due to the presence of surfaces which provide an effective friction. The motion is somewhat reminiscent of a person doing cartwheels on ice, where the friction is not high enough to avoid slip, but overall one can attain directed motion in one direction. Interestingly, the motion of the center of mass of these walkers is a non-monotonic function along one cycle of revolution. By exploiting this non-monotonicity, we show that motion reversal is possible in this systems if one carefully controls the friction properties of the surface as well as the confining "gravitational" field that maintains the beads near the surface. Our results our important in understanding the motion of micron scale organisms and may be useful in the development of virtual microfluidic platforms.

10:48AM A9.00015 Optimizing Nanopore Surface Properties for High-Efficiency Water Desalination , DAVID COHEN-TANUGI, JEFFREY GROSSMAN, Massachusetts Institute of Technology — As water resources worldwide become rapidly scarcer, it is becoming increasingly important to devise new techniques to obtain clean water from seawater. At present, water purification technologies are limited by costly energy requirements relative to the theoretical thermodynamic limit and by insufficient understanding of the physical processes underlying ion filtration and fluid transport at the molecular scale. New advances in computational materials science offer a promising way to deepen our understanding of these physical phenomena. In this presentation, we describe a new approach for high-efficiency water desalination based on surface-engineered porous materials. This approach is especially relevant for promising technologies such as nanofiltration and membrane distillation, which offers promising advantages over traditional desalination technologies using mesoporous membranes that are only permeable to pure water vapor. More accurate molecular modeling of mesoporous and nanoporous materials represents a key step towards efficient large-scale treatment of seawater. Results regarding the effect of pore properties (surface texture, morphology, density, tortuosity) on desired performance characteristics such as ion selectivity, maximal water flux and energy requirements will be presented.

Monday, March 21, 2011 8:00AM - 10:48AM –
Session A10 DCMP: Structure and Morphology of Oxide Surfaces and Interfaces D221

8:00AM A10.00001 The interactions of bridging oxygen vacancies on the rutile (110) surface , CRISTIAN CIOBANU, BRANDEN KAPPES, WILLIAM MADDOX, Colorado School of Mines, DANDA ACHARYA, PETER SUTTER, Brookhaven National Laboratory — Using density functional theory calculations at the level of Hubbard-corrected generalized gradient approximation (GGA+U), we calculate the formation and interaction energies of oxygen vacancies on the (110) surface of rutile for neutral and positively charged slabs for different values of the Hubbard parameter U. We find that the interaction of vacancies is elastically repulsive at long range, and that there is a short-range attraction between nearest neighbor vacancies (or oxygen vacancy pairs). With this physical description of the interactions, we derive a closed formula for the surface energy of reduced (110) rutile surface with two same-row vacancies within a given spatial periodicity along the bridge oxygen row, as well as a simple statistical mechanics description of the probability of finding two vacancies at a given distance d. The results of our theoretical model are consistent with our scanning tunneling microscopy determination of the distribution of inter-vacancy separations, and provide a framework for interpreting previous works in the literature.

8:12AM A10.00002 Revisiting Low-Temperature Reconstruction of TiO_2(001) , N.-H. YU, K.T. PARK, V.B. NASCIMENTO, Z. LIAO, G. LI, X. HE, J. TENG, J. ZHANG, E.W. PLUMMER, DEPARTMENT OF PHYSICS, BAYLOR UNIVERSITY TEAM, DEPARTMENT OF PHYSICS AND ASTRONOMY, LOUISIANA STATE UNIVERSITY TEAM — TiO_2(001) has been investigated by scanning tunneling microscopy (STM) and low energy electron diffraction (LEED). After cycles of Ar sputtering and surface annealing at moderate temperatures (up to 600 °C for 15 minutes), TiO_2(001) reveals the so-called latticework reconstruction: row-like linear structures running along [110] and [1-10] directions. Each row further consists of bright spots separated by 6.5 Å. In some areas, the rows are separated by 13 Å consistent with the lattice domains of $(2\sqrt{2}\times\sqrt{2})$ R45 observed by LEED. In other areas, the rows are distributed in a more random fashion. Thus various nearest neighbor distances and relative heights of the rows form different microfacets. From the LEED and STM data, the surface reconstruction is modeled by added rows of stoichiometric TiO_2, aligned along [110] and [1-10] directions.

8:24AM A10.00003 Cu/Cu oxide growth on ZnO and TiO2 for CO2 reduction , FEI WANG, ZIYU ZHANG, RICHARD KURTZ, PHILLIP SPRUNGER, Louisiana State University — Monolayer copper growth on ZnO(10-10) and TiO2(110) have been studied with STM, EELS and LEED. These systems are attractive due to their photochemical and electrochemical reduction of CO2. However, determination of the particular reaction pathway(s) has been elusive because final reduction products strongly depend on the coverage and size of Cu clusters. In order to detangle substrate effects, single crystal ZnO(10-10) and TiO2(110) have been chosen as supports for Cu growth. STM is employed to investigate the nucleation and growth of Cu on both substrates. Cu tends to grow nanoclusters on both substrates with preferred nucleation sites and directions. Upon annealing, Cu clusters ripening have been seen on ZnO substrate but not on TiO2. Subsequent oxidation of Cu clusters is also studied with STM. CO2 vibrational modes on both substrates will be studied with EELS.

8:36AM A10.00004 First-Principles Calculations of Palladium Nanostructures Formed on γ-Alumina[1] , XIN LIU, SANWU WANG, The University of Tulsa — Palladium clusters supported on the γ-alumina surface serve as a catalyst for a variety of important chemical reactions. We report results of our first-principles quantum mechanical calculations for the bonding configurations of palladium atoms and clusters that are supported on the γ-Al_2O_3(110) surface. In particular, our results show that while a single Pd atom prefers to be bonded on the bridge sites of two surface aluminum atoms, a chain nanostructure and a ring-like nanostructure may be formed when more Pd atoms are adsorbed on the surface.

8:48AM A10.00005 Atomic structure and interfacial energy of copper and cuprous oxide forming heterojunctions with the ZnO(0001) surface[1] , OLIVER WARSCHKOW, KATAWUT CHUASIRIPATTANA, MATTHEW LYLE, School of Physics, The University of Sydney, BERNARD DELLEY, Paul-Scherrer-Institut, CATHY STAMPFL, School of Physics, The University of Sydney — The system Cu/ZnO is industrially important as a catalyst for methanol synthesis and water-gas-shift reactions. The pairing of copper and zinc oxide is crucial to catalytic efficacy; however, the atomic-scale interactions between the two phases are far from resolved. This presentation will focus on three heterojunctions of relevance to catalytic action, namely, Cu(111):ZnO(0001), Cu_2O(110):ZnO(0001), and Cu_2O(111):ZnO(0001). We use density functional theory to characterize these interfaces in terms of their environment-dependent structure and energetics. This allows us to assess the relative stability of competing structures, and discuss their possible roles in an active catalyst.

9:00AM A10.00006 Hydrogen Adsorption on polar ZnO(0001)-Zn - extending equilibrium surface phase diagrams to kinetically stabilised structures , MIRA TODOROVA, Dept. for Computational Materials Design, Max-Planck-Institut fuer Eisenforschung GmbH, Duesseldorf, Germany, MARKUS VALTINER[1], Dept. for Interface Chemistry and Surface Engineering, Max-Planck-Insitut fuer Eisenforschung GmbH, Duesseldorf, Germany, JOERG NEUGEBAUER, Dept. for Computational Materials Design, Max-Planck-Institut fuer Eisenforschung GmbH, Duesseldorf, Germany — Hydrogen adsorption on the Zn-terminated polar ZnO(0001) surface is studied by a combination of density-functional theory calculations and *atomistic thermodynamics*. Going beyond the thermodynamic limit and constructing meta-stable phase diagrams we extend the concept of equilibrium surface phase diagrams to include kinetically stabilised surface reconstructions. Using this approach we were able to identify new and hitherto not reported structures that become stable under non-equilibrium extreme H-rich conditions. Experimental situations that realise such conditions will be discussed.

9:12AM A10.00007 DFT Study on ZnO Nanoplate Towards Magnetic Property , SEUNG SOON JANG, JI-IL CHOI, JUNG-IL HONG, ZHONG LIN WANG, ROBERT SNYDER, Georgia Institute of Technology, School of Materials Science and Engineering — Using a GGA+U method and Density Functional Theory, we present a theoretical study for the existence of a magnetic moment in ZnO nanoplate without any extrinsic doping of magnetic impurities. Nanoplate are configured with a Zn-terminated (0001) surface and O-terminated $(000\bar{1})$ surfaces. The surface reconstruction was considered by optimizing the structures. Using GGA PBE, we calculated the spin density of states for both spin states and individual density of states for each orbital to clarify the degree of contributions. Compared to the electronic configuration of bulk wurtzite ZnO, net spins are observed in ZnO nanoplates depending on the plate thickness, which is thought to be due to large changes in the degree of hybridization throughout the plate. As the electronic configuration of a ZnO nanoplate is converged to that of bulk ZnO with increasing plate thickness, its net spin disappears. Specifically, It is found that the net spin of the ZnO nanoplate disappears when its thickness increases beyond $\sim$ 6 nm. In our presentation, we will discuss the change of the electronic configurations as a function of the plate thickness with a rationalization of this change.

9:24AM A10.00008 Ultrathin film growth of iron oxides on YSZ(001) and (111) , GARY KELLOGG, IVAN ERMANOSKI, Sandia National Laboratories — We use low energy electron microscopy (LEEM) and low energy electron diffraction (LEED) to study in real time the growth of iron oxides on the (001) and (111) surfaces of yttriastabilized zirconia (YSZ). Investigations of the FeO_x-YSZ system are motivated by its use as a working oxide for thermochemical fuel production via splitting of H_2O and CO_2. LEED patterns obtained from YSZ(001) during Fe deposition in $\sim 10^{-6}$ Torr O_2 at 600°C and above indicate first-layer growth of FeO(111) and second-layer growth of Fe_2O_3(0001). LEEM imaging shows highly anisotropic first-layer growth into four non-equivalent domains (two rotations and two stacking orientations). Distinct LEEM-IV (intensity-voltage) spectra are obtained for the two stoichiometries providing unique fingerprints of the observed oxide phases. On YSZ(111), growth $>$800°C in O_2 is similar to (001) in that FeO is observed in the first layer and Fe_3O_4 in the second. Sandia is a multiprogram laboratory operated by Sandia Corporation, a subsidiary of Lockheed Martin, for the U.S. DOE's NNSA under contract DEAC0494AL85000. Funding was provided through Sandia's LDRD Office.

9:36AM A10.00009 *In Situ* Synchrotron Studies of a Model Catalyst: WO_x/α-Fe_2O_3 , MARTIN MCBRIARTY, ZHENXING FENG, Northwestern University, JOSEPH LIBERA, JEFFREY ELAM, Argonne National Laboratory, DONALD ELLIS, MICHAEL BEDZYK, Northwestern University — Statistically averaging surface-sensitive X-ray techniques are employed to elucidate the surface morphology of a model oxide-supported heterogeneous catalyst, tungsten oxide (WO_x) on hematite (α-Fe_2O_3). Atomically flat α-Fe_2O_3 (0001) single crystals were coated with sub-monolayer WO_x by atomic layer deposition (ALD). *In situ* X-ray standing wave (XSW) imaging with X-ray fluorescence (XRF) was used to determine W position relative to bulk-like cation lattice sites under nominally reducing and oxidizing chemical conditions. X-ray absorption fine structure (XAFS) reveals details of W coordination, bond length, and chemical state on WO_x-coated hematite single crystals and nanopowders. Synchrotron characterization results are compared with morphologies predicted by density functional theory (DFT) calculations for clean WO_x/α-Fe_2O_3 surfaces. Thermodynamics and atomic configurations for H_2O and CO adsorption are also predicted. Excited-state self-consistent field (SCF) calculations are used to model X-ray photoelectron spectroscopy (XPS) results.

9:48AM A10.00010 First-Principles Investigations of Oxygen Vacancies on SnO2 Nanofilms[1] , DANIEL CELLUCCI, STEVEN LEWIS, University of Georgia — The n-type semiconductor tin dioxide (SnO2) has long been used as the working material for robust, inexpensive oxidizable-gas sensors. In recent years, advances in nanofabrication have made possible the well-controlled formation of SnO2 nanocrystals. Since gas sensing in SnO2 involves changes in surface resistivity as a function of gas concentration, nanocrystalline SnO2 holds great promise for high-sensitivity gas sensors, due to the high surface-to-volume ratio. A key feature of the sensing mechanism is the facile formation and destruction of oxygen vacancies at (or near) the surface. In this talk I will discuss our ongoing first-principles investigations of surface oxygen vacancies in SnO2 nanofilms. We have focused on vacancy formation among the so-called bridging oxygen atoms on the (110) surface of rutile SnO2, as a function of vacancy concentration and film thickness, studying the effect on local atomic and electronic structure. This work is the first phase of a longer-term investigation of surface vacancy phases on SnO2 (110) as a function of temperature and oxygen vapor pressure.

10:00AM A10.00011 Microstructural relaxation phenomena on laser-modified fused silica surfaces , MANYALIBO MATTHEWS, THOMAS SOULES, JAMES STOLKEN, RYAN VIGNES, STEVEN YANG, SELIM ELHADJ, Lawrence Livermore National Laboratory — Laser-driven phase transformations and associated morphological deformations on vitreous SiO_2surfaces are presented. Direct imaging of Si-O-Si asymmetric stretch transverse-optic (TO) mode shifts using a combination of scanning Infrared and Raman spectromicroscopy revealed the creation of the high pressure phase stishovite through the nonlinear absorption of ultraviolet laser pulses. Structural relaxation at $\sim$1900 K of modified surfaces back to the amorphous state could be correlated with Si-O bond angle shifts and used to describe the thermally-driven transformation kinetics. Kohlrausch relaxation functions are applied through finite element modeling of the calculated sub-surface thermal histories to extract reasonable values for the activation enthalpy and annealing point relaxation time of laser-modified silica. Lawrence Livermore National Laboratory is operated by Lawrence Livermore National Security, LLC, for the U.S. Department of Energy, National Nuclear Security Administration under Contract DE-AC52-07NA27344.

10:12AM A10.00012 Polarizing-Depolarizing fields competition on $PbTiO_3$ nanocapacitors[1] , MIGUEL ANGEL MENDEZ POLANCO, ILYA GRINBERG, ANDREW RAPPE, University of Pennsylvania, Department of Chemistry — We analyzed the stability of various interfacial atomic arrangements in $PbTiO_3$ (PTO) based nanocapacitors, using density functional theory (DFT). We observed that particular constructions induce a large polarization enhancement via a net field depolarizing-to-polarizing swap within the PTO layers, as revealed by analysis of electrostatic potential profiles. In contrast to those with a dominant depolarizing field, possessing a polarization below that of the bulk, the polar structures are stable in the thin-film regime. Interface atomic relaxation is also observed to be a key factor in determining the overall stability of the different capacitor configurations. This boosted charge screening capacity along with appropriate engineering of the interface chemistry, are potential how-to pointers to alleviate the critical thickness in ferroelectric-based nanocapacitors.

10:24AM A10.00013 ABSTRACT WITHDRAWN –

10:36AM A10.00014 Growth of vanadium dioxide thin films using magnetron sputtering , FANGFANG SONG, B.E. WHITE, Binghamton University — The unique electronic properties of vanadium dioxide have been a focus of intense experimental and theoretical investigation. Although the origin of the metal-insulator transition in this material is still under investigation, the magnitude of the resistivity change at the metal-insulator transition and closeness of the transition temperature to room temperature suggest this material has high potential for future electronic devices. However, the existence of a large number of distinct stable vanadium oxide phases offers a particular challenge to the growth of thin films of this material. In this work, we present our experimental investigation of vanadium dioxide thin film deposition. RF and DC Magnetron sputtering are used for thin film deposition and the effect of oxygen partial pressure, substrate material, and deposition temperature are studied. The impact of deposition conditions on the structural and morphological properties of the thin films, as determined by x-ray diffraction and scanning electron microscopy, will be discussed. Results indicate that on the technologically relevant silicon dioxide surface, the transitional phase of vanadium dioxide can be stabilized with an appropriate post deposition anneal.

Monday, March 21, 2011 8:00AM - 11:00AM –

Session A11 FIAP: Semiconductor Growths D222

8:00AM A11.00001 Kinectic Monte Carlo Simulation of Strained Heteroepitaxial Growth[1] , PETER SMEREKA, University of Michigan, TIM SCHULZE, University of Tennessee — An efficient algorithm for the simulation of strained heteroepitaxial growth with intermixing in 2+1 dimensions is presented. The talk will first describe a KMC solid-on-solid model that has been modified to incorporate elastic interaction. The simulation of such models is computationally difficult due to the need to repeatedly update the elastic displacement field. This hurdle can be overcome by using local updates of the displacement field combined with a multigrid approach for global updates (when needed). The validity of this technique can be theoretically justified. This algorithm is efficient enough to allow the simulation of heteropitaxy on macroscopic time scales. Simulations will have 100 million to 10 billion atomistic moves. Results will be presented showing how various parameters (e.g. temperature, misfit, and deposition rate) effect the morphology of growing films. Annealing simulations of a single 3d island reveal something akin to the pyramid to dome transition observed for Ge islands on Si. Simulations of stacked quantum dots will be presented, these simulations show the capping layer can erode the dots and the alignment of the dots is somewhat different than is often proposed in the literature.

[1]Funded by NSF.

8:12AM A11.00002 Fabrication and characterization of cryogenic complementary devices on Si/SiGe heterostructures , T.M. LU, Princeton University, C.-H. LEE, National Taiwan University, D.C. TSUI, Princeton University, C.W. LIU, National Taiwan University — We have fabricated cryogenic complementary devices using undoped Si/SiGe heterostructures which contain an electron quantum well and a hole quantum well. The highest temperature in the fabrication process is as low as 440°C, preserving the quality of the epitaxial films. By properly biasing the gate voltage, two-dimensional (2D) electrons and holes are induced capacitively in the quantum wells. The electron mobility, $\sim 2\times 10^4$ cm^2/Vs, is significantly lower than that in a heterostructure without any hole quantum well. Nevertheless, the induced 2D electrons show the integer and fractional quantum Hall effect characteristics. The mobility of the 2D holes is $\sim 7\times 10^3$ cm^2/Vs, consistent with previous reports, and is limited by alloy scattering. A proof-of-principle inverter is demonstrated.

8:24AM A11.00003 Mechanisms of Stranski Krastanov Growth , ARVIND BASKARAN, University of California, Irvine, PETER SMEREKA, University of Michigan, Ann Arbor — During the Heteroepitaxial growth of strained semiconductor films (like Ge on Si) the self assembly of quantum dots is observed. This is often reported in experiments to take place though the Stranski Krastanov (SK) growth mode, where the film grows in a layer by layer fashion up to a certain critical thickness after which islands (dots) form. In this talk we present a study of the SK growth mode using a solid on solid Kinetic Monte Carlo model. The importance of the use of such an discrete stochastic model and its merits over the continuum approach will be outlined. Entropy is found to play a very crucial role in the SK growth mode. The mechanism of the SK growth is understood in the context of a delicate balance of the energy and entropy. This is joint work with Peter Smereka.

8:36AM A11.00004 High-purity germanium crystal growth for DUSEL experiments , WENCHANG XIANG, YONGCHEN SUN, DONGMING MEI, YUTONG GUAN, CHAO ZHANG, The University of South Dakota, CUBED TEAM — High-purity Germanium single crystals can be fabricated into ultra-low background detectors for dark matter and neutrinoless double-beta decay experiments at DUSEL. If the crystals are grown in underground environment, the cosmogenic production can be minimized and hence the crystals can be ultra-pure for the next generation experiments at DUSEL. Growing high-purity germanium crystals represents one of the most difficult tasks in semiconductor field. We adopt Czochralski method in growing single crystal in order to understand various technical challenges. With the pioneers' work done in the past, we are moving rapidly toward growing high quality single crystals on the surface. With the available valuable papers and accumulation of the growing experience, our growing process is being improved on weekly basis. This paper will report the grown crystals produced by our equipment and address versions issues with the growing processes.

8:48AM A11.00005 Strain-promoted growth of Mn silicide nanowires on Si(001)[1] , KAZUSHI MIKI, HONGJUN LIU, National Institute for Materials Science, 1-1 Namiki, Tsukuba, Ibaraki 305-0044, Japan., JAMES H.G. OWEN, CHRISTOPH RENNER, Université de Genève, Section de Physique/DPMC, Quai Ernest-Ansermet 24, 1211 Genève 4 — We have discovered a method to promote the growth of Mn silicide nanowires on the Si(001) at 450°C. Deposition of sub-monolayer quantities of Mn onto a Si(001) surface with a high density of Bi nanolines results in the formation of nanowires, 5-10 nm wide, and up to 600 nm long. These nanowires are never formed if the same growth procedure is followed in the absence of the Bi nanolines. The Haiku core of the Bi nanoline is known to induce short-range stress in the surrounding silicon surface, straining neighbouring dimers, and repelling step edges [1]. We discuss the possible mechanisms for this effect, including the effect of the Bi nanolines on the surface stress tensor and alteration of the available diffusion channels on the surface.

9:00AM A11.00006 Hyperthermal epitaxy of enriched ^{28}Si , KEVIN DWYER, University of Maryland, College Park, JOSHUA POMEROY, National Institute of Standards and Technology — In the effort to produce devices suitable for quantum computation, it is necessary to increase as much as possible the T_2 coherence time of the electron or nuclear spin being used as a qubit. For silicon devices this means using isotopically enriched ^{28}Si. This is because ^{28}Si has no net nuclear spin while the spin of ^{29}Si present in natural Si (4.67%) interacts with the qubit spin and reduces the T_2 time greatly. Sufficiently long T_2 times are necessary for successful operation of quantum computers and we will demonstrate a method for producing epitaxial layers of ^{28}Si on a Si substrate. Ideally, the silicon layers produced must not only be isotopically enriched, but chemically pure and defect free for best performance. These qualities are produced by deposition from a hyperthermal energy beam line using a mass selecting magnet. Depositing silicon epilayers at hyperthermal energies allows for greater manipulation of layer quality. This process is tested and calibrated initially using carbon dioxide. As a preliminary test, isotopically enriched ^{13}C is implanted into semiconductor grade silicon and analyzed by secondary ion mass spectroscopy as an independent check on estimated levels of isotopic and chemical purity.

9:12AM A11.00007 Anti-phase domain suppression and increased electron mobilities in InSb epilayers and quantum wells on off-axis Ge(211) and GeOI(001) substrates[1] , MUKUL C. DEBNATH, TETSUYA D. MISHIMA, MICHAEL B. SANTOS, University of Oklahoma, KHALID HOSSAIN, ORIN W. HOLLAND, Amethyst Research Inc. — We report on the molecular beam epitaxy of InSb epilayers and Si δ-doped InSb/$Al_xIn_{1-x}Sb$ quantum wells (QWs) on off-axis Ge(211) and Ge-On-Insulator (GeOI)-On-Si substrates. The high carrier mobilities in n-type InSb and p-type Ge QWs provide a motivation to integrate these structures on a single substrate for an improved CMOS technology. Growth on GeOI substrates may also make possible the integration of InSb infrared detectors with Si transistors. We evaluate the suppression of anti-phase domains (APDs) through analysis of Reflection High-Energy Electron Diffraction (RHEED) patterns obtained during growth on off-axis substrates. The narrowest X-ray rocking curve width is 100 arc sec for a 4.0-μm-thick InSb epilayer. The highest room temperature electron mobilities of a 4.0-μm-thick InSb epilayer and an InSb QW are 64,000 and 23,500 cm^2/V-s for growth on off-axis Ge(211) and GeOI(001) substrates, respectively. We attribute the single-domain RHEED patterns, reduced X-ray rocking curve widths, and increased electron mobilities to the suppression of APDs in the structures grown on off-axis Ge(211) and GeOI(001) substrates.

9:24AM A11.00008 Synthesis of large-area graphene on cobalt film by thermal cracker enhanced gas source molecular beam epitaxy , NING ZHAN, GUOPING WANG, JIANLIN LIU, Department of Electrical Engineering,University of California, Riverside, QUANTUM STRUCTURES LABORATORY TEAM — Recently, synthesis of large-area graphene has become increasingly important. Various metal substrates have been tested. Among these substrates, cobalt (Co) has been used to absorb carbon and form hexagonal structures on its surface. Nevertheless, only small graphene piece or nano carbon islands have been achieved. Here, we propose a method to grow graphene on Co using thermal cracker enhanced gas source molecular beam epitaxy. Atomic carbon beam provided by thermal cracker impinges to Co film and forms graphene epitaxially. Raman spectroscopy and transmission electron microscopy measurements confirmed mis-oriented stacking order between layers rather than strict AB Bernal stacking. The coverage of single layer and bi-layer is more than 90%. Growth temperature- and time-dependent analyses indicate a narrow growth window for the growth of few-layer graphene.

9:36AM A11.00009 Studies on magneto-transport properties of dilute magnetic semiconductors , R. GUPTA, A. GHOSH, Missouri State University, Y. KOLEKAR, Pune University, K. GHOSH, P. KAHOL, Missouri State University — Diluted magnetic semiconductors (DMS) are rare group of promising semiconductors in which a fraction of the constituent ions is replaced by magnetic ions. This study is aimed to understand the magneto-transport properties of magnetic ion doped In2O3 thin films. The films were grown under different temperature and partial oxygen pressures by pulsed laser deposition. The films were characterized using various techniques such as X-ray diffraction, UV-VIS spectroscopy and magneto-transport. Anomalous magneto-resistive (MR) behavior has been observed for these films, which largely depends on growth conditions. For example, Co doped In2O3 films show presence of negative as well as positive MR at low temperatures. However, the film grown at 400 0C at a partial oxygen pressure of 1×10-4 mbar shows negative MR with a maximum value of around -0.3%. Films grown under higher partial oxygen pressures show large positive MR. Maximum positive MR of 8.9% is seen for the film grown at partial oxygen pressure of 4.3×10- 4 mbar at 400 0C. The effect of growth conditions on MR properties of these films will be presented in detailed. This work is supported by National Science Foundation (Award Number DMR-0907037).

9:48AM A11.00010 Phase evolution and microstructure growth of $CuInSe_2$ by sonochemistry , EMRE YASSITEPE, University of Delaware, WILLIAM N. SHAFARMAN, Institute of Energy Conversion, University of Delaware, S.ISMAT SHAH, University of Delaware — Non toxic chemical routes that enable formation of high quality $CuInSe_2$ thin films with high materials utilization are desired for low production cost of solar cells. Sonochemistry provides a well known route to form reactive surfaces in metallic particles and , in the literature, CuSe has been reactively formed by using organic precursors. We will present results of the effects of ultrasound on the reactivity between Cu, In and Se elemental particles. The reaction between these elements facilitates binary selenide phase formation which promotes single phase growth of $CuInSe_2$ with further annealing. XRD analyses showed that binary phases of $CuSe_2$, CuSe and In_4Se_3 are formed by sonication. Annealing these binary phases led to the single phase formation of $CuInSe_2$ at 350 °C. We have found that if In has not reacted with Se during sonication, the structure is not completely transformed to $CuInSe_2$ at 350 °C.

10:00AM A11.00011 Structural and magnetic properties of Cr and Co doped indium oxide dilute magnetic semiconductors , K. GHOSH, E. NAHLIK, M. LANGHOFF, R. GUPTA, Missouri State University, Y. KOLEKAR, Pune University, P. KAHOL, Missouri State University — Dilute magnetic semiconductors have attracted considerable attention for development of next generation multifunctional spintronics devices. Indium oxide is a wide band gap semiconductor with unique optical and electrical properties. Here, we investigate the effect of Co and Cr doping on structural and magnetic properties of Indium oxide. Different amounts of Co and Cr were doped in In2O3 using solid state reaction method. Structural and magnetic properties have been measured using standard techniques. X-ray diffraction analysis confirmed single phase Indium oxide with no impurity phases due to addition of Co and Cr. Magnetization (M) as a function of applied magnetic field (H) and temperature (T) were collected on all the samples using a superconducting quantum interference device magnetometer. M vs T measurements for Co doped Indium oxide showed the presence of a hump around 50K which could be due to paramagnetic to ferromagnetic transition and the M vs H field study show the hysteresis behavior which confirms the ferromagnetism. This work is supported by National Science Foundation (Award Number DMR-0907037)

10:12AM A11.00012 High-Purity Germanium Crystal Characterization for DUSEL Experiments[1] , DONGMING MEI, CHAOYANG JIANG, OLEG PEREVOZCHIKOV, NICK WEINANDT, YONGCHEN SUN, The University of South Dakota, CUBED COLLABORATION — Understanding the nature of neutrinos and dark matter was identified by a National Academy of Sciences panel as one of the key problems facing physicists today. The CUBED (Center for Ultra-Low Background Experiments at DUSEL) collaboration is working on the development of techniques to manufacture crystals in an underground environment with unprecedented purity levels that may be used by experiments proposed for DUSEL. Growing high-purity germanium crystals depends strongly on the understanding of various impurities in the grown crystals and developing new techniques to eliminate them. This paper will present the characterization techniques to identify the impurity levels according to their energy levels and distributions. The results will provide feedback for the crystal growth process that would eliminate the impurities in the grown crystals for DUSEL experiments.

10:24AM A11.00013 Stable Nanocrystals vs. Ostwald Ripening: A Theoretical Investigation , MICHAEL CLARK, SANAT KUMAR, Columbia University, KUMAR GROUP TEAM — Previous studies have shown that stable, monodisperse-sized nanocrystals (NCs) have been produced through the use of strongly binding surfactants, e.g. Au NCs with alkylthiols or Co NCs with oleic acid, to name a few. Through a first-principles theoretical investigation, we determine that these stable sized NCs are in an equilibrium state, and we establish what conditions lead to stable, monodisperse nanocrystals instead of polydisperse nanocrystals undergoing Ostwald ripening. Our results further describe how the equilibrium NC size can be tuned through experimentally adjustable parameters (concentration, temperature, reactant proportions), providing novel concepts for controlling the synthesis of monodisperse nanocrystals. Our theoretical results are compared directly with experimental NC syntheses, providing additional insight into the microscopic properties and dynamics of these stable NC mixtures.

10:36AM A11.00014 Extreme electronic sensitivity of carbon nanotubes to internal wetting , DI CAO, Arizona State University — It is now possible to pass a solution of an analyte through the interior of individual single-walled carbon nanotube (SWCNT) nanofluidic channels in a planar device connecting two fluid reservoirs. By building field-effect transistor connections onto the SWCNT nanofluidic channel, we have discovered that internal wetting of the SWCNT by pure water turns semiconducting tubes on, and renders them insensitive to back gating. Transistor action is restored when the devices are dried under vacuum. In contrast, external wetting has little effect. Theoretical simulations recapitulate this behavior, showing that the difference in response to internal and external wetting is a consequence of nanoconfinement, which enabled water molecule structure ordering and enhanced the water-CNT interaction. The dipole field of ordered water locks the CNT potential and the water-CNT interaction modifies the electronic structure of the CNT.

10:48AM A11.00015 CN-VFET Based Organic Nonvolatile Memory Elements Using a Floating Gate , PO-HSIANG WANG, BO LIU, MITCHELL MCCARTHY, ANDREW RINZLER, Dept. of Physics, UNIVERSITY OF FLORIDA, GAINESVILLE FL 32611 TEAM — We have demonstrated organic nonvolatile memory elements based on carbon nanotube enabled vertical field effect transistors (CN-VFETs) with a hybrid dielectric embedded floating metal gate used for charge storage. The electric field concentration around the high aspect ratio carbon nanotubes (acting as the source electrode in the vertical transistor) makes them excellent sources of charge injection of both polarities into the floating gate. This results in a large, fully programmable, hysteresis in cyclic transfer curves without sacrificing carrier mobility in the vertical organic channel layer. These features may provide for cost-effective, relatively high-density organic memory devices compared to more conventional TFT architecture organic devices.

Session A12 GERA DMP: Focus Session: Electricity-to-Light Conversion: Solid State Lighting I D223/224

8:00AM A12.00001 Surface phase matched templates for GaN hetroepitaxial growth[1] , PRAVEEN KUMAR, NPL New Delhi India, JITHESH KUYYALIL, SHIVAPRASAD SM, JNCASR Bangalore India — Surface structural modifications are performed on Si(111)-7x7 surface, to find the appropriate template for high quality GaN growth. Adsorption of Ga forms stable superstructural phases of (1x1), (6.3x6.3) and (rt3xrt3) at 1.5ML, 0.8ML and 0.33ML respectively on a (7x7) reconstructed Si(111) surface. Using PA-MBE system, GaN of 0.75microns is grown at a relatively low temperature of 450oC on each of these phases. The films formed grow in the wurtzite phase with c-axis perpendicular to the Si(111) substrate surface. Now XRD, PL, XPS, AFM, FESEM and RHEED are employed to evaluate the structural, optical, compositional and morphological aspects of the GaN films. It is clearly observed that the 0.33ML (rt3xrt3) Ga phase results in the best quality GaN films, followed by the (6.3x6.3) phase and then the (1x1) phase. The (rt3xrt3) unit cell dimension matches with 2xa of GaN unit cell size, and thus GaN grows epitaxially on this surface with oriented single crystal grains. Thus, the results clearly demonstrate the possibility of employing low coverage metal induced surface phases as templates to form matched GaN films of high structural & optical quality.

8:12AM A12.00002 Quantum Photovoltaics via Coherent Drive[1] , KONSTANTIN DORFMAN, ANATOLY SVIDZINSKY, MARLAN SCULLY, Texas A&M University — We study the fundamental limit to photovoltaic efficiency that is widely thought to be due to detailed balance between radiative recombination and radiative absorption. Quantum coherence in fact can break the detailed balance yielding vanishing emission of incident resonant radiation with nonzero absorption. This results in the enhancement of the quantum efficiency of the photovoltaic (PV) cell as compared to the "two-level" system. Similar to lasing without inversion and photo-Carnot quantum heat engine, in a quantum dot PV cell with coherently driven doublet in the excited state it is possible to suppress the radiative recombination and increase the quantum limit of photovoltaic operation compare to classical one. Our approach is consistent and does not violate the laws of thermodynamics.

8:24AM A12.00003 New Type of Core-Shell Nanocrystal Quantum Dots for Applications in Light Emitting Diodes (LEDs) , B.N. PAL, S. BROVELLI, Y. GOSH, V.I. KLIMOV, J.A. HOLLINGSWORTH, H. HTOON, LANL, CHEMISTRY DIVISION TEAM, CENTER FOR ADVANCED SOLAR PHOTOPHYSICS TEAM, CENTER FOR INTEGRATED NANOTECHNOLOGIES TEAM — We demonstrate a proof of principle for LEDs based on giant nanocrystal quantum dots (g-NQDs). These dots consist of a CdSe core overcoated with a thick CdS shell built one monolayer at a time. Our device structure is composed only of a PEDOT:PSS coated indium-tin oxide (ITO) anode and a LiF-Al cathode. These simple devices exhibit a maximum external quantum efficiency (EQE) and luminance of 0.12% and 1000 Cd/m2 respectively when 16 shell g-NQDs are used for the active layer. This performance is already comparable to that of more sophisticated all-inorganic NQD LEDs. Thick shell (>13 monolayer) g-NQD devices show EQEs about one order of magnitude higher than those of thin-shell (4 monolayer) NQD devices, as well as much greater stability for operation under ambient conditions. Although current g-NQD devices do not set any new performance records, this work demonstrates a significant potential of g-NQDs for LED applications.

8:36AM A12.00004 Lattice-mismatched phosphide-based LEDs for color mixing white light applications , KIRSTIN ALBERI, National Renewable Energy Laboratory — The most promising means of achieving high efficiency white light emitting diodes (LEDs) with high color rendering indices (CRI) is to combine individual red (615 nm), yellow (573 nm), green (535 nm) and blue (459 nm) solid-state LEDs in a four color RYGB architecture. Due to their high bandgaps and the availability of bulk substrates, phosphide-based alloys are currently leading candidates for achieving the longer wavelengths, of which AlGaInP lattice-matched to GaAs has been extensively explored. In a departure from this approach, we investigate phosphide alloys at compositions that are lattice-mismatched with respect to GaAs for color mixing white light applications. Lifting the lattice-matching requirement extends the options for active and cladding layer design and optimization, thereby providing additional avenues for reducing carrier loss pathways and improving device efficiency. This talk covers our work on issues central to the success of this technology: metamorphic growth of high quality epilayers, the competing trade-off between operating wavelength and intervalley carrier transfer loss, and the availability of optimal cladding layers for high power operation. Support from the DOE EERE-SSL and BES-DMS programs and the LDRD program at NREL is gratefully acknowledged.

9:12AM A12.00005 Ab initio study of MOCVD synthesis of InN and GaN , WERONIKA WALKOSZ[1], Argonne National Laboratory, PETER ZAPOL, MATTHEW J. HIGHLAND, PAUL H. FUOSS, GREGORY B. STEPHENSON — A detailed understanding of MOCVD growth of group III nitrides is important for improved control over their properties and performance in a wide range of applications. Because of the relative instability of InN, chemically active precursors such as NH_3 are typically used to provide the high nitrogen activity needed for growth. Our goal is to understand the mechanism and species involved in active nitrogen formation on the growth surface. Here we present results of density functional theory calculations for the decomposition of NH_3 on InN and GaN (0001) surfaces through reaction intermediates such as adsorbed NH_2 and NH. The calculated equilibrium surface structures along with the reaction barriers for the dissociation pathways of NH_3 on these surfaces are described. Kinetic modeling based on the calculated barriers to determine reaction mechanisms and effective nitrogen activities is discussed. The results will be used to elucidate chemical kinetics on GaN and InN (0001) surfaces under MOCVD growth conditions with the aim to optimize synthesis conditions and precursors for effective growth of metastable nitrides. 9:24AM A12.00006 Band Gap Tuning and Structural Transformation in GaN through Equi-biaxial In-plane Strains and Alloying with InN , LIANG DONG, Department of Physics, University of Connecticut, S. PAMIR ALPAY, Department of Physics and Institute of Materials Science, University of Connecticut — Gallium nitride (GaN)-based semiconductor devices play a key role in modern optoelectronics and photovoltaics. Structural and electronic properties of the GaN can be tuned through external/internal stresses or by alloying it with InN. In this study, we present an *ab initio* analysis using density functional theory to understand the effects of equi-biaxial strains and indium additions to the crystallographic structure, electronic properties, and polarization of GaN and band bending in GaN-InN heterostructures. It is shown that internal strains in GaN may result in significant changes in the band gap and may even give rise to structural transformations from wurtzite to a graphite-like semi-metallic phase. For the InGaN alloys, possible stable crystal structures (besides the prototypical wurtzite structure), lattice parameters, the band gap, and the spontaneous polarization are calculated as function of indium composition.

9:36AM A12.00007 Structural and Optical properties of Si-doped AlN , SASHIKANTH MAJETY, BED PANTHA, ASHOK SEDHAIN, JING LI, HONGXING JIANG, JINGYU LIN, Texas Tech University — A lot of research has focused on controlling the conductivity in AlN by Silicon doping. AlN has the widest bandgap (∼6.1 eV) among III-Nitride semiconductors and exhibits excellent properties such as high temperature stability, high thermal conductivity, and deep ultraviolet transparency. In the AlN material system, doping causes crystal imperfections which can affect the structural and optical properties of the AlN epilayers. In this work, we investigated the impact of Si incorporation on the structural and optical properties of AlN epilayers. The formation of edge dislocations in Si-doped AlN is explained by the built-up tensile stress in the epilayers as revealed by X-ray diffraction measurement. Photoluminescence (PL) studies revealed that the full width at half maximum of both band-edge emission and impurity related transitions are correlated with the density of screw dislocations, N_{screw}, which is found to increase with increasing doping concentration of Si (N_{Si}). In addition, it was formulated that the band-edge (impurity) PL emission linewidth increases linearly with increasing N_{screw} at a rate of ∼3.3±0.7 meV/10^8 cm^{-2} (26.5±4 meV/10^8 cm^{-2}), thereby establishing PL measurement as a simple and effective method to estimate screw dislocation density in AlN epilayers.

9:48AM A12.00008 Causes of yellow luminescence in GaN , ANDERSON JANOTTI, University of California Santa Barbara — Although GaN is already used in light-emitting diodes and laser diodes, the origins of a number of frequently observed sub-band-gap luminescence bands are still under debate. For instance, the broad yellow luminescence that is invariably seen in n-type GaN has been long attributed to Ga vacancies. However, its presence in semi-insulating or p-type material, in which the Ga-vacancy concentration is low, has remained unexplained. The yellow luminescence has also been associated with the presence of carbon impurities, yet no credible, C-related configuration has been suggested. Using first-principles calculations we investigate the electronic and structural properties associated with defects and impurities in GaN. We employ a hybrid functional method to overcome the well-known band-gap problem of density functional calculations, and obtain accurate, quantitative results for defect transition levels. We find that C substituting for N (C_N) is a deep acceptor in GaN, with an ionization energy of 0.90 eV, in contrast to the commonly accepted view that C_N acts as a shallow acceptor. Incorporating C_N will therefore not result in p-type conductivity [1]. By inspecting the calculated configuration coordinate diagrams, we find that the absorption and emission lines of C_N are in remarkable agreement with the experimental results for yellow luminescence. This solves the longstanding puzzle regarding the nature of the defect responsible for yellow emission in C-containing GaN, and suggests that previous experimental data, analyzed under the assumption that C_N acts as a shallow acceptor, should be revisited. Work performed in collaboration with J. L. Lyons and C. G. Van de Walle, and supported by the NSF and by the UCSB Solid State Lighting and Energy Center.

[1] J. L. Lyons, A. Janotti, and C. G. Van de Walle, Appl. Phys. Lett. 97, 152108 (2010).

10:24AM A12.00009 Hybrid functional calculations of DX centers in AlN, GaN and AlGaN[1] , LUKE GORDON, JOHN L. LYONS, ANDERSON JANOTTI, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara, CA 93106-5050 — The group-III nitrides have important commercial applications in optoelectronic devices. To achieve high-efficiency UV lasers and LEDs, AlN substrates and high Al-content AlGaN alloys will likely be required. A better understanding of the role of defects and impurities in AlN is crucial. One of the outstanding problems in the study of AlN and high-Al-content AlGaN is the formation of the so-called DX centers, which consist of donor impurities that self-compensate by turning to acceptors as the Fermi level approaches the conduction band. In this work, we employ density functional calculations using a hybrid functional to investigate the possibility of DX-center formation for Si and O donors in AlN and GaN. The functional includes a portion of Fock exchange and gives band gaps and lattice parameters very close to the experimental values, allowing for quantitative predictions of defect levels. Based on the analysis of the stability of DX centers in AlN and GaN, we discuss the onset of DX behavior in AlGaN alloys.

10:36AM A12.00010 Role of nitrogen vacancies and related complexes in compensation and luminescence of Mg-doped GaN , QIMIN YAN, ANDERSON JANOTTI, University of California at Santa Barbara, MATTHIAS SCHEFFLER, UCSB and Fritz-Haber-Institut, D-14195 Berlin, CHRIS G. VAN DE WALLE, University of California at Santa Barbara — Using first-principles calculations with the hybrid functional method (HSE), we investigate the effects of nitrogen vacancies and related complexes on the electrical and optical properties of Mg-doped GaN. We obtain information about the expected defect concentration, stable charge states, and defect levels by calculating the formation energies of vacancies and Mg−vacancy complexes. The $3+$ state of the nitrogen vacancy and the $2+$ state of the complex are found to be most stable when the Fermi level is near the valence-band maximum (VBM). Our calculations also enable us to study the role of these defects in luminescence. Vacancy-dopant complexes (including $\mathrm{Mg_{Ga}}-V_{\mathrm{N}}$) have been proposed as the origin of a deep level involved in the red (1.8 eV) photoluminescence (PL) band often observed in Mg−doped GaN. We investigate the optical absorption and emission energies by calculating the configuration coordinate diagram for the vacancy and for the $\mathrm{Mg_{Ga}}-V_{\mathrm{N}}$ complex. The emission, in which an electron in the conduction band is transferred to $(\mathrm{Mg_{Ga}}-V_{\mathrm{N}})^{2+}$, resulting in $(\mathrm{Mg_{Ga}}-V_{\mathrm{N}})^{+}$, peaks at 1.81 eV. Our calculated emission lines thus indicate that $\mathrm{Mg_{Ga}}-V_{\mathrm{N}}$ is a likely source for the red luminescence observed in Mg-doped GaN.

10:48AM A12.00011 Effects of strain on effective masses in GaN and AlN[1] , CYRUS E. DREYER, ANDERSON JANOTTI, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara, CA 93106-5050 — Strain caused by lattice mismatch or alloying is present in almost all heterostructure-based semiconductor devices. One of the fundamental effects of strain on semiconducting materials is to alter their band gap and thus the effective mass of their carriers. Because of the lack of native substrates for GaN and the mismatch between different layers, these effects are particularly important in GaN/AlGaN based devices. Using first-principles calculations, we have investigated the effects of hydrostatic and c-plane biaxial strain on the band structure of GaN and AlN, specifically on the band gap and effective mass in the direction parallel and perpendicular to the c direction. In general, the effective mass decreases with increased hydrostatic or biaxial tensile strain, as expected from k.p theory. However, the opposite trend is observed for the effective mass of AlN in the c direction under biaxial strain. This is explained by analyzing the strained band structure of AlN using a two-band Kane model.

Session A13 DFD DPOLY: Focus Session: Polymer Colloids: Structure, Function, and Dynamics I D225/226

8:00AM A13.00001 Osmotic pressure of microgel suspensions , JUAN JOSE LIETOR-SANTOS, BENJAMIN SIERRA-MARTIN, JUSTIN FREDERICK, YESENIA LAPORTE, GEORGE MARKOU, ALBERTO FERNANDEZ-NIEVES, Georgia Institute of Technology — Microgels are crosslinked-polymeric networks in the colloidal domain, whose size can be change in response to external stimuli. They are soft particles by construction and can exhibit a very different behavior compared to hard sphere suspensions. In some cases, this different behavior has been understood by alluding to particle de-swelling at low volume fractions. For this to happen, the suspension osmotic pressure at such volume fraction should be comparable to the particle bulk modulus. In this work, we independently measure the bulk modulus of microgel particles and the suspension osmotic pressure and find that both magnitudes become comparable at a volume fraction corresponding to a liquid-to-solid transition, which we asses using rheology. Interestingly, in the solid region, the shear and compressional moduli of the suspension exhibit the same behavior with volume fraction, in analogy to emulsions. However, by contrast to emulsions, they are almost two orders of magnitude apart. This reflects the contributions from the internal modes of the microgel particles, which are absent for the case of an emulsion drop.

8:12AM A13.00002 Particle Charging and Interaction in Nonpolar Colloidal Dispersions Mediated by Nonionic Surfactants , SVEN BEHRENS, Georgia Tech — The electrostatic stabilization of colloidal dispersions is usually considered the domain of polar media only, but some surfactants are known to raise the conductivity of liquids with low electric permittivity and to mediate charge-stabilization of nonpolar dispersions. Here we report an example of the counterintuitive electrostatic effects of nonionic surfactants on colloidal particles in nonpolar solvents. PMMA particles in hexane solutions of sorbitan oleate (Span) surfactants exhibit a field-dependent electrophoretic mobility. In the zero field limit, we find large surface potentials whose decay with increasing surfactant concentration resembles the salt-induced screening in aqueous solutions. The amount of surface charge and screening ions in the nonpolar bulk is further characterized via ensemble measurements of the particles' pair interaction energy. In contrast to the behavior reported for systems with *ionic* surfactants, we observe particle charging and a screened Coulomb type interaction both above and below the surfactant's critical micelle concentration.

8:24AM A13.00003 Experimental Studies of the Brownian Diffusion of Boomerang Colloidal Particle in a Confined Geometry , AYAN CHAKRABARTY, FENG WANG, BHUWAN JOSHI, QI-HUO WEI, Kent State University — Recent studies shows that the boomerang shaped molecules can form various kinds of liquid crystalline phases. One debated topic related to boomerang molecules is the existence of biaxial nematic liquid crystalline phase. Developing and optical microscopic studies of colloidal systems of boomerang particles would allow us to gain better understanding of orientation ordering and dynamics at "single molecule" level. Here we report the fabrication and experimental studies of the Brownian motion of individual boomerang colloidal particles confined between two glass plates. We used dark-field optical microscopy to directly visualize the Brownian motion of the single colloidal particles in a quasi two dimensional geometry. An EMCCD was used to capture the motion in real time. An indigenously developed imaging processing algorithm based on MatLab program was used to precisely track the position and orientation of the particles with sub-pixel accuracy. The experimental finding of the Brownian diffusion of a single boomerang colloidal particle will be discussed.

8:36AM A13.00004 Effect of Boundary Mobility on the Dynamics of Confined Colloidal Suspensions , GARY L. HUNTER, KAZEM V. EDMOND, ERIC R. WEEKS, Emory University — We use high-speed confocal microscopy to study the influence of boundary mobility on the dynamics of confined colloidal suspensions. Experiments in molecular super-cooled liquids show that confinement can enhance or hinder sample mobility, depending on whether the confining boundary is "soft" (mobile) or "hard" (immobile). We confine suspensions of PMMA microspheres within emulsion droplets of different sizes to examine the consequences of confinement. By changing the viscosity of the external, continuous phase, we also vary the boundary mobility of our samples. In this way, we decouple the effects of confinement and boundary mobility, and draw comparisons between colloidal suspensions and molecular liquids.

8:48AM A13.00005 Observing liquid-gas nucleation in a colloid-polymer solution , RYAN MCGORTY, VINOTHAN N. MANOHARAN, Harvard Unversity, Dept. of Physics — We study liquid-gas nucleation in a colloid-polymer solution. Though the colloidal particles are too small to resolve, we are able to observe nucleating droplets due to the refractive index mismatch between the two fluid phases. By using digital holographic microscopy and thermally-responsive colloids we are able to observe the micron-sized nucleating droplets and their fluctuations in three-dimensions. From the droplets' fluctuations we can back out the interfacial tension. Additionally, our three-dimensional imaging technique allows us to capture individual nucleation events and their rate of occurrence. We hope that our data will allow us to better understand nucleation kinetics.

9:00AM A13.00006 Measuring the translational and rotational diffusion of colloidal clusters with digital holographic microscopy , JEROME FUNG, KRISTOPHER ERIC MARTIN, RYAN MCGORTY, DAVID M. KAZ, REBECCA W. PERRY, Harvard University, JOHN A. KELLER, Eastern Nazarene College, GUANGNAN MENG, VINOTHAN N. MANOHARAN, Harvard University — We measure the rotational and translational diffusion coefficients of individual non-spherical colloidal clusters undergoing three-dimensional Brownian motion. We image clusters comprised of spheres approximately 1 μm in diameter using digital holographic microscopy. Fitting the measured holograms to exact electromagnetic scattering calculations allows us to determine cluster positions and orientations with millisecond temporal resolution and $\sim$10 nm spatial resolution. For dimers of polystyrene spheres in an aqueous solution, our measurements of the coefficients for rotational diffusion as well as translational diffusion parallel and perpendicular to the dimer axis are consistent with theory. We discuss the extension of this work to non-axisymmetric trimers and potential applications.

9:12AM A13.00007 Density of States of a Two-Dimensional NIPA-Polystyrene Colloidal Crystal[1] , MATTHEW GRATALE, PETER YUNKER, KE CHEN, ARJUN YODH, Department of Physics and Astronomy, University of Pennsylvania — In this work we are interested in how "dopants" affect the vibrational properties of crystals. We study the vibrational density of states of a two-dimensional colloidal crystal consisting of a mixture of hard polystyrene particles and soft NIPA microgel particles. Thus, depending on the particles involved, multiple inter-particle potentials are present in these crystals. The number ratio of hard to soft particles is varied, creating crystals consisting primarily of soft particles doped with hard particles and vice versa. We employ video microscopy to derive the phonon density of states of corresponding "shadow" crystals with the same geometric configuration and interactions as the experimental colloidal system, but absent damping [1,2,3]. Preliminary data reveal low frequency plane-like waves in all crystals, regardless of composition. Participation in higher frequency modes is often enhanced in one species of particles and diminished in the other.

9:24AM A13.00008 Structure and dynamics of confined colloid-polymer mixtures , JACINTA CONRAD, Department of Chemical and Biomolecular Engineering, University of Houston, BINH TRINH, GILDARDO CEBALLOS, Department of Chemical and Biomolecular Engineering, University of Houston — Colloidal processing routes typically require attractive suspensions to be flowed through fine geometries such as microchannels, nozzles, or thin films. To elucidate the effects of confinement on attractive suspensions during processing, we use confocal microscopy to image the structure and dynamics of model colloid-polymer mixtures as a function of confinement dimensionality and thickness, colloid volume fraction, and the strength and range of the attraction. We characterize the phase behavior of the confined suspensions, and find that confinement induces non-uniform structural changes within colloidal gels.

9:36AM A13.00009 Controlling the size distribution of self-assembled colloidal clusters[1] , NICHOLAS SCHADE, Harvard Department of Physics, JESSE COLLINS, JONATHAN FAN, MIRANDA HOLMES-CERFON, Harvard SEAS, VINOTHAN MANOHARAN, Harvard Department of Physics — Using a combination of experiment and simulation, we investigate the structures that form when spherical colloidal particles cluster around spheres of different sizes in a binary mixture. We use either oppositely charged particles or particles coated with complementary DNA sequences to form the clusters. Using optical microscopy, we examine the effect of the stoichiometric ratio, the size ratio, and the type of interaction on the distribution of clusters. These parameters serve as useful control mechanisms for the synthesis of nanostructures with tunable properties. For example, a high density of tetrahedral clusters of metallo-dielectric spheres could be used to create a bulk, isotropic metamaterial.

[1]We acknowledge support from NSF grant no. ECCS-0709323 as well as the DOE Office of Science Graduate Fellowship Program.

9:48AM A13.00010 Dynamics of interfacial breach by colloidal spheres , DAVID M. KAZ, RYAN MCGORTY, Harvard University, MADHAV MANI, University of California at Santa Barbara, VINOTHAN N. MANOHARAN, Harvard University — We present observations of individual colloidal spheres as they approach and penetrate a flat aqueous interface. Polystyrene spheres with various surface chemistries (sulfate, carboxyl, etc) are brought to the boundary between an oil phase (decane) and an aqueous phase (water+glycerol+NaCl) using radiation pressure from a tightly focused laser. Holographic images are recorded at up to 24,000 frames per second and subsequently compared with Mie-scattering calculations to obtain positional data at a resolution of 5nm in x,y, and z. Typical trajectories consist of an approach to the interface that is dominated by hydrodynamics; a discontinuous jump at the point of penetration (POP); and a very long timescale relaxation that is logarithmic in time. We find that the concentration of salt in the aqueous phase must be above a certain threshold (depending on species) for breach to occur. Well above this threshold, trajectories just prior to the POP are characterized by short-timescale features that are non-monotonic in salt concentration. DLVO type calculations reproduce some aspects of these features, but the non-monotonicity remains mysterious.

10:00AM A13.00011 Sub-diffusion of DNA Coated Particles Near a Complementary DNA Covered Surface[1] , LANG FENG, QIN XU, Center for Soft Matter Research, New York University, RUOJIE SHA, NADRIAN SEEMAN, Chemistry Department, New York University, PAUL CHAIKIN, Center for Soft Matter Research, New York University — We have measured the diffusive behavior of micrometer sized colloids in a DNA covered particle-surface system. Near the particle-surface melting temperature of $\sim 45^\circ$ C we observe conventional diffusion but as temperature is lowered we see a crossover to sub-diffusion over a narrow temperature range. The sub-diffusive behavior is intimately related to the broad distribution of local trapping times. We present a theoretical model which explains the sub-diffusion exponent μ in $< R^2(t) > \sim t^\mu$, which ranges from $\mu = 1$ at 44.7° C to $\mu = 0.33$ at 44.1° C. From the distribution of number of DNA bonds we calculate the trapping time distribution and average trapping time. When the measurement time exceeds the average trapping time the system is in equilibrium and exhibits conventional diffusion. When the measurement time is less than the average trapping time the system is not in equilibrium and is sub-diffusive.

[1]NASA NNX08AK04G

10:12AM A13.00012 Multiple-Stage Melting and Freezing of Colloidal Crystallites with Short-range Attraction , LIQUAN PEI, Department of Physics, University of Massachusetts Amherst, J.R. SAVAGE, Department of Physics, Cornell University, A.D. DINSMORE, Department of Physics, University of Massachusetts Amherst — We study the dynamics of melting and freezing in a model colloidal system with short-range, temperature tunable attraction. In particular, we mix micron-sized, charge stabilized polystyrene spheres with salt and the surfactant micelles. The micelles induce depletion attraction whose range is less than 2% of the sphere diameter and whose magnitude changes strongly with temperature. We use optical microscopy to record the dynamics of freezing and melting following temperature changes. We use particle tracking algorithms to identify the particles with sub-pixel resolution. For samples with area fraction less than 40%, we have observed that melting and freezing occur in multiple stages, with a metastable liquid phase appearing in both processes. For the freezing sample at area fraction 55%, we have found that the gas droplets are nucleated from high area fraction backgound. The data also show how nucleation dynamics are affected by the metastable gas-liquid binodal. We are also investigating the role of the second, metastalbe solid phase in melting and freezing. Our results are relevant to systems where non-equilibrium states may play a role in phase separation.

10:24AM A13.00013 Colloidal aggregation in microgravity by critical Casimir forces , SANDRA VEEN, PETER SCHALL, University of Amsterdam, MARCO POTENZA, MATTEO ALAIMO, University of Milan, STEFANO MAZZONI, European Space Agency, GERARD WEGDAM, University of Amsterdam, VAN DER WAARLS ZEEMAN INSTITUTE, UNIVERSITY OF AMSTERDAM COLLABORATION, OPTICS AND MICROGRAVITY RESEARCH LABORATORY, UNIVERSITY OF MILAN COLLABORATION, PHYSICAL SCIENCE UNIT, EUROPEAN SPACE AGENCY COLLABORATION — We study aggregation and crystal growth of spherical Teflon colloids in binary liquid mixtures in microgravity by the critical Casimir effect. The critical Casimir effect induces interactions between colloids due to the confinement of bulk fluctuations (density or concentration) near the critical point of liquids. The strength and range of the interaction depends on the length scale of these fluctuations which increase as one approaches the critical point. The interaction potential can thus be tuned with temperature. We follow the growth of structures in real time with Near Field Scattering. Measurements are performed in microgravity in order to study pure diffusion limited aggregation, without disturbance by sedimentation or flow.

10:36AM A13.00014 Particle interactions in colloids are revealed in a nonlinear effect in light transmission , JINSUK SONG, DANIEL OU-YANG — Studies on interactions between particles in highly concentrated suspensions are rare because the solutions are opaque and the interpretations from methods such as diffusing wave spectroscopy are often complicated. We propose a simple method of probing particle interactions in the opaque solution by measuring light transmission affected by optically induced particle concentration enhancement. The increase in the particle concentration with the input light intensity depends on the interactions between particles. We demonstrate how this method can be used to determine single particle trapping energy and the virial coefficients in aqueous suspensions of 190 nm polystyrene spheres.

10:48AM A13.00015 Nano-dumbells pack densely to form birefringent photonic crystals , JASON FORSTER, JIN-GYU PARK, Yale, MANISH MITTAL, University of Delaware, VINODKUMAR SARANATHAN, HEESO NOH, CARL SCHRECK, RICHARD PRUM, COREY O'HERN, HUI CAO, Yale, ERIC FURST, University of Delaware, ERIC DUFRESNE, Yale — Monodisperse spherical colloidal particles robustly self-assemble into crystals at high concentration. We study the the self-assembly of polymer nano-dumbells and find that they crystallize only under strong confinement - in thin films less than three particles thick. On the other hand, external electric fields can readily align dumbbell- shaped particles to make a birefringent suspension. When the electric field is turned off, the dumbbells rapidly lose their orientational order and the birefringence quickly goes away. However, if the solvent is removed with the electric field on, the particles self-assemble into a novel dense crystalline packing hundreds of particles thick. We describe the essential physics of self-assembly of these structures through an interplay of the applied electric field and capillary forces.

Session A14 FEd: Focus Session: New Ways of Communicating Physics D227

8:00AM A14.00001 The Need For "Pleasure in Finding Things Out:" The Use of History and Our Greatest Scientists for Human Survival and Scientific Integrity , JOSHUA BORCHARDT, North Dakota State University — Why Homo sapiens search for interesting things and the methods of which we do so. The use of philosophical, theoretical, and demonstrated processes for exploration of the natural, and not so natural world are presented based on the ideas and wishes of some of History's greatest scientists, with concentration on Richard P. Feynman's lens on scientific discovery and pursuit, for which the abstract gets its title. This talk is presented towards the layman as well as the physicist, and gives insight to the nature of discovery and what it means to have pleasure in finding things out for the betterment of all mankind.

8:12AM A14.00002 Energy Experiments for STEM Students , JOHN FANCHI, TCU — Texas Christian University (TCU) is developing an undergraduate program that prepares students to become engineers with an emphasis in energy systems. One of the courses in the program is a technical overview of traditional energy (coal, oil and gas), nuclear energy, and renewable energy that requires as a pre-requisite two semesters of calculus-based physics. Energy experiments are being developed that will facilitate student involvement and provide hands-on learning opportunities. Students participating in the course will improve their understanding of energy systems; be introduced to outstanding scientific and engineering problems; learn about the role of energy in a global and societal context; and evaluate contemporary issues associated with energy. This talk will present the status of experiments being developed for the technical energy survey course.

8:24AM A14.00003 Physics Learning Strategies with Multi-touch Technology , MARK POTTER, SUNY Oswego, C. ILIE, SUNY Oswego Physics Dept., D. SCHOFIELD, SUNY Oswego CS Dept. — Advancements in technology have opened doorways to build new teaching and learning methods. Through conjunctive use of these technologies and methods, a classroom can be enriched to stimulate and improve student learning. The purpose of our research is to ascertain whether or not multi-touch technology enhances students' abilities to better comprehend and retain the knowledge taught in physics. At their basis, students learn via visual, aural, reading/writing, and kinesthetic styles. Labs provide for all but the aural style, while lectures lack kinesthetic learning. Pedagogical research indicates that kinesthetic learning is a fundamental, powerful, and ubiquitous learning style [1]. By using multi-touch technology in lecture, not only can we accommodate kinesthetic learners, but we can also enrich the experiences of visual learners. Ushering to this wider array of students will hopefully lead to an increase in meaningful learning.

[1] Wieman, C.E, Perkins, K.K., Adams, W.K., -Oersted Medal Lecture 2007: "Interactive Simulations for teaching physics: What works, what doesn't and why," American Journal of Physics. 76 393-99.

8:36AM A14.00004 Why the New York Times Science Tuesday section is only eight pages and what to do about it , BRIAN SCHWARTZ, The Graduate Center of CUNY — Communicating science to the public is the responsibility of all scientists and necessary for an informed electorate and as an inspiration to young minds. Yet successful national strategies for communicating science and the venues for such communication seem limited. Science museums and TV programs like NOVA reach millions of people but still only a very small fraction of the US population. In terms of daily science reporting very few newspapers have a devoted science reporter and it is only the New York Times which has a significant weekly reporting section on science (and health). What can one do about reaching wider and new audiences? We recently ran an NSF sponsored international conference entitled Communicating Science to the Public through the Performing Arts (www.sciartconference2010.com). At the conference there were sessions on science and theater, science and TV and film, science and dance, science and music and science festivals, cafes and events (web.gc.cuny.edu/sciart). Using these new approaches one can reach a new and wider audience and one can also take advantage of the seemingly insatiable interest of the press in the arts. Examples of successful new strategies for communicating science will be presented, evaluated and shown to be replicable at a relatively modest cost of time and money.

9:12AM A14.00005 Teaching Physics Through Comic Books , REBECCA THOMPSON[1], TASSIA OWEN, American Physical Society — Comics have been around as a form of entertainment for decades. They are often as seen as one of the distracting vices of kids (and adults!), but comics and their more adult version, the graphic novel, are increasingly valued as a legitimate genre of literature. The APS Outreach Department has created three comic books, one featuring Nikola Tesla and his battles with the evil Thomas Edison, and two about laser super hero Spectra and her continuing battles with the nefarious Miss Alignment. These comics have struck a delicate balance between education and entertainment being well received by both the comic book and education communities. By creating a compelling comic story that has correct physics, it is possible to use this under-appreciated medium to excite middle-school students who might otherwise be turned off by traditional teaching methods. One lesson-learned is that It is very important to make sure first and foremost that the students enjoy the story and that they feel a connection to the characters. Students are thus hooked and once they are drawn in, the learning happens automatically..

[1]APS Head of Public Outreach

9:24AM A14.00006 Khan Academy: the world's free virtual school[1] , JOSHUA A. DIJKSMAN, Duke University, SALMAN KHAN, Khan Academy — Khan Academy offers an unprecedented set of educational material for science and math education, in the form of short, free, publicly available video clips. With a growing set of already over 2000 videos, it is easily the most exhaustive collection of structured educational material on the Internet. The content is made in digestible 10-20 minute chunks; the granular nature of the material allows learners to fill in almost any of their knowledge "gaps." Importantly, the conversational style used in the videos offers a fresh, new perspective on math and science instruction. With our 2 M$ funding grant from Google and support from the Gates foundation, we envision covering all topics that would appear in typical high-school or collegiate-level Math and Science courses, and translating these videos to the major languages across the globe. Moreover, we also offer a free and fully integrated assessment system, which allows students to practice problems at their own pace and focus on the appropriate instruction to fill in their individual gaps. Many testimonials have already proven our methods to be a highly successful educational tool. Our goal is to allow educators to improve their teaching, but above all to bring simple, rewarding and enjoyable education to the minds of many young students.

[1]Supported by Google, the Gates Foundation, donors and volunteers.

9:36AM A14.00007 How to Talk Science to Homer Simpson , MICHAEL LUCIBELLA, The American Physical Society — Communicating scientific information to the general public is an important but often underappreciated skill. Researchers who can clearly and concisely describe the science they do are critical to helping create a scientifically literate public, something that is sorely lacking in this country. Public understanding of science is crucial because people who understand and appreciate science are more likely to support research funding, the public has to vote on issues of science and technology more than ever, and it helps sow the next generation of scientists. Plus there are many people interested in learning about science who but don't have the training to digest technical language. Writing or talking to a public with minimal background in science and or the media is very different from communicating members of the scientific community. I'll go over a few strategies to keep your message as clear as possible, and will offer some communication guidelines that will ensure that the media and public understand what you say.

9:48AM A14.00008 School for Scientific Thought: Saturday sessions that bring high school and STEM graduate students together , ELISABETH GWINN, Physics Department, UCSB, WENDY IBSEN, CNSI, UCSB — The School for Scientific Thought (http://csep.cnsi.ucsb.edu/k12/sst) is a Saturday morning program that exposes high school students to current research in STEM fields, through 5-week miniclasses that are conceived, developed and taught by graduate students. Now in its second year of sponsorship by UCSB's California Nanosystems Institute, this NSF-supported program provides graduate students with a creative opportunity to communicate their own favorite science to a young audience. The experience solidifies the graduate student's own knowledge while developing expository skills during a limited time commitment that allows them to also progress in their research objectives. High school students make contact with positive scientist role models while learning about exciting topics that are beyond the high school curriculum. SST courses have ranged from "Surfing the Waves of Light and Matter" to "Nanotechnology: Using the Very Small to Solve the World's Problems". The selection of graduate student instructors and recruitment of high school students will be discussed. SST is an outgrowth of the NSF GK-12 program "Let's Explore Applied Physical Science" (LEAPS).

10:00AM A14.00009 The Changing Landscape of Science News , JAMES RIORDON, American Physical Society — Social media are revolutionizing the ways that people communicate and the ways they get their news. Traditional news outlets are in decline, and no subject area is declining faster than science news. Every day there are fewer professional science journalists working in traditional media. On the other hand, ever greater numbers of scientists, science enthusiasts, and online journalists are turning to blogs, podcasts, eBooks, twitter feeds, and social media sites like Facebook and Tumbler to spread news about science. I will present an overview of the state of science journalism and speculate on the likely directions it seems to be heading. I will also offer some general guidelines to help scientists understand what makes a good science news story, as well as suggesting ways that they can get their work in the news.

10:12AM A14.00010 Interactive NMR: A Simulation Based Teaching Tool for Fundamentals to Applications with Tangible Analogies[1] , SARAH GRIESSE-NASCIMENTO, Boston University, JOSHUA BRIDGER, Dover Sherborn HS, KEITH BROWN, ROBERT WESTERVELT, Harvard University — Interactive computer simulations increase students' understanding of difficult concepts and their ability to explain complex ideas. We created a module of eight interactive programs and accompanying lesson plans for teaching the fundamental concepts of Nuclear Magnetic Resonance (NMR) and Magnetic Resonance Imaging (MRI) that we call interactive NMR (iNMR). We begin with an analogy between nuclear spins and metronomes to start to build intuition about the dynamics of spins in a magnetic field. We continue to explain T1, T2, and pulse sequences with the metronome analogy. The final three programs are used to introduce and explain the Magnetic Resonance Switch, a recent diagnostic technique based on NMR. A modern relevant application is useful to generate interest in the topic and confidence in the students' ability to apply their knowledge. The iNMR module was incorporated into a high school AP physics class. In a preliminary evaluation of implementation, students expressed enthusiasm and demonstrated enhanced understanding of the material relative to the previous year.

[1]Funded by NSF PHY-0646094 grant

10:24AM A14.00011 ALPhA: The Advanced Laboratory Physics Association , ERIC BLACK, California Institute of Technology, LOWELL MCCANN, University of Wisconsin at River Falls, JONATHAN REICHERT, TeachSpin, Inc., GABE SPALDING, Illinois Wesleyan, JOHN ESSICK, Reed College, DAVID VAN BAAK, Calvin College, STEVE WONNELL, Johns Hopkins University — The Advanced Laboratory Physics Association (ALPhA) is a group of people with a shared interest in teaching physics labs at the advanced undergraduate or graduate level. ALPhA works closely with the American Physical Society (APS), the Optical Society of America (OSA), and the American Association of Physics Teachers (AAPT) to develop new methods for teaching modern experimental physics. In the summer of 2010 we initiated the ALPhA Immersion Program, a three-day short course where instructors visit a lab, do one or more of the local experiments (home-built or commercial) with the local instructor, and learn the experiments well enough to incorporate them into their own programs. These immersions were very well received, with attendees filling up all available slots. In this talk I will describe ALPhA and the Immersions Program and solicit input from the broader community.

10:36AM A14.00012 Back to the old questions: physics as culture , LEONARDO COLLETTI, Dipartimento di Fisica and INFN, Università di Trento, 38123 Povo (TN), Italy — My thesis is that, when communicating physics to a large public, more effort should be put into presenting it as an invaluable cultural resource. In fact, by insisting only, as it often happens, on its strategic role as technology booster, one would rather understate physics' very core values. People do certainly appreciate new devices which make their life easier, but they also love thinking about general questions, such as "What is the Universe?" and "How do we know something about it?", which make life truly worth living. I am convinced that not introducing properly the large public to the intellectual beauty of physics' ideas, would represent a waste of knowledge which may result in a society that is even poorer than that resulting from scarce investment in innovation. I will propose a variety of approaches that can be used to highlight the conceptual richness of physics at the aesthetic and inspiring level. Not unlike art and literature, physics can be offered in a way that shows its transformative power of our vision of the universe and its capability of matching human desire for understanding.

Monday, March 21, 2011 8:00AM - 10:48AM –
Session A15 DMP GMAG FIAP: Focus Session: Spins in Semiconductors - Spin Dynamics D171

8:00AM A15.00001 "Listening" to the spin noise of electrons and holes in semiconductor quantum dots[1] , SCOTT CROOKER, National High Magnetic Field Laboratory, Los Alamos National Lab — The coherence and dynamical properties of spins in semiconductors are usually studied with powerful techniques based on optical pump-probe or spin resonance methods. Such methods are necessarily perturbative, in that one measures the (dissipative) response of the spins resulting from an external drive or excitation field (*eg*, free-induction decays). However, in accord with the fluctuation-dissipation theorem, the intrinsic fluctuations of the spin system - if experimentally measurable - can also reveal the same dynamical properties (such as g-factors and decoherence times) without ever perturbing the spin ensemble from thermal equilibrium. This talk describes how we measure electron and hole spin dynamics in semiconductors by passively "listening" to these small spin noise signals [1]. We employ a spin noise spectrometer based on a sensitive optical Faraday rotation magnetometer that is coupled to a digitizer and field-programmable gate array (FPGA), to acquire noise spectra from 0-1 GHz in real time with picoradian/root-Hz sensitivity. In doped (In,Ga)As/GaAs quantum dots, both electron and hole spin fluctuations generate distinct noise peaks whose shift and broadening with magnetic field directly reveal their g-factors and dephasing rates. A large, energy-dependent anisotropy of in-plane hole g-factors is clearly exposed, reflecting systematic variations in the average confinement potential. In contrast with conventional pump-probe studies, noise signals increase as the probed volume shrinks, suggesting possible routes towards non-perturbative, sourceless magnetic resonance of few-spin systems.

8:36AM A15.00002 Understanding the modulation frequency dependence of continuous wave optically/electrically detected magnetic resonance , SANG-YUN LEE, SEOYOUNG PAIK, DANE R. MCCAMEY, CHRISTOPH BOEHME, Department of Physics and Astronomy, University of Utah — Continuous wave optically and electrically detected magnetic resonance spectroscopy (cwODMR/cwEDMR) are powerful methods which allow the investigation of the microscopic nature of paramagnetic states involved in spin-dependent transitions, like recombination and transport. Although experimentally similar to conventional electron spin resonance (ESR), there exist limitations when applying conventional theoretical models originally developed for ESR to explain how the observables (luminescence and electric current) of cwODMR and cwEDMR behave under the influences of various experimental parameters. Here we present closed-form solutions for the modulation frequency dependence of cwODMR and cw EDMR based on an intermediate pair recombination model [1] and discuss ambiguities which arise when attempting to distinguishing the dominant spin-dependent processes underlying experimental data. These include: 1) a large number of quantitatively different models cannot be differentiated, 2) signs of signal are determined not only by recombination, but also by other processes like dissociation, intersystem-crossing, pair generation, and even an experimental parameter, modulation frequency.
[1] D. Kaplan, I. Solomon, and N. Mott, Journal de Physique Lettres 39, 51 (1978).

8:48AM A15.00003 Observation of Long Spin Coherence Times in CdSe/CdS Colloidal Nanostructures , K.J. VAN SCHOOTEN, Department of Physics and Astronomy, University of Utah, Salt Lake City, Utah, 84112, USA, J. HUANG, D.V. TALAPIN, Department of Chemistry, The University of Chicago, Chicago, Illinois 60637, USA, W.J. BAKER, C. BOEHME, J.M. LUPTON, Department of Physics and Astronomy, University of Utah, Salt Lake City, Utah, 84112, USA — Spin states in colloidal quantum dots have been intensively studied over the past decade, usually through various all optical time-resolved pump-probe techniques of excitonic fine-structure. Coherence times measured in this manner, which are usually limited to T_2^*, have ranged in order from 1ps to 1ns, thus limiting the potential to use these types of quantum dots in quantum memory schemes. Here, we describe coherence times (T_2) on the order of 100ns for optical excitations in ensembles of CdSe/CdS heterostructure colloidal nanocrystals at 10K. In contrast to the more conventional pump-probe techniques, we employ a time-correlated optically-detected magnetic resonance scheme to measure the true T_2 of optically generated excitations via a Hahn echo sequence. A strong temperature dependence of the spin-dependent luminescence rate is observed, demonstrating that longitudinal spin-relaxation in these strongly spin-orbit coupled semiconductors is thermally activated.

9:00AM A15.00004 Universal scheme for optically-detected T_1 measurements , JOHN COLTON, KEN CLARK, TYLER PARK, DALLAS SMITH, SCOTT THALMAN, Brigham Young University — A two laser pump-probe scheme for measuring spin flip (T_1) lifetimes in GaAs-related materials has been developed. The pump and probe beams are switched on and off electronically, with pulse widths and delays controlled by a two-channel pulse generator. The effect of the pump beam on the probe beam is seen by monitoring the Kerr rotation of the reflected probe beam. The technique has broad applicability, and should work for any material in which Kerr rotation spin measurement can be employed. The authors have applied this technique to a lightly-doped GaAs layer (n=3E14 cm^{-3}), to compare it with two other samples (at slightly higher[1] and slightly lower[2] doping levels) whose T_1 dependence on field had substantial qualitative and quantitative differences from each other. Results for this sample will be presented.

[1]Colton et al., Phys. Rev. B **75**, 205201 (2007).
[2]Fu, et al., Phys. Rev. B **74**, 121304(R) (2006).

9:12AM A15.00005 Ultrafast Measurement of Critical Slowing Down of Hole-Spin Relaxation in Ferromagnetic GaMnAs , AARON PATZ, TIANQI LI, Ames Laboratory and Department of Physics and Astronomy, Iowa State University, ILIAS PERAKIS, Department of Physics, University of Crete, Greece, XINYU LIU, JACEK FURDYNA, Department of Physics, University of Norte Dame, JIGANG WANG, Ames Laboratory and Department of Physics and Astronomy, Iowa State University — We have studied ultrafast photoinduced hole spin relaxation in GaMnAs via degenerate ultrafast magneto-optical Kerr spectroscopy. Near-infrared pump pulses strongly excite the sample, and probe pulses at the same photon energy reveal subpicosecond demagnetization accompanied by energy and spin relaxation of holes manifesting themselves as a fast (∼200fs) and a slow (ps) recovery of transient MOKE signals. By carefully analyzing the temporal profiles at different temperatures, we are able to isolate femtosecond hole spin relaxation processes, which are subject to a critical slowing down near the critical temperature of 77K. These results demonstrate a new spectroscopy tool to study the highly elusive hole spin relaxation processes in heavily-doped, correlated spin systems, and have important implications for future applications of these materials in spintronics and magnetic-photonic-electronic multifunctional devices.

9:24AM A15.00006 A Model Study of Photomagnetization in Diluted Magnetic Semiconductors , S.N. BEHERA, IIT/Bhubaneswar, S.M. BOSE, Drexel University, J.T. SCHICK, Villanova University — In the context of application to spintronics, photon induced magnetization or photomagnetization (PM) of diluted magnetic semiconductors (DMS) like $Hg_{1-x}Mn_xTe$ [1] has been the subject of many recent investigations. We present results of a model calculation of the dependence of the PM on the photon power in a DMS for different temperatures and different magnetic impurity concentrations. The model which includes kinetic energies of the charge carriers created by the incident light, the attractive Coulomb interaction between the electrons and the holes treated in the mean field approximation, the coupling of the photon with the exciton density, and the magnetic interaction between the spins of the charge carriers and the magnetic moments of the magnetic impurity atoms in the semiconductor is solved exactly using the equation of motion of the Green's functions method. Expressions for the densities of spin up and spin down charge carriers, and their magnetization and that of the magnetic impurities obtained in the form of a set of coupled equations are solved self consistently to determine the PM. Interestingly there is a temperature dependent threshold in photon power for the appearance of the PM. A detailed study of the dependence of the PM on different parameters will be presented.

[1] H. Krenn et al., PRL **55**, 1510 (1985).

9:36AM A15.00007 Dynamic Magnetic Polarization in Semi-magnetic II-VI Quantum Dots via Electrical/Optical Carrier Injection , BAHMAN ROUSTAI, University of Cologne, RAMIN ABOLFATH, U. Texas at Dallas, THOMAS BRABEC, U. Ottawa, PAWEL HAWRYLAK, NRC, Ottawa — Theory of Dynamic Magnetic Polarization (DMP), the enhancement of collective spin polarization of magnetic impurities (MI) in semi-magnetic II-VI quantum dots is presented. DMP, known for nuclear spins, is the result of the transfer of electron's spin to MI's spin polarization as a function of time. DMP has been recently observed in various opto-electronic experiments [1]. We study the interplay of optically/electrically pumped electrons from the leads to the quantum dot and their effects on DMP in the dot. The interaction of MI's with electron spin and orbital degrees of freedom is modeled. In the weak coupling (t>>J), the DMP is the result of electron tunneling followed by the exchange interaction J with MI. In the strong coupling (J>>t) the electrons in the lead and the magnetic impurity in the dot form a Kondo-type bound state resulting in even stronger DMP.

[1] Ochsenbein et al. Nature Nanotechnology 4, 681 (2009).

9:48AM A15.00008 Carrier spin polarization and magneto-polaron formation in colloidal quantum dots[1] , SAVAS DELIKANLI, ANDREAS RUSS, LARS SCHWEIDENBACK, SUNGJIN KIM, JOSEPH MURPHY, ALEXANDER CARTWRIGHT, ATHOS PETROU, HAO ZENG, SUNY at Buffalo — We present a magneto-optical study of magnetic polarons in Mn-doped II-VI colloidal quantum dots. The polarons are formed due to the exchange coupling between the spins of the holes and those of the Mn ions, both of which are localized in the dots. The long lifetime of the excitons allows the observation of the complete formation process of the magneto polaron. The spin alignment occurs at the time scale of hundreds of ps. The extra energy is dissipated through spin lattice interactions, during the next hundreds of nanoseconds. The dependence of these effects on quantum confinement are studied in different systems.

10:00AM A15.00009 Non-equilibrium Magnetic Ordering in Quantum Dots , JAMES PIENTKA, RAFAL OSZWALDOWSKI, IGOR ZUTIC, JONG HAN, University at Buffalo, ANDRE PETUKHOV, South Dakota School of Mines and Technology — We study semiconductor Quantum Dots (QDs) with magnetic impurities. The magnetism in these systems can be controlled in ways not possible in bulk semiconductors [1]. Robust magnetic effects have been observed recently in both colloidal and self-assembled QDs [2,3]. Here, we develop a rate-equations approach to describe the carrier-mediated magnetic ordering in QDs. In this situation, the magnetic properties are different from the steady-state scenario, due to different carrier spin density, which affects the magnetic-impurity alignment. We focus on a type-II QD band profile, where the electrons reside in the barrier, while the holes are localized in the QD interior, which contains the magnetic impurities. Supported by DOE-BES, US ONR, AFOSR, NSF-DMR and NSF-ECCS CAREER.

10:12AM A15.00010 Magneto-optical studies of magnetic polarons in type-II (Zn,Mn)Te/ZnSe quantum dots[1] , BIPLOB BARMAN, ANDREAS RUSS, LARS SCHWEIDENBACK, JOSEPH MURPHY, RAFAL OSZWALDOWSKI, IAN SELLERS, ATHOS PETROU, IGOR ZUTIC, BRUCE MCCOMBE, ALEXANDER CARTWRIGHT, SUNY Buffalo, ANDRE PETUKHOV, South Dakota School of Mines & Technology, WU-CHING CHOU, WEN CHUNG FAN, National Chiao Tung University — We have recorded time-resolved emission spectra from a series of MBE grown (Zn,Mn)Te/ZnSe quantum dots (QDs) at 7 K in the 0 - 4 tesla magnetic field range. The photoluminescence (PL) spectra were analyzed into their $\sigma+$ and $\sigma-$ circularly-polarized components. The holes in this type-II system are confined in the (Zn,Mn)Te QDs, while the electrons reside in the surrounding ZnSe matrix. The PL intensity, peak energy, and circular polarization were recorded as a function of time and magnetic field. These studies show evidence of exchange coupling between the holes and Mn spins in the (Zn,Mn)Te QDs, which leads to the formation of magnetic polarons. The time scale of polaron formation is shorter than the recombination time in this type-II system. We discuss our results within the framework of a model that describes the magnetic polaron formation in this system.

10:24AM A15.00011 Prediction of extremely long mobile electron spin lifetimes at room temperature in low-Z wurtzite semiconductor quantum wells , NICHOLAS HARMON, WILLIAM PUTIKKA, The Ohio State University, ROBERT JOYNT, University of Wisconsin — Many proposed spintronics devices require mobile electrons at room temperature with very long spin lifetimes. One route to achieving this is to use quantum wells with tunable spin-orbit (SO) parameters. Research has focused on materials with the zincblende structure such as GaAs, which however, do not have long spin lifetimes at room temperature. We show that low-Z materials with the wurtzite structure are much better suited for spintronics applications. Their hexagonal symmetry implies that SO couplings can be completely canceled over a very wide range of electron momenta at zero temperature. Low-Z materials possess smaller SO couplings resulting in long spin lifetimes at room temperature. This leads to predictions of spin lifetimes exceeding 2 ms at helium temperatures in wurtzite AlN and, most relevant to spintronic devices, spin lifetimes up to 0.5 μs are predicted for tuned AlN wells at room temperature.

10:36AM A15.00012 Conductance signatures of spin correlations and quantum phase transitions in parallel quantum dots[1] , ARTURO WONG, Ohio U., WILLIAM LANE, Jacksonville U., LUIS DIAS, U. of Sao Paulo, KEVIN INGERSENT, U. of Florida, NANCY SANDLER, SERGIO ULLOA, Ohio U. — Semiconductor quantum dots provide a highly controllable environment to study strongly correlated phenomena and quantum phase transitions (QPT). A parallel double-quantum-dot system, in which dot 1 is in the Kondo regime and dot 2 behaves as a non-interacting resonant level, shows a QPT separating Kondo-screened and local-moment phases [1]. In this work, we use the numerical renormalization-group approach to explore the effect of a nonzero Coulomb interaction U_2 in dot 2. When dot-2 level is fixed at the Fermi energy, a critical value of U_2 separates local-moment and Kondo-screened phases. By contrast, if U_2 is increased keeping particle-hole symmetry in dot 2, the system evolves from a local-moment regime to an underscreened spin-1 regime. Signatures of these behaviors can be experimentally identified through the conductance of the system. We also calculated the spin-spin correlations between the dots and between each dot and the leads to identify how the spin-spin interactions are distributed throughout the structure.

Session A16 DMP GMAG: Focus Session: Magnetic Nanostructures I D173

8:00AM A16.00001 Cantilever torque magnetometry studies of the in-plane to out-of-plane transition in a single nickel magnetic nanorod , ERIC W. MOORE, SANGGAP LEE, STEVEN A. HICKMAN, JONILYN G. LONGENECKER, JOHN A. MAROHN, Cornell University — Torque magnetometry, using attonewton-sensitivity cantilevers, is extremely sensitive to both the average magnetic moment and magnetization fluctuations within a small magnetic tip. Operating at $T = 4\,\mathrm{K}$ with such a system, we study in-plane to out-of-plane magnetization switching in a single, electron beam lithographically defined nickel nanorod, of radius $r \approx 50\,\mathrm{nm}$. Numerous, simultaneous, peaks are visible in cantilever frequency, dissipation and jitter as well as Barkhausen like steps. A analytic model is developed that achieves order of magnitude agreement with the frequency and dissipation peaks.

8:12AM A16.00002 Interedge magnetic coupling in metal-terminated graphene nanoribbons[1] , YAN WANG, CHAO CAO, HAI-PING CHENG, Department of Physics and Quantum Theory Project, University of Florida — Graphene nanoribbons (GNRs) with armchair or zigzag edges, a novel organic material system produced by cutting graphene along two crystallographic directions, have recently attracted considerable attention in spintronics. GNR with zigzag edges is known to be magnetic with two spin-polarized edge states, which are ferromagnetically ordered but antiferromagnetically coupled to each other. Most of the previous studies focus ribbons with zigzag edges and hydrogen terminations. Here we present a first-principles study[2] of zigzag and armchair GNRs terminated with 3*d* transition-metals and noble metals. Specifically, we investigate the long-range interedge magnetic coupling as a function of the ribbon's width. We also show that the proposed hybrid metal-terminated GN[3]Rs can be excellent candidate for spintronic applications.

8:24AM A16.00003 Magnetic Properties of Single Crystal Nickel Nanowires[1] , JIMMY KAN, KEITH CHAN, ERIK SHIPTON, ERIC FULLERTON, University of California - San Diego — Toward the goal of understanding magnetism in confined dimensions, we have synthesized Nickel nanowires (NWs) by chemical vapor deposition and characterized their magnetic properties. By tuning chemical vapor deposition synthesis parameters, we can controllably synthesize a variety of morphologically dissimilar Ni products onto untreated amorphous SiO2||Si substrates [1]. These structures include polycrystalline core-shell NWs, single-crystal cubes, in-plane wires, and vertically-oriented single crystal arrays. To probe the magnetic properties of individual NWs, we combined magneto-transport, XPEEM, and magnetic modeling. For polycrystalline NWs, the magnetic properties are dominated by shape anisotropy. However, for single-crystal NWs, there is a competition between the shape anisotropy along the (001) direction and magneto-crystalline anisotropy along the (111) direction. This gives rise to complex magnetic stripe domain patterns along the wires, interesting magneto-transport properties, and novel reversal modes not typically observed in magnetic wires.

8:36AM A16.00004 Tunable magnetism in nanomaterials and systems , WANLIN GUO, Nanjing University of Aeronautics and Astronautics, ZHUHUA ZHANG — Tunable magnetism in nanomaterials and systems are especially attractive and hold great promise for applications in nanoelectronics and spintronics. Here we show some of our recent findings along this direction. First, we present a novel magnetoelectric effect in graphene nanoribbons settled on silicon substrates whereby the ribbon edge magnetization can be tuned linearly by applied bias voltage (**Phys.Rev.Lett**, **103**, 187204, 2009), and this effect is robust to material and geometry variations (**Phys.Rev.B** 81, 155428, 2010). We also realize an electrical control of magnetism in ZnO ribbons (**ACS Nano 4**, 2124, 2010**)**, and even a tunable magnetic ordering in sandwich nanowires by changing charge states (**J.Am.Chem.Soc**.**132**, 10215, 2010). Contrast to the zero-gap graphene, both hexagon-BN sheets and nanotubes are generally insulating. We provide two efficient recipes to narrow the wide gap of BN: applying external electric fields for nanoribbons and increasing tube curvature for nanotubes. Of more interesting is that ferromagnetic ordering is obtained in BN nanotubes by fluorination and it can be remarkably modulated by applying radial pressure (**J.Am.Chem.Soc**.**131**, 6874, 2009). Our revealed control of magnetism in a wide range of nanomaterials may open up new vistas towards spintronics.

8:48AM A16.00005 Magnetic Properties of Iron-added Titanium Oxide Nanotubes[1] , EUGEN PANAITESCU, PEGAH HOSSEINPOUR, LAURA H. LEWIS, LATIKA MENON, Northeastern University — Titanium oxide represents a promising candidate as the support material for dilute magnetic semiconductors (DMSs), especially in a nanostructured form. Titania nanotubes ordered arrays produced by anodization have been used in this study as the base material for the addition of a ferromagnetic component, iron in particular. Several routes such as titanium-iron films co-deposition before anodization, anodization in iron cations containing solutions, and post-anodization iron deposition have been used for the incorporation of iron into the titanium oxide nanotubes matrix. Samples morphology and structure was analyzed by electron microscopy, and by EDS and XRD spectroscopy. Subsequent magnetic measurements were performed on both amorphous and crystalline samples, and compared with references such as blank nanotubes and commercial anatase nanoparticles powder.

9:00AM A16.00006 Synthesis and Characterization of CoFe nanowires , PO-CHING TSAI, YAJING ZHANG, GIRIJA S. CHAUBEY, NARAYAN POUDYAL , CHUANBING RONG, J. PING LIU, Department of Physics, The University of Texas at Arlington, Arlington, TX 76019 — CoFe and CoNi nanocrystals with different size, shape and compositions were successfully synthesized via a non-catalyst chemical solution method. It was found that the structure and morphology of the nanocrystals with high aspect ratio can be controlled by varying parameters such as solvent amount, surfactant ratio, reducing agent and heating rate. The elongation of the nanowires can be adjusted by changing surfactant ratio and catalyst amount. It has also been observed that the growth mechanisms for CoFe and CoNi nanowires are different. Magnetic properties of the nanocrystals are size and shape dependent. By optimizing the synthesis conditions, nanowires with enhanced magnetization and coercivity can be obtained.

9:12AM A16.00007 Focused electron beam induced deposition of magnetic nanostructures[1] , JOSE M. DE TERESA, CSIC-University of Zaragoza (Spain) — Nanopatterning strategies of magnetic materials normally rely on standard techniques such as electron-beam lithography using electron-sensitive resists. Focused electron beam induced deposition (FEBID) is currently being investigated as an alternative single-step route to produce functional magnetic nanostructures. Thus, Co-based [1] and Fe-based [2] precursors have been recently investigated for the growth of magnetic nanostructures by FEBID. In the present contribution, I will give an overview of the existing literature on magnetic nanostructures by FEBID and I will focus on the growth of Co nanostructures by FEBID using $Co_2(CO)_8$ as precursor gas. The Co content in the nanostructures can reach 95% [3]. Magnetotransport experiments indicate that full metallic behaviour is displayed with relatively low residual resistivity and standard anisotropic magnetoresistance (0.8%) [3]. The coercive field of nanowires with changing aspect ratio has been determined in nanowires with width down to 150 nm by means of Magneto-optical Kerr Effect [4] and the magnetization reversal has been imaged by means of Magnetic Force Microscopy, Scanning Transmission X-ray Microscopy as well as Lorentz Microscopy experiments. Nano-Hall probes have been grown with remarkable minimum detectable magnetic flux. Noticeably, it has been found that the domain-wall propagation field is lower than the domain-wall nucleation field in L-shaped nanowires, with potential applications in magnetic logic, sensing and storage [5]. The spin polarization of these Co nanodeposits has been determined through Andreev-Reflection experiments in ferromagnetic-superconducting nanocontacts and amounts to 35% [6]. Recent results obtained in Fe-based nanostructures by FEBID using $Fe_2(CO)_9$ precursor will be also presented [7].

9:48AM A16.00008 Memory effect in magnetic nanowire arrays[1] , XIAOMING KOU, XIN FAN, Department of Physics and Astronomy, University of Delaware, RANDY DUMAS, Department of Physics, University of California, Davis, QI LU, Department of Physics and Astronomy, University of Delaware, YAPING ZHANG, Department of Physics, University of Science and Technology Beijing, HAO ZHU, XIAOKAI ZHANG, Spectrum Magnetics, LLC, KAI LIU, Department of Physics, University of California, Davis, JOHN XIAO, Department of Physics and Astronomy, University of Delaware — A memory effect has been demonstrated in magnetic nanowire arrays. The magnetic nanowire array has the ability to record the maximum magnetic field that the array has been exposed to after the field has been turned off. The origin of the memory effect is the strong magnetic dipole interaction among the nanowires. Switching field distributions among nanowires was studied with a first order reversal curve technique to elucidate the discrepancy between the experimental result and the theoretical explanation. Based on the memory effect, a novel and extremely low cost EMP detection scheme is proposed. It has the potential to measure magnetic field pulses as high as a few hundred Oe without breaking down.

10:00AM A16.00009 ABSTRACT WITHDRAWN –

10:12AM A16.00010 Magnetic hyperthermia in frozen and liquid ferrofluids , R. REGMI, Wayne State University, A. NAIK, University of Wisconsin, J.S. THAKUR, Wayne State University, P.P. VAISHNAVA, Kettering University, G. LAWES, Wayne State University — We report magnetic hyperthermia in dextran coated Fe_3O_4 nanoparticles suspended in an aqueous solution over a temperature range from -40 ^oC to +40 ^oC to investigate heating mechanisms in the solid and liquid states. We used an alternating magnetic field of 70 Oe at frequency of 395 kHz to produce heating in the 12 nm Fe_3O_4nanoparticles. We found that at the lowest and highest temperatures, ambient heat flow to or from the environment produced small but non negligible effects. After correcting for this ambient heat flow, we found an average magnetic heating of 4.7 W/g, 11.2 W/g, and 6.5 W/g in the solid, mixed solid-liquid, and liquid phases, respectively. These values in the solid and liquid phases are consistent for models for magnetic heating considering Neel heating only and Neel and Brownian heating together, respectively.

10:24AM A16.00011 Characterization of iron oxide-dextran magnetic nanoparticle suspensions , J. SHIH, R. BAI, W. CHIOU, R.M. BRIBER, University of Maryland, College Park, J.A. BORCHERS, C.L. DENNIS, NIST, Gaithersburg, MD, C. GRUETTNER, Micromod Partikeltechnologie, GmbH — Magnetic nanoparticles, with structures from core-shell to nanocrystallites in a matrix, are candidates for use in biomedical applications. "Superparamagnetic iron oxide" (SPIO) nanoparticles are nanocrystallites of iron oxide in a dextran matrix, with sizes between 20nm and 250nm. Dynamic light scattering (DLS), transmission electron microscopy (TEM), atomic force microscopy (AFM), and hysteresis measurements were used for structural and magnetic characterization. Additionally, cryoquench-TEM was performed, allowing direct imaging without false aggregation from drying. The DLS-determined size of the particles is 250nm, but cryoquench-TEM yields a smaller size of 150nm. In addition, the particles are relatively well-dispersed, but dimers and trimers are observed. This corresponds with the evidence of weak interactions in magnetic hysteresis measurements. Further magnetic characterization will provide information on how the magnetic properties of these SPIO particles correlate with their size and structure.

10:36AM A16.00012 Thermosensitive Nanostructured Media for imaging and Hyperthermia Cancer Treatment[1] , KAREN MARTIROSYAN, University of Texas at Brownsville — Hyperthermia has been used for many years to treat a wide variety of tumors in patients. The most commonly applied method of hyperthermia is capacitive heating by using microwave. Magnetic fluids based on iron oxide (Fe3O4), stabilized by biocompatible surfactants are typically used as heating agent. However, significant limitations of using commercial available magnetic particles are non-selectivity and overheating of surrounding normal tissues. To improve the efficacy of hyperthermia treatment we intend to develop Curie temperature (Tc)-tuned nanostructured media having T2 relaxation response on MRI for selective and self-controlled hyperthermia cancer treatment. As an active part of this media we fabricated superparamagnetic, biocompatible and dextran coated ferrite nanoparticles Mg1+xTixFe2(1-x)O4 at 0.3<x<0.5 with low Curie temperature. To tune Tc we produced a large number of ferrites powders with x=0.05 by aqueous combustion synthesis. This process typically involves a reaction in a solution containing metal nitrates and different fuels, which are classified based on the type of reactive groups (e.g., amino, hydroxyl, carboxyl) connected to a hydrocarbon chain, such as glycine, hydrazine, or urea. Our experiments revealed that ferrite with formula Mg1.35Ti0.35Fe1.3O4 appears with Curie temperature within 46-50 $^\circ$C.

10:48AM A16.00013 Magnetism of Au Nanoparticles on *Sulfolubus Acidocaldarius* S-Layer , JUAN BARTOLOME, F. BARTOLOME, L.M. GARCIA, A.I. FIGUEROA, ICMA, Universidad de Zaragoza - CSIC, Spain, T. HERRMANNSDOERFER, R. SKROTZKI, R. SCHOENEMANN, J. WOSNITZA, Dresden High Magnetic Field Laboratory, HZDR, Dresden, Germany, S. SELENSKA-POBELL, A. GEISSLER, T. REITZ, Institute of Radiochemistry, HZDR, Dresden, Germany, F. WILHELM, A. ROGALEV, ESRF, Grenoble, France — Au nanoparticles (NP) with diameters of a few nm have been synthesized on a protein S-layer of *Sulfolobus Acidocaldarius* bacteria. SQUID magnetization (1.8 K $<$ T $<$ 300 K and 0 $<$ B $<$ 7 T) shows superparamagnetic behavior at low-T. Its origin lays at the Au NP's, as has been proven by Au $L_{2,3-}$edge XMCD spectroscopy, performed in the range 2.2$<$T$<$20 K and up to B_{app}=17 T. XMCD analysis yields a total magnetic moment per Au atom μ_{Au}= 0.050(1) μ_B, a particle average moment m_{part}= 2.3 μ_B, Au orbital to spin moment ratio of m_L/m_S= 0.29, and Curie-like superparamagnetism. Au-S bonds are detected by S K-edge XAS measurements. Besides, EXAFS at the Au L_3-edge shows that the Au NP internal structure is fcc, and Au-S bonds are located at the particle surface. An increase of the hole charge carrier density in the Au 5d band due to electron transfer with the S-layer explains the Au magnetism. The observed magnetic moment per Au atom is 25 times larger than those previously found by XMCD in Au-thiol capped NPs.

8:00AM A17.00001 Enhanced magneto-elastic coupling in hexagonal multiferroic $HoMnO_3$, MARIO POIRIER, JULIEN CAMIRAND LEMYRE, PIERRE-OLIVIER LAHAIE, Universite de Sherbrooke, LOREYNNE PINSARD-GAUDART, ALEXANDRE REVCOLEVSCHI, Universite Paris-Sud — From ultrasonic velocity measurements, we report a study of the magneto-elastic coupling occurring on elastic moduli C_{11} and C_{33} at the different magnetically induced phase transitions in $HoMnO_3$. Although both the Ho-Mn and Ho-Ho interactions soften the the elastic moduli, the largest softening in observed on C_{11} over a wide temperature range extending well beyond the Néel temperature. An in-plane orientation of the magnetic field reduces strongly the softening due to a stabilization of the Mn moments order; concurrently, the Ho magnetic order is destroyed. When the field is rather oriented along the c axis, the elastic softening is enhanced as if the Ho-Mn interactions were reinforced and the Mn order consequently destabilized. The phase diagram deduced from the elastic anomalies observed at the several phase transitions are in agreement with microwave measurements performed on the same sample. An in-plane anisotropy of the diagram is also proposed.

8:12AM A17.00002 Multiferroics in $Eu_{1-x}Tb_xMnO_3$ system[1] , YUNG-YUAN HSU, H.C. HSU, H.C. CHEN, W.Y. TSENG, C.D. YANG, National Taiwan Normal University, H.C. KU, National Tsing Hua University — A low-T phase diagram of the $Eu_{1-x}Tb_xMnO_3$ ($0 \leq x \leq 1$) is reported. Systematic substation of Tb into the system changes the perovskite lattice structure which further varies the electronic and magnetic behaviors of the system from a paraelectric-canted-AFM to a ferroelectric-spiral-AFM ground state. The Mn^{3+} spins ordered, presumably, in a collinear incommensurate sinusoidal antiferromagnetic structure below T_N = 52-45 K (x = 0 to 1). Then system enters a canted-AFM (weak- ferromagnetic) state below T_{cant} for the $x \leq 0.5$ compounds, which decreases from 42 K to 25 K with increasing x. For the $x \geq 0.5$ compounds, ferroelectricity was found below $T_C \sim 28$ K with a presumably spiral spin arrangement as that in $TbMnO_3$. At the boundary, $x = 0.5$, the multiferroics coexists with the weak-ferromagnetism. The Rietveld refinement shows an Mn-O2-Mn angle of 145.9° for the $Eu_{0.5}Tb_{0.5}MnO_3$ suggesting a critical Mn-O2- Mn angle of ∼146° that multiferroics appears at the smaller angle side.

[1]This work was supported by NSC of Taiwan under No. NSC -97-2112-M-003-001-MY3.

8:24AM A17.00003 Ferromagnetically charge ordered nanoclusters in $La_{0.52}Ca_{0.48}MnO_3$[1] , JING TAO, Brookhaven National Laboratory, D. NIEBIESKIKWIAT, Universidad San Francisco de Quito, Q. JIE, M. A. SCHOFIELD, L. WU, Q. LI, Y. ZHU, Brookhaven National Laboratory — A charge-ordered (CO) nanoscale phase was reported to appear in coincidence with the well known colossal magnetoresistance (CMR) in a wide doping range in manganites. The competition between the CO nanoscale phase and the surrounding ferromagnetic (FM) phase has been considered as the key to understand the CMR phenomenon. However, the role of this nanoscale phase in the CMR effect is not fully established because the magnetic and physical properties of the CO nanoscale phase remain elusive. In particular, the CO nanoscale phase was hypothesized to be antiferromagnetic, the same as its long range counterpart. Here we report the experimental evidences showing the unexpected magnetism and resistivity in the CO nanoclusters in $La_{0.52}Ca_{0.48}MnO_3$. Correlated with a number of bulk property measurements, the transmission electron microscopic observations strongly suggest that the CO nanoclusters are FM and probably conducting. Such results could substantially alter the role of the CO nanoclusters in the CMR.

[1]Research at BNL was sponsored by the U.S. DOE/BES under Contract No. DE-AC02-98CH10886.

8:36AM A17.00004 Structural and Magneto-electric properties of substituted $R\mathrm{MnO}_3$ crystals (R=*Sm, Gd*) , G. BALAKRISHNAN, D. O'FLYNN, DA-QIAN LIAO, R.A. MCKINNON, D.S. KEEBLE, M.R. LEES, Department of Physics, University of Warwick, UK, A. DAOUD-ALADINE, ISIS Facility, STFC, Didcot, UK — In order to understand the emergence of multiferroic behaviour in the $R\mathrm{MnO}_3$ type compounds, it is educational to study the relationship between ferroelectricity and magnetoelastically induced lattice modulations. The Mn-O-Mn bond angle is a crucial parameter in these systems and it varies with the ionic radii (r_R) of the R atoms. Multiferroic behaviour may be induced in large Rsystems by substituting the R site with a smaller ion (e.g. *Y, Lu*). We have studied the effect of substituting Y in *Sm*MnO_3 and *Lu* in *Gd*MnO_3 respectively. In the optimally substituted compounds, we observe a strong coupling between the magnetic and dielectric properties. We have investigated the local structural distortions in the MnO_6 octahedra in both these systems using single crystal X-ray studies. Additionally, neutron powder diffraction has been used to investigate the nature of the low temperature magnetic ordering in the Sm system. Investigations of the dielectric properties of the Y and *Lu* substituted crystals reveal anomalies in the dielectric properties coincident with an additional magnetic transition, indicative of multiferroic behaviour. We present detailed investigations of the magnetic, dielectric and structural properties on single crystals of selected compositions.

8:48AM A17.00005 Synthesis and Oxygen Content Dependent Properties of Hexagonal Manganites[1] , B. DABROWSKI, S. REMSEN, S. KOLESNIK, O. CHMAISSEM, J. MAIS, Department of Physics, Northern Illinois University, DeKalb, IL 60115, USA — Oxygen deficient samples of hexagonal ($P6_3cm$) $DyMnO_{3+\delta}$(δ=-0.04) were synthesized in Ar by intentional decomposition of the perovskite phase obtained in air. Hexagonal samples annealed under oxidizing conditions exhibit unusually large excess oxygen content (δ <0.4) and two new structural phases below 350 °C. We will demonstrate how structural, resistive, magnetic, and thermal expansion properties are sensitively dependent δ. Similar observations were made for other hexagonal manganites $RMnO_{3+\delta}$ indicating that their multiferroic properties can be controlled by the synthesis and annealing conditions.

[1]Work supported by NSF-DMR-0706610.

9:00AM A17.00006 Spin and Lattice excitations in Ferromagnetic Insulating Manganites[1] , DALGIS MESA, JIANDI ZHANG, Dept. of Physics, Louisiana State University, Baton Rouge, LA 70802, USA, JAIME FERNANDEZ-BACA, FENG YE, MARK HAGEN, Neutron Scattering Science Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, T. TOMIOKA, YOSHINORI TOKURA, National Institute of Advanced Industrial Science and Technology (AIST), Japan — Though double-exchange interaction has been recognized as a major driving force for the couple magnetic and electronic phase transition, the nature of insulating ground state with ferromagnetic ordering in low-doping manganites is still not fully understood. Here we report on an inelastic neutron scattering study of spin and lattice excitations in the ferromagnetic insulating (FMI) phase of $La_{1-x}Ca_xMnO_3$ with x(Ca) = 0.2. Dispersion relations for both phonons and spin waves along high-symmetry directions were obtained for temperatures of 5 and 225 K, respectively. At low temperatures, our results indicate an anomalous softening and broadening of the magnons near the zone boundary, especially when the magnon energy E ∼ 20 meV, where a longitudinal optical phonon is present. Additional phonon and magnon branches observed will also be discussed.

9:12AM A17.00007 X-ray Absorption Spectroscopy studies of photo-induced and magnetic-field-induced phase transitions in $Pr_{0.7}Ca_{0.3}MnO_3$, YI ZHU, MATTEO RINI, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, California, 94720, USA, JOHN FREELAND, Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois, 60439, USA, ROBERT SCHOENLEIN, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, California, 94720, USA — Changes in the electronic structure underpinning the ultrafast photo- and magnetic-field-induced insulator to metal phase transition in $Pr_{0.7}Ca_{0.3}MnO_3$ are compared directly via x-ray absorption near edge spectroscopy (XANES). Static and time-resolved XANES at the O K-edge and Mn L-edge directly monitor the evolution of the density of Mn-3d/O-2p electronic states as the system is driven across phase boundaries. Our results reveal the non-thermal nature of the photoinduced phase transition and show that the CMR magnetic-field-induced and the photoinduced phase-transitions rely on identical rearrangements of the electronic structure.

9:24AM A17.00008 Striped Multiferroic Phases in Narrow Bandwidth Hole-Doped Manganites[1] , SHUHUA LIANG, Univ. of Tennessee, ORNL, SHUAI DONG, Southeast University, China, CENGIZ SEN, UTK, ORNL, MARIA DAGHOFER, IFW Dresden, ELBIO DAGOTTO, UTK, ORNL — A novel phase with diagonal charge stripes and a complex spin arrangement that allows for ferroelectricity to develop has been recently reported in a model for hole-quarter-doped manganites (S. Dong et al., Phys. Rev. Lett. **103**, 107204 (2009)). The study of this "spin-orthogonal stripe" (SOS) phase is here generalized to other hole doping fractions $x = 1/N$ ($N = 3, 5, 6, ...$), to search for analogous multiferroic states. In this effort, the two-orbital double-exchange model for manganites is studied, employing variational, Monte Carlo, and zero temperature optimization techniques. The phase diagrams obtained by varying the electron-lattice and superexchange couplings also contains exotic C_xE_{1-x} phases. A systematic procedure to construct new C_xE_{1-x}/SOS_x phases is discussed. Both the Dzyaloshinskii-Moriya interaction and exchange-striction effect may work in these C_xE_{1-x}/SOS_x phases, giving rise to ferroelectricity. In addition, these SOS_x/C_xE_{1-x} phases can be extended into many other similar states, with (almost) degenerate energies but different multiferroic properties.

9:36AM A17.00009 Magnetic imaging of domains and walls in multiferroic $ErMnO_3$, YANAN GENG, EDWARD LOCHOCKI, NARA LEE, YOUNGJAI CHOI, SANG-WOOK CHEONG, WEIDA WU, RUTGERS CENTER FOR EMERGENT MATERIALS & DEPT OF PHYSICS & ASTRONOMY, RUTGERS UNIV, PISCATAWAY TEAM — Multiferroic hexagonal rare-earth manganities $RMnO_3$ (R = Ho... Lu, Y, Sc) have generated great interest because of the coexistence of ferroelectric and magnetic orders. Herein we conducted low temperature magnetic force microscopy (LT-MFM) studies on flux-grown $ErMnO_3$ single crystals. The ferroelectric transition T_C is ∼1300 K while antiferromagnetic transition T_N is ∼ 80 K. We observed intriguing behaviors of magnetic domains & walls in $ErMnO_3$ from the temperature and magnetic field dependence of local magnetic contrast. In addition, we will present results of comparison between LT-MFM images and room temperature piezoresponse force microscopy (PFM) images of the same sample to understand the mechanism of cross-coupling between ferroelectricity & magnetism in $RMnO_3$.

9:48AM A17.00010 Multiferroic Perovskite Manganites with Symmetric Exchange Striction , SHINTARO ISHIWATA, Dept. of Appl. Phys. and Quantum-Phase Electronics Center (QPEC), University of Tokyo — Orthorhombic perovskite manganites have been extensively studied as a representative system hosting versatile multiferroic phases such as the cycloidal spin phase and the E-type antiferromagnetic phase with an exchange striction mechanism. Recently, the latter phase has been the subject of growing interest for a potentially giant polarization as large as 60000 $\mu C/m^2$, which might involve a significant contribution from the orbital polarization.[1] However, while several groups have reported ferroelectricity in this phase, further experimental progress on the clarification of the multiferroic properties and the microscopic mechanism has been hampered by the difficulty in sample preparation. In this talk, we report a series of multiferroic perovskite $RMnO_3$ with R = Dy-Yb, $Eu_{1-x}Y_x$ and $Y_{1-y}Lu_y$, synthesized under high pressure and show the complete phase diagram.[2,3] The magnitude of the polarization in the E-type phase was estimated to be about 5000 $\mu C/m^2$ (10 times larger than that of the *bc*-cycloidal phase) and an enhanced magnetoelectric response was discovered near the first-order phase boundary. Furthermore, we have succeeded in synthesizing single crystals of perovskite $YMnO_3$ under a high pressure and succeeded in structure refinements for the E-type phase with a polar space group of $P2_1nm$.[4] This work demonstrates for the first time the quantitative estimation of ferroelectric lattice displacements induced by a magnetic order. This work was done in collaboration with D. Okuyama, Y. Kaneko, Y. Takahashi, H. Sakai, K. Sugimoto, K. Yamauchi, S. Picozzi, Y. Tokunaga, R. Shimano, Y. Taguchi, T. Arima and Y. Tokura, and in part supported by JSPS FIRST program.

10:24AM A17.00011 Dynamical Magnetoelectric Phenomena in the Multiferroic Mn Perovskites , MASAHITO MOCHIZUKI, Dept. of Applied Physics, Univ. of Tokyo — Electric manipulation of magnetic structures is an urgent issue in the field of spintronics. Concurrently magnetic and ferroelectric materials, i.e., multiferroics offers a promising route to attain this goal, and its dynamical aspects are now attracting a great deal of interest. In this talk, we will discuss the recent progress of theoretical study on the dynamical magnetoelectric phenomena in the multiferroic Mn perovskites $RMnO_3$ (R=Tb, Dy, $Eu_{1-x}Y_x$, ...). In these materials, a spiral order of the Mn spins induces spontaneous electric polarization through breaking the inversion symmetry, and thus the strong coupling between electric and magnetic dipoles is realized. Using an accurate spin Hamiltonian describing $RMnO_3$, we first study the electromagnon excitation in these materials at THz frequencies, i.e., collective motion of spins with oscillating electric dipoles activated by the electric-field component of light. The optical spectra with two specific peaks are explained by a symmetric magnetostriction model for the spiral spin order with higher harmonic components. After clarification of its mechanism and nature, we then study the nonlinear dynamical processes of magnetic system caused by the intense electromagnon excitations through the optical pumping. The excitation by the electric field can be more intense and faster than that by the magnetic field. This necessarily leads to novel and intriguing phenomena which can never be expected in the conventional magnetic-field-induced magnon excitation. As one of the most interesting phenomena, we will theoretically propose a picosecond optical switching of spin chirality in $RMnO_3$. We will demonstrate that by tuning strength, shape and length of the optical pulse, we can control the spin chirality at will. This proposal will pave a new way to control the magnetism in the picosecond/THz time domain.

Session A18 GMAG DMP: Focus Session: Low D/Frustrated Magnetism - Pyrochlore, et al.

D172

8:00AM A18.00001 From Two Dimensional Correlations to a Disordered Ground State in the XY Pyrochlore, $Yb_2Ti_2O_7$[1] , KATE ROSS, Department of Physics and Astronomy, McMaster University — The tetrahedral geometry of the cubic pyrochlore lattice lends itself to strong geometric frustration, which has the effect of suppressing transitions to long range magnetic order (LRO) for certain types of magnetic exchange and single-ion anisotropy. $Yb_2Ti_2O_7$, whose magnetic Yb^{3+} ions decorate the pyrochlore lattice, is known to have ferromagnetic exchange combined with XY single-ion anisotropy. Hence it is not expected to be frustrated, and should develop an LRO state below some Tc on the order of the exchange energy ($\theta_{CW} \simeq$ 600mK). Indeed, $Yb_2Ti_2O_7$ displays a specific heat anomaly around 240mK, but this does not lead to an LRO state. Our recent triple-axis neutron scattering results have revealed that the specific heat anomaly is directly related to a change in dimensionality of the magnetic correlations, causing a transition from an unusual two-dimensionally correlated state above Tc to a short range correlated 3D state below Tc. Combined with recent specific heat results, we argue that the exact transition temperature depends on the precise level of weak structural disorder in the samples, implying that structurally perfect samples may lead to a fully developed LRO state below Tc. Furthermore, our earlier time-of-flight neutron scattering measurements revealed that even for the structurally imperfect systems, an ordered state can easily be induced by the application of a small magnetic field at low temperatures, as evidenced by the appearance of sharp spin wave excitations [1].

8:36AM A18.00002 Order and disorder in the local and long-range structure of the spin-glass pyrochlore, $Tb_2Mo_2O_7$, YU JIANG, Lawrence Berkeley National Laboratory, ASHFIA HUQ, Oak Ridge National Laboratory, CORWIN H. BOOTH, Lawrence Berkeley National Laboratory, GEORG EHLERS, Oak Ridge National Laboratory, JOHN E. GREEDAN, McMaster University, JASON S. GARDNER, Indiana University and National Institute of Standards and Technology — The structure of $Tb_2Mo_2O_7$ is investigated using two techniques: the long-range lattice structure was measured using neutron powder diffraction, and local structure information was obtained from extended x-ray absorption fine structure measurements. While the long-range structure appears generally well ordered, enhanced mean-squared site displacements on the O(1) site and the lack of temperature dependence of the strongly anisotropic displacement parameters for both the Mo and O(1) sites indicates some disorder exists. Likewise, the local structure measurements indicate some Mo-Mo and Tb-O(1) nearest-neighbor disorder exists, similar to that found in the related spin-glass pyrochlore, $Y_2Mo_2O_7$. Although the freezing temperature in $Tb_2Mo_2O_7$, 25 K, is slightly higher than in $Y_2Mo_2O_7$, 22 K, the degree of local pair distance disorder is actually less in $Tb_2Mo_2O_7$. This apparent contradiction is considered in light of the interactions involved in the freezing process.

8:48AM A18.00003 An Exchange Hamiltonian for $Yb_2Ti_2O_7$, JORDAN THOMPSON, PAUL MCCLARTY, University of Waterloo, HENRIK RøNNOW, Laboratory for Quantum Magnetism, EPFL, LOUIS-PIERRE REGNAULT, CEA-Grenoble, ANDREAS SORGE, Network Dynamics Group, MPI for Dynamics and Self-Organization, MICHEL GINGRAS, University of Waterloo — $Yb_2Ti_2O_7$ is a pyrochlore material with many strange properties at low temperature. Specific heat measurements on this material find evidence for a first order phase transition at a temperature of $\mathrm{T_c} \approx 240$ mK, but several experiments fail to find any evidence of long range order below $\mathrm{T_c}$. In order to understand the behaviour of the magnetic moments of the Yb^{3+} ions below $\mathrm{T_c}$ it is necessary to quantift how they interact. I will present work based on using diffuse neutron scattering measurements to find a magnetic interaction Hamiltonian for $Yb_2Ti_2O_7$. We propose a Hamiltonian based on all of the symmetry allowed interactions on the pyrochlore lattice, along with long-range dipolar interactions. Using the energies of the symmetry allowed nearest-neighbor exchange interactions as free parameters, we perform simulated annealing to minimize the difference between experimental neutron scattering and neutron scattering computed from our exchange Hamiltonian using the random phase approximation. I will present the results of this fitting, and discuss the predictions of the resulting model for the behaviour of $Yb_2Ti_2O_7$, including calculations of the local susceptibility.

9:00AM A18.00004 Low temperature freezing and dynamics in Tb2Sn2O7[1] , MARIA MATTHEWS, MARIA DAHLBERG, Pennsylvania State University, PAWINA JIRAMONGKOLCHAI, ROBERT CAVA, Princeton University, PETER SCHIFFER, Pennsylvania State University — We have probed the low temperature magnetic behavior of the ordered spin ice material Tb2Sn2O7 through ac magnetic susceptibility measurements of both the pure material and samples with small percentages of Ti substituted on the Sn sublattice.. Our aim is to qualitatively probe the nature low temperature spin state of the stanate by slowly adjusting the chemical composition towards a known spin liquid— terbium titanate. In pure Tb2Sn2O7, we observe a clear signature for the previously reported ordering transition at Tc = 850 mK, and we also observe evidence for dynamic freezing at temperatures well below Tc, confirming the persistence of significant magnetic fluctuations deep in the spin-ordered regime. We found that the long range ordering transition was completely suppressed by substitution with as little as 5 percent Ti, whereas larger Ti substitution resulted in a spin-glass-like spin freezing transition near 250 mK. The suppression of ordering with minimal substitution demonstrates a remarkable fragility to the spin ordering in this system.

9:12AM A18.00005 Magnetic Diffuse Scattering in spinels GeCo2O4 (GCO) and GeNi2O4 (GNO) , P. MANUEL, M.K. CRAWFORD, D.T. ADROJA, L.C. CHAPON, S. HARA, Y. YOSHIDA, S.I. IKEDA, J.W. LYNN, Y. CHEN, R.A. FISHER — Materials exhibiting geometrical magnetic frustration have been very topical in condensed matter physics due to their large ground state degeneracy usually leading to a great variety of behavior. GCO and GNO are spinels where the Co/Ni ions form a sublattice identical to the pyrochlore. This topology naturally leads to magnetic frustration which can be relieved to permit the appearance of longrange magnetic order. GCO has a Néel temperature of 21 K, below which a tetragonal distortion is observed. However, our heat capacity measurements show only about half of the entropy expected when integrated up to 75 K. This strongly suggests the existence of frustration which is evidenced by our neutron data where strong diffuse scattering (DF) is observed. GNO also exhibits strong DF at the same q-position but with different shape. We will present the neutron data alongside a Monte-Carlo analysis of the DF and the implications on the nature and strength of the different interactions in these two systems.

9:24AM A18.00006 Dimerized Excitations in $La_4Ru_2O_{10}$[1] , JOHN-PAUL CASTELLAN, R. OSBORN, S. ROSENKRANZ, Argonne National Laboratory, Argonne, IL 60439, M.B. STONE, S.E. NAGLER, M.A. LUMSDEN, Oak Ridge National Laboratory, Oak Ridge, TN 37831, P. KHALIFAH, SUNY Stony Brook, Stony Brook, NY 11794. — The interplay between orbital, spin and charge degrees of freedom is at the forefront of condensed matter physics. The discovery of orbital ordering in $La_4Ru_2O_{10}$ [1] offers a unique opportunity to study orbital phenomena in a 4d transition metal oxide. $La_4Ru_2O_{10}$ undergoes a structural phase transition at ∼158K, below which there is a spin gap of ∼40 meV caused by Ru-O-Ru dimerization. We have performed single crystal time-of-flight neutron scattering measurements on the ARCS spectrometer at the SNS in "sweep" mode, a new technique in which neutron events are measured during continuous sample rotation, in order to quickly and efficiently map out four-dimensional volumes of S(q,w). With this method, we measured the structure factors and full dispersion of the singlet-triplet excitations as a function of **Q** and w. A model of the orbital ordering producing the magnetic excitations and the event-based technique used for their measurement will be discussed.

9:36AM A18.00007 Strong spin-orbit coupling in ordered double perovskites , GANG CHEN, University of Colorado Boulder, LEON BALENTS, UCSB — We construct and analyze a microscopic model for insulating rock salt ordered double perovskites, with the chemical formula $A_2BB'O_6$, where the B' atom has a $4d^2$ or $5d^2$ electronic configuration and forms a face centered cubic (fcc) lattice. The combination of the triply-degenerate t_{2g} orbital and strong spin-orbit coupling favors an effective local spin moment $j = 2$. Moreover, due to strongly orbital-dependent exchange, the effective spins have substantial biquadratic and bicubic interactions (fourth and sixth order in the spins, respectively). This leads, at the mean field level, to several interesting phases with high magnetic multipolar orders. We discovered a fundamental difference between integer spin system (considered in present work) and half-integer spin system (studied in previous work), that is, there exists a spin nematic ground state at zero temperature for integer-spin system. We also address the finite temperature properties of different phases. Existing and possible future experiments are discussed in light of these results.

9:48AM A18.00008 Interplay between Lattice Distortion and Spin-Orbit Coupling in Double Perovskites , TYLER DODDS, University of Toronto, TING-PONG CHOY, Universiteit Leiden, YONG BAEK KIM, University of Toronto — We develop anisotropic pseudo-spin nearest-neighbour antiferromagnetic Heisenberg models for monoclinically distorted double perovskites. We focus on these $A_2BB'O_6$ materials that have magnetic moments on the $4d$ or $5d$ transition metal B′ ions, which form a face-centred cubic lattice. In these models, we consider tetragonal distortion of B′-O octahedra, affecting relative occupancy of t_{2g} orbitals, along with geometric effects of the distortion and spin-orbit coupling. The resulting pseudo-spin-$1/2$ models are solved in the saddle-point limit of the Sp(N) generalization of the Heisenberg model. The spin S in the SU(2) case generalizes as a parameter κ controlling quantum fluctuation in the Sp(N) case. We consider two different models that may be appropriate for these systems. In particular, using Heisenberg exchange parameters for La_2LiMoO_6 from a spin-dimer calculation [T. Aharen *et al.*, Phys. Rev. B **8**1, 224409 (2010)], we conclude that this $S = 1/2$ system may order, but must be very close to a disordered spin liquid state.

10:00AM A18.00009 Elastic and inelastic neutron scattering study on $(CuCl)LaTa_2O_7$, SEUNGHUN LEE, KAZUKI IIDA, University of Virginia, ATSUSHI KITADA, YOSHIHIRO TSUJIMOTO, HIROSHI KAGEYAMA, Kyoto University, BELLA LAKE, HZB, SEIKO KAWAMURA, J-PARC, KAZUHISA KAKURAI, JAEA, YIMING QIU, MARK GREEN, NCNR, UNIVERSITY OF VIRGINIA TEAM, KYOTO UNIVERSITY COLLABORATION, HELMHOLTZ-ZENTRUM BERLIN COLLABORATION, JAPAN ATOMIC ENERGY AGENCY COLLABORATION, NIST CENTER FOR NEUTRON RESEARCH COLLABORATION — A quasi-two-dimensional frustrated spin system, $(CuCl)La(Nb_{1-x}Ta_x)_2O_7$, shows a quantum phase transition upon doping of Ta ions from a singlet state to an ordered state at $x \sim 0.4$. $(CuCl)LaNb_2O_7$ has been reported as the first ferromagnetically coupled Shastry-Sutherland singlets with the triplet excitations centered at 2 meV. We report elastic and inelastic neutron scattering measurements on a powder sample of $(CuCl)LaTa_2O_7$ with and without an magnetic field. Our results show that upon cooling this system undergoes a magnetic ordering below 7 K with a characteristic wave vector of $Q = (1/2\ 0\ 1/2)$. The magnetic excitations in the ordered phase are dominated by a nearly dispersionless mode centered at 2 meV similar to the triplet excitations observed in $(CuCl)LaNb_2O_7$. Under field, however, the 2 meV mode in $(CuCl)LaTa_2O_7$ splits into two modes, clearly indicating that it is a spin wave expected for an ordered state.

10:12AM A18.00010 Structure and phase transitions of a magnetic kink crystal , SEBASTIAN MUEHLBAUER, ANDREY ZHELUDEV, ETH Zurich, Neutron Scattering and Magnetism Group, Switzerland, EKATERINA POMJAKUSHINA, PSI, Villingen, Switzerland — The insulator $Ba_2CuGe_2O_7$ crystallizes in the non-centrosymmetric space group $P-4_21m$ allowing for the Dzyaloshinskii-Moriya interaction. Below T_N=3.2K $Ba_2CuGe_2O_7$ exhibits an almost antiferromagnetic cycloidal magnetic order. For H parallel to the c-axis, the cycloid distorts to solitions or kink domain walls. Using small angle neutron scattering and neutron diffraction the structure and phase transitions of a magnetic kink crystal have been examined in $Ba_2CuGe_2O_7$. A magnetic phase transition seen with SANS and complementary measurements of the magnetization is interpreted in terms of a transition from a Neel domain wall with the propagation vector $parallel$ to its plane of spin rotation to a Bloch domain wall with a propagation vector $perpendicular$ to its plane of spin rotation. Indicated by the occurrence of satellite reflections with even and odd harmonics around the AF Neel point (1,0,0) and around the FM zone center (0,0,0) it was further shown that the AF cycloidal magnetic structure of $Ba_2CuGe_2O_7$ is considerably distorted by the staggered Dzyaloshinskii vector D_z.

10:24AM A18.00011 Neutron Scattering Study of Frustration and Magnetic Order in Spinels[1] , GREGORY MACDOUGALL, Oak Ridge National Laboratory — The 'A-site spinels' are materials with magnetic cations constrained to lie on the diamond sublattice of the spinel structure. These systems have been of increasing interest, as novel theoretical and experimental results have emphasized the central role of frustration arising from competing interactions. In particular, the sub-family of diamond lattice antiferromagnets with spin-only degrees-of-freedom is predicted to exhibit novel 'spiral-spin-liquid' and order-by-disorder physics (Bergman et al., Nature Physics (2007)). Real systems MnSc2S4 (Krimmel et al., PRB (2006)) and CoAl2O4 (Krimmel et al., Physica B (2006)) have been studied with powder neutron diffraction, and the results are argued to be consistent with this theory. However, as has been expressed on several occasions, studies on single-crystals are needed for a definitive answer. Here I will discuss neutron scattering results on single-crystalline CoAl2O4, which have given a much more complete picture of magnetic correlations in this material. Both elastic and inelastic measurements have been made using triple-axis and cold chopper spectrometry. With decreasing temperature, we observe intense diffuse scattering centred about locations in reciprocal space associated with collinear antiferromagnetism. At T* 6.5K, we further observe an unexpected change in the diffuse scattering lineshape, coupled with the emergence of well-defined spin-wave excitations. This temperature has been associated with an anomalous spin glass transition in the past, but we argue instead that the available data implies a first-order phase transition to an ordered state, possibly via the order-by-disorder mechanism. The ground state is degenerate, and kinetically frozen walls separating different domains give rise to the broadened scattering at magnetic wavevectors. This scenario may be present in many other frustrated systems. If time permits, I will also talk about new results on crystals of related systems MnAl2O4 and FeAl2O4.

Session A20 FIAP/DMP GERA/DCOMP: Focus Session: Physics of Energy Storage Materials I – Cathodes and Electrolytes D168

8:00AM A20.00001 Extracting the LiV3O8 Phase diagram by cluster expansion[1] , TONGHU JIANG, MICHAEL FALK, Department of Materials Science and Engineering, Johns Hopkins University — LiV3O8 as a lithium battery cathode material has many advantages over current commercialized counterparts, which has prompted interest in improving its electrochemical behavior. However, no clear picture of its structural chemistry and phase behavior has emerged from experimental investigations. In the current work, LiV3O8 was studied using computational methods. A cluster expansion was constructed based on energetic data from density functional theory calculation. The CE was employed to reveal structural information regarding this material. DFT calculation using the local density approximation were found to be deficient in correctly predicting ground states leading to mismatch between experimental and computational results, while generalized gradient approximation gives closer agreement with experimental data. A tentative phase diagram was obtained with the help of Metropolis Monte Carlo calculations.

8:12AM A20.00002 Magnetic and spectroscopic characterization of C-$LiFePO_4$ nanoparticles for cathode material for Li ion batteries , AMBESH DIXIT, K. BAZZI, M.B. SAHANA, C. SUDAKAR, Wayne State University, M. NAZRI, 2Applied Sciences Inc., Cedarville, Ohio, P.P. VAISHNAVA, Kettering University, Flint, Michigan , V. NAIK, University of Michigan-Dearborn, V.K. GARG, A.C. OLIVEIRA, Universidade de Brasilia, Instituto de Fisica, G.A. NAZRI, R. NAIK, Wayne State University — We synthesized pure and carbon coated $LiFePO_4$ nanoparticles (size ∼25 nm) by sol-gel technique. All the samples were characterized by X-ray diffraction, XPS, SQUID, and Mossbauer spectroscopy measurements. The elemental chemical states for Li 1s, Fe 2p, P 2p, O 1s and C 1s were examined by using XPS for $LiFePO_4$ and compared with those of C-$LiFePO_4$ material. Temperature dependent magnetic measurements suggest an antiferromagnetic transition ∼50 K in both $LiFePO_4$ and C-$LiFePO_4$ samples. The role of various phases, such as $LiFePO_4$ Fe_xP, α-Fe and Fe_3O_4 identified by Fe^{57} Mossbauer spectroscopy, will be discussed in relationship with the electrochemical properties of the cathode materials.

8:24AM A20.00003 First-principles modeling of Li-air battery materials , MAXWELL RADIN, Mechanical Engineering Department, University of Michigan, DONALD SIEGEL, Department of Physics, University of Michigan — Of the many possible battery chemistries, the so-called "Li-air" system is noteworthy in that its theoretical capacity (∼5 kWh/kg, including mass of oxygen) exceeds that of any electrochemical system. Perhaps more importantly, the simplified composition of its air cathode – involving only the inlet of oxygen from the atmosphere – has the potential to provide cost benefits in comparison to the Li-ion systems of today. Although the first rechargeable Li-air battery was demonstrated by Abraham and Jiang 14 years ago, its performance in many dimensions remains poor, and relatively little computational work has been done to elucidate performance-limiting phenomena. This talk will introduce the basic properties and main performance issues associated with Li-air batteries. Opportunities for first-principles modeling to assist in overcoming these obstacles will be highlighted.

8:36AM A20.00004 Materials Challenges and Opportunities of Lithium-ion Batteries for Electrical Energy Storage , ARUMUGAM MANTHIRAM, University of Texas at Austin — Electrical energy storage has emerged as a topic of national and global importance with respect to establishing a cleaner environment and reducing the dependence on foreign oil. Batteries are the prime candidates for electrical energy storage. They are the most viable near-term option for vehicle applications and the efficient utilization of intermittent energy sources like solar and wind. Lithium-ion batteries are attractive for these applications as they offer much higher energy density than other rechargeable battery systems. However, the adoption of lithium-ion battery technology for vehicle and stationary storage applications is hampered by high cost, safety concerns, and limitations in energy, power, and cycle life, which are in turn linked to severe materials challenges. This presentation, after providing an overview of the current status, will focus on the physics and chemistry of new materials that can address these challenges. Specifically, it will focus on the design and development of (i) high-capacity, high-voltage layered oxide cathodes, (ii) high-voltage, high-power spinel oxide cathodes, (iii) high-capacity silicate cathodes, and (iv) nano-engineered, high-capacity alloy anodes. With high-voltage cathodes, a critical issue is the instability of the electrolyte in contact with the highly oxidized cathode surface and the formation of solid-electrolyte interfacial (SEI) layers that degrade the performance. Accordingly, surface modification of cathodes with nanostructured materials and self-surface segregation during the synthesis process to suppress SEI layer formation and enhance the energy, power, and cycle life will be emphasized. With the high-capacity alloy anodes, a critical issue is the huge volume change occurring during the charge-discharge process and the consequent poor cycle life. Dispersion of the active alloy nanoparticles in an inactive metal oxide-carbon matrix to mitigate this problem and realize long cycle life will be presented.

9:12AM A20.00005 Vacancy-driven anisotropic defect distribution in $LiFePO_4$[1] , JAEKWANG LEE, WU ZHOU, JUAN CARLOS IDROBO, Department of Physics and Astronomy, Vanderbilt University, Nashville, STEPHEN PENNYCOOK, Materials Science & Technology Division, Oak Ridge National Laboratory Oak Ridge, SOKRATES PANTELIDES, Department of Physics and Astronomy, Vanderbilt University, Nashville — It has been reported that iron cations occupying Li sites (Fe_{Li}) in $LiFePO_4$ are locally aggregated rather than homogeneously distributed in the lattice.[1] Here we report a combination of density-functional calculations, statistical mechanics, electron-energy-loss spectra (EELS) and show the following. There is a strong binding energy between $Fe_{Li}$and a lithium vacancy (V_{Li}), leading to clustering of Fe_{Li} along the b-axis, as observed, corresponding to the shortest separation of the Fe_{Li}-V_{Li} pair. EELS data find that a small fraction of Fe atoms are Fe^{3+}, which can be accounted for in terms V_{Li}-Fe_{Li}-V_{Li} clusters formed along the b-axis.

9:24AM A20.00006 Polaron formation and transport in olivine cathode materials , MICHELLE JOHANNES, Naval Research Laboratory, KHANG HOANG, Naval Research Laboratory; George Mason University — One of the critical factors limiting Li ion battery performance is electronic conduction through the cathode material. In the olivine structure type materials, such as $LiFePO_4$, the parent materials are insulators with a gap of approximately 4 (or more) eV. The withdrawal of an electron results not in a band-type hole state, but rather a localized polaronic state. Transport then occurs via hopping of the polaron through the crystal. The measured electronic conduction in olivine materials depends on the transition metal cation type. In this study, we use density functional theory to compare formation of polarons in olivine materials with different transition metal cations: Mn, Fe, Co, and Ni. We show that the underlying electronic structure of the fully lithiated material (or fully delithiated material) essentially determines whether or not polaron formation is possible in localized d-states or whether the holes that result from adding or removing an electron reside in oxygen-derived states. We also investigate the facility of polaronic hopping by calculating the barrier between adjacent polaron sites in each of the four materials.

9:36AM A20.00007 First-principles studies of native defects in olivine phosphates , KHANG HOANG, George Mason University and Naval Research Laboratory, MICHELLE JOHANNES, Naval Research Laboratory — Olivine phosphates Li$M$$PO_4$ (M=Mn, Fe, Co, Ni) are promising candidates for rechargeable Li-ion battery electrodes because of their energy storage capacity and electrochemical and thermal stability. It is known that native defects have strong effects on the performance of olivine phosphates. Yet, the formation and migration of these defects are not fully understood, and we expect that once such understanding has been established, one can envisage a solution for improving the materials' performance. In this talk, we present our first-principles density-functional theory studies of native point defects and defect complexes in Li$M$$PO_4$, and discuss the implications of these defects on the performance of the materials. Our results also provide guidelines for obtaining different native defects in experiments.

9:48AM A20.00008 Electronic structure of lithium borocarbide as a cathode material for a rechargeable Li-ion battery: First-principles calculation , QIANG XU, CHUNMEI BAN, ANNE DILLON, SUHUAI WEI, YUFENG ZHAO, National Renewable Energy Laboratory — Traditional cathode materials, such as transition-metal oxides, are heavy, expensive, and often not benign. Therefore, alternative materials without transition metal elements are highly desirable in order to design high-capacity Li-ion batteries of light weight and low price. Here we report on potential application of the LiBC compound as cathode materials, in which graphene-like BC sheets are intercalated by Li ions. The crystal structure and properties of LiBC were firstly reported by Wörle et al. in 1995. Importantly, it was found that the 75% Li ions can be retrieved out of the compound without changing the layered structure. We have performed first-principles calculations based on density functional theory, as implemented in the Vienna Ab-initio Simulation Package. According to our calculation, the layered Li_xBC structure can be well preserved at $x > 0.5$. The reversible electrochemical reaction, LiBC $\leftrightarrow$ $Li_{0.5}BC$ + 0.5Li, gives an energy capacity of 609mAh/g and an open-circuit voltage of 2.42V. The volume change is only about 5% during the charging and discharging process. All these results point to a potentially promising application of LiBC as a novel cathode material for high-capacity Li-ion batteries in replacement of the transition metal oxides.

10:00AM A20.00009 Competing stability of inverse and normal spinel structures for lithium battery cathodes , JISHNU BHATTACHARYA, CHRISTOPHER WOLVERTON, Northwestern University — Transition metal oxides comprise of an important class of cathode materials in rechargeable lithium ion batteries. Many of these materials occur in the spinel crystal structure, in which metal atoms are present in octahedral and tetrahedral interstices of a close-packed oxygen sublattice. Depending on whether the Li or the transition metal ions are found in the tetrahedral sites, one can form either the "normal" or "inverse" spinel structures. In the present study, we calculate from first principles the relative stability of the inverse vs. normal spinel for a series of transition metal oxides both at lithiated and delithiated limits. We find trends in the stability of the normal vs. inverse spinel are a strong function of lithium content, and explain these results in terms of the preference for metal/Li tetrahedral/octahedral coordination. Despite the similarities between these two structures, they can have a profound effect on the Li diffusivity. We also use our framework to address the stability of multicomponent inverse spinel electrodes, such as $LiNiVO_4$.

10:12AM A20.00010 Atomistic Simulation Study of Lithium Manganese Oxides for Li-Ion Batteries , PHUTI NGOEPE, KENNETH KGATWANE, RAPELA MAPHANGA, Materials Modelling Centre, Private Bag x1106, University of Limpopo, Sovenga 0727, South Africa, THI SAYLE, DEAN SAYLE, DEAS, Cranfield University, Defence Academy of the United Kingdom, Shrivenham, Swindon, SN6 8LA, UK. — Simulated amorphisation recrystallisation (A+R) technique has been successfully used to generate models of various nano-forms of the complex manganese dioxides [1]. We apply the method to study lithium insertion into the nano - spheres, sheets, rods and porous structures of the binary MnO_2. The variation of mechanical properties and microstructural features with lithium concentration are investigated. The bulk ternary Li_2MnO_3 provides structural integrity for lithium-ion battery cathodes and is electrochemically inactive. The nanocrystalline Li_2MnO_3 has a structure similar to that of the bulk, but shows different lithium intercalation properties [2]. We simulated such a nanophase by the A+R method, and the resulting microstructures provide insights into the origins of the electrochemical activity which renders it suitable for battery electrodes.

10:24AM A20.00011 Computer modeling of crystalline electrolytes – lithium thiophosphates and phosphates[1] , NICHOLAS LEPLEY, N.A.W. HOLZWARTH, Wake Forest University — During the last 5 years, lithium thiophosphate solid electrolyte materials have been developed[2] for use in all-solid-state rechargeable batteries. In particular, crystalline $Li_7P_3S_{11}$ has been characterized as a superionic conducting material having room temperature conductivities as high as 10^{-3} S/cm, which is 1000 times greater than that of the commercial solid electrolyte material LiPON. Building on our previous work,[3] we report computer modeling studies of this material as well as those of related phosphates and phosphonitrides. We present results on meta-stable crystal structures, formation energies, and mechanisms of Li ion migration. The calculational methods are based on density functional theory. The calculations were carried out using the Quantum Espresso (PWSCF) package.[4]

10:36AM A20.00012 Effect of electrolytes on the evolution of the solid electrolyte interphase (SEI) in Li-ion batteries: a Molecular Dynamics study , SANG-PIL KIM, VIVEK SHENOY, Brown University, BROWN UNIVERSITY TEAM — Controlling and understanding the atomic level reactions at the interface between electrode and electrolyte is a prerequisite for the improvement of the performance of Li-ion batteries. The solid electrolyte interphase (SEI), which forms on the negative electrode of Li-ion batteries, is known to significantly affect the battery performance leading to irreversible charge loss, exfoliation of graphite anode and affecting the safety. In spite of the large body of work on SEI, a quantitative understanding of the mechanisms of SEI formation is currently not available. In this work, we employ molecular dynamics simulations with reactive force fields to investigate the compositional and structural properties of the SEI. Our simulations capture the mechanisms of SEI formation as Li atoms react with different kinds of electrolytes (ethylene carbonate (EC), dimethyl carbonate (DMC), and their mixtures) and are able to quantitatively predict the properties in terms of the SEI thickness, byproducts, charge loss, and rigidity.

10:48AM A20.00013 Properties of Liquid Electrolytes for Li-ion Battery Applications from First Principles Molecular Dynamics Simulation , PAUL KENT, PANCHAPAKESAN GANESH, DEEN JIANG, Oak Ridge National Laboratory, Oak Ridge, TN 37831 — A judicious choice of the liquid electrolytes used in battery systems is required to achieve a good balance between high energy storage, fast charging and long lifetime. Ethylene-carbonate (EC) and propylene-carbonate (PC) are popular electrolytes used for this purpose. To date, molecular-dynamics simulations typically rely on classical force-fields, which do not capture the true quantum-mechanical nature of the electrons, most important for the charging/discharging dynamics. We perform accurate first principles molecular-dynamics simulations of EC and PC with $LiPF_6$ at experimental concentrations to build solvation models which explain available Neutron and NMR results as well as to compute Li-ion solvation energies and diffusion constants. Our results throw light on why EC is a more popular choice for battery applications over PC. Insights into the formation of solid-electrolyte interphases in the presence of carbon electrodes in conventional Li-ion batteries will also be discussed, and perspectives into the likely future scope of these simulation methods presented. Supported by the Fluid Interface Reactions, Structures and Transport (FIRST) Center, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Basic Energy Sciences under Award Number ERKCC61.

Session A21 GIMS: Focus Session: Advances in Scanned Probe Microscopy I – Novel Tip and Material Control D161

8:00AM A21.00001 Vacuum Phonon Tunneling in Variable Temperature STM[1] , IGOR ALTFEDER, ANDREY VOEVODIN, AJIT ROY, Air Force Research Laboratory — We demonstrate that the temperature of the terminating atom of STM tip can be directly measured by inelastic electron tunneling spectroscopy. A previously unknown mechanism of interfacial thermal transport, field-induced phonon tunneling, has been revealed by ultrahigh vacuum scanning tunneling microscopy. Using thermally broadened Fermi-Dirac distribution in the STM tip as in-situ atomic scale thermometer we found that thermal vibrations of the last tip atom are effectively transmitted to sample surface despite few angstroms wide vacuum gap. We show that phonon tunneling is driven by interfacial electric fields and thermally vibrating image charges, "thermal mirages". By comparing experimental data and theory, we show that the thermal energy transmitted through atomically narrow vacuum gap due to thermal vibration of image charges exceeds, by ten orders of magnitude, the Planck's thermal radiation energy. [1]Research is funded by AFOSR

8:12AM A21.00002 A Dual Tip STM for Imaging the Superconducting Phase Difference[1] , ANITA ROYCHOWDHURY, M.A. GUBRUD, Physics Department, University of Maryland, College Park and Laboratory for Physical Sciences, DAN SULLIVAN, NASA/Goddard, MICHAEL DREYER, Physics Department, University of Maryland and Laboratory for Physical Sciences, J.R. ANDERSON, C.J. LOBB, F.C. WELLSTOOD, Physics Department, University of Maryland, College Park — We have built a dual tipped STM, with each tip capable of independently scanning a sample. We will use the STM at ultra-low (mK) temperatures to study superconducting samples. The two tips along with the superconducting sample constitute a SQUID. This configuration is designed to minimize fluctuations in the Josephson phase of one of the tips, which scans the sample, while the other tip acts as a reference junction. Calculations and separate experiments on test SQUIDs indicate this arrangement will enable us to measure spatial variations of the gauge-invariant phase difference at the atomic scale.

[1]This project was funded in part by NSF and the Laboratory for Physical Sciences.

8:24AM A21.00003 Nanoelectrical probing with multiprobe SPM Systems compatible with scanning electron microscopes , AARON LEWIS, Hebrew University of Jerusalem, ANDREY IGNATOV, HESHAM TAHA, Nanonics Imaging Ltd., OLEG ZHINOVIEV, ANATOLY KOMISSAR, ALEXANDER KROL, DAVID LEWIS, Nanonics Imaging Ltd. — A scanning electron microscope compatible platform that permits multiprobe atomic force microscopy based nanoelectrical characterization will be described. To achieve such multiple parameter nanocharacterization with scanning electron microscope compatibility involves a number of innovations both in instrument and probe design. This presentation will focus on how these advances were achieved and the results obtained with such instrumentation on electrical nano-characterization and electrical nano-manipulation. The advances include: 1. Specialized scanners; 2. An ultrasensitive feedback mechanism based on tuning forks with no optical feedback interference that can induce carriers in semiconductor devices; and 3. Unique probes compatible with multiprobe geometries in which the probe tips can be brought into physical contact with one another. Experiments will be described with such systems that will include multiprobe electrical measurements with metal and glass coated coaxial nanowires of platinum. This combination of scanning electron microscopes integrated with multiprobe instrumentation allows for important applications not available today in the field of semiconductor processing technology.

8:36AM A21.00004 Imaging and manipulation of nanoscale materials with coaxial and triaxial AFM probes , KEITH A. BROWN, R.M. WESTERVELT, Harvard SEAS and Physics — We present coaxial and triaxial Atomic Force Microscope (AFM) probes and demonstrate their applications to imaging and manipulating nanoscale materials. A coaxial probe with concentric electrodes at its tip creates a highly confined electric field that decays as a dipole field, making the coaxial probe useful for near field imaging of electrical properties. We show nearly an order of magnitude improvement in the step resolution of Kelvin probe force microscopy with coaxial probes. We further demonstrate that coaxial probes can image dielectric materials with the dielectrophoretic force. In addition to imaging, the capacitive structure that makes up the cantilever of a coaxial probe is used to locally mechanically drive the probe, making them self-driving probes. Finally, coaxial probes can create strong forces with dielectrophoresis (DEP) which we combine with the nanometer precision of the AFM to create a nanometer scale pick-and-place tool. We demonstrate 3D assembly of micrometer scale objects with coaxial probes using positive DEP and discuss the assembly of nanometer scale objects with triaxial probes using negative DEP.

8:48AM A21.00005 Deterministic Single Atom STM Tip Technology for Atomically Precise Manufacturing , JOSHUA BALLARD, JUSTIN ALEXANDER, ADRIAN RADOCEA, Zyvex Labs, MAIA BISCHOF, DAVID JAEGER, University of North Texas, JOHN RANDALL, Zyvex Labs, BRIAN GORMAN, Colorado School of Mines, JIM VON EHR, Zyvex Labs, RICK REIDY, University of North Texas — Deterministic tip fabrication for Scanning Tunneling Microscopy (STM) has long been an elusive goal, where the primary method of tip preparation usually includes significant "tip conditioning" once the tip has been incorporated into the STM. We have developed a process for generating reproducible single atom tips (SATs) with a small radius of curvature (r.o.c.) of less than 10nm. First, W(111) or W(110) tips are sputter sharpened using a self-limiting process to yield with r.o.c. of $<$3nm; the consistent r.o.c. greatly improves the reliability of the process. Next, we use a Field Ion Microscope (FIM) to perform field evaporation and analysis of the tips. Once a clear crystal structure is determined, an SAT is formed. Transmission Electron Microscopy is used to verify that after field evaporation the r.o.c. remains small. Correlations between FIM and tip performance in STM are determined, and long term STM stability is discussed.

9:00AM A21.00006 Atmospheric Stability of Tungsten STM Tips for Atomically Precise Manufacturing (APM) , MAIA BISCHOF, DAVID JAEGER, University of North Texas, JOSHUA BALLARD, JUSTIN ALEXANDER, JOHN RANDALL, Zyvex Labs, RICHARD REIDY, University of North Texas, BRIAN GORMAN, Colorado School of Mines, JIM VON EHR, Zyvex Labs, ATOMICALLY PRECISE MANUFACTURING CONSORTIUM COLLABORATION — In APM, STM tungsten tips are used to selectively remove or add surface atoms to build atomically precise 3D structures. Therefore, the development of stable atomically sharp tips is crucial for long term tip performance and process efficiency. These tips have been shown to be extremely sensitive to electrostatic discharge (ESD) events and some environmental conditions. However, recent work has demonstrated that tungsten tips with three to eight atoms at their apex can be stable structurally and chemically after days of ambient exposure with ESD-safe practices. Whereas macroscale W surfaces will oxidize under atmospheric oxygen, HRTEM and 3-D atom probe measurements confirm that no oxide is formed on these tips with an extremely stable surface structure; however, some oxygen does diffuse into the material. In addition to the description of the chemical and structural characterization employed in this work, several possible explanations for the stability of these tips will be offered.

9:12AM A21.00007 STM manipulation and measurement of charged species in semiconductors[1] , JAY GUPTA, Ohio State University — The scaling of transistors to nanometer dimensions requires more precise control of individual dopants in semiconductor nanostructures, as statistical fluctuations in dopant distributions can significantly impact device performance. Proposals for next-generation quantum- and spin-based electronics also rely on the tuning of the charge, spin and interactions of dopant atoms with local electric fields. Using a scanning tunneling microscope (STM), we demonstrate how to control the binding energy and ionization state of individual acceptors in p- GaAs [1]. Charged species such as native dopants, vacancies and adatoms directly influence the acceptor binding energy via the Coulomb interaction. In addition, a combination of defect- and tip-induced band bending can be used to remotely tune the acceptors' ionization state. We find that by applying voltage pulses with the STM tip, charged vacancies and adatoms can be positioned on the surface. These experiments suggest a new and direct method for quantifying the charge of adsorbates (e.g. adatoms or molecules) as well as defects (e.g. vacancies, antisites, interstitials) at semiconductor surfaces.

9:48AM A21.00008 Dirac Fermions in Nanoassembled Artificial Graphene[1] , KENJIRO K. GOMES, WONHEE KO, WARREN MAR, HARI C. MANOHARAN, Stanford University — In condensed matter, electronic properties derive from the energy band structure created by a periodic potential formed by the atoms that constitute a particular material. The power to design unique electronic states is ultimately tied to the power to design the atomic lattice. Utilizing the technique of atomic manipulation with a scanning tunneling microscope, we create an artificial lattice potential that reshapes the band structure of a normal 2D electron gas—found in the surface states of a normal metal—into a unique and distinct 2D gas of massless Dirac fermions. We present scanning tunneling spectroscopic measurements of nanoassembled honeycomb electron lattices, and we characterize their band structure through Fourier transform analysis of impurity scattering maps. The control of every atomic position in the lattice provides unprecedented control over physical parameters elusive in natural graphene systems. These abilities include atomically sharp doping configurations and the power to embed topological singularities, resulting in unique electronic states rarely encountered in natural systems.

10:00AM A21.00009 Topological properties of artificial graphene assembled by atom manipulation[1] , WONHEE KO, WARREN MAR, KENJIRO K. GOMES, HARI C. MANOHARAN, Stanford University — Graphene exhibits special electronic properties stemming from its two-dimensional (2D) structure and embedded relativistic Dirac cones. However, many proposed topologically ordered ground states remain elusive in conventional measurements due to the difficulty in arranging the necessary quantum textures into natural graphene. By exploiting atomic manipulation with a custom-built ultrastable scanning tunneling microscope, we have constructed graphene-like structures by arranging molecules to create a honeycomb lattice of electrons drawn from normal 2D surface states. Spectroscopy reveals a spectacular transformation of nonrelativistic massive 2D electrons into massless Dirac fermions carrying a chiral pseudospin symmetry. We demonstrate the tailoring of this new class of graphene to reveal signature topological properties: an energy gap and emergent mass created by breaking the pseudospin symmetry or changing the hopping term non-uniformly with a Kekulé bond distortion; gauge fields generated by applying atomically engineered strains; and the condensation of electrons into quantum Hall-like states and topologically confined phases.

10:12AM A21.00010 Self-navigation of STM tip toward a micron sized sample[1] , GUOHONG LI, ADINA LUICAN, EVA ANDREI, Department of Physics & Astronomy, Rutgers University, DEPARTMENT OF PHYSICS & ASTRONOMY, RUTGERS UNIVERSITY TEAM — Scanning probe microscopy (SPM) of small samples on insulating substrates, for example graphene devices, is of significant current interest as it can provide invaluable information on the electronic, structural chemical and optical properties of these materials. Accessing such samples with SPM often requires locating a micron sized area within a much larger region of several mm. This is a very difficult task because SPM is intrinsically nearsighted and in many cases combining it with larger scan probes such as optical microscopy is not practical. Here we report a simple capacitance-based method to navigate a STM tip operating at low temperatures in strong magnetic field which allows to find such small samples quickly and efficiently. The method consists of back-gate compensation, refocusing during the search, and distinguishing edges of conducting electrodes and the sample.

10:24AM A21.00011 Magnetic Particle Imagining with a Cantilever Detector , JACOB ALLDREDGE, JOHN MORELAND, NIST — We present a novel detection scheme for magnetic nano and micro particles using a magnetic force microscope (MFM) that allows for the local measurement of AC magnetic susceptibility. The method makes use of the nonlinearities in the magnetic response of a particle that come from its intrinsic magnetic susceptibility as well as its interaction with the surrounding environment. We excite the particle at subharmonic frequencies of the resonator detector to minimize cross talk similar to Magnetic Particle Imagining (MPI) (Gleich B, Weizenecker, J. Nature 435, 1214 2005) although here a cantilever acts as a detector instead of a tuned coil. This allows for the detection and characterization of magnetic particles with high signal to noise and low distortion making it ideal for characterizing magnetic nanoparticles over larger distances compared to typical scanned probe tip-sample separation. It also allows for the reconstruction of the local susceptibility curve.

10:36AM A21.00012 The importance of cantilever mechanics in the quantitative interpretation of Kelvin Probe Force Microscopy , KEVIN J. SATZINGER, Truman State University, KEITH A. BROWN, R.M. WESTERVELT, Harvard SEAS and Physics — A realistic interpretation of the measured contact potential difference (CPD) in Kelvin Probe Force Microscopy (KPFM) is crucial in order to extract quantitative information. Thus far, simulations of KPFM have treated the cantilever as a rigid object. We present a technique to simulate KPFM measurements by simulating a realistic three dimensional probe above a planar sample. We study three methods of weighing the probe-sample interactions to include cantilever mechanics. (1) The commonly-used force method treats the probe-sample interaction from all parts of the probe equally. This method only allows for translation of the probe. (2) The torque method allows for rotation of the probe, taking into account the fixed cantilever end. (3) The bending method acknowledges the flexibility of the cantilever by modeling it as an Euler-Bernoulli beam. We compare simulated step responses from each method to experimental data. We find the force and torque methods overestimate the effect of the cantilever and that the bending method produces the best agreement with experiment.

10:48AM A21.00013 Nm-Scale Surface Potential Transient Measurements of the E_C-0.57eV Trap in an AlGaN/GaN High Electron Mobility Transistor , D. CARDWELL, A.R. AREHART, S.A. RINGEL, J.P. PELZ, Ohio State University — AlGaN/GaN high electron mobility transistors (HEMTs) are intrinsically ideal for high frequency and high power applications, but have degraded performance due to charge trapping. A suspected virtual gate-related trap at E_C-0.57eV (with $\sim$30 ms emission time constant at 300 K) has been shown to have a significant impact on HEMT performance and reliability [1]. Using scanning Kelvin probe microscopy, we report on nm-scale measurements of surface potential transients consistent with the E_C-0.57 eV level at different locations across the surface of an AlGaN/GaN HEMT immediately after bias switching. We find that the amplitude of this surface potential transient is largest at locations close to the drain side of the gate, consistent with the "virtual gate model" where charge leaks and is stored near the gate edge in the drain –gate access region. Comparison of nm-scale measurements and electrostatic simulations will be discussed, to quantify the spatial distribution of this $\sim$30ms trap as a function of gate- and drain-biasing. Work supported by ONR-DRIFT (P. Maki).

Monday, March 21, 2011 8:00AM - 10:48AM –
Session A22 DCMP: Charge Density Wave Materials D163

8:00AM A22.00001 New High Energy Scales in Quasi-One-Dimensional $K_{0.3}MoO_3$ Revealed by High Resolution Angle-Resolved Photoemission Spectroscopy , DAIXIANG MU, WENTAO ZHANG, LIN ZHAO, HAIYUN LIU, XIAOWEN JIA, SHANYU LIU, GUODONG LIU, XIAOLI DONG, JUN ZHANG, X.J. ZHOU, National Laboratory for Superconductivity, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, XIAOYANG WANG, QINJUN PENG, ZHIMIN WANG, SHENJIN ZHANG, FENG YANG, CHUANGTIAN CHEN, ZUYAN XU, Technical Institute of Physics and Chemistry, Chinese Academy of Sciences — High resolution angle-resolved photoemission (ARPES) measurements have been carried out on $K_{0.3}MoO_3$, a proto-typical quasi-one-dimensional material that exhibits Peierls transition at 180 K. Two high energy scales around 100meV and 300meV are revealed in the dispersion measured using super-high resolution vacuum ultra-violet (VUV) laser-based ARPES measurements. These new high energy features emerge in the charge-density-wave state. The origin of these new energy scales will be discussed.

8:12AM A22.00002 Variable Temperature Scanning Tunneling Microscope study on CDW material 2H-$TaSe_2$, JIXIA DAI, YUE CAO, EDUARDO CALLEJA, DANIEL DESSAU, Department of Physics, University of Colorado at Boulder, Boulder, CO 80302, HELMUTH BERGER, Department de Physique, EPF Lausanne, CH-1015 Lausanne, Switzerland, KYLE MCELROY, Department of Physics, University of Colorado at Boulder, Boulder, CO 80302 — As a layered quasi-2D material, 2H-$TaSe_2$ has a very rich phase diagram including a second order phase transition at 122K, a first order phase transition at 90K, and a superconductivity transition at 133mK. With our UHV Scanning Tunneling Microscope, we have performed temperature-controlled STM work to study the incommensurate and commensurate CDW phases of 2H-$TaSe_2$, from 77K to 110K. We will present temperature and tunneling bias voltage dependant topograph data, together with IV and dI/dV spectra in order to help understanding the nature of these two different CDW phases and the gapping mechanism of this material.

8:24AM A22.00003 The Role of Electron-Phonon Coupling in the CDW phase transitions in $TaSe_2$, YUE CAO, ZHE SUN, QIANG WANG, JIXIA DAI, KYLE MCELROY, MICHAEL HERMELE, University of Colorado, HELMUTH BERGER, Institute of Condensed Matter Physics, EPFL, Switzerland, DANIEL DESSAU, University of Colorado — In this talk, we will report our research progress of the classical charge density wave material 2H-$TaSe_2$. The formation of the CDW can be driven by the electronic instability or by the interplay between electrons and phonons, which is an essential ingredient of CDW. In this talk, we will provide a novel analyzing technique that can help distinguish the two scenarios. We will discuss the three possible nesting schemes in this talk and compare its electronic instability. We employ a novel band dissected technique to analyze the characteristic correlation functions for the CDW phase. By comparing the electronic instability to the actual band folding in the incommensurate CDW phase, we can tell the role of electronic structure / electron phonon coupling in this material. This discussion will help improve our understanding of the CDW and of the nesting picture in general.

8:36AM A22.00004 Extended phonon collapse in the charge density wave compound $NbSe_2$, S. ROSENKRANZ, F. WEBER, J.P. CASTELLAN, R. OSBORN, A. SAID, Argonne National Laboratory, R. HOTT, R. HEID, Karlsruhe Institute of Technology, D. REZNIK, Univ. Colorado at Boulder — The soft-phonons in the charge density wave (CDW) compound $NbSe_2$ were investigated using high-resolution inelastic X-ray scattering. As the CDW transition at T_C=33K is approached from high temperature, we observe a breakdown of the dispersion with the phonons becoming overdapmed over an extended region around the CDW wavevector. This is in contrast to the cusp in the phonon dispersion expected from the commonly invoked electronic nesting scenario of the CDW transition. Instead, our results, combined with $ab\ initio$ calculations, show that the wavevector of the CDW order is dictated by the momentum dependence of the intrinsic electron-phonon coupling. The strong influence of electron-phonon matrix-elements could also be of importance to other systems, where CDW-like correlations have been attributed to unusual physical properties.
Work supported by US DOE BES-DMS DE-AC02-06CH11357.

8:48AM A22.00005 Pressure induced enhancement of CDW fluctuations in 1T-TiSe2[1] , Y.I. JOE, X.M. CHEN, University of Illinois, J. GECK, IFW-Dresden, Germany, M. VON ZIMMERMANN, DESY HASYLAB, Germany, S. YUAN, S.L. COOPER, PETER ABBAMONTE, University of Illinois — 1T-TiSe2 is atypical quasi 2-dimensional CDW material showing a 2x2x2 superlattice modulation at low temperature. It's is known that high pressure suppresses the CDW order and interestingly induces superconductivity. While it is not agreed what drives the CDW transition, it has been proposed that the CDW fluctuations are closely related to the emergence of superconductivity . Here we present a detailed high pressure X-ray diffraction study of the CDW order in -TiSe2. We can directly probe not only the order parameter but also the fluctuations of the CDW order. At low pressure we observe no sizable deviation from mean field predictions. For pressures above around 2.5GPa, however, we observe changes in the CDW line shape, indicating enhanced CDW fluctuations. Those results are consistent with previous high pressure transport measurements and suggest a relationship between the superconductivity and the charge density wave in this system.

[1]Funding DOE BES grant number DE-FG02-07ER46453

9:00AM A22.00006 Fluctuations of CDW order at a quantum phase transition , YEJUN FENG, J. VAN WEZEL, S. HARAVIFARD, G. SRAJER, J. MITCHELL, Argonne National Lab, JIYANG WANG, T.F. ROSENBAUM, University of Chicago, R. JARAMILLO, Harvard University, Z.-A. XU, Zhejiang University, Y. LIU, Penn State University — 2H-NbSe2 is the archetypical two-dimensional charge-density-wave system. Using x-ray diffraction in a diamond anvil cell, we track the evolution of the CDW order towards the buried quantum critical point inside the superconducting phase. We observe a pressure-dependent nesting vector as well as fluctuation broadening, and compare these results to the behavior of the three-dimensional spin-density-wave system, Chromium, at its quantum critical point.

9:12AM A22.00007 The effect of quantum fluctuations on charge ordered $NbSe_2$, JASPER VAN WEZEL, YEJUN FENG, JIYANG WANG, R. JARAMILLO, T.F. ROSENBAUM — Among materials displaying charge density wave order, $NbSe_2$ stands out because its ordering vector does not correspond to any obvious nesting properties of its Fermi surface or band structure. The well known Peierls mechanism is thus less effective in singling out an ordering vector for $NbSe_2$, and the transition is driven instead by an increase of the susceptibility over a wide range of wave numbers. As the CDW transition is suppressed towards zero temperature, such a broad susceptibility gives rise to quantum fluctuations with an equally broad span in wavelengths. Here, we examine the role of these quantum fluctuations as the critical point is approached. We compare our theoretical findings to recent measurements of the ordering wave vector of $NbSe_2$ under pressure and show that its properties can be understood as arising from the combined effect of the presence of quantum fluctuations and the coupling of the CDW order parameter to the lattice.

9:24AM A22.00008 Field-Effect Modulation of Charge Density Wave Conduction[1] , ETHAN GEIL, ROBERT THORNE, Cornell University — We have constructed field-effect devices, analogous to MOSFETs, with crystals of the charge-density wave (CDW) conductor NbSe3 as the channel. Applying a gate voltage across an oxide insulator modulates the carrier density in the NbSe3 and also applies a transverse electric field. Surprisingly, relatively small ($\sim$ 0.1%) changes in carrier density (as measured by the single particle conductivity) produce large ($\sim$ 40%) decreases in the threshold field for collective conduction. We discuss this result in terms of collective screening of the applied field and modulation of the CDW order parameter.

9:36AM A22.00009 Torque dependence of the voltage-induced torsional strain in tantalum trisulfide associated with charge-density-wave depinning[1] , J. NICHOLS, H. ZHANG, J.W. BRILL, University of Kentucky — Crystals of orthorhombic tantalum trisulfide slowly twist (by $\sim 1/4$ degree) when voltages near the charge-density-wave depinning threshold are applied. We have studied how this hysteretic voltage-induced torsional strain (VITS) is affected by additional torques applied to the sample by attaching a magnetized steel wire to the center of the sample. The torsional strain in the crystal was measured by placing the sample in an RF cavity in a small, variable magnetic field. We have found that twisting the sample by a few degrees can have large effects on the induced strain: i) twisting can change the magnitude and dynamics of the VITS; ii) in some cases, twisting can change the direction of the VITS. The latter effect suggests that the VITS is caused by dislocation lines in the crystal causing transverse gradients in the CDW phase. As these gradients compress and dilate with alternating applied voltage, they can cause torsional strains in the crystal. A puzzle, however, is what causes the voltage-induced torsional strain to be so slow (time constants $\sim$ 1 sec near the depinning threshold).

9:48AM A22.00010 High Field Proton NMR Studies of Single Crystal $Per_2Pt[mnt]_2$[1] , ELIZABETH L. GREEN, J.S. BROOKS, NHMFL/FSU, P.L. KUHNS, A.P. REYES, NHMFL, S. BROWN, UCLA, M. ALMEIDA, Instituto-Tecnológico e Nuclear, Portugal — $Per_2Pt[mnt]_2$ is a quasi-one-dimensional organic conductor that has been studied for over thirty years. It consists of perylene and $Pt[mnt]_2$chains that undergo a spin-peierls (SP)-charge density wave (CDW) transition below 8 K. The phase diagram has previously been mapped out up to 42 T using transport measurements. The work we present here is the first single crystal NMR experiment, primarily focusing on the physics of the localized moment present on the platinum site. By measuring relaxation rates and spectra at high fields, up to 26 T, and low temperatures, down to 1.5 K, we were able to map out the SP phase boundary. Preliminary results indicate that the SP transition occurs at a lower temperature than the CDW boundary determined from transport, suggesting that the lattice instability on the perylene drives the dimerization of the platinum moment. Our ultimate goal is to use NMR spectra to observe the platinum moment in the field induced charge density wave (FICDW) state in the range 25-42 T.

10:00AM A22.00011 Spin frustration and charge ordering in TMTTF salts , KAZUYOSHI YOSHIMI, NRI "RICS," AIST, Department of Physics, University of Tokyo, HITOSHI SEO, Advanced Science Institute, RIKEN, CREST JST, SHOJI ISHIBASHI, NRI "RICS," AIST, STUART BROWN, Department of Physics and Astronomy, UCLA — Quasi-one-dimensional organic conductors $(TMTTF)_2X$ salts exhibit various types of phase transitions such as magnetic ordering, charge ordering (CO), and superconducting transitions. Among them, $(TMTTF)_2SbF_6$ shows a peculiar behavior under pressure: a cooperative reduction of CO and anti-ferromagnetic (AF) phase transition temperatures by the application of pressure has been reported by NMR measurements [1]. This result naively does not coincide with the case for typical CO transitions, where CO suppresses the tendency toward magnetic ordering due to decrease of the effective spin exchange coupling. To explain this behavior, we investigate a 1/4-filled quasi-one-dimensional extended Hubbard model with Coulomb interactions and inter-chain hopping which causes spin frustration between the dimers on the one-dimensional chains. By numerical exact diagonalization method, we find that CO relaxes spin frustration and enhances two-dimensionality which stabilizes AF ordering. To compare our results with experiments, we determine the hopping parameters by first principles band calculation for several TMTTF salts and discuss the relation between spin frustration and CO.

10:12AM A22.00012 The Paired Electron Crystal: order from frustration in the quarter-filled band[1] , S. DAYAL, R.T. CLAY, Mississippi State University, H. LI, S. MAZUMDAR, University of Arizona — The effect of lattice frustration on two dimensional (2D) quantum spin models and the 2D half-filled Hubbard model has been intensively studied in order to understand the connections between antiferromagnetism (AFM), valence-bond ordered states, candidate spin-liquid states, and unconventional superconductivity. For several classes of unconventional superconductors, including the organic charge-transfer solids and superconducting spinels such as $LiTi_2O_4$, the correct starting point is however the quarter-filled rather than $\frac{1}{2}$-filled band. We present a study of the effect of frustration on the 2D $\frac{1}{4}$-filled interacting band. We demonstrate that in addition to the well known AFM state occurring with lattice dimerization, and Wigner crystal (WC) state, a paired insulating state occurs in the frustrated region of the phase diagram. This paired electron crystal (PEC) state has coexisting charge order and bond order and a spin-gap due to the formation of nearest-neighbor singlets in the pairs. We investigate fully the phase diagram, including effects of varying the strength of on-site and nearest-neighbor Coulomb interactions as well as electron phonon coupling strength. We present the full phase diagram showing the extent of AFM, PEC and WC phases.

10:24AM A22.00013 The Paired Electron Crystal in quarter-filled organic superconductors[1] , R.T. CLAY, S. DAYAL, Mississippi State University, H. LI, S. MAZUMDAR, University of Arizona — In the 2D organic superconductors the underlying carrier density in the conducting layers is 1/2 electron per molecule. Because molecules often occur in dimer pairs, an effective model is frequently used with one electron per dimer. With strong electron-electron correlations, this effective model describes the occurrence of antiferromagnetism. Because of lattice frustration, κ-$(ET)_2Cu_2(CN)_3$ and other organics have been suggested to have spin liquid ground states. Recent experiments however have found strong lattice effects at low temperature in this material and raised uncertainty whether excitations are gapped or gapless. We argue that to resolve these issues one must go beyond the effective dimer model and instead start from the underlying 1/4-filled band. We have recently shown that in 2D 1/4-filled strongly correlated systems a commensurate insulating state forms that we have termed a Paired Electron Crystal (PEC). While in the antiferromagnetic state charge densities are uniform within a dimer, in the spin-gapped PEC state dimer charges become unequal and pairs of charge-rich sites are separated by pairs of charge-poor sites. We review the PEC concept and explain how it can provide a unified theoretical view of the 2D organics.

10:36AM A22.00014 Oscillating magnetothermopower in a Q2D organic conductor[1] , DANICA KRSTOVSKA, Ss. Cyril and Methodius University, Skopje, Macedonia and National High Magnetic Field Lab/FSU, Tallahassee, FL, USA — The beating oscillations of the interlayer thermopower with a large amplitude on both the magnetic field magnitude and an angle between the normal to the Q2D layer plane and the magnetic field are shown to occur when the cyclotron energy is comparable with the interlayer transfer integral. It is found that, in a Q2D organic conductor with a simple slightly warped FS, the amplitude of the quantum oscillations of the interlayer thermopower substantially exceeds the amplitude of its classical part due to the presence of features of the DoS of the charge carriers when their energy spectrum is quantized. The semi-classical Boltzmann theory predicts that the position of the beats in the magnetic oscillations of the interlayer thermopower are shifted with respect of those in the interlayer magnetoresistance. The shift is even bigger with increasing magnetic field. It might be expected that the difference between the beats in the interlayer thermopower and Shubnikov de Haass angular oscillations is not magnetic field dependent. However, experiments will be necessary for more detailed analysis of the magnetothermopower in Q2D organic metals to be made.

Session A23 DCMP: Superconductivity: ARPES on BSCCO and SRO D165

8:00AM A23.00001 Deviation from $d_{x^2-y^2}$ gap form in Bi2201 revealed by photon-energy-dependent ARPES study , MAKOTO HASHIMOTO, SLAC, RUIHUA HE, LBNL, ROB MOORE, DONGHUI LU, SLAC, YOSHIYUKI YOSHIDA, HIROSHI EISAKI, AIST, ZAHID HUSSAIN, LBNL, ZHI-XUN SHEN, Stanford University — Previous ARPES studies on optimally doped cuprate superconductor Bi2201 with moderate incident photon energies ($>$ 20 eV) reported that the gap function deviates from simple $d_{x^2-y^2}$ functional form in the antinode, implying that the pseudogap is different from superconductivity. On the other hand, some other ARPES studies using low photon energies ($<$ 10 eV) found that simple $d_{x^2-y^2}$ functional form extends to the antinode, suggesting that the pseudogap has the same origin as superconductivity. We study this contradiction by photon-energy-dependent ARPES. We show that, at low photon energies, background signal is dominant in the antinode and conceals the true gap magnitude. This confirms that the gap function in optimally doped Bi2201 is not simple $d_{x^2-y^2}$ functional form, and supports that the pseudogap is different order from simple superconductivity.

8:12AM A23.00002 Laser-ARPES studies on Bi-2212 , I.M. VISHIK, W.-S. LEE, F. SCHMITT, Stanford University, T. SASAGAWA, Tokyo Institute of Technology, S. ISHIDA, University of Tokyo, K. FUJITA, Cornell University, S. UCHIDA, University of Tokyo, T.P. DEVEREAUX, Z.-X. SHEN, Stanford University — Temperature-dependent ARPES measurements of the gap function in $Bi_2Sr_2CaCu_2O_{8+\delta}$ (Bi-2212) have given support for a 'two-gap' picture, where superconductivity and the pseudogap represent competing states, but the dichotomy between these gaps in momentum space and temperature is subtle. For instance, the pseudogap is observed by spectroscopy even below T_c, and ARPES observes superconducting quasiparticles in Bi-2212 even in the antinodal region, where the pseudogap is dominant. Thus, the gap measured at a particular momentum may contain contributions from both states. We have performed laser ARPES measurements on underdoped Bi-2212, using the superior energy resolution of this technique in conjunction with a detailed doping-and-temperature-dependence study, to elucidate the relative contributions of the pseudogap and superconducting gap at different temperatures and momenta. We report our findings on how the superconducting gap evolves into the pseudogap for various dopings.

8:24AM A23.00003 Structural origin of apparent Fermi surface pockets in angle-resolved photoemission of $Bi_2Sr_{2-x}La_xCuO_{6+\delta}$, PHIL D.C. KING, W. MEEVASANA, University of St Andrews, J.A. ROSEN, University of British Columbia, A. TAMAI, E. ROZBICKI, University of St Andrews, R. COMIN, G. LEVY, D. FOURNIER, University of British Columbia, Y. YOSHIDA, H. EISAKI, NIAIST, Tsukuba, K.M. SHEN, Cornell University, N.J.C. INGLE, A. DAMASCELLI, University of British Columbia, F. BAUMBERGER, University of St Andrews — We observe *apparent* hole pockets in the Fermi surfaces of single-layer Bi-based cuprate superconductors from angle-resolved photoemission (ARPES). However, from an analysis of their polarization-dependence and detailed low-energy electron diffraction measurements, we show that these are not intrinsic, but due to multiple overlapping superstructure replicas of the main and shadow bands. We demonstrate that the hole pockets reported recently from APRES [Meng *et al.*, Nature **462**, 335 (2009)] have a similar structural origin, and are inconsistent with an intrinsic hole pocket associated with the electronic structure of a doped CuO_2 plane. The true nature of the Fermi surface topology in the enigmatic pseudogap phase therefore remains an open question.

8:36AM A23.00004 Photoemission Evidence for New Microscopic Scaling Relation in the Cuprate Superconductors[1] , JONATHAN RAMEAU, ZHIHUI PAN, HONGBO YANG, GENDA GU, PETER JOHNSON, Brookhaven National Laboratory — We use angle resolved photoemission spectroscopy (ARPES) to investigate the relationship between the superconducting gap at low temperature and the quasiparticle scattering rates in the normal state, on the Fermi arc, for optimal and underdoped Bi2212 cuprate high temperature superconductors. Combining these results with similar data on Bi2201 from the literature we find evidence of a new and simple microscopic scaling relation connecting the normal and superconducting states of the cuprates. The result suggests that while nodal-region Cooper pairs decohere above T_c they retain the signature of a strong pairing amplitude. The anomalous momentum dependence of excitation lifetimes on the Fermi arc, above T_c, are dominated by the same interactions that induce superconductivity at and below T_c.

8:48AM A23.00005 Evidence for Strong Forward Scattering and Coupling to Acoustic Phonon Modes in the High-Tc Cuprates[1] , STEVEN JOHNSTON, IFW Dresden., I.M. VISHIK, W.S. LEE, Stanford University, F. SCHMITT, Stanford Universtiy, S. UCHIDA, University of Tokyo, K. KUJITA, Cornell University, S. ISHIDA, N. NAGAOSA, University of Tokyo, Z.X. SHEN, T.P. DEVEREAUX, Stanford University — The improved resolution of laser ARPES has revealed the presence of a new low-energy kink in the nodal dispersion of $Bi_2Sr_2Ca_2Cu_2O_{8+\delta}$, occuring at an energy below the maximum of the superconducting gap. This observation makes it difficult to interpret this renormalization in terms of coupling to any sharp bosonic modes. We examine coupling to the in-plane acoustic phonon branch via the modulation of the screened Coulomb interaction as an alternative explanation. We demonstrate that such a coupling is strongly peaked in the forward scattering direction and the resulting kink occurs at an energy shifted by the local gap $\Delta(\mathbf{k})$. Considerations for the reduction in screening with underdoping also provides a mechanism for understanding the doping dependence of the kink. These results indicate the importance of coupling to the acoustic branch with a strong forward scattering peak with important implications for the cuprates.

9:00AM A23.00006 The single-particle self-energy and fluctuation spectrum of slightly underdoped Bi2212 from ARPES experiment , JIN MO BOK, JAE HYUN YUN, HAN-YONG CHOI, SungKyunKwan Univ., WENTAO ZHANG, X.J. ZHOU, Chinese Academy of Sciences, CHANDRA M. VARMA, University of California, SUNGKYUNKWAN UNIV. TEAM, CHINESE ACADEMY OF SCIENCES TEAM, UNIVERSITY OF CALIFORNIA TEAM — We extract the single particle self-energy $\Sigma(\theta,\omega)$ and Eliashberg function $\alpha^2F(\theta,\omega)$ of normal and superconducting state Bi2212 from ARPES experiments. The self-energies along the cuts at tilt angle θ were extracted by fitting ARPES momentum distribution curves. Then, using the extracted self-energy as input, the Eliashberg function is deduced by inverting the d- wave Eliashberg equation employing the adaptive maximum entropy method (MEM). The momentum dependence of self-energy was decomposed in terms of $\Sigma(\theta,\omega) = \Sigma_0(\omega) + \Sigma_4(\omega)cos4\theta$ at 16, 70, 80, 97, and 107 K. We will present the temperature evolution and momentum dependence of the deduced Eliashberg function and self-energy.

9:12AM A23.00007 Emergence of superconductivity in HighTc copper oxide superconductors via two crossovers , UTPAL CHATTERJEE, MIKE NORMAN, Argonne National Laboratory, MOHIT RANDERIA, Ohio State University, STEPHAN ROSENKRANZ, JUAN CARLOS CAMPUZANO, Argonne National Laboratory — From our detailed ARPES measurements on BISCO 2212 High Tc Superconductors we found that unlike in conventional superconductors, where there is a single temperature scale Tc separating the normal from the superconducting state, HTSCs exhibit with two additional temperature scales. One is T*, below which electronic excitations are gapped. And the other one is Tcoh, below which electronic states are long-lived. We observed that T* and Tcoh change strongly with doping. They cross each other near optimal doping. There is a region in the normal state where the single particle excitations are gapped as well as coherent. Quite remarkably, this is the region from which superconductivity with highest Tc emerges. Our experimental finding that the two crossover lines intersect is not consistent with a "single quantum critical" point near optimal doping, rather it is more naturally consistent with theories of superconductivity for doped Mott insulators.

9:24AM A23.00008 Low energy kink in the band dispersions of Sr_2RuO_4 studied by ARPES , CHUL KIM, Institute of Physics and Applied Physics, Yonsei University, CHOONGHYUN KIM, epartment of Physics and Astronomy, Seoul National University, Y.Y. KOH, Institute of Physics and Applied Physics, Yonsei University, JAEJUN YU, epartment of Physics and Astronomy, Seoul National University, M. ARITA, K. SHIMADA, Hiroshima Synchrotron Radiation Center, Hiroshima University, Y. YOSHIDA, National institute of Advanced Industrial Science and Technology, C. KIM, Institute of Physics and Applied Physics, Yonsei University — In Sr_2RuO_4 , incommensurate antiferromagnetic fluctuations (IAF) were reported to have 4 - 10 meV energy with $\mathbf{q} = (0.6\pi, 0.6\pi)$ while the lowest optical phonon is at 12meV. If an electron is coupled to AIF in Sr_2RuO_4, the electronic band dispersions will kink below 10meV. Then, one can attribute the low energy kinks below 10meV to the electron-IAF coupling. In spite of the fact that multiple kink energies were recently reported in Sr_2RuO_4, kinks below 10meV has not been observed. To look for the so far unobserved electron-IAF coupling in Sr_2RuO_4, we performed ultra high resolution angle resolved photoemission (ARPES) experiments on Sr_2RuO_4 with clean surfaces. In the results, we observe kinks in the band dispersions at energies below 10 meV which show strong momentum dependence. To elucidate the origin of these new kinks, we compare ARPES results with inelastic neutron scattering and band calculation results.

9:36AM A23.00009 ARPES lineshapes, coherent to incoherent ratios, and the waterfall self-energy of Bi2212 cuprate superconductors , QIANG WANG, ZHE SUN, TANMOY DAS, ALEXANDER BALATSKY, ELI ROTENBERG, HELMUTH BERGER, HIROSHI EISAKI, YOSHIHIRO AIURA, DANIEL DESSAU — We report a detailed lineshape analysis of ARPES data on Bi2212 in which we separate out the sharp coherent peaks from the higher energy incoherent "background" portions, which includes and makes up the famous waterfall regions. We find that the ratio of the incoherent to coherent weights scales quadratically with the peak energy of the coherent portion of the spectra over a very wide energy range. We show that this behavior, including the waterfalls, can be understood with a simple model electron self-energy, giving a new and powerful experimental tool for determining self-energy effects in correlated electron systems.

9:48AM A23.00010 Effects of a particle-hole asymmetric pseudogap on Bogoliubov quasiparticles in ARPES , J.P.F. LEBLANC, University of Guelph, J.P. CARBOTTE, Mcmaster University, E.J. NICOL, University of Guelph — Motivated by recent angle-resolved photoemission experiments (ARPES) on the underdoped cuprates [1], we show that the particle-hole asymmetry of the pseudogap energy bands acts to reveal new spectral peaks due to Bogoliubov quasiparticles in the superconducting state. With sufficient broadening, the Bogoliubov peaks will merge with existing peaks and will lead to the anomalous observation, seen in experiment, that the carrier spectral density appears to broaden with reduced temperature. Using the resonating valence bond (RVB) spin liquid model [2], we compare with recent experimental data to empirically determine the temperature dependence of the pseudogap. Further, we demonstrate that the d-density wave model cannot explain the same data.

10:00AM A23.00011 Intrinsic Scattering Rates and the "Filling" Gap of Bi2212 , T.J. REBER, N.C. PLUMB, Z. SUN, Y. CAO, Q. WANG, Univ. of Colorado, H. IWASAWA, M. ARITA, HiSor, J.S. WEN, Z.J. XU, G. GU, Brookhaven National Lab, Y. YOSHIDA, H. EISAKI, Aist Tsukuba Central, Y. AIURA, Hiroshima Synchrotron Radiation Center, D.S. DESSAU, Univ. of Colorado — As a direct measure of the electronic interactions in a solid, knowledge of the electronic scattering rates is essential for understanding a material's behavior. Since angle resolved photoemission spectroscopy (ARPES) can probe an individual momentum state, it holds great promise for the most detailed and accurate measurements of the k-dependent electron scattering rates. Unfortunately, the scattering rates determined from ARPES are typically an order of magnitude greater than those obtained from other probes, (e.g. optical spectroscopy). Here we present a new type of spectrum, the ARPES tunneling spectrum (ATS), which resolves this discrepancy, as well as provides a qualitatively different understanding of the gaps and scattering rates along the Fermi surface. Applying this technique to the study of Bi2212, we find that the scattering rates are approximately independent of Fermi surface position but grow exponentially with temperature. Furthermore, we find that this strongly temperature dependent scattering rate is the source of the long observed but not understood "filling" of the superconducting gap in the cuprates.

10:12AM A23.00012 Pairing fluctuations determine low energy electronic spectra in cuprate superconductors , SUMILAN BANERJEE, Department of Physics, Indian Institute of Science, Bangalore-560012, India, TIRUPPATTUR RAMAKRISHNAN, Department of Physics, Banaras Hindu University, Varanasi-221005, India, CHANDAN DASGUPTA, Department of Physics, Indian Institute of Science, Bangalore 560012, India — Over the years, Angle Resolved Photo Emission Spectroscopy (ARPES) has uncovered a number of unusual spectral properties of near Fermi energy electrons with definite in-plane momenta in the hole doped cuprates. We describe here a minimal theory of tight binding electrons moving on the square planar Cu lattice of the cuprates, mixed quantum mechanically with pairs of them (Cooper pairs); superconductivity occurring at T_c is their long range (d-wave symmetry) phase coherence. Fluctuations necessarily associated with incipient long range superconducting order have a generic large distance behavior near T_c. We calculate the spectral density of electrons coupled to such Cooper pair fluctuations and show that properties observed in ARPES above T_c for different cuprates as a function of doping x and temperature T emerge inevitably; e.g. the 'Fermi arcs' with T dependent length and an antinodal pseudogap which fills up linearly as T increases towards the pseudogap temperature T^*. Below T_c, the effects of nonzero superfluid density and thermal fluctuations are calculated and compared successfully with experiment.

10:24AM A23.00013 The0ry 0f Dipolon-Phonom Interaction and Isotope Shift in Superconducting Cuprates , RAM SHARMA, University of Illinois at Chicago — Quite recently we have deduced five principles of photoemission and not only we have explained the observed low energy kink but we have also predicted two more high energy kinks [1,2] in quasiparticle energydistribution which have now been observed experimentally, all by means of the dipolon theory [3,4]. Here, the Hamiltonian for the interaction of dipolons with phonons will be presented.The Hamiltonian requires the evaluation of phonon-generated dynamic polarization fields at the oxygen sites in the $Cu-O_2$-planes. The quasi-dipolons (phonon-dressed dipolons) now play role as mediators of electron-electron pairing. Expression for the change in the transition temprature T_C due to change in oxygen isotopic mass has been derived. We have found a small decrease of about 1 per cent in T_C due to $^{16}O \rightarrow ^{18}O$, in agree ment with experiments [5]. The change in dipolon frequencies owing to the interaction with phonons has been calculated. [1] R. R. Sharma, "Dipolon Theory of Kink Structure.....", in Superconducting Cuprates....", Ed. K. N. Courtlandt, P. 81-100, Nova Sc, Pub., New York, 2009. [2] R. R. Sharma, Physica **C 468**, 190 (2008). [3] R. R. Sharma, Phy. Rev. **B 63**, 054506 (2001). [4] R. R. 10:36AM A23.00014 New Fermi Surface Sheets Revealed in Sr2RuO4 Revealed by High Resolution Angle-Resolved Photoemission Spectroscopy , SHANYU LIU, WENTAO ZHANG, LIN ZHAO, HAIYUN LIU, XIAOWEN JIA, DAIXIANG MU, GUODONG LIU, XIAOLI DONG, JUN ZHANG, XIAOYANG WANG, QINJUN PENG, ZHIMIN WANG, SHENJIN ZHANG, FENG YANG, Z. Q. MAO, CHUANGTIAN CHEN, ZUYAN XU, X. J. ZHOU, NATIONAL LABORATORY FOR SUPERCONDUCTIVITY, BEIJING NATIONAL LABORATORY FOR CONDENSED MATTER PHYSICS, TEAM[1], TECHNICAL INSTITUTE OF PHYSICS AND CHEMISTRY, CHINESE ACADEMY OF SCIENCES, BEIJING 100190, CHINA COLLABORATION, DEPARTMENT OF PHYSICS, TULANE UNIVERSITY, NEW ORLEANS, LOUISIANA 70118, USA COLLABORATION — We will present our detailed Fermi surface measurements on Sr2RuO4 by high resolution angle-resolved photoemission spectroscopy (ARPES) including vacuum ultra-violet (VUV) laser-based ARPES. In addition to the three sets of Fermi surface sheets originating from the bulk bands, the surface bands and the shadow bands of the surface bands, we have revealed two new Fermi surface sheets. The origin of these new Fermi surface sheets will be discussed.

[1]Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China

10:48AM A23.00015 Anisotropic mass renormalization in Sr2RuO4 , E.J. ROZBICKI, A. TAMAI, P.D.C. KING, Univ. of St Andrews, W. MEEVASANA, Suranaree Univ.of Technology, A. GIBBS, D.G. SLOBINSKY, A.P. MACKENZIE, F. BAUMBERGER, Univ. of St Andrews — The layered perovskite Sr_2RuO_4 continues to attract interest as a model system of a multiband Fermi liquid. Previous dHvA and ARPES studies successfully determined its Fermi surface [1, 2] and reported a large and sheet dependent renormalization of the Fermi velocity due to electron-electron interactions with v_{band}/v_F ranging from ≈ 3 for the $d_{xz/yz}$ derived α and β sheets to ≈ 5.5 for the γ sheet with dominant dxy orbital character [1, 3]. Here, we report new high-resolution ARPES data revealing an additional strong momentum dependence of the renormalization within a single Fermi surface sheet. This effect is most pronounced in the γ band and is larger than expected from the mixing of the orbital composition along individual Fermi surface sheets induced by spin-orbit coupling [4,5]. Our observations therefore provide evidence for a genuinely momentum dependent self-energy in the vicinity of a van Hove singularity.

Session A24 DCOMP: Computational Methods I: Numerical Methods for Strongly Correlated Systems D167

8:00AM A24.00001 Modeling pump-probe spectroscopy in systems with electron-phonon coupling[1] , ALEXANDER F. KEMPER, BRIAN MORITZ, THOMAS P. DEVEREAUX, Stanford University — In pump-probe experiments, the electronic system is driven out of equilibrium by the application of a strong electric field. Phonons are of critical importance in returning the system to its original state, as they dissipate the energy introduced by the field. Using the non-equilibrium Keldysh formalism, we study how phonons affect the electronic current and energy in the Migdal limit, for both pulsed and continuous fields, and how this affects various spectroscopic measurements. Finally, we consider charge density- wave systems and their behavior in pump-probe experiments.

[1]Supported under DOE Contract No. DE-AC02-76SF00515

8:12AM A24.00002 Pulsed-field pump-probe response in correlated systems[1] , B. MORITZ, T.P. DEVEREAUX, SLAC National Accelerator Laboratory and Stanford University, J.K. FREERICKS, Georgetown University — We describe pump-probe dynamics of the spinless Falicov-Kimball model subject to strong pulsed driving fields. The photoemission response shows a rapid evolution toward a new steady-state following decay of the pump pulse. We characterize the behavior by analyzing the power delivered to the system by the driving field and the corresponding change in the total energy. This prescription allows us to fit the result to an equilibrium response at a higher temperature determined self-consistently. For strong driving fields and correlations on the metallic side of the metal-insulator transition, the response can be described well by that of a system at a higher temperature; however, for correlations on the insulating side of the transition, the response in the nonequilibrium steady-state deviates significantly from that anticipated in quasi-thermal equilibrium.

[1]This work was supported by the U.S. DOE under Contract Nos. DE-AC02-76SF00515, DE-FG02-08ER46542, and DE-FG02-08ER46540.

8:24AM A24.00003 Numerical study of interacting systems driven by a constant electric field , JANEZ BONCA, J. Stefan Institute, 1000 Ljubljana, Slovenia and FMF, University of Ljubljana, 1000 Ljubljana, Slovenia, LEV VIDMAR, J. Stefan Institute, 1000 Ljubljana, Slovenia, MARCIN MIERZEJEWSKI, Institute of Physics, University of Silesia, 40-007 Katowice, Poland, PETER PRELOVSEK, J. Stefan Institute, 1000 Ljubljana, Slovenia and FMF, University of Ljubljana, 1000 Ljubljana, Slovenia, STUART TRUGMAN, Theoretical Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA — I will present a fundamental study of a Holstein polaron in one dimension and a single hole in the two dimensional t-J model driven away from the equilibrium by a constant electric field. Taking fully into account quantum effects we follow the time-evolution of systems from their ground state as the constant electric field is switched on at t=0, until they reach a steady state. At small electron phonon coupling (EP) the Holstein polaron experiences damped Bloch oscillations (BO) characteristic for a free electron band. An analytic expression of the steady state current is proposed in terms of EP coupling and electric field. We as well analyze the shape of the phonon tail that forms behind the traveling polaron. In the case of the t-J model we demonstrate that there exist three distinct regimes of the electric field (adiabatic, dissipative and the BO regime) which differ with respect to the real-time response. The d.c. current is shown to be maximal for a finite value of the electric field.

8:36AM A24.00004 Dependence of Condensate Formation in Graphene Bilayers on Relative Layer Orientation , XUEHAO MOU[1], DIPANJAN BASU, LEONARD REGISTER, SANJAY BANERJEE, The University of Texas at Austin — It has been recently predicted that condensates can form between paired n-type and p-type graphene layers separated by a dielectric at room temperature under certain conditions. Recent works by the authors have explored the dependence of the condensate on dielectric thickness, dielectric constant, and charge densities including charge imbalance. However, to date only adjacent layers with the same crystal orientation have been modeled, such that the Dirac cones in each layer are precisely aligned with each other. In practice, obtaining such orientational alignment across a thin dielectric may be problematic. Therefore, the design of experiments to either prove or disprove the theory, and of devices to exploit this room temperature condensation should it exist, may depend critically on orientation dependence. In this work, we will theoretically consider the effects of crystal rotation on the existence and strength of the condensate using mean-field theory much as in the original works on the subject.

8:48AM A24.00005 Self-consistent implementation of the multi-band Gutzwiller variational method: Formalism and combination with DFT , NICOLA LANATA', HUGO STRAND, University of Gothenburg, SE-412 96 Gothenburg, Sweden, XI DAI, Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, BO HELLSING, University of Gothenburg, SE-412 96 Gothenburg, Sweden — We have generalized the approach for solving the multi-band Gutzwiller variational problem with density-density interaction to an arbitrary local interaction. The main advantage of our formulation is that it allows for a self-consistent numerical implementation which doesn't require any additional computational effort as compared to the simpler case of density-density interaction. Combined with DFT and the Local Density Approximation (LDA+Gutzwiller) our method allows for ab-initio study of multi-band correlated materials with full (rotationally invariant) Hund's rule coupling. We briefly introduce the method and present applications to several systems of correlated electrons.

9:00AM A24.00006 Hole dynamics in a 2D doped quantum antiferromagnet within the non-crossing approximation , SATYAKI KAR, University of North Florida, EFSTRATIOS MANOUSAKIS, Florida State University; University of Athens, Greece — We study the doping evolution of the hole and magnon spectral functions of the two-dimensional $t-J$ and $t-t'-t''-J$ models by solving the Dyson's equations self-consistently within the non-crossing approximation. The doping dependence of the staggered magnetization and the hole spectral function are calculated for doping concentration where there is antiferromagnetic order for both of these models. We find that the intensity plot of the hole spectral function has characteristics similar to the "waterfall" features observed in the underdoped cuprates by ARPES.

9:12AM A24.00007 Exact quantum dynamics of spin systems using the positive-P representation , RAY NG, ERIK SORENSEN, McMaster University — We discuss a scheme for simulating the exact real time quantum dynamics of interacting quantum spin systems within the positive-P formalism. As model systems we study the transverse field Ising model as well as the Heisenberg model undergoing a quench away from the classical ferromagnetic ordered state. In using the positive-P representation (PPR), the dynamics of the interacting quantum spin system is mapped onto a set of stochastic differential equations (SDEs). The number of which scales linearly with the number of spins, N, compared to an exact solution through diagonalization that in the case of the Heisenberg model would require matrices exponentially large in N. This mapping is exact and can in principle be extended to higher dimensional interacting systems as well as to systems with an explicit coupling to the environment. We compare the results from using a PPR approach based on both the optical coherent states as well as SU(2) Radcliff coherent states.

9:24AM A24.00008 Stochastic evaluation of Bold diagrammatic series for interacting Fermion problems: application to equilibrium and non-equilibrium quantum impurity models[1] , EMANUEL GULL, DAVID R. REICHMAN, ANDREW J. MILLIS, Columbia University — We present the first implementation of a bold expansion, i.e. a numerical sampling of the diagrammatic corrections to an analytic resummation. Our method is based on an expansion around the non-crossing approximation. The method is exact and applicable to both equilibrium and non-equilibrium problems. In equilibrium we show results for the single impurity Anderson model. In the non-equilibrium case we study an interacting quantum dot coupled to two leads and present results for current and occupation numbers for up to three times larger timescales than are reachable using a bare expansion.

9:36AM A24.00009 Non-Local Corrections to the Dynamical Mean Field Theory for the Hubbard Model , HERBERT FOTSO, Department of Physics and Astronomy, Louisiana Sate University, SHUXIANG YANG, KA-MING TAM, JUANA MORENO, MARK JARRELL, Department of Physics and Astronomy, Louisiana State University, HARTMUT HAFERMANN, Centre de Physique Theorique, Ecole Polytechnique, Paris, France, DEPARTMENT OF PHYSICS AND ASTRONOMY, LOUISIANA STATE UNIVERSITY COLLABORATION, CENTRE DE PHYSIQUE THEORIQUE, ECOLE POLYTECHNIQUE, PARIS, FRANCE COLLABORATION — We use the diagrammatic parquet formalism to calculate the non-local corrections to the Dynamical Mean Field Theory ($DMFT$) solution for the two-dimensional Hubbard model. The Dynamical Mean Field Theory vertex and Green's function are used as input to calculate the Feynman diagrams on a finite size cluster. This approach properly addresses the local as well as the short-range correlations, as illustrated by the agreement of the obtained local moment and the Neel critical temperature with Quantum Monte Carlo calculations on a 4x4 cluster.

9:48AM A24.00010 Regularization of Diagrammatic Series with Zero Convergence Radius , BORIS SVISTUNOV, University of Massachusetts, Amherst, LODE POLLET, ETH, Zurich, NIKOLAY PROKOF'EV, University of Massachusetts, Amherst — The divergence of perturbative expansions which occurs for the vast majority of macroscopic systems and follows from Dyson's collapse argument, prevents the direct use of Feynman's diagrammatic technique for controllable studies of strongly interacting systems. We show how the problem of divergence can be solved by replacing the original model with a convergent sequence of successive approximations which have a convergent perturbative series while maintaining the diagrammatic structure. As an instructive model, we consider the zero-dimensional $|\psi|^4$ theory. We believe that this approach opens up an opportunity to utilize Feynman's diagrams as a generic tool to address strongly correlated classical- and quantum-field systems, especially in the context of Diagrammatic Monte Carlo.

10:00AM A24.00011 Discretization of the imaginary-time Greens function , ANDRO SABASHVILI, MATS GRANATH, HUGO STRAND, STELLAN OSTLUND, Gothenburg University — Finite temperature Greens functions are defined on an infinite set of Matsubara frequencies. A well known numerical difficulty is that the discontinuity in the Greens function in the imaginary time domain generates a long tail in the frequency representation which makes truncating a numerical calculation to to finite numbers of frequencies difficult. We have explored a particular "periodization" procedure designed to (1) close the Greens function approximation with a finite and relatively small number of Matsubara frequencies and (2) to be consistent with the Ward-Luttinger-Baym-Kadanoff variational principle. In addition to describing our truncation procedure we will show results of applying the method to standard DMFT calculations. We obtain results that are consistent with other well known but numerically more complex methods.

10:12AM A24.00012 A general method for testing validity of one-particle spectral functions , JUN LIU — Based on the fact that the one-particle spectral function is uniquely extracted from a temperature Green function, a scheme is proposed to test the validity of a one-particle spectral function derived from any temperature Green function of any interacting system under thermal equilibrium. The physical implication of the scheme is discussed. An example is worked out to explicitly show the effectiveness of the scheme.

10:24AM A24.00013 DMRG Study of the $S = 1/2$ Kagome Antiferromagnetic Heisenberg Model , SIMENG YAN, UCI, STEVEN WHITE, DAVID HUSE — Recently we have completed a density matrix renormalization group (DMRG) study of the spin-$\frac{1}{2}$ Kagome antiferromagnetic Heisenberg model. We studied a variety of cylindrical geometries, with widths up to 12 lattice spacings and total sizes up to 400-500 sites. We found a spin liquid ground state with much lower energies than the valence bond crystal found using other approaches. Our energies are variational except for very tiny edge effects, and are comparable to Lanczos energies on 36 or 42 site. The spin liquid can be viewed as a melted valence bond crystal formed from 8 site diamond loops and dimers, with a 12 site unit cell, called the "diamond pattern." In this talk we will focus on the narrowest cylinders, in particular a cylinder with a circumference of 4 lattice spacings which accomodates the diamond pattern, but for which the spin liquid ground state, while metastable in DMRG, is higher in energy than another state with a "topological string" and a resulting "valence bond density wave" broken translational symmetry. We discuss singlet and triplet gaps relative to these two states. The peculiar behavior of this narrow cylinder is presumably due to short resonance loops around the cylinder.

10:36AM A24.00014 DMRG-optimized NRG treatment of sub-ohmic spin-boson model[1] , CHENG GUO, ANDREAS WEICHSELBAUM, Physics Departement of LMU Munich, MATTHIAS VOJTA, Institute for Theoretical Physics, University Cologne, JAN VON DELFT, Physics Departement of LMU Munich — The sub-ohmic spin-boson model exhibits an interesting and much-studied quantum phase transition from a delocalized phase at weak spin-bath coupling to a localized phase at strong coupling. Previous works using NRG to calculate the critical exponents of this model near the phase transition failed partly because it cannot deal with the large number of states per bath oscillator required to describe the localized phase [1]. We show how this problem can be overcome by using DMRG to construct, for each site of the Wilson chain, an optimized boson basis containing only a small number of states, and using the resulting basis for standard NRG calculations. Our results are in good agreement with analytical predictions for this model. The approach presented here should be generalizable to other quantum impurity models with complex baths.

10:48AM A24.00015 Resonant Inelastic X-ray Scattering in the Falicov-Kimball model[1] , NANDAN PAKHIRA, JAMES FREERICKS, Georgetown University, ANDRIJ SHVAIKA, Institute for Condensed Matter Physics of the National Academy of Sciences of Ukraine — We calculate Resonant Inelastic X-ray Scattering (RIXS) spectra in the Falicov-Kimball model. Using Dynamical Mean Field Theory (DMFT) we do a detailed study of the RIXS response as a function of incident photon energy (ω_{in}) or photon energy transfer (Ω) for various photon momentums transfer ($\mathbf{q}$), temperature and other parameters of the model. We also calculate the dynamic structure factor, $S(\mathbf{q}, \Omega)$, for this model and study its possible relation with the RIXS spectra. We find that for large incident photon energy (much larger than the resonant energy) the resonant contribution to RIXS spectra essentially vanishes and $S(\mathbf{q}, \Omega)$ is proportional to the non-resonant part of the response. Finally, time permitting, we will also present Auger life time broadening effects on the RIXS spectra.

Session A25 DCMP: Superconductivity: Phases and Phase Transitions D166

8:00AM A25.00001 Two-dimensional Quantum Critical Point in Underdoped $Bi_2Sr_2CaCu_2O_{8+\delta}$, THOMAS LEMBERGER, JIE YONG, ANDREW MCCRAY, The Ohio State University, MUNTASER NAAMNEH, AMIT KANIGEL, Technion - Israel Inst. of Technology, MOHIT RANDERIA, The Ohio State University — Underdoped $Bi_2Sr_2CaCu_2O_{8+\delta}$ films with T_c's from 5 to 70 K are fabricated by sputtering and Pulsed Laser Deposition (PLD). Temperature dependences of superfluid densities are measured to study the superconductor-to-insulator quantum phase transition. Sputtered films, which tend have higher dopings, show superfluid densities that are weakly linear in T at low-T and drop dramatically where Kosterlitz-Thouless-Berezinski theory predicts, assuming that individual CuO_2bilayers are uncoupled. However, our PLD films, which are more underdoped than the sputtered films, have superfluid densities that are roughly linear from low T to T_c. Also, There is no indication of thermal critical behavior near T_c. Underdoped YBCO crystals also lack critical behavior, even though critical behavior is strong in optimally doped and moderately underdoped samples. Near the superconductor-to-insulator phase transition, T_c and $n_s(0)$ have a linear relationship that mimics that of ultrathin, two-dimensional films of Ca-doped $YBa_2Cu_3O_{7-\delta}$, thereby indicating a 2-D quantum critical point at low doping.

8:12AM A25.00002 Magnetoresistance Peak in Quench Deposited Ultra-Thin Amorphous Bismuth Films[1] , YEN-HSIANG LIN, ALLEN GOLDMAN, School of Physics and Astronomy, University of Minnesota, SCHOOL OF PHYSICS AND ASTRONOMY, UNIVERSITY OF MINNESOTA TEAM — A magnetoresistance peak in perpendicular magnetic field has been found on the insulating side of the thickness-tuned superconductor-insulator (SI) transition of quench-deposited amorphous bismuth films. The presence of a peak suggests the presence of local superconductivity in these insulating films. Arrhenius type conduction and non-linear I-V characteristics are also observed in the peak regime. The magnitude of this magnetoresistance peak increases substantially with decreasing temperature and with increasing film thickness. The dependence of the peak magnetic field on temperature and thickness may help to explain the underlying mechanism of the magnetoresistance peak.

[1]This work is supported in part by the National Science Foundation under grant NSF/DMR-0854742.

8:24AM A25.00003 Chemical Activity in $YBa_2Cu_3O_{7-\delta}$ Acrosst the Transition to Superconductivity[1] , JUANA V. ACRIVOS, San Jose' State University — Changes in the Gibbs free enthalpy, chemical activity across the transition temperature to superconductivity T_c in $YBa_2Cu_3O_{7-\delta}$ is described by enhanced element X-Ray absorption XAS and diffraction XRD [HKL] reflections. Critical oscillations in the index of refraction within the XAS line width ($\pm$ 2.5eV) at the Ba L2, L3 and Y K-edges observed $\sim$30K above $T_c \approx$93K in [HKL] reflections indicates their activity. Enhanced absorbance A versus T obtains the activation enthalpy and entropy: $\Delta H^{\neq}_{>}$=-220 meV, $\Delta S^{\neq}_{>}$=-2 meV/K ($121 \geq T \geq 93$K) for mixed normal and superconducting phases, which compensates the reported O atom ordering activation energy near T_c by 50 meV. The activation needed to mix differently ordered superconducting phases: $\Delta H^{\neq}_{<}$= -67 meV, $\Delta S^{\neq}_{<}$ = -1 meV/K ($60K \leq T \leq 93$K) indicates lattice ordering persists to 60K. Enhanced XRD scattering induced near the transition to superconductivity in 3D solids indicates that the role of 2D reactive [HKL] planes is similar to the chemical activity of reactive linear bonds in molecular reactions.

8:36AM A25.00004 Unitarity in periodic potentials and correlated s-wave Cooper pair insulators , PREDRAG NIKOLIC, George Mason University, ZLATKO TESANOVIC, Johns Hopkins University — We explore the emergence of novel universal regimes and correlated states in strongly interacting band insulators. Lattice potentials introduce Cooper, exciton and inter-valley channels for scattering resonances, which can be studied in the BCS-BEC framework. This is revealed by characterizing a large number of renormalization group fixed points. The superfluid-insulator transition is found to be pair-breaking in the weak-coupling BCS limit, while it belongs to the bosonic mean-field or XY universality class in the strong-coupling BEC limit as fermionic excitations remain gapped. The latter leads to correlated bosonic Mott insulators of Cooper pairs, and is the only option in two dimensions. Such an insulator may break lattice symmetries, but even if it doesn't it can be sharply distinguished from the band insulator out of equilibrium. The models we study can be realized with ultra-cold gases of alkali atoms tuned to a broad Feshbach resonance in an optical lattice. We discuss possible consequences for cuprate superconductors, where antinodal pair dynamics has certain features in common with our simple s-wave picture.

8:48AM A25.00005 Cooper pair localization in a-Bi thin films near the superconductor-insulator transition[1] , S.M. HOLLEN, H.Q. NGUYEN, E. RUDISAILE, J. SHAINLINE, Brown University, Department of Physics, G. FERNANDES, J.M. XU, Brown University, Division of Engineering, J.M. VALLES, JR., Brown University, Department of Physics — Ultrathin films near the Superconductor-Insulator Transition (SIT) can exhibit Cooper pair transport in their insulating phase. This Cooper Pair Insulator state is achieved in amorphous Bi films patterned with a nanohoneycomb array of holes. We will present evidence from a number of experiments on these substrates supporting that 1) thickness variations, which result in variations in T_c and Δ, serve to localize the Cooper pairs; 2) the weak links between these superconducting islands control the SIT. Finally, we will discuss our most recent experiments that aim to characterize this Cooper pair insulator state and confirm the role of the thickness variations in the localization of Cooper pairs.

[1]This work was supported by the NSF through No. DMR-0907357, by the AFRL, and by the ONR.

9:00AM A25.00006 Study of granular two-band superconducting films: existence of a zero-temperature metallic phase , BOJUN YAN, TAI-KAI NG — A variational approach is used to study the zero-temperature phase transition of two-band granular superconducting films. For s+(-) superconductors with strong enough disorder, we show the plausible existence of a metallic phase between the superconducting and insulator phases which is absent in normal single band granular superconducting films. We propose that the metallic phase may be observed in granular films of pnictide superconductors. Novel possibilities such as charge 2e metal and "topological metal" are also discussed.

9:12AM A25.00007 Phase diagram of electrostatically doped SrTiO3[1] , YEONBAE LEE, STEVE SNYDER, JACK HELLERSTEDT, COLIN CLEMENT, LAURA KINNISCHTZKE, JOSEPH KINNEY, ALLEN GOLDMAN, School of Physics, University of Minnesota, UNIVERSITY OF MINNESOTA TEAM — We report on the properties of electrostatically doped SrTiO3 over broad ranges of temperature and carrier concentration. Electrostatic doping has been carried out with the use of an electric double layer transistor employing an ionic liquid as a gate dielectric. The result is an apparent carrier-density dependent metal insulator transition that may be associated with the reduction of the density of thermally excited carriers in the conduction band derived from shallow states in the band gap. This results in a phase diagram that is analogous to that found for cuprate superconductors, however, with superconductivity appearing at much lower temperatures. In addition for doping levels short of those inducing superconductivity, an anomalous Hall effect is observed, suggesting the appearance of ferromagnetism near the boundary between the insulating and superconducting regimes of the doping layer.

[1]This work was supported by the National Science Foundation under Grant No. NSF/DMR-0854752

9:24AM A25.00008 Thermodynamic signature for the phase transition at the pseudogap temperature in underdoped YBCO (6.56) , VICTOR FANELLI, National High Magnetic Field Laboratory, Los Alamos National Laboratory, SCOTT RIGGS, ARKADY SHEKHTER, National High Magnetic Field Laboratory, Florida State University, YOKO SUZUKI, JONATHAN BETTS, ALBERT MIGLIORI, National High Magnetic Field Laboratory, Los Alamos National Laboratory, GREG BOEBINGER, National High Magnetic Field Laboratory, Florida State University, BRAD RAMSHAW, RUIXING LIANG, WALTER HARDY, DOUG BONN, Department of Physics and Astronomy, University of British Columbia — The physics of the pseudogap, and its connection to the strange metal phase remain poorly understood. The outstanding problem is whether the apparent crossover between these two regimes is a thermodynamic phase boundary. We performed high precision resonant ultrasound spectroscopy measurement on de-twinned monocrystals of underdoped YBCO (6.56) in a broad temperature range up to 300 K. We find a compelling thermodynamic signature for the phase transition at the pseudogap temperature T = 270 K.

9:36AM A25.00009 Signature of Aslamazov-Larkin fluctuation Hall conductivity in Tantalum Nitride films above their superconducting transition temperature , NICHOLAS BREZNAY, MIHIR TENDULKAR, AHARON KAPITULNIK, Stanford University, KAREN MICHAELI, M.I.T., ALEXANDER FINKEL'STEIN, Texas A&M University — We have studied the Hall effect in superconducting Tantalum Nitride films. We find a large contribution to the Hall conductivity near the superconducting transition, which we can track to temperatures well above Tc and magnetic fields well above the upper critical field, Hc2(0). This contribution arises from Aslamazov-Larkin superconducting fluctuations, and we find quantitative agreement between our data and theoretical analysis based on time dependent Ginzburg-Landau theory. We will also remark on the appearance of a sign change in the Hall effect and on the high field fluctuation conductivity in superconducting Tantalum and Indium Oxide thin films.

9:48AM A25.00010 Magnetic Phase Diagram of the electron-doped high-T_c superconductor $Nd_{2-x}Ce_xCuO_4$, M.K. CHAN[1], E.M. MOTOYAMA[2], G. YU[1], Y. LI[2], J.P. CARLO[3], T.J. WILLIAMS[4], S.K. KIM[3], T. GOKO[3,4], Y.J. UEMURA[3], G.M. LUKE[4], M. GREVEN[1], [1]University of Minnesota, [2]Stanford University, [3]Columbia University, [4]McMaster University — An intriguing issue in high-T_c superconductivity is the phase diagram asymmetry with respect to electron and hole-doping. The antiferromagnetic phase extends further with electron doping and appears to overlap with superconductivity. Our prior results suggested that genuine long-range antiferromagnetic order and superconductivity do not co-exist in $Nd_{2-x}Ce_xCuO_4$ [Motoyama *et al.* Nature 445, 186 (2007)]. However, some uncertainty remained due to Ce concentration inhomogeneity in large single crystals. Here we report neutron scattering and μSR measurements on crystals with improved Ce homogeneity. Inelastic neutron scattering indicates that genuine long-range antiferromagnetic order indeed disappears within a small doping window around x =0.12. Meanwhile, μSR measurements show that static magnetic order persists up to x = 0.14, where bulk superconductivity first unambiguously appears. Our results suggest a possible first-order phase transition in a narrow region of the phase diagram, between x = 0.12 and x =0.14, characterized by clusters of short-range static magnetic order and traces of superconductivity.

10:00AM A25.00011 Multiple Phase Transitions: Phase Diagram with Interacting Phase Boundaries of Different Order , BOHDAN ANDRAKA, PRADEEP KUMAR, University of Florida, AVADH SAXENA, Los Alamos National Laboratory — We present a thermodynamic discussion of the consequences of interacting phase boundaries. The particular focus here is when the superconducting phase boundaries are of different order in a phase diagram in the magnetic field-temperature (H-T) plane. Thus depending on the form of the dominant interaction, we derive thermodynamic observables such as specific heat, superfluid density (as could be measured by lower critical field) and thermal expansion as a function of field and temperature and especially their discontinuities at the phase boundaries. We suggest that these considerations have relevance for the superconducting transition and the phase diagram in PrOs4Sb12.

10:12AM A25.00012 Properties and behavior of superconductors exhibiting a Fulde-Ferrell-Larkin-Ovchinnikov phase[1] , WILLIAM A. CONIGLIO, CHARLES C. AGOSTA, Clark University — The body of data on the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state in 2d organic superconductors has grown to a critical mass where we may begin studying the boundaries of the FFLO phase in detail. In some very clean layered superconductors, when a magnetic field is aligned exactly parallel to the conducting layers, a superconducting phase develops at fields above the Pauli paramagnetic limit H_p and temperatures below about $T_c/3$. The phase is widely ascribed to FFLO behavior. We focus on the superconductors κ-(ET)$_2$Cu(NCS)$_2$, β''-(ET)$_2$SF$_5$CH$_2$CF$_2$SO$_3$, and λ-(BETS)$_2$GaCl$_4$, which have been studied by rf penetration depth and other techniques. We have probed the boundaries of the FFLO phase using alignment angle to tune the amount of spin-orbit scattering and temperature to control the degree of Pauli paramagnetic limiting. Using our data collected in pulsed magnetic fields at low temperature, we have gained new understanding about the behavior of the state and the conditions necessary for it to develop.

[1]We acknowledge Department of Energy support from ER46214.

10:24AM A25.00013 Exploration of the pressure-induced superconducting phase in rare-earth tritellurides (RTe$_3$)[1] , DIEGO A. ZOCCO, JAMES J. HAMLIN, M. BRIAN MAPLE, Department of Physics, University of California, San Diego, JIUN-HAW CHU, IAN R. FISHER, Department of Applied Physics, Geballe Laboratory for Advanced Materials, Stanford University — It has recently been reported that the low-dimensional rare-earth tritellurides RTe$_3$ (R = La-Nd, Sm, Gd-Tm) enter an unidirectional, incommensurate charge-density-wave (CDW) state when cooled below a temperature $T_{CDW1} \sim$ 450 - 250 K, which decreases with increasing rare earth atomic number, due to the effect of chemical pressure. For the heavier R (*i.e.*, Dy-Tm), a second CDW appears at $T_{CDW2} < T_{CDW1}$, orthogonal to the first one. We have recently found that the application of external pressure induces a superconducting (SC) state in TbTe$_3$ at low temperatures, coexisting with the two CDWs and the local moment rare-earth magnetism. In this talk, we present the results of experiments we have performed on these materials at high pressures and very low temperatures, to help develop an understanding of the origin of the superconducting state.

10:36AM A25.00014 Violation of Onsager reciprocity in underdoped cuprates? , VICTOR YAKOVENKO, University of Maryland, CHANDRA VARMA, University of California at Riverside, AHARON KAPITULNIK, Stanford University — One of the canons of condensed matter physics is the Onsager reciprocity principle for systems in which the Hamiltonian commutes with the time-reversal operator. Recent results of measurements of the Nernst coefficient [1] in underdoped $YBa_2Cu_30_{6+x}$, together with the measurements of the anisotropy of conductivity and the inferred anisotropy of the thermopower, imply that this principle is violated [2]. The probable violation and its temperature dependence are shown to be consistent with the loop-current phase which has been directly observed in other experiments. The violation is related directly to the magneto-electric symmetry of such a phase in which an applied electric field generates an effective magnetic field at right angle to it and to the order parameter vector, and vice versa.

Session A26 DMP DCOMP: Focus Session: Iron Based Superconductors – Theory D162/164

8:00AM A26.00001 Domain Walls in Normal and Superconducting States of Iron Pnictides , HUAIXIANG HUANG, DEGANG ZHANG, TAO ZHOU, C.S. TING, University of Houston — The electronic and magnetic structures in the normal and superconducting states of iron pnictides are investigated by solving self-consistently the Bogoliubov-de Gennes equation. It is shown that strong electron correlations can induce domain walls, which separate regions with different spin density wave orders. At zero or low electron doping, 90° domain walls are formed while anti-phase domain walls are produced at higher electron doping. On the domain walls, there always exist larger electron densities. The results agree qualitatively with recent observations of scanning tunneling microscopy and superconducting quantum interference device microscopy.

8:12AM A26.00002 Correlation, magnetization and conduction in iron pnictides and iron chalcogenides , ZHIPING YIN, Department of Physics, Rutgers and Stony Brook University, KRISTJAN HAULE, GABRIEL KOTLIAR, Department of Physics, Rutgers University — By combining density functional theory (DFT) and dynamical mean field theory (DMFT), we study the electronic properties of iron pnictides and iron chalcogenides in both the paramagnetic and magnetic states. With ab initio derived realistic Coulomb interaction U and Hund's exchange coupling J, we find detailed agreements bewtween our calculations and many experimental observations in these compounds, including ARPES, magnetic properties, optical conductivity and anisotropy, and so on, WITHOUT any adjustment such as shifting of atomic positions, Fermi level and bands and renormalizations of bands which are commonly needed in DFT calculations in order to compare with experiments. Our theory explains the origin of the different magnetizations in FeTe and other iron pnictides and provides a unique physical picture. We find that in the magnetic phase of the iron pnictides, both the spin and the orbital polarization are strongly energy dependent. The spin polarization becomes weaker around Fermi level when the orbital polarization is stronger and vice verse at high energies. We stress on the role of the Hund's J rather than the Coulomb U and show how the iron pnictides and iron chalcogenides differ from other compounds.

8:24AM A26.00003 Charged Stripes in the Two-Orbital Hubbard Model for Pnictides[1] , DAO-XIN YAO, State Key Lab of Optoelectronic Materials and Technologies, Sun Yat-sen University, QINLONG LUO, Department of Physics and Astronomy, The University of Tennessee, and Materials Science and Technology Division, Oak Ridge National Lab, THOMAS PRESTEL, MARIA DAGHOFER, IFW Dresden, Germany, ADRIANA MOREO, ELBIO DAGOTTO, Department of Physics and Astronomy, The University of Tennessee, and Materials Science and Technology Division, Oak Ridge National Lab — The two-orbital Hubbard model for the pnictides is studied numerically in the real-space Hartree-Fock approximation. Upon electron doping, states with a nonuniform ditribution of charge are stabilized. The patterns observed correspond to charge stripes that run perpendicular to the direction of the spin stripes of the undoped magnetic ground state. These striped states are robust when the undoped state has a gap, although with a decreasing amplitude as the gap decreases. Results for hole doping and implications for recent experiments that reported electronic nematic states and spin incommensurability in the pnictides are also discussed.

8:36AM A26.00004 Computational studies of models for the magnetism and superconductivity in iron pnictides

, ADRIANA MOREO, University of Tennessee and Oak Ridge National Lab — The properties of multiorbital electronic model Hamiltonians for the pnictides are explored using a variety of many-body techniques. Via mean-field approximations, a regime where the undoped system develops $(\pi, 0)$ magnetic order while remaining metallic is found at intermediate values of the Hubbard repulsion U. Comparison of our results against ARPES and neutron scattering data allows us to determine a range of realistic values for the parameters in the models [1]. The orbital spectral weight redistribution that occurs near the Fermi surface in the $(\pi, 0)$ magnetic state without long-range orbital order is also discussed [2]. The two-orbital "t-U-J" Hubbard model at intermediate U, with magnetic order and pairing tendencies enhanced by the addition of Heisenberg terms that arise from the strong coupling expansion, is studied via exact diagonalization. At intermediate couplings and considering two extra electrons added to the undoped system, an A_{1g} bound state is found compatible with the "extended s±" pairing discussed in the RPA approximation. Bound states with B_{2g} symmetry, involving intra- and inter-band components, are also stable in portions of the phase diagram, while states with B_{1g} symmetry are close in energy, suggesting that small changes in parameters may render any of the three channels stable [3]. Finally, using the real-space Hartree-Fock approximation on finite clusters the presence of charge stripes at intermediate U is also observed for electron-doped systems. The patterns of charge, spin, and orbital order, as well as the influence of quenched disorder will be discussed [4].

9:12AM A26.00005 Order-Parameter Anisotropies in the Pnictides - An Optimization Principle for Multi-Band Superconductivity

, CHRISTIAN PLATT, Institute for Theoretical Physics and Astrophysics, University of Wuerzburg, RONNY THOMALE, Department of Physics, Princeton University, WERNER HANKE, Institute for Theoretical Physics and Astrophysics, University of Wuerzburg — Using general arguments of an optimization taking place between the pair wave function and the repulsive part of the electron-electron interaction, we analyze the superconducting gap in materials with multiple Fermi-surface (FS) pockets, with application to two proto-type (P-based and As-based) ferropnictides. The main point of our work is to show that the SC state, its gap and, in particular, its anisotropy in momentum space is determined by an optimization, which balances the interplay between the attractive interaction in the sign-reversing $s_{\pm}$-channel and the Coulomb repulsion. This Coulomb repulsion, as discussed below, is unavoidable in a multi-band SC situation: it appears because of a kind of frustration in the $s_{\pm}$-channel, when more than two FS-pockets are involved in setting up the pairing interaction. On the basis of functional Renormalization Group (fRG) calculations for a wide parameter span of the bare interactions and for the different FS topologies applying to these two characteristic Fe-based superconductors, we show that the symmetry of the gap and the nodal versus nodeless behavior is driven by this optimization requirement.

9:24AM A26.00006 Electronic Structure of High-T_c Iron-Pnictide Superconductors from the Strong Correlation Limit[1]

, JOSE RODRIGUEZ, California State University at Los Angeles — A two-orbital t-J model for a square lattice of iron (pnictide) atoms that includes magnetic frustration and Hund's rule coupling is studied in the limit where inter-orbital hopping of holes is prohibited. A hidden half-metal phase is predicted at weak enough Hund's rule coupling, where holes move coherently through opposing ferromagnetic spin arrangments that are assigned to each orbital. In particular, two Fermi surface hole pockets centered at zero momentum that have unrenormalized Fermi velocities are predicted. Next, the same model is studied at the quantum critical point that separates the hidden ferromagnet from the commensurate spin-density wave (cSDW), where low-energy spinwaves disperse anisotropically away from cSDW wave numbers. Composite hole-spinwave excitations result in "shadow" hole Fermi surfaces that are centered at cSDW wave numbers. We explore the possibility that these "shadow" bands are intrinsically diffuse enough that they simulate electron bands. Last, determinations of the low-energy spectrum of one hole by numerical exact diagonalization confirms the existence of degenerate ground states at momenta $(0, 0)$ and $(\pi, 0)$ at a quantum critical point.

9:36AM A26.00007 Pair hopping mechanism of enhancement in T_c for layered superconductors

, KOICHI KUSAKABE, Osaka University — Two body effective interactions coming from the quantum charge fluctuation may induce pairs tunneling between adjacent layers in high-Tc materials including cuprates, iron-pnictides, MgB_2, and MNX. This mechanism [1] is favored when 1) the one-body Hamiltonian shows negligible inter-layer single electron hopping for the 2D liquid around the Fermi level, and 2) unfilled extended orbitals support the pair tunneling via local two-electron scattering. Localized nature of the 2D liquid is essential. The density functional theory (DFT) can prove this picture in two steps. The Kohn-Sham scheme tells that the single-particle effective Hamiltonian possess these aspects most clearly for the highest T_c material. The multi-reference generalization of DFT allows us to evaluate existence and relevance of the super pair tunneling. A possible mechanism for layered organic superconductors is also discussed.

9:48AM A26.00008 Charge Density Wave Induction by Spin Density Wave in Iron-Based Superconductors[1]

, ALEXANDER BALATSKY, Los Alamos National Laboratory, DMITRI BASOV, UC San Diego, JIAN-XIN ZHU, Los Alamos National Laboratory — We argue that spin density wave (SDW) phase in ferrous superconductors contains charge density wave (CDW) with the modulation momentum that is a double of characteristic momenta of SDW [1]. We discuss symmetry constraints on allowed momenta of CDW generated by coupling to spin modulations. To be specific we considered the CDW that could be realized in Fe-11 (e.g., FeTe) and Fe-122 (e.g., BaFe2As2) compounds. In case of commensurate SDW, the CDW modulation vector is at the Bragg peaks positions and could be revealed by local scanned probes. In case of incommensurate SDW, the CDW is incommensurate and can be seen also by x-ray and elastic neutron scattering. We also discuss observable charge modulation due to CDW formation near defects and twin boundaries.

10:00AM A26.00009 Theory of Valley-Density Wave and Hidden Order in Iron-Pnictides[1]

, JIAN KANG, ZLATKO TESANOVIC, Institute for Quantum Matter, Johns Hopkins University, Baltimore, MD 21218 — In the limit of perfect nesting, the physics of iron-pnictides is governed by the density wave formation at the zone-edge vector **M**. At high energies, various spin- (SDW), charge- (CDW), orbital/pocket- (PDW) density waves, and their mutually orthogonal linear combinations, all appear equally likely, unified within the unitary order parameter of the $U(4) \times U(4)$ symmetry. Nesting imperfections and low-energy interactions reduce this symmetry to that of real materials. Nevertheless, the generic ground state preserves a distinct signature of its highly symmetric origins: an SDW along one axis of the square iron lattice is predicted to *coexist* with a PDW along the perpendicular axis, accompanied by a modulated pattern of weak charge currents on inter-iron bonds. This "hidden" order induces the tetragonal-orthorhombic structural transition in our theory, naturally insures $T_s \geq T_N$, and leads to other observable consequences.

10:12AM A26.00010 Topological and Transport Properties of Dirac Fermions in Antiferromagnetic Metallic Phase of Iron-Based Superconductors , TAKAMI TOHYAMA, TAKAO MORINARI, Yukawa Institute for Theoretical Physics, Kyoto University, EIJI KANESHITA, Sendai National College of Technology, KOUDAI SUGIMOTO, Yukawa Institute for Theoretical Physics, Kyoto University — We investigate Dirac fermions in the antifferomagnetic metallic state of iron-based superconductors [1]. Deriving an effective Hamiltonian for Dirac fermions, we reveal that there exist two Dirac cones carrying the same chirality, contrary to graphene, compensated by a Fermi surface with a quadratic energy dispersion as a consequence of a non-trivial topological property inherent in the band structure. We also find that the presence of the Dirac fermions gives the difference of sign-change temperatures between the Hall coefficient and the thermopower. This is consistent with available experimental data. The Dirac ferimons also contribute to in-plane anisotropy of the optical conductivity [2].

10:24AM A26.00011 Quasiparticle states around a nonmagnetic impurity in the spin-density-wave state of iron-pnictide superconductors , TAO ZHOU, HUAIXIANG HUANG, YI GAO, University of Houston, JIANXIN ZHU, Los Alamos National Laboratory, C.S. TING, University of Houston — The quasiparticle states around a non-magnetic impurity in the electron doped iron-based superconductors with the presence of spin-density-wave (SDW) ordering will be investigated as a function of doping and for various impurity strengths. We found that In the undoped sample,two resonance peaks are found to approach the Fermi level on the impurity site with the strength of scattering potential increasing from weak to moderate. For doped samples, where the SDW order and the superconducting order coexist, there are two intra-gap resonance peaks for weak scattering potential. For strong scattering potential, one sharp peak appears near fermi energy in underdoped sample and separates to two peaks for larger dopings. For all the cases, the local density of states exhibits clear C_2 symmetry. Our results provide an effective tool to detect the SDW order and probe the coexistence of the SDW and superconducting orders.

10:36AM A26.00012 Renormalization group flow, competing phases, and gap structure in multi-band models of Fe-based superconductors , ANDREY CHUBUKOV, SAURABH MAITI, University of Wisconsin — We perform an analytical renormalization group (RG) study to address the role of Coulomb repulsion, the competition between extended s-wave superconducting order ($s\pm$) and the spin density wave (SDW) order, and the angular dependence of the superconducting gap in multi-pocket models of Fe-based superconductors. Previous analytic RG studies considered a toy 2-pockets model (one hole and one electron). We consider more realistic models of 4 and 5 pockets (2 electron and 2 or 3 hole pockets), and also incorporate angular dependences of the interactions caused by the transformation from orbital to band description. In a toy 2-pocket model, SDW order always wins over $s\pm$ order at perfect nesting; $s\pm$ order only appears when doping is finite and RG flow extends long enough to overcome intra-pocket Coulomb repulsion. In multi-pocket models, there are two new effects. First, the pairing interaction projected onto $s\pm$ channel has an attractive component no matter how strong intra-pocket repulsion is. Second, in 4-pocket model (but not in 5-pocket model), $s\pm$ order wins over SDW order even for perfect nesting, if parquet RG flow extends long enough, suggesting that SDW order is not a necessary pre-condition for the $s\pm$ order. Our analytic results are in full agreement with recent numerical functional RG studies by Thomale et. al.

10:48AM A26.00013 Large D-2 Theory of Superconducting Fluctuations in a Magnetic Field and its Application to Iron Pnictides[1] , JAMES MURRAY, ZLATKO TESANOVIC, Johns Hopkins University — A Ginzburg-Landau approach to fluctuations of a layered superconductor in a magnetic field is used to show that the interlayer coupling can be incorporated within an interacting self-consistent theory of a single layer, in the limit of a large number of neighboring layers [1]. The theory exhibits two phase transitions: a vortex liquid-to-solid transition is followed by a Bose-Einstein condensation into the Abrikosov lattice, illustrating the essential role of interlayer coupling. By using this theory, explicit expressions for magnetization, specific heat, and fluctuation conductivity are derived. We compare our results with recent experimental data on the iron-pnictide superconductors.

8:00AM A27.00001 Quantum temperature of a modulated oscillator: spectral signatures , MARK DYKMAN, Department of Physics and Astronomy, Michigan State University, East Lansing, Michigan 48824, MICHAEL MARTHALER, Institut fuer Theoretische Festkoerperphysik and DFG-Center for Functional Nanostructures (CFN), Karlsruhe Institue of Technology, D-76128 Karlsruh, VITTORIO PEANO, Department of Physics and Astronomy, Michigan State University, East Lansing, Michigan 48824 — Relaxation of a quantum system is usually due to emission of excitations of a thermal reservoir. The emission events happen at random. For periodically modulated systems, the corresponding noise leads to a finite-width distribution over the quasi-energy (Floquet) states. It can be characterized by an effective nonzero quantum temperature even where the temperature of the reservoir is zero. We show that, as a result, the spectra of fluctuations and response of a parametrically modulated underdamped nonlinear oscillator can display a fine structure. The form of the spectra sensitively depends on the temperature of the reservoir.

8:12AM A27.00002 Switching in modulated quantum oscillators beyond the rotating wave approximation. , VITTORIO PEANO[1], Albert-Ludwigs University Freiburg, MICHAEL MARTHALER, Karlsruhe University, MARK DYKMAN, Michigan State University — Experiments with Josephson bifurcation amplifiers have reached the regime where the switching between different metastable states is governed by quantum fluctuations [1]. The existing theoretical analysis of the metastable decay relies on the rotating wave approximation (RWA) and gives an exponentially small switching rate [2]. Therefore if corrections to the RWA modify the switching rate, they can become substantial even where they are small. We incorporate them within a semiclassical perturbation theory in the Floquet basis. Our analytical results are corroborated by numerical calculations and suggest a switching mechanism that had been previously overlooked.

8:24AM A27.00003 Many-body effects of quantum impurity models via circuit QED , PRASENJIT DUTT, MICHEL DEVORET, KARYN LE HUR, Yale University, New Haven, CT. — Circuit QED systems serve as an ideal quantum simulator of condensed matter models, given the great degree of experimental precision and control with which they can be manipulated. Quantum impurity models exhibiting renormalization and confinement ideas reminiscent of QCD, can be realized in circuits comprising superconducting qubits and long transmission lines, which play the role of macroscopic bosonic baths. In particular, it is possible to use such systems to engineer standard low energy many-body Hamiltonians such as the spin-boson or anisotropic Kondo model. We develop a framework combining input-output theory and many-body techniques to study correlated photon transport and specifically the qubit response in such circuits.

8:36AM A27.00004 Autoresonant vs. ladder climbing response in a superconducting Josephson phase circuit , NADAV KATZ, YAARA ROFE, YONI SHALIBO, Hebrew University, RADOSLAW BIALCZAK, JOHN MARTINIS, UCSB, IDO BARTH, LAZAR FRIEDLAND, Hebrew University — Anharmonic oscillators exhibit a unique response to a chirped drive, referred to as either autoresonance or ladder climbing. This typically involves a bifurcation of the oscillation amplitude depending both on the strength of the drive and on the system's anharmonicity. In this parameter space, the threshold of bifurcation exhibits a transition between sequential state excitation (quantum ladder climbing) and the population of coherent-like states (classical autoresonance). Previous attempts to experimentally map this transition have only been possible in either classical or quantum conditions. Superconducting Josephson phase circuits enable us to map these two regimes, including the intermediate regime, due to their tunable anharmonicity. We measure the bifurcation phenomena in this system over the relevant parameter space where the transition is observed. We compare to numerical simulations and theoretical analysis.

8:48AM A27.00005 Quantum Transport of Strongly-Correlated Photons in Waveguide QED , HUAIXIU ZHENG, DANIEL J. GAUTHIER, HAROLD U. BARANGER, Duke University — We present an exact solution of the quantum transport problem of multi-mode photons in a waveguide quantum electrodynamics (QED) system, which may be realized in a variety of circuit-QED, plasmonic, photonic, or cold-atom contexts. The bosonic modes are strongly coupled to a local atomic or qubit system, which can be a two-level, Gamma-type three-level, or N-type four-level system. We show that strong coupling produces dramatic quantum optics effects. In particular, multi-photon bound states emerge in the scattering of two or more photons. Such bound states have a large impact on the transport of coherent-state wave-packets. For a two-level system, the single-photon probability is suppressed while multi-photon probabilities are strongly enhanced, resulting in non-classical statistics. For a three-level system, as one tunes the coupling strength and the control field, the transmitted light can show bunching or antibunching, indicating effective attractive or repulsive interactions. Finally, for a N-type four-level system, we demonstrate that the multi-photon components can be largely suppressed, leading to a potential single-photon filter.

9:00AM A27.00006 Superradiance and Phase Multistability in Circuit Quantum Electrodynamics , MICHAEL DELANTY, STOJAN REBIC, JASON TWAMLEY, Centre for Engineered Quantum Systems, Macquarie University, Sydney, NSW 2109, Australia — By modelling the coupling of multiple superconducting qubits to a single cavity in the circuit-quantum electrodynamics (QED) framework we find that it should be possible to observe superradiance and phase multistability using currently available technology (M. Delanty, S. Rebić and J. Twamley, arxiv:1007.2231). Due to the exceptionally large couplings present in circuit-QED we predict that superradiant microwave pulses should be observable with only a very small number of qubits (just three or four), in the presence of energy relaxation and small differences in the qubit-field coupling strengths. This paves the way for circuit-QED implementations of superradiant state readout and decoherence free subspace state encoding in subradiant states. The system considered here also exhibits phase multistability when driven with large field amplitudes, and this effect may have applications for collective qubit readout and for quantum feedback protocols. Furthermore, we extend our analysis to superradiance and collective effects in multi-resonator circuit-QED systems.

9:12AM A27.00007 Design and Calibration of an Improved Josephson Parametric Amplifier , WILLIAM F. KINDEL, HSIANG-SHENG KU, University of Colorado, FRANCOIS MALLET, JILA, LEILA R. VALE, GENE C. HILTON, KENT D. IRWIN, National Institute of Standards and Technology, KONRAD W. LEHNERT, JILA — Phase sensitive amplifiers are of interested because in principal they can amplify one quadrature of a tone without any added noise, unlike phase insensitive amplifiers which amplify both quadratures but must add half a quanta of noise. In situations where a signal of interest is encoded in the modulation of only one quadrature of a tone, phase sensitive detection is clearly dvantageous. With the goal of creating a microwave-frequency phase-sensitive amplifier that adds no noise, we will present the design and performance of a recently tested Josephson Parametric Amplifier (JPA). Initial measurements indicate that the JPAs added noise is no greater than 0.1 quanta. This is a substantial improvement over a previous design for which the added noise was 0.3 quanta [1]. I will discuss changes made to the design and possible reason for the improvement.

9:24AM A27.00008 Parametric processes in a cavity resonator terminated with a DC-SQUID , FRANCOIS NGUYEN, EVA ZAKKA BAJJANI, NIST Boulder, MINHYEA LEE, University of Colorado, LAFE SPIETZ, LEILA VALE, RAYMOND SIMMONDS, JOSE AUMENTADO, NIST Boulder — The coplanar waveguide resonators with SQUIDs have become common to several recent superconducting quantum information experiments. In this talk, we will present some recent results which demonstrate the manipulation of the internal harmonic modes of a microwave cavity resonator using a flux-driven SQUID as a parametric mode mixing resource.

9:36AM A27.00009 Quantum non-demolition measurement of microwave photons in superconducting circuits using engineered quadratic interactions , CHUNQING DENG, University of Waterloo, JAY GAMBETTA, ADRIAN LUPASCU — We present a quantum electrical circuit with Josephson junctions formed by two anharmonic oscillators coupled with an interaction of the form $g\gamma_1^2\gamma_2^2$ where γ_1 and γ_2 are position-like coordinates. This type of coupling allows the quantum non-demolition measurement of the energy of one oscillator by monitoring the frequency of the second oscillator. We find that the optimized coupling strength g scales as $\sqrt{\omega_1\omega_2}/\sqrt{n_1 n_2}$, with $\omega_{1,2}$ the frequency, and $n_{1,2}$ the maximum photon storage capacity of each resonator. With an optimized coupling, it is possible to achieve high fidelity detection of up to 10 photons over a time of the order of microseconds. We discuss the possibility of observing quantum jumps in the number of photons and related applications. We also present our experimental work on the implementation of this detection scheme. C. Deng, J. M. Gambetta, and A. Lupascu, arXiv:1008.3363 (2010).

9:48AM A27.00010 Lossless on-chip microwave circulator using Josephson parametric converters[1] , BALEEGH ABDO, ARCHANA KAMAL, MICHAEL HATRIDGE, FLAVIUS SCHACKERT, KURTIS GEERLINGS, MICHEL DEVORET, Applied Physics Department, Yale University — Motivated by our recent theoretical work on non-reciprocal parametric devices [1], we propose a novel scheme for realizing a four-port, lossless, on-chip microwave circulator using a compact design of Josephson parametric converters (JPC's) and hybrids. The JPC, which is normally used as a phase-preserving quantum-limited amplifier, is operated here in a pure conversion mode with unity photon gain. The non-reciprocity of the device is induced by a phase shift between the two pump signals feeding two JPC's sharing a common idler port. The non-reciprocity direction can thus be reversed much more rapidly than by changing a magnetic field. Furthermore, since the device consists only of purely dispersive components, the proposed circulator should not add any noise to signals it processes.

10:00AM A27.00011 Dynamic range and noise of the Josephson parametric converter[1] , FLAVIUS SCHACKERT, BALEEGH ABDO, MICHAEL HATRIDGE, LUIGI FRUNZIO, ROBERT J. SCHOELKOPF, MICHEL H. DEVORET, Yale University — We present recent progress in characterizing key properties of the Josephson parametric converter (JPC): its dynamic range and noise performance. The JPC is a phase-preserving parametric amplifier operating in the microwave regime. It is based on a ring of four Josephson junctions, which provides the non-linearity, coupled to two microwave resonators, which increase the effective interaction between the incoming signal and this non-linearity. The JPC operates with a minimal number of modes, which simplifies its analysis, and is close to the ideal non-degenerate parametric amplifier operating at the quantum limit of noise. Besides having sufficient gain and bandwidth, a practical amplifier useful for e.g. the readout of superconducting qubits will need to exhibit a sufficiently low noise temperature and dynamic range. While dynamic range ensures that an incoming signal does not saturate the amplifier, a low noise temperature is necessary to minimally degrade signal-to-noise ratio.

[1]Work supported by IARPA, ARO and NSF.

10:12AM A27.00012 Microwave Photon Counter Based on Josephson Junctions , Y.-F. CHEN, D. HOVER, S. SENDELBACH, L. MAURER, R. MCDERMOTT, University of Wisconsin, S.T. MERKEL, E.J. PRITCHETT, F.K. WILHELM, Institute for Quantum Computing, University of Waterloo — We describe a microwave photon counter based on current-biased Josephson junctions. The absorption of a single microwave photon causes a junction to switch to the voltage state, producing a large and easily measured classical signal. With a two-junction circuit, we have performed a microwave version of the Hanbury Brown and Twiss experiment at 4 GHz, and demonstrated a clear signature of photon bunching for a thermal source. The design is readily scalable to tens of parallelized junctions, a configuration that would allow number-resolved counting of microwave photons. We discuss possible applications to cavity state readout and to measurement of the counting statistics of microwave photons emitted by mesoscopic conductors.

10:24AM A27.00013 Quantum Limited Amplification and Detection with a Non-Linear Cavity Detector , CATHERINE LAFLAMME, AASHISH CLERK, Department of Physics, McGill University — A variety of recent experiments demonstrate the power of using driven microwave resonators for quantum measurement and amplification. Here, we consider theoretically the use of a driven cavity with a Kerr-type non-linearity to amplify a dispersively coupled signal. We consider the regime where there is no multi-stability in the cavity dynamics; this is similar to recent experiments.[1,2] The amplifier quantum-limit in this case involves the physics of backaction, unlike the more studied 'scattering' mode of operation. We calculate the added noise of this nonlinear cavity amplifier, and show that it exhibits universal scaling in the vicinity of the bifurcation point. We also show that for low frequencies the nonlinear cavity amplifier reaches the fundamental quantum limit on its noise temperature, but has large backaction - imprecision noise correlations. This implies that the non-linear cavity cannot be simply used for QND qubit measurement, but could have interesting applications to non-resonant force sensing. Our results have applications to quantum information processing, electromechanics and optomechanics.

[2]F.R. Ong *et al.*, arXiv:1010.6248v1

10:36AM A27.00014 A flux-driven Josephson parametric amplifier for experiments with propagating quantum microwaves[1] , E.P. MENZEL, A. BAUST, F. DEPPE, T. NIEMCZYK, E. HOFFMANN, M. HAEBERLEIN, A. MARX, R. GROSS, Walther-Meissner-Institut and TU Muenchen, Garching, Germany, E. SOLANO, Universidad del Pais Vasco and IKERBASQUE Foundation, Bilbao, Spain, K. INOMATA, RIKEN, Wako-shi, Japan, T. YAMAMOTO, Y. NAKAMURA, NEC, Tsukuba and RIKEN, Wako-shi, Japan — For the detection of propagating quantum microwaves in circuit QED linear amplifiers are key ingredients. Phase sensitive amplifiers [e.g., Josephson parametric amplifiers (JPA)] in principle allow for the amplification of one signal quadrature without adding noise. In practice, however, internal losses often introduce a finite amount of noise. We have recently shown that, despite such a residual noise, signals on the quantum level can be fully characterized using two amplification chains and suitable correlations [E.P. Menzel et al., PRL 105, 100401 (2010)]. In this work, we characterize a flux-driven JPA. At 5.64 GHz the maximum degenerate gain is 25.5 dB and the signal bandwidth is 1.8 MHz. Phase-insensitive measurements yield a noise temperature of 100$\pm$20 mK, which is below the standard quantum limit of 135 mK.

10:48AM A27.00015 Microstrip SQUID amplifiers at gigahertz frequencies[1] , M.P. DEFEO, P. BHUPATHI, M. WARE, B.L.T. PLOURDE, Syracuse University — SQUID amplifiers based on the microstrip resonance formed between the input coil and SQUID washer have demonstrated substantial gain and low noise at frequencies of several hundred MHz. Operation at higher frequencies requires shorter input coils and the corresponding reduced mutual inductance must be compensated with an increased transfer function in order to avoid loss of gain. We have fabricated microstrip SQUID amplifiers using low capacitance Al-AlOx-Al submicron junctions and large resistive shunts to increase the transfer function while keeping the SQUID non-hysteretic. These devices have demonstrated gains beyond 20dB at frequencies in the gigahertz range. Gain and noise measurements as well as applications of these devices in the field of quantum information science will be discussed.

Session A28 DMP: Focus Session: Carbon Nanotubes and Related Materials: Fundamentals and Applications C156

8:00AM A28.00001 Carbon nanotube – catalyst composites: from nano-complexes to aerogel functionalization[1] , GORDANA N. OSTOJIC, MARK C. HERSAM, Materials Science and Engineering Department, Northwestern University — Here we present three different strategies to achieve attachment of catalytic nanoparticles to SWNTs and discuss their physical properties. In nano-complex scheme, DNA that solubilizes SWNTs is used as an anchor for Pt nanoparticle growth. Attached platinum strongly influences nanotube phonon and charge carrier distribution. For macroscopic electrodes, no special chemistry is needed. Simple solubilization of both nanoparticles (Pt) and nanotubes in polar surfactants and joint deposition on a porous membrane will result in charge coupled SWNT/Pt electrode. A particularly difficult problem in SWNT research is a task of electrically connecting nanotubes and at the same time keeping the surface available. We present an innovative solution to this problem in which SWNTs are connected through point contacts that leave the majority of the surface free. This method creates self-assembled carbon nanotube aerogel of a record low density that is both luminescent and conductive. Additional value of this material is that it is suitable for subsequent functionalizations. Platinum and titanium dioxide deposition on aerogel suggests that carbon aerogel can be used as a framework for complex structures.

8:12AM A28.00002 Reinforced Epoxy Nanocomposite Sheets Utilizing Large Interfacial Area from a High Surface Area Single-Walled Carbon Nanotube Scaffold , KAZUFUMI KOBASHI, HIDEKAZU NISHINO, TAKEO YAMADA, DON FUTABA, MOTOO YUMURA, KENJI HATA, AIST — We employed single-walled carbon nanotubes (SWNTs) with the available highest specific surface area (more than 1000 m2/g) that provided very large interfacial area for the matrix to fabricate epoxy composite sheets. Through mechanical redirection of the SWNT alignment to horizontal to create a laterally aligned scaffold sheet, into which epoxy resin was impregnated. The SWNT scaffold was engineered in structure to meet the these two nearly mutually exclusive demands, i.e. to have nanometer meso-pores (2-50 nm) to facilitate homogeneous impregnation of the epoxy resin and to have mechanical strength to tolerate the compaction forces generated during impregnation. Through this approach, a SWNT/epoxy composite sheet with a nearly ideal morphology was realized where long and aligned SWNTs were loaded at high weight fraction (33 percent) with an intertube distance approaching the radius of gyration for polymers. The resultant composite showed a Young's modulus of 15.0 GPa and a tensile strength of 104 MPa, thus achieving 5.4 and 2.1 times reinforcement as compared to the neat epoxy resin.

8:24AM A28.00003 Single-walled carbon nanotube buckypaper and mesophase pitch carbon/carbon composites[1] , JIN GYU PARK, NAM GYUN YUN, YOUNG BIN PARK, RICHARD LIANG, LLOYD LUMATA, JAMES BROOKS, CHUCK ZHANG, BEN WANG, HIGH-PERFORMANCE MATERIALS INSTITUTE, FSU COLLABORATION, NATIONAL HIGH MAGNETIC FIELD LABORATORY, FSU COLLABORATION — Carbon/carbon composites consisting of single-walled carbon nanotube (SWCNT) buckypaper (BP) and mesophase pitch resin have been produced through impregnation of BP with pitch using toluene as a solvent. Drying, stabilization and carbonization processes were performed sequentially, and repeated to increase the pitch content. Voids in the carbon/carbon composite samples decreased with increasing impregnation process cycles. Electrical conductivity and density of the composites increased with carbonization by two to three times that of pristine BP. These results indicate that discontinuity and intertube contact barriers of SWCNTs in the BP are partially overcome by the carbonization process of pitch. The temperature dependence of the Raman shift shows that mechanical strain is increased since carbonized pitch matrix surrounds the nanotubes.

8:36AM A28.00004 Biscrolling nanotube sheets and functional guests into yarns , RAY BAUGHMAN, The University of Texas at Dallas/ Alan G. MacDiarmid NanoTech Institute — Multifunctional applications of textiles have been limited by the inability to spin important materials into yarns. Generically applicable methods are demonstrated for producing weavable yarns comprising up to 95 wt % of otherwise unspinnable particulate or nanofiber powders that remain highly functional. Scrolled 50 nm thick carbon nanotube sheets confine these powders in the galleries of irregular scroll sacks, whose observed complex structures are related to twist-dependent extension of Archimedean spirals, Fermat spirals, or spiral pairs into scrolls. The strength and electronic connectivity of a small weight fraction of scrolled carbon nanotube sheet enables yarn weaving, sewing, knotting, braiding, and charge collection. This technology is used to make yarns of superconductors, Li-ion battery materials, graphene ribbons, catalytic nanofibers for fuel cells, and TiO_2 for photocatalysis.

Work done in collaboration with Shaoli Fang, Xavier Lepro-Chavez, Chihye Lewis, Raquel Ovalle-Robles, Javier Carratero-Gonzalez, Elisabet Castillo-Martinez, Mikhail Kozlov, Jiyoung Oh, Neema Rawat, Carter Haines, Mohammed Haque, Vaishnavi Aare, Stephanie Stoughton, Anvar Zakhidov, and Ray Baughman, The University of Texas at Dallas / Alan G. MacDiarmid NanoTech Institute.

9:12AM A28.00005 Load transfer mechanisms in cross-linked DWNT fibers , T. FILLETER, M. NARAGHI, A. MORAVSKY, R. BERNAL, R.O. LOUTFY, H.D. ESPINOSA — The application of carbon nanotubes (CNT) to macroscopic composite fibers has been limited by weak shear interfaces between adjacent CNT shells and composite matrix elements. A fundamental understanding of load transfer at multiple length-scales is needed to identify how the exceptional mechanical properties of CNTs can be scaled to produce high-performance fibers. Through in-situ electron microscopy tensile testing we have elucidated load transfer mechanisms across multiple scales of cross-linked double-walled nanotube (DWNT) fibers. A low density of polymer cross-links is found to increase the total energy dissipated at failure and ductility of fibers by 5 and 10X, respectively, without reducing strength. This mutiscale approach has identified a need to enhance shear interactions between individual DWNTs within the hierarchical DWNT fiber structures. Through in-situ TEM electron irradiation studies we have shown that load can be effectively transferred to inner DWNTs within bundles by covalently cross-linking the interfaces of adjacent DWNTs and shells. We have observed order of magnitude increases in strength and modulus and identified their dependence on irradiation dose. In future a combined approach of irradiation induced covalent and polymer cross-linking may lead to high-performance DWNT-based fibers and composites with tunable mechanical properties.

9:24AM A28.00006 Aligned Carbon Nanotubes Embedded in Elastic Polymer as Stretchable Conductors , YINGYING ZHANG, Los Alamos National Laboratory, QUANXI JIA, CENTER FOR INTERGRATED NANOTECHNOLOGY TEAM — Stretchable electronics enable new applications in a wide range of fields. Carbon nanotube (CNT) ribbons, composed of bundles of aligned millimeter-long CNTs, represent a unique opportunity for high performance stretchable conductors. In this work, we embedded CNT ribbons in elastic poly(dimethylsiloxane) (PDMS) film (or CNT/PDMS films) and systematically investigated the dependence of film resistance on the tensile strains. The CNT/PDMS films fabricated by this approach are flexible, transparent, and show constant resistance under strains in the range of 0%-100%. We believe that the unique stretchability of CNT ribbons reported here will open new potential applications of CNTs in the next generation intelligent electronics.

9:36AM A28.00007 The Anisotropic Physical Properties of Polyethylene Oxide/Magnetic Carbon Nanotubes Composite Films , IL TAE KIM, ALLEN TANNENBAUM, RINA TANNENBAUM, Georgia Institute of Technology — Magnetic carbon nanotubes (m-CNTs) were synthesized by the tethering of γ-Fe_2O_3 nanoparticles. Subsequently, the m-CNTs were dispersed and aligned in a PEO matrix under a low externally-applied magnetic field ($<$0.3 T). The degree of crystallinity, crystal size, and crystal structure of the composite films were investigated using DSC and XRD. The electrical conductivity of the composite films showed anisotropic characteristics that were correlated to the parallel and perpendicular direction of the applied magnetic field. Young's modulus and tensile strength of the composite films increased with the increasing weight fraction of m-CNT up to 170 % and 157 %, respectively. The elongation at break of the composites improved as well compared to that of the pure-PEO film, due to the lowering of the glass transition temperature (T_g) and was also correlated to m-CNT content and the alignment directions.

9:48AM A28.00008 Changing Carbon Nanostructures by Irradiation[1] , DAVID TOMÁNEK, Michigan State University — Changes in the force field of carbon nanostructures immediately following irradiation by light and electrons may cause important structural changes. Exposure to light may modify the morphology at the apex of carbon nanohorns during Raman spectroscopy observations [1], or exfoliate graphite layer-by-layer upon exposure to specifically shaped femtosecond laser pulses [2]. Irradiation by electrons may significantly improve the structural integrity and mechanical properties of low-quality multi-wall carbon nanotubes grown by Chemical Vapor Deposition [3]. *Ab initio* molecular dynamics calculations in the electronic ground and excited state help to analyze the microscopic mechanisms underlying these structural changes including photo-activated Stone-Wales transformations, cross-linking of nanotube walls at extended defect sites, and charge redistribution causing detachment of graphene monolayers.

10:00AM A28.00009 N-type Doping of Single-walled Carbon Nanotubes: Fundamental Properties, Spectroscopic Signatures, and Transparent Conducting Electrodes , KEVIN MISTRY, BRIAN LARSEN, JEREMY BERGESON, MATTHEW REESE, TERESA BARNES, JEFFREY BLACKBURN, National Renewable Energy Laboratory — Controllable p- and n-type doping of single-walled carbon nanotube (SWNT) films enables technologies such as FETs, LEDs, and solar cells. Because many p-type dopants for SWNTs are environmentally stable, they have been studied in greater detail and used in far more applications than their less stable n-type counterparts. As a result, further studies on n-type SWNTs are needed. We report on the effectiveness of small molecule and polymer amines as n-type dopants on thin film nanotube networks. We find significant doping-induced changes in NMR, XPS, and Raman spectra that can be used in future studies to characterize n-type SWNTs. Moreover, we find that the best amines can produce n-type transparent conducting films with nearly the same sheet resistance (at a given transparency) as p-doped HNO_3 treated films. These results serve both to increase the knowledge base in the community regarding the fundamental properties and spectroscopic signatures of n-type doped SWNTs and to expand the versatility of functional SWNT network electrodes that are typically resigned to p-type SWNTs.

10:12AM A28.00010 From ^{3}He to Xe: adsorption isotherms on the same batch of BuckyPearls^{TM} carbon nanotube bundles[1] , OSCAR VILCHES, EVAN MATTSON, KRISTINE KIM, DAVID COBDEN, University of Washington — We report a study of the adsorption of ^{3}He, ^{4}He, H_2, HD, D_2, Ne, Ar, N_2, Kr and Xe adsorbed on samples of BuckyPearls^{TM}, a form of HiPCo-type^{TM} carbon nanotube bundles, from the same batch used for neutron diffraction studies of the structure of ^{4}He and Ne at low temperatures. For each gas, except ^{3}He and ^{4}He, we have measured three or more isotherms in a range of temperatures where we can observe the completion of both the three-line phase and the first layer. We can correlate the helium and hydrogen isotopes data and the Ne data with previous neutron and/or heat capacity measurements on BuckyPearls and HiPCo bundles. By taking ratios of monolayer completion coverage for the various gases to the N_2 monolayer completion coverage we can compare nanotube adsorption to adsorption on exfoliated graphite. Quantum effects on adsorption can be seen by comparing areas per atom or molecule to Lennard-Jones hard core radii.

10:24AM A28.00011 Comparative study of small alkane and alkene molecules adsorbed on purified HiPco Single-walled carbon nanotubes[1] , DINESH RAWAT, TOYO FURUHASHI, ALDO MIGONE, Department of Physics, Southern Illinois University, Carbondale, IL-62901 — We have measured adsorption isotherms for ethylene on purified HiPco SWNTs at 11 different temperatures (between 110 and 220K). Our findings for ethylene will be compared to the results of ethane adsorption on the same substrate. Consistent with what we had found for ethane, two groups of distinct binding energy sites are observed for ethylene molecules adsorbed on the nanotube substrate. However, unlike in the case of ethane, no feature suggesting the existence of a phase transition was observed for the ethylene films. In addition, we have determined the coverage dependence of the isosteric heat of adsorption for ethylene on the same substrate. The values of the isosteric heats that we had previously determined for ethane are slightly higher than the ones obtained for ethylene, for the same fractional coverage. Our experimental isosteric heat results will also be compared with simulation results that indicate a similar trend.

10:36AM A28.00012 Studying of kinetics of rear earth ion (REI) nanoscale complex formation by resonant energy transfer , TETYANA IGNATOVA, Department of Physics, Lehigh University, Bethlehem, PA 18015, DENIS PRISTINSKI, Polymers Division of National Institute of Standards and Technology, Gaithersburg, MD 20899, SLAVA V. ROTKIN, (1) Department of Physics and (2) Center for Advanced Materials and Nanotechnologies, Lehigh University, Bethlehem, PA 18015 — We observed formation of nanoscale complexes between multivalent REIs (Tb and Eu) and negatively charged DNA wrapped SWNTs, ionized in the water solution. Foerster Resonance Energy Transfer (FRET) was found to be an ideal method to confirm the complex formation. Because of its high sensitivity and non-destructive characterization approach FRET can be used to trace the kinetics of the complex formation. Strong dependence of SWNT photoluminescence (PL) on the REI concentration was detected and interpreted as a competition between the REI absorption on the SWNTs and subsequent FRET enhanced PL and the SWNT agglomeration followed by PL quenching. We measured the distance between REI and SWNT which appears to be much shorter than the one from their relative concentration in solution. We speculate that Manning condensation of the REIs on the SWNT/DNA surface happens thereby significantly reducing their spacing and making FRET possible.

10:48AM A28.00013 Attachment of a Genetically Engineered Antibody to a Carbon Nanotube Transistor for Detection of Prostate Cancer Biomarkers , MITCHELL LERNER, JENNIFER DAILEY, BRETT GOLDSMITH, University of Pennsylvania Department of Physics and Astronomy, MATTHEW ROBINSON, Fox Chase Cancer Center, A.T. CHARLIE JOHNSON, University of Pennsylvania Department of Physics and Astronomy — We have developed a novel detection method for osteopontin (OPN) by attaching an engineered single chain variable fragment (scFv) protein with high binding affinity for OPN to a carbon nanotube transistor. Osteopontin is a potential new biomarker for prostate cancer; its presence in humans is already associated with several forms of cancer, arthritis, osteoporosis and stress. Prostate cancer is the most commonly diagnosed cancer and second leading cause of cancer deaths among American men and as such represents a major public health issue. Detection of early-stage cancer often results in successful treatment, with long term disease-free survival in 60-90% of patients. Electronic transport measurements are used to detect the presence of OPN in solution at clinically relevant concentrations.

Session A29 GQI: Quantum Communication, Theoretical Entanglement, and Cryptography

8:00AM A29.00001 Intrinsic Quantum Correlations of Weak Coherent States for Quantum Communication , YONG MENG SUA, ERIN SCANLON, TRAVIS BEAULIEU, VIKTOR BOLLEN, KIM FOOK LEE, Michigan Technological University — Intrinsic quantum correlations of weak coherent states are observed between two parties, which can be used as a supplement to the existence decoy-state BB84 and differential phase-shift quantum key distribution protocols. In a proof-of-principle experiment, we generate bi-partite correlations of weak coherent states using weak local oscillator fields in two spatially separated balanced homodyne detections. We employ non-linearity of post-measurement method to obtain the bi-partite correlations from two single-field interferences at individual homodyne measurement. This scheme is then used to demonstrate bits correlations in a transmission fiber over a distance of 10 km. We believe that the scheme can add another physical layer of security to these protocols for quantum key distribution and implement linear optics quantum computing with weak coherent states.

8:12AM A29.00002 Achieving the physical limits of the bounded-storage model , PRABHA MANDAYAM, Caltech, STEPHANIE WEHNER, Centre for Quantum Technologies — The security of most cryptographic systems in use today is based on the premise that certain computational problems are hard to solve for the adversary. However, recent cryptographic models such as the bounded-storage model and the noisy-storage model, are based on more physical assumptions regarding the two parties' resources and allow us to obtain security without relying on any additional hardness results. In the bounded-storage model, where the adversary's quantum storage is limited, it is known that security can be achieved if the adversary can store strictly less then half of the qubits transmitted during the protocol. It has been an open question whether security can still be achieved if the adversary's storage were any larger. Here, we answer this question positively and demonstrate a two-party protocol which is secure as long as the adversary cannot store even a small fraction of the transmitted pulses. This not only settles the question, but also highlights the sharp contrast to classical bounded storage, where it is known that security can only be obtained if the adversary's classical storage is at most quadratic in the storage required by the honest players. In the more general setting of the noisy-storage model, where the adversary's memory is simply assumed to be imperfect, we show that our protocol extends security to a larger class of noisy quantum memories. (Reference: arXiV - quant-ph 1009.1596)

8:24AM A29.00003 High-speed single-photon signaling for daytime QKD , JOSHUA BIENFANG, ALESSANDRO RESTELLI, CHARLES CLARK, NIST/JQI — The distribution of quantum-generated cryptographic key at high throughputs can be critically limited by the performance of the systems' single-photon detectors. While noise and afterpulsing are considerations for all single-photon QKD systems, high-transmission rate systems also have critical detector timing-resolution and recovery time requirements. We present experimental results exploiting the high timing resolution and count-rate stability of modified single-photon avalanche diodes (SPADs) in our GHz QKD system operating over a 1.5 km free-space link that demonstrate the ability to apply extremely short temporal gates, enabling daytime free-space QKD with a 4% QBER.[1] We also discuss recent advances in gating techniques for InGaAs SPADs that are suitable for high-speed fiber-based QKD. We present afterpulse-probability measurements that demonstrate the ability to support single-photon count rates above 100 MHz with low afterpulse probability. These results will benefit the design and characterization of free-space and fiber QKD systems.

[1]A. Restelli, J.C. Bienfang A. Mink, and C.W. Clark, *IEEE J. Sel. Topics in Quant. Electron* **16**, 1084 (2010).

8:36AM A29.00004 Security Proof for QKD Using Qudits and Finite Key Length Analysis of Protocols , LANA SHERIDAN, THINH LE, Centre for Quantum Technologies, National University of Singapore, VALERIO SCARANI, Department of Physics and Centre for Quantum Technologies, National University of Singapore — It is advantageous to use d-dimensional quantum systems for QKD because each signal carries $\log d > 1$ bits, allowing a larger amount of information to be sent per transmission through the channel, and moreover, studies have indicated that the resistance to noise of the protocols increases when the dimension is increased. We provide a security bound against coherent attacks that takes into account finite-key effects for two families of protocols: two-basis protocols, the natural generalization of the Bennett-Brassard 1984 protocol for qubits, and $(d+1)$-basis protocols, the generalization of the six-state protocol for qubits. In the asymptotic limit, our bound vindicates the previous partial results concerning the higher resistance to noise. We also show that for finite key lengths the key rate corrections vary little with d for $2 \leq d \leq 20$ indicating the protocol can be effective in realistic conditions. Finally, we consider some other finite key techniques for more general protocols.

8:48AM A29.00005 Quantum Spread Spectrum Communication , TRAVIS HUMBLE, Oak Ridge National Laboratory — Spread spectrum techniques are widely used in classical contexts, including sensing and communication, for establishing low probability of intercept, resistance to narrowband jamming, and multiuser access protocols. In SS, the spectrum of the signal is spread much larger than the minimal information bandwidth to yield a boost in channel capacity. In this contribution, we apply SS modulation to the transmission and detection of the single-photon spectral probability amplitude (as opposed to SS of the field). We draw upon previous methods for coherently dilating single-photon spectral states to motivate our ideas. Techniques for direct modulation of the spectral amplitude, modulation via pumped single-photon up-conversion, and modulation via spread spectral teleportation are developed as particular modulation schemes for quantum spread spectrum communication. We quantify QSSC performance using the channel capacity and process gain expressed in terms of the spread bandwidth, and we investigate its behavior for a frequency-selective fading model. We conclude by discussing the potential for QSSC to underlie a QKD multiuser access control (MAC) protocol.

9:00AM A29.00006 Remote Semi-State Preparation as SuperDense Quantum Teleportation[1] , HERBERT J. BERNSTEIN, ISIS Institute & School NS, Hampshire College — Recent advances in experimental technique make SuperDense Teleportation (SDT) possible. The effect uses remote state preparation to send more state-specifying parameters per bit than ordinary quantum teleportation (QT) can transmit. SDT uses a maximal entanglement to teleport the relative phases of an **n**-dimensional equimodular state. This means that one can send only **n**-1 of the total (2**n**-2) parameters – comprising the relative phases and amplitudes – of a general state. Nevertheless, for **n**$\geq$ 3, SDT sends more of these state-specifying parameters than QT for a given number of classical bits. In the limit of large **n** the ratio is 2 to 1, hence the nomenclature Bennett suggested, SDT, by analogy with Super Dense Coding. Alice's measurements and Bob's transformations are simpler than in QT. The roles of Charles the state chooser, and Diana who deploys it, are different than in QT. I briefly review possible experimental realizations, including two that are under consideration at the present time by an experimental group leading in higher-dimension entanglement work.

[1]Supported in part by NSF grants PHY97-22614 & 07-58149 & KITP, UCSB, including an ITP Scholar-ship.

9:12AM A29.00007 Entanglment assisted zero-error codes , WILLIAM MATTHEWS, LAURA MANCINSKA, DEBBIE LEUNG, MARIS OZOLS, AIDAN ROY, University of Waterloo — Zero-error information theory studies the transmission of data over noisy communication channels with strictly zero error probability. For classical channels and data, much of the theory can be studied in terms of combinatorial graph properties and is a source of hard open problems in that domain. In recent work, we investigated how entanglement between sender and receiver can be used in this task. We found that entanglement-assisted zero-error codes (which are still naturally studied in terms of graphs) sometimes offer an increased bit rate of zero-error communication even in the large block length limit. The assisted codes that we have constructed are closely related to Kochen-Specker proofs of non-contextuality as studied in the context of foundational physics, and our results on asymptotic rates of assisted zero-error communication yield non-contextuality proofs which are particularly 'strong' in a certain quantitive sense. I will also describe formal connections to the multi-prover games known as pseudo-telepathy games.

9:24AM A29.00008 Extreme Spin Squeezing Beyond Spin-1/2 Ensembles , COLLIN TRAIL, LEIGH NORRIS, IVAN DEUTSCH, University of New Mexico — We consider a protocol for squeezing the collective spin of a cold atomic ensemble through coherent control of the spin and light-polarization interactions. By retro-reflecting a short pulse of light through the ensemble followed by a quantum eraser and phase matching, we achieve exponential scaling of the squeezing with optical density. We show how these results can be extended using state preparation and mapping techniques for s¿1/2 systems, and extend our model of photon-atom scattering to account for decoherence in the higher dimensional case.

9:36AM A29.00009 Engineered optical nonlinearity for a quantum light source , AGATA BRANCZYK, ALESSANDRO FEDRIZZI, TOM STACE, TIM RALPH, ANDREW WHITE, The University of Queensland — Many applications in optical quantum information processing benefit from careful spectral shaping of single-photon wave-packets. By engineering the nonlinearity profile of a poled crystal, we were able to tailor the joint spectral wave-function of photons created in parametric down-conversion. We designed a crystal with an approximately Gaussian nonlinearity profile and confirmed successful wave-packet shaping by two-photon interference experiments. To further explore the underlying spectral correlations in the spectral amplitude, we also measured spatial quantum beating patterns. We numerically show how our method can be applied for attaining one of the currently most important goals of single-photon quantum optics, the creation of pure single photons without spectral correlations.

9:48AM A29.00010 Disappearance of entanglement: a topological point of view[1] , DONG ZHOU, ROBERT JOYNT, GIA-WEI CHERN, JIANJIA FEI, University of Wisconsin-Madison — We give a topological classification of the evolution of entanglement, particularly the different ways the entanglement can disappear. Four categories exhaust all possibilities given the initial quantum state is entangled and the final one is not. Exponential decay of entanglement, entanglement sudden death and sudden birth can all be understood and visualized in the associated geometrical picture - the polarization vector representation. The entanglement evolution categories of any model are determined by the topology of the state space, the limiting state and the memory effect of the environment. Transitions between these types of behaviors as a function of physical parameters are also possible. These transitions are thus of topological nature. We illustrate the general concepts with a visualizable model.

10:00AM A29.00011 Optimal Entanglement Transformations Among N-qubit W-Class States[1] , WEI CUI, ERIC CHITAMBAR, HOI-KWONG LO, University of Toronto — We investigate the physically allowed probabilities for transforming one N-partite W-class state to another by means of local operations assisted with classical communication (LOCC). Recently, Kintaş and Turgut have obtained an upper bound for the maximum probability of transforming two such states [1]. Here, we provide a simple sufficient and necessary condition for when this upper bound can be satisfied and thus when optimality of state transformation can be achieved. Our discussion involves obtaining lower bounds for the transformation of arbitrary W-class states and showing precisely when this bound saturates the bound of [1]. Finally, we consider the question of transforming symmetric W-class states and find that in general, the optimal one-shot procedure for converting two symmetric states requires a non-symmetric filter by all the parties.

[1]We thank Benjamin Fortescue for helpful discussions in the development of this work as well as support from the funding agencies CIFAR, CRC, NSERC, and QuantumWorks.

10:12AM A29.00012 Negativity Fonts in Four qubit Maximally Entangled States[1] , SANTOSH SHELLY SHARMA, Depto. de Física, Universidade Estadual de Londrina, Londrina 86051-990, PR Brazil, NARESH KUMAR SHARMA, Depto. de Matemática, Universidade Estadual de Londrina, Londrina 86051-990 PR, Brazil — Recently, we introduced negativity fonts as the basic units of multipartite entanglement in pure states. We show that the relation between global negativity of partial transpose of N- qubit state and linear entropy of reduced single qubit state yields an expression for global negativity in terms of determinants of negativity fonts. Transformation equations for determinants of negativity fonts under local unitaries (LU's) are used to construct N-qubit LU invariant and N-tangle (an entanglement monotone). The difference of squared negativity and N-tangle is an N qubit invariant which contains information on entanglement of the state caused by quantum coherences that are not annihilated by removing a single qubit. Entanglement monotones that detect the entanglement of specific parts of a four qubit state are also constructed. It is shown that these entanglement monotones bring out distinct features of several states which have been proposed to be the maximally entangled four qubit states.

10:24AM A29.00013 ABSTRACT WITHDRAWN —

10:36AM A29.00014 Density matrix renormalization group study of the Kitaev honeycomb lattice model , ZHENYUE ZHU, University of California, Irvine, STEVEN WHITE — The Kitaev model on the honeycomb lattice can be solved exactly through mapping into free majorana fermions with a Z_2 gauge field. As a benchmark for DMRG on this two dimensional system, we have simulated this model with a cylindrical geometry with varying widths. The ground state energy and degeneracy match well with theoretical predictions. The different degenerate ground states exhibit the same short range spin-spin correlation patterns. The von Newmann entanglement entropy and its spectrum are evaluated. We show that the entropy of the Kitaev model satisfies the area law, with the entropy being more specifically proportional to the number of bonds cut at the boundary between the two different regions. The degeneracy of entanglement spectrum can also be determined by the number of dangling majorana fermions at the cut. The above results hold for both the gapped and gapless phase. The non-Abelian phase obtained by applying a magnetic field, which is not exactly solvable, will also be discussed.

10:48AM A29.00015 Towards entanglement of very high orbital angular momentum[1] , ROBERT FICKLER, RADEK LAPKIEWICZ, CHRISTOPH SCHAEFF, PEIZHE LI, SVEN RAMELOW, MARCIN WIESNIAK, ANTON ZEILINGER, University of Vienna, Faculty of Physics, IQOQI Vienna, Austrian Academy of Sciences, Austria — Orbital angular momentum (OAM) of single photons has become an often used tool to realize entanglement in higher dimensions [1,2]. Laguerre-Gaussian modes of light with their helical phase structure carry photonic OAM and thus can be used to define an infinitely dimensional discrete Hilbert. However, the creation of photonic OAM entanglement using the well known spontaneous parametric downconversion process is limited by the strongly reduced efficiency for higher momenta [3]. We investigate novel methods to create this entanglement between two photons with a very high difference in their OAM quantum number and momentum respectively. Furthermore we explore hybrid entanglement of photons in these spatial modes and polarization degree of freedom.

Monday, March 21, 2011 8:00AM - 11:00AM –
Session A30 DCMP: Graphene: Growth, Properties and Devices C147/154

8:00AM A30.00001 The effects of copper substrate structure and impurities on the quality of graphene growth , CARL W. MAGNUSON, SHANSHAN CHEN, Univ. of Texas at Austin, LUIGI COLOMBO, Texas Instruments, RICHARD D. PINER, RODNEY S. RUOFF, Univ. of Texas at Austin — Since we discovered growth of mono-layer graphene on Cu substrates, most researchers use the same 99.8% pure foil from Afla-Aesar as sited in our original publication. We have investigated several other copper substrates for their suitability for graphene growth. We find that the purity and thickness of the copper foil have measureable effects on the quality of the graphene and growth parameters needed to obtain large mono-layer coverage. We will present our findings and summarize the effects that we have seen. Our methods for determining graphene quality include SEM, scanning micro-Raman, and AFM.

8:12AM A30.00002 Graphene Films Grown on Insulating Substrates[1] , SIARHEI V. SAMSONAU, College of Staten Island CUNY, Graduate Center CUNY, ANNEMARIE L. EXARHOS, MICHAEL E. TURK, JING CAI, The University of Pennsylvania, YURY DESHKO, College of Staten Island CUNY, Graduate Center CUNY, ANSHEL A. GOROKHOVSKY, College of Staten Island CUNY, JAY M. KIKKAWA, The University of Pennsylvania, ALEXANDER M. ZAITSEV, College of Staten Island CUNY — We report a method of direct CVD growth of carbon films on quartz substrates. The films are grown at temperatures from 650 to 1200 °C in a graphite container filled with methane. Films grown at 1200 °C reveal clear G and 2D Raman bands characteristic of graphene. A combination of Raman, absorption and electrical measurements allows us to conclude that carbon films grown by this method are polycrystalline graphene, large areas of which may be composed of single carbon layer. Sheet resistivity of these graphene films is low enough to make them interesting objects for electronic applications. Advantages of our synthetic approach include simplicity and the ability to deposit films on any insulating substrate, which can stand temperature of at least 650 °C. Thus far, no factors limiting the area of deposition and uniformity of the deposited graphene films have been identified.

8:24AM A30.00003 Electron Stimulated Decomposition of Acetylene as a Precursor for Graphene , MAHESH KUMAR, National Physical Laboratory, New Delhi, SARA ROTHWELL, PHILIP COHEN, University of Minnesota — We report here on the deposition of carbon via C_2H_2 dissociation by electron beam irradiation and thermal decomposition. The substrates investigated include sapphire, silicon, ALD deposited Al_2O_3/SiO_2, and GaN/sapphire. Raman analyses show that on C-plane sapphire both thermal decomposition and electron beam stimulated dissociation of C_2H_2 deposit carbon successfully. On other substrates these methods were inactive, showing the decomposition of C_2H_2 on sapphire is catalytic. We tested different annealing times and C_2H_2 pressures, gauging absorption saturation with RHEED. Samples exposed to 15 min. C_2H_2 adsorption during 400 eV electron irradiation and then annealed for 2 hr. to above 600°C in high vacuum showed the greatest proportion of sp2 to sp3 bonding by Raman analysis. The Raman spectra also suggest hydrogen adsorption, which may hinder further sp2 bonding. Annealing samples in a hydrogen atmosphere does not change their Raman spectra, suggesting hydrogen saturation. Partial support from the University of Minnesota Institute for Renewable Energy and the Environment

8:36AM A30.00004 Electrical and Raman characterizations of chemical vapor deposited (CVD) graphene grains and grain boundaries , LUIS A. JAUREGUI, HELIN CAO, Purdue University, QINGKAI YU, University of Houston, YONG P. CHEN, Purdue University — We performed Raman spectroscopy and electrical transport studies on graphene grains grown on copper foils by ambient pressure CVD. These grains are found to be hexagonally-shaped with edges macroscopically parallel to zig-zag directions as evidenced by scanning tunneling microscopy and transmission electrical microscopy. After the grains are transferred to SiO_2/Si, Raman spectroscopy and mapping are performed. The intensity of the D peak (I_D) is negligibly small over most grain area with the notable exception of a few isolated spots, attributed mostly as nucleation centers. We show Raman mapping is a convenient tool to identify grain boundaries, which show large I_D. Simultaneous measurements of both intra-grain and inter-grain electronic transport were performed on merged grains. We found the inter-grain resistivity to be always larger than the intra-grain resistivity. Low temperature inter-grain magneto-resistance (R_{xx}(B)) displays a prominent weak localization (WL) feature, which was not observable or was much weaker for intra-grain R_{xx}(B). Our observation indicates that grain boundaries are major sources of intervalley scattering and strongly affect electron transport in polycrystalline CVD graphene.

8:48AM A30.00005 Cyclotron Resonance in Graphene at Ultrahigh Magnetic Fields , L.G. BOOSHEHRI, Rice Univ., LANL, C.H. MIELKE, S.A. CROOKER, LANL, L. REN, E.H. HAROZ, Z. JIN, Z. SUN, Z. YAN, J.M. TOUR, J. KONO, Rice Univ. — To investigate the effects of intentional and unintentional doping on the conduction properties of CVD-grown large-area graphene, we have performed high-field cyclotron resonance (CR) measurements on graphene. We accessed ultrahigh magnetic fields using the Single-Turn Coil System at NHMFL-Los Alamos, which can produce peak fields over 300 T in $\sim$2.5 μs pulses. We investigated magneto-infrared transmission at 10.6 μm in pulsed ultrahigh magnetic fields up to 170 T for a variety of graphene samples on KRS-5 substrates with different levels of doping. Circularly polarized CO_2 light was used to determine the carrier type of the doping, and temperature-dependent measurements were also performed. We observed a clear CR peak at $\sim$50 T corresponding to the n = 1 to n = 2 Landau level transition, which indicates that the Fermi energy measured from the Dirac point has to be $\sim$250-400 meV.

9:00AM A30.00006 Measurement of nanomechanical properties of suspended graphene membranes , JI WON SUK, CARL W. MAGNUSON, RICHARD D. PINER, RODNEY S. RUOFF, Univ. of Texas at Austin — Since graphene was first isolated from graphite, its unique properties have been intensively investigated in various ways. Recently, a method to grow large-area, uniform monolayer graphene has been realized by chemical vapor deposition (CVD) on metal substrates. In this respect various properties of CVD-grown graphene need to be studied and compared with those measured from mechanically exfoliated graphene. In this talk we report mechanical measurement of suspended graphene membranes made by CVD on copper foils. Monolayer graphene was transferred onto through holes to make suspended graphene membranes. Bulge testing with uniform pressure was done on those membranes to extract the mechanical properties of CVD-grown monolayer graphene. Moreover, nanoindentation was performed on those suspended graphene membranes and the result is compared with that obtained by bulge testing.

9:12AM A30.00007 Thermal Conductivity of CVD grown graphene , ANTON SIDOROV, DANIEL BENJAMIN, CHRISTOPHER FOY, ZHIGANG JIANG, Georgia Institute of Tecnology, QINGKAI YU, HELIN CAO, WEI WU, ZHIHONG LIU, JIMING BAO, STEVEN PEI, University of Houston, YONG CHEN, Purdue University — When suspended, CVD grown graphene has a high thermal conductivity (k) of 2,500$\pm$1100 W/mK near 350 K. But for practical applications, graphene would be attached to a substrate. Previously it was reported that the CVD grown graphene supported on Si/SiO2 has a k value as low as 370+650/-320 W/mK in ambient. We find that the k of CVD grown graphene on glass varies in a range of 1100 - 2000 W/mK and depends on the growth parameters. The k of graphene is measured by a differential thermocouple technique and compared with that obtained by scanning thermal microscopy. Moreover, the samples grown in ambient pressure have shown higher k compared to the graphene grown at low pressure.

9:24AM A30.00008 Electrochemistry of individual monolayer graphene sheets , WAN LI, CEN TAN, MICHAEL A. LOWE, HÉCTOR D. ABRUÑA, D.C. RALPH, Cornell University — We report on the fabrication and measurement of devices designed to study the electrochemical behavior of individual monolayer graphene sheets. We have examined both mechanically exfoliated and chemical vapor deposited (CVD) graphene. The effective device areas, determined from cyclic voltammetric measurements, show good agreement with the geometric area of the graphene, indicating that the redox reactions occur on relatively clean graphene surfaces. The electron transfer rates of ferrocenemethanol at both types of graphene electrodes were found to be more than 10-fold faster than at the basal plane of bulk graphite, which we ascribe to corrugations in the graphene sheets. We also demonstrate real-time electrochemical detection of molecular desorption from graphene surfaces. Our results show that electrochemistry can provide a powerful means of investigating the kinetics of interactions between molecules and graphene.

9:36AM A30.00009 Mechanical and Electrical Properties of Polycrystalline Graphene , CARLOS RUIZ-VARGAS, AREND VAN DER ZANDE, PINSHANE HUANG, WILLIAM WHITNEY, MARK LEVENDORF, JOSHUA KEVEK, SHIVANK GARG, JONATHAN ALDEN, DAVID MULLER, PAUL MCEUEN, JIWOONG PARK, Cornell University — Graphene grown by chemical vapor deposition (CVD) has enabled large scale fabrication of graphene-based devices [1]. We apply transmission electron microscopy and AFM techniques to identify individual grain boundaries [2]. This further allows the direct investigation of mechanical and electrical properties of polycrystalline graphene in correlation with its grain structure. We used atomic force microscopy in order to induce and image tearing along individual grain boundaries and find a decreased mechanical strength in CVD graphene compared with pristine exfoliated graphene [3]. Our electrical measurements of CVD graphene devices show that charge mobility is sensitive to different growth conditions. However, we found that average grain size is not directly correlated with the charge mobility, suggesting that grain boundaries are not necessarily a dominating factor.

9:48AM A30.00010 Transparent and Flexible Large-scale Graphene-based Heater , JUNMO KANG, SKKU Advanced Institute of Nanotechnology (SAINT) and Center of Human Interface Nano Technology (HINT), Sungkyunkwan University, CHANGGU LEE, YOUNG-JIN KIM, JAE-BOONG CHOI, School of Mechanical Engineering, Sungkyunkwan University, BYUNG HEE HONG, Department of Chemistry, Sungkyunkwan University — We report the application of transparent and flexible heater with high optical transmittance and low sheet resistance using graphene films, showing outstanding thermal and electrical properties. The large-scale graphene films were grown on Cu foil by chemical vapor deposition methods, and transferred to transparent substrates by multiple stacking. The wet chemical doping process enhanced the electrical properties, showing a sheet resistance as low as 35 ohm/sq with 88.5 % transmittance. The temperature response usually depends on the dimension and the sheet resistance of the graphene-based heater. We show that a 4x4 cm^2 heater can reach 80 °C within 40 seconds and large-scale (9x9 cm^2) heater shows uniformly heating performance, which was measured using thermocouple and infra-red camera. These heaters would be very useful for defogging systems and smart windows.

10:00AM A30.00011 Large Area Chemical Vapor Deposition Graphene Photodetectors[1] , ALLEN HSU, MIT, HAN WANG, KI KANG KIM, JING KONG, TOMAS PALACIOS — We investigate large area graphene photodetectors based on graphene grown by Chemical Vapor Deposition on Cu foils and then transferred to SiO_2/Si wafers. Through scanning photocurrent microscopy (SPM) at 532 nm, we compare the performance of CVD fabricated devices using Ti/Pd/Au, Au, and Pt graphene metal junctions with those from literature fabricated through mechanical exfoliation. Our initial experiments show that photocurrent from CVD graphene is about an order of magnitude smaller than devices in literature. Non-idealities related to material properties, defects, and transfer related inhomogenities are believed to be the cause of the discrepancy. These effects are studied through concurrent registration of atomic force microscopy, optical microscopy, Raman Microscopy, and SPM. In addition to intrinsic material property effects, fabrication related issues of graphene-metal junctions are also explored.

10:12AM A30.00012 Solution-gated Field Effect Transistors based on CVD grown Graphene for chemical and bio sensing applications , BENJAMIN MAILLY GIACCHETTI, ALLEN HSU, HAN WANG, KI KANG KIM, JING KONG, TOMAS PALACIOS, MIT — Graphene holds great potential for bioelectronic applications and, more specifically, for fast high-sensitivity pH measurements and biosensing. Its monolayer structure (just one carbon atom thick) in combination with its very high carrier mobility enable very high transconductance, low noise and biocompatibility which are key parameters for chemical sensors with electronic readout. In fact, single molecule detection has already been demonstrated in graphene gas sensors. In this paper we report on the fabrication and characterization of solution-gated field effect transistors (SGFET) arrays based on CVD grown graphene films on copper that can operate in various liquid environments. These devices exhibit transconductances around 20 μSiemens, which highlights their excellent sensitivity. We also performed some pH sensing experiments and demonstrated that the transfer characteristics of the GFET are pH dependent with a pH sensitivity of 14 mV/pH. These results drive the way for chemical and bio-sensing by functionalized graphene, which is the aim of our future work.

10:24AM A30.00013 PECVD silicon nitride gate dielectrics and band-gap engineering in graphene devices , WENJUAN ZHU, DEBORAH NEUMAYER, VASILI PEREBEINOS, PHAEDON AVOURIS, IBM - T.J. Watson Research Center — We found that silicon nitride can provide excellent coverage of graphene in field-effect transistors while preserving its good carrier mobilities, without the need of a seed layer. Moreover, the silicon nitride film has the advantage of higher dielectric constant and higher surface polar optical phonon energy (i.e. less remote phonon scattering in the graphene channel) compared to silicon oxide. The breakdown strength in silicon nitride is high as well. The effect of a perpendicular electric field on the band-structure of different numbers of graphene layers used as channels of the transistor was also studied and the induced band-gap or band-overlap was obtained accounting for the effects of the variation of the surface potential near the Dirac/neutrality point.

10:36AM A30.00014 Graphene: Atomically thin protective coating , DHIRAJ PRASAI, KIRILL BOLOTIN, Department of Physics and Astronomy, Vanderbilt University, JUAN TUBERQUIA, ROBERT HARL, KANE JENNINGS, Chemical and Biomolecular Engineering, Vanderbilt University — We explore the properties of graphene as a cathodic coating to protect copper substrates from oxidation and further corrosion. High-quality and large area graphene films are grown on copper substrates by chemical vapor deposition. Samples were thermally oxidized in an oxygen-rich environment. X-ray photoelectron spectroscopy (XPS) characterization of a Graphene/copper and bare copper samples reveals the absence of oxidized copper at the graphene/copper interface indicating that the graphene monolayer protects the underlying copper. We also determine the protective properties of graphene in aqueous media using electrochemical characterization techniques. First, we use Electrochemical Impedance Spectroscopy (EIS) to show that graphene coated substrates lower frequencies (1Hz) exhibit impedance values 2 orders of magnitude higher compared to bare Cu substrates. Cyclic voltammetry also shows that a monolayer of graphene significantly reduces the oxygen reduction, thus exhibiting little charge transfer at the solid-liquid interface. Finally, we use Tafel analysis to estimate that the corrosion rate exhibited by Graphene/Cu is ~ 7 times lower than that of bare Cu substrates.

10:48AM A30.00015 Ordered carbon nanotube growth on graphene and few-layer graphene , D. PATRICK HUNLEY, STEPHEN JOHNSON, JOSEPH STIEHA, ABHISHEK SUNDARARAJAN, AARON MEACHAM, DOUGLAS STRACHAN, University of Kentucky — Carbon nanotubes are grown on graphene and few-layer graphene films through chemical vapor deposition. The nanotube growth is found to depend on the thickness of the few-layer graphene films. The thinnest films show significant alignment of the nanotubes with the crystallographic axes of the graphene. This alignment is compared to the orientation of the crystallographic etch tracks, permitting the orientation of the nanotubes to be determined. Related nanotube/graphene structures will also be presented and discussed. Supported in part by NSF Award No. DMR-0805136, the Kentucky NSF EPSCoR program, the University of Kentucky Center for Advanced Materials, and the University of Kentucky Center for Nanoscale Science and Engineering.

Monday, March 21, 2011 8:00AM - 11:00AM –

Session A31 DMP: Focus Session: van der Waals Bonding in Advanced Materials: Fundamentals and Simple Systems C145

8:00AM A31.00001 Cohesive Properties of Graphitics and the Random Phase Approximation[1] , JOHN DOBSON, Micro and Nano Technology Centre, Griffith University, Australia — The van der Waals-dominated cohesive energetics of graphitic systems is important in the assembly of many graphene-based nanostructures of current technological interest. In 2006 an unusual power law E = - cD^{-3} was predicted [1] for the van der Waals (vdW, dispersion) interaction energy between parallel graphene sheets at large separations D. By contrast, a conventional sum of pairwise R^{-6} contributions yields E = .- kD^{-4}. The unexpected D^{-3} result came from the electronic correlation energy within the Random Phase Approximation (RPA), which can be solved analytically in the distant regime D .→ .∞. In keeping with other unusual properties of graphene, in this distant non-overlapping regime the relevant response function of a graphene sheet is dominated by the gapless electronic transitions near the Dirac points in the Brillouin Zone where the .π_z and .π_z Bloch bands touch. The D·$^{-3}$ result corresponds to a severe failure of pairwise additivity of the vdW interaction between local spatial regions of the sheets, and so could have implications for the most-used nanoscale energy functionals (e.g. [2,3]); these embody pairwise additivity at various levels. It has remained unclear what this result might imply for the interaction between graphene sheets at smaller spacings near to the equilibrium separation, where the response is sampled at shorter wavelengths so that analytic results cannot be obtained. Very recently, numerically well-converged exact-exchange and RPA correlation energies have been obtained for stretched graphite at a wide range of inter-layer spacings down to the equilibrium distance. These results and their implications will be discussed.

[1]Support is acknowledged from FAST, Egide and the Australian Research Council.

8:36AM A31.00002 Self-consistent calculations of correlation energies within the random phase approximation[1] , STEFANO DE GIRONCOLI, NGOC LINH NGUYEN, SISSA and CNR-IOM DEMOCRITOS,Trieste, Italy, VIET HUY NGUYEN, GIULIA GALLI, University of California, Davis, USA — Calculations of correlation energies within the the formally exact Adiabatic Connection Fluctuation-Dissipation (ACFD) formalism, within the Random Phase Approximation (RPA) for the exchange-correlation kernel, have been recently carried out for a number of isolated and condensed systems. The efficiency of such calculations has been greatly improved by exploiting iterative algorithms to diagonalize RPA dielectric matrices [1]. Unfortunately, for several systems, it has been found that RPA correlation energies may significantly depend about the choice of input single particle wavefunctions [2]. In this work, we derive an expression of the RPA self-consistent potential based on Density Functional Perturbation theory and we present self-consistent RPA calculations for weakly bound molecular dimers, including the controversial case of the Beryllium dimer.

8:48AM A31.00003 Beyond RPA correlation energies: Evaluation of model exchange-correlation kernels , DEYU LU, Center for Functional Nanomaterials, Brookhaven National Laboratory, GIULIA GALLI, Department of Chemistry and Department of Physics, University of California, Davis — The description of van der Waals dispersion interactions using the so called EXX/RPA method has recently attracted a widespread interest. Overall, equilibrium distances and cohesive energies of weakly bound molecular systems exhibit a significant improvement over the the results of semi-local Density Functional Theory calculations [1,2], due to the proper inclusion of long-range correlation effects. However, cohesive energies still result to be underestimated with respect to experiments in several cases. This is mainly due to the neglect of the exchange-correlation kernel in evaluating response functions entering the correlation energy expression. In this work, we study the effect of several model exchange-correlation kernels and evaluate their performance for molecular systems.

[2] Y. Li, D. Lu, H-V Nguyen and G. Galli, J. Phys. Chem. A, 114, 1944-1952 (2010) and D. Lu, H-V Nguyen, and G. Galli, J. Chem. Phys. 133, 154110 (2010)

9:00AM A31.00004 Van der Waals interactions in complex materials: Beyond the pairwise approximation , ALEXANDRE TKATCHENKO, Fritz-Haber-Institut der MPG, ROBERT A. DISTASIO, JR., ROBERTO CAR, Princeton University, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG — Despite the well-known fact that van der Waals (vdW) interactions are many-body in nature and the polarizability is a non-local function, popular vdW-DF [1] and DFT+vdW [2] methods are based on (semi)-local approximations for the polarizability and only model the pairwise part of vdW interactions. Here we show how to go beyond the pairwise (semi)-local approximation to vdW interactions by coupling the recently developed TS scheme [2] with the Fluctuating-Coupled-Dipole Model (CFDM) [3]. The TS scheme provides parameter-free input atomic polarizability distributions and the CFDM allows to model both polarizing and depolarizing local fields, and captures the many-body nature of vdW interactions. Results are presented for small and medium-size molecules, as well as solids. We find that the many-body screening plays a major role in modifying the polarizability of large systems. Our results for vdW coefficients in semiconductor clusters and solids are in excellent agreement with TDDFT calculations. [1] M. Dion *et al.*, Phys. Rev. Lett., **92**, 246401 (2004); [2] A. Tkatchenko and M. Scheffler, Phys. Rev. Lett., **102**, 073005 (2009); [3] M. W. Cole *et al.*, Mol. Simul. **35**, 849 (2009).

9:12AM A31.00005 Van der Waals materials: what is the origin of the disagreement between ab initio calculations and experiments? , LOREDANA VALENZANO, WARREN PERGER, JACKSON CRISWELL, WILLIAM SLOUGH, Michigan Tech Univ — The robust prediction of accurate physical properties for molecular solids from first-principles calculations continues to present a significant challenge across a wide variety of scientific disciplines. Comparison between computed and experimental values for physical properties derived from differences between states is often promising (such as bulk modulus), however the result is disappointing for absolute values (such as density). Accurate ab initio calculations describe physics occurring at zero Kelvin; but, properties evaluated experimentally are mostly reported at room temperature. Therefore it should hardly be surprising that ab initio results differ dramatically from experimentally measured values. We show how the results from a calculation at zero Kelvin may be compared to experimental values at higher temperatures, helping to foster a stronger linkage between computational and experimental work on systems such as energetic and pharmaceutical materials and metal-organic frameworks in interaction with guest molecules. Among others, investigated behavior comprises mechanical (elastic constants) and vibrational (infrared and Raman spectra) properties. The computational approach adopted, takes into account van der Waals long-range dispersion interaction through an empirical "a posteriori" approach, appropriately fitted to investigate solid materials.

9:24AM A31.00006 Van der Waals interactions in semiconductor solids , GUO-XU ZHANG, ALEXANDRE TKATCHENKO, JOACHIM PAIER, HEIKO APPEL, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der Max-Planck-Gesellschaft — The binding in semiconductor solids arises mainly from the covalent hybridization of atomic orbitals. Hence, it is typically assumed that van der Waals (vdW) interactions play a minor role for their cohesion. In order to probe this conventional wisdom we develop a method to calculate accurate long-range vdW coefficients for ions and atoms in crystals. We first assess the validity of the Clausius-Mossotti relation between the polarizability and dielectric function for bulk semiconductors by comparing periodic TDDFT calculations to direct extrapolation of the frequency-dependent TDDFT polarizability for finite clusters. We find a good agreement between these two approaches for computing vdW $C_6(V)$ coefficients for a broad variation in the unit cell volume V for diamond, Si, and Ge crystals. When using TDDFT@HSE with the Nanoquanta kernel, the volume-dependent dielectric constant of Si and Ge is in excellent agreement with experimental data. The crystal-field screening reduces the vdW coefficients by a factor of two compared to corresponding free-atom and effective hybridized $C_6[n(r)]$ values [1]. The use of accurate $C_6(V)$ coefficients in the PBE+vdW method [1] improves cohesive properties of Si and Ge in comparison to experimental data. [1] A. Tkatchenko and M. Scheffler, Phys. Rev. Lett. **102**, 073005 (2009).

9:36AM A31.00007 Van der Waals density functionals applied to solids , JIRI KLIMES, London Centre for Nanotechnology, University College London, DAVID BOWLER, London Centre for Nanotechnology and Department of Physics and Astronomy, University College London, ANGELOS MICHAELIDES, London Centre for Nanotechnology, University College London — Dispersion interactions are ubiquitous in nature and contribute to the binding in biomolecules or to the adsorption of molecules on surfaces. However, due to their non-local nature they are difficult to describe accurately with electronic structure methods. It is now well established that standard density functional theory functionals give misleading results for systems where dispersion is important. The van der Waals density functional (vdW-DF) of Dion et al. [Dion et al., Phys. Rev. Lett. 92, 246401 (2004)] is one of several promising approaches for accounting for dispersion. We have shown that with an improved treatment of the exchange part it can offer much better than chemical accuracy for a range of weakly interacting molecular systems [Klimeš et al., J. Phys.: Cond. Matt. 22, 022201 (2010)]. Here we extend this work beyond the weakly bonded regime and report results for lattice constants of solids (metals, semiconductors, ionic solids) and geometries and atomization energies of molecules. This extensive and rigorous test of vdW-DF shows how to a large extent such properties are dependent on its underlying exchange functional. We use this new insight to discuss prospects for further improvement of the method.

9:48AM A31.00008 Application of van der Waals Density Functionals to Extended Systems[1] , KYUHO LEE, DAVID C. LANGRETH, Rutgers University — Recently we proposed[2] a second version of a van der Waals density functional[3] and showed its accuracy for small molecular duplexes as well as a few extended systems. As further applications to extended systems, we present results for molecular adsorptions on surfaces, molecular crystals, and organic ferroelectrics. A comparison with experiments is also given for different functionals.

10:00AM A31.00009 An Efficient Real-Space Implementation of the van der Waals Energy and Analytical Forces in Plane-Wave Ab Initio Molecular Dynamics , ROBERT DISTASIO, ZHAOFENG LI, ULRICH ASCHAUER, Princeton University, XIFAN WU, Temple University, ROBERTO CAR, Princeton University — In this work, we present an efficient algorithmic implementation of the energy and analytical forces of the recent density functional based van der Waals (vdW) correction proposed by Tkatchenko and Scheffler (PRL 102, 073005 (2009)) within the framework of plane-wave based ab initio molecular dynamics. The algorithm presented herein is a highly parallelizable, order (N) formulation that allows for accurate treatment of large molecular systems with a computational cost that is negligible with respect to the underlying evaluation of the exchange-correlation functional. The computational resources and performance of our algorithm, which utilizes a real-space implementation of the molecular pro-density, will be analyzed and compared against a reciprocal-space formulation of the Hirshfeld volume based on a spherical wave expansion of the underlying plane-wave basis. The effects of this vdW correction are demonstrated within the context of the oxygen-oxygen and oxygen-hydrogen radial distribution functions obtained via highly accurate PBE0-based liquid water simulations.

10:12AM A31.00010 Comparison of methods for inclusion of van der Waals interactions: the case of physisorption of nucleobases on graphene[1] , DUY LE, ABDELKADER KARA, TALAT S. RAHMAN, University of Central Florida — The physisorption of the nucleobases adenine (A), cytosine (C), guanine (G), thymine (T), and uracil (U) on graphene is studied using many flavors of density functional theory (DFT): the generalized gradient approximation (GGA) with the inclusion of van der Waals (vdW) interaction based on the TS approach [A. Tkatchenko and M. Scheffler, *PRL* **102**, 073005 (2009)], our simplified version of this approach, the vdW density functional (vdW-DF) [M. Dion *et al.*, *PRL* **92**, 246401 (2004)], and the vdW-DF2 [K. Lee *et al.*, *PRB* **82**, 081101 (2010)] methods. The binding energies of nucleobases on graphene lie in the range of 496962 meV and are found to be in the following order G>A>T>C>U within vdW-DF, vdW-DF2 and our method and G>A>T∼C>U in the TS approach. The binding separations lie between 3.293.53 Å and are found to be about 0.1 0.2 Å shorter in DFT-D, as compared to vdW-DF approaches. We comment on the efficiency of combining the DFT-D and vdW-DF methods to study vdW interactions in molecular adsorption.

[1]Work supported by DOE Grant No. DE-FG02-07ER15842.

10:24AM A31.00011 Spinodal de-wetting of thin films in the presence of oscillatory Casimir forces

, LEONARDO GOLUBOVIC, ADI CONSTANTINESCU, West Virginia University — Long range de-wetting forces, e.g., van der Waals interactions, may drive the formation of large clusters in thin films of polymeric materials, and in liquid and solid metals films. We elucidate film de-wetting in the presence of spatially oscillatory Casimir forces, such as the fermionic Casimir forces mediated by conducting electrons in metal films. What happens with interfaces of a liquid metal film in the presence of the spatially oscillating forces? Is the film going to exhibit spinodal de-wetting instability yielding the formation of clusters ? We find that, at low temperatures, the film interface pins to the minima of the oscillatory Casimir force potential. This suppresses the spinodal de-wetting. However, at elevated temperatures, the interface efficiently hops between the minima of the oscillatory potential, and the film quickly de-wets and structures into clusters. The spinodal de-wetting is governed by an effective non-oscillatory de-wetting potential that entropically emerges from a coarse-graining of the oscillatory Casimir force potential.

10:36AM A31.00012 Dynamic Precision Measurement of the Casimir Force Using Gold Surface

, CHIA-CHENG CHANG, UC Riverside Physics Dept., UMAR MOHIDEEN — High precision dynamic Casimir force measurements between a gold coated sphere and plate are performed in UHV with short coherence length light source interferometer will be presented. A comparison to the theory using generalized Plasma and Drude model at room temperature will be discussed.

10:48AM A31.00013 Inelastic Helium Atom Scattering from the Commensurate Monolayer Solid H_2/NaCl(001)

, L.W. BRUCH, Department of Physics, University of Wisconsin-Madison, F.Y. HANSEN, Department of Chemistry, Technical University of Denmark — A calculation of inelastic low energy helium atomic scattering by a monolayer with one-phonon creation[1] is reported for the dilated quantum monolayer solid H_2/NaCl(001). The shear horizontal phonon mode again is accessed for small misalignment of the scattering plane relative to the monolayer axes. Qualitative agreement for the systematic trends in the inelastic scattering experiments[2] is achieved. Two monolayer phonon branches are identified. The role of the Debye-Waller attenuation in diffraction intensities is discussed.

8:00AM A32.00001 Ultra-low Damping of Surface Plasmon Polaritons in Atomically Smooth Epitaxial Ag Films: An Extraordinary Optical Transmission Study

, CHARLOTTE E. SANDERS, UT Austin, B.H. LI, Chinese Academy of Sciences, Institute of Physics, Beijing, JAMES MCILHARGEY, S. HOSSEIN MOUSAVI, ALEXANDER B. KHANIKAEV, UT Austin, X.G. QIU, Chinese Academy of Sciences, Institute of Physics, Beijing, GENNADY SHVETS, C.K. SHIH, UT Austin — When an electro-magnetic radiation field couples strongly to surface plasmons, a surface plasmon polariton (SPP) is formed. In recent years, studies of SPPs in metal films perforated with hole lattices have revealed broad technological implications ranging from exotic metamaterials for sub-wavelength resolution microscopy to ultra-compact plasmonic waveguides for optical interconnects, as well as many other exciting technological applications. Thus far, most investigations have employed dielectric/metal hybrid structures with granular polycrystalline metal films. Although many conceptual devices have been demonstrated, one factor significantly limits their technological potential: the strong damping of SPP propagation. By using atomically smooth, epitaxial Ag films we show that such a damping effect can be mostly eliminated, resulting in nearly ideal extraordinary optical transmission (EOT) through sub-wavelength hole arrays in the mid-infrared range. This also allows us to map out very detailed SPP band structure, with analogy to the electronic band structure in solids.

8:12AM A32.00002 Visualization of Coherent Processes in Plasmonic Interference Transparency

, ZILIANG YE, SHUANG ZHANG, YUAN WANG, YONG-SHIK PARK, XIAOBO YIN, THOMAS ZENTGRAF, GUY BARTAL, XIANG ZHANG[1], University of California, Berkeley — Recently, optical analogs that mimic the dynamics of atomic EIT are attracting attention since they could maintain coherence at room temperature and are easier to fabricate as well as to integrate. However, the understanding of the relationship between atomic EIT and its classical counterparts still remains on the spectroscopic level, which strongly limits the applicability of the analogy. As the coherent evolution of a quantum system is characterized by the oscillatory population transferring between the states, here, we map the coherent oscillation strength of a plamonic interference transparency (PIT) structure and show that there is a deeper resemblance embedded in the analogy: both systems are populated in the 'dark' state at the transparency point.

8:24AM A32.00003 Polarization-sensitive optical response of plasmonic metasurfaces[1]

, PAUL G. THOMPSON, CLAUDIU G. BIRIS, EDWARD J. OSLEY, University College London, RICHARD M. OSGOOD, JR., Columbia University, NICOLAE C. PANOIU, PAUL A. WARBURTON, University College London — We have fabricated arrays of nanoscale asymmetric cruciform apertures that support localized surface-plasmon polaritons (LSPPs) in the lower mid-infrared. The cruciform apertures were created by focussed ion beam milling into a gold film on a CaF_2 substrate. The measured transmission spectra of these arrays show two distinct maxima that correspond to the excitation of LSPPs, the magnitude of which can be tuned by varying the in-plane electric-field polarization of the incident photons. These findings are further validated by simulations based on the rigorous coupled-wave analysis method, namely, the maxima of the transmission spectra correspond to hybridized localized surface plasmon resonances in the two arms of the cruciform aperture. More generally speaking, it is demonstrated that the planar distribution of polarization-dependent LSPPs can be viewed to form a polarization-sensitive plasmonic metasurface. We will discuss possible applications of these plasmonic arrays in biosensing.

[1]Supported by NSF/EPSRC Materials World Network

8:36AM A32.00004 Designer plasmonic structures and metamaterials for subwavelength photonics , FEDERICO CAPASSO, Harvard University — Plasmonic structures and metamaterials have opened up new opportunities for manipulating light at subwavelength scales thus opening up new frontiers in optical materials design and photonics in such areas as imaging, sensing and new optical sources. In this talk I will present recent research from our group in this area. Through innovative use of plasmonic structures we have demonstrated how one can design the far field and near field of state of the art semiconductor lasers and optical fibers. Examples are plasmonic laser antennas creating ultrahigh intense near field nanospots in the near infrared, mid-infrared semiconductor lasers with very low divergence and control of polarization (linear/circular) as well as multibeam lasers. Metamaterials have created unique opportunities for nanophotonics. Recently we have shown that by patterning the facet of Terahertz quantum cascade lasers with subwavelength periodic structures one can dramatically modify the surface plasmon dispersion curve which leads to a highly collimated THz beam with divergence reduced from 180 deg to 5 deg. I will also discuss work on new clusters of colloidal core-shell metallic nanoparticles using self-assembly techniques. Magnetic activity in trimers at near infrared wavelengths and strikingly pronounced Fano-like resonances in heptamers are among the exciting new findings from light scattering experiments. Such building blocks are an important stepping stone towards novel designer metamaterials synthesized bottom up. Finally experiments with gold plasmonic nanocavity gratings have shown that the latter can dramatically enhance surface nonlinear optical processes. The four-wave mixing signal was enhanced by a factor up to 2000, two orders of magnitude higher than previously reported.

9:12AM A32.00005 Experimental demonstration of gradient index plasmonics , MAIKEN H. MIKKELSEN, THOMAS ZENTGRAF, YONGMIN LIU, JASON VALENTINE, XIANG ZHANG, NSF Nanoscale Science and Engineering Center, University of California, Berkeley — Plasmonics is an emerging field essential for bridging nanoelectronics and diffraction-limited photonics. One central objective of plasmonics research is modifying the propagation of surface plasmon polaritons (SPPs) in order to implement diverse functionalities in the context of two-dimensional optics. Here, we demonstrate an effective approach to manipulate SPPs by adiabatically tailoring the topology of a dielectric layer adjacent to a metal surface using grey-scale lithography. In such a way, we are able to continuously modify the propagation constant of SPPs, analogous to traditional gradient index optics. Applying this method, we design and experimentally demonstrate two different devices: a plasmonic Luneburg lens to focus SPPs and a plasmonic Eaton lens to bend SPPs.[1] Our approach has the potential to achieve low-loss functional plasmonic elements and provides a scheme to realize more complex structures using transformation optics.

9:24AM A32.00006 Propagation of surface plasmons on highly anisotropic dielectric substrates[1] , NAGARAJ NAGARAJ, ARKADII KROKHIN, University of North Texas — We calculate the propagation length of surface plasmons in dielectric-metal-dielectric structures with anisotropic substrates. We show that the proper orientation of the optical axis of the crystal with respect to the metal surface minimizes Joule losses enhancing the propagation length of surface plasmons. The propagation length in a wide range of frequencies including the telecommunications region is analyzed. A simple Kronig-Penney model for anisotropic plasmonic crystal where the substrate is a periodic sequence of dielectric delta-peaks is also proposed. In this model the dispersion relation for surface plasmon has a band structure where the band width tends to zero when the frequency approaches the resonant frequency.

[1]This work was supported by the US Department of Energy through Grant No. DE-FG02-06ER46312.

9:36AM A32.00007 Metal-less Plasmonics: Surface Electromagnetic Waves in Dielectric Mulitlayers , WILLIAM ROBERTSON, Department of Physics & Astronomy and Computational Science Program, Middle Tennessee State University — The use of suitably designed dielectric multilayers is demonstrated as an alternative to metal films for the generation of surface-bound electromagnetic waves. The growing field of plasmonics invokes the sub-wavelength resolution, resonant optical coupling, and high surface fields of surface plasmons for applications such as high-resolution lithography, biosensing, optical circuits, and enhanced non-linear optic phenomena. Surface electromagnetic waves with characteristics similar to surface plasmons can be generated in dielectric multilayer stacks. The dielectric loss in multilayers is much less than for surface plasmons in metal films leading to sharper coupling resonances, higher surface fields, and longer propagation distances than for surface plasmons. These features are advantageous for current and projected applications in plasmonics. Additionally, the wavelength of coupling and the dispersion of the surface electromagnetic waves can be engineered by the multilayer design. Examples of the use of surface electromagnetic waves in multilayers for bio-sensing will be presented.

9:48AM A32.00008 Dispersion and Mirage of Surface Plasmon Waves in Metallic Photonic Crystals[1] , CHEUNG WAI CHAU, YUN SAN CHAN, MING JIE ZHENG[2], KIN WAH YU, The Chinese University of Hong Kong — We have studied the dispersion and propagation of surface plasmon (SP) waves in a one-dimensional metallic photonic crystal composed of metal-dielectric multilayered films by a transfer matrix method. By virtue of Bloch theorem, we are able to obtain the dispersion (frequency-wavevector) relation for arbitrary oblique propagation of SP waves for various non-zero transverse wavevectors. Model calculations are performed for alternative gold and MgF_2 films to obtain the photonic band-gap structure. For a progressively decreasing gold film thickness, the band (gap) width increases (decreases), rendering a precise and feasible tunability of photonic band gaps. Moreover, by imposing a gradual variation in the thickness of dielectric along the multilayers, it is possible to alter the dispersion relation locally, allowing us to study the bending of SP wave at various incident angles. We use Hamiltonian optics approach to obtain the trajectories of propagation. As the transverse wavevector is a constant of motion for a certain incident angle, we obtain different mirage at various oblique incidence. The results are useful for achieving superbending of SP waves.

10:00AM A32.00009 Plasmonic Forces in Nanoscale Metal Clusters , PHILIP BATSON, Rutgers University, USA, ALEJANDRO REYES-CORONADO, Donostia International Physics Center, Spain, RUBEN BARRERA, Universidad Nacional Autonoma de Mexico, Mexico, PEDRO ECHENIQUE, JAVIER AIZPURUA, Donostia International Physics Center, Spain — Passage of keV-energy electrons near nanometer-sized metal clusters is known to transfer energy from the electron to the clusters by excitation of surface plasmons. In groups of clusters, these plasmon modes couple, producing inter-cluster forces which favor coalescence. A single cluster is also expected to experience a smaller, attractive, force in the presence of a passing electron from simple image charge considerations. Detailed calculations that evaluate the Maxwell Force Tensor for plasmonic modes confirm this for large impact parameters, but for small impact parameters, comparable or less than the cluster diameter, the plasmonic force becomes repulsive. We have verified this behavior experimentally, using a sub-Angstrom electron beam at 120 KeV to move nano-scale Au clusters, discovering a weak attractive motion for large impact parameters and a stronger, repulsive motion for small impact parameters. We will present this finding and suggest physical reasons for this non-intuitive behavior.

10:12AM A32.00010 Optical properties of subwavelength plasmonic structures , ZHU YONGYUAN, Nanjing University — Some recent progress achieved in our group will be reported here, focusing on the optical properties of subwavelength holes and metallic particles. By dressing the periodic holes with the metallic components, new transmission features, such as the enhanced transmission due to the magnetic resonance, the peak splitting due to the hole symmetry breaking etc. can be obtained. With the multilayer slit gratings, the transmission resonance associated with the longitudinal interference effect as well as the tuning of spectrum by the temperature control have been realized. In addition, the plasmon resonance of isolated gold nanorod particles and the plasmonic waveguiding using a linear chain of nanorod particles have been studied. In addition, due to the strong coupling between the incident light and vibrations of free electrons, a bulk polariton mode can be induced in a plasmonic crystal composed of gold nanorod particles. The fundamental equations governing the coupling have been developed and the long-wavelength optical properties of the crystal have been suggested.

10:24AM A32.00011 Screening effect on the polaron by surface plasmons[1] , XIAOYING XU, XIAOSHAN XU, Oak Ridge National Lab, KATYAYANI SEAL, HANGWEN GUO, Oak Ridge National Lab; The University of Tennessee, JIAN SHEN, Fudan University; The University of Tennessee, LOW DIMENSIONAL MATERIALS PHYSICS, OAK RIDGE NATIONAL LAB TEAM, THE UNIVERSITY OF TENNESSEE TEAM, PHYSICS DEPARTMENT, FUDAN UNIVERSITY TEAM — Surface plasmons occur when the conduction electrons at a metal/dielectric interface resonantly interact with external electromagnetic fields. While surface plasmons in vicinity of a polaron in the dielectric material, a strong screening effect on polaron characteristics is introduced. In this work, we observed the reduction of polarons in multiferroic LuFe2O4, which is mainly contributed by surface plasmons.

10:36AM A32.00012 Surface Plasmon Polaritons: Geometric Resonance at Singularities , YUN-SHAN WANG, University of Notre Dame, Department of Chemical and Biomolecular Engineering, Graduate Student, HSUEH-CHIA CHANG, University of Notre Dame, Department of Chemical and Biomolecular Engineering, Professor — Unlike planar plasmonic waves, the electric field of radially confined surface plasmon polariton (SPP) at a geometric singularity does not decay from the interface, but rather interacts around the singularity. A discrete SPP spectral theory for solid and hollow cones/wedges shows that the resulting azimuthal optical capacitor produces an infra-red shift of the classical planar plasmonic resonant frequency with a larger bandwidth at small angles. An analysis of the conformal map between the complex spectral space and the complex permittivity space shows the resonant SPPs can be sustained by materials with positive permittivity, although negative permittivity provides higher intensification. Asymptotic analysis of the SPP dispersion relationship also provides a closed-form estimate of the optimum angle due to enhanced conductive loss at small angles and also a prediction of optimal frequency. Experimental confirmation with transmission and scattering measurements will also be reported.

10:48AM A32.00013 ABSTRACT WITHDRAWN –

Monday, March 21, 2011 8:00AM - 11:00AM –

Session A33 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides: Piezoelectrics, Oxides on Semiconductors, and Applications C143/149

8:00AM A33.00001 High-Throughput Density Functional Theory Categorization of Ferroelectric Ternary Perovskite Oxides for Use as High-Performance Piezoelectrics , RICKARD ARMIENTO, Massachusetts Institute of Technology, BORIS KOZINSKY, Bosch Research and Technology Center, MARCO FORNARI, Central Michigan University, GERBRAND CEDER, Massachusetts Institute of Technology — We present a nearly exhaustive density functional theory (DFT) survey over the chemical space of perovskite compounds on ABO3 form, with the aim of identifying alloy end points for new piezoelectric materials. Our screening criteria on the DFT results selects 85 relevant compounds, among which all well known alloy end points for high performance piezoelectrics are present. We analyze the compounds with respect to macroscopic polarization, born effective charges, and energy differences between different structure distortions. We discuss the energy features that cause the high piezoelectric performance of the well known piezoelectric lead zirconate titanate (PZT), and to what extent these features are rare among the found compounds. The results are used to discuss relevant isovalent alloys of the selected compounds.

8:12AM A33.00002 Searching for ferroelectricity and piezoelectricity in Heusler compounds using first-principles calculations , ANINDYA ROY, JOSEPH BENNETT, KARIN M. RABE, DAVID VANDERBILT, Rutgers University — Hundreds of half Heusler (HH) and full Heusler (FH) compounds have been synthesized, and they exhibit a multitude of properties. However, we are unaware of any Heusler compounds showing ferroelectricity (FE), or for which the piezoelectricity (PzE) has been measured. Determining these polar properties would be of theoretical interest as well as having practical importance for the design of new functional materials. In this *ab initio* study, we search a large set of HH and FH compounds, both known and hypothetical, for FE/PzE. We screen the zone-center phonons, computed with first-principles density-functional-theory methods, for unstable polar modes that would drive a distortion to a ferroelectric phase, and calculate PzE coefficients of compounds in the $F\bar{4}3m$ space group, which includes all HH and many FH, using density-functional perturbation theory. Preliminary results from our calculations confirm that the Heusler compounds are very robust against FE instabilities. However, we found several HH compounds having e_{14} coefficients in the range of 0.5-1.0 C/m^2, comparable to that of some well-known piezoelectric materials such as ZnO. We also investigate the effects of epitaxial constraints on these properties, both for bulk materials and for superlattices built of Heusler materials.

8:24AM A33.00003 Origin of the anomalous piezoelectric response in wurtzite $Sc_xAl_{1-x}N$ alloys[1] , FERENC TASNADI, BJORN ALLING, CARINA HOGLUND, GUNILLA WINGQVIST, JENS BIRCH, LARS HULTMAN, IGOR A. ABRIKOSOV[2], Department of Physics, Chemistry and Biology (IFM), Linkoping University, Sweden, IFM COLLABORATION — We present the theory that reveals the origin of the observed anomalous enhancement of piezoelectric response in wurtzite $Sc_xAl_{1-x}N$ alloys [1]. Our first-principles calculations confirm that the 400% increase of the piezoelectric constant is an intrinsic alloying effect. The energy surface topology is found to be strongly influenced by the alloying, being elongated around the global minimum along c=a direction. This leads to the large elastic softening along the crystal parameter c, and raises significantly the intrinsic sensitivity to axial strain resulting in the highly increased piezoelectric constant. The effect is particularly accentuated at intermediate compositions where the elongated double-minimum energy landscape is flattened due to the energy proximity of the wurtzite and so far experimentally unknown hexagonal phases of these alloys. Our observation provides a route for the design of materials with high piezoelectric response.

8:36AM A33.00004 Giant piezoelectricity on Si for hyper-active MEMS , CHANG-BEOM EOM, University of Wisconsin-Madison — Smart materials that can sense, manipulate, and position are crucial to the functionality of micro- and nano-machines. Integration of single crystal piezoelectric films on silicon offers the opportunity of high performance piezoelectric microelectromechanical systems (MEMS) incorporating all the advantages of large scale integration on silicon substrates with on-board electronic circuits, improving performance and eliminating common failure points associated with heterogeneous integration. We have fabricated oxide heterostructures with the highest piezoelectric coefficients and figure of merit for piezoelectric energy harvesting system ever realized on silicon substrates by synthesizing epitaxial thin films of $Pb(Mg_{1/3}Nb_{2/3})O_3$-$PbTiO_3$(PMN-PT) on vicinal (001) Si wafers using an epitaxial (001) $SrTiO_3$ template layer. We have also demonstrated fabrication of PMN-PT cantilevers, whose mechanical behavior is consistent with theoretical calculations using the material constants of a bulk PMN-PT single crystal. These epitaxial heterostructures with giant piezoelectricity can be used for MEMS or NEMS devices that function with low drive voltage such as transducers for ultrasound medical imaging, micro-fluidic control and energy harvesting. Beyond electromechanical devices, our approach will open a new avenue to tune and modulate the properties of other multifunctional materials by dynamic strain control. This work was done in collaboration with S. H. Baek, J. Park, D. M. Kim, V. Aksyuk, R. R. Das, S. D. Bu, D. A. Felker, J. Lettieri, V. Vaithyanathan, S. S. N. Bharadwaja, N. Bassiri-Gharb, Y. B. Chen, H. P. Sun, H. W. Jang, D. J. Kreft, S. K. Streiffer, R. Ramesh, X. Q. Pan, S. Trolier-McKinstry, D. G. Schlom, M. S. Rzchowski, R. Blick. This work was supported by the National Science Foundation through grants ECCS-0708759.

9:12AM A33.00005 Monolayer modification of interface dipoles between a-Al_2O_3 and silicon , STEPHANIE FERNANDEZ-PEÑA, University of Geneva, A.M. KOLPAK, S. ISMAIL-BEIGI, C.H. AHN, F.J. WALKER, Center for Research on Interface Structures and Phenomena, Yale University, New Haven, Connecticut — Interface dipoles occurring at high-k oxide-silicon interfaces play an important role in the function of electronic devices. The magnitude and sign of the dipole depend sensitively on the chemistry of the first few atomic planes around the interface. In this work, we control the dipole between a-Al_2O_3 and silicon by monolayer modifications of interface chemistry. The interface composition ranges from a clean 2×1 Si (001) surface prepared by SiO desorption in ultra high vacuum to surfaces having thicknesses of SiO_x as thin as 1 monolayer. In these materials, we observe using x-ray photoelectron spectroscopy band-offset changes induced by a modified interface dipole as large as 0.4 eV. From the capacitance-voltage behavior of metal oxide semiconductor (MOS) devices, we find that this dipole responds to an applied electric field in a non-linear way. We understand this non- linear behavior using first principles theory of complex oxide- electrode interfaces.

9:24AM A33.00006 Alloyed Hf-La High-k Oxide Film Grown by Remote Plasma Atomic Layer Deposition[1] , FU TANG, CHIYU ZHU, ROBERT NEMANICH, Arizona State University — The growth of alloyed Hf-La oxide was investigated using remote plasma atomic layer deposition (RPALD) at low temperatures ranging from 80 to 250C. The low temperature process is particularly important for the applications in thin film transistors, where the device is very often fabricated on flexible plastic substrate. Alloyed oxide films were deposited with 1-3 cycles of La oxide between two adjacent Hf oxide cycles. The atomic bonding structure was determined by in situ XPS. AFM and TEM were used to characterize the morphology and crystalline structure. The XPS results indicated that the percentages of Hf and La components in the alloyed films can be controlled by the ratio of the number of Hf and La cycles. In addition, carbon residue in the alloyed film is reduced compared with that of a pure La oxide film. This is attributed to the role of Hf in preventing formation of La carbonate. The AFM and TEM images indicated that the periodic alloying has suppressed the crystallization of HfO2 and led to improvement of the morphology compared with the roughness of the pure Hf oxide film. The IV curves show that the alloyed Hf-La oxide film has a break down voltage of 3 MV/cm.

[1]Supported through US Army Cooperative Agreement W911NF-04-2-0005 (FDC-10-4.6)

9:36AM A33.00007 Linking the Electronic and Atomic Structure of Epitaxial Complex Oxides on Semiconductors , DIVINE KUMAH, JAMES REINER, JOSEPH NGAI, YARON SEGAL, ALEXIE KOLPAK, DIANA QIU, SOHRAB ISMAIL-BEIGI, CHARLES AHN, FRED WALKER, Department of Applied Physics, Yale University, DONG SU, YI ZHU, Brookhaven National Laboratory, ZHAN ZHANG, Argonne National Laboratory — Understanding the interfacial coupling between materials with different electronic properties is critical to achieve the integration of epitaxial complex oxides with semiconductors. Using a combination of synchrotron x-ray diffraction and first principles calculations, we show that the electronic properties and atomic structure of epitaxial $SrTiO_3$ films on Si, and $BaTiO_3$ films on Ge are directly linked to the chemical composition at their respective interfaces. Sub-angstrom [001] cation-anion displacements observed in the $SrTiO_3$/Si system, lead to a positively polarized film. The polar distortions are found to arise from an interplay between compressive strain and localized interface states. In contrast to $SrTiO_3$/Si, we find that the $BaTiO_3$/Ge interface has a 2x1 structure that drives an in-plane polarization.

9:48AM A33.00008 Piezoelectric force microscopy of crystalline oxide-semiconductor heterostructures[1] , MATTHEW S.J. MARSHALL, JAMES W. REINER, DIVINE KUMAH, CRISP, Dept. of Applied Physics, Yale University, PETER MAKSYMOVYCH, ART P. BADDORF, CNMS, Oak Ridge National Lab, CHARLES AHN, FRED J. WALKER, CRISP, Dept. of Applied Physics, Yale University — Coupling the properties of a ferroelectric material to a semiconductor has been pursued for decades. Epitaxial, coherently strained thin films of ferroelectric BaTiO3 can be grown on germanium with out-of-plane polarization using molecular beam epitaxy (MBE). Similarly, epitaxial thin films of SrTiO3 can be grown on Si with some indication that these films can be ferroelectric. In this work, we use oxide MBE to grow epitaxial films of SrTiO3 and BaTiO3 on Si and Ge, respectively, and we use both ambient and ultrahigh vacuum (UHV) piezoelectric force microscopy (PFM) to study the question of ferroelectricity in these systems. We find that the modulation of the PFM amplitude for thin films of SrTiO3 (6 uc. and 25 uc) on Si is the result of an electrostatic mechanism that can be traced back to tip-induced or as-grown defects in the film. These results are compared to results on thin films of BaTiO3 on Ge.

[1]A portion of this research was conducted at the Center for Nanophase Materials Sciences, which is sponsored at Oak Ridge National Laboratory by the Scientific User Facilities Division, U.S. Dept. of Energy.

10:00AM A33.00009 Molecular Beam Epitaxy of YInO3 on GaN , CAMERON KEENAN, FELIO PEREZ, DAVID LEDERMAN, West Virginia University — Novel non-volatile ferroelectric materials are of significant interest in the field of materials science as devices and integrated circuits approach smaller dimensions and broader use. Materials and device structures incorporating GaN are also of particular interest as devices transition away from relying solely on silicon. Oxide materials, such as YMnO3 on GaN, have been researched in an effort to fill this niche, but problems associated with lattice mismatch and interfacial degradation have limited sample quality and utility. YInO3 is another material that may provide an avenue for oxide device integration with GaN. YInO3 thin films were prepared on metal organic chemical vapor deposition GaN templates via molecular beam epitaxy. Atomic force microscopy was used to determine surface roughness and morphology. X-ray reflectivity and x-ray diffraction were implemented in order to determine the thickness, crystallinity, and crystal structure of the films. Results for structural analysis, as well as, ferroelectric measurements will be presented and discussed.

10:12AM A33.00010 Electrocaloric and Pyroelectric Properties of Ferroelectric Films , JIALAN ZHANG, GEORGE ROSSETTI, PAMIR ALPAY, University of Connecticut — We use a non-linear thermodynamic model to investigate the electrocaloric and pyroelectric response of thin film perovskite ferroelectrics under the influence of differing electrical, thermal and mechanical boundary conditions including bias and driving field, temperature, lateral clamping, and misfit strain. A comparison of ferroelectric solid solutions comprised of $BaTiO_3$, $PbTiO_3$ and/or $SrTiO_3$ illustrates the influence of composition and lateral clamping effect on the electrocaloric properties. The theoretical analysis of a variety of ferroelectric thin films on IC-friendly substrates such as Si and sapphire shows that the room temperature dielectric and electrothermal responses of these films depend strongly on the synthesis/processing temperature. These combined results provide insights concerning how the deposition temperature, substrate material and composition can be adjusted to obtain desired electrothermal properties.

10:24AM A33.00011 Polarization switching in Ferroelectric capacitors , ASIF KHAN, UC Berkleey, RAMAMOORTHY RAMESH, SALAHUDDIN SAYEEF, UC Berkeley — A capacitor is an electrical circuit element that stores energy in the form of electric field. A ferroelectric is essentially analogous to an ordinary capacitor with an electrically switchable built-in polarization. The properties of ferroelectrics had been well described by Landau's phenomenological framework. However, during polarization switching in realistic ferroelectrics, switching occurs via "non-ideal" defect mediated domain nucleation and domain wall movement. It can be argued that, within the framework of nucleation based models of FE switching, energy injected into the FE is not stored in the form of electric field, which makes capacitor like description of FE during switching "unclear." In this talk, we will revisit the different switching based models of ferroelectrics and discus the properties of FE as a circuit element during switching.

10:36AM A33.00012 Synthesis and characterization of novel high energy density capacitors for green energy , VENKATA S. PULI, ASHOK KUMAR, RAM S. KATIYAR, Department of Physics and Institute for Functional Nanomaterials, University of Puerto Rico, San Juan, Puerto Rico 00931-3343, USA — We have developed lead free high energy density capacitor materials, $\{Ba(Zr_{0.2}Ti_{0.8})O_3\}_{(1-x)}$ $\{(Ba_{0.7}Ca_{0.3})TiO_3\}x$ [x = 0.10,0.15,0.20 ($BZT_{(1-x)}BCT_x$] with high dielectric constant and moderate breakdown voltage. The ceramic materials were prepared using high energy ball milling for 4 hours at 400 rpm. The ball milled powders were calcined at 1250^{o}C for 10hrs. Ceramic pellets having 13mm diameter were prepared using hydraulic press (2 ton) and sintered at 1400^{o}C-1500^{o}C for 4 hrs. X-ray diffraction studies of the sintered pellets revealed the rhombohedral/pseudo cubic crystal structure. The crystal structure was further confirmed by Raman spectra and TEM analysis. High dielectric constant and moderate polarization ($\sim P_s \sim$ 15-25 μC/cm^2) were obtained in the sintered pellets. The SEM images revealed monolithic grain growth in samples sintered at 1500^{o}C. Preliminary data show moderate breakdown field $\sim$ 15-20 kV/cm and energy density of 0.12-0.3 J/cm^3 for all compositions. Details of the results will be presented.

10:48AM A33.00013 Capacitance response and strain sensing properties of barium titanate thin film[1] , SATREERAT HODAK, PAVARIT PROMSENA, Department of Physics, Faculty of Science, Chulalongkorn University, ANURAT WISITTSORAAT, Nanoelectronics and MEMS Laboratory, National Electronics and Computer Technology Center, JOSE HODAK, Department of Inorganic Analytic and Physical Chemistry, Faculty of Exact and Natural Sciences, University of Buenos Aires — Strain gauges are devices that convert mechanical stress into an electronic signal. In this research, barium titanate ($BaTiO_3$) films were deposited on flexible borosilicate glasses using a sol-gel method. Interdigitated electrodes were patterned on the films to fabricate a strain gauge. The strain gauge comprised of an array of individual coplanar capacitors on a 1.2x0.4 cm rectangular borosilicate glass of 0.16 mm thickness. A parallelogram clamp and a mechanically amplified piezoelectric actuator were used for supporting the device under test and for the application of the strain, respectively. Measurements of the strain were carried out on a cantilever beam by monitoring the changes in device capacitance and the frequency shift of an oscillator circuit. We obtained the frequency change per unit stress equal to 0.00163 MHz/MPa and the frequency change per unit strain equal to 1.038x10^{-4} MHz/unit strain, respectively.

Session A34 DMP: Focus Session: Interfaces in Complex Oxides - LaAlO3/SrTiO3 Transport

C141

8:00AM A34.00001 Tailoring a two-dimensional electron gas at the $LaAlO_3/SrTiO_3$ (001) interface by epitaxial strain , DAVID FELKER, C.W. BARK, University of Wisconsin, Y. WANG, University of Nebraska, Y. ZHANG, University of Michigan, H.W. JANG, C.M. FOLKMAN, J.W. PARK, S.H. BAEK, University of Wisconsin, X.Q. PAN, University of Michigan, E.Y. TSYMBAL, University of Nebraska, M.S. RZCHOWSKI, C.B. EOM, University of Wisconsin — Recently a two-dimensional electron gas (2DEG) was discovered at the interface between insulating oxides $LaAlO_3$ and $SrTiO_3$. Properties of this 2DEG have attracted interest due to its potential applications in nanoelectronics. Control over the carrier density and mobility is essential for applications of these novel systems, and may be achieved by epitaxial strain. The relationship between the strain and electrical properties of this 2DEG remains largely unexplored. We use different lattice constant single crystal substrates to produce $LaAlO_3/SrTiO_3$ interfaces with controlled levels of biaxial epitaxial strain. We have found that tensile strained $SrTiO_3$ destroys the conducting 2DEG, while compressively strained $SrTiO_3$ retains the 2DEG, but with a carrier concentration reduced in comparison to the unstrained $LaAlO_3/SrTiO_3$ interface. We have also found that the critical $LaAlO_3$ overlayer thickness for 2DEG formation increases with $SrTiO_3$ compressive strain. Our first-principles calculations suggest that a strain-induced electric polarization in the $SrTiO_3$ layer is responsible for this behavior.

8:12AM A34.00002 The effect of epitaxial strain and R^{3+} magnetism on interfaces between $RAlO_3$ and $SrTiO_3$, MARK C. MONTI, SHIRIN MOZAFFARI, JOHN T. MARKERT, Department of Physics, The University of Texas at Austin — We have embarked on a systematic study of novel charge states at oxide interfaces. We have performed pulsed laser deposition (PLD) growth of epitaxial oxide thin films on single crystal oxide substrates. We are studying the effects of epitaxial strain and rare-earth composition of the metal oxide thin films. We have successfully created TiO_2 terminated $SrTiO_3$ (STO) substrates and have grown epitaxial thin films of $LaAlO_3$ (LAO), $LaGaO_3$ (LGO), and $EuAlO_3$ (EAO) on STO using a KrF pulsed excimer laser. Current work emphasizes the importance of understanding the effect of both epitaxial strain and R^{3+} magnetism on the interface between $RAlO_3$ and STO. We have demonstrated that the interfaces between LAO/STO and LGO/STO are metallic with carrier concentrations of 1.1 x 10^{14} cm^{-2} and 4.5 x 10^{14} cm^{-2}, respectively. Surprisingly, we find that even good epitaxial interfaces between EAO/STO are insulating. We will investigate the effect of strain by growing $La_xY_{1-x}AlO_3$ on STO: for example $La_{0.4}Y_{0.6}AlO_3$ mimics the lattice size of EAO. We will systematically vary the magnetism of the $RAlO_3$ thin films for R = Ce, Pr, Nd, Sm, Eu, Gd, Tb, La_xEu_{1-x}, ect. This work was supported by: Texas Advanced Research Program 003658-0126, The Robert A. Welch Foundation F-1191, and the National Science Foundation DMR-0605828.

8:24AM A34.00003 High mobility interface electron gas by defect engineering in a modulation doped oxide heterostructure , GUUS RIJNDERS, MARK HUIJBEN, University of Twente/MESA+ Institute for Nanotechnology, GERTJAN KOSTER, HAJO MOLEGRAAF, SANDER WENDERICH, JOSEE KLEIBEUKER, ALEXANDER BRINKMAN, HANS HILGENKAMP, DAVE BLANK, MICHELLE KRUIZE, University of Twente/MESA+ Institute for Nanotechnology, A. MCCOLLAM, V.K. GUDURU, ULI ZEITLER, JAN CEES MAAN, Radboud University, High Field Magnet Laboratory, UNIVERSITY OF TWENTE/MESA+ INSTITUTE FOR NANOTECHNOLOGY TEAM, RADBOUD UNIVERSITY, HIGH FIELD MAGNET LABORATORY TEAM — The manifestation of quantum behavior in two dimensional electron gases in semiconducting heterostructures and their progressive complexity towards fractional quantum Hall effect went hand-in-hand with the efforts to remove the effect of impurity scattering. For oxide materials, history is repeating itself and to date sample quality is reaching levels where quantum behavior starts to become accessible. To really understand the ground state of two dimensional electron gases in oxide systems, where electron-electron correlation effects seem more important, a step towards modulation doping is necessary, removing dopants away from a conduction channel. We will show that the impurity scattering of a 2DEG at the LaAlO3/SrTiO3 interfaces can be significantly suppressed by defect engineering, allowing the observation of quantum transport in a modulation doped oxide system.

8:36AM A34.00004 Effect of stoichiometry on the interface conductivity of MBE-grown $LaAlO_3/SrTiO_3$ heterostructures , M.P. WARUSAWITHANA, J. LUDWIG, P. ROY, A.A. PAWLICKI, Department of Physics and NHMFL, Florida State University, T. HEEG, D.G. SCHLOM, Department of Materials Science and Engineering, Cornell University, C. RICHTER, S. PAETEL, J. MANNHART, Experimentalphysik VI, University of Augsburg, L. FITTING KOURKOUTIS, J. MUNDY, D.A. MULLER, School of Applied and Engineering Physics, Cornell University, M. ZHENG, B. MULCAHY, J.N. ECKSTEIN, Department of Physics, University of Illinois at Urbana - Champaign, W. ZANDER, J. SCHUBERT, Inst. of Bio and Nanosystems IBN1-IT and JARA-FIT, Research Centre Jülich — Through careful control of the stoichiometry in molecular-beam epitaxy grown $LaAlO_3/SrTiO_3$ samples, we find that a 2-dimensional electron gas occurs at the interface between the two insulating oxides as reported in samples grown by pulsed-laser deposition. In this talk, I will discuss the controlled experiments that we have carried out, which effectively eliminate the extrinsic effects that have been suggested as possible mechanisms of conductivity, for the conductivity observed in our MBE-grown samples. We find that the cation stoichiometry of the $La_{(1-x)}Al_{(1+x)}O_3$ layer is key to the existence of the interface 2-dimensional electron gas and that a La/Al ratio, (1-x)/(1+x) less than or equal to 0.97 $\pm$ 0.03 is a necessary condition to obtain a conducting interface in this system.

8:48AM A34.00005 Importance of defects and stoichiometry in the interfacial metal-insulator transition in LaAlO3 thin films on SrTiO3 , C. STEPHEN HELLBERG, Naval Research Lab — The observed metal-insulator transition in thin films of LaAlO3 on SrTiO3 depends critically on the stoichiometry of the film: metallic interfaces are found for Al-rich films, while growing even slightly La-rich results in insulating interfaces. Using first-principles density functional calculations, we examine the effects of changing the stoichiometry of the films. We find that Al will substitute for La, but La will not substitute for Al. Instead, Al-vacancy structures occur in La-rich films. The Al vacancies can migrate to the interface, screening the potential divergence and preventing a metallic interface from forming.

9:00AM A34.00006 Interfacial superconductivity and its magnetic field dependence in MBE-grown $LaAlO_3/SrTiO_3$ heterostructures , P. ROY, J. LUDWIG, E. STEVEN, A. KISWANDHI, A.A. PAWLICKI, J. BROOKS, M.P. WARUSAWITHANA, Department of Physics and NHMFL, Florida State University, D.G. SCHLOM, Department of Materials Science and Engineering, Cornell University, C. RICHTER, J. MANNHART, Experimentalphysik VI, University of Augsburg — In our MBE-grown $LaAlO_3/SrTiO_3$ samples we find the interface to be conducting and sometimes even superconducting when the La/Al ratio is less than or equal to 0.97 $\pm$ 0.03. Here, we report on the superconducting behavior observed in some samples with La/Al ratio above 0.84 $\pm$ 0.03 and below 0.97 $\pm$ 0.03. The superconducting critical temperature is found to be between 160 – 235 mK on different samples. We measure the magnetic field dependence of superconductivity and find that the critical magnetic field required to quench superconductivity depends on the direction of the applied magnetic field. The strong anisotropy in the critical field suggests that the superconductivity in these MBE-grown samples is confined to a thin layer at the interface.

9:12AM A34.00007 Low temperature, high magnetic field magnetoresistance and Hall measurements on MBE-Grown $LaAlO_3/SrTiO_3$ interfaces , J. LUDWIG, P. ROY, E. STEVEN, A. KISWANDHI, A.A. PAWLICKI, J. BROOKS, M.P. WARUSAWITHANA, Department of Physics and NHMFL, Florida State University, D.G. SCHLOM, Department of Materials Science and Engineering, Cornell University, C. RICHTER, J. MANNHART, Experimentalphysik VI, University of Augsburg — We have measured MBE-grown $LaAlO_3/SrTiO_3$ samples at temperatures ranging from room temperature to 20mK and at magnetic fields up to 18 Tesla. The $La_{(1-x)}Al_{(1+x)}O_3$ films studied were grown with a stoichiometry gradient (varying x). We report on the low-temperature sheet carrier density and mobility of the conducting samples – samples with La/Al ratio less than or equal to 0.97 $\pm$ 0.03. We discuss the dependence of sheet carrier density and mobility on stoichiometry by using samples grown on the same substrate and then isolated by using a wire saw. In the devices we measured, the low-temperature sheet carrier densities are on the order of $1x10^{13}$ cm^{-2} with an approximate variation of $2x10^{12} cm^{-2}$ form device to device. The mobilities observed are on the order of $1x10^3$ $cm^2V^{-1}s^{-1}$.

9:24AM A34.00008 Two-dimensional quantum oscillations of the conductance at the $LaAlO_3/SrTiO_3$ interface , ANDREA CAVIGLIA, STEFANO GARIGLIO, NICOLAS REYREN, CLAUDIA CANCELLIERI, ALEXANDRE FETE, BENJAMIN SACEPE, DPMC University of Geneva, MARC GABAY, University of Paris, ALBERTO MORPURGO, JEAN-MARC TRISCONE, DPMC University of Geneva, DPMC UNIVERSITY OF GENEVA TEAM, LABORATOIRE DE PHYSIQUE DES SOLIDES, UNIVERSITÉ PARIS-SUD TEAM — Electronic states with unusual properties can be promoted at interfaces between complex oxides. A striking example is the interface between the band insulators $LaAlO_3$ and $SrTiO_3$, which displays conductivity with high mobility and 2D superconductivity. We report on a study of magnetotransport in $LaAlO_3/SrTiO_3$ interfaces characterized by mobilities of the order of several thousands cm^2/Vs. We observe Shubnikov-de Haas oscillations whose period depends only on the perpendicular component of the magnetic field. This observation directly indicates that the electron gas is two-dimensional and originates from quantum confinement at the interface. From the temperature dependence of the oscillation amplitude we extract an effective carrier mass $m* \simeq 1.45 m_e$. We discuss the relevance of spin effects on the observed phenomenology.

9:36AM A34.00009 Direct Magnetization Measurement of the $LaAlO_3/SrTiO_3$ heterostructure , LU LI, Massachusetts Institute of Technology, CHRISTOPH RICHTER, JOCHEN MANNHART, Univ. Augsburg, RAY ASHOORI, Masschusetts Institute of Technology — The $LaAlO_3/SrTiO_3$ heterostructure is a potential candidate for a high mobility two-dimensional electron system with novel electronic and magnetic properties. Although $LaAlO_3$ and $SrTiO_3$ are both large-gap band insulators, the interface is conductive and even superconducts below 200 mK. Magnetic ordering has been proposed to arise from the polarization-driven charge transfer, but the magnetization of this system has not previously been studied, likely due to the small volume of the interface. Using torque magnetometry, we detect directly the magnetic moment of the interface system. Control experiments with samples without $LaAlO_3$ display a background signal two orders of magnitude smaller, indicating that the observed magnetic moment arises from the deposition of $LaAlO_3$. The measured equilibrium $M - H$ curve resembles that of a soft ferromagnet. Our results indicate the existence of a magnetic ordering at the two-dimensional conductive interface.

9:48AM A34.00010 Quantum Oscillations at the $LaAlO_3/SrTiO_3$ Interface , A. MCCOLLAM, V.K. GUDURU, U. ZEITLER, J.C. MAAN, High Field Magnet Laboratory, Radboud University Nijmegen, Netherlands, M.K. KRUIZE, S. WENDERICH, H. HILGENKAMP, D.H.A. BLANK, MESA+ Institute for Nanotechnology, University of Twente, Netherlands — Under certain growth and preparation conditions, the interface between the perovskite oxides $LaAlO_3$ and $SrTiO_3$ can support a 2-dimensional electron gas (2deg) with diverse and remarkable electronic properties. When the mobility of this 2deg becomes high enough, quantum oscillations appear in the magnetoresistance and provide important information about the origin of the electronic behavior. Here we present an angle-dependent magnetotransport study of a high mobility $LaAlO_3/SrTiO_3$ interface, at millikelvin temperatures and in magnetic fields of up to 30 T. Large quantum oscillations are observed, with a complex dependence on the applied magnetic field and its orientation with respect to the plane of the interface. We propose that the unusual properties of the oscillations have their origin in the multi-subband character of the 2deg, and present a simple model, based on two-dimensional conductivity, which supports the scenario that several spin-split subbands, with field and angle-dependent occupancy, are contributing to the quantum transport in this system.

10:00AM A34.00011 Magnetotransport in the 2DEG at Interface Between $LaAlO_3$ and Thin Film $SrTiO_3$[1] , T. HERNANDEZ, D.A. FELKER, C.W. BARK, C.B. EOM, M.S. RZCHOWSKI, University of Wisconsin-Madison — Transport properties of the 2DEG formed at the heterointerface between $LaAlO_3$ (LAO) and $SrTiO_3$ (STO) grown on Si and $(LaAlO_3)_{0.3}$-$(Sr_2AlTaO_3)_{0.7}$ (LSAT) were compared to those of the LAO on single crystal STO interface. The STO layer on Si was grown by molecular beam epitaxy and on LSAT by pulsed laser deposition (PLD). In all cases, the LAO overlayers were grown using PLD. Mobility, carrier concentration, and magnetoresistance (MR) were measured over the range 3-300K and magnetic fields of 0-8T. The transport properties were similar at room temperature for the different structures. However, at low temperatures, the structures on single crystal STO showed metallic behavior and positive MR, constant in temperature in the 3-20K regime, whereas the ones on Si and LSAT substrates showed a temperature dependence consistent with Mott-type variable range hopping and negative MR with power law behavior in temperature.

10:12AM A34.00012 Hysteretic magneto-resistance at the $LaAlO_3$-$SrTiO_3$ interface - interplay between superconducting and ferromagnetic properties[1] , MANAN MEHTA, DIMITRY DIKIN, Northwestern University, CHUNG WUNG BARK, CHAD FOLKMAN, CHANG-BEOM EOM, University of Wisconsin-Madison, VENKAT CHANDRASEKHAR, Northwestern University — The conducting interface formed between $LaAlO_3$ (LAO) and $SrTiO_3$ (STO) has been shown to have both magnetic and superconducting properties. The behaviour can be tuned from one to the other by changing the applied gate voltage, thus changing the density of carriers at the interface. We will present magneto-transport data on a Hall-bar geometry patterned LAO/STO interface, with 10 unit cells LAO thickness. The longitudinal magneto-resistance shows strong hysteretic behaviour, indicating a ferromagnetic state, at negative gate voltages; the transverse magneto-resistance being linear. However, the hysteresis survives even into the superconducting state, and also shows up in the transverse magneto-resistance. This suggests an interplay between the superconducting and ferromagnetic order parameters of this system.

10:24AM A34.00013 Oxygen vacancies at the $LaAlO_3/SrTiO_3$ interface: formation energies and metal-insulator transition , HANGHUI CHEN, Department of Physics, Yale University, ALEXIE KOLPAK, Department of Material Science and Engineering, MIT, SOHRAB ISMAIL-BEIGI, Department of Applied Physics, Yale University — The intriguing transport properties observed at the $LaAlO_3/SrTiO_3$ interface have stimulated numerous studies in the past few years. However, the microscopic mechanism that leads to the formation of the two-dimensional conducting electron gas at the interface remains elusive, partly due to the fact that both intrinsic and extrinsic factors can contribute. We report first principles results on the formation energies of oxygen vacancies on the $LaAlO_3$ thin film surface as a function of coverage and film thickness. In addition to electrostatic contributions to the formation energy due to the polar field in $LaAlO_3$, structural distortions also play an important role in the energetics. We build a simple analytical model to describe our findings which allows us to determine the critical thickness for an oxygen vacancy-induced metal-insulator transition. We discuss the relation of these predictions to the experimental results on this interfacial system.

10:36AM A34.00014 Electronic Phase Separation at the $LaAlO_3/SrTiO_3$ Interface , A. ARIANDO, X. WANG, Z.Q. LIU, J.B. YI, A. ANNADI, A. ROY BARMAN, A. RUSYDI, S. DHAR, Y.P. FENG, J. DING, T. VENKATESAN, National University of Singapore, Singapore, G. BASKARAN, The Institute of Mathematical Sciences, India, J. HUIJBEN, H. HILGENKAMP, University of Twente, The Netherlands — Among the wealth of electronic and magnetic properties exhibited by complex oxides, electronic phase separation (EPS) is one of those whose presence can be linked to many types of exotic behavior, such as colossal magnetoresistance, metal- insulator transition and high-temperature superconductivity. Recently, the oxide community has once again been energized by the observation of a variety of new and unusual electronic phases at the interfaces between the complex oxides, in particular between two nonmagnetic insulators $LaAlO_3$ and $SrTiO_3$. However, no EPS has been observed thus far in this system despite a theoretical prediction. Here, we will show the observation of a ferromagnetic phase and its coexistence with a paramagnetic or a giant diamagnetic phase below 60 K at the interface between $LaAlO_3$ and $SrTiO_3$. The ferromagnetic phase persists even above room-temperature. The coexistence of these multiple magnetic phases along with the interface quasi- 2D electron gas suggests that EPS exists in this system, which can be explained on the basis of selective occupancy of interface sub-bands derived from the nearly degenerate t_{2g}- orbitals of Ti $3d$-states in the $SrTiO_3$.

10:48AM A34.00015 Electronic Phases and Phase Separation in the Hubbard-Holstein Model of a Polar Interface[1] , BIRABAR NANDA, SASHI SATPATHY, University of Missouri — From a mean-field solution of the Hubbard-Holstein model, we show that a rich variety of different electronic phases can result at the interface between two polar materials such as $LaAlO_3/SrTiO_3$. Depending on the strengths of the various competing interactions, viz., electronic kinetic energy, electron-phonon interaction, Coulomb energy, and electronic screening strength, the electrons could (i) either be strongly confined to the interface forming a 2D metallic or an insulating phase, (ii) spread deeper into the bulk making a 3D phase, or (iii) become localized at individual sites forming a Jahn-Teller polaronic phase. In the polaronic phase, the Coulomb interaction could lead to unpaired electrons resulting in magnetic Kondo centers. Under appropriate conditions, electronic phase separation may also occur resulting in the coexistence of metallic and insulating regions at the interface.

Monday, March 21, 2011 8:00AM - 10:48AM –
Session A35 DCMP: Topological Insulators: Growth C140

8:00AM A35.00001 Epitaxial Growth of Bi2Se3 Topological Insulator Thin Films on Si (111) , LIANG HE, FAXIAN XIU, Dept. of Elec. Eng., UCLA, YONG WANG, The University of Queensland, ALEXEI V. FEDOROV, Lawrence Berkeley National Laboratory, GUAN HUANG, XUFENG KOU, Dept. of Elec. Eng., UCLA, WARD P. BEYERMANN, Dept. of Phys., UCR, JIN ZOU, University of Queensland, KANG L. WANG, Dept. of Elec. Eng., UCLA, DEPT. OF ELEC. ENG., UCLA TEAM, MATERIAS ENGINEERING, THE UNIVERSITY OF QUEENSLAND COLLABORATION, ADVANCED LIGHT SOURCE DIVISION, LAWRENCE BERKELEY NATIONA LABORATORY COLLABORATION, DEPT. OF PHYS., UCR COLLABORATION — We report the studies of Bi2Se3 epitaxial films on Si(111) substrate using molecular beam epitaxial techniques. The structural properties of as-grown films have been investigated by AFM, STM and TEM, which exhibit good crystalline quality and terrace-like quintuple layers on the surfaces. Single-Dirac-cone-like surface states with a linear (E-K) dispersion have been observed through ARPES. Temperature- and thickness-dependent magneto-transport measurements indicate a combination of shallow impurity band hopping and surface-state electron conductions. More significantly, a very high surface contribution up to 50% can be estimated in these ultrathin films, promising a potential applications in nanoelectornics and spintronics.

8:12AM A35.00002 Topological insulator Bi2Se3 thin film growth by MBE , SHUANG LI, YIJIE HUO, DONG LIANG, Stanford University, THORSTEN HESJEDAL, University of Waterloo, JAMES HARRIS, Stanford University — Single crystalline high quality Bi2Se3 thin films were growth by molecular beam epitaxy (MBE) on sapphire c-plain substrate in UHV environment. X-ray diffraction (XRD) proved single crystal growth is achieved. Atomic ratio was measured by x-ray photoelectron spectroscopy (XPS) and Auger electron spectroscopy. The growth parameters, including substrate temperatures ranging from room temperature to 400°C, growth rate ranging from 0.5 nm/minute to 10 nm/minute and bismuth and selenium flux ratio, were optimized based on the results from scanning electron microscope (SEM), atomic force microscopy (AFM), XRD, and Raman spectroscopy. Triangle and hexagonal single crystals were preferred in the beginning of the growth at high temperature. More Bi2Se3 growth mechanisms will be discussed in the conference.

8:24AM A35.00003 Crystal growth and physical property of Bi-Sb-Te-Se topological insulator materials[1] , GENDA GU, ZHIJUN XU, WEIDONG SI, ZHIHUI PAN, TONICA VALLA, JOHN TRANQUADA, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory — The discovery of 3D topological insulator materials opens up a new research field in the condensed matter physics. In order to exploit the novel surface properties of these topological insulators, it is crucial to achieve a bulk-insulating state in these topological insulator crystals. Unfortunately, all available topological insulator crystals are not bulk-insulating. We have grown a number of Bi-Se, Bi-Te, Sb-Te-Se, Bi-Sb-Se and Bi-Sb-Te-Se topological insulator single crystals by using 5N and 6N pure elements. We have measured the physical properties on these single crystals. We have studied the effect of growth condition and impurity on the bulk electrical conductivity of these single crystals. We try to answer two questions if it is possible to grow the bulk-insulating topological insulator single crystals and Which maximum resistivity of these topological insulator single crystals we can grow.

[1]The work was supported by the DOE under contract No. DE-AC02-98CH10886.

8:36AM A35.00004 MBE growth of topological insulator Bi2Se3 and Bi2Te3 films , TONG ZHANG, 1. Center for Nanoscale Science and Technology, NIST, Gaithersburg, MD, 2. Maryland NanoCenter, UMD, College Park, MD, NIV LEVY, YOUNG JAE SONG, JUNGSEOK CHAE, JOSEPH A. STROSCIO, Center for Nanoscale Science and Technology, NIST, Gaithersburg, MD — Three-dimensional (3D) topological insulators are a new state of quantum matter with a band gap in bulk but gapless states on the surface. The surface states with spin helicity can be the host of many striking quantum phenomena. In this work, we use ultrahigh vacuum molecular beam epitaxy to grow atomically flat topological insulator (TI) Bi2Se3 and Bi2Te3 films. High quality TI films were obtained using epitaxial graphene on SiC as a substrate for TI growth. The growth dynamics was characterized by real time reflection high-energy electron diffraction (RHEED). The growth condition was optimized by adjusting for proper flux rate and substrate temperature while monitoring the RHEED patterns. In situ Auger spectroscopy and scanning tunneling microscopy (STM) measurements at 5K are used to study the as-grown films for their stoichiometry and defect density. We expect these MBE grown samples will provide a good candidate for studying the topological surface states and related phenomena, which will be studied using scanning tunneling spectroscopy at millikelvin temperatures [1]. 1. Y. J. Song et al., Nature 467, 185 [2010].

8:48AM A35.00005 Growth of the topological insulator Bi2Se3 on Al2O3 by molecular beam epitaxy , PHILLIP TABOR, CAMERON KEENAN, DAVID LEDERMAN, SERGEI URAZHDIN, West Viginia University Department of Physics — We report the growth of single crystalline Bi_2Se_3 on Al_2O_3 (110) by molecular beam epitaxy. Previous studies utilizing silicon as a substrate demonstrate favorable structural, optical and transport properties, although this can include contributions from the substrate-film interface. In contrast, growth on Al_2O_3 may influence substrate-film interfacial contributions to structural and electronic properties. Films grown under a range of temperatures and relative selenium to bismuth deposition rates were characterized by ex-situ XPS, XRD, and Hall measurements and will be compared to previous measurements using silicon as a substrate.

9:00AM A35.00006 Growth of topological insulator Bi2Se3 thin films by the van-der-Waals epitaxy on vicinal Si(111) substrate , Z.Y. WANG, Physics Department, The University of Hong Kong, Pokfulam Road, Hong Kong, China, H.D. LI, Physics Department, The University of Hong Kong, Pokfulam Road, Hong Kong, China; and Department of Physics, Beijing Jiaotong University, Beijing, X. KAN, X. GUO, Physics Department, The University of Hong Kong, Pokfulam Road, Hong Kong, China, H.T. HE, Z. WANG, J.N. WANG, T.L. WONG, N. WANG, Physics Department, Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong, People's Republic of China, M.H. XIE, Physics Department, The University of Hong Kong, Pokfulam Road, Hong Kong, China — Thin films of Bi2Se3, a three-dimensional topological insulator, have been synthesized by molecular-beam epitaxy with varying thicknesses. Their surface, structural and transport properties have been characterized. For the purpose of lowering the structural defects in film, van-der-Waals epitaxy (vdWe) was adopted in a "two-step" growth process, where the initial low-temperature seed layer is followed by a crystalline layer grown at elevated temperatures. Employing vicinal Si(111) substrates, the crystallinity and surface morphology of the epiflm is further improved. Relatively high magnetoresistance along with its linear dependence on the magnetic field at high fields have been observed in the vicinal samples.

9:12AM A35.00007 Coherent heteroepitaxy of Bi_2Se_3 on GaAs and ZnSe , A. RICHARDELLA, D.M. ZHANG, J.S. LEE, A. KOSER, N. SAMARTH, Physics Dept., Penn State University, University Park PA 16802, A. YEATS, B.B. BUCKLEY, D.D. AWSCHALOM, Physics Dept., University of California, Santa Barbara CA 93106 — Bi_2Se_3 is considered to be one to the most promising topological insulator candidate materials currently known because of its 0.3eV bandgap and mid-gap Dirac point. We use molecular beam epitaxy to deposit high quality c-axis oriented single crystal thin films of Bi_2Se_3 on (111) surfaces of GaAs after the growth of either GaAs or ZnSe buffer layers. Atomic force microscopy reveals films with large single quintuple layer terraces hundreds of nanometers wide. Transmission electron microscopy shows an atomically sharp interface at the heterostructure and narrow X-ray diffraction rocking curves indicate good quality single crystalline growth. We discuss the variation in carrier density, mobility and magnetoresistance with growth conditions. Spatially- and temporally-resolved Kerr spectroscopy allows us to explore coherent electron spin dynamics at the interface between this promising topological insulator and conventional semiconductor heterostructures. Supported by NSF and ONR.

9:24AM A35.00008 MBE growth of topological insulator Bi_2Se_3 on epitaxial graphene on 6H-SiC(0001) , Y. LIU, University of Wisconsin-Milwaukee, M. WEINERT, L. LI — In this work, we report results on the MBE growth of Bi_2Se_3, a prototypical topological insulator, on epitaxial graphene on 6H-SiC(0001). Step flow growth is observed, characterized by atomically smooth terraces that are 10 to 50 nm in width and separated by steps of 1-2 quintuple-layer in height. Two characteristic peaks at 130.21 and 171.48 cm^{-1} are observed by Raman spectroscopy, corresponding to the in-plane E_g^2 and out-of-plane A_{1g}^2 vibrational modes, respectively. The close resemblance of the positions and line shapes of both peaks to that of bulk Bi_2Se_3 demonstrates the very high quality of the film. Oscillations are also observed near the steps in dI/dV imaging, attesting to the metallic nature of the surface states of the topological insulator Bi_2Se_3.

9:36AM A35.00009 Transition-metal impurities and intercalation in Bi_2Se_3 , M. WEINERT, Y. LIU, L. LI, U. Wisconsin-Milwaukee — The prototype topological insulator Bi_2Se_3 consists of 5-layer (QL) units. Using first-principles calculations, we show that even for large (20%) elongations along the c-axis, the in-plane lattice constant remains essential unchanged and the nearest neighbor bond lengths within a QL vary by only $\sim$0.02 Å. These results suggest that impurities may preferentially intercalate between the QLs, possibly leading to δ-doped topological insulator superlattices. For Cu-intercalated Bi_2Se_3, the calculated separation between QLs slightly contracts ($\sim$2%), and the Cu intercalation layer provides the internal surfaces necessary for the material to exhibit a Dirac cone. The competition between substitutional impurities and intercalation layers for Cu and Mn will be discussed and compared to experiment.

9:48AM A35.00010 Epitaxial Bi_2Se_3 films on Si (111) with atomically sharp interface , ELIAV EDREY, YONG SEUNG KIM, NAMRATA BANSAL, YOICHI HORIBE, SEONGSHIK OH, Rutgers University, OH GROUP TEAM — Atomically sharp epitaxial growth of Bi_2Se_3 films has been achieved on Si (111) substrate with MBE. The growth was self-limited; that is, growth rate was determined completely by Bi flux with excess Se species around. The Bi:Se flux ratio, measured by QCM, was kept $\sim$1:15. Two step growth temperatures were a key to achieving second-phase-free high quality Bi_2Se_3 films on Si substrates. With single-step high temperature growth, second phase, presumably $SiSe_2$ clusters, was formed at the early stage of growth. On the other hand, with low temperature growth, crystalline quality of the films was poor even if second phase was absent. With low temperature initial growth followed by high temperature growth, second-phase-free atomically sharp interface was obtained between Bi_2Se_3 and Si substrate, as verified by RHEED, TEM and XRD. The lattice constant of Bi_2Se_3 relaxed to its bulk value during the first quintuple layer based on the RHEED analysis, implying the absence of strain from the substrate. Single-crystalline XRD peaks of Bi_2Se_3 were observed in films as thin as 4 QL. TEM shows full epitaxial structure of Bi_2Se_3film down to the first quintuple layer without any second phases. This growth method was used to grow high quality epitaxial Bi_2Se_3 films from 3 QL to 3600 QL.

10:00AM A35.00011 Robust surface state and bulk carrier density in transport properties of Bi2Se3 films grown with MBE , YONG SEUNG KIM, Sejong University, NAMRATA BANSAL, ELIAV EDREY, MATHEW BRAHLEK, GARY A. KAPILEVICH, SANG-WOOK CHEONG, SEONGSHIK OH, Rutgers University — One of the main predictions of 3D topological insulators (TI) is the existence of a surface metallic state, independent of the sample thickness. However, so far this simple prediction has never been experimentally verified because of significant parallel bulk conduction. Here, we report observation of a robust 2D surface state for MBE-grown thin films in their magneto-transport properties. We also observed that volume carrier density tends to decrease as film gets thicker. Even if a robust 2D surface state exists, its topological protection seems to degrade in thin films due to interference with the bulk carriers, and thus this bulk carrier problem will be the most important next step to solve in order to implement the full topological protection on this surface state.

10:12AM A35.00012 Controlling the topological states of Bi_2Se_3 by silver atom intercalation , M. YE, K. KURODA, M. NAKATAKE, S. KIM, Y. YAMADA, A. KIMURA, K. MIYAMOTO, M. ARITA, T. OKUDA, K. SHIMADA, Hiroshima University, Y. UEDA, Kure National College of Technology, H. NAMATAME, M. TANIGUCHI, Hiroshima University — Among the known topological insulators, the layered material, Bi_2Se_3, is one of the most promising candidates for potential applications to ultra-low power consumption quantum devices that can work stably at room temperature due to a sufficiently large energy gap in the bulk. The realization of quantum devices generally requires the exposure of the materials to ambient conditions, which significantly disturbs the topological properties through absorption. While intercalation of impurities into layered materials might be thought to be usually detrimental, we show here that that intercalation of Ag into Bi_2Se_3 has a benefit. After depositing silver atoms on the surface of Bi_2Se_3, massive electrons can be formed on the surface due to the decoupling of the layer-structure by silver intercalation. The newly formed massive electron observed on the surface serves as an evidence of an extremely weak interaction between the decoupled layers and the bulk TI crystal. These results strongly suggest the existence of a new non-trivial boundary state, which opens a pathway to realizing topological insulator-based electronic and spintronic devices, and fault tolerant quantum computation.

10:24AM A35.00013 Magnetically doped nanoplate crystals of topological insulators Sb_2Te_3 and Bi_2Te_3[1] , LUKAS ZHAO, LIN BO, LIMIN HUANG, ALISA AGAFONOVA, SIMON DIVILOV, STEPHEN O'BRIEN, MYRIAM SARACHIK, LIA KRUSIN-ELBAUM, CCNY — The surface states of topological insulators are robustly protected by time-reversal symmetry. Introducing magnetic impurities should open a gap in the otherwise gapless surface states. Recent first-principle calculations predict that when topological insulators are doped with transition metal elements, such as Cr or Fe, a *magnetically ordered* insulating state will form, a state distinctly different from the conventional dilute magnetic semiconductors. In thin (quasi-2D) samples, this magnetic order gives rise to a topological electronic structure, with the quantized Hall conductance. Here we report synthesis and electrical and magnetic characterization of Fe and Cr doped *thin* nanoplates of topological insulators Sb_2Te_3 and Bi_2Te_3. Nanoplate crystals were grown by catalyst-free vapor-liquid-solid method and were doped using the *in situ* exchange of sources. Low-temperature magnetic, in-plane resistivity, and Hall measurements were performed in magnetic fields up to 9 T fields. The effects of magnetic dopant concentration on susceptibility and charge transport will be discussed.

[1]Supported in part by CCNY Center for Exploitation of Nanostructures in Sensors and Energy Systems (CENSES) and by NSF-DMR-0451605

10:36AM A35.00014 Atmospheric Doping Affects on the Transport Properties of the Topological Insulator Bismuth Selenide (Bi_2Se_3) Grown By MBE , MATTHEW BRAHLEK, YONG SEUNG KIM, NAMRATA BANSAL, ELIAV EDREY, SEONGSHIK OH, Rutgers University — During the last five years much experimental work has been done to determine if the theoretical prediction of topological insulting (TI) states truly exist. Angle resolved photo emission spectroscopy (ARPES) measurements have shown that a Dirac type linear dispersion does exist for a variety of materials, and the surface states have been observed by direct transport measurements. The next challenge is to isolate the surface electrons by removing the bulk conduction. This not trivial because bismuth selenide's Fermi energy sits in the conduction band, and most of the measured carriers are due to these bulk states. The prediction is that the surface states are robust under perturbation, but like standard semiconductors, Bi_2Se_3's bulk states are sensitive to doping. I will report on our work done on how the transport properties of MBE grown Bi_2Se_3 thin films are affected by atmospheric dopants such as oxygen and water vapor. Future prospects for studying TIs such Bi_2Se_3 and ultimately building a device depend on being able to tune the Fermi level into the gap thereby isolating the surface states, and then passivating the surface against contamination due to atmospheric oxygen and water vapor.

Session A36 DMP GERA: Focus Session: Scalable Technologies for Terawatt Photovoltaics

C142

8:00AM A36.00001 Film Si photovoltaics from high quality c-Si layers on inexpensive substrates[1] , PAUL STRADINS, National Renewable Energy Laboratory — We develop crystalline silicon film photovoltaic (PV) technology to approach the efficiency of wafer silicon PV at thin-film manufacturing costs. Epitaxial c-Si layers can be grown by a fast, scalable hot-wire CVD technique at rates that exceed those of amorphous and nanocrystalline thin film PV by factor of 20, with quality approaching that of the crystalline Si wafer. This approach greatly reduces the absorber material costs that today account for about half the cost of a Si wafer PV module while bypassing the low growth-rate bottleneck that dominates thin film Si PV economics. As part of this equation, devices must also be fabricated on inexpensive substrates. To this end, we explore homo- and hetero-epitaxy at display glass-compatible temperatures as well as collaborate with several groups on promising high crystal quality seed layer technology. In the talk, we discuss key physics issues associated with film Si PV and describe recent experimental results, including: 1) device physics showing feasibility of 2 -10 microns thick c-Si PV absorber layers and their relative tolerance to defects and impurities; 2) demonstration of epitaxial cells on Si wafers with open-circuit voltages up to 600 mV; 3) understanding of high-rate, high-quality epitaxial growth in the temperature range 620 to 760C; 4) growth on seed layers on display glass and metal foils; 5) novel light trapping schemes that result in improved spectral response without texturing the growth template or etching away valuable absorber layer material.

[1]This work is supported by the U.S. Department of Energy Solar Energy Technology Program under Contract No. DE-AC36-99GO10337.

8:36AM A36.00002 CdTe Solar Cells Scaling to Grid Parity , DAVID EAGLESHAM, First Solar — CdTe thin-film solar cells are leading the technology race to deliver low-cost and sustainable photovoltaics. The technology has an inherent cost advantage over c-Si, and has achieved volume manufacturing ahead of any other thin-film technology. TF-CdTe is also more sustainable than other approaches, with a lower carbon-footprint and far faster energy-payback than c-Si. Having achieved the long-standing target of $1/W module and well over 1GW/year in volume, the technology is continuing to drive down costs towards a levelised cost of electricity comparable to fossil fuels.

9:12AM A36.00003 Challenges to Scaling CIGS Photovoltaics , B.J. STANBERY, HelioVolt — The challenges of scaling any photovoltaic technology to terawatts of global capacity are arguably more economic than technological or resource constraints. All commercial thin-film PV technologies are based on direct bandgap semiconductors whose absorption coefficient and bandgap alignment with the solar spectrum enable micron-thick coatings in lieu to hundreds of microns required using indirect-bandgap c-Si. Although thin-film PV reduces semiconductor materials cost, its manufacture is more capital intensive than c-Si production, and proportional to deposition rate. Only when combined with sufficient efficiency and cost of capital does this tradeoff yield lower manufacturing cost. CIGS has the potential to become the first thin film technology to achieve the terawatt benchmark because of its superior conversion efficiency, making it the only commercial thin film technology which demonstrably delivers performance comparable to the dominant incumbent, c-Si. Since module performance leverages total systems cost, this competitive advantage bears directly on CIGS' potential to displace c-Si and attract the requisite capital to finance the tens of gigawatts of annual production capacity needed to manufacture terawatts of PV modules apace with global demand growth.

9:48AM A36.00004 CZTSSe: Materials and Physics Challenges[1] , OKI GUNAWAN, IBM T J Watson Research Center — Thin-film photovoltaic (PV) technologies led by CdTe and Cu(In,Ga)Se_2 (CIGS) are enjoying growing market share, due to their high performance and cost competitiveness, in the quest for renewable energy for the future. However the reliance on non-earth abundant elements tellurium and indium in these technologies presents a potential obstacle to ultimate terawatt deployment. We recently demonstrated kesterite $Cu_2ZnSn(Se,S)_4$ (CZTSSe) solar cells, comprised of the earth abundant metals copper, zinc and tin, with world record efficiency of 9.7%. In this talk we present a comprehensive device characterization study that pinpoints the key performance bottlenecks in these cells. We find strong buffer-absorber interface recombination and low minority carrier lifetimes that limit the open circuit voltage and a high and diverging device series resistance at lower temperature that suggests a blocking back contact that may limit the fill factor. These findings help to identify key areas for improvement for these CZTSSe cells in the pursuit of a high performance terawatt-scalable PV technology.

[1]In collaboration with Teodor K. Todorov, Aaron Barkhouse, Kejia Wang, David B. Mitzi, Supratik Guha, IBM T J Watson Research Center.

10:24AM A36.00005 Screening of inorganic wide-bandgap p-type semiconductors for high performance hole transport layers in organic photovoltaic devices , DAVID GINLEY, ANDRIY ZAKUTAYEV, ANDREAS GARCIA, NICODEMUS WIDJONARKO, PAUL NDIONE, AJAYA SIGDEL, PHILLIP PARILLA, DANA OLSON, JOHN PERKINS, JOSEPH BERRY, National Renewable Energy Laboratory — We will report on the development of novel inorganic hole transport layers (HTL) for organic photovoltaics (OPV). All the studied materials belong to the general class of wide-bandgap p-type oxide semiconductors. Potential candidates suitable for HTL applications include SnO, NiO, Cu2O (and related CuAlO2, CuCrO2, SrCu2O4 etc) and Co3O4 (and related ZnCo2O4, NiCo2O4, MgCo2O4 etc.). Materials have been optimized by high-throughput combinatorial approaches. The thin films were deposited by RF sputtering and pulsed laser deposition at ambient and elevated temperatures. Performance of the inorganic HTLs and that of the reference organic PEDOT:PSS HTL were compared by measuring the power conversion efficiencies and spectral responses of the P3HT/PCBM- and PCDTBT/PCBM-based OPV devices. Preliminary results indicate that Co3O4-based HTLs have performance comparable to that of our previously reported NiOs and PEDOT:PSS HTLs, leading to a power conversion efficiency of about 4 percent. The effect of composition and work function of the ternary materials on their performance in OPV devices is under investigation.

10:36AM A36.00006 A New Paradigm for Multijunction Solar Cells , MARINA LEITE, CALTECH, ROBYN WOO, Spectrolab Inc., EMILY WARMANN, Caltech, DANIEL LAW, Spectrolab Inc., HARRY ATWATER, Caltech — We propose an approach for a multijunction solar cell (MJSC) based on direct band gap InAlAs/InGaP/InGaAsP/InGaAs alloys. Device simulations indicate that the proposed design can achieve over 50 % efficiency at 100-suns illumination by using an alloy combination with lattice parameter of 5.80 Å. For that, we created a virtual substrate for epitaxial growth. By relieving 40nm thick coherently-strained $In_xGa_{1-x}As$ films from InP substrates, full relaxation occurs preserving the crystalline quality of the films, as confirmed by X-ray diffraction, transmission electron microscpy and photoluminescence measurements. Once these films are transferred to a cheap support they can be used as a template for epitaxial growth with specifically chosen lattice parameter and therefore band gap energy. Our realization demonstrates the ability to control the lattice parameter and energy band structure of single layer crystalline alloy semiconductors in an unprecedented way. For the top subcell, we fabricated InAlAs solar cells with efficiencies > 14 % and Voc $= 1$ V. These results indicate that the novel MJSC design is feasible. Future directions and subcells performance will be presented.

10:48AM A36.00007 Resonant TCO nanostructures for improved light trapping in thin-film photovoltaics , ALOK VASUDEV, MARK BRONGERSMA, Stanford University — The desire for widespread photovoltaic (PV) adoption has motivated many recent efforts in advanced photon management in thin-film solar cells. Approaches to enhance PV optical absorption by exploiting surface plasmon resonances in metallic nanostructures, in particular, have been extensively studied. Here we present an alternative means to improve light trapping in thin-film solar cells using resonant transparent conductive oxide (TCO) nanostructures. Dielectric nanowires support leaky mode resonances, which, in poorly absorbing media, can scatter light efficiently. This resonant scattering can enhance optical absorption in a nearby photoabsorber. Using finite difference frequency domain (FDFD) techniques we show that an optimized planar solar cell's performance is improved by patterning the TCO into resonant scatters. Unlike their plasmonic counterparts, these resonators do not suffer large absorption losses, depend strongly on polarization or force a radical change in processing. We will discuss scalability, future improvements and application to a variety of solar cell configurations.

Monday, March 21, 2011 8:00AM - 11:00AM –

Session A37 DMP: Focus Session: Graphene: Growth, Characterization and Devices: Theory and Transport C146

8:00AM A37.00001 Engineering gate-controlled potential barrier and nano-constriction in bi-layer graphene , CHING-TZU CHEN, IBM TJ Watson Research Center, HSIN-YING CHIU, DAVID DIVINCENZO, SIYURANGA KOSWATTA — Graphene, as a material with zero net nuclear spin and a small spin-orbit coupling, is a natural candidate for building quantum-dot-based spin qubits, since electron spin coherence time can potentially be much longer compared to the prevailing GaAs-based systems. To date, graphene quantum dots have largely been realized using etch-defined nanoribbons or nano-islands. Due to fabrication-related edge defects or channel doping inhomogeneity, these etch-defined nanostructures generally suffer from randomly distributed incidental dots, causing undesirable resonance peaks in transport. To eliminate the disorder-induced localized states, we explore the possibility of electron confinement by using electric-field-controlled band gap opening in bilayer graphene. In this talk, we discuss various nanostructure designs towards this aim. We will present the transport characteristics of the dual-gated and side-gated devices, compare their performance, and analyze the gate tunability in various configurations. We will also comment on their use in quantum dots and other device applications.

8:12AM A37.00002 First Principle Simulations of Dual Gate Bilayer Graphene Field Effect Nanotransistors , J.E. PADILHA, M.P. LIMA, A.J.R. DA SILVA, A. FAZZIO, University of São Paulo — In this work we present, via first principle calculations, a study of bilayer graphene dual-gate field effect nanotransistor. We show the $I_{ds} \times V_{ds}$ curves as a function of the channel length, back(V_{bg})/top(V_{tg}) gate voltages, temperature and charge excess on the system. For this study we use Landauer-Büttiker model with Hamiltonian generated through ab initio Density Functional Theory coupled with non-equilibrium Green's Function formalism. To investigate finite gates we implement a multigrig real space Poisson solver. Our results shows that the current can be tuned varying the strength of the electric field by setting different values of $V_{bg}(V_{tg})$ as well as modifying the channel length. We also show that the current depends on the amount of net charge in the system, controlled by the $V_{bg}(V_{tg})$ values, and the minimum of flowing current occurs when the system is neutral (charge neutrality point) only for gate lengths bigger than $4nm$. In all calculations we find a finite current due to a temperature effect associated with the Fermi-Dirac distribution. Decreasing the temperature from $300K$ to $4.5K$ the current diminishes one order of magnitude. Our study predicts that bilayer graphene dual gate field effect nanotransistors with small channel lengths ($< 5nm$) presents a upper limit for the ON/OFF current ratio of 10 for $300K$ and 100 for $4.5K$. This ratio can be increased using larger channel lengths.

8:24AM A37.00003 Charge transport in dual-gated bilayer-graphene Corbino-disk[1] , JUN YAN, MICHAEL FUHRER, Center for Nanophysics and Advanced Materials, University of Maryland, College Park, MD 20742-4111, USA — We use the Corbino-disk geometry to study the electron transport behavior of dual-gated bilayer graphene devices. Experimental exclusion of the edge states enables us to probe the bulk of bilayer graphene and its electronic properties. The temperature dependence of the maximum resistivity is found to be well described by simple thermal activation at high temperatures and variable range hopping at low temperatures, consistent with other transport studies. The electric-field-dependent band gap extracted from thermal activation is found to be in good agreement with infrared spectroscopic studies (Zhang et al. Nature 459, 820 (2009)). The similarity of our data to those of conventional dual-gated bilayer graphene devices with edges suggests that edges do not play a significant role in such devices at least for temperatures above 5 K, and points to the importance of reducing bulk disorder for improving device performance.

8:36AM A37.00004 Theory of the electronic and transport properties of epitaxial graphene[1] , MARCO BUONGIORNO NARDELLI, North Carolina State University — Advances in the epitaxial growth of graphene films on SiC have the potential to open new classes of device applications that may revolutionize the semiconductor roadmap for future decades. However, this progress will require an in-depth understanding and utilization of the electronic processes that take place at the nanoscale. In this talk I will review our recent results on the electronic and transport properties of epitaxial graphene on SiC. Using calculations from first principles, I will discuss the the role of the interface buffer layer in the tuning of the band alignment and the magnetic doping at the heterojunction; I will describe the effect of electron-phonon interactions in mono- and bi-layer graphene in determining the intrinsic carrier-phonon scattering properties of this material and thus the ultimate limit of any electronic device; finally, I will briefly discuss the thermal properties of the graphene/SiC interface, since understanding of the heat transfer properties is essential for optimal thermal management and heat removal in device applications.

9:12AM A37.00005 Strong Enhancement of Doping in Graphene via Substrate , BING HUANG, SU-HUAI WEI, National Renewable Energy Lab — Controlling the type and density of charge carriers by doping is the key step for developing graphene electronics. Based on first-principles calculations, we demonstrate that doping could be strongly enhanced in epitaxial graphene on silicon carbide (SiC) substrate. Compared to free- standing graphene, the formation energies of dopants decrease dramatically by 2 $\sim$ 8 eV. The dopants prefer to stay in the interface buffer layer between epitaxial graphene and substrate, which could tune the interface dipoles evidently. The type and density of charge carriers of epitaxial graphene layer can be effectively manipulated by suitable dopants and surface passivation. Contrasting to the direct doping of graphene, the charge carriers in epitaxial graphene layer are weakly scattered by dopants due to the spatial separation between dopants and conducting channel, in the spirit of modulation doping, which takes advantages in maintaining the high carrier mobility of graphene. Beyond controlling the charge carriers via buffer layer doping, we find that the reconstructed vacancy in the interface buffer layer breaks the spin symmetry of epitaxial graphene, which induces a half-metallic state without magnetic impurities doping.

9:24AM A37.00006 Magnetic impurities in graphene with defects , FEIMING HU, RISTO NIEMINEN, COMP/Department of Applied Physics, School of Science and Technology, Aalto University, Finland — We theoretically study magnetic impurities in graphene with defects. The defects are described by vacancies which can be realized in graphene experimentally. The occupancy number, local moment and spin susceptibility of the impurities are calculated by quantum Monte Carlo simulations. When the Fermi energy of the system is changed by gate voltage, it is found that the behaviors of these physical quantities are very different from those in perfect graphene. The spectral density of the impurity is also studied by maximum entropy methods to explain these unusual behaviors.

9:36AM A37.00007 Carrier Transport in Epitaxial Multi-layer Graphene , YU-MING LIN, CHRISTOS DIMITRAKOPOULOS, DAMON FARMER, SHU-JEN HAN, YANQING WU, WENJUAN ZHU, IBM, D. KURT GASKILL, JOSEPH TEDESCO, RACHAEL MYERS-WARD, CHARLES EDDY, JR., NRL, ALFRED GRILL, PHAEDON AVOURIS, IBM, IBM TEAM, NRL TEAM — Significant attention has been focused recently on the electrical properties of graphene grown epitaxially on SiC substrates, because it offers an ideal platform for carbon-based electronics using conventional top-down lithography techniques. The transport properties of graphene are usually studied via Hall effect measurements, which provide information on the carrier mobility and density. Hall measurements performed at a single magnetic field yield a weighted average of carrier mobility and density, and are strictly applicable to homogeneous samples. In this study, we performed variable-field Hall and resistivity measurements on epitaxial graphene, and the results were analyzed with a multi-carrier model. Good agreements were obtained between experimental data and the model, providing further evidence of multi-carrier transport in the C-face grown MLG. This work is supported by DARPA under contract FA8650-08-C-7838 through the CERA program and by the Office of Naval Research.

9:48AM A37.00008 Hole-channel conductivity in epitaxial graphene determined by terahertz optical Hall-effect and midinfrared ellipsometry[1] , T. HOFMANN, A. BOOSALIS, P. KÜHNE, University of Nebraska-Lincoln, J.L. TEDESCO, D.K. GASKILL, U.S. Naval Research Laboratory, C.M. HERZINGER, J.A. Woollam Co. Inc., Lincoln, NE, J.A. WOOLLAM, M. SCHUBERT, University of Nebraska-Lincoln — We report non-contact, optical determination of free-charge carrier mobility, sheet density, and effective mass parameters in epitaxial graphene at room temperature using terahertz and midinfrared ellipsometry and optical Hall-effect (generalized ellipsometry in magnetic fields) measurements. The graphene layers are grown on Si- and C-terminated semi-insulating 6H silicon carbide polar surfaces. Data analysis using classical Drude functions and multilayer modeling render the existence of a p-type channel with different sheet densities and effective mass parameters for the two polar surfaces. The optically obtained parameters are in excellent agreement with results from electrical Hall effect measurements.

[1]ARO (W911NF-09-C-0097), NSF (MRSEC DMR-0820521, MRI DMR-0922937, DMR-0907475), and Office of Naval Research

10:00AM A37.00009 Quantum corrections to the conductivity in graphene , ALEKSEY KOZIKOV, University of Exeter, FEDOR TIKHONENKO, University of Southampton, ALEX SAVCHENKO, University of Exeter, BORIS NAROZHNY, Karlsruhe Institute of Technology, ANDREI SHYTOV, University of Exeter — The low-temperature conductivity in electron systems is determined by two quantum corrections. They originate from the interference of electron waves scattered by impurities (weak localisation, WL) and electron-electron interaction (EEI) in the presence of disorder. In graphene, due to the chirality of charged carriers, the quantum interference is sensitive not only to inelastic, dephasing, scattering, but also to elastic, inter- and intra-valley, scattering processes. It was theoretically predicted that depending on the scattering rates of such processes, weak antilocalisation (WAL) is possible in graphene. In this work we study both magnetoresistance and the temperature dependence of the conductivity and observe a transition from WL to WAL by tuning the carrier density and temperature. We show that quantum interference in graphene can survive at temperatures up to 200 K due to weak electron-phonon scattering. We also investigate the EEI correction, which is separated from the WL correction by two methods, and show that it is also affected by intra-valley scattering. This scattering leads to a new temperature regime of EEI. We find the Fermi liquid constant to be small, -0.1, and discuss the origin of this value.

10:12AM A37.00010 First-principles Theory of Nonlocal Screening in Graphene[1] , MARK VAN SCHILFGAARDE, Arizona State University, MIKHAIL KATSNELSON, Radboud University Nijmegen — Using the quasiparticle self-consistent *GW* (QS*GW*) and local-density (LD) approximations, we calculate the q-dependent static dielectric function, and derive an effective 2D dielectric function corresponding to screening of point charges. In the $q\rightarrow 0$ limit, the 2D dielectric constant is found to scale approximately as the square root of the macroscopic dielectric function. Its value is $\simeq 4$, in agreement with the predictions of Dirac model. At the same time, in contrast with the Dirac model, the dielectric function is strongly dependent on q. The QS*GW* approximation is shown to describe QP levels very well, with small systematic errors analogous to bulk sp semiconductors. Local-field effects are rather more important in graphene than in bulk semiconductors.

10:24AM A37.00011 First-Principles Investigation of Polymer Binding to Graphene and Carbon Nanotubes[1] , OGUZ GULSEREN, AYJAMAL ABDURAHMAN, Bilkent University — The interactions between a polymer (Poly[(phenylene)-co-(9,9- bis-(6-bromohexyl)uorene)]) and graphene and carbon nanotubes are investigated by using pseudopotential planewave calculations based on density functional theory (DFT). In the quest of searching the most favorable binding configurations, the monomer under investigation is placed at different orientations on graphene. In order to obtain further insight into the binding interactions of polymer-graphene system, we also calculated the binding energy for the structure in which the polymer is attached to graphene sheet via atomic oxygen. Considering the graphene impurity, we have also further investigated the polymer approaching from the chain side onto graphene with a vacancy. However, our results demonstrated that the interaction between the (Poly[(phenylene)-co-(9,9-bis-(6-bromohexyl) uorene)]) polymer and graphene is weak, mostly dispersive, but this interaction is slightly stronger when the graphene has structural defects, like vacancies. The implications of these results to the polymer and carbon nanotube interactions also are discussed.

10:36AM A37.00012 Spectral and optical properties of doped graphene with charged impurities in the self-consistent Born approximation , FERNANDO DE JUAN, Instituto de Ciencia de Materiales de Madrid (ICMM-CSIC), EUYHEON H. HWANG, Condensed Matter Theory Center, Physics Department, University of Maryland, MARIA A. H. VOZMEDIANO, Instituto de Ciencia de Materiales de Madrid (ICMM-CSIC) — Spectral and transport properties of doped (or gated) graphene with long range charged impurities are discussed within the self-consistent Born approximation. It is shown how, for impurity concentrations greater than the electron concentration, $n_{imp} \geq n$, a finite DOS appears at the Dirac point, the one-particle lifetime no longer scales linearly with the Fermi momentum, and the lineshapes in the spectral function become non-lorentzian. These behaviors are different from the results calculated within the Born approximation. We also calculate the optical conductivity from the Kubo formula by using the self-consistently calculated spectral function in the presence of charged impurities.

10:48AM A37.00013 ABSTRACT WITHDRAWN –

Session A38 DCP: Focus Session: Ultrafast Dynamics and Imaging I A130/131

8:00AM A38.00001 Attosecond Physics: Time-dependent electronic dynamics in atoms, molecules, and solids[1] , JOACHIM BURGDOERFER, Institute for Theoretícal Physics, Vienna University of Technology — With the advent of sub-femtosecond ultrashort XUV pulses and of phase-stabilized IR pulses with sub-cycle time resolution, novel pathways have been opened up for studying time-resolved electronic quantum dynamics on the attosecond scale. These experiments pose challenges for theory: How do short pulses interact with matter? Which novel information can be extracted from time-resolved spectroscopies that cannot be gained from precision experiments in the spectral domain? In this talk, these issues will be addressed with the help of a few examples. Attosecond streaking allows a direct look at electronic correlations and rearrangement processes. Photoemissions from solid surfaces reveal an attosecond time delay between conduction electrons and core electrons and provide time-resolved information on electron transport, plasmon excitation, and dissipation. Attosecond pulses allow not only to probe but also to control and manipulate electronic dynamics which we will illustrate for two-electron emission from atoms and molecular break-up.

[1]In collaboration with J. Feist, S. Graefe, C. Lemell, S. Nagele, R. Pazourek, F. Krausz, V. Yakovlev, L. Collins, and B. Schneider, work supported by FWF-SFB 016 ADLIS.

8:36AM A38.00002 Simulation of Transmission Electron Microscopy in Time Domain[1] , JIA-AN YAN, Department of Physics, Georgia Southern University, J. DRISCOLL, KALMAN VARGA, S.T. PANTELIDES, Department of Physics, Vanderbilt University — Based on the time-dependent Schrodinger equation, a new method of simulating transmission electron microscope (TEM) images by directly propagating an electron wave packet in real time and real space is presented. Compared to other widely used methods, the new technique yields an accurate description of the electron scattering in solid thin films for both low-energy and the high-energy electrons. We demonstrate the method by simulating TEM images for silicon crystalline films and low-energy-electron diffraction (LEED) images of Si surfaces and graphene. The time-dependent simulations described here could be useful for studying ultrafast electron dynamics in solids.

[1]This work was supported in part by DOE grant DE-FG02-09ER46554.

8:48AM A38.00003 Ultrafast imaging of nanoclusters with intense x-ray laser pulses , CHRISTOPH BOSTEDT, Linac Coherent Light Source, SLAC National Accelerator Laboratory, Menlo Park, CA 94025 — Ultrafast x-ray scattering opens the door for unprecedented insight into the structure and dynamics of matter with atomic resolution. Any sample in an x-ray laser flash, however, will be converted into a highly excited, non-equilibrium plasma during the pulse. The scatter signal itself is sensitive to changes in the electronic structure of the sample leading to distortions of the signal intensities with respect to the ground state configuration. On the other hand, the information about the electronic structure carried by the scatter signal can be exploited to gain insight into transient electronic states on the femtosecond time scale of the x-ray pulse. We have performed single shot – single particle scattering experiments on clusters to investigate the interplay between excitation and scattering in nanoscale objects with x-ray pulses from both, the FLASH and LCLS free electron lasers. Atomic clusters have been proven ideal to investigate the interaction between intense light pulses and matter in a wide spectral regime from the infrared to x-rays due to their finite size and simple electronic structure. Spectroscopy data recorded in coincidence with the scattering patterns revealed strong power-density dependent ionization dynamics of the clusters. The scattering patterns themselves provide information on the 2-dim as well as 3-dim structure of clusters and of cluster ensembles. Modeling the scattering patterns indicates that the optical constants of the clusters, which are inherently coupled to its electronic structure and thus charge states, change during the femtosecond pulse. Time resolved experiments with pump – probe techniques have started which allow following the time evolution of cluster ionization up to several ps.

9:24AM A38.00004 Thermal transport in thin films measured by time-resolved grazing-incidence x-ray diffraction[1] , D.A. WALKO, Advanced Photon Source, Argonne National Laboratory, Y.-M. SHEU, University of Michigan, M. TRIGO, D.A. REIS, SLAC National Accelerator Laboratory and Stanford University — Depth- and time-resolved x-ray diffraction were used to study thermal transport across single crystal Bi films grown on sapphire, to determine the thermal conductivity of the films and the Kapitza conductance of the interfaces. Ultrafast Ti:sapphire laser pulses heated the films; x-ray diffraction measured the subsequent lattice expansion. Use of grazing incidence geometry provided depth sensitivity with the x-ray angle of incidence near the critical angle, in contrast to symmetric Bragg geometries which only measure the average temperature of the film. The shift of the film's Bragg peak position with time was used to determine the film temperature, averaged over an x-ray penetration depth that could be selected by choice of the angle of incidence. Films that were thick compared to the laser penetration depth exhibited a large temperature gradient at early times; in this case, measurements with the incident angle below and above the critical angle were more sensitive to the film conductivity and Kapitza conductance, respectively. For thinner films, however, cooling was dominated by the Kapitza conductance on all accessible time scales.

9:36AM A38.00005 Probing electron correlations by laser-induced tunnel ionization , ANDRÉ STAUDTE, National Research Council of Canada — Pairwise electron correlation has been intensely studied by projecting two electrons to the continuum simultaneously via a well controlled perturbation, e.g. a collision with an energetic electron, a fast ion or a single XUV photon. Electron correlation studies using multiphoton ionization remain an exception. One reason may be that recollision aside, studies in rare gas atoms have largely suggested that multiphoton multiple ionization in the tunneling limit proceeds sequentially - each successive ionization stage loosing memory of previous electronic correlations. On the other hand, laser tunnel ionization has been known to access multiple electronic states. Recent evidence, corroborating the notion that tunneling can prepare these correlated multielectron states in a coherent superposition, suggests that sequential multiple ionization may provide insight into dynamical correlations in the parent ion. Here, we demonstrate how dynamics of electron correlation can be investigated using laser-induced tunnel ionization by interrogating valence shell electrons in rare gas atoms with intense laser pulses. We find a strong spatial propensity in the sequential double tunnel ionization regime. For instantaneous emission, we find that the two electrons are preferentially emitted in perpendicular directions. Applying laser scanning tunneling microscopy in a pump-probe scheme we directly observe the periodic charge redistribution in the valence shell of singly charged noble gas atoms that was predicted by Santra and coworkers and recently inferred in an attosecond pump-probe experiment using XUV probe pulses. In contrast to single photon ionization, tunneling is highly directional. Here, we exploit that property of tunnel ionization to remove an electron from a rare gas atom along a specific spatial direction. We then probe the correlation by ionizing a second electron via a laser-induced tunneling gate. Since our tunneling gates are optically controlled, the second gate can be opened at any angle and at any time relative to the first. Hence, not only spatial but also temporal variations of the correlation can be probed. We demonstrate the generality of this concept by extending our measurements to a small molecule (HCl).

10:12AM A38.00006 2D Fano-resonances in momentum space , WAI-LUN CHAN, JOHN TRITSCH, ANDREI DOLOCAN, XIAOYANG ZHU, University of Texas at Austin — Using the model system of molecular quantum wells and image potential states at the C_{60}/Au(111) interface and the experimental technique of time- and angle-resolved two photon photoemission spectroscopy, we probe many body interaction in coupled two-dimensional (2D) systems. Transiently populated 2D bands with different effective masses are found to intersect with each other in the reciprocal space. At the points of intersection, we observe strong modulations in the photoemission intensity as a function of parallel momentum vector. The intensity modulation in the reciprocal space can be explained by the well-known Fano resonances – the interference between different quantum mechanical pathways in optical excitation. The experimental results agree semi-quantitatively with simulation based on optical Bloch's equations. Differing from conventional Fano resonances in energy space, our observation establishes the existence of 2D Fano resonance in momentum space.

Session A39 DBP: Focus Session: Energy Future: Biological and Biometric Systems A124/127

8:00AM A39.00001 Energy conversion in photosynthesis[1] , GARY BRUDVIG, Yale University — Photosystem II (PSII) uses light energy to split water into protons, electrons and O_2 [1]. In this reaction, Nature has solved the difficult chemical problem of efficient four-electron oxidation of water to yield O_2 without significant side reactions. In order to use Nature's solution for the design of materials that split water for solar fuel production, it is important to understand the mechanism of the reaction. The X ray crystal structures of cyanobacterial PSII provide information on the structure of the Mn and Ca ions, the redox-active tyrosine called Y_Z, and the surrounding amino acids that comprise the O_2 evolving complex (OEC) [2,3]. We have used computational studies used to refine the structure of the OEC to obtain a complete structural model of the OEC that is in agreement with spectroscopic data [4,5]. The structure of the OEC and the mechanism of water oxidation by PSII will be discussed in the light of biophysical and computational studies, inorganic chemistry and X-ray crystallographic information.

8:36AM A39.00002 Engineered and Artificial Photosynthesis , TOM MOORE, Arizona State University — This abstract not available.

9:12AM A39.00003 QM/MM and MD study on a light-harvesting molecular triad[1] , GUOXIONG SU, ARKADIUSZ CZADER, MARGARET CHEUNG, University of Houston — We investigated the hydrophobic interactions of an artificial photosynthetic molecular triad in nanoconfinement in various sizes using a combined approach of QM/MM method and all-atomistic molecular dynamics simulations with explicit water models. We use the Replica Exchange Method Dynamics (REMD) to investigate the effect of solvation and confinement on the distribution of the ensemble structures and the energy landscape of triad. The relationship of the charge distribution computed from QM/MM and the radial distribution function of water molecules at the proximity of triad will be discussed. The work presented here has profound implications for future studies of the photosynthetic function of triad that provides the opportunity for the insight into the molecular device of green energy.

9:24AM A39.00004 Nanophotonics of Chloroplasts for Bio-Inspired Solar Energy Materials , PAUL L. GOURLEY, CHERYL R. GOURLEY, HighLight Research — In the search for new energy sources, lessons can be learned from chloroplast photonics. The nano-architecture of chloroplasts is remarkably well-adapted to mediate sunlight interactions for efficient energy conversion. We carried out experiments with chloroplasts isolated from spinach and leaf lettuce to elucidate the relationship between nano-architecture, biomolecular composition and photonic properties. We obtained high-resolution microscopic images of single chloroplasts to identify geometries of chloroplasts and interior grana. We performed micro-spectroscopy to identify strengths of absorption and fluorescence transitions and related them to broadband reflectance and transmittance spectra of whole leaf structures. Finally, the nonlinear optical properties were investigated with nanolaser spectroscopy by placing chloroplasts into micro-resonators and optically pumping. These spectra reveal chloroplast photonic modes and allow measurement of single chloroplast light scattering cross section, polarizability, and refractive index. The nanolaser spectra recorded at increasing pump powers enabled us to observe non-linear optics, photon dynamics, and stimulated emission from single chloroplasts. All of these experiments provide insight into plant photonics and inspiration of paradigms for synthetic biomaterials to harness sunlight in new ways.

9:36AM A39.00005 Direct Enzymatic Oxidation of Glucose with a Poly(Ionic Liquid) - Gold-Nanoparticle Composite , MILLICENT FIRESTONE, SUNGWON LEE, SOENKE SEIFERT, Argonne National Laboratory — In this work we describe the synthesis, fabrication and characterization of a gold nanoparticle - ionic liquid-derived polymer composite for conversion of biofuels into electricity. Glucose oxidase (GOx) electrostatically adsorbed on an ionic liquid-derived polymer containing internally organized columns of Au nanoparticles exhibits bioelectrocatalytic properties in the oxidation of glucose. The cationic poly(ionic liquid) provides an ideal substrate for the immobilization of GOx. The encapsulated Au nanoparticles serve two roles: promoting direct electron transfer with the recessed enzyme redox centers, and imparting electronic conduction to the composite, thereby allowing it to function as an electrode for electrochemical detection.

9:48AM A39.00006 Photosystem I assembly on chemically tailored SAM/ Au substrates for bio-hybrid device fabrication[1] , DIBYENDU MUKHERJEE, BAMIN KHOMAMI, Department of Chemical and Biomolecular Engineering, University of Tennessee — Photosystem I (PS I), a supra-molecular protein complex and a biological photodiode responsible for driving natural photosynthesis mechanism, charge separates upon exposure to light. Effective use of the photo-electrochemical activities of PS I for future bio-hybrid electronic devices requires controlled attachment of these proteins onto organic/ inorganic substrates. Our results indicate that various experimental parameters alter the surface topography of PS I deposited from colloidal aqueous buffer suspensions onto OH-terminated alkanethiolate SAM /Au substrates, thereby resulting in complex columnar structures that affect the electron capture pathway of PS I. Specifically, solution phase characterizations indicate that specific detergents used for PS I stabilization in buffer solutions drive the unique colloidal chemistry to tune protein-protein interactions and prevent aggregation, thereby allowing us to tailor the morphology of surface immobilized PS I. We present surface topographical, adsorption, and electrochemical characterizations of PSI /SAM/Au substrates to elucidate protein-surface attachment dynamics and its effect on the photo-activated electronic activities of surface immobilized PS I.

Session A40 DPOLY: New Experimental, Theoretical, and Computational Methods in Polymer and Soft Matter Physics A122/123

8:00AM A40.00001 A First Principle Approach to Rescale the Dynamics of Simulated Coarse-Grained Macromolecular Liquids , IVAN LYUBIMOV, MARINA GUENZA, University of Oregon — A first-principle approach has been developed to rescale dynamical data from mesoscopic molecular dynamics simulations of polymer liquids. We derive rescaling factors from Generalized Langevin Equations (GLE) for the coarse-grained at the monomer level representation and coarse-grained at the mesoscopic level representation of the liquid, exploiting the Mori-Zwanzig projection operator formalism. The rescaling factors explicitly depend on coarse-grained model parameters and thermodynamic parameters. Two corrections need to be accounted to compensate the acceleration effect on dynamics caused by higher level of coarse-graining: change in entropy and change in friction. After applying our rescaling to data from mesoscopic simulations of unentangled and weakly entangled polyolefin melts we observe a good agreement with data of translational diffusion measured experimentally and from UA simulations. The method is used to predict self-diffusion coefficients for systems not yet investigated experimentally.

8:12AM A40.00002 Phase behavior of disk-coil molecules , YONGJOO KIM, ALFREDO ALEXANDER-KATZ, MIT — Using Monte Carlo simulations, we investigate the self-assembly of disk-coil molecules in the NPT ensemble. By changing the interaction parameters between the disk and the coil portion of the molecules, a full phase diagram of these four phases is constructed. Furthermore, we study the ordering of disks within the crystal phase and we find that the confinement imposed by the mesophase segregation induces stronger order compared to the pure disk case, which was also explicitly simulated. Our results show that by reducing the dimensionality of a system it is possible to induce higher order of the molecules and help orient the disks in the crystal phase. Furthermore, we simulated molecules with additional interaction and obtained interesting additional phases. Our results are relevant for organic photoactive (typically planar) molecules that are functionalized with tails to improve their processability and long-range order in the solid phase.

8:24AM A40.00003 A unified model Hamiltonian for polythiophene, polypyrrole, polyfuran, free base porphyrin, and polyaniline: Accuracy, transferability, and computational efficiency , ANDRE BOTELHO, XI LIN, Division of Materials Science and Engineering, Boston University, Boston MA — Two fully transferable physical parameters are incorporated into the historical Su-Schrieffer-Heeger Hamiltonian to model conducting polymers beyond polyacetylene, one parameter γ scales the electron-phonon coupling strength in aromatic rings and the other parameter ε specifies the heterogeneous core charges. This generic Hamiltonian predicts the fundamental band gaps of polythiophene, polypyrrole, polyfuran, free base porphyrin, polyaniline, and their oligomers of all lengths with an accuracy exceeding the time-dependent density functional theory. Additionally, its computational costs are four orders of magnitude or more lower than first-principles approaches.

8:36AM A40.00004 Fluctuating lattice-Boltzmann model for complex fluids , SANTTU OLLILA, Aalto University School of Science, COLIN DENNISTON, MIKKO KARTTUNEN, University of Western Ontario, TAPIO ALA-NISSILA, Aalto University School of Science — We develop, and test numerically, a lattice-Boltzmann (LB) model for non-ideal fluids that incorporates thermal fluctuations through a random component in the local stress tensor. The fluid model is a momentum-conserving thermostat, for which we demonstrate how the temperature can be made equal at all length scales present in the system by having noise both in the stress tensor of the fluid and by shaking the whole system in accord with the local temperature. The validity of the model is extended to a broad range of values of the sound velocity. Furthermore, our model features a consistent coupling scheme between the fluid and solid molecular dynamics objects, which allows us to use the LB fluid as a heat bath for solutes evolving in time $without$ external Langevin noise added to the solute. This property expands the applicability of LB models to dense, strongly correlated systems with thermal fluctuations and potentially non-ideal equations of state. We benchmark our model by performing tests on the fluid itself and on the static and dynamic properties of a coarse-grained polymer chain under strong hydrodynamic interactions. We find that our model produces results for single-chain diffusion that are in quantitative agreement with theory

8:48AM A40.00005 Polymer network stretching during electrospinning[1] , ISRAEL GREENFELD, ARKADII ARINSTEIN, Technion, KAMEL FEZZAA, Argonne National Laboratory, MIRIAM RAFAILOVICH, State University of New York, Stony Brook, EYAL ZUSSMAN, Technion — Fast X-ray phase contrast imaging is used to observe the flow of a semi-dilute polyethylene oxide solution during electrospinning. Micron-size glass particles mixed in the polymer solution allow viewing of the jet flow field, and reveal a high-gradient flow that has both longitudinal and radial components that grow rapidly along the jet. The resulting hydrodynamic forces cause substantial longitudinal stretching and transversal contraction of the polymer network within the jet, as confirmed by random walk simulation and theoretical modeling. The polymer network therefore concentrates towards the jet center, and its conformation may transform from a free state to a fully-stretched state within a short distance from the jet start.

9:00AM A40.00006 Microscopic theory of topological entanglement constraints in fluids of rigid macromolecules , DANIEL SUSSMAN, KEN SCHWEIZER, University of Illinois at Urbana-Champaign — A theoretical description of the slow dynamics of an ideal gas of infinitely thin, non-rotating rods or three-dimensional crosses is presented. As objects with no excluded volume their equilibrium structure is trivial, and thus slow dynamics are determined solely by bond uncrossability and macromolecular connectivity. Our work builds on the dynamic mean-field theory of Szamel, which successfully predicted tube localization and reptation for non-rotating uncrossable rods. We derive an effective diffusion constant by exactly enforcing uncrossability at the two-molecule level in conjunction with a self-consistent renormalization to account for many-particle effects. For crosses and isotropically translating rods a topological localization transition is predicted at a critical density above which macromolecules are localized by a confinement potential with very strong anharmonicities. The spatial nature of the latter, including the density-dependent localization length, is analyzed and contrasted with recent experiments on entangled F-actin filaments. The stability of the localization transition to both an external force (yielding) and macromolecular collective density fluctuations is examined, and comparison with simulations on entangled crosses is performed.

9:12AM A40.00007 Tying Polymer Knots to Find the Entanglement Length , JIAN QIN, SCOTT MILNER, ChE at Penn State University — We propose two relations between the entanglement length and the probability distribution of topological states accessed by topologically equilibrated ring polymer melts. The first states that the rings are most likely entangled when the ring length exceeds the entanglement length. The second states that the topological entropy measuring the number of accessible topological states is about k_B per entanglement strand. To test these ideas, we simulated melts of ring polymers with hybrid MC/MD moves, and sampled their topological states by using various ring rebridging moves. Topological states are identified by mapping the molecular configurations to knots, and knots are distinguished by computing their invariant polynomials. We accumulated the state statistics, their ring length dependence, and extracted the entanglement length using these two approaches. The results are consistent with each other, and agree with those from the heuristic methods.

9:24AM A40.00008 Towards simulation of charges in the presence of varying dielectric response , VIKRAM JADHAO, Northwestern University, FRANCISCO SOLIS, Arizona State University, GUILLERMO GUERRERO-GARCIA, MONICA OLVERA DE LA CRUZ, Northwestern University — A variational formulation of electrostatics suitable for carrying out simulations of charges interacting in the presence of different dielectric media is developed. The variational principle employs the polarization charge density as the only variational field. A true energy functional is constructed to yield the correct electrostatic energy at its minimum and the correct force during the approach to the minimum. In the hope of applying the method to more realistic and complicated geometries, some numerical investigations of the variational procedure are also presented.

9:36AM A40.00009 Colloidal Particle Vibration Spectroscopy , TIM STILL, MPI for Polymer Research, Mainz, Germany, GEORGE FYTAS, MPI for Polymer Research, Mainz, Germany; Univ. of Crete and FORTH, Heraklion, Greece, MAURIZIO MATTARELLI, MAURIZIO MONTAGNA, Univ. Trento, italy — Brillouin light scattering (BLS) on dry colloidal particles resolves a large number of resonance vibrations (eigenmodes),[1] allowing determining the elastic properties at meso- and nanoscale and measure (polymer) physical properties not accessible by other methods.[2] So far, only the frequencies of the different eigenmodes, labeled by the "quantum numbers" (n,l) and calculated following Lamb's 19th century approach, were taken to identify the nature of the measured signals, however leading to some ambiguities. Herein, we present the first full theoretical representation of BLS eigenmode spectra, allowing an unprecedentedly precise access to the individual colloid's thermomechanical properties.[3] A longstanding discussion is resolved, showing that both even and odd l spheroidal modes are active. The theoretically predicted scattering angle dependence of the BLS intensity is verified.

9:48AM A40.00010 Physical properties of two-dimensional directed polymer systems obtained via bosonization and related techniques[1] , DAVID ZEB ROCKLIN, PAUL M. GOLDBART, University of Illinois at Urbana-Champaign — Classical directed polymers in 2 dimensions are well known to be equivalent to quantum particles in 1+1 dimensions, with polymer configurations corresponding to particle worldlines. This equivalence motivates the use of techniques designed for one-dimensional quantum systems for exploring many-polymer systems, as first exploited by de Gennes [1]. We discuss how thermodynamic quantities and certain correlation functions of a particular model polymer system can be calculated exactly from the Bethe ansatz solution for the Lieb-Liniger model of bosons with repulsive local interactions. We also discuss how the universal properties of more general polymer systems can be captured via Haldane's harmonic-fluid approach. Via this approach, we address various properties of strongly interacting many-polymer systems, focusing on aspects that display qualitative differences from those displayed by single polymers.

10:00AM A40.00011 Adapted Su-Schrieffer-Heeger Hamiltonian for PPV, PPP, and polyacenes , YONGWOO SHIN, XI LIN, Boston university — This work presents a unified model Hamiltonian for poly-p-phenylenevinylene (PPV), poly-p-phenylene (PPP), and polyacenes based on the classical Su- Schrieffer-Heeger Hamiltonian for polyacetylene, with one single extra electron- phonon coupling parameter. Predicted band gaps of all these polymers and their oligomers of all lengths closely match to the available experimental results, with an accuracy exceeding the time-dependent density functional theory. Self-localized polaron states and their mobility are computed without any constraints.

10:12AM A40.00012 Rigid body constraints in HOOMD-Blue, a general purpose molecular dynamics code on graphics processing units , TRUNG D. NGUYEN, CAROLYN L. PHILLIPS, JOSHUA A. ANDERSON, SHARON C. GLOTZER, University of Michigan, Ann Arbor — Rigid body constraints are commonly used in a wide range of molecular modeling applications from the atomistic scale, modeling the bonds in molecules such as water, carbon dioxide, and benzene, to the colloidal scale, modeling macroscopic rods, plates and patchy nanoparticles. While the parallel implementations of rigid constraints for molecular dynamics simulations for distributed memory clusters have poor performance scaling, on shared memory systems, such as multi-core CPUs and many-core graphics processing units (GPUs), rigid body constraints can be parallelized so that significantly better performance is possible. We have designed a massively parallel rigid body constraint algorithm and implemented it in HOOMD-Blue, a GPU-accelerated, open-source, general purpose molecular dynamics simulation package. For typical simulations, the GPU implementation running on a single NVIDIA® GTX 480 card is twice as fast as LAMMPS running on 32 CPU cores. In the HOOMD-blue code package, rigid constraints can be used seamlessly with non-rigid parts of the system and with different integration methods, including NVE, NVT, NPT, and Brownian Dynamics. We have also incorporated the FIRE energy minimization algorithm, reformulated to be applicable to mixed systems of rigid bodies and non-rigid particles.

Monday, March 21, 2011 8:00AM - 11:00AM –
Session A41 DPOLY: Focus Session: Active Biopolymers and Biomaterials A115/117

8:00AM A41.00001 Connecting Atomic Structures with Continuum Mechanics in Cytoskeletal Polymers[1] , DAVID SEPT, University of Michigan — The mechanics of the cytoskeleton, namely actin filaments and microtubules, are key to many of their cellular functions. These polymers have been extensively studied using a wide range of biophysical techniques, and we have sought to connect the dynamics we observe in all-atom molecular dynamics simulations with continuum mechanics properties. We have developed coarse-graining techniques that allow us calculate mechanical properties of these polymers using a simple mesoscopic description. Our findings match very well with experimental measurements and allow us to probe how the atomic level effects of small molecules and/or point mutations manifest themselves at the level of the polymer.

[1]Supported by NSF Grant CMMI-0928540.

8:36AM A41.00002 The Interplay of Nonlinearity and Architecture and Nonequilibrium Dynamics in Cytoskeletal Mechanics , SHENSHEN WANG, Dept of Physics, UCSD, TONGYE SHEN, Dept of Biochemistry, Cellular and Molecular Biology, Univ. of Tennessee, PETER WOLYNES, Dept of Physics, Dept of Chemistry and Biochemistry, UCSD — The interplay between cytoskeletal architecture and the nonlinearity of the interactions due to bucklable filaments plays a key role in modulating the cell's mechanical stability and its structural rearrangements. We first study a model of cytoskeletal structure treating it as an amorphous network of hard centers rigidly cross-linked by nonlinear elastic strings, neglecting the effects of motorization. Using simulations along with a self-consistent phonon method, we show that this minimal model exhibits diverse thermodynamically stable mechanical phases that depend on excluded volume, crosslink concentration, filament length and stiffness. Within the framework set by the free energy functional formulation and making use of the random first order transition theory of structural glasses, we further estimate the characteristic densities for a kinetic glass transition to occur in this model system. Network connectivity strongly modulates the transition boundaries between various equilibrium phases, as well as the kinetic glass transition density. We further study the effects of motorization and polymerization upon the stability and dynamics of this model system.

8:48AM A41.00003 Buckling of Branched Cytoskeletal Filaments , D.A. QUINT, J.M. SCHWARZ, Syracuse University — *In vitro* experiments of growing dendritic actin networks demonstrate reversible stress-softening at high loads, above some critical load. The transition to the stress-softening regime has been attributed to the elastic buckling of individual actin filaments. To estimate the critical load above which softening should occur, we extend the elastic theory of buckling of individual filaments embedded in a network to include the buckling of branched filaments, a signature trait of growing dendritic actin networks. Under certain assumptions, there will be approximately a seven-fold increase in the classical critical bucking load, when compared to the unbranched filament, which is entirely due to the presence of a branch. Moreover, we go beyond the classical buckling regime to investigate the effect of entropic fluctuations. The result of compressing the filament in this case leads to an increase in these fluctuations and eventually the harmonic approximation breaks down signifying the onset of the buckling transition. We compute corrections to the classical critical buckling load near this breakdown.

9:00AM A41.00004 "Twist-state" transitions in parallel actin bundles induced by crosslinking proteins , HOMIN SHIN, GREGORY GRASON, University of Massachusetts Amherst — Parallel actin bundles are common structural motifs in many crucial cellular specializations, from filopodia to mechanosensory bundles of the inner ear. Here, we study a model of actin bundles, crosslinked by compact globular bundling proteins, known to modify the torsional state of filaments due to frustration between helical structure of the filaments and in-plane ordering of the bundle. Our coarse-grained model of parallel bundles maps the linker-induced "twist-state" transition of actin filament onto a *commensurate-incommensurate* phase transition, described by an effective Frenkel-Kontorowa model. We predict that the transition from the uncrosslinked, incommensurate helical symmetry to fully crosslinked, commensurate symmetry is highly sensitive to linker flexibility: flexible crosslinking smoothly distorts the twist state of bundled filaments, while rigidly crosslinked bundles undergo a phase transition, rapidly overtwisting filaments over a narrow range of free crosslinker concentrations. Additionally, we predict a rich spectrum of intermediate structures, composed of alternating domains of sparsely bound (untwisted) and strongly bound (overtwisted) filaments. This model reveals that subtle differences in crosslinking agents themselves modify not only the detailed structure of parallel actin bundles, but also the thermodynamic pathway by which they form.

9:12AM A41.00005 Elasticity of a cross-linked active bundle[1] , SILKE HENKES, Syracuse University, TANNIEMOLA B. LIVERPOOL, University of Bristol, M. CRISTINA MARCHETTI, A. ALAN MIDDLETON, JENNIFER M. SCHWARZ, Syracuse University — Understanding the effect of motor proteins, such as myosins, on the elasticity of crosslinked actin networks is essential to our understanding of cell mechanics. Both in vivo and in vitro, these active networks have radically different mechanical properties from their equilibrium counterparts, including contractile behavior and higher elastic moduli. Existing theoretical models do not address the relative role of passive and active crosslinkers in controlling the network contractility and stiffening. We construct a one dimensional lattice model with minimal ingredients, that is, rigid polar filaments, spring-like passive crosslinks and active crosslinks with on/off dynamics implemented through non-equilibrium Monte Carlo solution of the corresponding master equations. We find, consistent with experiments, that the network needs to be percolated through the passive crosslinks to be mechanically stable. Contractile behavior is observed for all concentrations of active crosslinks. We study the mechanical properties of the gel in the phase space of motor processivity, crosslink stiffness, and concentration of active crosslinks.

[1]This work is supported by the NSF through grants DMR-0806511, DMR-1004789, DMR-1006731 and DMR-0645373.

9:24AM A41.00006 Bursts of active transport in living cells , BO WANG, JAMES KUO, SUNG CHUL BAE, STEVE GRANICK, University of Illinois — This study of cargo motion in living cells, performed with nm resolution and an unprecedented large database, shows that the instantaneous speed of active transport deviates pervasively from the average speed yet with striking statistical regularity over several decades of time and space. The experimental approach involves single-particle tracking and special wavelet-based methods to discriminate active transport from passive diffusion, thus quantifying the instantaneous speed of endosomal and lysosomal active transport in living cells at times just longer than the motor stepping time. Pervasive bursts of acceleration stem from viscoelastic relaxation of the cytoplasm, the individual bursts displaying a time-averaged shape that we interpret to reflect stress buildup followed by rapid release. These statistical regularities did not change in response to changing the experimental conditions, specifically to changing the cell line and motor type, or to overexpressing microtubule binding proteins, thus indicating redundancy in regulation of cellular active transport. The power law of scaling is the same as seen in driven jammed colloids, powders, and magnetic systems, and is consistent with a simple heuristic argument. The implied regulation of active transport by environmental obstruction in the cytoplasm extends the classical notion of "molecular crowding."

9:36AM A41.00007 Mechanically Activated Motion of a Single Self-Propelled Polymeric Microcapsule , GERMAN KOLMAKOV, ALEXANDER SCHAEFER, Chemical Engineering Department, University of Pittsburgh, IGOR ARANSON, Materials Science Division, Argonne National Laboratory, ANNA BALAZS, Chemical Engineering Department, University of Pittsburgh — Using a hybrid computational approach, we demonstrate that a single nanoparticle-filled microcapsule on a rigid substrate can undergo self-sustained motion in response to initial mechanical deformation. Nanoparticles released from the capsule modify the underlying substrate and the adhesion gradients of the nanoparticle concentration formed at the surface sustain the motion of the capsule. The permeability of the microcapsule's shell increases with its deformation and therefore, more deformed microcapsules release nanoparticles at higher rates. An initial, non-uniform mechanical deformation of the capsule by an applied force causes an asymmetry in the nanoparticle distribution on the substrate that initiates the microcapsule motion. We also develop a two-dimensional model of the phenomenon within the phase-field approximation and compare the results of the two approaches.

9:48AM A41.00008 Coarse-grained models for biological simulations , ZHE WU, QIANG CUI, ARUN YETHIRAJ, UW Madison — The large timescales and length-scales of interest in biophysics preclude atomistic study of many systems and processes. One appealing approach is to use coarse-grained (CG) models where several atoms are grouped into a single CG site. In this work we describe a new CG force field for lipids, surfactants, and amino acids. The topology of CG sites is the same as in the MARTINI force field, but the new model is compatible with a recently developed CG electrostatic water (Big Multiple Water, BMW) model. The model not only gives correct structural, elastic properties and phase behavior for lipid and surfactants, but also reproduces electrostatic properties at water-membrane interface that agree with experiment and atomistic simulations, including the potential of mean force for charged amino acid residuals at membrane. Consequently, the model predicts stable attachment of cationic peptides (i.e., poly-Arg) on lipid bilayer surface, which is not shown in previous models with non-electrostatic water.

10:00AM A41.00009 Guided Transport of a Transmembrane Nanochannel , MEENAKSHI DUTT, OLGA KUKSENOK, ANNA BALAZS, University of Pittsburgh — Via the Dissipative Particle Dynamics approach, we design a system that allows transport of a nanochannel to a desired location by applying an external force. Each nanochannel encompasses an ABA architecture, with a hydrophobic shaft (B) with two hydrophilic ends (A). One of the hydrophilic ends of the nanochannel is functionalized with hydrophilic functional groups, or hairs. The hydrophilic hairs serve a dual role: (1) control transport across the membrane barrier when the channel diffuses freely in the membrane, and (2) enable the channel relocation to a specific membrane site. Our system comprises a transmembrane hairy nanochannel with the hairs extending into solution. In our earlier work, we demonstrated the spontaneous insertion of such a hairy nanochannel into a lipid bilayer (Nanoscale DOI: 10.1039/C0NR00578A). First, we hold a suitably functionalized pipette stationary above the membrane while the nanochannel freely diffuses within the membrane. For an optimal range of parameters, we demonstrate that the hairs find the pipette and spontaneously anchor onto it. We then show that by moving the pipette for a range of velocities, we can effectively transport the channel to any location within the membrane. This prototype system can provide guidelines for designing a number of biomimetic applications.

10:12AM A41.00010 Accidental Interactions and Purposeful Flaws in Polymer Brushes: Variations in Bioadhesive Mechanisms , MARIA SANTORE, University of Massachusetts — Water soluble brushes, such as polyethylene glycol and poly(hydroxyethyl methacrylate) are grafted, in many applications, to or from surfaces to prevent protein and cell adhesion. When brushes fail, as can be frequent in practice, protein adsorption becomes aggressive. Failure can occur if the brush architecture is simply too thin such that proteins can experience van der Waals and electrostatic attractions with the underlying substrate, or if the brush has flaws or holes, where the grafting procedure did not succeed. This talk compares the interactions of proteins and bacteria with nearly uniform brushes to the interactions of proteins and bacteria with patchy brushes. The latter are deliberately flawed by the inclusion of nanoscale adhesive elements (polymer coils and nanoparticles) at their base, which prevent local brush formation. The adhesive elements are smaller than the proteins themselves, but sufficient to perturb local brush structure. This talk demonstrates that large quantities of the appropriate types of random-coil (denatured) and globular (native) proteins can penetrate a brush and even displace it (if it is otherwise held in place by adsorbing anchor groups), while other proteins can be entirely repelled. The same is also true of the patchy brushes, but with patchy brushes, but the mechanism is different. With uniform brushes, small proteins and random coils sometimes penetrate sufficiently to experience electrostatic attractions once inside the brush. With patchy brushes, all proteins have the opportunity to interact electrostatically with the adhesive elements, but because large proteins can interact with greater numbers of adhesive elements, their capture is preferred. The result is different rankings of proteins which can ultimately adhere to thin uniform brushes or thicker patchy ones.

10:48AM A41.00011 Nanoparticle Self-Lighting Photodynamic Therapy For Cancer Treatment , WEI CHEN, University of Texas at Arlington — Photodynamic therapy has been designated as a "promising new modality in the treatment of cancer" since the early 1980s. Light must be delivered in order to activate photodynamic therapy. Most photosensitizers have strong absorption in the ultraviolet – blue range, therefore, UV -blue light is needed for their activation. Unfortunately, UV-blue light has minimal penetration into tissue and its application for *in vivo* activation is a problem. To solve the problem and to enhance the PDT treatment for deep cancers, we introduce a new PDT system in which the light is generated by afterglow nanoparticles with attached photosensitizers. When the nanoparticle-photosensitizer conjugates are targeted to tumor, the light from afterglow nanoparticles will activate the photosensitizers for photodynamic therapy. Therefore, no external light is required for treatment. More importantly, it can be used to treat deep tumor such as breast cancer because the light source is attached to the photosensitizers and are delivered to the tumor cells all together. This modality is referred as nanoparticle self-lighting photodynamic therapy.

Monday, March 21, 2011 8:00AM - 11:00AM –
Session A42 DPOLY: Focus Session: Directed Assembly of Hybrid Nanomaterials A302/303

8:00AM A42.00001 Magnetically Actuated Artificial Cilia with Controlled Length and Areal Density , JASON BENKOSKI, JENNIFER BREIDENICH, MICHAEL WEI, GUY CLATTERBAUGH, Johns Hopkins University APL, PEI-YUIN KENG, JEFFREY PYUN, University of Arizona — Artificial cilia have been explored for use in microrobotics, MEMS, and lab-on-a-chip devices for applications ranging from micromixers, microfluidic pumps, locomotion, acoustic detection, and heat transfer. We have previously demonstrated the ability to assemble dense brushes of magnetically actuated artificial cilia from the dipolar assembly of 24 nm ferromagnetic cobalt nanoparticles. Despite areal densities exceeding 1 cilim/μm^2, diameters below 25 nm, aspect ratios exceeding 400, and flexural rigidities below 3 x 10^{-28} Nm^2, these seemingly delicate structures resist collapse upon each other or the underlying substrate. The current study demonstrates the ability to rationally control their average length and areal density by changing the nanoparticle concentration and the dimensions of the rectangular capillary tube. We find that the length and areal density obey a simple conservation of mass relationship with concentration and capillary height such that the product of the former equals the product of the latter. Detailed statistical analysis supports a mechanism in which the role of the external field is to align pre-existing chains with the external field, assist stacking of chains along the axis of the field, and then draw them towards the ends of the permanent magnets, where the magnetic field gradient is steepest.

8:12AM A42.00002 Ordered ferrofluidic assemblies in polymer film formed by magnetically induced polymer-solvent phase separation , NATARAJ SANNA KOTRAPPANAVAR, MYUNGHWAN BYUN, PAUL ZAVAL-REVIERA, KEVIN CHONNON, Biological and Soft Sciences Sector, Cavendish Laboratory, University of Cambridge, Cambridge CB3 0HE, UK, SHAHEEN S.A. AL-MUHTASEB, Department of Chemical Engineering, Qatar University, P.O. Box 2713, Doha, Qatar, EASAN SIVANIAH, Biological and Soft Sciences Sector, Cavendish Laboratory, University of Cambridge, Cambridge CB3 0HE, UK, BIOLOGICAL AND SOFT SCIENCES SECTOR, CAVENDISH LABORATORY, UNIVERSITY OF CAMBRIDGE, CAMBRIDGE CB3 0H TEAM, DEPARTMENT OF CHEMICAL ENGINEERING, QATAR UNIVERSITY, P.O. BOX 2713, DOHA, QATAR COLLABORATION — Tri-block copolymer has been used as nonferrofluid to generate permanent magnetic structures with controlled dimension and architecture in a partially miscible ferrofluid-nonferrofluid mixture under the influence of a perpendicular magnetic field. The nature of the resultant assemblies was strongly dependent on the magnetic field and concentration of ferro/nonferrofluidic systems. These ordered cluster assemblies in a polymer film that can be used either directly, in applications such as membrane, or subsequently as a template for the formation of other nanostructured materials. The origin of the permanent structures, which have characteristic lateral dimensions ranging from 5 μm to submicron range, is the repartitioning of the ferrofluid carrier solvent into the nonferrofluid polymeric phase.

8:24AM A42.00003 Manipulating nanoparticles via polymer crystallization , CHRISTOPHER LI, BIN DONG, BING LI, XI CHEN, WENDA WANG, Department of Materials Science and Engineering, Drexel University, Philadelphia, PA 19104, USA — Directed nanoparticle (NP) assembly is of great interest in order to achieve desired NP structures for various application purposes. In this presentation, we will present our recent results on employing polymer single crystals (PSC) to direct NP assembly. First, tailor-made, free-standing NP frames and wires containing single or multiple types of NPs have been obtained by using an in-situ polymer crystallization method. End functionalized poly(ethylene oxide) single crystals were used as the templates. Gold and magnetite NPs were successfully patterned as evidenced by transmission electron microscopy experiments. Secondly, carbon nanotube induced PSCs were used to guide AuNPs to assemble into periodic pattern with controlled periodicity. Thirdly, polymer nanofibers decorated with block copolymer single crystals were used as templates to induce the formation of hydroxyapatite (HA) nanocrystals and the resultant nanofiber/HA hybrids mimic the structure of natural bones.

8:36AM A42.00004 Directed Assembly of Nano-Colloids: Toward Discrete and Defined Polymer-Inorganic Architectures , RICHARD VAIA, Air Force Research Laboratory — Analogies between controlled flocculation and the chemistry of macromolecular polymerization are informing new methods for bottom up fabrication of discrete polymer-inorganic architectures. Conceptually, hybrid nano-colloids with a narrow distribution of composition and structure ("monomers") are assembled via external control of the agglomeration kinetics ("polymerization"). The challenge however is to impart a level of predictability between nanoparticle design and resultant assembly, as embodied in monomer design and macromolecular architecture. Depending on the magnitude and directionality of the interparticle interactions, the controlled assembly of these hybrid nano-colloids can span from discrete, soluble proto-assemblies to single-component, bulk mediums with local order ranging from liquid-like to long-range translational coherence. Using nanoparticle shape, organic corona structure, and processing conditions (e.g. modulating the stability of the nano-colloid via solvent quality rather than number density), we demonstrate the fabrication of various discrete and defined metallic and metal oxide hybrid architectures, and discuss the unique properties of the assemblies, which reflect the uniformity of structure, nano-scale separation of the inorganic particles, and confinement of the polymer chains.

9:12AM A42.00005 Designing Functionalized Nanoparticles for Controlled Assembly in Polymer Matrix: Self consistent PRISM Theory and Monte Carlo simulation Study , ARTHI JAYARAMAN, NITISH NAIR, University of Colorado at Boulder — Significant interest has grown around the ability to create hybrid materials with controlled spatial arrangement of nanoparticles mediated by a polymer matrix. By functionalizing or grafting polymers on to nanoparticle surfaces and systematically tuning the composition, chemistry, molecular weight and grafting density of the grafted polymers one can tailor the inter-particle interactions and control the assembly/dispersion of the particles in the polymer matrix. In our recent work using self-consistent Polymer Reference Interaction Site Model (PRISM) theory- Monte Carlo simulations we have shown that tailoring the monomer sequences in the grafted copolymers provides a novel route to tuning the effective inter-particle interactions between the functionalized nanoparticles in a polymer matrix. In this talk I will present how monomer sequence and molecular weights (with and without polydispersity) of the grafted polymers, compatibility of the graft and matrix polymers, and nanoparticle size affect the chain conformations of the grafted polymers and the potential of mean force between the grafted nanoparticles in the matrix.

9:24AM A42.00006 High Fidelity Detection of Defects in Polymer Films using Surface-Modified Nanoparticles , ALAMGIR KARIM, MATTHEW BECKER, CHAITANYA PRATIWADA, Dept. of Polmyer Engg., University of Akron, Akron, OH, USA, UNIVERSITY OF AKRON TEAM — Surface defects are ubiquitous for most thin films, yet their systematic detection poses one of the most difficult challenges even to modern day technology. Polymer thin films are no exception to these problems. We address this issue by developing a novel, efficient method for the optical detection of surface topographical features using fluorescent nanoprobes, which are surface-modified CdSe quantum dots whose ability to detect surface features can be tuned via size and chemical properties. We have successfully applied this approach to detect numerous types of artificial and natural defects in polymer films including lines, pinholes, sharp edges, and chemically variant defect surfaces. This method can elucidate the surface structure of large areas in a minimal amount of time. It is estimated that this new method will decrease imaging time compared to traditional imaging methods like AFM and SEM by 50 fold. Our defect detection approach could be applicable for many problems where polymers are used as a component in hybrid nanomaterial films

9:36AM A42.00007 Directed Hierarchical Assemblies of Nanoparticles in Thin Films[1] , TING XU, UC, Berkeley — Controlling nanoparticle (NP) assemblies in thin films will enable one to capitalize on the unique properties of NPs so as to generate functional devices, such as hybrid photovoltaic, capacitors and optical devices. To this end, it is mandatory to control the macroscopic alignment of NP assemblies and inter-particle ordering with high precision to achieve a specific property. Recently, we described a new approach to assemble NPs over multiple length scales by combining small molecules with block copolymers (BCPs). Small molecules that favorably interact with NP ligands mediate polymer-NP interactions and solublize the NPs within the BCP microdomains. The small molecules also direct the spatial distribution of NPs within the BCP microdomains with exquisite precision. In the bulk, NPs were shown to readily assemble into ordered 1-D, 2-D and 3-D arrays. I will discuss our recent studies on directed hierarchical assemblies of NPs in thin films. Specifically I will focus on how to manipulate the macroscopic alignment and long-range ordering of NPs and generating NP superlattice within the BCP microdomains.

[1]Supported by NSF-DMR, ONR-YIP and DOE-BES

9:48AM A42.00008 Adsorption of particles at fluid interfaces: Jamming, structure control, and rheology , SACHIN VELANKAR, University of Pittsburgh — Various types of particles readily adsorb at the interface between two immiscible liquids or at the surface of a liquid. Such particles bear some similarity to conventional molecular surfactants. However, unlike surfactants, particles adsorb almost irreversibly at interfaces - a fact that can lead to interesting phenomena such as the stability of non-spherical jammed drops, spontaneous climbing of particle films, and particle-bridged emulsions. Similar phenomena - albeit with important differences - can be observed in polymeric systems and may lead to interesting new materials. This talk will review some of these phenomena, with a particular focus on the jamming of fluid interfaces due to particles, and discuss applications for controlling the structure of two-phase polymer systems such as polymer blends and foams.

10:24AM A42.00009 Additive-driven assembly of block copolymers , YING LIN, VIKRAM DAGA, ERIC ANDERSON, JAMES WATKINS, University of Massachusetts — One challenge to the formation of well ordered hybrid materials is the incorporation of nanoscale additives including metal, semiconductor and dielectric nanoparticles at high loadings while maintaining strong segregation. Here we describe the molecular and functional design of small molecule and nanoparticle additives that enhance phase segregation in their block copolymer host and enable high additive loadings. Our approach includes the use of hydrogen bond interactions between the functional groups on the additive or particle that serve as hydrogen bond donors and one segment of the block copolymer containing hydrogen bond acceptors. Further, the additives show strong selectively towards the targeted domains, leading to enhancements in contrast between properties of the phases. In addition to structural changes, we explore how large changes in the thermal and mechanical properties occur upon incorporation of the additives. Generalization of this additive-induced ordering strategy to various block copolymers will be discussed.

10:36AM A42.00010 Supramolecular Assembly of Gold Nanoparticles in PS-b-P2VP Diblock Copolymers via Hydrogen Bonding , SE GYU JANG, CRAIG J. HAWKER, EDWARD J. KRAMER, University of California Santa Barbara — We report a simple route to control the spatial distribution of Au nanoparticles (Au-NPs) in PS-*b*-P2VP diblock copolymers using hydrogen bonding between P2VP and the hydroxyl-containing (PI-OH) units in PS-*b*-PIOH thiol-terminated ligands on Au-NP. End-functional thiol ligands of poly(styrene-*b*-1,2&3,4-isoprene-SH) are synthesized by anionic polymerization. After synthesis of Au-NPs, the inner PI block is hydroxylated by hydroboration and the resulting micelle-like Au-NPs consist of a hydrophobic PS outer brush and a hydrophilic inner PI-OH block. The influence of the hydroxyl groups is significant with strong segregation being observed to the PS/P2VP interface and then to the P2VP domain of lamellar-forming PS-b-P2VP diblock copolymers as the length of the PI-OH block is increased. The strong hydrogen bonding between nanoparticle block copolymer ligands and the P2VP block allows the Au-NPs to be incorporated within the P2VP domain to high Au–NP volume fractions $\phi_p$without macrophase separation, driving transitions from lamellar to bicontinuous morphologies as ϕ_p increases.

10:48AM A42.00011 Role of defects on self-assembly of nanoparticles in block copolymer thin film , JENNY KIM, Universiy of Michigan, PETER GREEN, University of Michigan — The structure of A-b-B block copolymer (BCP) thin films is often exploited as scaffolds for directing nanoparticles into various, long-range ordered geometries. Depending on the affinity between nanoparticles and block chains, nanoparticles preferentially segregate to either A or B domains. We show that dislocations may play a dominant role in the assembly of large nanoparticles in BCP thin film that order at suboptimal thicknesses. Edge dislocations are ubiquitous in lamellar BCP thin films forming a partial surface layer, i.e. holes or island structures. When the ratio of the nanoparticle diameter, d, to the domain dimension, L, d/L < 0.15, the nanoparticles were distributed uniformly throughout the film. However for larger values of d/L, the nanoparticles reside primarily at the dislocation cores. In the case of films of initial film thicknesses between L $<$ h $<$ 3L the nanoparticles self-assemble into 2-dimensional planar shapes at the boundaries of holes or islands where edge dislocations are located.

Monday, March 21, 2011 8:00AM - 11:00AM –

Session A43 DPOLY: Focus Session: Thin Film Block Copolymers I A306/307

8:00AM A43.00001 Study of Complex Morphology of ABC Triblock Copolymer with Resonant Soft X-ray Scattering , CHENG WANG, DONG HYUN LEE, LBNL, WEI ZHAO, THOMAS RUSSELL, UMASS, MYUNG IM KIM, TING XU, UCB, HIROKAZU HASEGAWA, UKyoto, ALEXANDER HEXEMER, LBNL — Combining the spectroscopy sensitivity with scattering, resonant soft x-ray scattering (RSoXS) is an ideal tool for characterizing morphology of multi-component soft materials thin films. Both elemental and chemical sensitivity can be achieved by changing incident photon energy close to the absorption edge of the constituent atoms. In this work, the morphologies in thin film and bulk of A-B-C triblock copolymer, Poly(1,4-isoprene)-block-polystyrene-block-poly(2-vinlypyridine), were investigated with RSoXS together with scanning force microscopy, small angle x-ray scattering and transmission electron microscopy. In thin film, hexagonal array of nanostructures were observed by all the techniques, however, RSoXS revealed the core-shell nanostructures. In bulk, hexagonally packed cylindrical microdomains was observed. By selectively staining different polymer block, TEM tomography results suggested spatial arrangement of two different cylindrical microdomains consisted of poly(1,4-isoprene) and poly(2-vinlypyridine) in polystyrene matrix. Using soft x-ray at selected photon energies to isolate the scattering contribution from two different polymer blocks, RSoXS unambiguously revealed the two different hexagonally packed lattice.

8:12AM A43.00002 STED Microscopy as a Characterization Tool for Three Dimensionally Nanostructured Block Copolymer Thin Films , CHAITANYA ULLAL, ROMAN SCHMIDT, ULRIKE BOEHM, Max Planck Institute for Biophysical Chemistry, SEBASTIAN PRIMPKE, PHILIPP VANA, Georg August Universitaet, Goettingen, STEFAN HELL, Max Planck Institute for Biophysical Chemistry — STED microscopy is an emerging method in the characterization of block copolymer film morphologies. We demonstrate a complete experimental platform that allows us to obtain in situ Three Dimensional images with microdomain specificity. IsoSTED, a variant of STED microscopy that coherently combines two opposing lenses, yields the necessary resolution, while the necessary fluorescence contrast is achieved by deterministically confining fluorophores to the targeted microdomain. These capabilities are combined to provide unambiguous images of various nano-structured block copolymer morphologies.

8:24AM A43.00003 Interfaces between Block Copolymer Domains , JAEUP KIM, UNIST, Korea, SEONG-JUN JEONG, University of California, Berkeley, SANG OUK KIM, KAIST, Korea — Block copolymers naturally form nanometer scale structures which repeat their geometry on a larger scale. Such a small scale periodic pattern can be used for various applications such as storage media, nano-circuits and optical filters. However, perfect alignment of block copolymer domains in the macroscopic scale is still a distant dream. The nanostructure formation usually occurs with spontaneously broken symmetry; hence it is easily infected by topological defects which sneak in due to entropic fluctuation and incomplete annealing. Careful annealing can gradually reduce the number of defects, but once kinetically trapped, it is extremely difficult to remove all the defects. One of the main reasons is that the defect finds a locally metastable morphology whose potential depth is large enough to prohibit further morphology evolution. In this work, the domain boundaries between differently oriented lamellar structures in thin film are studied. For the first time, it became possible to quantitatively study the block copolymer morphology in the transitional region, and it was shown that the twisted grain boundary is energetically favorable compared to the T-junction grain boundary. [Nano Letters, **9**, 2300 (2010)]. This theoretical method successfully explained the experimental results.

8:36AM A43.00004 Patterning of Multiple Block Copolymers per Layer with Orthogonal Processing , WEI MIN CHAN, Department of Electrical Engineering, Cornell University, EVAN L. SCHWARTZ, Department of Materials Science and Engineering, Cornell University, JIN-KYUN LEE, Department of Polymer Science and Engineering, Inha University, JOAN K. BOSWORTH, Hitachi Global Storage Technologies, JOHN DEFRANCO, Orthogonal Inc, SANDIP TIWARI, Department of Electrical Engineering, Cornell University, CHRISTOPHER K. OBER, Department of Materials Science and Engineering, Cornell University — In this work we demonstrate the concept of orthogonal processing of block copolymers. By using a semi-flourinated photoresist/solvent system, we are able to selectively pattern or lift-off and then recover the block copolymer film intact. This approach can enable removable templating of self- assembly and also multiple block copolymers, morphologies or domain sizes on the same layer which can open the door to self-assembly of a wider range of geometries than possible before. We highlight the interplay between the various parameters for a successful additive and subtractive patterning and directions for further theoretical investigation as well as the limitations of this technique.

8:48AM A43.00005 Highly specific placement of Au Nanoparticles on chemical brush patterns prepared by combination of top-down and block copolymer lithography , SERDAR ONSES, CHI-CHUN LIU, CHRISTOPHER THODE, SHENGXIANG JI, PAUL NEALEY, University of Wisconson-Madison — Metallic nanoparticles (NPs) with interesting optical, electronic and reactivity properties show great promise for a range of scientific fields and technological applications, such as plasmonics, catalysis, and nanowire growth. However taking advantage of these properties, particularly for device fabrication often requires immobilization of pre-synthesized particles with high specificity and precise control of density and spacing of NPs at sub 100 nm scale. Here we show that lithographic patterning of a cross-linkable polystyrene brush and subsequent filling with poly(2-vinyl pyridine) (P2VP) leads to high contrast chemical patterns leading to site-specific placement of pre-synthesized Au NPs (13 nm) with the precise control of number from single to tens of particles per spot. Moreover we show that this approach is extendible to large area patterning of NPs with costs and process times suitable for technological applications using block-copolymer (BCP) lithography.

9:00AM A43.00006 Synthesis and graphoepitaxial placement control of block copolymer mediated silver nanoparticles , DONG WOOK KIM, NOEL ARELLANO, CHARLES RETTNER, LESLIE KRUPP, TEYA TOPURIA, PHILIP RICE, GABRIELE RAINO, THILO STOFERLE, RAINER MAHRT, HO-CHEOL KIM, KRICT TEAM, IBM ZURICH RESEARCH CENTER TEAM — The strong interactions of plasmons in metal nanoparticle assemblies can render many possible applications ranging from sensors to imaging and information technology. To realize such applications, synthesis of well defined metal nanoparticles and precise control over assembly are critical. In this paper, we report a synthetic scheme of silver nanoparticles and their combination with dielectrics and/or gain media and their assembly on substrates. Silver nanoparticles are synthesized using a block copolymer of polystyrene and poly(4-vinyl pyridine) (PS-b-P4VP). Well defined nanoparticles were assembled on substrates using a graphoepitaxial approach with topographic patterns prepared by E-beam lithography. The effect of shapes and scales of topographic patterns on the nanoparticle assembly was investigated. Careful optical characterization and potential applications will be discussed.

9:12AM A43.00007 Functional Nanomaterials based on Nanoporous Block Copolymer Templates[1] , JIN KON KIM, Pohang University of Science and Technology — Nanoporous templates have been widely used for the development of new functional nanostructured materials suitable for electronics, optics, magnetism, and energy storage materials. We have prepared nanoporous templates by using thin films of mixtures of polystyrene-*block*-poly(methyl methacrylate) (PS-*b*-PMMA) and PMMA homopolymers. These nanoporous films were found to be very effective for the separation of human Rhinovirus type 14, major pathogen of a common cold in humans. We found that when the pore size was effectively controlled down to 6 nm, a long-term constant *in vitro* release of BSA and hGH was achieved without their denaturation up to 2 months. The long-term constant delivery based on this membrane for protein drugs within the therapeutic range can be highly appreciated for the patients with hormone-deficiency.

Work done in collaboration with Seung Yun Yang, Pohang University of Science and Technology.

9:48AM A43.00008 Effect of Boundary Conditions on the Directed Self-Assembly of Block Copolymer on Chemical Patterned Surfaces , GUOLIANG LIU, Chemical and Biological Engineering, University of Wisconsin-Madison, PAUL NEALEY, Department of Chemical and Biological Engineering, University of Wisconsin-Madison — Previously we determined the morphological phase behavior of lamellae-forming poly(styrene-block-methyl methacrylate) (PS-b-PMMA) density multiplication on chemically patterned surfaces in thin films. The stripe density of the chemical pattern was half of the block copolymer domain density. Parallel lamellae, vertical lamellae, mixed lamellae, PS-dots, and PMMA-dots were observed depending on the pattern stripe width and interaction strength between the polymer and the patterned surfaces. The density multiplied vertical lamellae exhibited three dimensional profiles, which was problematic in the subsequent pattern transfer process. Here we found that the block copolymer domain profiles could be improved by revising the boundary conditions. In the meanwhile, better line width and line edge roughness were obtained. The addition of homopolymers into the block copolymer and subsequent molecular transfer printing could offer a chemically patterned surface with improved boundary conditions for block copolymer directed assembly. The printed chemical patterns had a stripe density and a stripe width matching with block copolymer domains. The interfacial energies of the stripes were favorable to the block copolymer domains.

10:00AM A43.00009 Directed assembly of supramolecular copolymers in thin films , MARCUS MULLER, KOSTAS CH. DAOULAS, Institute for Theoretical Physics, Georg-August University, Goettingen, Germany, ANNA CAVALLO, Dept. of Physics, Salerno University, Fisciano, Italy, ROY SHENHAR, Institute of Chemistry, Hebrew University, Jerusalem, Israel — Using computer simulation of a coarse-grained model for supramolecular polymers we investigate the potential of quasi-block copolymers (QBCP) assembled on chemically patterned substrates for creating device-oriented nanostructures. QBCP are comprised of AB diblock copolymers and supramolecular B segments that can reversibly bond to any available B terminus, either on the copolymers or the B oligomers, creating a polydisperse blend of B homopolymers, AB and ABA copolymers. We focus on an AB incompatibility, χ, and strength of supramolecular bonds where a lamellar morphology, a bicontinous structure and a macrophase-separated state have comparable free energy in the bulk. We consider substrate patterns with perpendicularly crossing, A-preferential lines and demonstrate their defect-free replication by QBCP. The same QBCP replicates simultaneously patterns differing by up to 50% in their length scales, illustrating the high versatility of QBCP materials. We discuss the interplay between pattern geometry and distribution of molecular architectures and verify the key role of supramolecular associations for replicating patterns with different length scales.

10:12AM A43.00010 Self-Assembly of Block Copolymers on Well-modulated Sawtoothed Surface , DONG HYUN LEE, Lawrence Berkeley National Laboratory, TING XU, University of California, Berkeley, SUNG WOO HONG, University of Massachusetts, Amherst, ALEXANDER HEXEMER, HOWARD PADMORE, Lawrence Berkeley National Laboratory, THOMAS RUSSELL, University of Massachusetts, Amherst — The self-assembly of block copolymers on the faceted surfaces of sapphire and silicon substrates were investigated as a function of the amplitude and pitch of the sawtooth pattern. To generate these surfaces, sapphire substrates, cut along the M plane, were annealed at temperatures above 1000°C. The pitch and amplitude of the sawtooth pattern was controlled by varying the annealing temperature. In addition, surfaces with a sawtooth pattern in silicon were generated by an anisotropic etching of the silicon. Block copolymers were spin-coated onto the pattered surfaces. To induce ordering of the BCP, the thin films were solvent-annealed in organic solvent vapors. Long-range lateral ordering of the BCP microdomains persisted across the entire surface with both types of substrates without further treatment. The ordering of the BCP is very sensitive to the geometry of sawtooth pattern.

10:24AM A43.00011 Templating non-hexagonal monolayers of block copolymer spheres in confined geometries , ADETUNJI ONIKOYI, EDWARD KRAMER, GLENN FREDRICKSON, SU-MI HUR, UCSB — We investigate the ordering of poly(styrene-b-2vinylpyridine) [PS-PVP Mn = 56 kg/mol] sphere monolayers in wells of various shapes and sizes. Recent self-consistent field theory results on ordering of block copolymer (BCP) cylinders in square surroundings suggest that adding homopolymers of higher Mn can allow square arrays of BCP to form in small (4 to 5 cylinders across) square wells by relieving packing frustration. Experimentally, we adopt a similar strategy for ordering BCP spheres on silicon nitride membranes patterned by electron beam lithography to produce SiOx mesas, adding various volume fractions of PS homopolymer of different Mn. Scanning force microscopy, transmission electron microscopy and X-ray scattering has been used in a complementary manner to quantify the structures obtained after thermal annealing at 150 C. In the absence of PS additions, only defective hexagonal structures are observed even in wells containing 16 spheres. Adding 10% PS of Mn = 112 kg/mol to the BCP results in a square packing of spheres in square wells containing as many as 81 spheres.

10:36AM A43.00012 ABSTRACT WITHDRAWN –

10:48AM A43.00013 Dynamics of interacting edge defects in copolymer lamellae[1] , KARI DALNOKI-VERESS, JOSHUA D. MCGRAW, IAN D.W. ROWE, Department of Physics and Astronomy and the Brockhouse Institute for Materials Research, McMaster University — It is known that terraces at the interface of lamella forming diblock copolymers do not make discontinuous jumps in height. Rather, their profiles are smoothly varying. The width of the transition region between two lamellar heights is typically several hundreds of nanometres, resulting from a balance between surface tension, chain stretching penalties, and the enthalpy of mixing. What is less well known in these systems is what happens when two transition regions approach one another. In this study, we show that time dependent experimental data of interacting copolymer lamellar edges is consistent with a model that assumes a repulsion between adjacent edges. The range of the interaction between edge defects is consistent with the profile width of noninteracting diblock terraces.

Session A44 DPOLY: Friction, Adhesion, and Fracture of Polymers A309

8:00AM A44.00001 Contact Adhesion of Wrinkled Surfaces , CHELSEA DAVIS, ALFRED CROSBY, University of Massachusetts Amherst — Inspired by examples in nature, recent research advances have demonstrated the ability to use topographic surface patterns rather than chemical modifications to control surface properties such as adhesion, wettability, and friction. Although most synthetic efforts have focused on the use of complicated lithographically-fabricated fibrillar structures, the use of spontaneously formed structures, such as surface wrinkles, have also proven advantageous. Wrinkles present many attributes, such as discretized length scales, which play an important role in adhesion control, yet the exact mechanisms for this control are not fully understood. We present a systematic study of the contact adhesion mechanics between a flat, rigid surface and a soft wrinkled surface. The wrinkles are fabricated using a technique that allows the effects of residual surface stresses and wrinkle topography to be decoupled in the context of adhesion control. We find that the maximum separation force for the wrinkled-flat interfaces increases with decreasing values of wrinkle wavelength and amplitude. These trends can be understood through the development of a simple scaling relationship, which links wrinkle geometry and materials properties to the maximum separation force.

8:12AM A44.00002 Structural Effects on the Friction of Tethered PDMS Networks[1] , CLAUDE COHEN, LUCAS LANDHERR, LYNDEN ARCHER, Cornell University — The interfacial properties of dry, surface-tethered end-linked polydimethylsiloxane (PDMS) films on silicon are examined. Thin network films (approximately 10 microns thick) were synthesized over a self-assembled monolayer supported on a silicon wafer. By systematically increasing the concentration of mono-functional PDMS chains in a mixture with telechelic precursor chains during cross-linking, structures ranging from near model elastic networks to very poorly cross-linked networks dominated by a preponderance of dangling/pendent chains were synthesized. Lateral force microscopy (LFM) employing a PE bead probe was used to quantify the effect of network structure and the role of viscoelasticity on the interfacial friction coefficient.

8:24AM A44.00003 Lithography-Free Microchannel Fabrication in PDMS[1] , JEYANTT S. SANKARAN, Department of Electrical Engineering, Nanotechnology Research and Teaching Facility, University of Texas at Arlington, WINTANA T. KAHSAI, UYEN H.T. PHAM, Department of Bioengineering, Nanotechnology Research and Teaching Facility, University of Texas at Arlington, SAMIR M. IQBAL, Department of Electrical Engineering, Nanotechnology Research and Teaching Facility, University of Texas at Arlington — We report a novel method for the fabrication of microchannels that could potentially be used for pervaporation experiments, cell adhesion and cell movement studies and detection of selective protein bio-markers. PDMS can sustain high temperatures, has a high young's modulus and it is biologically inert. Hydrophobic-hydrophilic interactions at gel point of PDMS form the basis of the presented technique. The repulsion of hydrophilic particles by the hydrophobic polymer matrix, stemming from the reduction of entropy and free energy variations during polymerization, provides an elegant lithography-independent approach for the fabrication of self-aligned microchannels.

8:36AM A44.00004 ABSTRACT WITHDRAWN –

8:48AM A44.00005 Polymer Brushes that Mimic Repulsive Properties of the Boundary Lubricant Glycoprotein Lubricin[1] , JAHN TORRES, Brown University/ Naval Undersea Warfare Center, GREGORY JAY, Brown University, QIAN NI, DAVID BELLO, GEOFFREY BOTHUN, University of Rhode Island, KYUNG-SUK KIM, Brown University — This is a report on the design of tailored functional groups which mimic the repulsive forces at work in the natural-joint boundary lubricant known as *lubricin*. *Lubricin*, an amphiphilic polyelectrolyte biomolecule, decreases friction and *cellular adhesion* by exhibiting surface force fields based on *steric hindrance*, *Debye electrostatic double layer repulsion* and *hydration repulsive forces*. We have identified a physically and chemically stable candidate polymers for anti-fouling coatings that will mimic lubricin's repulsive properties. Synthetic polymer brushes mimicking lubricin have been produced using these polymers grafted onto a glass surfaces. The average adhesive forces for the polymer brushes measured through atomic force microscopy are as low (56.796 $\pm$ 0.796 mN/m), similar to those exhibited by lubricin coated surfaces and on the same order of magnitude as superhydrophobic surfaces.

9:00AM A44.00006 Activation-deactivation of self-healing in supramolecular rubbers , LAURENT CORTE, FLORINE MAES, DAMIEN MONTARNAL, SABINE CANTOURNET, FRANCOIS TOURNILHAC, LUDWIK LEIBLER, MINES-PARISTECH CNRS (UMR7633) TEAM, ESPCI-PARISTECH CNRS (UMR7167) TEAM — Self-healing materials have the ability to restore autonomously their structural integrity after damage. Such a remarkable property was obtained recently in supramolecular rubbers formed by a network of small molecules associated via hydrogen bonds [1]. Here we explore this self-healing through an original tack experiment where two parts of supramolecular rubber are brought into contact and then separated. These experiments reveal that a strong self-healing ability is activated by damage even though the surfaces of a molded part are weakly self-adhesive. In our testing conditions, a five minute contact between crack faces is sufficient to recover most mechanical properties of the bulk while days are required to obtain such adhesion levels with melt-pressed surfaces. We show that the deactivation of this self-healing ability seems unexpectedly slow as compared to the predicted dynamics of supramolecular networks. Fracture faces stored apart at room temperature still self-heal after days but are fully deactivated within hours by annealing. Combining these results with microstructural observations gives us a deeper insight into the mechanisms involved in this self-healing process. [1] P. Cordier, F. Tournilhac, C. Soulie-Ziakovic & L. Leibler, Nature, 451, 2008.

9:12AM A44.00007 Self-Healing of Polyethylene Oxide , DORINA MAGDALENA CHIPARA, MARITZA FLORES, NANCY PUENTE, KAREN LOZANO, The University of Texas Pan American — Autonomic self-healing is expected to enhance the lifetime of polymeric materials, resins, and composites subjected to long term mechanical stresses. The self-healing process is initiated by the rupture of some polyurea-formaldehyde microcapsules filled with monomer. The self-healing polymer is actually a compound containing microcapsules filled with monomer and catalyst particles. The monomer released from these broken microcapsules is diffusing within the polymer, reacting with the catalyst and starting a polymerization reaction. This new polymer, growing within the propagating crack, stops the mechanical failure. While the process is pretty slow (timescale of the order of 10 to 100 s), there are many important technological applications that would benefit from the availability of self-healing polymers. We report about the addition of self-healing capabilities to polyethylene oxide by using polyurea formaldehyde microcapsules filled with dicyclopentadiene and first generation Grubbs catalysts. Details regarding the physical and chemical steps used to add self-healing capabilities to polyethylene oxide will be presented. Self-healing efficiency was assessed by fatigues tests.

9:24AM A44.00008 Modeling the Nano-indentation of Self-healing Materials , SOLOMON F. DUKI, GERMAN V. KOLMAKOV, VICTOR V. YASHIN, Department of Chemical Engineering, University of Pittsburgh, TOMASZ KOWALEWSKI, KRZYSZTOF MATYJASZEWSKI, Department of Chemistry, Carnegie Mellon University, ANNA C. BALAZS, Department of Chemical Engineering, University of Pittsburgh — We use computational modeling to determine the mechanical response of crosslinked nanogels to an atomic force microscope (AFM) tip that is moved through the sample. We focus on two-dimensional systems where the nanogels are interconnected by both strong and labile bonds. We model each nanogel as a deformable particle using the modified lattice spring model that is applicable to a broad range of elastic materials.We utilize the Bell model to describe the bonds between these nanogel particles, and subsequently, simulate the rupturing of bonds due the force exerted by the moving indenter. The ruptured labile bonds can readily reform and thus, can effectively mend the cavities formed by the moving AFM tip. We determine how the fraction of labile bonds, the nanogel stiffness, and the size and velocity of the moving tip affect the self-healing behavior of the material. We find that samples containing just 10% of labile bonds can heal to approximately 90% of their original, undeformed morphology.

9:36AM A44.00009 Viscoelastic solid glue produced by orb-weaving spiders[1] , VASAV SAHNI, TODD BLACKLEDGE, ALI DHINOJWALA, The University of Akron — Modern orb-weaving spiders have evolved well-designed adhesives to capture preys. This adhesive is laid on a pair of soft and highly extensible axial silk fibers as micron-sized glue droplets that are composed of an aqueous coat of salts surrounding the nodules made of glycoproteins. Understanding the adhesion mechanism of these glue droplets has been challenging because both the glue droplets and the axial fibers contribute to the adhesive forces required to detach a thread from a surface. Here, we have decoupled these contributions by developing a novel experimental method to probe individual glue droplets and an energy model to separate the strain energy of the axial silk fibers from the adhesion energy required to peel the glue droplets. We observe that the glue droplets behave as a viscoelastic solid and are strongly affected by humidity and the rate of peeling. Knowledge of the adhesion and the mechanics of the glue will aid in developing bioinspired adhesives in the future.

9:48AM A44.00010 Hydrophobic Interactions on a Protein-Polymer Functionalized Surface of Varying Hydrophilicity , KRISTEN KELLER, PINAR AKCORA, Stevens Institute of Technology — We have developed a novel heterogeneous surface consisting of streptavidin and poly(methyl methacrylate) (PMMA) grafted to silicon substrates. Such a system has been fabricated using the ever-growing click chemistry approach. Functionalities found at the surface of the substrates are characterized through FTIR while the hydrophobic effects arising from the interactions between the grafted components of differing hydrophilicities are investigated through AFM. Adhesive properties of such a heterogeneous surface are calculated using data acquired from force-distance measurements. Furthermore, changes in these properties resulting from variations in streptavidin surface coverage and PMMA chain length are similarly studied.

10:00AM A44.00011 Dissipative mechanisms of the lateral friction in contact-mode atomic force microscopy of flexible alkane molecule films , F.Y. HANSEN, Technical University Denmark, P. SOZA, Pontificia University Catolica Chile, H. TAUB, University of Missouri-Columbia, M. KIWI, U. VOLKMANN, Pontificia University Catolica Chile — Molecular dynamics simulations are used to investigate lateral friction in contact-mode Atomic Force Microscopy of tetracosane (n-$C_{24}H_{50}$) films. We find larger friction coefficients on the surface of monolayer and bilayer films in which the long axis of the molecules is parallel to the interface than on a surface of molecules with the long axis perpendicular to the surface, in agreement with experimental results. The simulations reveal that the strength of the attractive film-tip interaction is an important factor in energy dissipation and that molecular flexibility provides a major dissipative mechanism as manifested by torsional motion about the carbon-carbon bonds of the molecules.

10:12AM A44.00012 Stress-Induced Slip at Polymer-Polymer Boundaries , ANDREW GUSTAFSON, University of Minnesota — The phenomena of stress-induced tangential slip at polymer-polymer interfaces is studied by simulation and analytic theory. Simulations combine a slip-link model of entanglement with a self-consistent field description of the interface. We consider how the slip velocity depends upon shear stress, interfacial entanglement density, and polymer chain length. Our analysis assumes that the strongly non-linear shear thinning of the interface observed in experiment is a result of convective release of interfacial entanglements.

10:24AM A44.00013 Optical Properties of Isolated MEH-PPV polymers in Developing Crazes , MENG-KUAN WANG, Dept. of Photonics Engineering, Yuan Ze University, CHIAU-HENG TSAU, WEI-CHENG LI, ARNOLD CHANG-MOU YANG, Dept. of Materials Science, National Tsing Hua University, JUI-HUNG HSU, Dept. of Material Science and Opto-electronic Science, National Sun Yat-sen University, JONATHON D. WHITE, Dept. of Photonics Engineering, Yuan Ze University — Potential applications in light emitting devices and solar cells have led to extensive research into optimizing the optical properties of Luminescent Conjugated Polymers. Straining MEH- PPV/polystyrene thin films has been observed to result in craze formation and an enhancement of photoluminescence (PL). Using confocal microscopy, the optical properties of these crazes were investigated. Emission from developed crazes was found to be highly polarized while a variety of effects were found for developing crazes. The survival time of polymers in the crazed regions was increased by over 30% relative to the bulk. This suggests a stretch induced alignment of emitting segments in MEH-PPV as well as an increased resistance to photobleaching.

10:36AM A44.00014 Quantitative surface parameter maps using Intermodulation Atomic Force Microscopy , DANIEL FORCHHEIMER, DANIEL PLATZ, ERIK THOLÉN, CARSTEN HUTTER, DAVID HAVILAND, Royal Institute of Technology (KTH), Stockholm, Sweden — It is well known that the phase image in amplitude modulation atomic force microscopy (AM-AFM) is sensitive to material properties of the surface. However that information is not enough to fully quantify the tip-surface interaction. We have developed Intermodulation AFM, based on a spectral analysis of the cantilever's *nonlinear* dynamics, which increases the amount of information obtained without increasing scan time.[1] We show how it is possible to extract quantitative material properties of the surface from this additional information. The method works under the assumption of a tip-surface force model, such as the DMT model, fitting the model parameters to the measured spectral data. The parameters are obtained at each pixel of the AFM image and form surface property maps which can be displayed together with topography. We demonstrate this on different surfaces such as polymer blends, extracting stiffness and adhesive properties.

10:48AM A44.00015 Direct Measurement of Acid-Base Interaction Energy at Polymer-Solid Interfaces[1] , ANISH KURIAN, SHISHIR PRASAD, ALI DHINOJWALA, The University of Akron — We have studied acid-base interactions at solid-liquid and solid- solid interfaces using interface-sensitive sum frequency generation (SFG) spectroscopy. The shift of the sapphire hydroxyl peak in contact with several polar and non-polar liquids and polymers was used to determine the interaction energy. The trend in the interaction energies cannot be explained by only measuring water contact angles. Molecular rearrangements at the sapphire interface, to maximize the interaction of the acid-base groups, play a dominant role and these effects are not accounted for in the current theoretical models. These results provide important insights in understanding adhesion, friction, and wetting on solid interfaces. In addition, we will present the consequences of the acid-base interactions on understanding surface segregation in polymer blends and copolymers.

Session A45 DAMOP: Focus Session: Exploring Quantum Phases in Cold Atom Systems A310

8:00AM A45.00001 Correlated phases of bosons in tilted, frustrated lattices , SUSANNE PIELAWA, TAKUYA KITAGAWA, EREZ BERG, SUBIR SACHDEV, Physics Department, Harvard University, Cambridge, MA 02138, USA — The search for correlated quantum phases of cold atoms in optical lattices has focused mainly on entangling the spin degrees of freedom on different lattice sites. We show that there are also rich possibilities for correlated phases in the density sector, and these are likely to be readily accessible by tilting Mott insulators into metastable states. It has been previously shown that a Mott insulator in a potential gradient undergoes an Ising quantum phase transition when the potential drop per lattice spacing is close to the repulsive interaction energy [1]. Here we theoretically study bosons in tilted, frustrated, two-dimensional lattices. The phases we find include phases with charge density order, a sliding Luttinger liquid phase, and a liquid-like ground state with no broken lattice symmetry.

8:12AM A45.00002 Pure Mott Phases in a Trapped 2D Hubbard Model[1] , DAVE CONE, Univ of California-Davis, VALY ROUSSEAU, Louisiana State University, SIMONE CHIESA, Univ of Tennessee-Knoxville, RICHARD SCALETTAR, Univ of California-Davis, GEORGE BATROUNI, Universite de Nice-Sophia Antipolis — In this talk, we report on Quantum Monte Carlo simulations of a Hubbard Hamiltonian which incorporates a proposed new method for confining ultracold atoms in an optical lattice. Termed "Off Diagonal Confinement (ODC)," this method employs an inhomogeneous array of hopping matrix elements which traps atoms by going to zero at the lattice edges. In contrast, the more conventional diagonal confinement(DC) trap uses a parabolic potential coupled to (diagonal) density operators. ODC has the advantage of producing systems which, while still being inhomogeneous, are entirely in the Mott phase. This makes the insulating behavior and associated antiferromagnetism more apparent, and also allows simulations which are free of the sign problem at low temperatures. We analyze the effects of using different ODC traps and compare results with those from DC traps, for density, spin, and pairing correlation functions, as well as entropy and temperature profiles. Finally, we will discuss the advantages and importance of this new confinement technique for modeling correlated systems, including the potential for reaching lower temperature scales by following constant entropy curves.

8:24AM A45.00003 Exploring classical and quantum criticality in two-dimensional quantum gases , CHEN-LUNG HUNG, XIBO ZHANG, LICHUNG HA, SHIHKUANG TUNG, NATHAN GEMELKE[1], CHENG CHIN, The University of Chicago — Continuous phase transitions in two dimensions (2D) are expected to exhibit intriguing universal behaviors near the critical point. Prominent examples include the Berezinsky-Kosterlitz-Thouless (BKT) transition and the superfluid (SF) to Mott insulator (MI) transition described by the Bose-Hubbard model. Both transitions are investigated in our system based on ultracold Bose gases confined in a pancake-like optical trap with or without an optical lattice potential. In this talk, we will present a study of the universal behavior near the BKT transition by probing the density profiles and their fluctuations at various temperatures and atomic interaction strengths. We report the observation of global scale-invariance and universality in scaled thermodynamic observables. Our measurement agrees with the classical field theoretical prediction as well as the Monte Carlo calculations, and shows growing density-density correlations in the critical regime. Further extensions of this work, including exploration of quantum criticality near the SF-MI phase boundary, will be discussed.

8:36AM A45.00004 Fermions in Optical Lattices: Cooling Protocol to Observe Antiferromagnetism[1] , NANDINI TRIVEDI, The Ohio State University — Experiments on ultracold atoms in optical lattices have the potential of probing the complex phase diagrams arising from simple Hamiltonians. One of the most challenging problems for an optical lattice emulator is that of cooling fermions to observe interesting broken symmetry phases. In this talk I will discuss recent theoretical progress on this question for the simplest model of interacting fermions: the Hubbard model. We determine the equation of state, the density $\rho(\mu, T, U/t)$, and the entropy of the 3D repulsive Hubbard model using exact determinental Quantum Monte Carlo (QMC) simulations. Using the local density approximation (LDA), we calculate the spatial variation of density, entropy density, double-occupancy, local compressibility and local spin correlations for different trap curvatures and interaction strengths U/t. In contrast to a homogeneous system, we show that in a trap we can locally squeeze out the entropy from certain regions and observe antiferromagnetic order, even though the total entropy per particle in the cloud is quite high. We show that significant cooling due to entropy redistribution in the trap can be achieved by two mechanisms: (a) by increasing the lattice depth, and (b) by decompressing the cloud. Our calculations can be an important guide in the race to observe antiferromagnetic order in optical lattices.

9:12AM A45.00005 Criticality in Trapped Atomic Systems[1] , NIKOLAY PROKOFIEV, BORIS SVISTUNOV, Department of Physics, University of Massachusetts, Amherst, LODE POLLET, Theoretische Physik, ETH Zurich — We discuss generic limits posed by the trap in atomic systems on the accurate determination of critical parameters for second-order phase transitions, from which we deduce optimal protocols to extract them. We show that under current experimental conditions the in-situ density profiles are barely suitable for an accurate study of critical points in the strongly correlated regime. Contrary to recent claims, the proper analysis of time-of-fight images yields critical parameters accurately. L. POllet, N. Prokof'ev, and B. Svistunov, Phys. Rev. Lett. 104, 245705 (2010).

9:24AM A45.00006 Inter-band coupling induced novel condensates in a double-well lattice[1] , QI ZHOU, Joint Quantum Institute and Condensed Matter Theory Center, University of Maryland, JAMES V. PORTO, Joint Quantum Institute, University of Maryland, SANKAR DAS SARMA, Joint Quantum Institute and Condensed Matter Theory Center, University of Maryland — We predict novel inter-band physics for bosons in a double-well lattice. An intrinsic coupling between the s and px band due to interaction gives rise to larger Mott regions on the phase diagram at even fillings than the ones at odd fillings. On the other hand, the ground state can form various types of condensates, including a mixture of single-particle condensates of both bands, a mixture of a single-particle condensate of one band and a pair-condensate of the other band, and a pair-condensate composed of one particle from one band and one hole from the other band. The predicted phenomena should be observable in current experiments on double-well optical lattices.

9:36AM A45.00007 Unconventional Bose-Einstein condensation in high orbital bands , CONGJUN WU, The Department of Physics, University of Science and Technology of China, ZI CAI, The Department of Physics, University of California, San Diego, ANDREAS HEMMERICH, Institut für Laser-Physik, Universität Hamburg, Luruper Chaussee 149, 22761 Hamburg, Germany — We perform the theoretical study on unconventional Bose-Einstein condensations (UBEC) in higher orbital bands of optical lattices observed by Hemmerich's group. These exotic states of bosons are non-zero condensation wavevectors, and thus beyond the "no-node" paradigm. We have studied various effects on UBECs including lattice asymmetry and interactions. The interplay between the kinetic and interaction energies gives rise to two different UBECs with the real and complex-valued condensation wavefunctions, respectively. The latter spontaneously breaks time-reversal symmetry, which is impossible in usual BEC systems.

9:48AM A45.00008 Topological semimetal: a probable new state of quantum optical lattice gases protected by D_4 symmetry[1] , KAI SUN, JQI and CMTC, University Of Maryland, W. VINCENT LIU, University of Pittsburgh and KITP UCSB, S. DAS SARMA, JQI and CMTC, University of Maryland — We demonstrate that a novel topological semimetal emerges as a parity-protected critical theory for fermionic atoms loaded in the p and d orbital bands of a two-dimensional optical lattice. The new quantum state is characterized by a parabolic band-degeneracy point with Berry flux 2π, in sharp contrast to the π flux of Dirac points as in graphene. We prove that this topological liquid is a universal property for all lattices of D_4 point group symmetry and the band degeneracy is protected by odd parity. Turning on interparticle repulsive interaction, the system undergoes a phase transition to a topological insulator, whose experimental signature includes chiral gapless domain-wall modes, reminiscent of quantum Hall edge states.

[1]KS and SDS acknowledge the support of JQI-NSF-PFC, AFOSR-MURI, ARO-DARPA-OLE and ARO-MURI. W.V.L. is supported by ARO and ARO-DARPA-OLE. We thank the KITP at UCSB for its hospitality where this research is supported in part by NSF Grant No. PHY05-51164.

10:00AM A45.00009 Unconventional superfluidity with non-collinear orbital order , HUBERT NGUYEN, ZI CAI, CONGJUN WU, UC San Diego — We propose an unconventional superfluid with spontaneous time-reversal symmetry breaking in p-orbital bands of cubic optical lattices. We find that in contrast to the square lattice which exhibits an antiferromagnetic orbital angular momentum (OAM), quantum fluctuations in the cubic lattice select an exotic superfluid state with non-collinear orderings of OAM moments. The collective excitations and phase transitions in this unconventional superfluid have also been discussed. This exotic superfluid state has no counterpart in solid state systems.

10:12AM A45.00010 Two distinct Mott-Insulator to Bose-glass transitions and breakdown of self averaging in the disordered Bose-Hubbard model , SEUNGMIN HONG, FRANK KRUGER[1], PHILIP PHILLIPS, University of Illinois, Urbana-Champaign — We show that two fixed points govern the Mott insulator to Bose glass transition in the disordered Bose-Hubbard model. At incommensurate fillings, the correlation length and the inverse compressibility diverge with exponents of $\nu = 1/D$ and $\gamma = 4/D - 1$, respectively, D the spatial dimension. We show that it is the breakdown of self-averaging (rare-region Griffiths physics) in the Bose glass that leads to a violation of the bound $\nu \geq 2/D$. At commensurate fillings, the transition is controlled by a different fixed point at which both the disorder and interaction vertices are relevant.

10:24AM A45.00011 Unbalanced fermion mixtures on an optical lattice , CHUNTAI SHI, University of California Riverside, TUN WANG, IQOQI-University of Innsbruck, Austria, SHAN-WEN TSAI, University of California Riverside — We study a two component fermion mixture on a square lattice. We describe such system by a Hubbard model wherein there is only on-site interaction between fermions of different species. Such a model can be realized by loading ultra cold fermions onto an optical lattice and by tuning the interaction strength via Feshbach resonance. We investigate the phase diagram of this system near half filling using the functional renormalization group approach for interacting fermions[1]. We focus on the interesting case where one species is at half filling so that their Fermi surface is nested while the other species is slightly doped so that their Fermi surface is not perfectly nested. We study both the cases with repulsive interaction and the cases with attractive interaction. For the attractive interaction, triplet pairing BCS instability among majority species compete with the singlet s-wave inter-species BCS pairing instability when the populations of two species are different. For the repulsive interaction, fermions with equal population are known to display d-wave singlet BCS pairing when both species are slightly doped away from half filling. When only one species of fermions is doped away from half filling, such d-wave instability is weakened while triplet pairing among majority species becomes possible.

10:36AM A45.00012 Bosonic models with Fermi-liquid kinematics: realizations and properties , PAUL GOLDBART, SARANG GOPALAKRISHNAN, Univ. of Illinois at Urbana-Champaign, AUSTEN LAMACRAFT, Univ. of Virginia — We consider models of interacting bosons in which the single-particle kinetic energy achieves its minimum on a surface in momentum space. The kinematics of such models resembles that resulting from Pauli blocking in Fermi liquids; therefore, Shankar's renormalization-group treatment of Fermi liquids [1] can be adapted to investigate phase transitions in these bosonic systems. We explore possible experimental realizations of such models in cold atomic gases: e.g., via spin-orbit coupling [2], multimode-cavity-mediated interactions [3], and Cooper pairing of Fermi gases in spin-dependent lattices. We address the phase structure and critical behavior of the resulting models within the framework of Ref. [1], focusing in particular on Bose-Einstein condensation and on quantum versions of the Brazovskii transition from a superfluid to a supersolid [3].

10:48AM A45.00013 Pairing and crystallization of one-dimensional atomic mixtures with mass imbalance , TOMMASO ROSCILDE, Ecole Normale Superieure de Lyon - France, MARCELLO DALMONTE, CRISTIAN DEGLI ESPOSTI BOSCHI, Bologna University - Italy — We numerically investigate mass-imbalanced binary mixtures of hardcore bosons (or equivalently of fermions) loaded in one-dimensional optical lattices, with special focus on their instabilities towards the loss of first-order (one-body) coherence. We find a fundamental asymmetry between attractive and repulsive interactions. Attraction is found to always lead to pairing, and to pair crystallization for very strong mass imbalance and commensurate fillings. In the repulsive case away from half filling the two atomic components remain instead decoupled (and first-order coherent) over a large parameter range, and undergo crystallization or phase separation only for large mass-imbalance and/or strong interactions. This fundamental asymmetry is at odds with recent theoretical predictions, and can be tested directly via time-of-flight experiments on trapped cold atoms.

Monday, March 21, 2011 11:15AM - 2:15PM –
Session B1 DCMP: Quantum Devices Based on Semiconductor Nanowires Ballroom A1

11:15AM B1.00001 Cooper-pair splitter: towards an efficient source of spin-entangled EPR pairs , CHRISTIAN SCHONENBERGER, Department of Physics, University of Basel — In quantum mechanics the properties of two and more particles can be *entangled*. In basic science pairs of entangled particles, so called Einstein-Podolsky-Rosen (EPR) pairs, play a special role as toy objects for fundamental studies. They provide such things as "spooky interaction at distance," but they also enable secure encoding and teleportation and are thus important for applications in quantum information technology. Whereas EPR pairs of photons can be generated by parametric down conversion (PDC) in a crystal, a similar source for EPR pairs of electrons does not exists yet. In several theory papers, it has been suggested to use a superconductor for this purpose. The superconducting ground state is formed by a condensate of Cooper-pairs which are electron pairs in a spin-singlet state. Since there are many Cooper pairs in a metallic superconductor like Al, the main tasks are to extract Cooper pairs one by one and to split them into different arms. A controlled and efficient splitting is possible if one makes use of Coulomb interaction [1]. This has recently be demonstrated by two groups [2-4] using hybrid quantum-dot devices with both superconducting and normal metal contacts. In the present talk, I will discuss the Cooper-pair splitter results from the Basel-Budapest-Copenhagen team [3] and compare with the other experiments. As an outlook we discuss approaches that aim at entanglement detection. The Cooper pair splitter holds great promises because very large splitting efficiencies approaching 100% and large pair current rates appear feasible. This work has been done by L. Hofstetter, S. Csonka, A. Geresdi, M. Aagesen, J. Nygard and C. Schönenberger

11:51AM B1.00002 Spin-orbit qubit in a semiconductor nanowire , SERGEY FROLOV, Kavli Institute of Nanoscience, Delft University of Technology — Spin-orbit interaction in InAs nanowires is so strong that spin and motion cannot be separated. The eigenstates of a single electron confined to a quantum dot become a spin-orbital doublet. We perform coherent manipulation of spin-orbit states of a single electron, thereby demonstrating a spin-orbit qubit. Fast and universal qubit control is achieved using gigahertz electric fields, which couple to the orbital part of the wavefunction. Qubits in adjacent quantum dots are addressed separately due to a gate-tunable difference in g-factors. Dephasing due to interaction with nuclear spins is studied in a Ramsey experiment. Coherence is extended using Hahn echo as well as Carr-Purcell-Meiboom-Gill dynamical decoupling pulse sequences. The next step is the demonstration of entanglement between neighbor qubits which can be achieved using exchange interaction.

12:27PM B1.00003 Prospecting for elusive Majorana particles in nanowires[1] , ROMAN LUTCHYN, Microsoft Station Q, UCSB — We propose and analyze theoretically an experimental setup for detecting the elusive Majorana particle in quasi-one dimensional semiconductor-superconductor heterostructures. The experimental system consists of a quasi one-dimensional semiconductor nanowire with strong spin-orbit Rashba interaction proximity coupled with an s-wave superconductor. Under appropriate conditions, such system can realize a non-trivial topological state supporting Majorana zero energy modes localized at the ends of the wire. These emerging Majorana quasiparticles, i.e. particles that are at the same time their own antiparticles, are effectively fractionalized objects (anyons) obeying non-Abelian statistics. We discuss several experiments for detecting Majorana fermions in nanowires.

1:03PM B1.00004 Spin States, Spin Correlations, Supercurrent, and Multiple Andreev Reflections in InSb Nanowire Quantum Devices , HONGQI XU, Lund University — Bulk InSb is one of the most promising materials for applications in spintronics and quantum information processing, due to the fact that it has the highest electron mobility μ_e = 77000 cm2/Vs, the smallest electron effective mass m_e* = 0.015 me, and the largest electron magnetic moment |g*| = 51 among all III-V semiconductors. Here, we report on realization and electrical measurements of InSb quantum dots and superconductor/InSb/superconductor hybrid quantum devices. The devices are made on a SiO2-capped Si substrate from InSb segments of InAs/InSb heterostructured nanowires grown by metal-organic vapor phase epitaxy. Spin states, effective g-factors, and spin-orbit interaction energy are measured for the fabricated InSb nanowire quantum dots [1]. We have also studied strong correlation phenomena and observed a new spin-correlation-induced phenomenon in the devices, namely the conductance blockade at the degeneracy of two orbital states with the same spin [2]. We attribute this conductance blockade to the effect of electron interference between two equivalent, strongly correlated, many-body states in the quantum dots. In superconductor/InSb nanowire/superconductor hybrid devices, we have observed supercurrent and multiple Andreev reflections, and have found that the fluctuations in the supercurrent are correlated to the conductance fluctuations of the corresponding InSb nanowires in the normal state. We have also observed multiple Andreev reflections and interplay between the Kondo correlation and proximity effect in the Coulomb blockade regime.

Session B2 DCMP: Many-Body Effects for the Excited States of Graphene Ballroom A2

11:15AM B2.00001 Optical properties of single- and few-layer graphene: the role of interlayer and many-body interactions , JIE SHAN, Case Western Reserve University — Graphene, a single layer of carbon atoms, has attracted much attention in the past few years because of its unique 2D structure and linear dispersion relation near the K-point of the Brillouin zone. Optical spectroscopy provides a powerful tool for probing the electronic structure and interactions in graphene. In this talk we will discuss two types of interactions that affect the optical response – those arising from interlayer coupling of electrons and those arising from many-body effects. The possibility of altering the low-energy band structure of graphene through the interlayer interactions in few-layer graphene (FLG) was recognized theoretically several years ago and was demonstrated experimentally recently by infrared absorption spectroscopy. Two distinct classes of IR absorption spectra for crystalline samples of the same number of layers, but different stacking order, were also observed. These findings demonstrate the pronounced effect of interlayer interaction and stacking order on the electronic structure of FLG. Furthermore, significant many-body effects are revealed in the optical conductivity spectra. These were manifested as excitonic modifications to optical absorption near the saddle- point singularities. The strong electron-hole interactions produce an asymmetric resonance, significantly red-shifted from the value predicted by ab-initio GW calculations for the band- to-band transitions. Our experiment also showed a weak dependence of the excitonic resonance in FLG on layer thickness. This result reflects the effective cancellation of the increasingly screened repulsive electron-electron and attractive electron-hole interactions.

11:51AM B2.00002 Band structures of expitaxial graphene: the role of many-body interactions , ELI ROTENBERG, Lawrence Berkeley National Laboratory — This abstract not available.

12:27PM B2.00003 Ultrafast Carrier Dynamics in Graphene and Few Layer Graphite[1] , HENRY VAN DRIEL, University of Toronto — Graphene and its multilayer counterparts provide unique opportunities to study how the ultrafast carrier dynamics of layered systems evolve with layer number. We have carried out systematic investigations [1] of layered graphitic materials, from graphene to bulk graphite, exfoliated on to a Si/Silicon oxide substrate. The samples are excited using 150 fs, 800 nm pulses at room temperature and the time resolved reflectivity and transmission is probed using 150 fs, 1300 nm pulses. The response is governed by two times constants, one near 250 fs and the other near 3 ps, but both vary with the number of layers. The time constant are related to carrier cooling kinetics, interband transitions and hot phonon effects. The change in the first time constant with layer number is discussed in terms of alterations to the band structure with increasing number of layers over a few layers while the changes in the longer time constant over 10's of layers is related to substrate coupling effects. The results are compared with results from related experiments [2,3] using multilayer graphene, epitaxially grown on SiC, and also from results from experiments [4] using freestanding, thin graphite layers. *Work carried out with R.W. Newson and J.J. Dean.

1:03PM B2.00004 The Ordering and Electronic Structure of Multilayer Epitaxial Graphene on SiC[1] , EDWARD CONRAD, Georgia Institute of Technology — The structural definition of graphene as a single sheet of hexagonal carbon limits how we view this material. It is the electronic properties of a single isolated graphene sheet that actually defines and motivates current graphene research. Remarkably, the best example of the idealized band structure of graphene comes does not come from a single graphene layer but from multilayer films grown on SiC. Multilayer epitaxial graphene (MEG) not only shows all the 2D properties expected for an isolated graphene sheet, but it the scalability to large scale integrated carbon circuits. I will show that the reason for this remarkable property, i.e. that a multilayer graphene films behaving like a single graphene sheet, is due to MEG's unique stacking. MEG films have a quasi-ordered rotational stacking that breaks the Bernal stacking symmetry associated with graphite. Angle resolved photoemission spectroscopy (ARPES) data demonstrates that the bands are linear at the K-point of these films. We can also show that the rotated stacking is highly ordered and that less than 20% of the graphene sheets in the film are Bernal stacked. I will also show that ARPES measurements on MEG films demonstrate serious inadequacies with both tight binding and ab initio formalisms. In particular the data shows no reductions in the Fermi velocity or the formation of Van Hove singularity that have been consistently predicted for this material.

1:39PM B2.00005 Raman spectroscopy of pristine, defected and strained graphene , ANDREA FERRARI, University of Cambridge — Raman spectroscopy is the most common and informative characterization technique in graphene science and technology. It is used to determine the number of layers, doping, strain, defects, functional groups, quality and type of edges [1-15]. I will discuss the historical development of the identification of the main Raman bands in graphene, focussing on the 2D" peak around 2450cm^{-1}, and its deep-UV Raman spectrum. I will then discuss the effects of defects, uniaxial and biaxial strain on the Raman spectrum. Combining strain and Raman measurements one can derive the constitutive relation for graphene, and gain insights in the resonant Raman process. The results on graphene are the basis to explain and unify analogous measurements on graphite, carbon fibres and carbon nanotubes reported over the past 30 years.

Session B3 FHP: The History of Superconductivity from its Discovery by Kammerlingh Onnes in 1911 Ballroom A3

11:15AM B3.00001 Heike Kamerlingh Onnes and the Road to Superconductivity , DIRK VAN DELFT, Director Museum Boerhaave — The discovery of superconductivity on 8 April 1911 came as a big surprise. It was stumbled upon in the Leiden cryogenic laboratory of Heike Kamerlingh Onnes in a moment of serendipity. Three years before, the liquefaction of helium on the other hand had been the culmination of a long battle with nature. It was a meticulously prepared operation, "big science" in its first appearance. Until recently, careless notebook entries by Kamerlingh Onnes and his terrible handwriting had hindered a complete view to the road to superconductivity. Even a date of the fascinating discovery was lacking. How did the discovery fit into the Leiden research program? What about the research effort Kamerlingh Onnes had to put in to be sure he had found superconductivity rather than a short-circuit? What about superfluidity? Once the right interpretation of the notebooks is clear, the real story can be told.

11:51AM B3.00002 From the Meissner Effect to the Isotope Effect: Precursors to the Microscopic Theory of Superconductivity , BRIAN SCHWARTZ, The Graduate Center of CUNY — After the discovery by Kamerlingh Onnes in 1911 of the low temperature disappearance of resistance in mercury to a state of perfect conductivity, there was a long period of more than two decades before there was a major experimental advance. In 1933, Meissner and Ochsenfeld discovered that a superconductor is not only a perfect conductor but in addition it is a perfect diamagnet. In 1935 F. and H. London presented a phenomenological understanding of the electromagnetic properties of the superconducting state, which included the London penetration depth for applied magnetic fields and later introduced the concept of a "stiffness" of the superconducting wave function. In 1950, Ginzburg and Landau developed a phenomenological theory for the superconducting state using general thermodynamic arguments.In the same year, Maxwell, and Serin et.al discovered the Isotope Effect which indicated that the electron-phonon interaction would play an important role in the theory of superconductivity.

12:27PM B3.00003 BCS: 50 Years , LEON COOPER, Brown University — The road to and from BCS: This talk was presented before an audience at Brown University on December 10th, 2010. The recording of the talk will be shown at the session in Dallas, as Professor Cooper will not be able to be present.

1:03PM B3.00004 Giaever, Nb3Sn, and Josephson , JOHN ROWELL, Arizona State University — The late 1950s and 1960s were times of remarkable progress in both the understanding and utilization of superconductivity. The majority of today's applications can be traced to key scientific advances made during a period of less than a decade, and the majority of those advances were made in the industrial research laboratories of the United States. As examples, in this talk I will mention the measurement of the specific heat and the critical current of Nb3Sn in high magnetic fields, the discovery by Giaever of tunneling between metal films and his direct observation of the superconducting energy gap, the understanding of strong coupling superconductors, leading to the development of tunneling spectroscopy of the electron-phonon pairing interaction, and the prediction by Josephson of pair tunneling.

1:39PM B3.00005 The arrival of high temperature superconductors[1] , PAUL C. W. CHU, Texas Center for Superconductivity, University of Houston and Lawrence Berkeley National Laboratory — The attainment of high temperature superconductivity has been considered a major advancement of modern science. It was the seminal discovery of the first cuprate high temperature superconductor, the Ba-doped La_2CuO_4, with a T_c of 35 K in 1986 by Alex Müller and George Bednorz of IBM Zurich Lab,[2] who were awarded the Nobel Prize in 1987, that ushered in the era of cuprate high temperature superconductivity. It was the first liquid nitrogen high temperature superconductor, $YBa_2Cu_3O_7$ with a T_c of 93 K discovered in 1987 by Paul C. W. Chu, Maw-Kuen Wu and colleagues in the respective groups at the University of Houston and the University of Alabama at Huntsville[3] that heralded the new era of high temperature superconductivity, drastically changing the psyche of superconductivity research and bringing superconductivity applications a giant step closer to reality. In the ensuing years, many high temperature superconductors have been found, leading to the current record T_c of 134 K which was observed by A. Schilling et al.[4] of ETH in 1993 in $HgBa_2Ca_2Cu_3O_{9-\delta}$ at ambient and later raised to 164 K under 30 GPa by L. Gao et al.[5] In the present talk, I shall briefly recall a few events leading to and during the arrival of high temperature superconductivity. The prospects for future superconductors with higher T_c will also be discussed.

Monday, March 21, 2011 11:15AM - 2:15PM –

Session B4 DPOLY: Hybrid Nanomaterials Assembly Ballroom A4

11:15AM B4.00001 "Hairy" Nanoparticles in Block Copolymers and Homopolymers: Modeling using Hybrid Self-Consistent Field Theory , VALERIY GINZBURG, The Dow Chemical Company — Today, dispersed nanoparticles play important role in various applications (toughened plastics, healthcare, personal care, etc.) Mesoscale simulations and theory are important in understanding what governs the morphology of nanoparticles under various conditions. In particular, for nanoparticle/block copolymer mixtures, two popular simulation methods are Self-Consistent Field/Density Functional Theory (SCF-DFT) (Thompson, Ginzburg, Matsen, and Balazs, Science 292, 2469 [2001]), and Hybrid Self-Consistent Field Theory (HSCFT) (Sides et al., Phys Rev Lett 96, 250601 [2006]). The two methods are shown to be very similar in their assumptions and end-results; the choice of the method to be used can depend on the specific problem. Here, we use modified HSCFT to explicitly account for the complicated role of short-chain ligands grafted onto nanoparticles to promote dispersion. In particular, we discuss the phase diagrams of such "hairy" nanoparticles in diblock copolymers as function of diblock composition, nanoparticle volume fraction, and ligand length. Depending on the particle size and ligand coverage, particles could segregate into favorable domain, stay close to the interface, or phase-separate from the block copolymer altogether. We also consider the dispersion of "hairy" nanoparticles in a homopolymer and analyze the morphologies of particle clusters as function of ligand length. The results could have interesting implications for the design of new nanocomposite materials.

11:51AM B4.00002 Direct hierarchical assemblies of nanoparticles in thin films , TING XU, Univ of California - Berkeley — This abstract not available.

12:27PM B4.00003 Aqueous foams stabilised solely by nanoparticles , DOMINIQUE LANGEVIN, CNRS — Particles are being increasingly used to stabilise foams and emulsions, the corresponding emulsions being known as "Pickering" emulsions. One of the peculiarities of these systems is the absence of Ostwald ripening: since the bubbles or drops do not grow (coalescence seems also suppressed) both foams and emulsions are stable over extremely long periods of time (months). These features make particles very interesting surface active agents as compared to standard surfactants or polymers/proteins. The origin of the suppression of ripening can be traced to the unusual behaviour of the interfacial layers made by these particles. The layers are solid-like and the usual characterisation methods (surface tension, surface rheology) are not straightforward to use. In this presentation, we will illustrate these difficulties with experiments made with partially hydrophobic silica nanoparticles. We will also discuss the relevance of foam characterisations methods such as multiple light scattering and X-ray tomography.

1:03PM B4.00004 Control of Nanoparticle Organization in Thin Homopolymer Films , PETER F. GREEN, Department of Materials Science and Engineering, University of Michigan, Ann Arbor, MI 48109 — The morphological structure of mixtures of homopolymers with chain-grafted nanoparticles is determined by competing interactions between the nanoparticle cores, the free host chains and the grafted chains. In the bulk, when the nanoparticle grafting density is low, the phase behavior is largely determined by a competition between attractive nanoparticle core-nanoparticle core interactions, mediated by the chains grafted to the surface. At high grafting densities, the entropic brush layer/free host chain interactions are dominant, leading to miscibility or to microscopic/macroscopic phase separation. Thin film mixtures are thermodynamically less stable than their bulk analogs due to the preferential attraction of grafted nanoparticles to the external interfaces. The preferential attraction of the nanoparticles to the interfaces is driven by factors that include: entropic gains of the grafted nanoparticles and linear host chains; van der Waals interactions between the nanoparticles and the interfaces. If the grafted chains and host chains are of dissimilar chemical structure, then the nanoparticles exhibit a tendency to segregate to the free surface, provided its grafts possess a lower surface energy than the host chains. Consequences of these interactions on the overall nanoparticle organization in thin homopolymer films will be discussed.

1:39PM B4.00005 Nanoparticle Self-Assembly in a Polymer Matrix and Its Impact on Phase Separation , JACK DOUGLAS, Polymers Division, NIST — The ubiquitous clustering of nanoparticles (NPs) in solutions and polymer melts depends sensitively on the strength and directionality of the effective NP-NP interactions, as well as on the molecular geometry and interactions of the dispersing fluid. Surface functionalization apparently can also lead to emergent anisotropic interactions that can influence NP dispersion. Since NP clustering can strongly influence the properties of polymer nanocomposites and NP solutions, we investigate the reversible self-assembly of model NPs into clusters under equilibrium conditions through a combination of simulation and analytic methods. First, we performed molecular dynamics simulations of polyhedral NPs in a coarse-grained dense bead–spring polymer melt and find a transition from a dispersed to clustered NP state, consistent with the thermodynamic models of equilibrium particle association such as equilibrium polymerization. We also describe the competition between self-assembly and phase separation in an analytic lattice model of a mixture of polymers and NPs. We then focus on the particularly interesting situation where the associating "monomeric" NP species form high molecular mass dynamic polymeric clusters and where the assembly process then transforms the phase boundary from a form typical of a polymer solution to one that more resembles a polymer blend with increasing association near the critical point for phase separation. The model calculations elucidate basic physical principles governing the coupling of self-assembly and phase behavior in these complex mixtures.

Monday, March 21, 2011 11:15AM - 2:15PM –
Session B5 DCMP FEd: Mentoring Undergraduate Research Ballroom C1

11:15AM B5.00001 Using seminar-based instruction to convey contemporary research to undergraduates , ERIC MAZUR, Harvard University — This abstract not available.

11:51AM B5.00002 Flocking and self-defense: experiments and simulations of avian mobbing , SUZANNE AMADOR KANE, Physics Department, Haverford College, Haverford PA — We have performed motion capture studies in the field of avian mobbing, in which flocks of prey birds harass predatory birds. Our empirical studies cover both field observations of mobbing occurring in mid-air, where both predator and prey are in flight, and an experimental system using actual prey birds and simulated predator "perch and wait" strategies. To model our results and establish the effectiveness of mobbing flight paths at minimizing risk of capture while optimizing predator harassment, we have performed computer simulations using the actual measured trajectories of mobbing prey birds combined with model predator trajectories. To accurately simulate predator motion, we also measured raptor acceleration and flight dynamics, well as prey-pursuit strategies. These experiments and theoretical studies were all performed with undergraduate research assistants in a liberal arts college setting. This work illustrates how biological physics provides undergraduate research projects well-suited to the abilities of physics majors with interdisciplinary science interests and diverse backgrounds.

12:27PM B5.00003 Involving undergraduates in interdisciplinary research: The physics of biomineralization , PUPA GILBERT, University of Wisconsin-Madison — Biominerals include mollusk shells, the skeletons of sea urchins, corals, mammals, etc. Their formation mechanisms fascinate physicists, materials scientists, and chemists because they result in materials more robust than their components, with exquisitely intricate nano-structures, fill space more than synthetic nanoparticles, and directly control phase transitions. Because of the fundamental nature of research on the physical aspects of biominerals, their formation mechanisms, the potential for future bio-inspired materials synthesis, and the aesthetic beauty of biomineral structures, students of all ages are interested in biomineralization. While describing the involvement of undergraduates in this research, my talk will address two key questions: Q: How do biominerals achieve the beautiful morphologies we observe? A: By forming through amorphous precursor phases, with morphology and phase transitions directly under biological control [1, 2]. Q: How do organisms order their biominerals to be single-crystalline? A: By controlling crystal growth at the nanoscale, not atom by atom [3, 4].

1:03PM B5.00004 Processing and Characterization of New Materials at Pomona College with External Collaborations , DAVID TANENBAUM, Pomona College — My research program focuses on the evolution of novel lithographic, growth, and characterization processes for use with thin films for microelectronics and photovoltaic technologies. We have established facilities at Pomona College for wet chemistry, spin coating, thermal evaporation, micro-contact printing, ultra violet ozone cleaning, oxygen plasma cleaning, Au/Pd sputter coating, critical point drying, optical microscopy, optical lithography, ellipsometry, spectral reflectance, electrical conductivity, current-voltage characterization, atomic force microscopy, scanning tunneling microscopy, electron microscopy, electron beam lithography, and energy dispersive x-ray spectroscopy. Active collaborations with researchers at Cornell University and at Risø National Laboratory for Sustainable Energy (in Denmark) keep the research program vibrant and relevant. Since 2001, I have been an active member of the Cornell Center for Nanoscale Systems. Recent research and publications have focused on carbon nanotubes, graphene sheets, and organic photovoltaics. Pomona College students have played significant roles in all these projects, as well as in the development of our facilities. Connections to a wide range of researchers are invaluable not only for scientific discussions, but provide many opportunities for summer REU internships for my research students. This provides valuable training, access to facilities, and seeds future collaborations. Collaborations at Cornell span 15 years including two sabbatical years and regular summer visits to work at sites such as the Cornell Nanofabrication Facility, the Cornell Center for Materials Research, and the Cornell Center for Nanoscale Systems.

1:39PM B5.00005 Mentoring undergraduates for experimental research in physic , JEREMY LEVY, Univ of Pittsburgh — This abstract not available.

Monday, March 21, 2011 11:15AM - 2:15PM –
Session B6 DAMOP: Few-body Aspects of Cold Atomic Gases Ballroom C2

11:15AM B6.00001 Interacting and Rotating Gases of a Few Trapped Atoms , NATHAN GEMELKE, Penn State University — I will discuss attempts to generate motionally entangled states in small clusters of repulsively interacting Bosonic atoms at nonzero angular momentum in two-dimensional harmonic traps.[1] By constructing an "array of rotating buckets" from an optical lattice of spinning and precisely controlled on-site potentials, small clusters of interacting atoms can be adiabatically transferred from uncorrelated states at zero angular momentum through a tabulated sequence of ground state level crossings with increasing atomic correlation and total angular momentum. Results will be shown probing these states with both time-of- flight techniques and by directly interrogating atomic correlation via photo-association to excited molecules. Comparison will be made to numeric models with no free parameters. I will discuss extension of these results to future experiments using Feshbach-resonant interactions, and the use of dynamically modulated lattice potentials to generate effective gauge fields.

[1] Gemelke, N., Sarajlic, E., Chu, S., arXiv:1007.2677

11:51AM B6.00002 Deterministic preparation and control of a tunable few-fermion system[1] , GERHARD ZUERN, Heidelberg University — Systems consisting of only few interacting fermions play a fundamental role in nature with atoms and atomic nuclei being the most prominent examples. In our experiments with ultracold atoms we have recently been able to prepare and control few-atom quantum states consisting of 1-10 fermions. We prepare such a system using ultracold ^{6}Lithium atoms in an optical dipole trap in which the interparticle interaction can be tuned over a wide range using a Feshbach resonance. By spilling all atoms occupying higher energy quantum states we can deterministically prepare samples from 1-10 particles in the ground state with fidelities exceeding 90%. In my talk I will present our first experiments controlling the interaction between particles in the ground state of the trap.

[1]Work done in collaboration with Selim Jochim, University of Heidelberg.

12:27PM B6.00003 Four-body Efimov effect , YVAN CASTIN, LKB - ENS — The few-body problem with resonant two-body s-wave interaction (that is with an infinite scattering length) can now be studied experimentally with ultracold atomic gases. In particular, the three-body Efimov phenomenon (Efimov, 1971), consisting in the existence of an infinite number of trimer states with an asymptotically geometric spectrum in the vicinity of a zero energy accumulation point, has now obtained experimental evidence. On the contrary, the four-body Efimov effect has remained elusive, both theoretically and experimentally. Strictly speaking, for same spin state bosons, as pointed out by Amado and Greenwood (1973), it is *a priori* excluded by the existence of the three-body Efimov effect: A tetramer state with an energy arbitrarily close to zero has eventually an energy larger than an Efimov trimer state and may decay into this trimer plus a free atom. We have found a system where a four-body Efimov effect takes place: It is made of three same spin state fermions of mass M interacting only with a lighter particle of mass m. The mass ratio $\alpha = M/m$ is used as a control knob: This system experiences a three-body Efimov effect if and only if $\alpha > \alpha_c(2;1) \simeq 13.607$ (Efimov, 1973; Petrov, 2003). Using a combination of symmetry arguments and a numerical solution of an integral equation,we show that Efimov tetramers exist over the interval of mass ratio $\alpha_c(3;1) < \alpha < \alpha_c(2;1)$, with $\alpha_c(3;1) \simeq 13.384$. The four-body Efimov exponent $|s|$ is also calculated as a function of α over that interval, and the experimental feasibility is discussed.

1:03PM B6.00004 Interferometry with ultra-cold few-atom states , EITE TIESINGA, Joint Quantum Institute — I will explain some of our recent modeling of experiments that loaded an atomic Bose-Einstein condensate into a three-dimensional optical lattice. In an optical lattice, a periodic trap for atoms, the condensate can be divided into millions of independent atomic coherent states. These states are superpositions of different atom number and the analogue of coherent states of light or photons. As in the case of coherent laser light these atomic states can be made to interfere. In fact, the time-evolution of the states leads to collapse and revivals in interference patterns observed in the atomic momentum distribution. I show that long-period revivals are associated to effective three-body interactions that are due to virtual excitations to higher vibrational states within a site of an optical lattice. This work has been published as P. R. Johnson, E. Tiesinga, J. V. Porto, and C. J. Williams, New Journal of Physics **11**, 093022 (2009).

1:39PM B6.00005 Virial Expansion for a Strongly Correlated Fermi Gas , HUI HU, Centre for Atom Optics and Ultrafast Spectroscopy, Swinburne University of Technology — Few-body physics can give considerable insight into the challenging many-body problem. A concrete example is the exact Tan relations [1] linking the "hard" (few-body) physics at short distance, large-momentum and high frequency to the "soft" physics of the equation of state via a contact parameter. This has been demonstrated clearly using the operator product expansion (OPE) method [2] which separates in a natural way few-body from many-body physics. In this talk, we present another example: the quantum virial expansion that bridges few-body and many-body physics. At large temperatures, the properties of a strongly correlated Fermi gas, either static or dynamic, can be expanded in terms of virial coefficients or expansion functions, calculable from the few-fermion solutions [3]. For the equation of state in the resonant unitarity limit [3], we obtain for the first time an accurate third order virial coefficient. This has been experimentally verified in a measurement at ENS (Paris) [4]. For the single-particle spectral function [5], we demonstrate that an expansion up to second order is able to explain the main features of momentum-resolved RF spectroscopy in a resonantly interacting Fermi gas, as recently reported by JILA [6]. We also obtain a virial expansion of the dynamic structure function, as measured at Swinburne University (Melbourne), and check that the second order expansion functions give the correct OPE coefficients in the limit of large momentum and frequency. The important feature of this expansion is the existence of a small parameter, the fugacity, even for strong interactions. In the future, we anticipate that higher-order virial expansions of dynamic properties such as the single-particle spectral function may provide useful insights into clarifying the debate on the pseudo-gap issue in resonantly interacting Fermi gases.

Session B7 DPB: Superconductivity in Accelerators Ballroom C3

11:15AM B7.00001 Superconducting Accelerator Structures: An Historical Overview[1] , PERRY WILSON, SLAC, Stanford — In 1961 I began doing active research on RF superconducting cavities at the High Energy Physics Laboratory (HEPL) at Stanford University. At that time there were already nascent research programs exploring superconducting cavities at four other laboratories around the world, including the one at the Stanford physics department. However, all attempts to produce a substantial accelerating field in a superconducting cavity had failed. Since a cavity that is capable of acceleration always has a surface electric field, I decided that my first research effort would be to build and test a cavity with only a magnetic field at the surface. The frequency would need to be 2856 MHz, that of the electron linac at HEPL, so that available instrumentation could be used. In order to have only a magnetic field at the surface, the cavity would have to operate in the so-called TE mode. But there was a problem: at 2856 MHz such a cavity would be considerably larger than the single-cell accelerating mode cavities previously built at the Stanford physics department. In collaboration with the low temperature physics group in the Stanford physics department, a larger electroplating facility was built that was capable of handling the cylindrical cavity body and two end plates. The initial measurements gave stunning results: a Q factor of about 10^8 at 4°K for a lead-plated cavity was obtained, and there was no degradation in Q up to a surface magnetic field of about 10 mT, (limited by the oscillator power). The results were published in 1963. Experimentation on superconducting accelerator cavities increased rapidly in the decade or so following this initial success. Successful niobium TM-mode (accelerating mode) cavities were built with Q's of about 10^{11}. Within a few years the multipactor problem in accelerating cavities was solved by changing the shape of the outer boundary. The initial impetus for superconducting accelerator research at Stanford was to design and build a long pulse superconducting linac with an energy of about one GeV. Such a linac has still not been realized, but in the years from 1970 to 1990 there have been successful applications of RF superconducting structures to storage rings, rf separators, drive linacs for FEL's, and heavy ion accelerators. The evolution superconducting structures and their applications, as outlined above, will be discussed in more detail in my talk

[1]Work supported by Department of Energy contract DE-AC03-76SF00515

11:51AM B7.00002 Superconductors for superconducting magnets , DAVID LARBALESTIER, National High Magnetic Field Laboratory — Even in 1913 Kamerlingh Onnes envisioned the use of superconductors to create powerful magnetic fields well beyond the capability provided by cooling normal metals with liquid helium. Only some "bad places" in his Hg and Pb wires seemed to impede his first attempts at this dream, one that he imagined would be resolved in a few weeks of effort. In fact, of course, resolution required another 50 years and development of both a true understanding of the difference between type I and type II superconductors and the discovery of compounds such as Nb_3Sn that could remain superconducting to fields as high as 30 T. And then indeed, starting in the 1960s, Onnes's dreams were comfortably surpassed. In the last 45 years virtually all superconducting magnets have been made from just two Nb-base materials, Nb-Ti and Nb_3Sn. Now it seems that a new generation of magnets based on cuprate high temperature superconductors with fields well above 30 T are possible using Bi-Sr-Ca-Cu-O and the RE-Ba-Cu-O compounds. We hope that a first demonstration of this possibility will be an all-superconducting 32 T magnet with RE-Ba-Cu-O insert that we are building for NHMFL users. The magnet application potential of this new generation of superconducting conductors will be discussed.

12:27PM B7.00003 State of the art superconducting magnet development , GIANLUCA SABBI, LBNL — This abstract not available.

1:03PM B7.00004 RF Superconductivity: the ultimate limit , HASAN PADAMSEE, Cornell University — This abstract not available.

1:39PM B7.00005 Cryogenic Systems: Recent Trends and New Directions , JOHN WEISEND, NSCL Michigan State University — The production of reliable cryogenic temperatures is vital for the use of superconductivity in accelerators. Cryogenics is found in the accelerating structures and magnets of the accelerator as well as in the magnets and calorimeters of the detectors in the experimental areas. In the century since the discovery of superconductivity, cryogenic systems have gone from small laboratory devices to very large industrial scale systems involving multiple refrigeration plants, containing over 100 tonnes of liquid helium. These systems, while specialized, represent a mature, well understood technology. This paper will survey the current status of cryogenic systems in accelerators and describe recent trends including: the large scale use of He II (superfluid helium) and the development of higher reliability and higher efficiency systems. It will also discuss future directions including the increased use of HiTc current leads, possible applications for small cryocoolers and the potential impact of the world helium supply on accelerator cryogenics.

Monday, March 21, 2011 11:15AM - 2:15PM –

Session B8 FIP: Critical Materials for Global Science and Technology Ballroom C4

11:15AM B8.00001 Unobtainium? Critical Elements for New Energy Technologies , ROBERT JAFFE, MIT — I will report on a recently completed study jointly sponsored by the APS Panel on Public Affairs (POPA) and the Material Research Society (MRS). The twin pressures of increasing demand for energy and increasing concern about anthropogenic climate change have stimulated research into new sources of energy and novel ways to harvest, transmit, store, transform or conserve it. At the same time, advances in physics, chemistry, and material science have enabled researchers to identify chemical elements with properties that can be finely tuned to their specific needs and to employ them in new energy-related technologies. Elements like dysprosium, gallium, germanium, indium, lanthanum, neodymium, rhenium, or tellurium, which were once laboratory curiosities, now figure centrally when novel energy systems are discussed. Many of these elements are not at present mined, refined, or traded in large quantities. However new technologies can only impact our energy needs if they can be scaled from laboratory, to demonstration, to massive implementation. As a result, some previously unfamiliar elements will be needed in great quantities. We refer to these elements as energy-critical elements (ECEs). Although the technologies in which they are employed and their abundance in the Earth's crust vary greatly, ECEs have many features in common. The purpose of the POPA/MRS study was to evaluate constraints on availability of energy-critical elements and to make recommendations that can help avoid these obstructions.

11:51AM B8.00002 Using Earth Abundant Minerals for New Research Pathways in Solar PV and Battery Storage , CYRUS WADIA, Co-Director, Cleantech to Market - Directorate - Lawrence Berkeley National Laboratory — Dr. Wadia will provide an in-depth look at his research to discover and develop a new material system toward a more expansive solar photovoltaic future, covering topics of: materials selection based on abundance, new synthetic pathways for scaleable materials, and results of working solar cell devices he has fabricated with these principles in mind. He will also discuss the results of his latest paper exploring the resource constraints on electrochemical storage for both transportation and grid scale applications.

12:27PM B8.00003 Essentials for Successful and Widespread LED Lighting Adoption , NISA KHAN, LED Lighting Technologies — Solid-state lighting (SSL), with light-emitting diodes (LEDs) as the light source, is a growing and essential field, particularly in regard to the heightened need for global energy efficiency. In recent years, SSL has experienced remarkable advances in efficiency, light output magnitude and quality. Thus such diverse applications as signage, message centers, displays, and special lighting are now adopting LEDs, taking 2010's market to $9.1 billion - 68% growth from the previous year! While this is promising, future growth in both display and lighting applications will rely upon unveiling deeper understanding and key innovations in LED lighting science and technologies. In this presentation, some LED lighting fundamentals, engineering challenges and novel solutions will be discussed to address reduction in efficiency (a.k.a. droop) at high currents, and to obtain uniform light distribution for overcoming LEDs' directional nature. The droop phenomenon has been a subject of much controversy in the industry and despite several studies and claims, a widely-accepted explanation still lacks because of counter arguments and experiments. Recently several research studies have identified that the droop behavior in nitride-based LEDs beyond certain current density ranges can only be comprehensively explained if the current leaking beyond the LED active region is included. Although such studies have identified a few useful current leakage mechanisms outside the active region, no one has included current leakage, due to non-ideal, 3-D device structures that create undesirable current distribution inside and outside the active region. This talk will address achieving desirable current distributions from optimized 3-D device structures that should reduce current leakage and hence the droop behavior. In addition to novel LED design solutions for droop reduction and uniform light distribution, the talk will address cost and yield concerns as they pertain to core material scarcity. Such solutions are expected to make LED lights more energy efficient, pleasant in appearance, longer-lasting, affordable, and thus suitable for green living.

1:03PM B8.00004 Niobium and its Impact on Superconducting Radiofrequency Technology , ANDREW HUTTON, Thomas Jefferson National Accelerator Facility — The Continuous Electron Beam Accelerator Facility at Jefferson Lab in Newport News, Virginia, was the first large-scale deployment of superconducting radiofrequency (RF) technology, and was optimized for nuclear/high energy physics research. The success of this technology led to the creation of a Free Electron Laser (FEL) facility at Jefferson Lab that has achieved world-record power, and is leading the way towards the next generation of FELs based on superconducting energy-recovery linacs. Superconducting RF technology has been adopted for other large accelerators (LEP, SNS) and is proposed for many of the future large accelerator facilities (ESS, FRIB, ILC, Project X, etc.). All these applications rely on the superconducting properties of niobium. While the performance of niobium accelerating cavities has been excellent, there are still improvements being developed, in particular, the new ingot niobium technology. This talk will provide a review of superconducting RF technology and the impact it has had, and will continue to have, on the accelerator field.

1:39PM B8.00005 Isotopes for Research - Can We Continue to Depend on Them? , ROBERT ATCHER, Los Alamos National Laboratory — The use of isotopes as tracers has been critical to many scientific endeavors. The discovery of radioactivity was quickly followed by experiments in which radioisotopes were being used to trace the behavior of those elements in biologic systems including humans. More recently, the ability to separate and enrich stable isotopes has facilitated their use as probes in a variety of applications using magnetic resonance, mass spectrometry and post facto neutron activation to determine their distribution, concentration and chemical form. Recently, shortages of both stable enriched and radioisotopes have had an impact on endeavors on which they play an important role.

Monday, March 21, 2011 11:15AM - 1:51PM –
Session B9 DFD: Nanofluidics D220

11:15AM B9.00001 Message in a bottle: the statistical behavior of nanoparticles in optical confinement[1] , H. DANIEL OU-YANG, JOSEPH JUNIO, LIANGCHENG ZHOU, Lehigh University — In an aqueous medium, container surfaces can significantly alter the behavior of suspended nanoparticles. We propose a method to investigate nanoparticle behavior in a boundary-free environment by transiently trapping them with a focused laser beam. While optical confined, as in an optical bottle, these particles are affected by both particle-light and particle-particle interactions. Time-averaged fluorescence imaging produces results in 3D mapping of the nanoparticle concentration in the bottle. We report how we analyze the messages in the bottle, i.e. the statistical behavior of these particles, by using the 3D distributions obtained under both controlled optical and interparticle forces.

[1]This project is supported in part by NSF DMR 0923299, Pennsylvania Department of Commerce and Economic Development through the Center for Optical Technologies at Lehigh University and the Pennsylvania Department of Health CURE Formula Funds.

11:27AM B9.00002 Low-frequency dielectric response of a single particle in aqueous suspensions , JINGYU WANG, Physics, Lehigh University, Bethlehem, PA, USA 18015, H. DANIEL OU-YANG, Physics and Bioengineering, Lehigh University, Bethlehem, PA, USA 18015 — $\alpha-$relaxation, the counterion diffusion in the electric double layer, has been used to described the anomalous low frequency dielectric dispersion of aqueous suspensions of colloidal particles. A microscopic theory describing this relaxation process proposed by Schwarz, however, has not been investigated systematically. We propose to use a single particle dielectrophoresis (DEP) force spectroscopy to study the relaxation mechanism as a function of particles size, temperature and solvent viscosity. Specifically, we measure the dependence of the DEP crossover frequency force and compare results with predictions by Schwarz.

11:39AM B9.00003 Investigation of MEMS force sensors for nano-scale water measurements[1] , SOYOUNG KWON, WONHO JHE, COREY STAMBAUGH, Seoul National University — Nanoscale water formed by capillary condensation has typically been studied by means of an atomic force microscope (AFM). While this approach can provide details about the dynamic visco-elastic properties, it is limited in the type of information that can be measured. Here we propose replacing the fixed sample surface generally used in AFM systems with movable micro-mechanical force sensors (MEMS) fabricated specifically for tapping mode or shear mode. By incorporating a MEMS device we can directly measure the adhesion force, pull-in distance and capillary force of nano confined water while the AFM collects information pertaining to the dynamic visco-elastic properties. In this talk, we will characterize the force measurement in the system and discuss the behavior of the device in the presence of nano-scale water.

[1]Work supported NRF of Korea and NSF grant OISE #0853104.

11:51AM B9.00004 Investigation of the Static and Dynamic Mechanical Properties of Nano-scale Water[1] , COREY STAMBAUGH, SOYOUNG KWON, WONHO JHE, Seoul National University — The behavior of liquids on the nano-scale has become an area of interest as new fabrication techniques have allowed for increasingly smaller structures to be made. While much work has been done on the interactions forces at liquid and solid interfaces, questions still remain regarding the behavior of nano-scale liquids. By incorporating a micro-electromechanical force sensor (MEMS) into the quartz tuning fork based atomic force microscope (QTF-AFM) probe setup we are able to both manipulate and measure nano-scale water, which in turn provides information beyond the standard AFM approach. Here we look at both the static and dynamic mechanical properties of water formed between the tip of a (QTF-AFM) probe and the polysilicon surface of a MEMS device.

[1]Work supported by NSF grant OISE #0853104.

12:03PM B9.00005 Thermophoretic stretching of DNA in polymer nanochannels , JONAS PEDERSEN, LASSE THAMDRUP, HENRIK FLYVBJERG, ANDERS KRISTENSEN, Technical University of Denmark — We demonstrate that thermophoretic forces generated by light-induced local heating can enhance the extension of genomic-length DNA confined in a polymer nanochannel. By temperature control on the micron-scale, bacteriophage T4 DNA is locally stretched to 80% of its contour length, although the cross-section of the nanochannel is as large as 250x250nm^2. A coarse-grained model of the forces at play captures the DNA-molecule's response to thermophoretic forces with accuracy and precision, and allows for fitting the density profile of the stretched DNA with only a single fit-parameter. The forces involved are relatively strong, because they add up along the molecule. They are measured by using the molecule as an entropic spring balance. Pending a calculation of these forces, this experiment might discriminate between the competing theories for thermophoretic forces.

12:15PM B9.00006 Poisson or not Poisson: Probability distribution of colloidal nanoparticles in an optical trap , YI HU, XUANHONG CHENG, H. DANIEL OU-YANG — In a colloidal suspension of nanoparticles, the presence of an optical trap can exponentially enhance the probability of finding the particles in the vicinity of the trap. Intriguing questions arise regarding whether the probably distribution of particle number in the trap follows Poisson approximation, and if so, what is the upper limit of the trapping energy at which Poisson is followed. To answer these questions, we conduct experiments to determine directly the variance and the mean particle number in the trap at different trapping energies and compare with the predictions of the probability theory.

12:27PM B9.00007 Charging Dynamics of Sub-nanometer Pores , YING LIU, Clemson University, GUANG FENG, JINGSONG HUANG, BOBBY SUMPTER, Oak Ridge National Laboratory, VINCENT MEUNIER, Rensselaer Polytechnic Institute, RUI QIAO, Clemson University — Electrodes featuring sub-nanometer pores can potentially improve the energy density of supercapacitors significantly. However, ions entering such narrow pores often need to pay an energy penalty because part of their salvation shell must be removed. This can potentially limit the charging kinetics of such nanopores. In this work, we investigate the charging dynamics of sub-nanometer pores connected with an electrolyte bath. We quantify the energy barrier for ions to enter 0.82-nm wide slit pores and determine the time constant for charging of the pores using Molecular Dynamics simulations. Strong concentration polarization is found during the charging process and the charging kinetics is much slower than that predicted using the classical equivalent circuit model. The results are rationalized using a modified Poisson-Nernst-Planck model.

12:39PM B9.00008 Statics and Dynamics of Stretched Single DNA Molecules Tug-of-War at Micro-Nanofluidic Interfaces , JIAWEI YEH, Institude of Physics, National Taiwan University, ALESSANDRO TALONI, Tel Aviv University, YENG-LONG CHEN, CHIA-FU CHOU[1], Institute of Physics, Academia Sinica — Understanding single molecule dynamics at micro-nanoscale interfaces has implications to polymer transport in biological processes, device design for single molecule analysis and biotechnological applications. We report our study on single DNA molecules straddling across a nanoslit, bridging two micro-nanofluidic interfaces, for both its tug-of-war behavior and confinement-induced entropic recoiling at varying length and height (h: 30∼100 nm) of a nanoslit. From a modified worm-like chain model in the tug-of-war scenario and the scaling analysis in the entropic recoiling process, we demonstrate the entropic recoiling force is essentially constant, given the degree of confinement, irrespective of the DNA length inside the nanoslit and the slit length. The scaling exponents for the entropic force will also be discussed.

[1]corresponding author

12:51PM B9.00009 Long time dynamics of single linear and circular ds-DNA confined in sub-100nm nanoslits , PO-KENG LIN, JEN-FANG CHANG, I. STACHIV, CHIA-FU CHOU, Y.- L. CHEN, Institute of Physics, Academia Sinica, Taipei Taiwan — We investigate the role of topological constraints on DNA dynamics in very strong confinement to study the dynamics of nuclear chromosome and DNA viral packaging. Experiments and simulations were carried out to investigate the equilibrium shape and dynamics of the single linear and circular λ-DNA confined in a silicon/glass nanoslit. We measured the chain extension r, shape asphericity A, extensional ($\tau_{||}$) and rotational relaxation time τ_r, and examined the dependence on chain topology as functions of the slit height h(20 $\sim$ 780 nm) and the solvent ionic strength I (0.8 $\sim$250 mM). We observed that the shape asphericity increases as h and$I$ decrease as the chain shape becomes anisotropic. Moreover, in sub-Kuhn length confinement, the DNA relaxation time increases with decreasing h in a smooth and broad transition.

1:03PM B9.00010 Heat-Driven Release of a Drug Molecule From Carbon Nanotubes , VITALY CHABAN, OLEG PREZHDO, University of Rochester — Hydrophobicity and ability to absorb light that penetrates through living tissues make carbon nanotubes (CNTs) promising intracellular drug delivery agents. Following insertion of a drug molecule into a CNT, the latter is delivered into a tissue, is heated by near infrared radiation, and releases the drug. In order to assess the feasibility of this scheme, we investigate the rates of energy transfer between CNT, water and the drug molecule, and study the temperature and concentration dependence of the diffusion coefficient of the drug molecule inside CNTs. We use ciprofloxacin (CIP) as a sample drug: direct penetration of CIP through cell membranes is problematic due to its high polarity. The simulations show that a heated CNT rapidly deposits its energy to CIP and water. All estimated timescales for the vibrational energy exchange between CNT, CIP and water are less than 10 ps at 298 K. As the system temperature grows from 278 K to 363 K, the diffusion coefficient of the confined CIP increases 5-7 times, depending on CIP concentration. The diffusion coefficient slightly drops with increasing CIP concentration. This effect is more pronounced at higher temperatures. The simulations support the idea that optical heating of CNTs can assist in releasing encapsulated drugs.

1:15PM B9.00011 Characterization of Nanostructured Silicon Membranes for Control of Molecular Transport , BERNADETA SRIJANTO, SCOTT RETTERER, JASON FOWLKES , MITCHEL DOKTYCZ, Oak Ridge National Laboratory — Fabrication of nanoporous membranes for selective transport of molecular species requires precise engineering at the nanoscale. The membrane permeability can be tuned by controlling the physical structure and the surface chemistry of the pores. We use a combination of electron-beam and optical lithography, along with cryogenic deep reactive ion etching, to fabricate silicon membranes that are physically robust and have uniform pore sizes. Pore sizes are further reduced using plasma enhanced chemical vapor deposition and atomic layer deposition of silicon dioxide onto the membrane surfaces. Integrating nanoporous membranes within a microfluidic network provides a platform for tailoring molecular exchange between microchannels, independent of hydrodynamic effects. In enzymatic reactions, for example, tuning the pores size will allow smaller enzymatic substrates to traverse the membrane at controlled rates while larger enzymes remain spatially separated. Our results from membrane cross-sectioning using focused ion beam milling show that pore sizes can be controlled at dimensions below 10nm. Functional characterization was performed by quantitative fluorescence microscopy to observe the selective transport of molecular species of different sizes.

1:27PM B9.00012 Thermal resistance of thin water films during phase-change , NITIN SHUKLA, NENAD MILJKOVIC, RYAN ENRIGHT, EVELYN N. WANG, Device Research Laboratory, Department of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, MA 02139 — The thermal resistance of a thin water film during phase-change processes is of interest for fundamental studies and of importance for various engineering systems. In particular, as the thickness of the water film approaches the nanoscale, the thermal resistance across the liquid-vapor interface can contribute significantly to the overall heat transport. In this work, we experimentally investigate the thermal resistance of thin water films during phase change on metallic substrates using transient thermoreflectance (TTR) spectroscopy. This technique offers a novel method to examine heat transport in evaporating liquid films less than a 100 nm in thickness. The understanding gained from this work will aid in the design of high performance phase-change based micro/nanoscale devices.

1:39PM B9.00013 Effect of hydrogen bond cooperativity on the behavior of water , KEVIN STOKELY, Boston University — Four scenarios have been proposed for the low–temperature phase behavior of liquid water, each predicting different thermodynamics. The physical mechanism which leads to each is debated. Moreover, it is still unclear which of the scenarios best describes water, as there is no definitive experimental test. Here we address both open issues within the framework of a microscopic cell model by performing a study combining mean field calculations and Monte Carlo simulations. We show that a common physical mechanism underlies each of the four scenarios, and that two key physical quantities determine which of the four scenarios describes water: (i) the strength of the directional component of the hydrogen bond and (ii) the strength of the cooperative component of the hydrogen bond. The four scenarios may be mapped in the space of these two quantities. We argue that our conclusions are model-independent. Using estimates from experimental data for H bond properties the model predicts that the low-temperature phase diagram of water exhibits a liquid–liquid critical point at positive pressure.

Monday, March 21, 2011 11:15AM - 2:15PM –
Session B10 SPS: SPS Undergraduate Research I D221

11:15AM B10.00001 Which String Breaks? Revisited[1] , CHRISTOPHER FRYE, University of Central Florida — Many have seen the common introductory physics demonstration in which a heavy ball hangs from a string, with another identical string hanging freely from the ball. When the instructor pulls the bottom string slowly, the top string breaks. However, when the instructor pulls the bottom string very rapidly, the bottom string breaks. This simple experiment is used to demonstrate inertia and Newton's laws. In The Physics Teacher of November 1996, there is an article in which the authors create a model of this problem in an attempt to explain the outcomes quantitatively. However, their analysis gave strange results. Using an improved model, I will show that the results of this demonstration can be obtained using only simple calculations.

[1]This work was funded by a RAMP grant from the University of Central Florida.

11:27AM B10.00002 Synchronization effects in chaotic oscillators with spatially dependent frequency mismatch[1] , PHILIP JAVERNICK, TRINANJAN DATTA, Augusta State University — We investigate the phenomena of synchronization for two coupled chaotic oscillators with a frequency mismatch which is explicitly spatially dependent. We compute the frequency synchronization plot in the parameter space of coupling strength and frequency mismatch of the chaotic system. We find regimes where the system is frequency locked corresponding to a synchronous state and regimes of non-synchronous state. In the non-synchronous state the frequencies are either zero individually (quenched oscillations) or the difference between them is non-zero. We also find that the region with oscillation quenching is reduced compared to the case when the frequency mismatch is a constant.

[1]Automated Data Processing (ADP) research funds

11:39AM B10.00003 Rolling vs. Sliding: The inclusion of non-conservative work in the classic comparison , BENJAMIN LEE, JUSTIN MUELLER, California Baptist University, TERRY BUEHLER, U.C. Berkeley, ALEX CHEDIAK, California Baptist University — If a rolling and sliding object, each of the same material, were to race down the same incline plane, which would win? Last year, we presented a theoretical model with confirming experimental data which showed that the winning object depends on the angle, the effective coefficient of friction, C, and kinetic coefficients of friction: If C $<$ μ_{k_block}, the rolling object is faster, but if C $>$ μ_{k_block}, the sliding object is faster. Though the materials were the same, we previously reported that the $\mu_{s_sphere}$was apparently not equal to μ_{s_block}. This year, we are directly determining the coefficients of friction using a force sensor, seeking to resolve this apparent discrepancy. We plan to report more accurate values of $\mu_{s_sphere}$and μ_{s_block} and, if they are found to be different, explain why. Steps will be taken to improve track uniformity. We will more precisely determine the transition angle, where the block becomes faster than the sphere, by taking data at smaller angular increments. In addition, we will incorporate results for rolling *with* slipping, as it is expected that as slipping increases, so will linear velocity, as less energy is lost to rotational kinetic energy. Beyond this, we hope to extend the model to different geometries (with different moments of inertia).

11:51AM B10.00004 Is Ball Milling An Innovative Technique For the Production of Zn From ZnO?[1] , JEFF MCLEOD, ALI BAKHSHAI, Goucher College — The process of mechanical alloying using ball milling transfers mechanical energy to reactants in powder form, causing the particle size of the reactant powders to be reduced until defects in the lattice structure of the reactants are created. For reactions of sufficient exothermicity, this facilitates a complete mechanochemical reaction through self-heat propagating synthesis (SHS). The oxide reduction reaction of ZnO with Al, which yields pure Zn as a product, cannot be induced using ball milling alone because of its low exothermicity. This study used a systematic combination of ball milling and annealing in order to induce the reaction. Parameters tested were milling time, annealing time, and annealing temperature with the purpose of establishing the importance of each of these variables in inducing a complete reaction in the sample. The completeness of the reaction was determined using XRD analysis and inspection with an optical microscope. Results confirmed that neither ball milling nor heat treatment could induce the reaction individually; only ball milling followed by annealing could cause the reaction to take place. This study suggests that using ball milling in conjunction with heat treatment can produce Zn from ZnO in a less costly, more efficient, and less wasteful manner than traditional methods.

12:03PM B10.00005 Women in Physics: an Analysis of the Gender Gap , LILLIE GHOBRIAL, MICHAEL EVANS, GREGORY MASLAK, MARK STEWART, ANNA BONTORNO, BRITTANY BARRETT, NICOLE SCOTT, CAROLINA ILIE, Dept. of Physics, SUNY Oswego — It is not a surprise that the number of women in physics is not impressive, and the reasons are diverse and well-known [1]. We conducted several surveys at SUNY Oswego regarding the gender gap. We examined the source of the problem and we developed possible solutions. We propose herein various strategies for short-term and long-term improvement of female representation in Physics. This insight will hopefully benefit other physics departments in which women are underrepresented.

12:15PM B10.00006 STAIRSTEP – a research-oriented program for undergraduate students at Lamar University , CRISTIAN BAHRIM, Department of Physics, Lamar University — The relative low number of undergraduate STEM students in many science disciplines, and in particular in physics, represents a major concern for our faculty and the administration at Lamar University. Therefore, a collaborative effort between several science programs, including computer science, chemistry, geology, mathematics and physics was set up with the goal of increasing the number of science majors and to minimize the retention rate. Lamar's Student Advancing through Involvement in Research Student Talent Expansion Program (STAIRSTEP) is a NSF-DUE sponsored program designed to motivate STEM students to graduate with a science degree from one of these five disciplines by involving them in state-of-the-art research projects and various outreach activities organized on-campus or in road shows at the secondary and high schools [1]. The physics program offers hands-on experience in optics, such as computer-based experiments for studying the diffraction and interference of light incident on nettings or electronic wave packets incident on crystals, with applications in optical imaging, electron microscopy, and crystallography. The impact of the various activities done in STAIRSTEP on our Physics Program will be discussed. 12:27PM B10.00007 Modeling Surface Acoustic Waves on Liquid Loaded Surfaces , MICHAEL MITCHELL, MATTHEW KWAN, MADELEINE MSALL, Bowdoin College — Ultrasound excitation of crystals creates acoustic waves that propagate on the surface. The wave velocities vary with directions based on the properties of the crystal. Experiments typically use ultrasound transducers submerged in water. The water loading on the surface creates a perpendicular stress. This alters the boundary conditions of the surface waves, changing their propagation. We model the phase and group velocities of Rayleigh surface waves on water loaded Si (100) and $CaWO_4$. The addition of water loaded boundary conditions improves the match between model and experimental data.

12:39PM B10.00008 Characterization of a MEMS Actuator through Simulation[1] , ERIK GARCELL, MIGUEL GONZALEZ, BYOUNG HEE MOON, PRADEEP BHUPATHI, PAN ZHENG, GEORGE LING, YOONSEOK LEE, Department of Physics, University of Florida, Gainesville, FL 32611, HO BUN CHAN, Department of Physics, The Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong — Simulations of a laterally shifting micro-electro-mechanical-system (MEMS) were performed to characterize the device for use in liquid ^{3}He experimentation. Using the multiphysics software COMSOL, we were able to identify the relevant electrostatic and mechanical properties of our device, as well as its various vibrational modes. When actuated with a DC voltage, simulations demonstrated comparatively large out-of-plane displacements, which are in agreement with optical measurements taken from the actual device. New simulations were performed to test the effectiveness of possible efforts to dampen this displacement. Using the data collected from these simulations, future generations of the MEMS will be designed and improved for use in liquid ^{3}He experiments.

12:51PM B10.00009 Scanning Tunneling Microscopy of Manganites[1] , ICON MAZZACCARI, HYOUNGJEEN JEEN, AMLAN BISWAS, Department of Physics, University of Florida, Gainesville, FL 32611 — We have built a scanning tunneling microscope (STM) which employs a mechanical coarse approach mechanism. We have tested the mechanical and electronic components of the system and calibrated the piezoelectric scanning mechanism by imaging highly ordered pyrolytic graphite (HOPG) at room temperature. Atomic resolution HOPG images were obtained when the STM was placed inside a vibration isolated liquid helium dewar. We have also scanned single crystals and thin-films of hole-doped manganese oxides (manganites) and obtained images on the scale of about 100 nm to about 10 nm. After obtaining satisfactory images at room temperature, we will cool the apparatus first down to liquid nitrogen temperature (77 K) and then down to liquid helium temperature (4.2 K) to investigate micrometer and nanometer scale phase separation in manganites.

1:03PM B10.00010 Magnetic field dependence on neutrino-induced electron-positron creation rates[1] , HANNAH MCWILLIAMS, Hendrix College — The study of neutrino processes in magnetic fields are immensely important for astrophysical phenomena where neutrino interactions are the dominant mode of energy loss and large fields exist. In this talk I will present a phenomenological relationship for the production rate of one such process, the creation of electron-positron pairs $\nu \rightarrow \nu\ e\ \bar{e}$, as a function of the magnetic field. I will show that above the critical magnetic field strength and at large neutrino energies there exists a power law dependence on the magnetic field.

1:15PM B10.00011 Emergent magnetic monopoles and their dynamics in artificial spin ice[1] , YICHEN SHEN, OLGA PETROVA, PAULA MELLADO, OLEG TCHERNYSHYOV — Electrically charged particles such as electrons are common in our world. In contrast, no elementary particles with a net *magnetic* charge have ever been observed. After a recent discovery that magnetic monopoles can emerge in a system of magnetic dipoles [1], much attention has been paid to the behavior of magnetic monopoles in artificial spin ice, arrays of nano-scale magnetic islands or wires that mimic the behavior of geometrically frustrated materials [2]. We have developed a theoretical model of magnetization dynamics in artificial spin ice under the action of an external magnetic field [3]. Magnetization reversal is mediated by the creation, propagation and absorption of domain walls carrying two units of magnetic. Domain walls are emitted from lattice junctions when the local field becomes large enough to overcome the Coulomb attraction between the magnetic charges of the domain wall and the junction. This interaction is also responsible for a positive feedback that triggers magnetic avalanches observed experimentally in artificial spin ice.

1:27PM B10.00012 Antihydrogen Production in a Paul Trap[1] , GUY GEYER, REINHOLD BLUMEL, Wesleyan University — We investigate the dynamics of anti-hydrogen production within a Paul trap through computational means with the intent to develop a strategy for confining the anti-atom for further experimentation. We obtained first preliminary results on the transient production of anti-hydrogen. We present these results, discuss the experimental implementation of our system, and suggest ways to lengthen the lifetime of anti-hydrogen in the trap.

1:39PM B10.00013 Effects of interactions on interference pattern formed after release and expansion of two identical Bose-Einstein condensates[1] , CATHERINE LEE, COURTNEY LANNERT, Wellesley College — We numerically simulate the expansion and interference of two adjacent, identical Bose-Einstein condensates initially trapped by harmonic potentials. We use explicit finite-difference methods to solve the Gross-Pitaevskii equation and time-evolve the condensates. We repeat the simulation, varying the interaction strength of the condensates, and analyze how the interactions affect the time-evolution of the interference pattern.

1:51PM B10.00014 Search for an Entanglement Measure for N-Qubit States via Phase Symmetry[1] , JOSHUA GELLER, University of Rochester — While quantitative measures of entanglement exist for two-qubit systems, there are no equivalent measures for larger systems. Phase patterns within multi-qubit density matrices could yield clues to constructing quantitative measures for these larger systems. One such pattern within the N-qubit density matrix is observed by reordering the matrix according to the types of coherence terms in the first row and first column so the number of phases in each element increases from left to right in the first row, and from top to bottom in the first column. The resultant matrix contains blocks on its diagonal with elements having only bipartite entanglement. All remaining diagonal elements are part of GHZ-type states in this configuration. A benefit to this matrix structuring is the ability to apply concurrence, a measure of two-qubit entanglement, to the sub-matrix blocks formed on the diagonal. Exploring the meaning of these concurrences with regard to the entanglement of the whole system of N-qubits represented by the full density matrix is a possible next step toward finding a measure of N-qubit entanglement.

2:03PM B10.00015 Plasmon Enhancement of Organic Solar Cells using Embossed Gratings , DAVID SHOPE, Department of Chemistry and Physics, Trinity University, JENNIFER STEELE, Department of Physics and Astronomy, Trinity University — Organic photovoltaic cells (OPV) are attractive because of their low cost and easy fabrication. However, because the diffusion length of excitons in most organic photovoltaic material is about 100 nm, the overall thickness and therefore the optical absorbance of the device is limited, reducing the overall efficiency. Surface plasmon excitations have been studied as a possible mechanism to increase the absorption of light in solar cell active layers because of their ability to manipulate and enhance local electromagnetic fields. This work focuses on using metal gratings as one electrode. Gratings support a broad range of surface plasmons that can be tuned by changing the incident angle of light, making them ideal to isolate the contribution of surface plasmons to increases in the quantum efficiency of solar cells. OPV cells are made using a conjugated polymer and fullerene-based active layer with either an aluminum or silver bottom electrode patterned with a grating through microcontact printing. By measuring the efficiency of the solar cells as a function of both incident angle and wavelength, we can match increases in efficiency with specific surface plasmon modes.

Monday, March 21, 2011 11:15AM - 2:15PM –
Session B11 FIAP: Compound and Oxide Semiconductors D222

11:15AM B11.00001 Terahertz radiation mechanism of native n-Type InN with different carrier concentrations , KUANG-I LIN, JUNG-TSE TSAI, JENN-SHYONG HWANG, Department of Physics, National Cheng Kung University, HON-WAY LIN, SHANGJR GWO, Department of Physics, National Tsing Hua University, MENG-CHU CHEN, Institute of Nuclear Energy Research — InN has received considerable attention due to its lower effective mass, higher mobility, and higher velocity saturation compared with GaN or AlN. The fundamental band gap of InN has recently been reevaluated to be around 0.6–0.7 eV, being therefore a promising candidate for terahertz (THz) applications. In this study, the polarity and mechanism of THz radiation from native n-type InN excited by femtosecond optical pulses are investigated. The optical properties, electron concentrations, and crystalline quality are characterized by photoluminescence and Raman scattering spectra. The electron concentrations are estimated to be between 0.35×10^{19} and 3.87×10^{19} cm^{-3}. The intensity ratio of the A_1(LO) to E_2(high) mode increases with increasing electron concentration. The polarity of THz radiation field from the samples with higher electron concentrations is opposite to that from p-InAs, indicating that the dominant radiation mechanism is the drift current. However, the samples with lower electron concentrations show the same polarity as p-InAs. Under this condition, the radiation mechanism is dominated by the photo-Dember effect.

11:27AM B11.00002 Self-confined GaN hetero-phased quantum wells , YU-CHI HSU, IKAI LO, CHIA-HO HSIEH, WEN-YUAN PANG, Department of Physics, National Sun Yat-Sen University, Kaohsiung 80424, Taiwan, MITCH M.C. CHOU, Department of Materials and Optoelectronic Science, National Sun Yat-Sen University, Kaohsiung 80424, Taiwan, YEN-LIANG CHEN, CHENG-HUNG SHIH, YING-CHIEH WANG, Department of Physics, National Sun Yat-Sen University, Kaohsiung 80424, Taiwan — Wurtzite/zinc-blende/wurtzite GaN hetero-phased quantum wells (QWs) were grown by plasma-assisted molecular beam epitaxy. A self-assembling mechanism was used to simulate the hetero-phased QW, in which a wurtzite/zinc-blende phase transition was created by rotating the threefold symmetric N-Ga vertical bond of wurtzite 60°. From the cathodoluminescence measurement, we observed an additional peak (energy ∼3.2eV) associated with GaN zinc-blende phase. From the transmission electron microscopy images and selective area electron diffraction patterns, we confirmed the formation of hetero-phased quantum wells with a transition of wurtzite/zinc-blende GaN [1].

[1] I. Lo, Y.-C. Hsu, C.-H. Hsieh, W.-Y. Pang, M. M.C. Chou, Y.-L. Chen, C.-H. Shih, and Y.-C. Wang, Appl. Phys. Lett. **96**, 222105 (2010).

11:39AM B11.00003 Growths of InGaN Quantum Wells on GaN Micropyramids , RENBO SONG, LE ZHAO, GUANGYU LIU, JING ZHANG, NELSON TANSU, Lehigh University — Selective area epitaxy (SAE) of InGaN quantum wells on GaN micropyramids were grown by using metalorganic chemical vapor deposition (MOCVD). The pattern prepared for the SAE was fabricated by the deposition of 300 nm SiO_2 film on n-type GaN substrate by using plasma enhanced chemical vapor deposition (PECVD) and followed by photolithography. The grown micropyramid structures were characterized by scanning electron microscope (SEM) and photoluminescence (PL). Uniformly-distributed defect-free GaN micropyramids were observed by SEM. The growths of InGaN quantum wells were performed on the GaN micropyramids, and broadband luminescence were observed from the PL measurements applicable for white light-emitting diodes applications.

11:51AM B11.00004 Charge Carriers in Boron Nitride Nanotubes Appear to confirm Quantum Capillary Action , RICHARD KRISKE, University of Minnesota — A recent article in Physics Today confirmed a previous Theory put forward by this author in that electrons and perhaps other fundamental particles should find the easiest transmission path to be in the center of nanotubes not on the walls. Of course this is somewhat astonishing in that the center of the tube has nothing in it. This author had previously suggested that this might ultimately give a quantum mechanical explaination for capillary action. In any case a model could now be confirmed that this author previously put forward to show that in many cases the flow of particles should occur in the centers of nanotubes not on the walls and this would allow the exploration of the use of nanotubes as reaction devices, and transport devices with a general theory to show how molecules as well as elementary particles could be transported down the centers of these tubes and reacted in the tubes or in chambers attached to the tubes. This would also explain some vexing biological problems involving tubes and capillary action.

12:03PM B11.00005 Transport Electron Scattering by Structural Defects in InSb Quantum Wells , T.D. MISHIMA, M.B. SANTOS, University of Oklahoma — Among all the binary III-V semiconductors, InSb has the highest electron mobility and the narrowest band-gap. Field effect transistors and magnetic-field sensors are examples of devices based on InSb quantum wells (QWs) that exploit these material properties. In this study, we have investigated electron scattering due to two dominant structural defects, micro-twins (MTs) and threading dislocations (TDs), in InSb QWs grown on GaAs (001) substrates via AlInSb buffer layers. A linear regression analysis shows that the room-temperature electron mobility in InSb QWs has a strong correlation with the densities of both MTs and TDs, with an R^2 value of 0.9791. The MT-originated energy barrier and reflection coefficient for electron conduction in InSb QWs are estimated to be 0.09 eV and 0.33, respectively. The TD-limited electron mobility in InSb QWs is explained by electric charge with a density of 1.3 $\times10^{-10}$ C/m along a TD line. In addition to further discussion of the data, we will show the derivations of some key equations used for the mathematical analyses. This work was supported by the NSF under Grants Nos. DMR-0520550 and DMR- 0808086.

12:15PM B11.00006 Strain, Confinement and Density Dependence of the Effective Mass of Holes in InSb Quantum Wells , CHOMANI GASPE, M. EDIRISOORIYA, T.D. MISHIMA, R.E. DOEZEMA, M.B. SANTOS, University of Oklahoma, L.C. TUNG, Y.J. WANG, NHMFL, Florida State University — The valence band structure in a III-V quantum well (QW) is complicated by the presence of two highly non-parabolic bands. The lower (higher) energy band has a hole mass that is lighter (heavier) for motion in the plane of the QW. The energy separation between the two bands increases with increasing biaxial compressive strain and decreasing well width. An expected anticrossing between the two bands can add significantly to their non-parabolicity. We report an experimental study of the effective mass of 2D holes in a series of remotely doped InSb QWs under biaxial compressive strain. Only the lower energy band is occupied at low tempearture. Cyclotron resonance measurements at 4.2K show that the hole effective mass increases with increasing hole density from 0.045m$_e$ at 2.1×10^{11} cm^{-2} to 0.083m$_e$ at 5.1×0^{11} cm^{-2}. The smallest effective mass of 0.017m$_e$ was observed in the QW with the largest compressive strain (1.06%) and narrowest well width (7nm). This work was supported by the NSF Grants Nos. DMR-0520550 and DMR-088086.

12:27PM B11.00007 Carrier and Spin Dynamics in Narrow Gap Parabolic Quantum Well Structures[1] , M. BHOWMICK, T. MERRITT, G.A. KHODAPARAST, Virginia Tech, T.D. MISHIMA, M.B. SANTOS, University of Oklahoma, D. SAHA, G.D. SANDERS, C.J. STANTON, University of Florida — Heterostructures with parabolic confinement potentials are important systems to study for many reasons. In a perfect Parabolic Quantum Well (PQW), the subbands are equally spaced and electron-electron interactions are virtually non-existent, allowing coupling of long-wavelength radiation only to the center-of-mass coordinate of the electron system. Narrow band PQW systems are well suited for THz devices because by careful design, one can tune the transition frequency, temperature stability, and narrow-band emission. In our studies, the parabolic confinement was created by an effective parabolic Al compositional gradient inside each well. We studied carrier/spin dynamics in an InSb/$Al_xIn_{1-x}Sb$ multiple-PQW structure using several time resolved differential transmission schemes in the mid-infrared. Our results demonstrate the unique and complex dynamics in InSb heterostructures that can be important for electronic and optoelectronic devices.

12:39PM B11.00008 Electrical characterization of GeSn grown on Si using ultra high vacuum chemical vapor deposition method , MO AHOUJJA, S. ELHAMRI, University of Dayton, J. KOUVETAKIS, J. TOLLE, Department of Chemistry and Biochemistry, Arizona State University, Arizona, MEE YI RYU, Y.K. YEO, Department of Engineering Physics, Air Force Institute of Technology, Wright-Patterson AFB, Ohio — Recently, there has been considerable interest in growing $Ge_{1-x}Sn_x$ alloys on Si with x< 0.2 for the purpose of developing optoelectronic devices that can be integrated with Si-based electronic technology. Here we report Hall coefficient and resistivity measurements as a function of temperature from thin epitaxial layers of GeSn grown on Si substrates using ultra high vacuum chemical vapor deposition. The Hall measurements show that GeSn samples with Sn concentrations of 1.5 and 2 % are of high quality. The hole concentration for the boron doped $Ge_{0.98}Sn_{0.02}$ sample at room temperature is 7.1x10^{18} cm^{-3} while that of the as-grown undoped sample is 9.8x10^{16} cm^{-3}. The measured hole mobility for $Ge_{0.98}Sn_{0.02}$ alloys with carrier concentrations greater than 10^{18} cm^{-3} are found to be comparable to those found in Ge samples with similar doping concentrations.

12:51PM B11.00009 An extensive study to observe the effects of thermal annealing and ion fluences in the ion beam synthesis of β-SiC , P.R. POUDEL, B. ROUT, D.R. DIERCKS, F.D. MCDANIEL, University of North Texas, J.A. PARAMO, Y.M. STRZHEMECHNY, Texas Christian University — A systematic study of the formation of β-SiC structures by low energy carbon ion (C^-) implantation into Si followed by high temperature thermal annealing will be presented. The effects of thermal annealing in the formation of β-SiC structures has been studied. It is observed that the thermal annealing of 1100 $^\circ$C for 1 hr is required to observe the formation of β-SiC. The quantitative analysis in the formation of β-SiC nanostructures has been performed by the implantation of various carbon ion fluences in the range of 1×10^{17} - 8×10^{17} atoms /cm^2 at an ion energy of 65 keV into Si. It is observed that the average size of β-SiC crystals decreases whereas the amount of β-SiC increases monotonically with ion fluence up to a fluence of 5 $\times$ 10^{17} atoms/cm^2 and appears to saturate for a higher fluence of 8 $\times$ 10^{17} atoms/cm^2 when the samples were annealed at 1100 $^\circ$C for 1 hr. The stability of graphitic C-C bonds at 1100 $^\circ$C limits the growth of SiC precipitates in the sample implanted at a fluence of 8×10^{17} atoms /cm^2 which results in the saturation behavior of SiC formation in the present study as predicted by various characterization techniques such as FTIR, Raman, XRD, XPS and Transmission electron microscopy.

1:03PM B11.00010 Complimentary Ferromagnetic Mechanisms in Mn doped ZnO Thin films deposited using Pulsed Laser Ablation[1] , DEVAJYOTI MUKHERJEE, TARA DHAKAL, HARIHARAN SRIKANTH, PRITISH MUKHERJEE, SARATH WITANACHCHI, University of South Florida — We show evidence through experiments and analysis that the ferromagnetism (FM) in 2% Mn doped ZnO (ZMO) thin films is a combination of two complementary mechanisms - the bound magnetic polaron (BMP) percolation at low temperatures and the Ruderman-Kittel-Kasuya-Yosida (RKKY) exchange interaction at higher temperatures. Pulsed laser deposition was used to grow ZMO thin films on c-cut sapphire substrates. Films were deposited at various temperatures and background oxygen pressures to study the effect of growth parameters on the FM. While no impurity-phase contributions were detected, a strong correlation between effective carrier densities and FM was established. FM in amorphous films with high defect densities were described by the BMP model whereas that in highly conducting films was consistent with the RKKY mechanism. Detailed characterization of the structural, electrical and magnetic properties of the as-deposited ZMO films will be presented.

[1]This work was supported by NSF (Grant Nos. DMI-0217939 and DMI-0078917) and DOD (Grant No. W81XWH-07-1-0708).

1:15PM B11.00011 Excitation of atomic zinc during excimer laser ablation of zinc oxide at 193 nm , ENAMUL KHAN, STEPHEN LANGFORD, THOMAS DICKINSON, Washington State University — Atomic excitations during UV laser ablation usually involve collisions with energetic electrons. When zinc oxide is ablated with a 193 nm excimer laser, we observe light emission at pulse energies —well below the threshold for normal electron heating processes. At pulse energies near the threshold for visible light emission, the source is localized and moves away from the surface at a nearly constant velocity. Time-resolved quadrupole mass spectrometry confirms the presence of zinc atoms with velocities consistent with this motion. We propose that these excited zinc atoms are generated by two-photon excitation into the autoionizing $3d^{10}4p$ ($^2P^\circ_{3/2}$) 5s $^2[3/2]^\circ$ state of atomic zinc at 103 001 cm^{-1}. The broad "window resonance" associated with this state in single-photon absorption is associated with a *drop* in absorption, because the main decay channel (ionization) is hindered by destructive interference effects. We propose that radiative decay, which is otherwise a minor decay channel, produces bound excited states that subsequently decay to yield the observed light.

1:27PM B11.00012 Role of ligands on the photoluminescence of colloidal CdSe quantum dots and enhancement of photoconductivity of ZnO nanowires by quantum dots , SYAMANTA KUMAR GOSWAMI, TAE SOO KIM, BYOUNG WOO LEE, EUNSOON OH[1], CH. KIRAN KUMAR, EUI TAE KIM, Chungnam National University, DEPARTMENT OF PHYSICS TEAM, DEPARTMENT OF MATERIALS SCIENCE AND ENGINEERING TEAM — Colloidal core-shell CdSe/ZnS quantum dots (QDs) encapsulated by trioctylphosphine oxide ligand were synthesized via pyrolysis. Then the TOPO ligands by 3-mercaptopropionic acid ligands were replaced under Ar environment. ZnO nanowires were fabricated by sonochemical method on pre-patterned alumina electrodes. With increasing temperature above 220 K, the PL lifetime was found to be increased in case of the TOPO capped QDs, whereas for the MPA capped QDs, the lifetime was short and almost independent of temperature. The conductivity of ZnO nanorods was increased after the deposition of the QDs, which was further enhanced by the exposure of light. This increase in the conductivity with and without light can be explained by the photo-carrier transport and surface modification effect, respectively. The photo-generated electrons in the CdSe QDs will tend to move toward the ZnO nanowires, resulting in the enhancement of photo-conductivity in the ZnO nanowires.

[1]corresponding author

1:39PM B11.00013 Preparation and characterization of nanostructured ZIO thin films , VIPIN KUMAR JAIN, Thin film & Membrane Science Laboratory, University of Rajasthan, Jaipur -302004, India, PRAVEEN KUMAR, Surface Physics and Nanostructures Group, National Physical Laboratory, New Delhi -110012, India, Y.K. VIJAY, Thin film & Membrane Science Laboratory, University of Rajasthan, Jaipur -302004, India, VIPIN KUMAR JAIN TEAM, PRAVEEN KUMAR COLLABORATION — ZnO–In2O3 system has attracted much attention because of chemical and thermal stability in addition to properties comparable to those of ITO. In the present work Zinc indium oxide (ZIO) thin films were deposited on glass substrate with varying concentration (ZnO: In2O3 - 100:0, 90:10, 70:30 and 50:50 wt %) at room temperature by flash evaporation technique. These deposited ZIO films were annealed in vacuum to study the thermal stability and to see the effects on the structural, chemical and electrical properties. Each film has been characterized ex-situ by XRD, XPS, XRF, AFM, SEM, optical band gap and Hall measurements. Results show the properties of the ZIO films strongly depend on the In2O3 concentration and also influenced by the post annealing of these films. XPS core level spectra of Zn(2p), O(1s) and In(3d) have been deconvoluted into their Gaussian components, while valence band spectra shows the change in electronic structures of the films.

1:51PM B11.00014 M-plane ZnO grown on m-plane sapphire by radio-frequency magnetron sputtering , BI-HSUAN LIN, WEI-REIN LIU, SHAO-TING HSU, CHIN-CHIA KUO, SONG YANG, CHIA-HUNG HSU, WEN-FENG HSIEH, DEPARTMENT OF PHOTONICS AND INSTITUTE OF ELECTRO-OPTICAL ENGINEERING, NATIONAL CHIAO TUNG UNIVERSITY TEAM, DIVISION OF SCIENTIFIC RESEARCH, NATIONAL SYNCHROTRON RADIATION RESEARCH CENTER TEAM, DEPT OF PHOTONICS & INST. OF ELECTRO-OPTICAL SCIENCE AND ENGINEERING, NATL. CHENG KUNG UNIVERSITY TEAM — High quality m-plane orientated ZnO films with in-plane epitaxial relationship of $(0002)_{ZnO}||(11\text{-}20)_{sapphire}$ and $(11\text{-}20)_{ZnO}||(0006)_{sapphire}$ have been successfully grown on m-plane sapphire by using radio-frequency magnetron sputtering. The introduction of a nanometer thick low temperature grown ZnO buffer layer effectively eliminated other undesirable orientations. The significant anisotropy of the strain field breaks the hexagonal symmetry and leads to the different physical properties from that of c-plane oriented ZnO films. The structural properties, including crystalline quality, strain state, and defect structures, of the m-plane ZnO layers are thoroughly examined by synchrotron x-ray scattering, transmission electron microscopy and atomic force microscopy. The optical properties are investigated by temperature, polarization as well as power dependent photoluminescence, and polarization dependent Raman spectroscopy. The correlation between the structural and optical properties will be discussed.

2:03PM B11.00015 Phase diagram, structure, and electronic properties of $(Ga_{1-x}Zn_x)(N_{1-x}O_x)$ solid solution[1] , LI LI, PHILIP B. ALLEN, Stony Brook University — We studied $(Ga_{1-x}Zn_x)(N_{1-x}O_x)$ solid solution by Density Functional Theory (DFT). To conduct thermodynamic simulations, we built a database of structures and constructed a Cluster Expansion(CE). The subsequent Monte Carlo simulation gives a calculated phase diagram with a wide miscibility gap and an ordered x=0.5 compound. The disordered phase displays strong short range ordering (SRO) at experimental temperatures. We then used snapshots from MC to investigate structural and electronic properties by DFT on large supercells. Consistent with previous theoretical and experimental findings, lattice parameters appear to deviate from Vegard's law with small upward bowing. Bond lengths depend strongly on local environment, with a variation much larger than the difference of bond length between ZnO and GaN. The downward band gap bowing deviates from parabolic by having more rapid onset of bowing at low and high concentrations. Our results show that SRO influences both the structural and electronic properties.

11:15AM B12.00001 ABSTRACT WITHDRAWN –

11:27AM B12.00002 Optimized basis sets for coarse-grained electronic structure calculations of point defects , BJÖRN LANGE, CHRISTOPH FREYSOLDT, JÖRG NEUGEBAUER, MPIE Düsseldorf — Density-functional theory is a powerful tool to study the properties of point defects in the supercell approach. Yet, the size limitations make a description of the extended tails of defect states, especially for shallow defects, cumbersome. Atomic orbital basis sets are the method of choice to coarse-grain electronic structure calculations, but are in general not flexible enough for describing the unusual bonding situations, which occur in point defects. We employ a newly developed method that, based on a variational principle, allows to generate small atomic basis sets which optimally mimic the Kohn-Sham wavefunctions with a plane-wave basis set. We show that these basis sets accurately reproduce the underlying plane-wave calculation. We analyze how the atomic orbitals close to the defect are modified in comparison to their bulk counterparts. We are able to extend basis sets generated from small supercells and to reproduce the bandstructure of larger cells. Using this approach we construct and solve a reliable sparse model Hamiltonian for a shallow defect test system containing $10^3..10^4$ atoms.

11:39AM B12.00003 Strain-Enhanced Doping in Semiconductors: Effects of Dopant Size and Charge State[1] , JUNYI ZHU, 1 National Renewable Energy Lab 2 University of Utah, FENG LIU, GERALD STRINGFELLOW, University of Utah, SU-HUAI WEI, National Renewable Energy Lab — When a semiconductor host is doped by a foreign element, it is inevitable that a volume change will occur in the doped system. This volume change depends on both the size and charge state difference between the dopant and the host element. Unlike the "common expectation" that if the host is deformed to the same size as the dopant, then the formation energy of the dopant would reach a minimum, our first-principles calculations discovered that when an external hydrostatic strain is applied, the change of the impurity formation energy is monotonic: it decreases if the external hydrostatic strain is applied in the same direction as the volume change. This effect also exists when a biaxial strain is applied. A simple strain model is proposed to explain this unusual behavior, and we suggest that strain could be used to significantly improve the doping solubility in semiconductor systems.

11:51AM B12.00004 Defects and Carrier Compensation in CdTe[1] , MAO-HUA DU, Materials Science and Technology Division and Center for Radiation Detection Materials and Systems, Oak Ridge National Laboratory — CdTe is a very useful semiconductor material for its radiation detection and thin-film solar cell applications. Good carrier mobility and lifetime are needed for CdTe since efficient carrier collection is essential for the success of both applications. On the other hand, high resistivity is required for radiation detection for suppressing dark current and device noise. This is in contrast to CdTe-based solar cells, in which low resistivity is desired. In this talk, I will discuss the properties of native defects and impurities in CdTe with emphasis on carrier compensation and its implications in radiation detection and solar cell applications.

12:39PM B12.00006 Diffusion of ion implanted indium in ZnO crystals , FAISAL YAQOOB, MENGBING HUANG, University at Albany-SUNY, DAVID LOOK, Wright State University and Air Force Research Laboratory — We report on diffusion behaviors for ion implanted indium atoms in ZnO crystals. A c-plane ZnO crystal was implanted with In ions for four different energies (40, 100, 200, and 350 keV, respectively) and doses (8.0×10^{13}, 1.2×10^{14}, 1.6×10^{14} and 6.5×10^{14} /cm^2, respectively), resulting in a uniform concentration profile of In from surface to the depth $\sim$ 150 nm. The samples were annealed for 30 minutes at temperatures between 700-1000 $^\circ$C with an argon or oxygen gas flow. The distributions of In atoms, either aligned or nonaligned along the crystalline directions, were measured by Rutherford backscattering combined with ion channeling. The diffusivities for nonaligned (interstitial) and aligned In atoms varied with annealing temperature via the Arrhenius relationship. The diffusion activation energies (E_a) for aligned In atoms were lower than those for interstitial In atoms, e.g., for annealing in an Ar gas, $E_a \sim 0.61$ eV for <1010> aligned In atoms and $E_a \sim 1.1$ eV for interstitial In atoms between <1010> atomic rows. Furthermore, the diffusion activation energies were affected by the gas species used during annealing, e.g., for annealing in an O_2 gas, $E_a \sim 0.39$ eV for <1010> In atoms and $E_a \sim 0.79$ eV for interstitial In atoms between <1010> atomic rows. These experimental results will be compared with first-principle calculations for In diffusion in ZnO crystals.

12:51PM B12.00007 Surface effects in Co-doped ZnO nanocrystals[1] , ALINE L. SCHOENHALZ, GUSTAVO M. DALPIAN, Universidade Federal do ABC — Semiconducting nanostructures have received high attention by scientific community due to their unusual properties and wide rage of possible applications. In this scale, the understanding of the surface effects of the material is fundamental to explain its properties. By using the Density Functional Theory within the Local Density Approximation, we report on the effects of the surface on the magnetic properties of Co-doped ZnO nanocrystals. For bulk ZnO, it is well known that the most stable magnetic interaction between Co impurities is antiferromagnetic. This is also the case for saturated nanostructures, where surface effects are not taken into account. However, when surface effects are considered, the interaction between transition metal impurities becomes ferromagnetic. We will discuss the interaction between surface and impurity states, comparing our results to experimental findings.

1:03PM B12.00008 Vacancy-assisted migration of group-III impurities in ZnO[1] , DANIEL STEIAUF, JOHN L. LYONS, ANDERSON JANOTTI, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara, CA 93106 — Zinc oxide is a wide-band-gap material used as transparent conductor. As grown it often shows n-type conductivity, probably due to impurity contamination. High electron concentrations can be achieved by intentional doping with group-III elements, a process that usually involves annealing. It is thus important to understand the diffusion properties of the dopants. We perform first-principles calculations for the vacancy-assisted migration process of Al, Ga and In in ZnO, using both standard density functionals and hybrid functionals to correct the underestimated band gap. Indium induces the largest distortions in the lattice and has the highest formation energy. Its migration barrier to a neighboring Zn vacancy is the lowest. Al shows the highest barrier and thus has the best thermal stability. From the calculated migration barriers and formation energies, we determine diffusion activation energies and estimate annealing temperatures. The results are compared with recent experiments.

1:15PM B12.00009 Improved LDA+U model for band gap corrected ZnO defect calculations , ADISAK BOONCHUN, WALTER LAMBRECHT, Case Western Reserve University — The local density approximation (LDA) is known to fail dramatically for point defects in ZnO. In the case of the oxygen vacancy, the one electron level of the 1+ charge state lies above the conduction band and leads to improper filling of the levels. Different points of view on how to implement a-posterior gap corrections still leave large uncertainty on the position of the defect levels. For the Zn-vacancy, LDA leads incorrectly to a delocalized wave function of the hole on all four neighbors. Our approach is to apply LDA+U corrections to various orbitals, O-sp and Zn-spd. The U-parameters which lead to orbital shifts $V_i = U_i(1/2 - n_i)$ are adjusted to quasiparticle self-consistent GW (QSGW) calculations of the band structure, including the shifts of the band structure relative to the LDA one on an absolute scale. With this improved LDA+U model, good agreement is obtained for the minimum gap, the conduction band mass and the valence and conduction band shifts separately. The structural properties of ZnO also remain intact. When applied to the oxygen vacancy, we find the 2+/0 transition level in good agreement with recent hybrid functional calculations. Applications of the same LDA+U model to the Zn-vacancy are in progress and show that localization of the wave function on two oxygen neighbors is obtained.

1:27PM B12.00010 Hybrid density functional study of gallium in ZnO , DENIS DEMCHENKO, Virginia Commonwealth University — The properties of interstitial and substitutional gallium impurities as well as their complexes in wurtzite ZnO are modeled using hybrid density functional theory. This approach reproduces experimental band gap and avoids any artificial gap corrections necessary when using LDA/GGA/LDA+U methods. We find that the lattice relaxations at the LDA/GGA level can also introduce large errors to the defect formation energies (up to 1.5 eV). The error is particularly large in cases where shallow occupied defect levels are formed and LDA can produce incorrect charges. The correct defect structure therefore should be obtained by relaxation using hybrid DFT method. We find both interstitial and substitutional Ga forming donor-like defect states, with substitutional Ga being energetically favorable. Acceptor-like Zn vacancy has high formation energy in the isolated state but exhibits strong preference to form defect complexes with both substitutional and interstitial gallium. (Ga_i-V_{Zn}) complex acts as a shallow donor, while ($Ga_{Zn} - V_{Zn}$) is a deep acceptor. The low formation energies of both complexes suggests an appreciable degree of self-compensation.

1:39PM B12.00011 Study of defects in TlBr, InI as potential semiconductor radiation detectors[1] , KOUSHIK BISWAS, MAO-HUA DU, Materials Science and Technology Division and Center for Radiation Detection Materials and Systems, Oak Ridge National Laboratory, Oak Ridge, TN 37831 — Group III-halides such as TlBr and InI are receiving considerable attention for application in room temperature radiation detector devices. It is however, essential that these detector materials have favorable defect properties which enable good carrier transport when operating under an external bias voltage. We have studied the properties of native defects of InI and Tlbr and several important results emerge: (1) Schottky defects are the dominant low-energy defects in both materials that can potentially pin the Fermi level close to midgap, leading to high resistivity; (2) native defects in TlBr are benign in terms of electron trapping. However, anion-vacancy in InI induces a deep electron trap similar to the F-centers in alkali halides. This can reduce electron mobility-lifetime product in InI; (3) low diffusion barriers of vacancies and ionic conductivity could be responsible for the observed polarization phenomenon in both materials at room temperature.

1:51PM B12.00012 Information-based screens for deep traps in semiconducting materials[1] , KIM FERRIS, KUNAL SHAH, Pacific Northwest National Laboratory, DUMONT JONES, Proximate Technologies, LLC. — The key to a successful materials search is the ability to suggest promising materials and a priori eliminate unfruitful inquiry. For semiconducting radiation detection materials, performance is characterized by several key properties; band gap, density, electron mobility, and carrier lifetime. The material's proclivity to form defects is critical, as even simple antisite and vacancy defects can be sufficiently deep to affect effective carrier lifetime and mobility. We have developed a new model for defect formation proclivity, leveraging prior defect models (van Vechten and Feichter) and our information-based work. Our approach is based upon classification of materials chemistry and properties consistent with high concentrations of particular defects (e.g. antisites and vacancies). One issue is that nearly any charged local defect can potentially form a deep trap, so the screen must cover different defect types. Second, the screening model for new materials cannot rely on generally unknown factors such as 3D crystal geometry. The resulting model is intended to provide design guidance on expected defect behavior for candidate detection materials for which there is little or no prior information.

2:03PM B12.00013 Ab-Initio analysis of TlBr: limiting the ionic current without degrading the electronic one , CEDRIC ROCHA LEAO, VINCENZO LORDI, Lawrence Livermore National Lab — Although TlBr in principle presents all the theoretical requirements for making high resolution room temperature radiation detectors, practical applications of TlBr have proven to be nonviable due to the polarization that is observed in the crystal after relatively short periods of operation. This polarization, that is believed to be caused by accumulation of oppositely charged ionic species at the ends of the crystal, results in an electric field that opposes that of the applied bias, counter-acting its effect. In this work, we use state of the art quantum modeling to benchmark the theoretical limits for the performance of TlBr as a radiation detector, showing that the best experimental reports demonstrate near-ideal electronic characteristics. We then propose a model to inhibit the detrimental ionic current in the material without impacting the excellent properties of the electronic current. Prepared by LLNL under Contract DE-AC52-07NA27344.

Session B13 DFD: Focus Session: Polymer Colloids: Structure, Function, and Dynamics II

D225/226

11:15AM B13.00001 Predicting long-time Brownian dynamics of ultrasoft colloid suspensions from thermodynamics , MARK POND, The University of Texas at Austin, JEFFREY ERRINGTON, State University of New York at Buffalo, THOMAS TRUSKETT, The University of Texas at Austin — Suspensions of ultrasoft colloids, such as Gaussian-core particles and Hertzian spheres, have received significant research interest due to their reentrant melting behavior and dynamic anomalies. Many of the previous dynamic studies of these systems have focused on molecular dynamics simulations, which by their nature ignores the solvent medium. We have conducted Brownian dynamics simulations of these ultrasoft colloid suspensions to show their long-time dynamic behavior near the reentrant melting transition. In addition, we have developed a novel method for quantitatively and qualitatively predicting the long-time Brownian dynamics of ultrasoft colloidal suspensions from their thermodynamic properties.

11:27AM B13.00002 Development of surfaces repelling negatively buoyant solid particles , CARINA SEMMLER, ALEXANDER ALEXEEV, Georgia Institute of Technology — Using a hybrid computational method that integrates the lattice Boltzmann model for fluid dynamics and the lattice spring model for solids, we examine the motion of negatively buoyant solid microparticles in shear flow near a solid wall decorated with regularly distributed rigid posts. The posts are arranged in a square pattern and tilted relative to the flow direction. We show that when rigid posts are tilted against flow, secondary flows emerge that prevent the deposition of suspended particles on the solid surface. We probe the effect of post geometry on the development of secondary flows and identify the optimal post architecture in terms of the mass of levitated solid particles. Our results are useful for designing anti-fouling surfaces that repel colloidal particles carried by fluid.

11:39AM B13.00003 Microscopic structure of confined colloidal suspensions under shear , XIN-LIANG XU, STUART RICE, AARON DINNER, James Franck Institute, University of Chicago, XIANG CHENG, ITAI COHEN, Department of Physics, Cornell University — We report a study of driven colloidal suspensions by Stokesian dynamics simulation. The suspension is confined by two parallel plates, and is being driven far away from equilibrium by shearing induced by translation of the parallel plates. The separation of the plates is varied so the suspensions form either a single layer or two layers. Both the structure of the non-equilibrium steady state and the dynamics of the relaxation of the non-equilibrium state back to the equilibrium are examined, at a wide range of shearing strengths (the non-dimensional ratio quantifying the driven motion relative to the Brownian motion of the colloidal particles, the Peclet number is tuned from 0.1 to 100) and packing fractions. We observe string-like structures at low packing fractions and shear-induced crystallization at high fractions. A mechanism is proposed for how hydrodynamic interactions give rise to these structures.

11:51AM B13.00004 Evaporation of Lennard-Jones Fluids , SHENGFENG CHENG, JEREMY LECHMAN, STEVEN PLIMPTON, GARY GREST, Sandia National Laboratories — Solvent evaporation is a process frequently used to disperse particles in a bulk material or at a substrate. The local order and packing of particles can be controlled by controlling the evaporation rate. The first step to fully understand this complicated process is to understand the evaporation process of pure liquid at the microscopic scale. We have carried out large scale molecular dynamics simulations to study the evaporation of Lennard-Jones (LJ) fluids composed of monomers, dimers, or trimers. For LJ monomers in contact with a vacuum, the evaporation rate is found to be very high with significant evaporative cooling and an accompanying density gradient in the liquid domain near the liquid/vapor interface. Increasing the chain length to just dimers significantly reduces the evaporation rate. The velocity distributions of evaporated monomers are measured and compared to a kinetic theory and their dependence on the evaporation conditions is discussed. For nanoparticle suspensions, the nanoparticles order at the surface, which causes the evaporation to significantly slow down.

12:03PM B13.00005 Rotational and Translational Diffusion of PMMA Colloidal Clusters , HYUN JOO PARK, MARK T. ELSESSER, New York University, KAZEM V. EDMOND, Emory University, DAVID J. PINE, New York University, NEW YORK UNIVERSITY COLLABORATION, EMORY UNIVERSITY COLLABORATION — Colloidal clusters, 3-7 μm in size, are a good model system for various 2D and 3D structures depending on the aggregation number, N. We measure the translational and rotational diffusion of individual dyed PMMA clusters of dimers and trimers using high speed confocal scanning microscopy and particle tracking. We report measurements of the rotational and translational diffusion coefficients (and their ratios) as a function of volume fraction.

12:15PM B13.00006 A diversity of binary colloidal crystals using DNA-directed interactions , JOHN CROCKER, MARIE UNG, W. BEN ROGERS, RAYNALDO SCARLETT, TALID SINNO, University of Pennsylvania — DNA is the premier tool for directing the controlled self-assembly of nanoscopic and microscopic objects. The interactions between microspheres due to the hybridization of DNA strands grafted to their surface have been measured and can be modeled in detail, using well-known polymer physics and DNA thermodynamics. Knowledge of the potential, in turn, enables the exploration of the complex phase diagram and self-assembly kinetics in simulation. In experiment, at high densities of long grafted DNA strands, and temperatures where the binding is reversible, these system readily form colloidal crystals having a diverse range of symmetries. For interactions that favor alloying between two same-sized colloidal species, our experimental observations compare favorably to a simulation framework that predicts the equilibrium phase behavior, crystal growth kinetics and solid-solid transitions. We will discuss the crystallography of the novel alloy structures formed and address how particle size and heterogeneity affect nucleation and growth rates.

12:27PM B13.00007 Correlating Structural and Spectral Fluctuations in a Lasing Colloidal Suspension , JASON W. MERRILL, Yale University, Department of Physics, HUI CAO, Yale University, Departments of Physics and Applied Physics, ERIC R. DUFRESNE, Yale University, Departments of Mechanical Engineering, Physics, Chemical Engineering, and Cell Biology — When multiply scattering media with optical gain are optically pumped above a critical threshold, they emit coherent radiation in many spectral lines. This phenomenon is known as random lasing. The wavelengths of these spectral lines depend sensitively on the spatial distribution of scatterers, but this relationship has only just begun to be explored. We study the time and frequency domain statistics of random laser spectra emitted from dense colloidal suspensions doped with laser dye with an eye toward using this information as a probe of the underlying colloid dynamics.

12:39PM B13.00008 Smart colloidosomes with tunable permeability and a dissolution trigger , ADRIANA SAN MIGUEL, JAN SCRIMGEOUR, JENNIFER CURTIS, SVEN BEHRENS, Georgia Tech — Self-assembly of colloidal particles in the liquid interface of double emulsion droplets can be used to fabricate "colloidosome" microcapsules, which have great potential as vehicles for the controlled delivery of drugs or other cargoes. Here we present a novel class of aqueous core colloidosomes that combine the benefit of low capsule permeability (good cargo retention) with the option of a stimulus-triggered fast release in a target environment. Complete or partial dissolution of the capsule walls in response to a mild pH change is achieved in each case through the use of responsive particles made from polymers with pH-switchable solubility. We demonstrate three methods of controlling the capsule permeability prior to release while maintaining the intended response to the release trigger.

12:51PM B13.00009 A theoretical study of colloidal forces near an amphiphilic polymer brush , JIANZHONG WU, University of California, Riverside — Polymer-based "non-stick" coatings are promising as the next generation of effective, environmentally-friendly marine antifouling systems that minimize nonspecific adsorption of extracellular polymeric substances (EPS). However, design and development of such systems are impeded by the poor knowledge of polymer-mediated interactions of biomacromolecules with the protected substrate. In this work, a polymer density functional theory (DFT) is used to predict the potential of mean force between spherical biomacromolecules and amphiphilic copolymer brushes within a coarse-grained model that captures essential nonspecific interactions such as the molecular excluded volume effects and the hydrophobic energies. The relevance of theoretical results for practical control of the EPS adsorption is discussed in terms of the efficiency of different brush configurations to prevent biofouling. It is shown that the most effective antifouling surface may be accomplished by using amphiphilic brushes with a long hydrophilic backbone and a hydrophobic end at moderate grafting density.

1:03PM B13.00010 Phase transition of colloidal particles on curved surfaces , GUANGNAN MENG, JAYSON PAULOSE, DAVID NELSON, Department of Physics, Harvard University, VINOTHAN MANOHARAN, Department of Physics and School of Engineering and Applied Sciences, Harvard University — Defects and disclinations have to appear in crystalline domains on a curved surface with non-zero Gaussian curvature. These geometrical frustrations can qualitatively change the physics of phase transition. We encapsulate micron sized polystyrene (PS) colloidal particles within emulsion droplets and use nanometer sized polyNIPAM hydrogel particles to introduce depletion attraction between PS particle and interface, as well as between PS particles. We use this experimental model system and confocal microscopy to study phase transitions on curved surfaces. We will present both experimental phenomena and theoretical analysis.

1:15PM B13.00011 Dielectric effects in self-assembly of binary colloid mixtures , ERIK LUIJTEN, KIPTON BARROS[1], Northwestern University — Colloidal self-assembly is often controlled by electrostatic interactions. The solvent and colloids typically have different dielectric constants, thereby inducing polarization charge at the colloid surfaces. A shortcoming of previous simulations of charged colloids with implicit solvent is the neglect of the effective many-body interactions resulting from such dielectric effects. We study colloidal self-assembly using a method that properly accounts for polarization charge. In simulations of weakly charged colloids with large size asymmetry, we find that dielectric effects modify the pair correlation function in a nontrivial way and at low temperatures alter the observed crystal phase.

[1]Currently at Los Alamos National Laboratory.

1:27PM B13.00012 Formation of three-dimensional colloidal nanoparticle supercrystals and probing the formation kinetics , IRVING HERMAN, Columbia Univeristy, CHENGUANG LU, AUSTIN AKEY, Columbia University — A multiple solvent system consisting of colloidal nanoparticles in several solvents of gradually decreasing vapor pressures was investigated in the self assembly of hundred-layer thick colloidal nanoparticle superlattices in lithographically defined capillaries. Such a solvent system allows a very slow and tunable drying rate of solvents, which, together with the microfluidic flow into the capillaries, leads to the controllable formation of large, single crystalline 3D nanoparticle supercrystals. The underlying mechanism of superlattice formation was investigated via the drying rates for nanoparticle assembly for solvent systems of specific compositions. This technique generates single-crystalline 3D supercrystals of $\sim$micrometer size at spatially controlled locations, and large chunks (up to 40 μm by 40 μm by 5 μm) of single crystalline supercrystals on a flat Si substrate. The ordered nature of the structures formed was probed by high-resolution SEM and small angle x-ray scattering. In-situ x-ray scattering reveals the formation kinetics of the transition of nanoparticle assemblies from amorphous to ordered. This technique is versatile and has been applied to various types and sizes of colloidal nanocrystals, including those composed of CdSe, Au, PbS and Fe_3O_4.

1:39PM B13.00013 Nanoparticle-induced self-assembly of functionalized tetrapods , DANIEL W. SINKOVITS, University of Illinois at Urbana-Champaign, ERIK LUIJTEN, Northwestern University — Recent advances in synthesis have made it possible to create monodisperse particles with well-defined shapes. In particular, tetrapods have been fabricated in a wide range of well-controlled dimensions and have been functionalized in several different ways. We present Monte Carlo simulations of the self-assembly of functionalized tetrapods. We consider how the addition of charged spherical nanoparticles provides another means to control the self-assembled structure. In addition, we report the results of simulations of planar tripods confined to two dimensions and demonstrate that highly regular structures can be achieved without functionalization, through nanoparticle-mediated depletion interactions.

1:51PM B13.00014 A "diffusing diffusivity" model of "anomalous yet Brownian" diffusion of colloidal particles , MYKYTA V. CHUBYNSKY, GARY W. SLATER, Department of Physics, University of Ottawa, Canada — "Anomalous yet Brownian" diffusion of colloidal beads, with a mean-square displacement (MSD) exactly linear in time (as in simple Fickian diffusion) but an exponential (rather than Gaussian) displacement distribution (DD) at short times for large displacements, has been reported recently by Granick's group [1] in several systems. We argue that a strictly linear MSD with a non-Gaussian DD is a universal feature of systems with "diffusivity memory" (a particle diffusing faster is likely to keep diffusing faster for some time), but without "direction memory" (a jump in a particular direction does not change the probability of subsequent jumps in that direction). We consider a series of toy models reproducing this behavior in which a particle undergoes regular diffusion, but its diffusivity itself performs a (perhaps biased) random walk. The DD is strictly exponential at short times when the diffusivity distribution itself is exponential, but an exponential remains a good fit for a variety of diffusivity distributions.

2:03PM B13.00015 Reentrant and Isostructural Transitions in the Cluster-Crystal Forming GEM-4 , KAI ZHANG, PATRICK CHARBONNEAU, Duke University, BIANCA MLADEK, University of Cambridge — Systems governed by soft, bounded, purely repulsive interactions show two possible equilibrium behaviors under compression: reentrant melting, as in the Gaussian core model (GCM), or clustering, as in the penetrable sphere model (PSM). The generalized exponential model of power 4 (GEM-4), which is the intermedia of the GCM and PSM with a simple isotropic pair interaction $u(r) \sim e^{-r^4}$, is thought to belong to the second family and was indeed found to form clusters at sufficiently high densities at high temperatures. Here, we present the low-temperature behavior of GEM-4 through Monte Carlo simulations using a specially developed free energy integration scheme. We find the phase behavior to be hybrid between the GCM and the PSM limits, showing a surprisingly rich phase behavior in spite of the simplicity of the interaction form. For instance, S- shaped doubly reentrant phase sequences and evidence of a cascade of critical isostructural transitions between crystals of different average lattice site occupancy are observed. The possible annihilation of lattice sites and accompanying clustering moreover leads to an unusual softening upon compression, which suggest that these materials may have interesting mechanical properties. We discuss possible experimental realizations and challenges of this class of materials.

Monday, March 21, 2011 11:15AM - 2:03PM –

Session B14 GSNP: Applications of Statistical and Nonlinear Physics to Social Systems and GSNP Student Speaker Award Talks D227

11:15AM B14.00001 Characterization of stock market regimes by data compression[1] , EUGENIO E. VOGEL, GONZALO SARAVIA, Universidad de La Frontera, Temuco, Chile — It has been shown that data compression can characterize magnetic phases (Physica A 388 (2009) 4075). In the introduction of this presentation we briefly review this result. We then go onto introducing a new data compressor (wlzip) developed by us to optimize recognition of meaningful patterns in the compressing procedure, yielding sharp transition curves at the magnetic critical temperatures. The advantages of the new compressor, such as better definition and tuning capabilities are presented. The rest of the talk consists of applying wlzip to the Chilean stock market along several months during 2010. The accumulated daily data allow to recognizing days with different types of activity. Moreover, the data recorded every minute allow to analyzing the "present" status of the stock market by applying wlzip to the data of the last hour or couple of hours. Possible extensions of the application of this technique to other fields are discussed.

11:27AM B14.00002 Relativistic statistical arbitrage , ALEXANDER WISSNER-GROSS, Massachusetts Institute of Technology, CAMERON FREER, University of Hawaii — Recent advances in high-frequency financial trading have made light propagation delays between geographically separated exchanges relevant. Here we show that there exist optimal locations from which to coordinate the statistical arbitrage of pairs of spacelike separated securities, and calculate a representative map of such locations on Earth. Furthermore, trading local securities along chains of such intermediate locations results in a novel econophysical effect, in which the relativistic propagation of tradable information is effectively slowed or stopped by arbitrage.

11:39AM B14.00003 The Impact of Competing Time Delays in Stochastic Coordination Problems[1] , G. KORNISS, D. HUNT, B.K. SZYMANSKI, RPI — Coordinating, distributing, and balancing resources in coupled systems is a complex task as these operations are very sensitive to time delays. Delays are present in most real communication and information systems, including info-social and neuro-biological networks, and can be attributed to both non-zero transmission times between different units of the system and to non-zero times it takes to process the information and execute the desired action at the individual units. Here, we investigate the importance and impact of these two types of delays in a simple coordination (synchronization) problem in a noisy environment. We establish the scaling theory for the phase boundary of synchronization and for the steady-state fluctuations in the synchronizable regime[2]. Further, we provide the asymptotic behavior near the boundary of the synchronizable regime. Our results also imply the potential for optimization and trade-offs in stochastic synchronization and coordination problems with time delays.

11:51AM B14.00004 Statistical regularities in the rank-citation profile of individual scientists , ALEXANDER PETERSEN, H. EUGENE STANLEY, Boston University, SAURO SUCCI, Istituto Applicazioni Calcolo C.N.R. — Citation counts and paper tallies are ubiquitous in the achievement ratings of individual scientists. As a result, there have been many recent studies which propose measures for scientific impact (e.g. the h-index) and the distribution of impact measures among scientists. However, being just a single number, the h-index cannot account for the full impact information contained in an author's set of publications. Alternative "single-number" indices are also frequently proposed, but they too suffer from the shortfalls of not being comprehensive. In this talk I will discuss an alternative approach, which is to analyze the fundamental properties of the *entire* rank-citation profile (from which all single-value indices are derived). Using the complete publication careers of 200 highly-cited physicists and 100 Assistant professors, I will demonstrate remarkable statistical regularity in the functional form of the rank-citation profile $c_i(r)$ for each physicist $i = 1...300$. We find that $c_i(r)$ can be approximated by a discrete generalized beta distribution over the entire range of ranks r, which allows for the characterization and comparison of $c_i(r)$ using a common framework. Since two scientists can have equivalent h_i values while having different $c_i(r)$, our results demonstrate the utility of a scaling parameter, β_i, in conjunction with h_i, to quantify a scientist's publication impact.

12:03PM B14.00005 Modeling the decline of religion[1] , RICHARD WIENER, Research Corporation for Science Advancement and Department of Physics, University of Arizona, HALEY YAPLE, DANIEL ABRAMS, Department of Engineering Sciences and Applied Mathematics, Northwestern University — People claiming no religious affiliation constitute the fastest growing "religious" minority in many countries throughout the world.[2] Here we use a minimal model of competition between social groups[3] to explain historical data on the growth of religious non-affiliation in 85 regions around the world. We also describe numerical experiments that support the validity of the model. According to the model, for societies in which the perceived utility of not adhering is greater than the utility of adhering, religion will be driven toward extinction.

12:15PM B14.00006 Spontaneous Time Symmetry Breaking in System with Mixed Strategy Nash Equilibrium: Evidences in Experimental Economics Data , ZHIJIAN WANG, BIN XU, Experimental social science laboratory, Zhejiang University, ZHEJIANG UNIVERSITY COLLABORATION — In social science, laboratory experiment with human subjects' interaction is a standard test-bed for studying social processes in micro level. Usually, as in physics, the processes near equilibrium are suggested as stochastic processes with time-reversal symmetry (TRS). To the best of our knowledge, near equilibrium, the breaking time symmetry, as well as the existence of robust time anti-symmetry processes, has not been reported clearly in experimental economics till now. By employing Markov transition method to analysis the data from human subject 2x2 Games with wide parameters and mixed Nash equilibrium, we study the time symmetry of the social interaction process near Nash equilibrium. We find that, the time symmetry is broken, and there exists a robust time anti-symmetry processes. We also report the weight of the time anti-symmetry processes in the total processes of each the games. Evidences in laboratory marketing experiments, at the same time, are provided as one-dimension cases. In these cases, time anti-symmetry cycles can also be captured. The proposition of time anti-symmetry processes is small, but the cycles are distinguishable.

12:27PM B14.00007 The Sign Effect in Emerging Markets: the Inherent Instability of Bad News , JOEL TENENBAUM, Boston University Department of Physics, BORIS PODOBNIK, Faculty of Civil En- gineering, University of Rijeka, 51000 Rijeka, Croatia, DAVOR HORVATIC, Faculty of Natural Sciences, University of Zagreb, 10000 Zagreb, Croatia, SLAVICA BAJIC, Electrical Engineering Department, Polytechnic of Zagreb, 10000 Zagreb, Croatia, BECO PEHLIVANOVIC, Faculty of Educational Sciences, University of Bihac, Bihac, Bosnia and Hercegovina, H. EUGENE STANLEY, Boston University Department of Physics — In developed economy market indices, the sign of a term in a series influences the volatility in an asymmetric fashion — bad news results in larger subsequent fluctuations while good news results in smaller fluctuations. We study this phenomenon of volatility asymmetry using a stochastic process, exploring whether this asymmetry manifests in emerging markets, and if so, how such asymmetry changes over time as economies develop, mature, and react to crises such as the present one. We find that while both developed and emerging markets show distinctive behavior with respect to volatility asymmetry during times of economic tumult, they do so in ways that could be viewed either as universal or qualitatively different, posing interesting questions for further research. 12:39PM B14.00008 Quantized expected returns in terms of dividend yield at the money , LAMINE DIENG, City University of New York — We use the Bachelier (additive model) and the Black-Scholes (multiplicative model) as our models for the stock price movement for an investor who has entered into an America call option contract. We assume the investor to pay certain dividend yield on the expected rate of returns from buying stocks. In this work, we also assume the stock price to be initially in the out of the money state and eventually will move up through at the money state to the deep in the money state where the expected future payoffs and returns are positive for the stock holder. We call a singularity point at the money because the expected payoff vanishes at this point. Then, using martingale, supermartingale and Markov theories we obtain the Bachelier-type of the Black-Scholes and the Black-Scholes equations which we hedge in the limit where the change of the expected payoff of the call option is extremely small. Hence, by comparison we obtain the time-independent Schroedinger equation in Quantum Mechanics. We solve completely the time independent Schroedinger equation for both models to obtain the expected rate of returns and the expected payoffs for the stock holder at the money. We find the expected rate of returns to be quantized in terms of the dividend yield.

12:51PM B14.00009 Competition in social systems: three and a half models , DANIEL ABRAMS, HALEY YAPLE, Northwestern University, Department of Engineering Sciences and Applied Mathematics, RICHARD WIENER, Research Corporation for Science Advancement and Department of Physics, University of Arizona — When groups compete for members, the resulting dynamics of human social activity may be understandable with simple mathematical models. Here, we use techniques from dynamical systems and perturbation theory to analyze a theoretical framework for the growth and decline of competing social groups in three limits. We apply our analysis to an international data set tracking the growth of religious nonaffiliation, and find that data suggest a particular case of our general growth law, leading to clear predictions about possible future trends in society.

1:03PM B14.00010 Extraordinary Elasticity of the Distorted Kagome Lattice , ANTON SOUSLOV, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA 19104, KAI SUN, Joint Quantum Institute and Condensed Matter Theory Center, University of Maryland, College Park, MD 20742, XIAOMING MAO, TOM LUBENSKY, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA 19104 — J. C. Maxwell discovered that a system of particles in d-dimensions will be marginally rigid, or *isostatic*, if each particle interacts on average with $2d$ of its neighbors. Isostatic models have been used to describe such diverse soft phenomena as the jamming transition and the elasticity in networks of semi-flexible polymer gels. We develop models based on the isostatic kagome lattice, which has a subextensive number of floppy phonon modes. We show that these can be extended into soft deformations by changing the particle configurations while keeping the bond lengths fixed. Thus, we create families of novel isostatic lattices, which exhibit highly tunable elastic properties as a consequence of isotropic linear elasticity with a zero bulk modulus. They have a negative Poisson ratio, or auxetic (anti-rubber) behavior. Further, we find no bulk soft phonons at large length scales due to conformal symmetry. We discuss the intimate relationship between various symmetries and soft response in these models as well as the relation of these models to other marginally rigid systems.

1:15PM B14.00011 Theory of cooperation in a micro-organismal snow-drift game[1] , ZHENYU WANG, NIGEL GOLDENFELD, Department of Physics, Center for the Physics of Living Cells and Institute for Genomic Biology, University of Illinois at Urbana-Champaign — We present a mean field model for the phase diagram of a community of micro-organisms, interacting through their metabolism so that they are, in effect, engaging in a cooperative social game. We show that as a function of the concentration of the nutrients glucose and histidine, the community undergoes a phase transition separating a state in which one strain is dominant to a state which is characterized by coexisting populations. Our results are in good agreement with recent experimental results, correctly predicting quantitative trends and the phase diagram.

[1]We thank Jeff Gore for sharing with us his experimental data. This work was supported in part by the National Science Foundation through grant number NSF-EF-0526747.

1:27PM B14.00012 Intrinsic noise in stochastic models of gene expression with molecular memory and bursting , TAO JIA, RAHUL V. KULKARNI, Department of Physics, Virginia Polytechnic Institute and State University — Regulation of intrinsic noise in gene expression is essential for many cellular functions. Correspondingly, there is considerable interest in understanding how different molecular mechanisms of gene expression impact variations in protein levels across a population of cells. In this work, we analyze a stochastic model of bursty gene expression which considers general waiting-time distributions governing arrival and decay of proteins. By mapping the system to models analyzed in queueing theory, we derive analytical expressions for the noise in steady-state protein distributions. The derived results extend previous work by including the effects of arbitrary probability distributions representing the effects of molecular memory and bursting. The analytical expressions obtained provide insight into the role of transcriptional, post-transcriptional and post-translational mechanisms in controlling the noise in gene expression.

1:39PM B14.00013 Search for Euler Singularity using Vortex Filaments , SAHAND HORMOZ, MICHAEL BRENNER, Harvard University — A promising mechanism for generating a finite-time singularity in the incompressible Euler equations is stretching of vortex filaments. An exhaustive search of all possible initial conditions involving filaments, however, is not practically feasible. In this talk, I will show that two interacting vortex filaments can not generate a singularity for any initial conditions, by analyzing the asymptotic self-similar limit of their collapse. Essentially, our approach entails a separation of the dynamics of the filament shape, from the shrinking of its core. We solve for the dynamics using a self-similar ansatz and show that the core does not shrink fast enough for a self-consistent collapse. The similarity solution allows for many different collapse geometries, consistent with the tireless effort in the past of investigating new initial conditions. Potential for a singularity at higher number of filaments is also discussed.

1:51PM B14.00014 Vibrofluidized melting of geometrically cohesive granular media , NICK GRAVISH, GEOFFREY RUSSELL, Georgia Tech, SCOTT V. FRANKLIN, Rochester Institute of Technology, DAVID HU, DANIEL I. GOLDMAN, Georgia Tech — Dry granular media composed of particles of special shapes (e.g. long rods or c-shaped particles) can display cohesive effects through particle geometry alone. We study the solid to gas transition in piles of c-shaped particles under vertical vibration as we vary acceleration and frequency. A cylindrical solid of particles is formed with wall angles near 90° and is placed on a solid surface. For fixed frequency as acceleration increases, the pile undergoes two transitions. The first is from the solid-like state to a liquid-like state in which the wall angles relax but the mobile particles remain spatially localized. The second is from the liquid-like state to the gaseous state in which particles become separated (not entangled). Using video and accelerometer measurements, we record the temporal evolution of the spatial density and pile-plate collisional impulse. A critical energy scale, set by the particle geometry and gravitational potential energy, governs the liquid-gas transition.

Session B15 DMP GMAG FIAP: Focus Session: Spins in Semiconductors - Spin Currents I

D171

11:15AM B15.00001 Optical effects of spin currents in semiconductors[1] , JING WANG, Department of Physics, Tsinghua University — BANG-FEN ZHU, Department of Physics and Institute of Advanced Study, Tsinghua University, REN-BAO LIU, Department of Physics, The Chinese University of Hong Kong – We predict the linear and second-order nonlinear optical effects of spin currents in semiconductors, based on systematic symmetry analysis and microscopic calculations with realistic models [1, 2]. By an analogue to the Ampere effect and Oersted effect, we conceived and verified that a spin current can be coupled to a "photon spin curren" carried by a polarized light beam, which causes sizeable Faraday rotation without involving net magnetization. Furthermore, a spin current can have a strong second-order nonlinear optical effect with unique polarization-dependence due to the special symmetry properties of the spin current. In particular, for a longitudinal spin current, in which the spins point parallel or anti-parallel to the current direction is a chiral quantity, a chiral sum-frequency effect will be induced. The second-order optical effects of spin currents have been experimentally verified immediately after the theoretical prediction [3]. These discoveries represent new phenomena in magneto-optics, with potential spin-photonic applications. They bring new opportunities to research of spintronics and may also facilitate research of topological insulators where the edge states form pure spin currents. References:

11:51AM B15.00002 Magnetoelectric Photocurrent Generated by Direct Interband Transitions in InGaAs/InAlAs Two-Dimensional Electron Gas , JUNFENG DAI, HAI-ZHOU LU, The University of Hong Kong, CHUNLEI YANG, Sun Yat-Sen University, SHUN-QING SHEN, FU-CHUN ZHANG, XIAODONG CUI, The University of Hong Kong, NANOSTRUCTURE CHARACTERIZATION GROUP TEAM, CENTRE OF THEORETICAL AND COMPUTATIONAL PHYSICS COLLABORATION, DEPARTMENT OF PHYSICS IN SUN YAT-SEN UNIVERITY COLLABORATION — We report the observation of magnetoelectric photocurrent generated via direct interband transitions in an InGaAs/InAlAs two-dimensional electron gas by a linearly polarized incident light. The electric current is proportional to the in-plane magnetic field, which unbalances the velocities of the photoexcited carriers with opposite spins and consequently generates the electric current from a hidden spin photocurrent. The spin photocurrent can be evaluated from the measured electric current, and the conversion coefficient of spin photocurrent to electric current is self-consistently estimated to be 10^{-3}–10^{-2} per Tesla. The observed light-polarization dependence of the electric current is well explained by a theoretical model which reveals the wave vector angle dependence of the photoexcited carrier density.

12:03PM B15.00003 Anisotropic conductivity caused by spin-orbit interactions , DAVID H. BERMAN, MICHAEL E. FLATTÉ, University of Iowa — Free propagation in a two-dimensional electron gas with both Rashba and Dresselhaus spin-orbit coupling shows strong anisotropy depending on the ratio of the coupling strength to the Fermi energy and on the ratio of the strengths of the Rashba and Dresselhaus interactions [1]. This spin-orbit induced anisotropy appears also in the local density of states near impurities. In addition the non-local conductivity, $\sigma_{i,j}(\mathbf{r},\mathbf{r}')$, computed in the absence of impurities is anisotropic. This is in contrast to the macroscopic conductivity in the presence of impurities which shows no anisotropy when only ladder diagrams are considered [2]. In all these instances, the degree of anisotropy can be controlled by application of electric fields perpendicular to the 2DEG.

12:15PM B15.00004 Drift and diffusion of spin and charge density waves in a two-dimensional electron gas , LUYI YANG, J.D. KORALEK, J. ORENSTEIN, Lawrence Berkeley National Laboratory and University of California Berkeley, D.R. TIBBETTS, J.L. RENO, M.P. LILLY, Sandia National Laboratories — We use transient grating spectroscopy (TGS) to study the persistent spin helix (PSH) state and electron-hole density wave (EHDW) in a 2D electron gas in the presence of an in-plane electric field parallel to the wavevector of the PSH or EHDW. By directly measuring the phase, we can measure the PSH and EHDW displacement with 10 nm spatial and sub-picosecond time resolution. We obtain both the spin diffusion and mobility and ambipolar diffusion and mobility from the TGS measurements of PSH and EHDW, respectively. The spin transresistivity extracted from the spin diffusion is in excellent agreement with the RPA theory of spin Coulomb drag (SCD). The spin mobility data indicate that SCD may also play a role in the spin wave drifting process. From the ambipolar diffusion and mobility, we obtain the transresistivity of electrons and holes in the same layer, which is much stronger than is typically seen in the conventional Coulomb drag experiments on coupled quantum wells.

12:27PM B15.00005 Radial spin helix in two-dimensional electron systems with Rashba spin-orbit coupling , VALERIY SLIPKO, Department of Physics and Technology, V. N. Karazin Kharkov National University, 4 Svobody Sq., Kharkov 61077, Ukraine, YURIY PERSHIN, Department of Physics and Astronomy and USC Nanocenter, University of South Carolina, 712 Main Street, Columbia, SC 29208, USA — We suggest a new long-lived spin-polarization structure, a radial spin helix [1], and study its relaxation dynamics. For this purpose, starting with a system of equations for spin-polarization density, we find its general solution in the axially symmetric case. It is demonstrated that the radial spin helix of a certain period relaxes slower than homogeneous spin polarization and plain spin helix [2]. Importantly, the spin polarization at the center of the radial spin helix stays almost unchanged at short times. At longer times, when the initial nonexponential relaxation region ends, the relaxation of the radial spin helix occurs with the same time constant as that describing the relaxation of the plain spin helix. Experimentally, such a structure can be created using spin injection or extraction in a system with cylindrical electrodes or, possibly, by a modified spin gratings technique.

12:39PM B15.00006 Anholonomic spin manipulation in drift transport in semiconductors , BEN J. MOEHLMANN, MICHAEL E. FLATTÉ, Optical Science and Technology Center and Department of Physics and Astronomy, University of Iowa — We find that the electronic spin rotation induced by drift transport around a closed path in a wide variety of nonmagnetic semiconductors at zero magnetic field depends solely on the physical path taken. Physical paths that produce any possible spin rotation due to transport around a closed path are constructed for electrons experiencing strain or electric fields in (001), (110), or (111)-grown zincblende semiconductor quantum wells. Spin decoherence due to travel along the path is negligible compared to the background spin decoherence rate. The small size of the designed paths (< 100 nm scale in GaAs) may lead to applications in nanoscale spintronic circuits. This work was supported by an ONR MURI.[1]

12:51PM B15.00007 Mapping Spin-Orbit Splitting in Strained (In,Ga)As Epilayers , B.M. NORMAN, C.J. TROWBRIDGE, V. SIH, Department of Physics, University of Michigan, Ann Arbor, MI 48109, J. STEPHENS, A.C. GOSSARD, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106 — Time-resolved and spatially resolved Faraday rotation spectroscopy is used to measure the magnitude and direction of the momentum-dependent spin splitting in strained InGaAs epilayers. The epilayers are lattice-matched to the GaAs substrate and designed to reduce inhomogeneous effects related to strain relaxation. Measurements of momentum-dependent spin splitting as a function of electron spin drift velocity along [100], [010], [110] and $[1\bar{1}0]$ directions enable separation of isotropic and anisotropic effective magnetic fields that arise from uniaxial and biaxial strain along $\langle 110 \rangle$. Such electrically induced effective magnetic fields can be used for spin generation and manipulation in spintronics devices. We find that anisotropic and isotropic strain-induced effective magnetic fields are comparable in magnitude. [1]

[1]B. M. Norman, C. J. Trowbridge, J. Stevens, A. C. Gossard, D. D. Awschalom, and V. Sih, Phys. Rev. B. **82**, 081304(R) (2010).

1:03PM B15.00008 Spin-orbit interaction from low-symmetry localized defects in semiconductors[1] , OLEG CHALAEV, G. VIGNALE, University of Missouri, MICHAEL FLATTÉ, University of Iowa — The presence of low-symmetry impurities or defect complexes in the zinc-blende direct-gap semiconductors (e.g. interstitials, Jahn-Teller distortions) results in a novel spin-orbit term in the effective Hamiltonian for the conduction band. The new spin-orbit interaction is proportional to the matrix element of the defect potential between the conduction and the valence bands. Because this interaction arises already in the first order of the expansion of the effective Hamiltonian in powers of $\Delta/E_g \ll 1$ (where Δ is the valence band spin-orbit splitting, and E_g is the band gap), its contribution to the spin relaxation time may exceed that of previously studied contributions, such as the Rashba term, even for moderate concentrations of low-symmetry impurities.

1:15PM B15.00009 Modeling of diffusion of injected electron spins in spin-orbit coupled microchannels , LIVIU P. ZÂRBO, Institute of Physics ASCR, CZ, JAIRO SINOVA, Texas A & M University, USA, I. KNEZEVIC, University of Wisconsin-Madison, USA, J. WUNDERLICH, Hitachi Cambridge Laboratory, UK, T. JUNGWIRTH, Institute of Physics ASCR, CZ — Understanding of the collective electron spin dynamics under the influence of spin-orbit fields is a key requirement in the quest for all-electrical semiconductor spintronic devices. We investigate the spin dynamics of an ensemble of spin polarized electrons injected in the diffusive microchannel of a model device with linear Rashba and Dresselhaus spin-orbit coupling. Using a spin-dependent ensemble Monte Carlo method, we analyze the steady state spin density patterns dependence on channel dimension and orientation, spin-orbit coupling strengths and external magnetic fields. We show that in the persistent spin helix regime, the spin density patterns depend only on the system geometry and channel orientation. Magnetic fields of order of tesla are required to affect spin dynamics in the persistent spin helix regime. Our simulation results [PRB 82, 205320 (2010)] have been used to help understand the spin diffusion in the channel of the recently demonstrated spin Hall effect transistor [arXiv:1008.2844].

1:27PM B15.00010 Unitarity of scattering and edge spin accumulation in a ballistic and quasiballistic regimes , ALEXANDER KHAETSKII, University at Buffalo, SUNY, EUGENE SUKHORUKOV, University of Geneva, Switzerland — We consider a 2D ballistic structure with spin-orbit-related splitting of the electron spectrum. We calculated the edge spin density which appears in the presence of a charge current through the structure. Combined effect of the boundary scattering and spin precession leads to oscillations of the edge polarization. The problem is solved with the use of the method of scattering states. We clarified the important role of the unitarity of scattering for the problem of edge spin accumulation. For Rashba Hamiltonian, which is linear in momentum, and in the case of a straight boundary it leads to exact cancellation of long-wave oscillations of the spin density with a period order of spin precession length. However, this appears to be rather exceptional case. In general, the smooth spin oscillations recover, as it happens, e.g., for the wiggly boundary. For qubic Hamiltonian (2D holes) the unitarity scattering conditions are different, as a result, even in the case of a straight boundary the cancellation of the smooth oscillations in spin density does not occur. Similar problem is considered for the case when the sample size is large compared to the mean free path which in its turn is much larger than the spin precession length. For example, for the cubic Hamiltonian the "edge" contribution to the spin density can be larger than the "bulk" one which appears as a result of the spin flux from the bulk. This demands the reinterpretation of the experimental results [1]. [1]. J. Wunderlich et al., PRL 94, 047204 (2005).

1:39PM B15.00011 Visualizing zitterbewegung in spin-orbit coupled semiconductor quantum wires , MARKKU JAASKELAINEN, ULRICH ZULICKE — We study a spin-orbit coupled parabolic quantum wire in the ballistic regime and develop a method for visualizing zitterbewegung in phase space. We introduce a Husimi distribution on the transverse coordinate and calculate the distribution of spin by a decomposition into Bloch vector components. The Husimi distribution corresponds to the simultaneous, unsharp measurement of the transverse position and velocity in accordance with the uncertainty principle. In phase space, the distribution exhibits a combination of spin precession and coherent oscillation along the longitudinal coordinate, i.e. zitterbewegung. This behavior closely matches the semiclassical dynamics for small values of the spin-orbit coupling. For increasing spin-orbit coupling strength, the oscillation amplitude initially increases, whereas for very large values the oscillation amplitude is quenched.

1:51PM B15.00012 Theory of carrier dynamics in InSb parabolic quantum wells[1] , D. SAHA, G.D. SANDERS, C.J. STANTON, University of Florida, M. BHOWMICK, T. MERRITT, G.A. KHODAPARAST, Virginia Tech, T.D. MISHIMA, M.B. SANTOS, University of Oklahoma — InSb, with the narrowest gap among the III-V compound semiconductors, shows considerable promise as a quantum well material because its small conduction-band mass gives it a large room temperature electron mobility, and its large g-factor makes it attractive for spintronic devices. We present experiments and theoretical calculations for carrier dynamics in a strained 50-nm thick InSb/AlInSb parabolic quantum well. Our calculations are based on the 8-band Pidgeon-Brown model generalized to include the effects of the parabolic confinement potential as well as pseudomorphic strain. Optical properties are calculated within the golden rule approximation and compared with experiments. We model one and two color, time-resolved pump-probe differential transmission and reflectivity experiments. The change in the infrared probe pulse as a function of delay time provides information on carrier and spin relaxation dynamics. Both interband and intra-band dynamics are studied.

2:03PM B15.00013 Imaging spin transport in a semiconductor with an iron-filled carbon nanotube , ANDREW BERGER, VIDYA BHALLAMUDI, DOMINIC LABANOWSKI, PALASH BANERJEE, CAMELIA MARGINEAN, DENIS PELEKHOV, DAVID STROUD, P. CHRIS HAMMEL, The Ohio State University, KATHY MCCREARY, ROLAND KAWAKAMI, University of California, Riverside, FRANZISKA WOLNY, THOMAS MUEHL, Leibniz Institue for Solid State and Materials Research, Dresden — There has been much recent progress in the field of spintronic device fabrication, creating a need for characterization tools. We are developing a low-temperature scanned probe microscope with the ability to position, with high precision, a magnetized iron-filled carbon nanotube above a spin-injected semiconductor device [1]. The inhomogeneous field of this unique magnetic probe will be experienced by spins in the sample. We have developed a technique for simulating the effects of such an inhomogeneous field [2]. Crucially, we find that our scanned probe technique can create highly localized spin density features on a length scale comparable to the nanotube diameter. This will allow for spatial mapping of the spin density with high resolution – a capability not possible in current electrical detection schemes. Such experiments may provide information about interface effects, scattering, and material properties which influence spin behavior.

Monday, March 21, 2011 11:15AM - 2:15PM –
Session B16 DMP GMAG: Focus Session: Magnetic Nanostructures II D173

11:15AM B16.00001 Electronic structure and electron spectroscopy of magnetic iron oxide nanoparticles , J. GAZQUEZ, J. SALAFRANCA, Universidad Complutense de Madrid, Spain, M. VARELA, S. PENNYCOOK, Oak Ridge National Lab, S.T. PANTELIDES, Vanderbilt University, P. MORALES, ICMM-CSIC, Spain, N. PEREZ, A. LABARTA, X. BATLLE, Univ. Barcelona, Spain — Magnetic iron oxide nanoparticles are good candidates for biomedical applications due to their low toxicity and easy functionalization. We synthesized magnetite (Fe3O4) nanoparticles by a high temperature decomposition method. They present some very desirable properties for applications: very high saturation magnetization, and excellent degree of crystallinity. Transmission electron microscopy images, and electron energy loss spectroscopy with atomic resolution allow a composition map that shows small variations in relative composition between the core and the surface, and subtle changes in the absorption spectra. Our density functional (DFT) calculations address different factors contributing to the magnetic properties. Changes in the electronic structure correlate with different features in the experimental absorption spectra, yielding a better understanding of the magnetic order. We study the role of structural defects, the organic surfactant, stoichiometry and the nominal oxidation state of iron, and their effect in determining the equilibrium magnetic state. This work is supported by DOE Materials Sciences and Engineering Division and the European Research Council Starting Investigator Award.

11:27AM B16.00002 Magnetic properties of Fe/Fe_3O_4 core/shell nanostructure , VIVEK SINGH, MOHINDAR SEEHRA, West Virginia University, S. BALI, E. EYRING, University of Utah, N. SHAH, F. HUGGINS, G. HUFFMAN, University of Kentucky — Magnetic properties of a core/shell nanostructure with spherical core of Fe/FeB and a shell of Fe_3O_4/γ-Fe_2O_3 are reported employing magnetometry, electron magnetic resonance (EMR) and Mössbauer spectroscopy. This nanostructure was produced by reducing $FeCl_3{\cdot}6H_2O$ with $NaBH_4$. Combining the results from XRD, TEM and Mössbauer spectroscopy showed the nanostructure to consist of a core of diameter D$\simeq$20 nm containing both α-Fe with D$\simeq$7 nm and amorphous Fe-B alloy and a shell of thickness 5 nm containing Fe_3O_4/γ-Fe_2O_3. Measurements of the magnetization M vs. temperature (2 K to 370 K) and in H upto 65 kOe show a blocking temperature T_B $\simeq$30 K associated with the oxide shell and ferromagnetism upto 370 K with nearly temperature-independent saturation M_S $\simeq$70 emu/g and coercivity H_C $\simeq$100 Oe. In EMR studies at 9.28 GHz, two lines are observed: a narrower line with linewidth ΔH$\simeq$600 Oe and g$\simeq$2 and a broader line with ΔH$\simeq$4200 Oe and g$\simeq$2.2. These parameters of the narrower line combined with its disappearance below 50 K suggests its origin to be the oxide shell whereas the broader line is due to Fe/FeB core. Research supported by U. S. Dept. of Energy, Contract #DE-FC26-05NT42456.

11:39AM B16.00003 Fe and Fe oxide nanoparticles ensembles with macroscopic anisotropy[1] , MIGUEL ANGEL GARCIA, Institute for Ceramic and Glass - CSIC — We report here the fabrication Fe and Fe oxide nanoparticles over glass substrates exhibiting macroscopic anisotropy. Fe thin films were deposited onto glassy substrates by thermal evaporation and were subsequently annealed in air and argon atmosphere. The difference of thermal expansion coefficient between the substrate and the metallic film induces stresses in the substrate-metal interface leading to hole nucleation, growing and percolation, and finally to the formation of a metallic a nanoparticles layer. Anisotropic nanoparticles can be obtained by applying mechanical stress during the thin the film deposition or the annealing process. The applied stress induce anisotropy axis for the NPs shape that lead to the formation of elongated nanoparticles with macroscopic texture. Anisotropy can be increased by applying a magnetic field during thermal annealing. We analyze here the magnetization and anisotropy of individual nanoparticles and nanoparticles interactions and their relationship with the processing parameters.

11:51AM B16.00004 Magnetic Core-Shell Morphology of Structurally Uniform Magnetite Nanoparticles , KATHRYN KRYCKA, NIST Center for Neutron Research — Magnetic nanoscale structures are intriguing, in part, because of the exotic properties that emerge compared with bulk. The reduction of magnetic moment per atom in magnetite with decreasing nanoparticle size, for example, has been hypothesized to originate from surface disordering to anisotropy-induced radial canting, which are difficult to distinguish using conventional magnetometry. Small-angle neutron scattering (SANS) is ideal for probing structure, both chemical and magnetic, from nm to microns across an ensemble of particles. Adding polarization analysis (PASANS) of the neutron spin orientation before and after interaction with the scattering particles allows the magnetic structure to be separated into its vector components. Application of this novel technique to 9 nm magnetite nanoparticles closed-packed into face-centered crystallites with order of a micron revealed that at nominal saturation the missing magnetic moments unexpectedly interacted to form well-ordered shells 1.0 to 1.5 nm thick canted perpendicular to their ferrimagnetic cores between 160 to 320 K [1]. These shells additionally displayed intra-particle "cross-talk", selecting a common orientation over clusters of tens of nanoparticles. However, the shells disappeared when the external field was removed and interparticle magnetic interactions were negligible (300 K), confirming their magnetic origin. This work has been carried out in collaboration with Ryan Booth, Julie Borchers, Wangchun Chen, Liv Dedon, Thomas Gentile, Charles Hogg, Yumi Ijiri, Mark Laver, Sara Majetich, James Rhyne, and Shannon Watson.

12:27PM B16.00005 Magnetic Characterization of Ferrite Nanoparticles , MATTHEW BRYAN, PAUL SOKOL, Department of Physics, indiana University, GREG GUMINA, LYUDMILA BRONSTEIN, BOGDAN DRAGNEA, Department of Chemistry, Indiana University — Magnetic nanoparticles (NPs) of different compositions (FeO/Fe_3O_4, g-Fe_2O_3, FePt, and $CoFe_2O_4$) have been synthesized using high temperature organometallic routes described elsewhere. NPs (16.6 nm in diameter) of a mixed FeO/Fe_3O_4 (wuestite/magnetite) composition were prepared by thermal decomposition or iron oleate in the presence of oleic acid as a surfactant in dodocane at 370C in argon atmosphere. After the thermal treatment of the reaction solution at 200 C under air for 2 hours these NPs are transformed into maghemite (g-Fe_2O_3), the magnetization of which is significantly enhanced. NPs of $CoFe_2O_4$ (8 nm) have been prepared by simultaneous decomposition of Co(II) and Fe(III) acetylacetonates in the presence of oleic acid and oleylamine. The X-ray diffraction profile of these NPs is characteristic of cobalt ferrite. Alternatively, alloyed 1.8 nm FePt NPs prepared by simultaneous decomposition of Fe and Pt acetylacetonates in the reductive environment demonstrate a completely disordered structure, which is reflected in their magnetic properties. SQUID magnetometry was used to measure the magnetization of NPs at high and low temperatures. Zero-field cooling and field-cooling measurements were taken to demonstrate superparamagnetic behavior and an associated blocking temperature.

12:39PM B16.00006 Magnetically Tunable Polymer Nanocomposites for RF and Microwave Device Applications , K. STOJAK, S. PAL, H. SRIKANTH, University of South Florida-Physics, C. MORALES, J. DEWDNEY, J. WANG, T. WELLER, University of South Florida-Electrical Engineering — There has been much interest in polymer nanocomposites (PNC) recently due to potential applications for EMI shielding, tunable electromagnetic devices and flexible electronics. We report synthesis, structural, magnetic and RF characterization on PNCs ranging from 20-80 wt-% loadings of Fe_3O_4 and $CoFe_2O_4$ nanoparticles ($\sim$8nm) in a thermosetting resin from the Rogers Corporation. Nanoparticles were synthesized by thermal decomposition and characterized by XRD and TEM. Magnetic properties were studied using a Quantum Design PPMS. PNCs displayed characteristic features of superparamagnetism at room temperature and blocking at low temperature. Microwave transmission/reflection studies were done using a microstrip resonator. Strong tunability in the microwave absorption was observed. We extend our study to include nanoparticle-filled multi-walled carbon nanotubes synthesized by CVD. These high-aspect ratio magnetic nanostructures, with tunable anisotropy, are of particular interest in enhancing magnetic and microwave responses in existing PNCs.

12:51PM B16.00007 Field dependence of T_B in NiO and (Ni, Zn)O Nanoclusters[1] , YUNG HUH, Department of Physics, South Dakota State University, Brookings, SD 57007, M. PECK, R. SKOMSKI, R. ZHANG, P. KHAREL, M. ALLISON, D. SELLMYER, M. LANGELL — Size dependence of magnetic properties of rocksalt NiO and Zn substituted NiO nanoparticles are investigated. Nanoparticle diameters are determined from 8 to 30 nm by XRD and AFM. Uncompensated spins at the nanoparticle surface contribute to superparametism at low temperatures and their blocking temperatures increase with stronger applied field. The field induced spin canting of the antiferromagnetic sublattices is a bulk effect and studied by the substitution of Zn with transition metal. Nanoparticles start exhibiting bulk magnetic behavior with size greater than 18 nm. Magnetization rotation of uncompensated spins under the magnetic field is mainly due to nanoscale size effect. The anisotropy of the nanoparticle is about four times larger than that of the bulk NiO.

1:03PM B16.00008 Interacting Superparamagnetic Brownian Particles in an Array of 2D Asymmetric Magnetic Traps[1] , GREGORY VIEIRA, AARON CHEN, R. SOORYAKUMAR, The Ohio State University Department of Physics — We report on the ordering and fluctuation of multiple superparamagnetic particles confined by a thin liquid layer in a two-dimensional array of asymmetric magnetic trapping potentials. The repulsive dipolar interaction between magnetic particles and their confinement by the trapping potential cause the particles to form a cluster with characteristic inter-particle spacing within each trapping site, while the particles undergo thermal fluctuations. Applying an external magnetic field offers a convenient way to control the strength of the dipolar interactions and change the trapping potential landscape. Results on (a) Brownian motion of individual particles in the cluster, (b) re-distribution of particles into new clusters driven by a change in the external field, and (c) hopping of particles between clusters under fluid flow will be presented.

1:15PM B16.00009 Realization of a Bowl-like Potential and Its Confinement of Magnetic Microspheres[1] , AARON CHEN, THOMAS HENIGHAN, GREGORY VIEIRA, RATNASINGHAM SOORYAKUMAR — Field-induced self-assembly of fluid-borne superparamagnetic microspheres not only has its importance in nanotechnology, but it also serves as a model for studies of phase transitions at the nano- to micro-meter scale. In this report, we experimentally demonstrate and theoretically account for the dynamics and structural order of a two-dimensional cluster of microspheres in the presence of a bowl-like potential. The potential is derived from magnetic patterns imprinted on the surface together with externally applied magnetic fields. Due to competition between the repulsive dipolar interaction amongst the microspheres and the confining force provided by the bowl-like potential, a cluster of microspheres with characteristic inter-sphere spacing is stabilized within the potential. The role of external magnetic fields which provide a convenient means to tune the strength of the dipolar interactions, and thereby control the relative importance of the two competing interactions, will be presented.

[1]Support from ARO grant W911NF-10-1-0353 is acknowledged.

1:27PM B16.00010 Tailored Magnetostructural Transitions[1] , RADHIKA BARUA, FELIX JIMENEZ-VILLACORTA, DONALD HEIMAN, LAURA H. LEWIS, Northeastern University — Dominance of the surface atoms over the bulk atoms in nanoscaled magnetostructural systems may alter the ground state of the system and thereby change the transition character. Creation of a nanostructured magnetostuctural system was carried out via rapid solidification of $(FeRh)_5Cu_{95}$ to precipitate nanoscaled isolated FeRh precipitates in a Cu matrix upon annealing. Bulk FeRh has an abrupt antiferromagnetic - ferromagnetic transition around T =370 K. X-ray diffraction performed on the quenched $(FeRh)_5Cu_{95}$ alloy indicates only the presence of Cu of slightly expanded lattice parameter a=3.62 Å, with ferromagnetism confirmed at room temperature by SQUID magnetometry. Vacuum annealing at 200 °C causes a secondary phase to appear with an abrupt magnetic phase transition at T_t = 130 K. Details of the magnetic behavior of this nanostuctured phase will be discussed.

1:39PM B16.00011 Synthesis of Ferrimagnetic Fe_3Se_4 Nanostructures with Giant Coercivity[1] , HONGWANG ZHANG, GEN LONG, DA LI, HAO ZENG, Department of Physics, SUNY at Buffalo — In this study, we present the synthesis of Fe_3Se_4 nanostructures by a one-pot high temperature organic solution-phase method. The size of these nanostructures can be tuned from 50 to 500 nm and their shapes can be varied from nanosheets and nano-cactus to faceted nanoparticles by changing the precursors and reaction conditions. These nanostructures exhibit hard magnetic properties, with giant coercivity values reaching 40 kOe at 10 K, and 4 kOe at room temperature. The estimated lower bound of the magnetocrystalline anisotropy constant is 6×10^6 erg/cm^3, comparable to that of hcp Cobalt. The large coercivity/anisotropy is rare for compounds without noble metal or rare-earth elements. If Fe_3Se_4 based phases can be doped to enhance their Curie temperature and magnetization, they can be a low cost, non-toxic alternative to noble metal or rare earth based advanced magnets.

1:51PM B16.00012 Synthesis and Magnetic Properties of FePt@MnO Nano-*hetero*-Particles , THOMAS SCHLADT, TANJA GRAF, OSKAR KOEHLER, KERSTIN SCHNEIDER, WOLFGANG TREMEL, Johannes Gutenberg-University Mainz, Germany, INSTITUTE FOR INORGANIC AND ANALYTICAL CHEMISTRY TEAM — Monodisperse FePt@MnO nano-*hetero*-particles with different sizes and morphologies were prepared by a seed-mediated nucleation and growth technique. Both, size and morphology of the individual domains could be controlled by adjustment of the synthetic parameters. As a consequence, different particle constructs, including dimers, dumbbells and flowers, could be obtained by changing the polarity of the solvent. The FePt@MnO nano-*hetero*-particles were thoroughly characterized by (HR-)TEM- and XRD analysis and SQUID magnetometry. Due to a sufficient lattice match, the MnO NPs preferentially grow on the (111) surfaces of the *fcc*-FePt seeds. Furthermore, the surface spins of the antiferromagnetic MnO domains pin the magnetic moments of the ferromagnetic FePt NPs which leads to an exchanged biased magnetic hysteresis.

2:03PM B16.00013 Electron-electron correlations and magnetic properties of small FePt clusters[1] , ALAMGIR KABIR, NEHA NAYYAR, VOLODYMYR TURKOWSKI, TALAT S. RAHMAN, Department of Physics and NSTC, University of Central Florida, Orlando, FL 32816 — We have applied the DFT+U and the Nanoscale Dynamical Mean-Field Theory (NDMFT) [1] approaches to study the magnetic properties of small FePt clusters. The role of correlation effects in determining the geometry and the magnetic properties of the clusters as a function of chemical composition and the effective local Coulomb repulsion energy U is examined. We find that the magnetization to decrease with increasing number of Pt atoms. Interestingly, contrary to the bulk case, Pt clusters have nonzero magnetization. The magnetic properties are found to be very sensitive to the value of U, as a result of the dependence of the single particle energy levels on this parameter. Dynamical correlation effects, which are taken into account in the DFT+DMFT approach and which lead to an increase of the average in time double occupancy of the d-orbitals, results in a significant decrease of magnetization as compared to the results from the DFT+U case.

Session B17 GMAG DMP: Focus Session: Bulk Properties of Complex Oxides - Manganites II

D174

11:15AM B17.00001 Dynamics of bi-stripes and a colossal metal-insulator transition in the bi-layer manganite $La_{2-2x}Sr_{1+2x}Mn_2O_7$ $(x \sim 0.59)$, ZHE SUN, University of Colorado, Boulder — Electronic phases with stripe patterns have been intensively investigated for their vital roles in novel properties of correlated electronic materials. How these real-space patterns affect the conductivity and other properties of materials (which are usually described in momentum space) is one of the major challenges of modern condensed matter physics. By studying the electronic structure of $La_{2-2x}Sr_{1+2x}Mn_2O_7$ $(x \sim 0.59)$ and in combination with earlier scattering measurements, we demonstrate the variation of electronic properties accompanying the melting of so-called bi-stripes in this material. The static bi-stripes can strongly localize the electrons in the insulating phase above $T_c \sim 160$K, while mobile electrons grow up and coexist with a significant portion of localized electrons when the static bi-stripes melt below T_c. The presence of localized electrons below T_c suggests that the melting bi-stripes exist as a fluctuating counterpart. From static to melting, the bi-stripes lead to a "colossal" metal-insulator transition in this material. Work was done in collaboration with Q. Wang, A. V. Fedorov, H. Zheng, J. F. Mitchell, D. S. Dessau.

11:51AM B17.00002 Probing multiple magnetic transitions and phase coexistence in mixed phase manganites , M.H. PHAN, N.S. BINGHAM, H. SRIKANTH, University of South Florida, C.L. ZHANG, S.W. CHEONG, Rutgers University — $La_{5/8-y}Pr_yCa_{3/8}MnO_3$(LPCMO) manganites exhibit a complex phase diagram due to coexisting and competing magnetic and electronic phases. A complete understanding of the origin of phase coexistence and separation in this system has remained elusive. To resolve this, it is essential to employ experimental methods that allow detailed investigations of the temperature and magnetic field response of the different phases. In this study we introduce magnetocaloric effect (MCE) and radio-frequency transverse susceptibility (TS) experiments as being ideally suited for this purpose. While MCE is generally considered in the community as an "applied" measurement tool to characterize magnetic refrigerant materials, we demonstrate that it is actually a very useful probe of magnetic transitions and ground state magnetic properties in LPCMO. TS experiments probe a phase conversion between the charge-ordered and ferromagnetic phases and magnetic field-induced kinetic arrest. Our studies provide an important understanding of the phase coexistence and separation in mixed phase systems like LPCMO.

12:03PM B17.00003 Soft x-ray investigation on the spin and orbital states of $La_{1.4}Sr_{1.6}Mn_2O_7$, K.-T. KO, H. JANG, J.-H. PARK, Dept. Physics, POSTECH, B.-G. PARK, J.-Y. KIM, PAL, SUNG BAEK KIM, I-FEM & Dept. Physics, POSTECH, S-W. CHEONG, R-CEM & Dept. Physics and Astronomy, Rutgers University — The spin and orbital states of $La_{1.4}Sr_{1.6}Mn_2O_7$ was investigated by using the x-ray absorption spectroscopy (XAS) and the soft x-ray resonant scattering (SXRS) at Mn $L_{2,3}$-edge. The field induced spin reorientation transition was observed by SXRS. The polarization dependent analysis revealed that the AFM spin axis changes from out-of-plane to in-plane axis. Additionally, the orbital states were determined from the polarization dependent XAS and CI model calculation, where the orbital state were changed by cooling temperature and external magnetic field. Here, the orbital states of low temperature ferromagnetic and field induced ferromagnetic are identical. Finally, we discuss the magnetoelastic coupling including spin and orbital structure of $La_{1.4}Sr_{1.6}Mn_2O_7$.

12:15PM B17.00004 Optical Investigation on Collective Dynamics of Charge-Orbital Density Wave in Layered Manganites , JUN FUJIOKA, Multiferroics Project, ERATO, JST, YOSHIAKI IDA, Department of Applied Physics, University of Tokyo, YOUTAROU TAKAHASHI, NORIAKI KIDA, Multiferroics Project, ERATO, JST, RYO SHIMANO, Department of Physics, University of Tokyo, YOSHINORI TOKURA, Department of Applied Physics, University of Tokyo — We have investigated the broad band optical spectra on the layered manganites $R_{1-x}Sr_{1+x}MnO_4$ (R=Nd and La) to reveal the collective charge/orbital density wave dynamics by means of the terahertz time domain spectroscopy [1]. The collective charge/orbital density wave excitation is observed around 9 meV in the charge/orbital stripe phase, when the nominal e_g-electron filling (1-x) of Mn-ion is less than around 1/3. By contrast, such a collective mode almost vanishes at x=1/2, which is explained in terms of the enhanced Jahn-Teller interaction cooperative with the electron correlation effect.

12:27PM B17.00005 Bilayer manganites: polarons in the midst of a metallic breakdown , MARK GOLDEN, FREEK MASSEE, SANNE DE JONG[1], YINGKAI HUANG, University of Amsterdam, ANDREW BOOTHROYD, D. PRABHAKARAN, University of Oxford, ROLF FOLLATH, ANDREI VARYKHALOV, HZB, LUC PATTHEY, MING SHI, PSI, JEROEN GOEDKOOP, University of Amsterdam — The exact nature of the low temperature electronic phase of the manganite materials family, and hence the origin of their colossal magnetoresistive (CMR) transition is still a flagship issue in emergent correlated matter research. By combining new photoemission and tunneling data, we show that in the bilayer (N=2) manganite $La_{2-2x}Sr_{1+2x}Mn_2O_7$ the lattice/spin/orbital polaronic degrees of freedom win out, all across the CMR region of the phase diagram. This means that the generic ground state is that of a system in which strong interactions result in vanishing coherent quasi–particle spectral weight at the Fermi level for all locations in k–space. The incoherence of the charge carriers offers a unifying explanation for the anomalous charge-carrier dynamics seen in transport, optics and electron spectroscopic data. The stacking number N is the key factor for true metallic behavior, as an intergrowth-driven breakdown of the polaronic domination to give a robust metal possessing a traditional Fermi surface is seen in the bilayer system.

12:39PM B17.00006 Synthesis, Structure, and Physical Properties of $Ba_2Mn_2Sb_2O$ Single Crystals , JIANNENG LI, S. STADLER, A. KARKI, Y. XIONG, R. JIN, Louisiana State University — We have grown high-quality single crystals of $Ba_2Mn_2Sb_2O$, which possesses the hexagonal structure as determined by X-ray powder diffraction technique. The magnetic susceptibility (χ) is isotropic above $T_N \sim 60$ K, initially increasing with increasing temperature (T). After reaching the maximum at $T_{MAX} \sim 150$ K, χ decreases with increasing T and can be described by Curie-Weiss law with negative Curie-Weiss temperature. Below T_N, magnetic anisotropy is observed: χ_{ab} decreases sharply but χ_c increases with decreasing T, suggesting an antiferromagnetic type ordering at T_N. Interestingly, the temperature dependence of electrical resistivity along both *ab* plane and c direction changes from exponential dependence above T_{MAX} to logarithmic dependence below T_{MAX}, reflecting strong Kondo effect.

12:51PM B17.00007 Evaluating Born and local effective charges in nanoscale MnO[1] , Q.-C. SUN, X.S. XU, University of Tennessee, S.N. BAKER, A.D. CHRISTIANSON, Oak Ridge National Laboratory, J.L. MUSFELDT, University of Tennessee — Phonons are exquisitely sensitive to finite length scale effects in complex materials because they are intimately connected to charge, polarizability, and structure, and a quantitative analysis of their behavior can reveal microscopic aspects of chemical bonding. To investigate these effects in a model correlated oxide, we measured the infrared vibrational properties of 8 nm particles of MnO, compared the results with the analogous bulk material, and quantified the phonon confinement with a calculation of Born effective charge. Our analysis reveals that the Born effective charge decreases by ∼20% compared to the bulk material. This finding is important for understanding finite length scale effects in this simple binary oxide and the more complicated functional oxides that emanate from this parent compound.

1:03PM B17.00008 Collective Phase Mode and the Role of lattice distortions at $T_N \sim T_C$ in XMn_2O_5 (X= Bi, Pr, Sm, Gd, Tb) , N.E. MASSA, LANAIS EFO-CEQUINOR, UNLP, La Plata, Argentina, A.F. GARCÍA FLORES, E. GRANADO, IFGW, UNICAMP, Campinas, Brazil, G.F.L. FABBRIS, G. DE M. AZEVEDO, LNLS, Campinas, Brazil, L. DEL CAMPO, D. DE SOUSA MENESES, P. ECHEGUT, CNRS-CEMHTI, Orleans, France , M.J. MARTÍNEZ-LOPE, J.A. ALONSO, ICMM-CSIC, Madrid, Spain — We report on detailed temperature dependent infrared reflectivity, Raman, local structure, and X-ray diffraction measurements of multiferroic XMn_2O_5 (X= Bi, Pr, Sm, Gd, Tb). While for $BiMn_2O_5$ there are weak but distinct spectroscopic changes that together with high resolution diffraction patterns suggest a lattice role at $T_N \sim T_C$, for the rare earth (R) replaced infrared spectra have as a main feature a broad band at meV energies in addition to progressive rotation of Mn-O polyhedra. That band, independent of the R^{3+} ion size and common to all, suggests hopping of carriers through fluctuations at a local scale. It partially condenses below 40 K, i.e., the collective electronic behavior changes from delocalized to one partially localized. We assimilate that condensate to a CDW-like phase mode. It might indicate induced orbital correlation of charge transfers between Mn sites.Frequency Raman phonon shifts are observed at T∼60 K, due to spin-phonon coupling, and at $T_N \sim T_C$. Below $T_N \sim T_C$ there is no a Raman soft mode that might be associated to a CDW amplitude mode.

1:15PM B17.00009 Korringa-like relaxation in A-site ordered manganites , S. SCHAILE, H.-A. KRUG VON NIDDA, A. LOIDL, J. DEISENHOFER, Experimentalphysik V, Center for Electronic Correlations and Magnetism, Institute for Physics, Augsburg University, D-86135 Augsburg, Germany, T. NAKAJIMA, Y. UEDA, Material Design and Characterization Laboratory, Institute for Solid State Physics, University of Tokyo, 5-1-5 Kashiwanoha, Kashiwa, Chiba 277-8581, J — Half doped manganites exhibiting charge- and orbital ordering transitions are paradigm materials for studying colossal magnetoresistance, the existence of ferroelectricity or Zener polaron-type features. We report on high-temperature electron spin resonance studies of A-site ordered and disordered ABaMn$_2$O$_6$ A =Y,Sm,La. We find a Korringa-like spin-relaxation above the charge-ordering transition and extending up to 1000 K in the A-site ordered antiferromagnetic systems A =Y,Sm, a unique feature for a truly metallic state not having been reported in manganites before. In agreement with the ESR intensity this finding suggests that the ESR signal stems from Mn^{4+} core spins which relax via the quasi-delocalized e_g electrons. In contrast in the disordered AFM and the ferromagnetic samples no Korringa relaxation is observed. Hence, the conductivity does not significantly influence the spin relaxation in those compounds.

1:27PM B17.00010 Magnetic order in $La_{1-x}Ca_xMnO_3$ nanopowder , CHETAN DHITAL, Boston College, CLARINA DELA CRUZ, High flux Isotope reactor, Oak Ridge Tennessee, KEFONG WANG, Boston College, Chestnut Hill, MA,02467, JUN-MING LIU, Nanjing University, ZHIFENG REN, STEPHEN WILSON, Boston College, Chestnut Hill, MA,02467 — Here we present neutron diffraction studies exploring the spin behavior in nanocrystalline $La_{1-x}Ca_xMnO_3$ (LCMO). Confinement effects and the influence of phase separation have long been key issues within the underlying electronic behavior of the manganites. The coexistence of competing electronic phases has been reported across length scales exceeding 100nm in bulk manganites in proximity of the first-order metal-to-insulator phase transition in their phase diagrams. When the grain size of manganite crystals approaches the size of intrinsically phase-separated domains, new magnetic phases can be stabilized and the resulting electronic behavior dramatically altered. In this talk, we present results from our recent investigations of the magnetism in LCMO samples whose grain-size has been reduced to the nanometer scale. Newly stabilized static spin order and its relevance to phase separation in this manganite system will be discussed.

1:39PM B17.00011 Density functional investigation of the spin frustration and the field-driven long-range ordering in the honeycomb lattice system $Bi_3Mn_4O_{12}(NO_3)$, JIA LIU, WON-JOON SON, MIKE WHANGBO, NCSU — $Bi_3Mn_4O_{12}(NO_3)$, consisting of the honeycomb lattices of Mn^{4+} (d^3) ions, has dominant antiferromagnetic interactions ($\theta_{CW} = -257$ K) but its spins do not order down to 0.4 K. However, applied magnetic fields induce a long-range magnetic order, which is believed to arise from the spin canting due to the Dzyaloshinskii-Moriya interaction. To explain these observations, we examined the spin exchanges between the Mn^{4+} ions (J_1, J_2, J_c) by DFT+U calculations and the preferred orientation of their spins by DFT+U+SOC calculations. The spin frustration is reproduced by U close to zero with $J_2/J_1 \approx 1/2$. The cause for the field-induced long-range magnetic ordering was explored on the basis of DFT+U+SOC calculations.

1:51PM B17.00012 New magnetic structures in novel and conventional manganites , AZIZ DAOUD-ALADINE, STFC Rutheford Appleton Laboratories, JUAN RODRÍGUEZ-CARVAJAL, CRISTIAN PERCA, LOREYNNE PINSARD-GAUDART — The determination of the magnetic structures of manganites has always been at the root of their fundamental understanding [1]. We studied the magnetic structures of half-doped charge ordered manganites that are either show the prototype [1] CE-type magnetic structure ($Pr_{1/2}Ca_{1/2}MnO_3$), or variants of this order ($YBaMn_2O_6$ [2] and $Pr_{0.6}Ca_{0.4}MnO_3$) with neutron diffraction. The study of $Pr_{1/2}Ca_{1/2}MnO_3$ (ILL, France) is the first ever done on a single crystal and it essentially confirms the pioneering picture [1], whereas the NPD studies of $YBaMn_2O_6$ [2] (PSI, Switzerland) and $Pr_{0.6}Ca_{0.4}MnO_3$ [3] (ISIS, UK), give two unprecedented results. The $YBaMn_2O_6$ magnetic structure corroborates the hotly debated ordering of Zener Polarons [4], and high resolution NPD data evidence a new spin reorientation transition around T$\sim$20K far below its TN$\sim 170K$ in $Pr_{0.6}Ca_{0.4}MnO_3$ [3] that has so far only been vaguely observed. We will discuss the consequences that these results have on the still hotly debated understanding of the connection between charge/orbital and spin orderings in the manganites. Session B18 GMAG DMP: Focus Session: Low D/Frustrated Magnetism - Quantum Magnetism D172

11:15AM B18.00001 Abelian and Non-Abelian Height Models , R. ZACH LAMBERTY, STEFANOS PAPANIKOLAOU, CHRIS HENLEY, Cornell University — We present Monte Carlo simulations on a new class of lattice models in which the degrees of freedom are elements of an abelian or non-abelian finite group G, placed on directed edges of a two-dimensional lattice. The group product around any plaquette is constrained to be the group identity, as in a discrete gauge model, but in contrast a "height model" only allows a certain subset of group elements to appear on edges. These models often realize a classical form of topological order, in that the ensemble breaks up into sectors labeled by loop products (group products taken around topologically non-trivial loops). Our implementation uses a non-local Monte Carlo update, whereby a pair of topological defects is created and later recombined after one diffuses; this allows the simulation to visit different topological sector. We measured two quantities as diagnostics of topological order (i) The relative probabilities of different sectors, which were found to converge to unity with increasing system size L. (ii) The probability distribution of the separation R of a defect pair, which should approach a constant (be deconfined). Both results show exponential decay as a function of L or R, as expected for a liquid-like phase having only topological order. As a check, we measured the same two quantities in a model equivalent to the 6-vertex model, known to be a critical state, and confirmed the algebraic decay in that case.

11:27AM B18.00002 Application of DFT+U for calculating magnetic parameters for manganese based molecular magnets , SHRUBA GANGOPADHYAY, NanoScience Technology Center, Department of Chemistry, University of Central Florida, Orlando, FL, 32826, ARTEM MASUNOV, NanoScience Technology Center, Department of Chemistry, Department of Physics, University of Central Florida, Orlando, FL, 32826 — Single-molecule magnets are promising materials for molecular spintronics and quantum computing applications. Two methods feasible to predict the exchange coupling parameters of molecular magnets, broken symmetry Density Functional Theory and DFT with empirical Hubbard U parameter (DFT+U). In this contribution we apply DFT+U to study magnetic coupling for two Mn12-based molecular magnetic wheel using Vanderbilt Ultrasoft Pseudopotential plane wave DFT method implemented in Quantum ESPRESSO. Unlike most previous studies, we adjust U parameters for both metal and ligand atoms using five dineuclear organometallics as the benchmarks. Our study finds antiparallel spin alignment of the weakly interacting fragments of Mn_{12}, while the magnetic coupling inside the fragments are much stronger, both are in agreement with experimental observations.

11:39AM B18.00003 ABSTRACT WITHDRAWN –

11:51AM B18.00004 DMRG Study of Anisotropic Triangular Heisenberg Lattice

, ANDREAS WEICHSELBAUM, Ludwig Maximilians University, Munich, Germany, STEVEN R. WHITE, UC Irvine, USA — The anisotropic antiferromagnetic two-dimensional triangular Heisenberg lattice for spin $1/2$ describes certain classes of transition-metal oxides (TMOs) and chalcogenides (TMCs) supported by experimental data. The understanding of the ground state properties of this frustrated system from a theoretical point of view, however, has remained an extraordinary challenge. In the model under consideration, quasi-one-dimensional Heisenberg chains of uniform intrachain coupling strength J interact with their neighboring chains via the triangular interchain coupling J'. By varying the anisotropy ratio $j = J'/J$ from $j = 0$ (decoupled Heisenberg chains) to $j = 1$ (uniform triangular lattice with finite Neel order like local magnetization), it was pointed out [1,2] that spin liquid properties up to remarkably high values of j of about 0.85 exist. We present in detail our results on the incommensurable correlations using DMRG with special care given to finite size effects. We argue that incommensurable correlations persist throughout the entire range of $j \in [0, 1]$.

12:03PM B18.00005 Interacting antikinks on a diamondback ladder I

, MAYRA TOVAR, KIRILL SHTENGEL, University of California at Riverside — Recently introduced "antikinks" are spin $1/2$ excitations of the Heisenberg antiferromagnet on a sawtooth lattice. The idea is that they mimic spinons of the kagome antiferromagnet. Antikinks are triangles of spins which are not in their ground state. Treating antikinks as free non- interacting particles (a good approximation for the sawtooth chain), their energy was found to be substantially reduced by delocalization. We study antikinks on a "diamondback" ladder in which all spins are shared between two triangles. Consequently, in a uniform case the concentration of antikinks becomes $1/4$ and they strongly interact, making such a model a much better approximation for the kagome case. We treat these effects perturbatively by allowing different Heisenberg couplings on the up- and downward oriented triangles, the two limiting cases being the sawtooth and uniform diamondback ladder. We find a non-monotonic, power-law decay of induced interactions between the antikinks with their separation. The consequences of these interactions will be discussed in this talk.

12:15PM B18.00006 Interacting antikinks on a diamondback ladder II

, KIRILL SHTENGEL, MAYRA TOVAR, UC Riverside — Recently introduced "antikinks" are spin $1/2$ excitations of the Heisenberg antiferromagnet on a sawtooth lattice [1]. The idea is that they mimic spinons of the kagome antiferromagnet. Antikinks are triangles of spins which are not in their ground state. Treating antikinks as free non-interacting particles (a good approximation for the sawtooth chain), their energy was found to be substantially reduced by delocalization [1]. We study antikinks on a "diamondback" ladder in which all spins are shared between two triangles. Consequently, in a uniform case the concentration of antikinks becomes $1/4$ and they strongly interact, making such a model a much better approximation for the kagome case. We treat these effects perturbatively by allowing different Heisenberg couplings on the up- and downward oriented triangles, the two limiting cases being the sawtooth and uniform diamondback ladder. We find a non-monotonic, power-law decay of induced interactions between the antikinks with their separation. The consequences of these interactions will be discussed in this talk.

12:27PM B18.00007 Partial Kondo screening in geometrically frustrated Kondo lattice systems

, YUKITOSHI MOTOME, KYOYA NAKAMIKAWA, University of Tokyo, YOUHEI YAMAJI, Rutgers University, MASAFUMI UDAGAWA, University of Tokyo — One of the most important concepts in Kondo lattice systems is competition between the Kondo coupling and the RKKY interaction. The competition leads to a quantum critical point between a magnetically-ordered state and a Fermi liquid state, and furthermore, it is the origin of novel phenomena around the quantum critical point, such as a non-Fermi liquid behavior and a superconductivity. To explore a new quantum phase resulting from the competition, we investigate the ground state of geometrically-frustrated Kondo lattice systems by employing a high-precision variational Monte Carlo simulation. We find that a partially-ordered state, in which a magnetic order and a Kondo spin singlet coexists, emerges between a magnetically-ordered state stabilized by the RKKY interaction and a Kondo spin liquid state stabilized by the Kondo coupling. We clarified that this new quantum phase is stabilized by quantum fluctuations as well as magnetic anisotropy, and that it is accompanied by a charge disproportionation. Ref. Y. Motome *et al.*, Phys. Rev. Lett. **105**, 036403 (2010).

12:39PM B18.00008 Study of SU(N) magnets on the cubic lattice[1]

, HAO SONG, MICHAEL HERMELE, Department of Physics, University of Colorado at Boulder — We consider a class of $SU(N)$ magnets that have the same spin on every lattice site, which is obtained as the completely antisymmetric tensor product of $m < N$ fundamental representations. These models, which can be realized in ultracold gases of alkaline earth atoms in optical lattice potentials, have the remarkable property that more than two spins must be combined to form a singlet. A recent study of this model on the square lattice in the large-N limit found a chiral spin liquid ground state with topological order. Inspired by this result, we have studied the three-dimensional version of this model, solving it on the cubic lattice in the large-N limit, which addresses the competition among a variety of non-magnetic states, including some with exotic order. We present results on the phase diagram as the fraction m/N is varied.

12:51PM B18.00009 Trial wave function for the quantum Ising model at zero temperature

, JULIO F. FERNÁNDEZ, Universidad de Zaragoza, Spain — A trial wavefunction for the ground state of the transverse field Ising model is proposed. It is a product of pair wavefunctions, which is exact for up to three spins, and is amenable to Monte Carlo calculations. We study the phase transition that occurs at zero temperature as the transverse field varies. Results for the Ising ferromagnet and some spin-glass models will be given.

1:03PM B18.00010 Thermodynamics of deconfined bosonic spinons in two dimensions[1]

, VALERI KOTOV, University of Vermont, ANDERS SANDVIK, OLEG SUSHKOV, Boston University — We consider the quantum phase transition between a Neel antiferromagnet and a valence-bond solid (VBS) in a two-dimensional system of $S = 1/2$ spins. Assuming that the excitations of the critical ground state are linearly dispersing deconfined spinons obeying Bose statistics, we derive expressions for the specific heat and the magnetic susceptibility at low temperature T. Comparing with quantum Monte Carlo results for the J-Q model, which is a candidate for a deconfined Neel–VBS transition, we find excellent agreement, including a logarithmic correction in the susceptibility. In our treatment, this is a direct consequence of a confinement length scale $\Lambda \propto \xi^{1+a} \propto 1/T^{1+a}$, where ξ is the correlation length and $a > 0$ (with $a \approx 0.2$ in the model).

1:15PM B18.00011 Properties of Resonating-Valence-Bond Spin Liquids and Critical Dimer Models[1] , YING TANG, ANDERS W. SANDVIK, Boston University, CHRISTOPHER L. HENLEY, Cornell University — We use Monte Carlo simulations to study properties of resonating-valence-bond (RVB) spin liquid states for $s = 1/2$ spins on 2D square lattices. It is well known that the spin-spin correlations decay exponentially in these states, but we find that the four-spin (valence-bond-solid, VBS, type) correlations are critical [1]. We compare various properties of the RVB with those of the classical dimer model (CDM), i.e., the exact ground state wavefunction of the critical Rokhsar-Kivelson quantum dimer model. It is well known that the CDM maps to a height model with a gradient-squared elasticity governed by a stiffness constant K. We show that also the RVB has such an effective classical field theory description, namely its (i) four-spin (dimer) correlations (ii) probabilities of different winding number sectors, and (iii) separation of monomer defect pairs, are all consistent with the same value of K (which is higher than in the CDM, i.e., the RVB is closer to an ordered VBS state). In addition to the short-bond RVB we also consider systems with longer bonds, and again find consistency with the height-model description. We discuss implications of the critical fluctuations of the RVB states.

1:27PM B18.00012 Quantum spin liquid in two-dimensional Kagome lattice spin-1/2 XY model with 4-site ring exchange[1] , LONG DANG, ROGER MELKO, University of Waterloo — We have studied the 2D Kagome lattice spin-1/2 XY model with 4-site exchange. The ground state properties are investigated within the framework of the Stochastic Series Expansion quantum Monte Carlo (QMC) technique. We have found a featureless insulating phase in the regime of large 4-site exchange interaction. This novel phase is a potential candidate for a the Z_2 quantum spin liquid phase proposed by Balents, Girvin and Fisher [Phys. Rev. B, **65**, 224412 (2002)] in a related model. Our efforts to characterize this phase using large-scale QMC simulations are also discussed.

1:39PM B18.00013 Linear independence of nearest neighbor valence bond states on several 2D lattices[1] , JULIA WILDEBOER, ALEXANDER SEIDEL, Washington University in St. Louis — We show for several two-dimensional lattices that the spin-$1/2$ nearest neighbor valence bond states are linearly independent. To do so, we utilize and further develop a method recently introduced [1] for the kagome lattice. This method relies on the identification of an appropriate cell for the respective lattice, for which a certain local linear independence property can be demonstrated. Whenever this can be achieved, linear independence follows for arbitrarily large lattices that can be covered by such cells, for open or periodic boundary conditions. We report that this method is applicable to a number of 2D lattices including the kagome, honeycomb, square, pentagonal I and II, and the star lattice. Applications of general linear independence properties, such as the derivation of effective quantum dimer models, are discussed. Furthermore, motivated by a spin-$1/2$ Hamiltonian on the kagome lattice that has Anderson's resonating-valence-bond (RVB) spin liquid wave function(s) as ground state(s) [1], we mention possibilities to study the properties of this RVB wave function for the kagome and other frustrated lattices using Monte Carlo techniques. 1:51PM B18.00014 Symmetry Fractionalization in Two Dimensions , HONG YAO, Department of Physics, University of California Berkeley, LIANG FU, Department of Physics, Harvard University, XIAO-LIANG QI, Department of Physics, Stanford University — Topologically ordered states are often characterized by topological properties, such as braiding statistics and fusion rules, of their excitations. However, excitations also carry symmetry quantum number, namely a representation of a symmetry group, when a topologically ordered state respects the symmetry. If an excitation's symmetry quantum number cannot be obtained from a finite integer number of fundamental constituents of the system, we propose to call such phenomena "symmetry fractionalization." We introduce a solvable SO(3) spin-rotational and time reversal invariant spin-1 model on the honeycomb and decorated honeycomb lattices. We show that the ground state is the equal-weight superposition of all valence loops, which we call "resonating valence loop" (RVL) state and which is a quantum spin liquid respecting all the symmetries of the model. Ends of broken loops are excitations with spin-$1/2$, which are deconfined spinons. Since spin-$1/2$ cannot be obtained from an integer numbers of spin-1, the system exhibits symmetry fractionalization (specifically the "SO(3) symmetry fractionalization"). Moreover, for time-reversal T, a spinon has $T^2 =$ -1, while integer spins have $T^2 = +1$. Consequently, the system also has "time-reversal fractionalization."

2:03PM B18.00015 Defect-driven phase transitions out of the Coulomb phase , HYEJIN JU, UCSB, SIMON TREBST, Microsoft Station Q, UCSB, CHRISTOPHER HENLEY, Cornell University — Lattice models constrained by a local "conservation law," such as close-packed dimer models on 3D bipartite lattices, exhibit an emergent "Coulomb phase" with characteristic power-law correlations. We have studied, by Monte Carlo simulations, phase transitions out of the Coulomb phase induced by introducing a finite fugacity of defect excitations in dimer models. We report two cases. (1) In the simple cubic dimer covering, we admit non- bipartite dimers (connecting sites in the same sublattice), which appear as effective charges with Coulomb-like interactions. Non- bipartite defects induce a transition immediately out of the Coulomb phase, exponentially damping the critical correlations via Debye screening. We characterize this transition by extracting the screening length from our numerical calculation of the dimer structure factor.(2) In the diamond lattice, we initially restrict the dimers to a 2D layer forming a (bipartite) honeycomb lattice, and then admit interlayer dimers. These bipartite dimers appear as dipoles and do not destroy the Coulomb phase, but induce an immediate transition from a 2D to 3D Coulomb phase.

Session B19 GMAG DMP: Focus Session: Spin Transport & Magnetization Dynamics in Metals II D170

11:15AM B19.00001 Effects of disorder on magnetic vortex dynamics[1]

, HONGKI MIN, Condensed Matter Theory Center, Department of Physics, University of Maryland — Experimental measurements of domain wall propagation are typically interpreted by comparison to reduced models that ignore both the effects of disorder and the internal dynamics of the domain wall structure. Using micromagnetic simulations, first we study vortex wall propagation in magnetic nanowires induced by fields or currents in the presence of disorder. We show that the disorder leads to increases and decreases in the domain wall velocity depending on the conditions. These results can be understood in terms of an effective damping that increases as disorder increases. As a domain wall moves through disorder, internal degrees of freedom get excited, increasing the energy dissipation rate [1]. Next we study the effect of disorder on vortex gyration in a magnetic disc. A vortex gyrating in a magnetic disc has two regimes of motion in the presence of disorder. At large gyration amplitudes, the vortex core moves quasi-freely through the disorder potential. As the amplitude decreases, the core can become pinned at a particular point in the potential and precess with a significantly increased frequency. In the pinned regime, the amplitude of the gyration decreases more rapidly than it does at larger precession amplitudes in the quasi-free regime. In part, this decreased decay time is due to an increase in the effective damping constant and in part due to geometric distortion of the vortex. A simple model with a single pinning potential illustrates these two contributions [2].

11:51AM B19.00002 Spin-torque-driven excitations in magnetic thin films[1]

, C. WANG, H. SEINIGE, T. STAUDACHER, M. TSOI, Physics Department, University of Texas at Austin — Spin transfer torque (STT) refers to a novel method to control and manipulate magnetic moments using an electrical current. For the past decade it has proven to be a fascinating domain of research with a number of manifestations in various systems interesting both from fundamental science's point of view as well as for technological applications. In ferromagnetic/nonmagnetic (F/N) multilayers a dc electrical current can switch and/or drive its constituent F parts into high-frequency precession which is of interest for microwave and magnetic recording technologies. Interestingly, application of high-frequency currents can also drive the multilayer, e.g., into ferromagnetic resonance (STT-FMR) precession. In our experiments we use point contacts to inject high microwave currents into a variety of magnetic thin films including NiFe/Cu/NiFe/IrMn and NiFe/Cu/Co spin valves, and single ferromagnetic (NiFe or Co) films. The resulting magnetodynamics are detected electrically when a small rectified dc voltage appears across the contact at resonance. We find that in addition to a standard FMR, the microwave currents can excite other resonance modes in our point contacts. We study the behavior of the excitations as a function of applied magnetic field, dc bias current, and microwave frequency.

12:03PM B19.00003 Minimization of Ohmic losses for domain wall motion in ferromagnetic nanowires[1]

, ARTEM ABANOV, OLEG TRETIAKOV, YANG LIU, Texas A&M University — We study current-induced domain-wall motion in a narrow ferromagnetic wire. We propose a way to move domain walls with a resonant time-dependent current which dramatically decreases the Ohmic losses in the wire and allows driving of the domain wall with higher speed without burning the wire. For any domain wall velocity we find the time-dependence of the current needed to minimize the Ohmic losses. Below a critical domain-wall velocity specified by the parameters of the wire the minimal Ohmic losses are achieved by dc current. Furthermore, we identify the wire parameters for which the losses reduction from its dc value is the most dramatic.

12:15PM B19.00004 Equilibration in All-Perpendicular Spin Valves Subject to Short Current Pulses *

, DANIEL BEDAU, HUANLONG LIU, JONATHAN SUN, JORDAN KATINE, ERIC FULLERTON, STEPHANE MANGIN, ANDREW KENT, NEW YORK UNIVERSITY, NEW YORK, NY TEAM, IBM T.J. WATSON RESEARCH CENTER, P.O.BOX218 NY TEAM, HITACHI-GST, SAN JOSE, CA TEAM, UNIVERSITY OF CALIFORNIA,SAN DIEGO,CA TEAM, NANCY-UNIVERSITY, NANCY, FRANCE TEAM — Our recent experiments have shown that all-perpendicular spin valves can be switched by short current pulses (<5 ns) [1]. In this limit we found that the switching probability only depends on the spin-angular momentum in the pulse [1]. However, such studies do not directly resolve the magnetization dynamics and relaxation. To study equilibration of spin valves driven out of equilibrium by short current pulse we have developed a pump-probe method, capable of 50 ps resolution. A probe pulse, a variable delay after the pump pulse, is used to determine the magnetization relaxation rate. When the delay between the pump and probe pulses is less than 1 ns the net switching probability differs from that at longer delays. An analysis of this difference shows that the free layer angular-momentum decays exponentially with time after the pump pulse. From these studies we obtain a lifetime, which we use to estimate the free layer damping. [1] Bedau et. al. Appl. Phys. Lett. 96, 022514 (2010) & ArXiv:1009.5240 *supported by: USARO Grant No. W911NF0710643

12:27PM B19.00005 Enhanced magnetization drift velocity and current polarization in $(CoFe)_{1-x}Ge_x$ alloys[1]

, ROBERT MCMICHAEL, NIST, MENG ZHU[2], NIST and Maryland Nanocenter, BRIAN SOE, NIST and Harvey Mudd College, MATT CAREY, STEFAN MAAT, JEFF CHILDRESS, Hitachi Global Storage Technologies — We present measurements of current spin polarization and magnetization drift velocity in $(CoFe)_{1-x}Ge_x$ alloys ($x \leq 0 \leq 0.3$), using a spin wave Doppler technique where spin wave transmission is measured between fixed-wavevector antennas coupled to current-carrying wires [1,2]. In a current density J, the transmission resonance frequency is shifted by $\Delta f = kv/2\pi$, where $v = Jg\mu_B P/(2eM_s)$ is a magnetization drift velocity. Measurement of Δf allows calculation of v and current spin polarization P. With increasing Ge concentration, v increases dramatically from (3.1 $\pm$ 0.2) m/s for CoFe to (8.2 $\pm$ 0.6) m/s for $(CoFe)_{0.7}Ge_{0.3}$ ($J = 10^{11}$ A/m^2). We attribute this increase in drift velocity primarily to decreased magnetization. The current polarization increases from 0.84 $\pm$ 0.04 for CoFe and reaches a maximum of 0.95 $\pm$ 0.05 at approximately 25% Ge.

12:39PM B19.00006 Planar spin-transfer device with dynamical polarizer and analizer

, YAROSLAW BAZALIY, ANTON KRAVCHENKO — The behavior of the planar spin-transfer devices with monodomain magnetic layers can be described by the macrospin Landau-Lifshitz-Gilbert (LLG) equation with spin-transfer terms. The LLG description of a device with two layers is simplified after applying the overdamped, large easy-plane anisotropy approximation. A decrease of the magnetic layer thickness asymmetry creates a transition from the conventional polarizer-analizer ("fixed layer – free layer") operation regime to the regime of the nearly identical magnets. Here electric current leads to a "Slonczewski windmill" dynamic state, rather than producing the magnetic switching. The "windmill" precession state of a device with two free layers was investigated by numerical solution of the LLG equation.

12:51PM B19.00007 Optimal field sweep rate in magnetic switching of a single-domain particle , SHU YAN, YAROSLAW BAZALIY, University of South Carolina, ANDRZEJ STANKIEWICZ, NVE Corporation — The speed of magnetic switching is an important parameter of memory cells. We consider a magnetic moment with an easy axis anisotropy switched by an external field applied at a small angle to the axis. By solving the Landau-Lifshitz-Gilbert(LLG) equation numerically, it is found that the switching time of the magnet is not monotonically increasing with the field sweep rate of the applied field. The dependence has a minimum, i.e., there exists an optimal field sweep time. Analytic approximations are derived for the dependence of the switching time on the field sweep rate and for the value of the optimal field sweep time. Our results have important implications for the optimization of magnetic memory devices.

1:03PM B19.00008 Ballistic (precessional) contribution to the conventional magnetic switching[1] , ANDRZEJ STANKIEWICZ, NVE Corporation, YA. B. BAZALIY[2], SHU YAN, University of South Carolina — We consider a magnetic moment with an easy axis anisotropy energy, switched by an external field applied along the axis. Additional small constant bias field is applied perpendicular to the axis. It is found that the magnet's switching time is a non-monotonic function of the rate at which the field is swept from "up" to "down". Switching time exhibits a minimum at a particular optimal sweep time. This unusual behavior is explained by the admixture of a ballistic (precessional) rotation of the moment caused by the perpendicular bias field in the presence of a variable switching field. Analytic approximations are derived for the dependence of the switching time on the field sweep rate and for the value of the optimal field sweep time. The existence of the optimal field sweep time has important implications for the optimization of magnetic memory devices.

1:15PM B19.00009 ABSTRACT WITHDRAWN –

1:27PM B19.00010 AC Magnetic Susceptibility and μSR Study of Spin Dynamics and the Onset of Magnetic Correlations in $LiHo_xY_{1-x}F_4$[1] , R.C. JOHNSON, Boston College, B.Z. MALKIN, Kazan Federal University, A. LASCIALFARI, Univ. of Milan, A. AMATO, C. BAINES, Paul Scherrer Institute, J.S. LORD, S.R. GIBLIN, Rutherford Appleton Laboratory, B. BARBARA, Néel Institute, M.J. GRAF, Boston College — The onset of correlation effects in the magnetic Ho^{3+}-subsystem in $LiHo_xY_{1-x}F_4$ single crystals is studied by comparing measurements and simulations of the field and frequency dependent magnetic AC susceptibility at 1.8 K and field and temperature dependent muon depolarization rates (μSR) for the concentrations x=0.0017, 0.0085, 0.041 and 0.0855. Specific features in the field and frequency dependence of in-phase and out-of-phase susceptibilities, in particular, broadening of peaks (dips) in χ' (χ") that indicate enhanced relaxation processes at field induced avoided level crossings, can be associated with x-dependent changes of cross relaxation rates and the phonon bottleneck effect in the spin-lattice relaxation. The observed peak in the measured temperature dependent muon relaxation rate appears to be related to a maximum at the frequency 60 cm^{-1} in the acoustic phonon density of states.

1:39PM B19.00011 Temperature dependence of the effective exchange and biquadratic coupling in ferromagnets: Calculation in the disordered local moment method , PAUL LARSON, KIRILL BELASHCHENKO, University of Nebraska — We have implemented the disordered local moment (CPA-DLM) method within the tight-binding linear muffin-tin orbital (LMTO) basis. This implementation self-consistently determines the angular distribution function of the generalized Heisenberg model and the angular-dependent local potentials in the symmetry-broken state; the CPA procedure involves numerical integration over the polar angle of the spin. We present benchmark calculations for several materials including Fe, Co, FePd, FePt, and CoPt. We further extract the temperature dependence of the effective exchange and biquadratic coupling parameters from the angular dependence of the single-site grand potential. We find that the effective exchange parameter in Fe is almost temperature-independent, while the biquadratic interaction is entirely negligible at all temperatures. In FePd the effective exchange varies noticeably as a function of temperature, while the biquadratic coupling is somewhat more pronounced but still relatively small.

1:51PM B19.00012 Effect of occupation numbers on exchange coupling in low dimensional magnetic nanostructures[1] , D. TERRADE, H. X. YANG, A. KALITSOV, L. NISTOR, M. CHSHIEV, B. DIENY, SPINTEC, CEA/CNRS/UJF, Grenoble, France — Interlayer exchange coupling (IEC) has been of great interest for spintronic community and has been shown directly related to equilibrium spin current (ESC). Here we present a study of the influence of the electronic occupation numbers on the angular dependence of the IEC in magnetic layered nanostructures with finite thickness ferromagnetic (FM) layers. The calculations were performed within the tight-binding model using the nonequilibrium Green function technique both within perturbation theory and exact diagonalization approaches. We found that the period of IEC oscillations as a function of FM layer thickness has nonmonotonic variation with electronic states occupation numbers (Fermi level position). In the limit of 2-site model it is found that perturbation theory fails to describe correctly exchange coupling angular dependence always giving sinusoidal behavior for the ESC while the exact solution alternates between sinusoidal and strongly nonsinusoidal behavior as a number of electrons in the system is varied.

2:03PM B19.00013 Spin and phase coherence times in lithographically defined bismuth wires , MARTIN RUDOLPH, J.J. HEREMANS, Virginia Tech — We performed low temperature magnetotransport measurements on lithographically defined semimetal thin film bismuth wires and used the weak-antilocalization effect to determine spin and phase coherence times. Purpose-made Bi mesoscopic structures have not been extensively studied, yet are of interest due to the strong spin-orbit coupling in the material and its surface states. The spin and phase coherence times in mesoscopic Bi wires are here studied as function of temperature and wire width. The phase coherence time saturates at temperatures below 2 K, and appears limited by electron-phonon interactions above 2 K. The spin coherence time shows a dependence on width unexpected in Bi thin films. The spin coherence time increases as the width is reduced, similar to the dependence observed in wires fabricated on spin-orbit coupled semiconductor two-dimensional systems. The similarity may be an indication that the weak-antilocalization signature is dominated by two-dimensional strongly spin-orbit coupled Bi surface states (DOE DE-FG02-08ER46532).

Session B20 FIAP/DMP GERA/DCOMP: Focus Session: Physics of Energy Storage Materials II – Anodes and Capacitors D168

11:15AM B20.00001 Anode-electrolyte double-layer of Li-ion batteries: Structure and Li-ion intercalation[1] , DAVID O. WIPF, Department of Chemistry, Mississippi State University, IBRAHIM ABOU HAMAD, PER ARNE RIKVOLD, Department of Phsics, Florida State University, MARK A. NOVOTNY, Department of Phsics & Astronomy, Mississippi State University — The electrochemical double-layer structure plays an important role in Li-ion intercalation during charging of Li-ion batteries with a graphite anode. In our recent Molecular Dynamics studies of a proposed accelerated charging method [I. Abou Hamad *et al.*, Phys. Chem. Chem. Phys. **12**, 2740-2743 (2010)], we notice that ethylene carbonate and propylene carbonate molecules of the electrolyte assemble themselves in a preferred orientation at the electrode-electrolyte interface. On the other hand, they are randomly oriented in the bulk electrolyte. We show that the structure of the double layer is affected by the intercalating Li-ion: while the dipole moments of double-layer molecules far from the intercalating Li-ion point toward the graphite sheets of the anode, they point away from the intercalation site close to the intercalating Li-ion. This observation should contribute to a better understanding of the intercalation process.

11:27AM B20.00002 High Throughput Computational Discovery of Intermetallic Anodes for Li Batteries[1] , SCOTT KIRKLIN, Northwestern University, CHRIS WOLVERTON — We have developed a framework to perform high-throughput computational screening of intermetallic compounds as candidates for Li battery anodes. We have used our method to calculate, from density functional theory (DFT), more than 5000 anode lithiation reactions, based on more than 100 intermetallic compounds. We have specifically focused on the 3d-transition metal silicides, nidtrides and phosphides. Given the set of DFT total energies for all compounds, the reaction path upon lithiation is predicted using the recently-developed grand canonical linear programming (GCLP) method. The anode performance is then characterized by the cell potential vs lithium metal, energy density and volume expansion. The accuracy of this approach is first validated for pure silicon, and then extended to binary intermetallic compounds. Based on the results of these calculations, future experimental study can be guided toward systems with promising thermodynamic properties.

11:39AM B20.00003 Li and Si diffusion in Si anodes in Li-ion batteries: An *ab-initio* molecular-dynamics-based study , PRIYA JOHARI, VIVEK B. SHENOY, Division of Engineering, Brown University, Providence RI 02912, USA. — Several studies have been carried out in the past few years to understand the dynamics of Li diffusion in Si anodes of Li-ion batteries, however, most of these studies are restricted to the diffusion of a single Li atom in crystalline Si. While, it is well known that crystalline Si becomes amorphous on lithiation, this phenomenon has not been considered in previous computational work. Here, we report the results of molecular dynamics simulations that were carried out to study the diffusion of Li atoms in crystalline as well as amorphous Si for the LiSi phase. We have also analysed the dynamics of the Si atoms during lithiation to understand its role in stress generation/relaxation. We find that Li diffuses faster in amorphous Si as compared to crystalline Si, while the diffusivity of Si is around two orders of magnitude lesser than Li.

11:51AM B20.00004 Li-ion Battery Electrode Materials Design from First-Principles Calculations , KRISTIN PERSSON, Lawrence Berkeley National Laboratory — First-principles calculations can provide a powerful tool for investigating and optimizing electrode materials. While the strength of computations lies in the ability to control what is being calculated, the challenge is to ensure that the calculation is relevant for the physical processes that dominate the performance of the material. We will discuss this balance and show examples of how computations can aid in the design of current Li-ion rechargeable battery electrode materials by identifying and understanding the performance bottlenecks on the atomistic level. As the most commonly used anode in today's Li-ion batteries, graphite shows poor rate capability at lower temperatures, leading to over-potential and Li plating. Using first-principles calculations, coupled with a cluster expansion of Li interactions and kinetic Monte Carlo we were able to show that *intrinsic* Li diffusion in graphite can be very fast, providing guidance towards designing higher-rate carbonaceous anode materials. On the cathode side, we have studied the layered $Li(Ni_{1/3},Mn_{1/3},Co_{1/3})O_2$ material, which is an interesting candidate if Co is partially substituted by the cheaper Al. Li migration in this material is influenced by several factors such as Li slab space, cation ordering and interlayer mixing. We present ab initio calculations of Li diffusivity as a function of Al content and slab spacing in the layered material, which elucidates the intrinsic rate performance effect of the Al substitution in the bulk material.

12:27PM B20.00005 Crystalline-amorphous interfaces in Li-ion batteries[1] , MARIA K. CHAN, JEFFREY GREELEY, Argonne National Laboratory, CENTER FOR ELECTRICAL ENERGY STORAGE, DOE ENERGY FRONTIER RESEARCH CENTER COLLABORATION — Amorphous and crystalline materials are associated with fast ionic transport and long term structural stability, respectively, both desirable properties in lithium ion battery materials. It is therefore no surprise that amorphous-crystalline interfaces are ubiquitous in Li-ion batteries. Using first principles density functional theory (DFT), and primarily Si as an example, we study models of crystalline-amorphous interfaces in Li-ion batteries. We will discuss the structure of such an interface and its energetic and mechanical effects on lithium insertion, as well as the kinetics of Li ion transport near and across the interface. The mechanism of solid state amorphization will also be discussed.

[1]Work funded by Center for Electrical Energy Storage, DOE Energy Frontier Research Center

12:39PM B20.00006 Li Diffusion Characteristics and Energetics in TiO_2 , H. YILDIRIM, SUBRAMANIAN SANKARANARAYANAN, JEFF GREELEY, Argonne National Laboratory — We present the results of density functional theory-based calculations for the activation energies of Li diffusion in TiO_2 crystalline and amorphous structures. Additionally, molecular dynamics simulations using shell potential models are used to investigate the Li ion diffusion mechanisms for various titania morphology. The diffusion pathways and the corresponding energetics for each diffusion mechanism are further probed using the DFT-based Nudged Elastic Band Method. We will report the calculated diffusion energetics (MD and DFT) for each (Li-TiO_2) system and compare the atomic scale Li transport characteristics on crystalline and amorphous TiO_2 structures. We also discuss the effect of Li concentration on the diffusion energetics.

12:51PM B20.00007 Composite MnO2-Carbon Electrodes for High Energy Density Storage , BRAD CORSO, ISRAEL PEREZ, PHILIP COLLINS, Department of Physics and Astronomy, Univ. of California at Irvine, Irvine, CA 92697 — The development of batteries with ever higher power densities is challenged by fundamental materials limitations that might be solved with hybrid combinations of materials. For example, metal oxides with high lithium ion capacities lack the conductivity to be good battery anodes, but composites that add graphitic carbon can achieve both capacity and conductivity. In this case, fast interfacial electron transfer between the materials is critical to achieving high performance. Here, we describe an electrochemical synthesis that achieves precise, conformal MnO2 films on graphitic surfaces. Furthermore, by using single-walled nanotubes as the carbon support, we can control defect densities with single defect resolution. Charge-discharge cycling of these electrodes, combined with control over point defects, directly distinguishes the enhanced charge transfer of defects and illuminates the structure-function relationship in interfacial electron transfer. This research is supported by the NEES Energy Frontier Research Center of the U.S. DOE Office of Basic Energy Sciences (#DESC0001160).

1:03PM B20.00008 Charge-Driven Structural Transformation and Valence Versatility of Boron Sheets in Magnesium Borides[1] , YUFENG ZHAO, National Renewable Energy Laboratory, CHUNMEI BAN, QIANG XU, SUHUAI WEI, ANNE C. DILLON, NATIONAL RENEWABLE ENERGY LABORATORY TEAM — We show here that boron sheets exhibit highly versatile valence and the layered boron materials may hold the promise for a high energy-density magnesium-ion battery. Practically, boron is superior to previously known multi-valence materials, especially transition metal compounds, which are heavy, expensive, and often not benign. Based on Density Functional Theory simulations, we have predicted a series of stable magnesium borides MgBx with a broad range of stoichiometries, $2 < x \leq 16$, by removing magnesium atoms from MgB2. The layered boron structures are preserved through an in-plane topological transformation between the hexagonal lattice domains and triangular domains. The process can be reversibly switched as the charge transfer changes with Mg insertion/extraction. The mechanism of such a charge-driven transformation originates from the versatile valence state of boron in its planar form. The discovery of these new physical phenomena suggests the design of a high-capacity magnesium-boron battery.

1:15PM B20.00009 Nanostructured Mg Thin Film Electrodes for Mg-Air Batteries , TAHA DEMIRKAN, Department of Applied Science, University of Arkansas at Little Rock, Little Rock, AR 72204, WISAM KHUDHAYER, Department of Applied Science, Engineering Science and Systems, University of Arkansas at Little Rock, AR, 72204, FATIH CANSIZOGLU, TANSEL KARABACAK, Department of Applied Science, University of Arkansas at Little Rock, Little Rock, AR 72204 — Over the past decades, primary Mg-air batteries got the attention of several researchers due to their low cost, non-toxicity, and theoretically expected high terminal voltage and high specific capacity values. However, corrosion and formation of a passivation layer around the electrode have been among the major challenges resulting in low columbic efficiencies compared to theoretically expected values. In this study, we utilized a glancing angle deposition (GLAD) method for fabricating nanostructured Mg thin film electrodes with unique physical properties to overcome these problems. Electrodes were prepared using a thermal evaporation GLAD system. Magnesium coatings in various forms ranging from conventional dense thin films to highly porous nanoblades were prepared through the control of deposition angle from normal to oblique angles, respectively. We show that the properties of Mg-air batteries can be significantly improved using nanostructured Mg thin film electrodes and lead to enhanced terminal voltage and specific capacity values.

1:27PM B20.00010 1-pyrenecarboxylic acid Functionalization of Graphene: Effect on Capacitive Energy Storage , SUJOY GHOSH, RAKESH SHAH, Department of Physics, Southern Illinois University Carbondale, IL-62901, XIAOHONG AN, Department of Physics, Northeastern University, Boston, MA 02115, DINESH RAWAT, Department of Physics, Southern Illinois University Carbondale, IL-62901, SWASTIK KAR, Department of Physics, Northeastern University, Boston, MA 02115, SAIKAT TALAPATRA, Department of Physics, Southern Illinois University Carbondale, IL-62901, DEPARTMENT OF PHYSICS, SOUTHERN ILLINOIS UNIVERSITY CARBONDALE, IL-62901 COLLABORATION, DEPARTMENT OF PHYSICS, NORTHEASTERN UNIVERSITY, BOSTON, MA 02115 COLLABORATION — We will present a comparison of Electrolytic Double Layer Capacitance (EDLC) performance of membrane electrodes fabricated using pure and 1-pyrenecarboxylic acid (PCA)-functionalized graphene flakes. A significant increase in specific capacitance as well as energy and power density values in PCA graphene electrodes indicates that surface functionalization (that affects the hydrophilicity) of graphene-based materials is crucial for improving capacitive energy storage ability of these materials.

1:39PM B20.00011 Electrochemical Double Layer Capacitors Using Few Layers of Graphene Grown on Nickel Foil. , R. SHAH, U. PHILIPOSE, J.M. PEREZ, Department of Physics, University of North Texas, Denton, TX, 76203, S. TALAPATRA, Department of Physics, Southern Illinois University Carbondale, IL, 62901 — We report on the properties of Electrochemical Double Layer Capacitors (EDLCs) fabricated using few layers of graphene synthesized on Nickel (Ni) foil by Chemical Vapor Deposition (CVD). The graphene films were characterized by Raman spectroscopy and showed that the film comprised more than one layers of graphene. The capacitive behavior of the fabricated EDLCs was examined using cyclic voltammetry, constant current charge/discharge, and impedance spectroscopy. These measurements show that the charge storage phenomenon is non-Faradic in nature. The capacitance of graphene on Ni electrodes was then compared to blank Ni foil electrodes and it was found that the capacitance of graphene on Ni foil is substantially higher than the blank Ni foil electrode. These results show that the few layers of graphene film grown on Ni foil could be promising material to function as electrodes for electrochemical energy storage device applications.

1:51PM B20.00012 First-principles study of the structure of $RuO_2 \cdot x\mathbf{H_2O}$, FEI ZHOU, YONGDUO LIU, UCLA, MARK ASTA, UC Berkeley, VIDVUDS OZOLINS, UCLA — Hydrous ruthenia, $RuO_2 \cdot xH_2O$, is a high-performance electrode material for electrochemical supercapacitors. Two different structural models of hydrous ruthenia had been proposed. In one of them, hydrogen is incorporated in metal vacancies inside the oxide host (("bulk model"), while in the other model structural water associated with Ru-O occupies the region between rutile nanograins ("core + grain-boundary model"). We present a theoretical examination of the validity of the bulk model by optimizing hydrogen positions within RuO_2 with proton-compensated Ru vacancies using a combination of a systematic search algorithm based on electrostatics, database searching and density-functional theory calculations. We find that all the considered bulk model structures are unstable by $\sim 0.3 - 0.4$ eV per H_2O molecule with respect to phase separation into anhydrous RuO_2 and water. Structures with hydroxyl groups or aggregate H_2O are significantly lower in energy (though still unstable with respect to phase separation), demonstrating that the water prefers to agglomerate outside RuO_2. Our results strongly disfavor the bulk model with hydrogen inside RuO_2 and support the core+grain-boundary model of hydrous ruthenia.

2:03PM B20.00013 Ab initio study of the charge storage mechanism of ruthenium dioxide as an electrochemical ultracapacitor , YONGDUO LIU, FEI ZHOU, VIDVUDS OZOLINS, University of California, Los Angeles — The charge storage mechanisms of ruthenium dioxide were investigated by first principles calculations. Both H-injected bulk and H-adsorbed RuO2(110) surface have been studied in order to obtain a whole picture of the discharging process of ruthenium dioxide as a supercapacitor. We have predicted the crystal structure of ruthenium-oxy-hydroxide (ROOH). By ab-inito voltage calculations, we also found that the RuO2(110) surface is completely hydrated before the usual voltammagram measurements, which suggests that the redox reactions happen in deep layers and should be diffusion dominated processes.

Session B21 DCOMP: General Theory D161

11:15AM B21.00001 Optimization of Elastic Constant Values in Non-cubic Crystals using Computational Image Matching , MADELEINE MSALL, Bowdoin College, TIMOTHY HEAD, Abilene Christian University — Point excitation in ultrasound or heat pulse experiments excites non-equilibrium phonons that carry energy along the group velocity direction. Phonon images map the sharp boundaries between high and low flux regions, called caustics, which are directly related to folds in the acoustic wave surface. Computational simulations show that caustic positions are extremely sensitive to the values of the elastic constants. We explore methods of determining the elastic constants using image matching techniques. Given the dependence of single image features on a constellation of constants, there are many local minima encountered in the search. This talk will present quantifiable criteria for image matching in this context and discuss potential heuristic or stochastic methods to deal with the problem of local minima.

11:27AM B21.00002 Entropic sampling without windows[1] , RONALD DICKMAN, ANTÔNIO CUNHA-NETTO, UFMG — We describe an entropic sampling method that permits estimation of the number of configurations over the full range of energies, with dividing the latter into subsets or "windows." Our method involves progressive refinement of an initial approximation for the density of states, using a set of random walks that span the energy range. Applied to the two-dimensional Ising model the method yields the critical temperature to an accuracy of about 0.01%, and critical exponents to 0.5% or better. Predictions for system sizes $L = 10$ - 160, for the temperature of the specific heat maximum, and the specific heat at the critical temperature, are in very good agreement with exact results. The antiferromagnetic transition is well represented. Excellent results are also obtained for the three-dimensional Ising model (simple cubic lattice) and the lattice gas with nearest-neighbor exclusion. We observe that attempts to restrict the sampling to a subset of the full energy range lead to distortions in the density of states, even if the restriction is imposed in a smooth manner, rather than with a sharp barrier.

[1]We thank CNPq, Brazil for financial support.

11:39AM B21.00003 Nearly exact calculations of small atomic and molecular systems using explicilty correlated gaussians[1] , SERGIY BUBIN, KALMAN VARGA, Vanderbilt University, LUDWIK ADAMOWICZ, University of Arizona — We demonstrate how very precise (virtually exact) solutions of various quantum mechanical problems can be obtained using the variational method with explicitly correlated Gaussian basis functions (ECGFs). As examples we consider several benchmark systems, such as few-electron atoms and molecules, as well as Coulomb systems containing exotic particles. We also discuss the evaluation of relativistic corrections in the framework of ECGFs.

[1]This work has been partially supported by NSF

11:51AM B21.00004 Metallic Phase of Water Ice Predicted at Megabar Pressures[1] , BURKHARD MILITZER, HUGH WILSON, University of California, Berkeley — We predict water ice to attain two new crystal structures with Pbca and Cmcm symmetry at 7.6 and 15.5 Mbar, respectively [Phys. Rev. Lett. 105 (2010) 195701]. With density functional calculations, we analyze the structural and electronic properties of these phases at zero temperature. The Pbca phase, like the known high-pressure ice phases VII, VIII, X and Pbcm, is insulating and consists of two interpenetrating hydrogen bonded networks, but the Cmcm phase is metallic and consists of corrugated sheets of H and O atoms. The H atoms are squeezed into octahedral positions between next-nearest O atoms while they occupy tetrahedral positions between nearest O atoms in lower-pressure phases. Our predictions may be testable with ramp compression experiments that can reach megabar pressures at lower temperatures than conventional shock wave experiments. The predicted insulator-to-metal transition would lead to an increase in reflectivity that can be measured with spectroscopic techniques.

12:03PM B21.00005 Supersymmetric Quantum Mechanics in Multiple Dimensions Applied to Variational Monte Carlo - A Proof of Principle Study[1] , THOMAS MARKOVICH, KAUSHIK MAJI, ERIC BITTNER, DON KOURI, University of Houston — We present a new approach to variational monte carlo using our N-Dimensional generalization of Supersymmetric Quantum Mechanics. We do this by introducing a *vector* superpotential in an orthogonal hyperspace. In the case of N distinguishable particles in three dimensions this results in a vector superpotential with $3N$ orthogonal components. The original scalar Schrödinger operator can be factored into vector "charge" operators: $\vec{Q}_1$ and $\vec{Q}_1^\dagger$. Using these operators, we can write the original (scalar) Hamiltonian as $H_1 = \vec{Q}_1^\dagger \cdot \vec{Q}_1 + E_0^{(1)}$. The second sector Hamiltonian is a tensor given by $H_2 = \vec{Q}_1 \vec{Q}_1^\dagger + E_0^{(1)}$ and is isospectral with H_1. The vector ground state of sector two, $\vec{\psi}_0^{(2)}$, can be used with the charge operator $\vec{Q}_1^\dagger$ to obtain the excited state wave functions of the first sector. We demonstrate the approach with examples of a pair of separable 1D harmonic oscillators and the example of a non-separable 2D anharmonic oscillator (or equivalently a pair of coupled 1D oscillators).

[1]Supported by R.A. Welch Foundation Grant E-0608.

12:15PM B21.00006 Electromagnetic and gravitational signatures of black hole and neutron star mergers , STEVEN LIEBLING, Long Island University — Astrophysical binary systems composed of some combination of compact objects (black holes(BH) and neutron stars(NS)) are extremely interesting dynamical systems. Such systems are generally extremely good radiators of gravitational waves, and, in at least some cases, they should be excellent electromagnetic sources. As such, they hold great promise for concurrent detection from both recently completed gravitational wave observatories and from conventional telescopes. I describe recent results achieved with a fully relativistic adaptive code for the merger of BH-BH, BH-NS, and NS-NS systems with magnetic fields.

12:27PM B21.00007 Quantification of Partially Ordered Sets with Application to Special Relativity , NEWSHAW BAHREYNI, KEVIN H. KNUTH, Department of Physics, University at Albany, Albany NY — A partially ordered set is a set of elements ordered by a binary ordering relation. We have shown that a subset of a partially ordered set can be quantified by projecting elements onto a pair of chains where the elements of each chain are quantified by real numbers. This results in a quantification based on pairs of real numbers (pair). Intervals, defined by pairs of elements, can be quantified similarly. A pair can be decomposed into a sum of a symmetric pair and an antisymmetric pair and mapped to a unique scalar which results in the Minkowskian form. Changing the basis of quantification from one pair of chains to another, under special conditions, leads to the generalized Lorentz transformation for pairs. We apply these results to a causally-ordered set of events by identifying a chain of events with an observer equipped with a clock in an inertial frame. We obtain the Minkowski metric of flat space-time as well as Lorentz transformations, which results in there being a maximum invariant speed. We find that the mathematics of special relativity arises from quantifying causal relationships among events, and requires neither the principle of relativity nor the fact that the speed of light is constant.

12:39PM B21.00008 Lunar Orbit Anomaly and GM=tc^3 Cosmology , LOUISE RIOFRIO, University of Houston Clear Lake — Studies of the Moon at Johnson Space Center have confirmed a large anomaly in lunar orbital distance, with possible applications to Relativity. Our Lunar Laser Ranging Experiment has reported the Moon's semimajor axis increasing at 3.82 ± .07 cm/yr, anomalously high. If the Moon were gaining angular momentum at this rate, it would have coincided with Earth less than 2 Gyr ago. The Mansfield sediment (Bills, Ray 2000) measures lunar recession at 2.9 ± 0.6 cm/yr. Additional observations independently measure a recession rate of 2.82 ± .08 cm/yr. LLRE differs from independent experiments by 10 sigma. A cosmology where speed of light c is related to time t by GM=tc^3 has been suggested to predict the redshifts of Type Ia supernovae, and a 4.507034% proportion of baryonic matter (Riofrio 2004). If c were changing in the amount predicted, lunar orbital distance would appear to increase by an additional 0.935 cm/yr. An anomaly in the lunar orbit may be precisely accounted for, shedding light on puzzles of "dark energy." In Planck units this may be summarised as M=R=t.

12:51PM B21.00009 On a Broken Formal Symmetry between Kinetic and Gravitational Energy

, ARMIN NIKKHAH SHIRAZI, University of Michigan — Historically, the discovery of symmetries has played an important role in the progress of our fundamental understanding of nature. This paper will demonstrate that there exists in Newtonian theory in a spherical gravitational field a formal symmetry between the kinetic (KE) and gravitational potential energy (GPE) of a test mass. Put differently, there exists a way of expressing GPE such that the form of the mathematical expression remains invariant under an interchange of KE and GPE. When extended to relativity by a suitable assumption, it leads to a framework that bridges the general relativistic and Newtonian conceptions of gravitational energy, even though the symmetry is broken except in the infinitesimal limit. Recognizing this symmetry at infinitesimal scales makes it possible to write a relativistic equation of an individual graviton, the properties of which under under one interpretation may be unexpected.

1:03PM B21.00010 The Relativistic Quantized Force: Newton's Second Law, Inertial and Gravitational; Generalization of Schwarzschild Metric for Strong and Weak Gravitational Field

, AZZAM ALMOSALLAMI, SCSR — In this paper we derived the relativistic Quantized force, where the force given as a function of frequency[1]. Where, in this paper we defined the relativistic momentum as a function of frequency equivalent to the energy held by a body, and time, and then the quantized force is given as the first derivative of the momentum with respect to time. Subsequently we introduce in section one Newton's second law as it is relativistic quantized, and in section two we introduce the relativistic quantized inertial force, and then the relativistic quantized gravitational force, and the quantized gravitational time dilation. At the end we shall generalize the Schwartzschild metric to describe the weak and strong gravitational field.

Monday, March 21, 2011 11:15AM - 2:15PM –

Session B22 DCMP: Correlated Electrons Including "115" Materials D163

11:15AM B22.00001 Quantum critical point in $UCo_{1-x}Fe_xGe$[1]

, NORAVEE KANCHANAVATEE, KEVIN HUANG, JAMES HAMLIN, RYAN BAUMBACH, DIEGO ZOCCO, M. BRIAN MAPLE, Department of Physics, University of California, San Diego, La Jolla, California 92093, USA — We have carried out a comprehensive study of the $UCo_{1-x}Fe_xGe$ series across the entire range of compositions $0 \leq x \leq 1$, and report the results of x-ray diffraction, magnetization, specific heat, and electrical resistivity measurements to uncover the magnetic and superconducting phase diagram. Substitution of Fe into UCoGe initially results in an increase in the Curie temperature and a rapid destruction of the superconducting state. Near $x = 0.2$, the ferromagnetic transition is suppressed to zero temperature at an apparent quantum critical point, and the temperature dependences of the electrical resistivity and specific heat suggest non-Fermi liquid behavior.

[1]DOE: DE-FG02-04ER46105, NSF: DMR-0802478

11:27AM B22.00002 Non Fermi liquid properties of Ni-V close to the ferromagnetic quantum critical point[1]

, ALMUT SCHROEDER, SARA UBAID-KASSIS, BRENDAN WYATT, Kent State University, Kent OH, THOMAS VOJTA, Missouri University of Science and Technology, Rolla MO — Resistivity (ρ) and magnetization (M) data of the d-metal alloy $Ni_{1-x}V_x$ are presented in the vicinity of the critical vanadium concentration $x_c \approx 11\%$ where the onset of long-range ferromagnetic (FM) order is suppressed to zero temperature. Above x_c the temperature (T) dependence of the magnetic susceptibility is best described by simple nonuniversal power laws (e.g. $M/H(T,H\to 0) \sim T^{\alpha-1}$). Also the resistivity displays power laws ($\Delta\rho \sim T^n$). Both exponents α(x) and n(x) vary with x displaying signatures of a disordered quantum phase transition in a metal very different than of a clean 3D FM.

11:39AM B22.00003 Non-Fermi Liquid behavior in Itinerant Ferromagnet, $HfMnGa_2$

, CARLOS MARQUES, Brookhaven National Laboratory and Department of Physics and Astronomy, Stony Brook University, YURI JANSSEN, Brookhaven National Laboratory, MOO SUNG KIM, Brookhaven National Laboratory and Department of Physics and Astronomy, Stony Brook University, LIUSUO WU, Department of Physics and Astronomy, Stony Brook University, MEIGAN ARONSON, Brookhaven National Laboratory and Department of Physics and Astronomy, Stony Brook University — Single crystals of $HfMnGa_2$, space group Pnma, were grown using a Ga self flux technique. A sharp peak in the AC susceptibility χ_{AC} shows a phase transition at $T_C \approx 26K$, followed by Curie-Weiss behavior at higher temperatures. Arrott plot analysis confirms this transition is ferromagnetic with a spontaneous moment of $\mu_0 \cong 0.3\mu_B$/Mn. $HfMnGa_2$ has a coercive field of ~ 0.1 T as well as a large magnetic anisotropy that restricts the moments to point in the [010] direction. Both a large Rhodes-Wohlfarth parameter $\mu_{\text{fluct}}/\mu_0 \cong 3.6$ and low T_C suggest $HfMnGa_2$ is comparable to other itinerant ferromagnets MnSi, $ZrZn_2$ and Ni_3Al. Resistivity $\rho(T)$ shows $HfMnGa_2$ to be metallic with $\rho(T) - \rho_0$ having a $T^{5/3}$ dependance in the ordered state. This non-Fermi liquid relationship was also observed in Ni_3Al and $ZrZn_2$ over a more limited range of temperatures.

11:51AM B22.00004 Electronic, magnetic and structural properties of $Cr_{1-x}V_xN$

, CAMILO QUINTELA, Department of Applied Physics, University of Santiago de Compostela, Spain, FRANCISCO RIVADULLA, Departament of Physical Chemistry, University of Santiago de Compostela, Spain, JOSE RIVAS, Department of Applied Physics, University of Santiago de Compostela, Spain — We report a systematic study on the electronic, magnetic and structural properties of stoichiometric and hole-doped CrN and present the magnetic and electronic phase diagram for the $Cr_{1-x}V_xN$ series. Stoichiometric CrN is a narrow gap, correlation-induced, semiconductor that orders antiferromagnetically below 286 K. The changes in the chemical bond associated to the magnetic order result in a non-activated behavior of the resistivity in the antiferromagnetic state, showing some similarities with other materials proposed to be itinerant-AF, like $CaCrO_3$. Doping this state with holes drives the system towards itinerant electron behavior through a series of inhomogeneous magnetic/electronic states. Given the chemical and structural simplicity of this system, it could provide an interesting place to study the evolution from an antiferromagnet with a non-thermally activated charge transport to a paramagnetic metal in a non-oxide material.

12:03PM B22.00005 Magnetic Correlations in Yb_4LiGe_4: A μSR and ^{7}Li NMR Study[1]

, S. DISSELER, M.J. GRAF, Boston College, P. CARRETTA, University of Pavia, S. PETER, Northwestern University, N. SVENSSON, Boston College, S.R. GIBLIN, Rutherford Appleton Lab, A. AMATO, C. BAINES, Paul Scherrer Institute — We present results from zero and longitudinal μSR and ^{7}Li NMR together along with magnetization and dynamic susceptibility on the multivalent, intermetallic compound Yb_4LiGe_4. A magnetic transition at 1.4K in dynamic susceptibility is observed, corresponding to a rapid increase in the quasi-static relaxation component of the ZF MuSR spectra. The strong magnetic field dependence exhibited in these measurements demonstrates a non-trivial criticality, and suggests a close relation to the quantum critical phenomenon observed in other Yb and Ce based systems. Based on support from NMR spectra, we discuss the potential of competing low temperature phases, and the importance of the spin fluctuations in describing the observed phenomena.

[1]This research was sponsored by NSF grant DMR-0710525.

12:15PM B22.00006 Low-temperature specific heat of $Nd_{1-x}Ca_xB_6$ single crystals[1] , JOLANTA STANKIEWICZ, MARCO EVANGELISTI, ICMA, CSIC-Universidad de Zaragoza, ZACHARY FISK, Department of Physics, University of California, Irvine — We measured the heat capacity on random alloys of $Nd_{1-x}Ca_xB_6$ ($x < 0.4$) in the 0.4 to 40 K temperature range. We calculated the lattice contribution to the specific heat, arising from the Debye-type phonons of the boron framework and Einstein-type oscillators of the cation sublattice. To this end, we used data obtained for the heat capacity of a LaB_6 single crystal which we measured in the same temperature range. Subtracting lattice and Schottky-type contributions from the measured heat capacity, we find that the electronic portion, linear in temperature, decreases sharply upon doping with Ca, most likely owed to changes in the Fermi surface.

12:27PM B22.00007 High-pressure resistivity of $CeCoIn_5$ at low temperatures using four-point probe technique and finite element analysis[1] , NATHANIEL BRADY, GEORGIY TSOI, University of Alabama at Birmingham, TESFAYE GEBRE, National High Magnetic Field Lab, YOGESH VOHRA, DAVID HILTON, University of Alabama at Birmingham — We performed high-pressure electronic characterization of the heavy fermion superconductor, $CeCoIn_5$. Using a designer diamond anvil four-point probe system, we measured the temperature-dependent resistivity up to 25 GPa and found evidence for a decrease in the effective mass at high pressures. We determined the resistivity using Van Der Pauws method and a finite element analysis approach. Room temperature resistivity with increasing pressure was also measured and a maximum in resistivity was observed near $\sim$8 GPa. These data suggest the existence of a pressure-dependent modification of the $4f$ hybridization at the highest pressures

12:39PM B22.00008 Exploring the antiferromagnetic superconducting phase in $CeCoIn_5$, ELIZABETH BLACKBURN, TED FORGAN, University of Birmingham, PINAKI DAS, MORTEN RING ESKILDSEN, University of Notre Dame, MARK LAVER, CHRISTOF NIEDERMAYER, JONATHAN WHITE, Paul Scherrer Institut, CEDOMIR PETROVIC, Brookhaven National Laboratory — $CeCoIn_5$ is a heavy fermion type-II superconductor showing clear signs of Pauli-limited superconductivity. $CeCoIn_5$ is also very close to a magnetically ordered ground state; this can be achieved by, for instance, doping with Cd. A variety of measurements give evidence for a transition at high magnetic fields inside the superconducting state, when the field is applied either parallel to or perpendicular to the c axis. In the latter case, antiferromagnetic order develops on the high-field side of the transition, with a magnetic wavevector of (q q 0.5), where $q = 0.44$ reciprocal lattice units [1]. We show that this order remains as the field is rotated out of the basal plane, but that the associated moment eventually disappears above 17°, indicating that anomalies seen with the field parallel to the c axis are not related to this magnetic order [2]. Our measurements emphasise the fragility of this magnetic order.

12:51PM B22.00009 Electronic inhomogeneity in heavy Fermions[1] , ZACHARY FISK, Department of Physics and Astromony, University of California, Irvine, Irvine, CA 92697, ERIC BAUER, YI-FENG YANG, Los Alamos National Laboratory, Los Alamos, NM 87545, CIGDEM CAPAN, Physics and Astronomy, Washington State University, PO Box 642814, Pullman, WA 99164-2814, FILIP RONNING, JOE THOMPSON, ROMAN MOVSHOVICH, Los Alamos National Laboratory, Los Alamos, NM 87545, ANDREA BIANCHI, Department de Physique, Universite de Montreal, Montreal H3C 3J7, RICARDO URBANO, National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL 32306, HIRONORI SAKAI, Advanced Science Research Center, Japan Atomic Energy Agency, Tokai, Ibarakai 319-1195 — The experimentally determined superconducting condensation energy of La-doped $CeCoIn_5$ is interpreted to show that the superconducting fraction decreases linearly with La concentration, consistent with the measured residual normal fraction seen in the electronic specific gamma remaining in the superconducting state as T $\rightarrow$ 0K. The In NQR data is also discussed. Our result points to an electronically inhomogeneous state that appears to be common to doped heavy Fermion materials near a quantum critical point.

[1]NSF-DMR-0801253

1:03PM B22.00010 Cooperative Intermediate Valence and Anomalous Stability of the Kondo Lattice in $Ce_{1-x}Yb_xCoIn_5$[*1] , R.E. BAUMBACH, L. SHU, M. JANOSCHEK, E. GONZALES, K. HUANG, T.A. SAYLES, J.J. HAMLIN, D.A. ZOCCO, C.A. MCELROY, M.B. MAPLE, University of California, San Diego, J. PAGLIONE, University of Maryland, P.-C. HO, California State University, Fresno, J.R. O'BRIEN, Quantum Design — We have investigated the chemical substitution series $Ce_{1-x}Yb_xCoIn_5$ ($0 \leq x \leq 1.0$) by means of X-ray diffraction, energy dispersive X-ray, specific heat, electrical resistivity, and magnetic susceptibility measurements. As Yb is substituted for Ce, the lattice constants remain roughly constant up to $x = 0.775$, contrary to Vegard's law, after which phase separation is observed for $0.8 \leq x < 1$. The superconducting transition temperature shows only a weak linear suppression with increasing x, while the coherence temperature remains constant up to $x = 0.775$. We also observe non-Fermi-liquid behavior for $0 \leq x \leq 0.775$ which is sensitive to the exact value of x, although there is no indication for a quantum critical point in the $T - x$ phase diagram. These results suggest that the Ce and Yb ions adopt cooperative intermediate valence states which preserve the Kondo lattice behavior and SC, while the associated valence fluctuations lead to strong modifications in the non-Fermi-liquid behavior as a function of x.

1:15PM B22.00011 Scanning tunneling microscopy and spectroscopy measurements of heavy fermion compound $CeCoIn_5$[1] , EDUARDO DA SILVA NETO, PEGOR AYNAJIAN, COLIN PARKER, Princeton University, PAUL TOBASH, ERIC BAUER, Los Alamos National Laboratory, ALI YAZDANI, Princeton University — The heavy fermion compound $CeCoIn_5$ has a rich electronic phase diagram as a function of doping, pressure, and magnetic field. The interaction between Ce's f-electrons and the conduction bands is expected to form Kondo screening of the spins starting at relatively high temperatures. Below 2.3 K $CeCoIn_5$ is known to exhibit an unconventional superconducting ground state. We present scanning tunneling microscopy and spectroscopy (STM/S) as a function of temperature on $CeCoIn_5$. The in-situ cleaved samples show three different layer terminations. Acquiring structural information from STM topographies we identify the chemical character of each layer. STS measurements, on all surfaces, performed over a wide range of temperature show the rapid development of an energy gap in the tunneling density of states near the onset of coherence ($\sim$ 40 K). The origin of the observed energy gap and its relation to heavy band hybridization is addressed.

[1]Work primarily supported by DOE-BES. Infrastructure at Princeton Nanoscale Microscopy Laboratory also supported by NSF-DMR, NSF-MRSEC programme through PCCM, and the W. M. Keck foundation.

1:27PM B22.00012 Electron-spectroscopy of the heavy fermion alloy $Ce_{1-x}Yb_xCoIn_5$[1] , L. DUDY, J.W. ALLEN, University of Michigan, J. DENLINGER, Advanced Light Source, Lawrence Berkeley National Laboratory, L. SHU, M. JANOSCHEK, R.E. BAUMBACH, M.B. MAPLE, University of California, San Diego — $Ce_{1-x}Yb_xCoIn_5$ (YbCe115) is a new 115 alloy series with long range magnetic order suppressed in the whole substitution range. Measurements reveal a rich phase diagram in which the Kondo lattice is robust against Yb substitution, superconductivity persists to high values of x, and the non-Fermi-liquid behavior is enhanced by Yb substitution [1].We have characterized the electronic structure of this new alloy by x-ray and angle resolved photoemission spectroscopy (XPS and ARPES) performed at the Advanced Light Source (ALS). Yb 4f XPS spectra vary with increasing x from dominantly Yb^{3+} to a mix of Yb^{3+} and Yb^{2+}, in agreement with inferences from the magnetic susceptibility [1]. We will present ARPES data to show the x-dependence of the Fermi surface and discuss the relation of the electronic structure to the transport properties. The effect of surface contributions to the XPS and ARPES data will be assessed.

[1]Work supported by the U.S. Dept. of Energy under Contract No. DEFG02-07ER46379 at UM, DE-AC02-05CH11231 at the ALS and DEFG02-04ER46105 at UCSD.

1:39PM B22.00013 The Fermi surface of $CePt_2In_7$: a two-dimensional analog of $CeIn_3$, MOAZ ALTARAWNEH, MPA-CMMS. Los Alamos National Laboratory, NEIL HARRISON, ROSS MCDONALD, FEDOR BALAKIREV, CHARLES MIELKE, PAUL TOBASH, JIAN-XIN ZHU, JOE THOMPSON, FILIP RONNING, ERIC BAUER — We report magnetic quantum oscillations in magnetic fields extending to ∼60 T in single crystals of the body-centered tetragonal antiferromagnetic $CePt_2In_7$ recently discovered to exhibit pressure- induced superconductivity at T_c = 2.1 K. Despite two-dimensionality of its Fermi surface, the microscopic electronic properties of layered $CePt_2In_7$ are revealed to be more similar to cubic $CeIn_3$ than layered $CeRhIn_5$. A significant field-induced change in the Fermi surface occurs at H_m around 45 T in both $CePt_2In_7$ and $CeIn_3$, below which it is broken into small pockets with field-dependent effective masses -signaling 4f-electron involvement in the Fermi surface for $H < H_m$. Our findings suggest that $CePt_2In_7$ and $CeIn_3$ differ solely by the dimensionality of their Ce sublattices, thus realizing an ideal pair of compounds for investigating the effect of dimensionality on boosting superconductivity.

1:51PM B22.00014 Tuning the Quantum Critical Points in $CeCoIn_5$ and $CeRhIn_5$ Through Pt Doping: Synthesis, Single Crystal and Physical Property Studies , PAUL TOBASH, KRZYSZTOF GOFRYK, FILIP RONNING, JOE THOMPSON, Los Alamos National Laboratory, STANISLAV STOYKO, ARTHUR MAR, Department of Chemistry, University of Alberta, ERIC BAUER, Los Alamos National Laboratory — The well known $CeCoIn_5$ and $CeRhIn_5$ compounds provide an excellent opportunity for understanding the physics of heavy fermion superconductivity as well as quantum criticality in correlated electron intermetallics. Besides using hydrostatic pressure as a means to tune the physics of these materials, chemical doping has also proved essential for moving through the superconducting/magnetic boundary in these materials. We extend chemical substitution in $CeCoIn_5$ and $CeRhIn_5$ to another transition metal, Pt, and report on the synthesis, structure, and physical properties of single crystals of $CePt_xCo_{1-x}In_5$ and $CePt_xRh_{1-x}In_5$. Single crystal X-ray diffraction confirmed the tetragonal structure of both systems which crystallize with the $P4/mmm$ space group and are derivatives of the parent compounds $CeCoIn_5$ and $CeRhIn_5$, respectively. We report the physical property measurements, which include magnetic susceptibility, heat capacity, and electrical resistivity.

2:03PM B22.00015 Quantum criticality and Fermi surface topology in $CeRhIn_5$, H.Q. YUAN, L. JIAO, J.L. ZHANG, Department of Physics, Zhejiang University, Y. KOHAMA, M. JAIME, J. SINGLETON, E.D. BAUER, HAN-OH LEE, T. PARK, J.D. THOMPSON, Los Alamos National Laboratory — In the heavy fermion compound $CeRhIn_5$, superconductivity occurs upon partially suppressing the antiferromagnetic state via applying pressure. At the quantum critical point (p_c=2.3GPa), observations of a Fermi surface change from a small Fermi volume to a large one [1] seems to favor the scenario of local quantum criticality [2]. In this talk, we will present the first experimental evidence of a magnetic field induced quantum phase transition in $CeRhIn_5$ by measuring the ac specific heat and the de Hass van Alphen effect using the facilities of pulsed magnetic field at Los Alamos. The antiferromagnetic transition of $CeRhIn_5$ is eventually suppressed at a critical field of $H_c \simeq 50$ T. A dramatic change of the Fermi surface is found close to H_c, but still on the antiferromagnetic side. At sufficiently low temperatures, the Fermi surface in the antiferromagnetic state undergo a topological change from a small Fermi volume to a large one with increasing magnetic field, the latter being kept unchanged in the paramagnetic state at fields above H_c. These findings seem to support a different scenario for the field induced quantum phase transition in $CeRhIn_5$, e.g., the spin-density-wave-type quantum criticality. [1] H. Shishido et. al., J. Phys. Soc. Jpn. 74, 1103 (2005). [2] Q. Si et al., Nature 413, 804 (2001).

Session B23 DCOMP DMP: Focus Session: Iron Based Superconductors – Electronic Structure, Theory and Spectroscopy D165

11:15AM B23.00001 Point contact spectroscopy (PCS) on the Fe122 pnictides and Fe11 chalcogenides , H.Z. ARHAM, C.R. HUNT, W.K. PARK, L.H. GREENE, U. Illinois, U-C, J. GILLETT, S. SEBASTIAN, U. Cambridge, Z.J. XU, J.S. WEN, Z.W. LIN, Q. LI, G. GU, BNL, A. THALER, S.L. BUDKO, P.C. CANFIELD, Ames Lab., ISU — We present PCS results on $Ba(Fe_{1-x}Co_x)_2As_2$ and $Fe_{1+y}Te$. The superconducting (S) crystals (x=0.08) show multigap like Andreev peaks. The non-S crystals (x=0.015, y=0.03) also show a conductance enhancement with split peaks at low temperatures (T). This conductance enhancement does not match with the bulk antiferromagnetic (AFM) transition T and survives up to 90 K for y=0.03 (T_N ∼69 K) and 130 K for x=0.015 (T_N ∼115 K). For the S samples in the coexisting regime (x=0.05 & 0.055), in addition to the Andreev peaks below T_C, a zero bias conductance enhancement develops and survives for ∼5K above T_C. PCS detects conductance changes due to quasiparticles scattering off charge or spin ordering. These conductance enhancements may arise from orbital ordering as detected by photoemission spectroscopy[1] and AFM ordering (Q-scattering), respectively.[2] [1]Yi et.al, arXiv:1011.0050. [2]Bobkova et.al, PRL 94, 037005 (2005). UIUC work supported by NSF-DMR-0706013, U.S. DOE Award No.DE-AC02-98CH10886, BNL work by DOE Award No.DE-AC0298CH10886, Cambridge work by EPSRC, Trinity College, the Royal Society, the Commonwealth Trust. Ames Lab operated by ISU under DOE Contract No.DE-AC02-07CH11358.

11:27AM B23.00002 Point Contact Andreev Reflection Studies on Iron Pnictide Superconductors[1] , XIAOHANG ZHANG, S.R. SAHA, N.P. BUTCH, K. KIRSHENBAUM, J. PAGLIONE, R.L. GREENE, I. TAKEUCHI, Center for Nanophysics and Advanced Materials (CNAM), University of Maryland, Y.-S. OH, Y. LIU, L.Q. YAN, K.-H. KIM, Seoul National University — We have systematically investigated the temperature, doping and the directional dependence of the gap structure for various types of single crystal iron pnictide superconductors by point contact Andreev reflection spectroscopy. Our studies were performed on highly transparent junctions evidenced by sharp and dramatic conductance enhancements at low temperatures. For the 122 family, despite some small features occasionally observed on the spectroscopy curves which may originate from the multiband superconductivity, a more conclusive characteristic of our obtained spectra is the presence of one predominant superconducting gap. By applying the BTK model, we find that the determined gap size scales well with the transition temperature, resulting in the $2\Delta/k_BT_C$ value of ~ 3.1 for both potassium doped and cobalt doped single crystals. Directional studies suggest that this gap is highly isotropic. Results on chalcogenide and nickel doped 122 superconductors will also be discussed. [X. H. Zhang et al., Phys. Rev. B 81, 024518 (2010)].

[1]Supported by CNAM and NSF DMR-0653535

11:39AM B23.00003 Point contact spectroscopy of Co-doped pnictide superconductors[1] , JOHN TIMMERWILKE, ALESSANDRA GALLASTEGUI, J.S. KIM, G.R. STEWART, AMLAN BISWAS, Department of Physics, University of Florida, Gainesville, Florida 32611, N.H. SUNG, M.S. KIM, B.K. CHO, School of Materials Science and Engineering, Gwangju Institute of Science and Technology (GIST), Gwangju 500-712, Korea — Iron pnictides are an interesting material for superconductivity research, since they provide a contrasting system for high temperature superconductivity to the cuprates. Point-contact spectroscopy is a unique method which has been used for investigating the density of states of cuprate superconductors and can help shed light on the pnictide superconductors as well. Point-contact measurements have an advantage over tunneling spectroscopy since they are less sensitive to sample surface quality and the dimensionless barrier parameter Z, can be varied with contact pressure. We have performed point contact measurements using an apparatus with a capacitive displacement sensor which enables us to systematically vary Z. We will present point contact spectra obtained on single crystal $Ba(Fe_{0.926}Co_{0.074)2}As_2$ samples and other cobalt doped iron pnictide samples at various temperatures, magnetic fields, and Z.

[1]NSF DMR-0804452, DE-FG02-86ER45268, KOSEF R15-2008-006-01002-0

11:51AM B23.00004 First-principles studies for understanding diverse high-T_c[1] , HAI-PING CHENG, University of Florida — In this talk, I survey results and insights gained from first-principles calculations on materials that exhibit superconducting behavior at temperatures higher than those characteristic of conventional BCS superconductors. These range from highly correlated cuprate Mott insulators as represented by the bismuth-strontium-calcium-copper-oxides (BSCCOs) to border-line itinerant-Mott systems such as the recently discovered 1111 and 122 pnictides. ultimate goal of our studies is to correlate T_c with specific material composition using detailed first-principles calculations in conjunction with many-body physics techniques via the critical step of constructing real-materials model Hamiltonians. By manipulating impurity doping, which plays a crucial role in the phase diagrams of high T_c materials, we hope to find guidance for designing candidate systems with T_c higher than ones currently known. BSCCO material, density functional calculations using a good generalized-gradient approximation (GGA) yield structural information that is correlated to the experimentally observed (STM) super-modulation and impurity peak in the high energy regime ($\sim$1 eV), even though the Kohn-Sham bands from such functionals fail to have a band gap. For FeAs-based high-T_c systems, DFT band-structure calculations provide a very good starting point for constructing model Hamiltonians for studies of spin fluctuation and electron pairing mechanisms. Fermi sheets that have been constructed using Wannier transformed Kohn-Sham states have provided critical information for understanding this family of superconducting materials. Analysis of the details of magnetic ordering, density of states, and 2D vs. 3D features in both the 1111 and 122 materials have been valuable in understanding sometimes perplexing experimental findings. Effects of Co impurities have been studied and fully analyzed as well., I will discuss persistent challenges related to calculations on the structure of the non-magnetic state $Ba_1Fe_2As_2$ system. Both further examination of the underlying physics and development of new approximate functionals are needed.

[1]Supported by DOE/BES and NSF/DMR, computed at NERSC and UF/HPC.

12:27PM B23.00005 Point-Contact Andreev Reflection Spectroscopy of Iron-Based Superconductors[1] , YI-TANG YEN, J.Y.T. WEI, University of Toronto and Canadian Institute for Advanced Research, S.R. SAHA, T. DRYE, K. KIRSHENBAUM, J. PAGLIONE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, RONGWEI HU*, C. PETROVIC, Brookhaven National Laboratory, K.W. YEH, M.K. WU, Institute of Physics, Academia Sinica, Taiwan — We carry out point-contact Andreev reflection spectroscopic studies at cryogenic temperatures on single crystals of Fe-chalcogenide and Fe-pnictide superconductors, including $FeS_{1-x}Te_x$, $FeSe_{1-x}Te_x$, $SrFe_{1.84}Pt_{0.16}As_2$ and $BaFe_{1.9}Pt_{0.1}As_2$. Our data are analyzed using current theoretical models involving multiband superconductivity. Further interpretations will be made in comparison with scanning tunneling spectroscopy measurements on Fe-chalcogenides and $NbSe_2$. *Present address: Ames Laboratory, Iowa State University

[1]Work supported by NSERC, CFI/OIT, Taiwan National Science Council, AFOSR-MURI Grant FA9550-09-1-0603, U.S. D.O.E. and Brookhaven Science Associates (No.DE-Ac02-98CH10886), and Center for Emergent Superconductivity

12:39PM B23.00006 Observation of multiple superconducting gaps in $Fe_{1+y}Se_xTe_{1-x}$ through Andreev reflection , DEBTANU DE, CARLOS DIAZ-PINTO, ZHENG WU, PEI-HERNG HOR, HAIBING PENG, Department of Physics and Texas Center for Superconductivity, University of Houston — Iron-based superconductors have been under intensive study because of the high transition temperature and the intriguing physical mechanisms involving the superconductivity and magnetic orders. Theoretical studies on the role of spin fluctuation suggest unconventional S wave pairing and multiple superconducting (SC) gaps due to the five disjoint Fermi surfaces. However, this multiple SC-gap scenario has yet to be confirmed in experiments. Here we report the experimental observation of five SC gaps in $Fe_{1+y}Se_xTe_{1-x}$ from Andreev reflection spectra, along with negative differential conductance dips due to the pair breaking related to the largest SC gap. The evolution of the multiple SC gaps is further investigated as a function of both temperature and magnetic field. For the largest SC gap, the Andreev reflection signal persists above bulk Tc, suggesting the existence of phase incoherent Cooper pairs.

12:51PM B23.00007 Scanning Tunneling Microscopy/Spectroscopy study on Optimally Potassium Doped Single Crystal $BaFe_2As_2$, JIHUA MA, Department of Physics and Texas Center for Superconductivity, University of Houston/Department of Physics, Boston College, ANG LI, Department of Physics and Texas Center for Superconductivity, University of Houston, CHENGLIN ZHANG, PENGCHENG DAI, Department of Physics and Astronomy, University of Tennessee, SHUHENG PAN, Department of Physics and Texas Center for Superconductivity, University of Houston — The iron pnictide parent compound material can be brought into superconducting state by chemical doping. It is worthwhile to study and compare the hole- and electron-doped iron pnictides. Among the well-known family of $AEFe_2As_2$ (AE=Ca, Sr, Ba), the scanning tunneling microscopy/spectroscopy study on hole-doped samples is insufficient. In this talk we will present high resolution STM/STS results on (001) surface of the optimally doped single crystal $Ba_{0.6}K_{0.4}Fe_2As_2$ (Tc$\sim$37K). With the data we will discuss the spatial variation of the superconducting energy gap.

1:03PM B23.00008 STM Studies on the Surface Structure of Ba122 iron pnictides cleaved at Low Temperature , ANG LI, Department of Physics and Texas Center for Superconductivity, University of Houston, JIHUA MA, Department of Physics and Texas Center for Superconductivity, University of Houston/Department of Physics, Boston College, A. SEFAT, M. MCGUIRE, B. SALES, D. MANDRUS, Oak Ridge National Laboratory, R. JIN, Department of Physics and Astronomy, Louisiana State University, CHENGLIN ZHANG, PENGCHENG DAI, Physics Department, University of Tennessee, SHUHENG PAN, Department of Physics and Texas Center for Superconductivity, University of Houston — We have performed scanning tunneling microscopy/spectroscopy (STM/STS) studies on electron- and hole-doped $BaFe_2As_2$ iron pnictides ($Ba(Fe_{1-x}Co_x)_2As_2$ and $Ba_{1-x}K_xFe_2As_2$). Two types of surface topography are always found when the samples are cleaved at low temperature. One has a square-like structure and the other shows a dimerization into rows. Details of these two surfaces, particularly at their boundaries, will be utilized to argue about the surface termination. We also show the impacts of these two surface structures and some topographic features on the tunneling spectrum.

1:15PM B23.00009 STM Studies of the Lattice Distortion at the Surface of $Ba(Fe_{1-x}Co_x)_2As_2$, SHUHENG PAN, ANG LI, Department of Physics and Texas Center for Superconductivity, University of Houston, JIHUA MA, Department of Physics and Texas Center for Superconductivity, University of Houston/Department of Physics, Boston College, A. SEFAT, M. MCGUIRE, B. SALES, D. MANDRUS, Oak Ridge National Laboratory, R. JIN, E. PLUMMER, Department of Physics and Astronomy, Louisiana State University — At low temperatures the bulk of the iron pnictides such as $Ba(Fe_{1-x}Co_x)_2As_2$ goes from an orthorhombic structure phase to the tetragonal phase with doping. This phase transition is also accompanied by a magnetic phase transition. These phenomena have been discussed in the context of the mechanism of superconductivity in the iron pnictides. With careful examination of our low temperature STM topographic images on the single crystals of $Ba(Fe_{1-x}Co_x)_2As_2$, we found thatthe lattice distortions of the two observed surface structures, namely "Root 2" and "1×2", evolve with doping concentration x across the superconducting dome. Starting from parent compound, the orthorhombic "Root 2" structure evolves towards rhombic, while the "1×2" structure evolves from rhombic to orthorhombic. We will discuss the implications of such doping dependent lattice distortion.

1:27PM B23.00010 Observation of multiple gaps and vortex bound states in Ba0.6K0.4Fe2As2 by Scanning Tunneling Microscopy/Spectroscopy , LEI SHAN, YONG-LEI WANG, BING SHEN, BIN ZENG, JING GONG, YAN HUANG, HUAN YANG, CONG REN, HAI-HU WEN, Institute of Physics and National Laboratory for Condensed Matter Physics, Chinese Academy of Sciences, Beijing 100190, China, ANG LI, SHUHENG PAN, Department of Physics and Texas Center for Superconductivity, University of Houston, Houston, Texas 77204-5002, USA, DA WANG, QIANG-HUA WANG, National Laboratory of Solid State Microstructures and Department of Physics, Nanjing University, Nanjing 210093, China — We report on low-temperature scanning tunneling microscopy/spectroscopy studies of the electronic structure in single crystalline Ba0.6K0.4Fe2As2. Multiple superconducting gaps were observed in the density of states (DOS) and the sizes of the two dominant gaps are 7.6 meV and 3.3 meV, respectively. The flat bottom of the DOS spectra near zero bias indicates the nodeless feature of the gaps, while the global fitting to the spectra requires definitely the anisotropy. By applying magnetic fields, we observed ordered vortices with Andreev bound states in vortex cores. The bound states and their spatial evolution can be qualitatively explained by our numerical calculations when considering the multiband s-wave superconductivity.

1:39PM B23.00011 Quasiparticle Interference in Iron-Based Superconductors , JOHANNES KNOLLE, Max Planck Institute for the Physcis of Complex Systems, D-01187 Dresden, Germany, ALIREZA AKBARI, ILYA EREMIN, Ruhr-Universitat Bochum, D-44801 Bochum, Germany, RODERICH MOESSNER, Max Planck Institute for the Physcis of Complex Systems, D-01187 Dresden, Germany — The phase diagram of iron-based superconductors exhibits an anti ferromagnetic phase at low doping, an unconventional superconducting phase at larger carrier concentration, and possibly a coexistence regime of both orders in between. What are the signatures of the different orders in the electronic spectrum and how can phase sensitive measurements distinguish between different order parameter symmetries? To address these questions we systematically calculate quasiparticle interference (QPI) signatures for the relevant candidate phases of iron-based superconductors. Experimentally, QPI can be probed through spectroscopic imaging-scanning tunneling microscopy (SI-STM) thanks to impurities unavoidably present in the sample. We show that in the anti ferromagnetic phase the rotational symmetry of the electronic structure is broken, signatures of which are also seen in the coexistence regime with both superconducting and magnetic order. In the superconducting regime the different scattering behavior for magnetic and non-magnetic impurities allows us to verify the $s\pm$ symmetry of the order parameter. Furthermore, we discuss the effect of possible gap minima or nodes.

1:51PM B23.00012 Cryogenic Scanning Tunneling Spectroscopy of Superconducting Iron Chalcogenide Single Crystals[1] , J.Y.T. WEI, IGOR FRIDMAN, University of Toronto and Canadian Institute for Advanced Research, KUO-WEI YEH, MAW-KUEN WU, Institute of Physics, Academia Sinica,Taiwan, RONGWEI HU[2], C. PETROVIC, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory — We report scanning tunneling spectroscopy measurements on the iron-based superconductors of the "11" family including $Fe_{1-y}Te_{1-x}Se_x$ and $Fe_{1-y}Te_{1-x}S_x$. Conductance spectra and atomically-resolved images are obtained on single crystals down to 300 mK. A gap-like structure is observed, showing an asymmetric spectral background, non-trivial spatial variation and temperature dependence. We discuss our data in terms of possible gap anisotropy and doping inhomogeneities, and in relation to other recent spectroscopic measurements on iron-based superconductors.

[1]Work supported by NSERC, CFI/OIT, CIFAR, Taiwan National Science Council, U.S. DOE and Brookhaven Science Associates (No. DE-Ac02-98CH10886), and in part by the Center for Emergent Superconductivity, an Energy Frontier Research Center.

[2]Present address: Ames Laboratory and Iowa State University

2:03PM B23.00013 Surface lattice dynamics of the 122-type iron pnictides[1] , JING TENG, CHEN CHEN, GUORONG LI, AMAR KARKI, JIANDI ZHANG, RONGYING JIN, WARD PLUMMER, Louisiana State University — We present a systematic High Resolution Electron Energy Loss Spectra (HREELS) study of the surfaces lattice dynamics of the cleaved single crystals of the parent compounds AFe_2As_2 (A=Ba, Ca) as a function of temperature and sample treatment. The different phonon signatures on the competing surface reconstructions 1×2 phase and $(\sqrt{2}\times\sqrt{2})R45^\circ$ phase are studied. For Ba there are two optical phonon modes are observed at 18 and 29 meV, which can be identified as the A_{1g} and B_{1g} vibrations of the As and Fe atoms, respectively. A detailed discussion is given in terms of the interplay between the spin and lattice in this novel system

Monday, March 21, 2011 11:15AM - 2:15PM –

Session B24 DCOMP DMP: Focus Session: Multiscale Modeling - Methodology and applications D167

11:15AM B24.00001 Recent Advances in Accelerated Molecular Dynamics Methods[1] , ARTHUR VOTER, Los Alamos National Laboratory — Many important materials processes take place on time scales that vastly exceed the nanoseconds accessible to molecular dynamics simulation. Typically, this long-time dynamical evolution is characterized by a succession of thermally activated infrequent events involving defects in the material. Over the last 14 years, we have been developing a new class of methods, accelerated molecular dynamics, in which the known characteristics of infrequent-event systems are exploited to make reactive events take place more frequently, in a dynamically correct way. For certain processes, this approach has been remarkably successful, offering a view of complex dynamical evolution on time scales of microseconds, milliseconds, and sometimes beyond. Examples include metallic surface diffusion and growth, radiation damage annealing, and dynamics of nanotubes and nanoscale clusters. After an introduction to these methods, I will present some recent advances and results, and then describe the major ongoing challenges and our current thinking on how to overcome them.

[1]This research has been supported by DOE/BES, DOE/ASCR, DOE/SciDAC, and by the Los Alamos LDRD program.

11:51AM B24.00002 Multiscale (atomistic to mesoscopic) modeling of carbon nanotube materials[1] , LEONID ZHIGILEI, University of Virginia — A principal challenge in the development of computational models for investigation of collective dynamic phenomena in multi- component molecular systems or nanocomposites is presented by the gap between the atomistic description of the elementary structural units and the effective material behavior and properties. We approach this challenge through the development of computational models for dynamic simulations at intermediate (mesoscopic) length and time scales. An example of a mesoscopic model that is being currently designed in our group for carbon nanotube (CNT)-based materials and nanocomposites will be discussed in the presentation. The mesoscopic dynamic model for CNT materials is based on a coarse-grained representation of individual CNTs as chains of stretchable cylindrical segments [1] and a computationally- efficient "tubular potential" method describing the van der Waals interactions among the CNT segments [2]. Mesoscopic descriptions of CNT buckling and fracture are developed based on the results of atomistic simulations and incorporated into the model. Mesoscopic simulations performed for a system composed of randomly distributed and oriented CNTs predict a spontaneous self-assembly of CNTs into a continuous network of bundles with partial hexagonal ordering of CNTs within the bundles [2]. The structures produced in the simulations are similar to the structures of CNT films and mats observed in experiments. The first results illustrating the applications of the model for investigation of the response of CNT materials to dynamic mechanical loading, analysis of the structural dependence of the thermal transport properties [3] and gas permeability in CNT films will be briefly discussed in the presentation. Challenges and possible future directions in the development of a realistic mesoscopic description of nanocomposite materials will be outlined.

12:27PM B24.00003 Toward Distinct Element Method Simulations of Carbon Nanotube Systems[1] , EVGENIYA AKATYEVA, TYLER ANDERSON, ILIA NIKIFOROV, University of Minnesota, DAVID POTYONDY, Itasca Consulting Group, ROBERTO BALLARINI, TRAIAN DUMITRICA, University of Minnesota — We propose distinct element method modeling of carbon nanotube systems. The atomic-level description of an individual nanotube is coarse-grained into a chain of spherical elements that interact by parallel bonds located at their contacts. The spherical elements can lump multiple translational unit cells of the carbon nanotube and have both translational and rotational degrees of freedom. The discrete long ranged interaction between nanotubes is included in a van der Waals contact of nonmechanical nature that acts simultaneously with the parallel bonds. The created mesoscopic model is put into service by simulating a realistic carbon nanotube ring. The ring morphology arises from the energy balance stored in both parallel and van der Waals bonds.

[1]We thank NSF CAREER under Grant No. CMMI-0747684, NSF under Grant No. CMMI 0800896.

12:39PM B24.00004 Coarse-Grained Monte Carlo Simulations of Continuous Systems , XIAO LIU, WARREN SEIDER, TALID SINNO, University of Pennsylvania — Various types of Monte Carlo simulations are used extensively to simulate an enormous range of material properties. Restricting particle positions to fixed lattice sites can substantially increase the computational efficiency of a simulation, and this benefit increases as the lattice becomes coarser. However, the confinement of particle positions to a rigid lattice necessarily reduces the available configurational degrees of freedom in a system and this constraint can become very important at elevated temperatures. In this presentation, we discuss a new framework for performing Metropolis Monte Carlo and kinetic Monte Carlo (KMC) simulations of continuous systems on coarse, rigid lattices, while preserving the phase-space contributions of the missing degrees-of-freedom. The approach relies on the pre-computation of coarse-grained interaction potentials using equilibrium sampling of small systems. The coarse-grained simulation methodologies are shown to reproduce both equilibrium (e.g. phase diagram), and non-equilibrium (e.g. aggregation dynamics) features in the corresponding fully resolved systems. In the latter case, the coarse potential is used to compute rates for moves in a coarse-grained KMC system.

12:51PM B24.00005 Quantum-mechanical and QM/MM simulations of proton dissociation free energies in solution , NOAM BERNSTEIN, Naval Research Laboratory, CSILLA VARNAI, University of Cambridge, MONIKA FUXREITER, Hungarian Academy of Sciences, GÁBOR CSÁNYI, University of Cambridge — Chemical reactions often occur in the presence of a solvent, in particular water for biological systems. To describe such processes a quantum mechanical (QM) description of the reaction site is needed, combined with a large number of solvent molecules that affect the reaction via their electrostatic fields and free energy effects of their long-range structure. We have simulated the dissociation of a proton from the side chain of a tyrosine molecule, as a realistic model system. We compute a free energy difference, using umbrella integration, from the average restraint force as a function of O^{-}-H^{+} distance as the proton is transferred from the side-chain to nearby water molecules to form H_3O^{+}. We use a combination of periodic QM calculations using DFT and force-mixing QM/MM simulations implemented in QUIP and CP2K. The pure QM calculations are used for reference values and for determining appropriate restraint conditions for the free energy calculations. The force-mixing QM/MM method, which gives accurate forces throughout the system, is used to evaluate free energies for comparison with experiment. We extrapolate the free energy for the initial transfer of the proton to the bulk solvated proton regime by analytically computing electrostatic and entropy contributions.

1:03PM B24.00006 Understanding Vibrational Spectra of Silicon Nanocrystals , DUNDAR YILMAZ, CEM SEVIK, Texas A&M University, CEYHUN BULUTAY, Bilkent University, TAHIR CAGIN, Texas A&M University — After the discovery of light emission from porous Si, nanostructured Si became a promising material for opto-electronic applications. For two decades lots of both experimental and theoretical works done in order to understand mechanisms behind the interaction of light with low dimensional forms of Si. In this work we employed MD simulation technique. The simulation details are similar to our earlier work except we used Large Scale Atomistic Molecular Modeling Package Software (LAMMPS) with ReaxFF package as an integrator. We used constant pressure constant temperature (NPT) ensemble with a simulation box size around 4.2 nm. We inserted silicon nanocrystals into amorphous silicon dioxide matrix with diameter ranging from 2 nm to 3.2 nm using a scheme defined in our previous work7. We also simulated free standing hydrogen passivated nanocrystals with same diameters to compare effects of oxide matrix on the nanocrystals. The effect of strain on vibrational spectra of Silicon Nanocrystals is studied as a function of nanocrystal diameter using reactive molecular dynamics simulations technique for both embedded and hydrogen passivated nanocrystals. With use of refined parameters our calculations reproduce the redshift of the Raman active transverse optical peak of Si-Si vibrations with decreasing the nanocrystal size.

1:15PM B24.00007 *Ab initio* study of the *thermodynamic properties and the* phonon calculations of Zircon and Reidite , MRUNALKUMAR CHAUDHARI, JINCHENG DU, University of North texas — Zircon and Reidite are the polymorphs of Zirconium Silicate which find its importance geologically, because of its natural hosting to various radioactive elements in the crust of the earth. High permittivity also makes it a promising material for the gate dielectric material in metal-oxide semiconductors. Knowledge of the thermodynamic properties and the phonon based calculations is very critical to understand the high temperature and high pressure properties in order to consider its application as an effective natural storage for the radioactive wastes. These properties are thoroughly studied both computationally and experimentally for zircon, while significantly less attention was paid to reidite in the literature. The thermodynamic properties and phonon calculations of Zircon and Reidite were studied using ab initio based periodic density-functional theory (DFT) based calculations using the generalized gradient approximation (GGA). Various properties such as free energy, internal energy, entropy, heat capacity and thermal displacement as a function of temperature is calculated using the PHONON software. Various phonon based density of states and dispersion curves are calculated and compared with the experimental data. No first principles based computational results were reported up to now. Calculated bulk properties agree very well with the experimental data in the literature.

1:27PM B24.00008 One-dimensional model of interacting-step fluctuations on vicinal surfaces: Analytical formulas and kinetic Monte-Carlo simulations[1] , PAUL PATRONE, T.L. EINSTEIN, U. of Maryland, College Park, DIONISIOS MARGETIS, Math Dept., U. of Maryland, College Park — We study a 1+1D, stochastic, Burton-Cabrera-Frank (BCF) model of interacting steps fluctuating on a vicinal crystal. The step energy accounts for entropic and nearest-neighbor elastic-dipole interactions. Our goal is to formulate and validate a self-consistent mean-field (MF) formalism to approximately solve the system of coupled, nonlinear stochastic differential equations (SDEs) governing fluctuations in surface motion. We derive formulas for the time-dependent terrace width distribution (TWD) and its steady-state limit. By comparison with kinetic Monte-Carlo simulations, we show that our MF formalism improves upon models in which step interactions are linearized. We also indicate how fitting parameters of our steady state MF TWD may be used to determine the mass transport regime and step interaction energy of certain experimental systems.[2]

1:39PM B24.00009 Real-time visualization of excited-state dynamics in molecular chains[1] , YONGHUI LI, CARSTEN ULLRICH — Time-dependent density-functional theory allows one to calculate excitation energies and the associated transition densities in principle exactly. The transition density matrix (TDM) provides additional information on electron-hole localization and coherence of a specific excitation. We have extended the TDM concept into the real-time domain in order to visualize the excited-state dynamics in conjugated molecules. Our computational scheme is based on solving the time-dependent Kohn-Sham equations with the OCTOPUS code and then calculating the time-dependent Kohn-Sham TDM using a spatial partitioning scheme. The method is applied to show in real time how locally created electron-hole pairs spread out over neighboring conjugated molecular chains. The coupling mechanism, electron-hole coherence, and the possibility of charge separation are discussed.

1:51PM B24.00010 Thermal conductivity of bulk crystals from first-principles lattice dynamics[1] , KEIVAN ESFARJANI, MIT, JUNICHIRO SHIOMI, University of Tokyo, GANG CHEN, MIT — Based on first-principles density-functional calculations, we have developed and tested a force field for Silicon, which can be used for Molecular dynamics simulations and the calculation of its thermal properties. This force field uses the exact Taylor expansion of the total energy about the equilibrium positions up to 4th order. In this sense, it becomes systematically exact for small enough displacements, and can reproduce the thermodynamic properties of Si with high fidelity. Having the harmonic force constants, one can easily calculate the phonon spectrum of this system. The cubic force constants, on the other hand, will allow us to compute phonon lifetimes and scattering rates. Results on equilibrium Green-Kubo molecular dynamics simulations of thermal conductivity as well as an alternative calculation of the latter based on the relaxation-time approximation will be reported. The accuracy and ease of computation of the lattice thermal conductivity using these methods will be compared. Results on other non-trivial materials such as Heuslers will also be presented. This approach paves the way for the construction of accurate bulk interatomic potentials and force constants database, from which lattice dynamics and thermal properties can be calculated and used in larger scale simulation methods such as Monte Carlo.

2:03PM B24.00011 Optimizing laser pulses for controlled excitation of materials and molecules[1] , ROLAND ALLEN, Texas A&M University — This talk extends the ideas of recent papers, including [1] Zhou et al., Phys. Rev. B 82, 075433 (2010); [2] Lin et al., J. Phys. Cond. Mat. 21, 485503 (2009); and [3] Allen, Phys. Rev. B 78, 064305 (2008). There are three basic points: (1) A combination of analytical models and density-functional-based simulations provides guidance for tailoring laser pulses to achieve optimum vibrational and electronic excitation. In [1] it was found that the maximum relative response of a specific vibrational mode with period T is achieved when the FWHM duration of a pulse is equal to 0.42 T, and later work by Jiang et al. provided a similar criterion for the duration and delay times in a series of pulses. (2) It is possible for microscopic (density-functional-based) simulations to provide input for larger-scale simulations, in the form of stresses etc. (as demonstrated in [2]) and excitation-dependent interatomic potentials. (3) It is possible to extend current techniques for simulations of the coupled dynamics of electrons, nuclei, and the radiation field in highly-excited materials, using for example nonequilbrium Green's functions.

Monday, March 21, 2011 11:15AM - 2:15PM –
Session B25 DCMP: Superconductivity: Spin properties, Structure and Dynamics D166

11:15AM B25.00001 Structure, spin-stripe order, and superconductivity in $La_{1.905}Ba_{0.095}CuO_4$ with and without 1% Zn substitution of Cu[1] , JINSHENG WEN, UC Berkeley/BNL, Z. XU, G. XU, Q. JIE, M. HUCKER, BNL, A. ZHELUDEV, W. TIAN, B. WINN, J. ZARESTKY, ORNL, D. SINGH, NCNR, T. HONG, ORNL, Q. LI, G. GU, J. TRANQUADA, BNL — We have performed susceptibility, thermal transport, and neutron scattering measurements to study the effect of Zn and magnetic field on the structure, spin-stripe order and superconductivity, and the interplay between them in $La_{1.905}Ba_{0.095}CuO_4$ with and without 1% Zn. It is shown that the bulk superconductivity is depressed by either the Zn doping or the magnetic field, spin stripe order is enhanced, and the structure is unaffected. For a range of magnetic field, the spin stripe order appears to stabilize a quasi-two-dimensional vortex glass phase.

11:27AM B25.00002 Electron-Spin Excitation Coupling in an Electron Doped Copper Oxide Superconductor Pr0.88LaCe0.12CuO4-δ[1] , JUN ZHAO, Department of Physics, University of California, Berkeley, FRANCIS C. NIESTEMSKI, SHANKAR KUNWAR, Department of Physics, Boston College, SHILIANG LI, Institute of Physics, Chinese Academy of Sciences, PAUL STEFFENS, ARNO HIESS, Institut Laue Langevin, Grenoble, France, HYE JUNG KANG, NIST Center for Neutron Research, STEPHEN D. WILSON, ZIQIANG WANG, Department of Physics, Boston College, PENGCHENG DAI, Department of Physics and Astronomy, The University of Tennessee, Knoxville, VIDYA MADHAVAN, Department of Physics, Boston College — We use polarized and unpolarized inelastic neutron scattering to study the magnetic excitations of the electron doped copper oxide superconductors Pr0.88LaCe0.12CuO4-δ (PLCCO, Tc =21 K, 24 K) over a wide energy range. We found the energy dependence of the imaginary part of the dynamic susceptibility displays two distinct energy scales in both samples. Interestingly, the STS measurements on the same samples reveal two modes that evolve with T_c in a similar manner as neutron modes. A comparison of the spatial and temperature dependence of the neutron and STS modes suggests that the low energy mode is associated with antiferromagnetism while the high energy mode is connected with superconductivity. These results suggest that spin excitations are the mediating glue for the electron pairing in PLCCO.

11:39AM B25.00003 Fluctuating stripes at the onset of the pseudogap in the high-Tc superconductor Bi2Sr2CaCu2O8+x[1] , COLIN PARKER, PEGOR AYNAJIAN, EDUARDO H. DA SILVA NETO, AAKASH PUSHP, Princeton University, SHIMPEI ONO, CRIEPI, Japan, JINSHENG WEN, ZHIJUN XU, GENDA GU, Brookhaven National Laboratory, ALI YAZDANI, Princeton University — A long standing question in high-T_c cuprates has been the interplay between pseudogap, which is generic to all hole-doped cuprates, and stripes, whose static form occurs in only one family of cuprates over a narrow range of the phase diagram. I will present new data [1] on the spatial reorganization of electronic states at the onset of the pseudogap state ($T*$) in the high-temperature superconductor $Bi_2Sr_2CaCu_2O_8 + x$ taken with a scanning tunneling microscope (STM). The onset of the pseudogap phase coincides with the appearance of electronic patterns whose doping and energy dependence has the predicted characteristics of fluctuating stripes. While demonstrating that the fluctuating stripes emerge with the onset of the pseudogap state and occur over a large part of the cuprate phase diagram, these experiments indicate that they are a consequence of pseudogap behavior rather than its cause.

11:51AM B25.00004 Manipulating stripes in $La_{2-x}Ba_xCuO_4$ in extreme environments[1] , MARKUS HUECKER, GENDA GU, ZHIJUN XU, JINSHENG WEN, JOHN M. TRANQUADA, Brookhaven National Laboratory, MARTIN VON ZIMMERMANN, HASYLAB at DESY, Hamburg, Germany — Competing magnetic and electronic interactions in the copper-oxide high temperature superconductors often result in nanoscale inhomogeneity of the charge and spin density. Such observations motivated a proposal that dynamic electronic inhomogeneities are intrinsic to the copper-oxide planes, and can result in electronic states that break their four-fold symmetry. We have performed high-energy single-crystal X-ray diffraction in high magnetic fields and at high pressure to show that the charge and spin stripe phase in $La_{2-x}Ba_xCuO_4$ constitutes such a state. In particular, our results provide strong evidence that charge stripe correlations in the cuprates are electronically driven and are enhanced within vortices.

12:03PM B25.00005 Hidden itinerant-spin extreme in heavily-overdoped LSCO revealed by dilute Fe doping: A combined neutron scattering and ARPES study , RUIHUA HE, Stanford & ALS, M. FUJITA[1], M. ENOKI, Tohoku, M. HASHIMOTO, Stanford, S. IIKUBO, Tohoku, S.-K. MO, ALS, H. YAO, Berkeley, T. ADACHI, Y. KOIKE, Tohoku, Z. HUSSAIN, ALS, Z.-X. SHEN, Stanford, K. YAMADA, Tohoku — Fluctuations of the localized spins on Cu and the itinerant spins of doped holes have been theoretically conceived to be both essential for high-Tc superconductivity. While the former clearly leads to an antiferromagnetic order in the undoped Mott phase (the localized-spin extreme), it has remained open whether the latter has an inherent tendency towards the formation of some magnetic order at very high dopings where it becomes dominant (the itinerant-spin extreme). By perturbing the non-magnetically-ordered heavily-overdoped LSCO with 1% Fe doping, we found by elastic neutron scattering an incommensurate magnetic order induced below 20 K, which cannot be ascribed to the localized spins on Cu or doped Fe. ARPES study of the itinerant doped holes suggests that this order is driven by a strong Fermi surface nesting, which is inherent in the pristine LSCO but has so far eluded a clean revelation. Our finding presents the first experimental example of the long-sought itinerant-spin extreme for cuprates and supports its important fluctuations that should be considered along with its localized counterparts for HTSC at intermediate dopings.

12:15PM B25.00006 Two distinct electronic sites in the Cu-O plane of the (La, Sr)CuO(4) pseudogap state , ROBERT SMITH, PHILIP KUHNS, ARNEIL REYES, GREGORY BOEBINGER, NHMFL/FSU — At intense magnetic fields (30 T) ^{17}O NMR exhibits two distinct signatures for planar oxygen sites instead of the singular site expected from the identical lattice symmetry at oxygen sites in the copper-oxygen plane for underdoped, orthorhombic $La_{2-x}Sr_xCuO_4$. Analysis of Knight shift, linewidth, quadrupolar splitting and spectral asymmetry indicates that roughly 75% of the planar oxygens evidence antiferromagnetically- correlated nearest neighbor Cu moments at temperatures below ∼30 K, consistent with previous reports. A second planar oxygen site first observed in this study shows that there are mobile holes on roughly 25% of the planar oxygen sites that (a) suppress magnetism for all T<300K and (b) show a Knight shift that drops to zero below ∼60 K, evidencing pair formation at a temperature well above the superconducting transition temperature (∼4 K at 30 T) and more than twice the superconducting transition temperature at zero magnetic field.

12:27PM B25.00007 Oxygen staging in phase separated La2-xSrxCuO4+y , HASHINI MOHOTTALA, University of Hartford, 200 Bloomfield Avenue, LINDA UDBY, e-Science and Nanoscience Centres, Niels Bohr Institute, Universistetsparken 5, 2100, SAMUEL EMERY, B.O. WELLS, J. I. BUDNICK, University of Connecticut, 2152, Hillside road, Storrs CT-06269, CHRISTOF NIEDERMAYER, Laboratory for Neutron Scattering, ETHZ & PSI, CH-5232 Villigen PSI, Switzerland, KIM LEFMANN, e-Science and Nanoscience Centres, Niels Bohr Institute, Universistetsparken 5, 2100, N.H. ANDERSON, Materials Research Division, Risø DTU, Frederiksborgvej 399, 4000 Roskilde, Denmark, F.C. CHOU, Center for Condensed Matter Sciences, National Taiwan University, Taipei 10617, Taiwan — We studied oxygen staging in a series of La2-xSrxCuO4 (LSCO) samples using neutron scattering. The samples were oxidized using electrochemistry. Electronic phase separation was previously reported in the oxygen rich LSCO system with two stable phases identified as optimally doped superconducting phase and a magnetic phase (1/8th like) with the same ordering temperatures at 40 K [1]. Our present studies show staging in this system. Although staging was observed and extensively studied in the samples with no Sr [2], it has not been reported or systematically studied in the systems with both Sr and oxygen. We do find staging in the oxygenated LSCO system, but the staging peaks evolve as Sr concentration increases and excess oxygen concentration decreases. [1] H Mohottala et al. Nature Materials **5**, 377 - 382 (2006), [2] B.O. Wells et al., Z. Phys. B 100, 535 (1996).

12:39PM B25.00008 Tunable High Q Superconducting Microwave Resonator[1] , Z. KIM, JQI/UMD, C.P. VLAHACOS, CNAM/NASA, J.E. HOFFMAN, J.A. GROVER, JQI/UMD, B.K. COOPER, J.R. ANDERSON, A.J. DRAGT, C.J. LOBB, JQI/CNAM/UMD, L.A. OROZCO, S.L. ROLSTON, JQI/UMD, J.M. TAYLOR, JQI/NIST/UMD, F.C. WELLSTOOD, JQI/CNAM/UMD — We have developed a frequency tuning system for a "lumped-element" thin-film superconducting Nb microwave resonator on sapphire intended for coupling to cold trapped ^{87}Rb atoms. ^{87}Rb has hyperfine ground states, $|^5S_{1/2}, F = 1\rangle$ and $|^5S_{1/2}, F = 2\rangle$, which are separated by about 6.83 GHz and available as a two-level system for a qubit. The resonator consists of a meandering inductor and an interdigitated capacitor coupled to a transmission line. At T=12 mK and on resonance at 6.863 GHz, the loaded quality factor is 40,000. We employ an Al pin as a frequency tuner by placing it above the inductor using a piezo stage so that one can effectively change the inductance of the resonator.

12:51PM B25.00009 Nanomechanical Torque Magnetometry of Individual Mesoscopic Superconductors[1] , ABDUL SUHEL, University of Alberta, DOUG VICK, National Institute of Nanotechnology, MARK R. FREEMAN, University of Alberta and National Institute of Nanotechnology, JOHN P. DAVIS, University of Alberta — We have developed an extremely sensitive form of torque magnetometry based on thin nanomechanical resonators [1]. Previously, we applied this technique to study single magnetic vortices in nanomagnetic samples [2]. One advantage of this technique is that it has good time resolution, and each measurement can be performed quickly enough to gather significant statistics on such events [2]. We are now applying this technique to study single mesoscopic superconducting samples. We intend to measure the magnetic moment associated with superconducting vortices, as well as other magnetic effects that occur in mesoscopic superconductors [3,4]. We will discuss our progress towards this goal. [1] J.P. Davis, et al. Appl. Phys. Lett. **96**, 072513 (2010). [2] J.P. Davis, et al. New Journal of Physics **12**, 093033 (2010). [3] A.K. Geim, et al. Nature **396**, 144 (1998). [4] A.K. Geim, et al. Nature **407**, 55 (2000).

1:03PM B25.00010 Strong disorders in cuprate superconductors in d-density wave state , HONG-YI CHEN, National Taiwan Normal University, CHUNG-PIN CHOU, Academia Sinica — The local density of states on strong disordered d-wave superconductor in d-density wave state is studied. Recently, E.W. Hudson et al [Nature Physics 4, 108 (2008)], reported a method to investigate the pseudogap. We explore the selfconsistent Bogoliubov-de Genns' equations with strong disorders. The quantum interference leading to definitive quasipartical spectra has also been considered. Without d- density wave state, the numerical results are in satisfactory agreement with the observations from STM experiments. With d- densitywave state, a new result can be used to determine the properties of pseudogap.

1:15PM B25.00011 Resonant Inelastic X-Ray Studies on the Cu-L edge in 1-Dimensional Cuprate Chains[1] , JAMES LEE, M. YI, W.S. LEE, Stanford University, K. ZHOU, C. MONNEY, Swiss Light Source, PSI, S. JOHNSTON, J. VAN DEN BRINK, IFW Dresden, T. SCHMITT, L. PATTHEY, Swiss Light Source, PSI, T.P. DEVEREAUX, Stanford University, K. KUDO, Y. KOIKE, Tohoku University, Z.X. SHEN, Stanford University — Resonant Inelastic X-ray Scattering (RIXS) is a photon-in, photon-out spectroscopy technique with the capability of seeing many-body interactions in great detail. The recent achievement of sub-eV resolution in RIXS has opened up a new avenue for experiments to study these effects quantitatively. Here we present high-resolution RIXS data at the Cu L-edge on the quasi-one-dimensional edge-sharing chain compound, $Ca_{2+x}Y_{2-x}Cu_5O_{10}$, which is the only known dopable quasi-1D chain compound. Charge excitations corresponding to doped holes can be clearly resolved when the photon energy is tuned to the resonance at the hole band. In addition, we find that the d-d excitations appear to disperse with incident photon energy and momentum, and have a nontrivial intensity modulation. Effects of hole doping on these excitations will be discussed.

[1]Work supported by DOE Office of Basic Energy Science, Division of Materials Science and Engineering, under contract DE-AC02-76SF00515 and the Stanford Graduate Fellowship.

1:27PM B25.00012 High-resolution RIXS measurement at O K-edge on the edge-shared chain cuprates, $Ca_{2+x}Y_{2-x}Cu_5O_{10}$, W.S. LEE, SIMES, SLAC National Accelerator Lab., J. LEE, M. YI, Stanford University, K. ZHOU, Swiss Light Source, PSI, S. JOHNSTON, IFW Dresden, T. SCHMITT, Swiss Light Source, PSI, JEROEN VAN DEN BRINK, IFW Dresden, T.P. DEVEREAUX, SIMES, SLAC National Accelerator Lab., K. KUDO, Y. KOIKE, Tohoku University, L. PATTHEY, Swiss Light Source, PSI, Z.X. SHEN, SIMES, SLAC National Accelerator Lab. — Quasi one dimensional copper oxides have been model systems in the field of correlated electron physics, because of rich phenomena exhibited in a relatively simple geometry. Its magnetic ground states, fluctuations, and excitations have been investigated extensively by theorists and experimentalists. Among the known quasi 1-D spin-chain compounds, $Ca_{2+x}Y_{2-x}Cu_5O_{10}$ is the only compound that can be hole-doped in a wide doping range, providing a unique opportunity to study the dynamics of hole in the quasi-1D environment. Here, we report ultrahigh resolution resonant inelastic soft x-ray scattering experiment at the O K-edge. With an energy resolution of $\sim$50 meV, we resolved rich charge excitations in the sub-eV range that has not been observed in the previous RIXS measurement on the same materials. In particular, we have resolved clear multi-phonon excitations near the elastic peak, suggesting a strong electron-phonon coupling in this quasi-1D system. Doping dependence of these excitations will also be demonstrated.

1:39PM B25.00013 Suppression of superconductivity in the fully frustrated Josephson junction array with site dilution[1] , BRUNA DE OLIVEIRA, University of Southern California, TOMMASO ROSCILDE, Ecole Normale Superieure de Lyon, STEPHAN HAAS, University of Southern California — We study the effects of geometric randomness on the ordered phases and phase transitions of frustrated classical Josephson junction (JJ) arrays. In particular, we consider a square lattice array with maximal frustration (one half flux quantum through each plaquette) and with site dilution. The homogeneous model is known to feature two phase transitions: an Ising transition for the ordering of vortices into a crystalline state, and a Kosterlitz-Thouless transition for the appearance of superconductivity. A detailed Monte Carlo study shows a strong effect of disorder on the separation of the ordering temperatures. In particular, superconductivity is completely suppressed well before one reaches the percolation threshold of the lattice. We hence suggest that diluted JJ arrays with magnetic frustration are strong candidates for the experimental observation of a vortex crystal in the normal state.

[1]This work was supported by a Chateaubriand Fellowship, awarded by the French Embassy in Washington D.C., USA.

1:51PM B25.00014 Dynamical Spectral weight transfer in the cuprates is described by the Hubbard model , PHILIP PHILLIPS, university of illinois, MARK JARRELL, Louisiana State University — Recently, Peets and colleagues [1] measured the x-ray intensity at the oxygen K-edge in overdoped $La_{2-x}Sr_xCuO_{4\pm\delta}$ (LSCO) and $Tl_2Ba_2CuO_{6+\delta}$. They concluded that, unlike the underdoped samples of LSCO and $YBa_2Cu_3O_x$ in which the integrated intensity increases at least linearly with doping, it saturates abruptly for a hole count exceeding $x_c \approx 0.23$. They interpreted the saturation as a breakdown of the 1-band Hubbard model in the cuprates. We analyse all the available data and show that they are completely described by the 1-band Hubbard model. The purported saturation is shown to occur at the doping level at which the dynamical contribution to the spectral weight turns off.

[1] D. C. Peets, Phys. Rev. Lett. **103**, 087402 (2009).

2:03PM B25.00015 Superstructure and Magnetism in Na0.825CoO2 - A NMR study , P.Y. CHU, B.-L. YOUNG, J.Y. JUANG, G.J. SHU, M.-W. CHU, F.C. CHOU — We report our NMR study of the Na ordering and magnetism in the single crystal of Na0.825CoO2, as follows. 1. The atomic order of Na is observed from the well- resolved 23Na NMR peaks, which suggests 6 Na inequivalent sites. The 59Co NMR also suggests 4 distinct Co sites due to Na ordering. 2. The magnetic field-induced transition from antiferromagnet to ferromagnet is verified by our 23Na spectra at different temperatures and fields. A slow spin dynamic of glassy-like behavior is observed near the AFM and FM boundary. 3. We observed the NMR frequency shift anomaly near 50K, the same temperature where the susceptibility shows the curvature. The anomaly suggests the onset of the magnetic correlation in prior to magnetic ordering.

Monday, March 21, 2011 11:15AM - 1:39PM –

Session B26 DMP DCOMP: Focus Session: Iron Based Superconductors – Growth D162/164

11:15AM B26.00001 Influences of material processing on the microstructure and intergranular current of polycrystalline Sm1111 iron-pnictides , A. YAMAMOTO, Univ. of Tokyo, J. JIANG, F. KAMETANI, A. POLYANSKII, J. WEISS, E. HELLSTROM, D. LARBALESTIER, NHMFL, A. MARTINELLI, A. PALENZONA, M. TROPEANO, M. PUTTI, Univ. of Genova, CNR-SPIN — We have prepared polycrystalline Sm1111 bulk samples by sintering and hot isostatic pressing (HIP) and studied the influence of processing on the microstructure and intergranular current. After sintering and HIPping, samples are denser with much less impurity SmOF and grain boundary wetting FeAs. They then show significantly larger hysteresis loops than as- prepared samples. But Tc of HIPed samples is lower than samples with optimal doping, indicating loss of fluorine during later processing. Nevertheless, even after the fluorine loss and its associated carrier density reduction produced by the HIP treatment, both Magneto-Optical and remanent magnetization analyses showed that the intergranular current was enhanced. We conclude that the denser microstructure and smaller impurity phase content of HIPped samples enhances their connected fraction, even as the doping state of the sample is degraded by F loss. Our study emphasizes that current transport in polycrystalline pnictides is a complex balance involving the need to control carrier density, especially at grain boundaries, while densifying the microstructure and avoiding normal-state grain boundary wetting phases like FeAs.

11:27AM B26.00002 Synthesis and superconducting properties of FeTe1-xSe Single Crystals under high magnetic fields , TESFAYE GEBRE, G. LI, J. WHALEN, National High Magnetic Field Laboratory, Tallahassee, FL 32310, B. CONNER, National High Magnetic Field Laboratory,Tallahassee, FL 32310, M. KOSTOV, Department of Chemical and Biomedical Engineering, FSU, Tallahassee, FL 32310, T. SIEGRIST, Department of Chemical and Biomedical Engineering, FSU, and National High Magnetic Field Laboratory, Tallahassee, FL 32310, L. BALICAS, National High Magnetic Field Laboratory,Tallahassee, FL 32310 — Single crystals of superconductor $FeTe_{1-x}Se_x$ ($0.1 \leq x \leq 0.5$) were synthesized using optical floating zone, Bridgeman technique, and solid stat reaction. The samples were synthesized under various temperature gradients and cooling rates. Crystals were characterized via EDX, X-ray scattering, magnetization and transport measurements. Upper critical fields Hc_2as estimated through the Werthamer-Hohenberg-Helfand (WHH) formalism indicate that these materials strongly surpass the weak coupling Pauli limiting field indicating that the shape of their phase diagram under field is essentially controlled by the Pauli effect. Annealing, leads to a metallic temperature dependence of the resistivity, and to sharper superconducting transitions. Despite the relatively small increase in single crystallinity, as quantified by single crystal x-ray diffraction measurements, we observe a different phase diagram under high magnetic fields when compared to non-annealed samples.

11:39AM B26.00003 Single crystal growth and superconducting properties of LiFeAs , BUMSUNG LEE, SEUNGHYUN KHIM, JAE WOOK KIM, SNU, EUN SANG CHOI, NHMFL, JUNG SOO KIM, G. R. STEWART, UF, KEE HOON KIM, SNU — LiFeAs, a representative compound for '111' system of Fe-based superconductors, has a tetragonal Cu_2Sb-type structure and possesses a single Fe-As tetrahedral layer sandwiched by the double Li layers. This structural characteristic provides a unique opportunity to realize homogeneous Li terminating surface upon cleaving, and this possibility makes LiFeAs attractive for investigating the intrinsic properties of Fe-based superconductors with various spectroscopic tools. In this sense, growing a large LiFeAs single crystal is a necessary step for studying intrinsic properties of the Fe-based superconductors. We report the successful growth of high quality LiFeAs single crystal by Sn-flux. Electrical resistivity studies reveal the superconducting onset temperature is 18.2 K with a transition width less than 1.1 K and RRR is about 24. Bulk superconductivity is supported by perfect shielding in the magnetic susceptibility and a clear jump in the specific heat. Upper critical field slopes of $dH_{c2}^{c}/dT \approx$-1.39 and $dH_{c2}^{ab}/dT \approx$-2.99 T/K near T_c predict $H_{c2}^{c}(0)\approx$17.2 and $H_{c2}^{ab}(0)\approx$36.9 T, and it points to a modest superconducting anisotropy about 2.3 near T_c. This observed modest anisotropy is a bit smaller than the band calculation results based on the GGA approximation but larger than the prediction considered effects of electron correlation through the dynamic mean field theory.

11:51AM B26.00004 ABSTRACT WITHDRAWN –

12:03PM B26.00005 Superconductivity and wire fabrication of FeSe family , TOSHINORI OZAKI, KEITA DEGUCHI, YOSHIKAZU MIZUGUCHI, HIROAKI KUMAKURA, YOSHIHIKO TAKANO, National Institute for Materials Science, NATIONAL INSTITUTE FOR MATERIALS SCIENCE TEAM — The 11 family is an fascinating iron-based superconducting system for not only elucidation of superconducting mechanism but also technological applications because of the simplest crystal structures, the less toxic and high critical field. Recently, we found that the superconductivity appears in the specimen immersed in alcoholic beverages. Focused on the pressure dependence of Se height from Fe layer in FeSe, we found that the Tc is correlated to Se height. Moreover, the anion height dependence of T_c for all FeAs-based superconductor obeyed a universal curve with a peak around 1.38 Å. We succeeded in observing the transport J_c in the single- and 7-core wires of $FeTe_xSe_{1-x}$ superconductor using an in-situ powder-in-tube (PIT) method. The J_c values in single- and 7-core wire are as high as 159 A/cm^2 and 100 A/cm^2 at 4.2 K, respectively. It is considered that the optimization of the composition, together with the improvement of the grain boundary in $FeTe_xSe_{1-x}$ superconducting wires, will lead to higher J_c.

12:15PM B26.00006 Synthesis of Large Single Crystals of LaMnPO[1] , GREG SMITH, JACK SIMONSON, CARLOS MARQUES, Stony Brook University, VICTOR LEYVA, Rice University, MEIGAN ARONSON, Stony Brook University — The compound LaMnPO is isostructural with LaFeAsO, a recently discovered high-temperature superconductor, but optical spectroscopy and transport measurements of this compound have been heretofore limited by small crystal size. Accordingly, crystal syntheses from Sn, Pb and molten salt fluxes (including NaCl/KCl, LiCl/NaCl, KCl, $CaCl_2$, $BaCl_2/CaCl_2$ and $KCl/CaCl_2$) were investigated. Fluorine doping was explored; concentrations less than 30 at.% (nominal) had no effect on crystal size; concentrations greater than 40 at.% (nominal) did not yield crystals. Once growth parameters were optimized, the crystals grew in a flat rectangular shape with black luster; their composition was verified with powder and single crystal x-ray diffraction. Successful growths yielded crystals with dimensions up to 3.2 mm by 1 mm by 10 μm, a significant improvement upon previously reported growths in the literature. These large crystals enabled our group to perform a wide range of experiments that were previously restricted to polycrystalline materials. It may be feasible to extend these methods to the synthesis of similar compounds.

12:27PM B26.00007 ABSTRACT WITHDRAWN –

12:39PM B26.00008 Faceted nanocrystalline growth of FeTe on $SrTiO_3(001)$, YI LI, ZHAOLIANG LIAO, LINA CHEN, JIANNENG LI, AMAR KARKI, RONGYING JIN, WARD PLUMMER, JIANDI ZHANG, LOUISIANA STATE UNIVERSITY TEAM — The new class of iron based superconductors has ignited the materials community. Of all of these new superconductors, the Fe chalcogenide system is probably the simplest at least in structure. One of most interesting questions is how the properties of these systems change as the structure is manipulated. We have studied ultra thin films of FeTe grown on a $SrTiO_3$(001) surface by using Pulsed Laser Deposition (PLD) and characterized with surface techniques. We observe the formation of faceted nanocrystalline islands at the surface of thin films. The structure of the islanded surface, including the faceting angle of nanostructures, has been studied by Low Energy Electron Diffraction (LEED) as well as scanning tunneling microscope (STM). The correlation of such a 3D-type growth with growth conditions and substrate-induced strain in the ultra-thin films are discussed. *Supported by NSF-DMR1005562

12:51PM B26.00009 Superconducting Iron-Chalcogenide Thin Films and Coated Conductors , QIANG LI, WEIDONG SI, Brookhaven National Laboratory — Superconducting iron-chalcogenide superconducting films have been grown on a variety of substrates, including single crystalline and metallic substrates. In this presentation, we will report transport and structural properties of these films. The superconducting transition temperature of these films is significantly higher than that of the corresponding bulk materials. Analytical electron microcopy analysis indicates substantial structural difference between thee films and single crystals at atomistic level. Detailed measurement of the angular dependence of upper critical field and critical current density demonstrated that iron chalcogenide superconductors have lower anisotropy factor in comparison to the high Tc cuprates, that presents the unique opportunity for this class of materials in high field application.

1:03PM B26.00010 Superconducting properties of $FeSe_{0.5}Te_{0.5}$ and $FeTe{:}O_x$ thin films , WEIDONG SI, Brookhaven National Laboratory, AYAN BHATTACHARYA, SU JUNG HAN, IVO DIMITROV, LIJUN WU, QIANG LI — High quality superconducting thin films of $FeSe_{0.5}Te_{0.5}$ and $FeTe{:}O_x$ have been grown by pulsed laser deposition on various substrates including coated conductor. Thin films of $FeSe_{0.5}Te_{0.5}$ have a higher superonducting transition temperature Tc (onset start around 20K and zero resistance about 16 17K) than that of bulk. High resolution transmission electron microscopy has identified a microstructure only in thin films, which may be associated with the higher Tc. Magneto-transport measurement has been carried out to check the angular dependence of upper critical field Hc2 and the critical current density of the films with the direction of magnetic field. Both have shown a weak anisotropy. These films have a special high dHc2/dT at Tc, especially for $FeTe{:}O_x$ film.

1:15PM B26.00011 Maze-like surface reconstruction on pure $SrFe_2As_2$ observed by STM/STS[1] , MICHAEL DREYER, MARK GUBRUD, HUI WANG, SHANTA SAHA, NICK BUTCH, KEVIN KIRSHENBAUM, JOHNPIERRE PAGLIONE, University of Maryland — We measured undoped $SrFe_2As_2$ samples using a low temperature scanning tunneling microscope. Similar samples showed superconductivity in up to 15% of its volume in measurements of the diamagnetic screening although being undoped as confirmed by energy dispersive x-ray spectroscopy. The samples where cleaved at room temperature at a pressure $P < 10^{-8}$ mbar before introducing them into the low temperature scanning tunneling microscope (LTSTM) operating at a temperature of $T = 4.2$ K. Beside the usual striped surface reconstruction and disordered regions we observed areas showing a maze like reconstruction. Atomically resolved images strongly suggest that the maze structure is formed by adatoms and thus, by inference, is the striped phase. Scanning tunneling spectroscopy (STS) measurements showed a superconducting gap on both the striped and maze phase of the sample, similar to the spectra on a cobalt doped sample. The results will be discussed in detail.

1:27PM B26.00012 Cleavage behavior and surface states in iron pnictides , KLAUS KOEPERNIK, ALEXANDER LANKAU, HELMUT ESCHRIG, JEROEN VAN DEN BRINK, SERGEY BORISENKO, IFW Dresden, Germany, ERIK VAN HEUMEN, MARK S. GOLDEN, Zeeman institute, University of Amsterdam, Netherlands — We present a density functional study of the surface electronic structure and the cleavage behavior of LiFeAs and Co-doped $BaFe_2As_2$. The results are discussed together with angle resolved photo emission (ARPES) and low energy electron diffraction (LEED) data. The two systems behave rather differently and we conclude that LiFeAs will be the ideal system for surface sensitive probes among the iron pnictide familly.

Monday, March 21, 2011 11:15AM - 2:15PM –

Session B27 GQI: Focus Session: Superconducting Qubits - Measurement C155

11:15AM B27.00001 Quantum Noise in a Chirped Superconducting Nonlinear Resonator , KATER MURCH, R. VIJAY, QNL, UC Berkeley, IDO BARTH, LAZAR FRIEDLAND, Racah Institute of Physics, Hebrew University, IRFAN SIDDIQI, QNL, UC Berkeley — A nonlinear Josephson junction oscillator driven near resonance can exhibit bistability, forming the basis for sensitive, digital quantum state readout. We consider the case of a high-Q resonator embedded with a Josephson junction excited with a chirped frequency signal. For sufficient drive amplitude, the resonator phase locks with the drive signal and enters the high amplitude oscillation state, a phenomenon known as autoresonance. The probability of capture in a given chirped pulse depends on the initial phase difference between the drive signal and of the fluctuation induced oscillations of the resonator. We find that the width of this threshold is in agreement with recent theoretical predictions and is set by zero-point fluctuations of the resonator. Autoresonant capture forms the basis for fast readout of a superconducting qubit coupled to a high-Q resonator.

11:27AM B27.00002 Measurement backaction and the quantum Zeno effect in a superconducting qubit , DANIEL H. SLICHTER, R. VIJAY, IRFAN SIDDIQI, Quantum Nanoelectronics Laboratory, Dept. of Physics, UC Berkeley — Strong measurement of a quantum system can inhibit quantum state evolution, a phenomenon known as the quantum Zeno effect. If the measurement is not perfectly quantum non-demolition, it can also cause spurious transitions between states. We study these effects in a transmon qubit dispersively coupled to a superconducting microwave readout cavity. We use a fast, ultralow-noise parametric amplifier to amplify the microwave photons used to probe the qubit state, enabling continuous high-fidelity monitoring of the qubit. This arrangement allows us to observe quantum jumps between the qubit states in real time. We examine the dependence of the jump times on measurement strength and the qubit excitation protocol.

11:39AM B27.00003 Investigation of the measurement dynamics of a flux qubit inductively coupled to a readout dc-SQUID , PETER GROSZKOWSKI, JAY GAMBETTA, FRANK WILHELM, IQC, University of Waterloo — In this paper we investigate the measurement dynamics of a flux qubit inductively coupled to a capacitively shunted, readout dc-SQUID. We study how the measurement induced dephasing and relaxation rates scale as a function of the qubit operation point and measurement strength. We find analytical solutions when the measurement is quantum-non-demolition (QND) and provide a numerical investigation for non-QND operation. This is of importance as the measurement of the flux qubit when operated at its sweet spot is inherently non-QND. We conclude this with a discussion of the measurement efficiency and signal-to-noise ratio.

11:51AM B27.00004 Optimization of SQUID-based microwave parametric amplifiers for qubit readout , CHRIS MACKLIN, R. VIJAY, E. LEVENSON-FALK, D. SLICHTER, Z. MINEV, I. SIDDIQI, QNL, UC Berkeley — We present recent experimental and theoretical results on the optimization of SQUID-based parametric microwave amplifiers for ultra low noise readout of superconducting and spin-based qubits. The devices consist of an unshunted two-junction SQUID in parallel with an on-chip capacitor, forming a non-linear microwave resonator. The SQUID is operated in a non-linear regime below the critical current, thus producing no local dissipation. These amplifiers have gain exceeding 20 dB, 10 MHz of broadly tunable bandwidth, and quantum-limited noise performance. We present measurements on amplifiers with tunnel type and weak link Josephson junctions. We discuss the use of array structures to optimize dynamic range as well as a resonant flux-coupled input capable of operation in a transmission configuration and potentially suitable for on-chip integration.

12:03PM B27.00005 Fluxonium qubit readout with the Josephson parametric converter[1] , M. HATRIDGE, B. ABDO, A. KAMAL, N. MASLUK, F. SCHACKERT, M.H. DEVORET, Applied Phyics Dept., Yale University — Rapid, single shot quantum-non demolition readout is a prerequisite for proposed active quantum feedback and error correction experiments in superconducting qubit systems. The fluxonium qubit, an artificial atom comprised of a Josephson junction array inductively shunting a Cooper-pair box, is a non- Purcell limited system with excellent coherence times, making it a natural candidate for such experiments. The largest obstacle towards achieving single shot fluxonium readout is the severe signal-to-noise ratio degradation of the qubit readout by the microwave frequency amplification chain. This degradation can be minimized through the addition of a quantum-limited pre-amplifier to the chain. We have designed and constructed such an amplifier, the Josephson Parametric Converter (JPC), which achieves nearly quantum limited amplification with a bandwidth and dynamic range suitable for readout of our current fluxonium design, and are currently integrating the JPC and fluxonium. We will discuss experimental requirements of the combined JPC and fluxonium system and anticipated improvements in measurement fidelity and speed.

12:15PM B27.00006 Dispersive Readout of a Superconducting Flux Qubit Using a Microstrip SQUID Amplifier[1] , J.E. JOHNSON, UC Berkeley, E.M. HOSKINSON, C. MACKLIN, I. SIDDIQI, QNL, UC Berkeley, JOHN CLARKE, UC Berkeley — Dispersive techniques for the readout of superconducting qubits offer the possibility of high repetition-rate, quantum non-demolition measurement by avoiding dissipation close to the qubit. To achieve dispersive readout, we couple our three-junction aluminum flux qubit inductively to a 1-2 GHz non-linear oscillator formed by a capacitively shunted DC SQUID. The frequency of this resonator is modulated by the state of the qubit via the flux-dependent inductance of the SQUID. Readout is performed by probing the resonator in the linear (weak drive) regime with a microwave tone and monitoring the phase of the reflected signal. A microstrip SQUID amplifier (MSA) is used to increase the sensitivity of the measurement over that of a HEMT (high electron mobility transistor) amplifier. We report measurements of the performance of our amplification chain. Increased fidelity and reduced measurement backaction resulting from the implementation of the MSA will also be discussed.

12:27PM B27.00007 SQUID-tunable microwave lumped-element oscillators and distributed resonators[1] , P. BHUPATHI, M.P. DEFEO, M. WARE, J.D. STRAND, B.L.T. PLOURDE, Syracuse University — We have fabricated lumped-element microwave oscillators and coplanar waveguide resonators consisting of a dc SQUID using submicron Al-AlOx-Al junctions with resonance frequencies in the range of several GHz. The SQUID oscillators consist of a dc SQUID shunted with a capacitor formed from superconducting layers. The CPW resonators are formed from Nb $\lambda/2$ coplanar transmission lines with a center conductor interrupted by an Al dc SQUID at the current anti-node of the fundamental mode. The resonance frequency can be varied by tuning the Josephson inductance of the SQUID with on-chip flux and bias-current lines. We discuss applications employing these devices, including a new readout scheme for superconducting flux qubits and for the detection of microwave cavity photons.

12:39PM B27.00008 Multiplexing Readout of a Qubit Array via a Single Transmission Line , MARKUS JERGER, STEFANO POLETTO, ALEXANDER LUKASHENKO, ALEXEY V. USTINOV, Physikalisches Institut, Karlsruhe Institute of Technology and DFG-Center for Functional Nanostructures (CFN), D-76128 Karlsruhe, Germany, PASCAL MACHA, UWE HÜBNER, EVGENI IL'ICHEV, Institute of Photonic Technology, PO Box 100239, D-07702 Jena, Germany — A resonant circuit coupled to a qubit displays a shift of its resonance frequency depending on the quantum state of the qubit. The qubit state can be thus measured by probing the resonator near its resonance frequency. By coupling every qubit to its individual resonator of distinct frequency, one can read out the state of an array of many qubits through a single microwave line coupled to all resonators. Moreover, this readout can be performed simultaneously by using a multi-tone microwave pulse with frequency-division multiplexing. We will present measurements on an ensemble of 7 superconducting flux qubits located on one chip and each coupled to an individual transmission-line resonator. We performed spectroscopy of all qubits and determined their parameters in a single measurement run. Our latest experiments on simultaneous preparation and readout of the 7-qubit array will be presented.

12:51PM B27.00009 Multiplexed dispersive readout of superconducting phase qubits[1] , YU CHEN, RAMI BARENDS, RADOSLAW BIALCZAK, JULIAN KELLY, MICHEAL LENANDER, ERIK LUCERO, MATTEO MARIANTONI, MATTHEW NEELEY, AARON O'CONNELL, PETER O'MALLEY, Department of Physics, Uinversity of California-Santa Barbara, DANIEL SANK, AMIT VAINSENCHER, HAOHUA WANG, MARTIN WEIDES, JAMES WENNER, THEODORE WHITE, YI YIN, JIAN ZHAO, ANDREW CLELAND, JOHN MARTINIS, Department of Physics, Uinversity of California-Santa Barbara — A dispersive readout scheme is being developed for superconducting phase qubits. By inductively coupling to a LC resonator, the measured state of the qubit (left or right side of the potential well) can be read out as a shift of the resonance frequency. Compared to our current SQUID readout, this method eliminates the generation of quasiparticles, increases the reliability by reducing the junction count per qubit from 4 to 1, and reduces the chip wire count since the readout can be frequency multiplexed.

[1]This work is supported by IARPA under ARO award W911NF-08-1-0336 and under ARO award W911NF-09-1-0375.

1:03PM B27.00010 Non-linear dispersive interaction in superconducting circuit QED , YI YIN, HAOHUA WANG, MATTEO MARIANTONI, RADOSLAW C. BIALCZAK, MIKE LENANDER, ERIC LUCERO, MATTHEW NEELEY, AARON O'CONNELL, DANIEL SANK, JIM WENNER, Physics Department, University of California, Santa Barbara, TSUYOSHI YAMAMOTO, NanoElectronics Research Laboratories, NEC Corporation, Japan, ANDREW CLELAND, JOHN MARTINIS, Physics Department, University of California, Santa Barbara — In circuit quantum electrodynamics, the strong coupling between superconducting qubits and a coplanar waveguide resonator (CPW) has been utilized to study the light-atom interaction. When the qubit is detuned far away from the resonator in frequency, linear dispersive interaction has been used for the readout of qubit states by measuring the pulling frequency of the resonator. Alternatively, we investigate dispersive interaction in a broader regime by measuring the accumulated dynamic phase with Wigner tomography. In the quasi-adiabatic process of tuning the qubit frequency, the dynamic phase measurement can be pushed to the case of zero detuning with up to the five-photon Fock state in the CPW resonator. The exotic non-linear behaviors of the qubit on resonator cat state and coherent state have been revealed, strongly depending on the strength of dispersive interaction. Our experimental data are consistent with the numerical calculation using the Jaynes-Cumming model.

1:15PM B27.00011 Circuit QED with a Nonlinear Resonator: ac-Stark Shift and Dephasing , FLORIAN R. ONG, CEA-Saclay and University of Waterloo, M. BOISSONNEAULT, F. MALLET, A. PALACIOS-LALOY, A. DEWES, A.C. DOHERTY, A. BLAIS, P. BERTET, D. VION, D. ESTEVE, CEA-SACLAY TEAM, U. DE SHERBROOKE TEAM, U. OF QUEENSLAND TEAM — Coupling a superconducting qubit to a superconducting resonator enables to investigate the interaction between light and matter with a unique flexibility of design, and allows to reach coupling regimes hardly accessible otherwise [Wallraff Nature 2004]. In this talk, we discuss the ac-Stark shift and the measurement induced dephasing of a qubit embedded in a *nonlinear* resonator, an architecture that has demonstrated high fidelity single-shot qubit state readout [Mallet Nat. Phys. 2009]. In our experiment, a transmon qubit [Koch PRA 2007] is capacitively coupled to a coplanar waveguide resonator incorporating a Josephson junction that provides a Kerr nonlinearity. We have measured the qubit spectrum while pumping the nonlinear resonator with a microwave tone. Measurements of the qubit frequency shift provide a sensitive probe of the intracavity field, yielding a precise characterization of the resonator nonlinearity. The qubit linewidth has a complex dependence on the pump frequency and amplitude, which is correlated with the gain of the nonlinear resonator operated as a small-signal amplifier. The corresponding dephasing rate is found to be close to the quantum limit for most pump parameters.

1:27PM B27.00012 Improved Superconducting Qubit Readout by Qubit-Induced Nonlinearities in the Straddling Regime , MAXIME BOISSONNEAULT, Universite de Sherbrooke, J.M. GAMBETTA, IQC and University of Waterloo, J. BOURASSA, A. BLAIS, Universite de Sherbrooke — In dispersive readout schemes, qubit-induced nonlinearities have typically limited the measurement fidelities by reducing the signal-to-noise ratio (SNR) when the measurement power is increased [1]. However, it has been recently shown that these nonlinearities, together with the many-level system (MLS) nature of superconducting qubits, can be used to improve qubit readout in some regimes [2]. Moreover, for the transmon qubit [3], it has been shown that when the resonator's frequency sits between two of the MLS' transition frequencies – the so-called straddling regime – contributions of higher levels add constructively to improve the SNR [4]. In this talk, we explore the advantages of using both the qubit-induced nonlinearties and the straddling regime for qubit readout.

1:39PM B27.00013 Purcell Protection and Cycling Transition Measurement with a Superconducting V-system , ANTHONY HOFFMAN, SRIKANTH SRINIVASAN, Princeton University, JAY GAMBETTA, Institute for Quantum Computing, ANDREW HOUCK, Princeton University — We perform time-domain experiments on a superconducting qubit with a V-level energy structure coupled to a superconducting, coplanar waveguide resonator. Quantum interference and the V-level energy scheme allow independent control of the qubit energy and dipole via two on-chip fast flux bias lines [1]. The tunable dipole is predicted to protect the qubit from cavity-induced spontaneous emission. We probe this "Purcell protection" by measuring the qubit lifetime at constant cavity-qubit detuning for a range of coupling strengths. We also show how the coupled cavity-qubit energy spectrum allows for a cycling-type measurement that is predicted to improve the signal to noise ratio of qubit state readout by as much as an order of magnitude.

[1] J.M. Gambetta et al., arXiv:1009.4470v1

1:51PM B27.00014 Quantum State Tomography of a Cooper-pair Box , SERGEY NOVIKOV, V. ZARETSKEY, B. SURI, Z. KIM, Dept. of Physics, Univ. of Maryland, B.S. PALMER, Lab. for Physical Sciences, F.C. WELLSTOOD, JQI, CNAM, Dept. of Physics, Univ. of Maryland — A 4-8 GHz microwave pulse shaping system with 3 ns Gaussian pulse rise time, arbitrary pulse envelope and phase control has been implemented. The system utilizes a two-channel 1 GSa/s DAC board[1] to supply control voltages to an IQ mixer. The signals to the mixer have been optimized to obtain an on-off ratio of > 85 dB and phase deviations $< 5\%$. The setup has been used to manipulate an $Al/AlO_x/Al$ Cooper-pair box (CPB) qubit coupled to a lumped-element microwave resonator ($f_0 = 5.446$ GHz). The CPB has a charging energy $E_C/h = 6.25$ GHz and a maximum $E_J/h = 19$ GHz which was decreased to an effective $E_J/h = 6.1$ GHz by an external magnetic field. By measuring the microwave transmission at f_0 in a pulsed-probe scheme, we perform a dispersive readout of the qubit. We present tomography data on the $|g\rangle$, $|e\rangle$, $(|g\rangle + |e\rangle)/\sqrt{2}$ and $(|g\rangle + i|e\rangle)/\sqrt{2}$ states. We find good agreement with theory, confirming that we have achieved the desired microwave pulse control.

[1]Designed by J. Martinis at UCSB and fabricated by HSCC.

2:03PM B27.00015 A phase qubit coupled to an RF-SQUID resonator , JED WHITTAKER, SHANE ALLMAN, University of Colorado at Boulder, KATARINA CICAK, FRANCOIS NGUYEN, NIST, ADAM SIROIS, University of Colorado at Boulder, JOHN TEUFEL, EVA ZAKKA-BAJJANI, RAYMOND SIMMONDS, NIST — We have coupled a tunable cavity (an RF-SQUID resonator) to a phase qubit. The resonator can be used both for state transfer experiments as well as a measurement/readout device for the qubit. Specifically, it can be used in three different ways to help interrogate the state of the qubit. First, changes in the resonator frequency can be monitored in order to read out the qubit state after a conventional fast measure pulse is applied to the qubit bias flux. Second, we can perform a linear dispersive measurement of the qubit state using the coupled interaction between the qubit and the resonator. Here, the resonator will have a qubit-state dependent frequency shift. Finally, we can exploit the nonlinearity of the resonator by driving it into the bifurcated regime and performing a single- shot measurement of the state of the qubit. I will discuss the design, fabrication, and operation of this system.

Monday, March 21, 2011 11:15AM - 2:15PM –

Session B28 DMP: Focus Session: Carbon Nanotubes and Related Materials: Growth, Sorting and Properties C156

11:15AM B28.00001 Fundamentals and applications of monodisperse carbon-based nanomaterials , MARK HERSAM, Northwestern University — Carbon-based nanomaterials have attracted significant attention due to their potential to enable and/or improve applications such as transistors, transparent conductors, solar cells, batteries, water purification systems, infrastructure materials, drug delivery, and biosensors. This talk will delineate chemical strategies for tuning and enhancing the properties of these promising nanomaterials. For example, we have developed and commercialized a scalable technique for sorting single-walled carbon nanotubes (SWCNTs) by their physical and electronic structure using density gradient ultracentrifugation (DGU). The resulting monodisperse SWCNTs possess unprecedented uniformity in their electronic and optical properties, which enables the fabrication of high performance thin film field-effect transistors, optoelectronic devices, and transparent conductors. The DGU technique also enables multi-walled carbon nanotubes to be sorted by the number of walls, and solution phase graphene to be sorted by thickness, thus expanding the suite of monodisperse carbon-based nanomaterials. By recently extending our DGU efforts to SWCNTs and graphene dispersed in biocompatible polymers (e.g., DNA, poloxamers, etc.), new opportunities have emerged in biomedical applications. Ultimately, the ability to control structure and surface chemistry with sub-nanometer precision enables optimized properties for a diverse range of technologies that employ carbon-based nanomaterials.

11:51AM B28.00002 Electronic separation of dispersed carbon nanotubes in solution by Lorentz forces , CHARISHMA SUBBAIAH, JOSHUA WOOD, JOSEPH LYDING, University of Illinois at Urbana-Champaign — Use of single-walled carbon nanotubes (SWNTs) in industry compatible device applications requires top-down control of SWNT electronic type. Therefore, we develop a technique for SWNT electronic separation, increasing the relative distribution of metallic SWNTs in solution by a magnetically induced Lorentz force. We take solutions of SWNTs in n-methylpyrrolidone and sonicate them, making a disperse solution on which we apply a non-uniform voltage waveform. This waveform generates a magnetic field that couples more strongly with metallic SWNTs than semiconducting SWNTs, due to a higher metallic SWNT magnetic moment, separating the tubes by Lorentz force. By conducting SWNT spectrophotometric measurements in the UV-vis-IR region, we assess the separation effectiveness. From the extracted supernatant solution, we observe a multi-fold absorbance enhancement in the metallic SWNT transition regions [1]. Additionally, the small full-width at half maximum in the absorbance peaks suggests that we are selecting a small number of metallic chiralities in our separation.

[1] Ausman et al., J. Phys. Chem. B. 104, 8911 (2000).

12:03PM B28.00003 Horizontally Aligned Carbon Nanotube Growth: Defects and Film Density[1] , W.D. TENNYSON, D. SHI, E.S. SANCHEZ, J.C. KEAY, M.B. JOHNSON, D.E. RESASCO, University of Oklahoma — Horizontally-aligned single-walled carbon nanotubes (SWNTs) were grown on ST-cut quartz by chemical vapor deposition (CVD). The 0.2-0.3 nm thick thermally evaporated Fe catalyst was patterned using standard liftoff processes both parallel and perpendicular to the $< 2\bar{1}\bar{1}0 >$ quartz surface (the SWNT alignment axis). Enhanced SWNT film density and improved film uniformity were observed by atomic force microscopy (AFM) and scanning electron microscopy (SEM) when water was included with the carbon feed source (ethanol). For SWNT films without water, the SWNT linear density within 1 μm of the catalyst edge was 8 SWNT/μm and down to 2 SWNT/μm at 10 μm from the edge. However, films grown with water exhibited similar linear densities both near and far from the catalyst edge, 6 SWNT/μm. AFM observations suggest that tube-tube interactions during growth contribute to a reduced the linear SWNT density. Aligned SWNTs were observed to terminate when they intersected a non-aligned SWNT. Water-assisted growth reduced the concentration of unaligned SWNTs near the catalyst edge, resulting in a higher fraction of nanotubes extending from the catalyst.

12:15PM B28.00004 Utilizing real time transmission electron microscopy to understand the mechanisms of nanotube nucleation, growth and growth termination , ERIC A. STACH, Purdue University — In order for carbon nanotubes to find widespread application, we must have a deeper understanding of the mechanisms by which they nucleate, growth and cease growth, in an effort to fully control the resulting structures. Here we will describe how we can exploit the unique capabilities of in-situ environmental cell transmission electron microscopy to observe multiple aspects of these processes. With this approach we can directly visualize how the catalysts that mediate nanotube growth respond to various changes in the growth environment, and correlate these changes with the resulting nanotube structures. In the first part of the presentation, we will investigate how dynamic changes in the catalyst morphology are correlated with the termination of growth in vertically aligned SWNT arrays. In particular, we have investigate how the processes of catalyst coarsening, Ostwald ripening and diffusion into the catalyst support can lead to growth termination, and we will describe how changes in the growth feedstock - in particular the incorporation of controlled amounts of water vapor - can alter the catalyst evolution. In the second portion of the presentation, we will describe how altering other aspects of the growth feedstock - in this case the carrier gas, in combination with the water vapor content - can not only affect catalyst morphological evolution, but can also significantly bias the chiral distribution of the resulting nanotubes. We will correlate the changes in growth ambient with a faceting / defacting transition, as well as a resulting change in the rate of Ostwald ripening.

12:51PM B28.00005 In situ diagnostics of the pulsed growth of graphene and carbon nanotubes , DAVID GEOHEGAN, ALEX PURETZKY, JASON READLE, CHRISTOPHER ROULEAU, MURARI REGMI, GYULA ERES, GERD DUSCHER, MINA YOON, Oak Ridge National Laboratory, OAK RIDGE NATIONAL LABORATORY TEAM — Non-equilibrium, pulsed gas delivery and pulsed heating synthesis approaches are used to explore and compare the kinetics and mechanisms of carbon nanotube and graphene growth on metal thin-films. Time-resolved, in situ optical reflectivity of growing nanotubes and graphene reveal the growth kinetics resulting from well-controlled, pulsed fluxes of acetylene by chemical vapor deposition. Alternatively, pulsed laser heating of substrates is used to provide well-defined transient growth temperature profiles for growth by chemical vapor deposition. Pulsed gas fluxes are shown to control the density and diameter of nanotubes in vertically-aligned nanotube arrays with nanoparticles of different size repeatedly nucleating, growing, and terminating growth in accordance with an empirical growth model. The pulsed processing approach is used to grow vertically aligned nanotube arrays with variable density. Research sponsored by the Materials Science and Engineering Division, Basic Energy Sciences, U.S. Department of Energy. A portion of this research was conducted at the Center for Nanophase Materials Sciences, which is sponsored at Oak Ridge National Laboratory by the Scientific User Facilities Division, U.S. Department of Energy.

1:03PM B28.00006 Growth of Ultra-High Density Vertically-Aligned Carbon Nanotube Forests , JOHN ROBERTSON, SANTIAGO ESCONJAUREGUI, MARTIN FOUQUET, BERNHARD BAYER, STEPHAN HOFMANN, Cambridge University — We present a general catalyst design method to synthesise ultra-high density, aligned forests of carbon nanotubes by cyclic deposition and annealing of catalyst thin-films. This leads to nanotube forests with an area density of at least 10^{13} cm^{-2}, over one order of magnitude higher than existing values (Hata 2004, Zhong 2006), and close to the limit of a fully dense forest. The technique consists of cycles of ultra-thin metal film deposition, annealing, and immobilisation. The nanotubes are then grown as normally by Chemical Vapor Deposition. These ultra-dense forests are needed to use carbon nanotubes as vias and interconnects in integrated circuits and as thermal interface materials. Further density increase to 10^{14} cm^{-2} by reducing nanotube diameter is possible.

1:15PM B28.00007 Carbon Nanotubes with Temperature Invariant Viscoelasticity from -196°C to 1000°C , MING XU, Technology Research Association for Single Wall Carbon Nanotubes (TASC); AIST, Japan — Viscoelasticity describes the ability of a material to possess both elasticity and viscosity. Viscoelastic materials, such as rubbers, possess a limited operational temperature range, (e.g., for silicone rubber: -55 to 300°C) above which the material breaks down and below which the material undergoes a glass transition and hardens. This is because molecular motion that is the origin of viscoelasticity is a thermally activated process. We created a viscoelastic material composed from a random network of long interconnected carbon nanotubes that exhibited an operational temperature range from -196°C to 1000°C [1]. The viscoelastic properties (storage modulus, loss modulus, and damping ratio) measured by DMA in N_2 ambient were nearly constant over an exceptionally wide temperature range (-140°C∼600°C). As exemplified by the vibration isolator demonstration, the CNT material showed viscoelasticity beyond the DMA limitation at -190°C (immersed in liquid nitrogen) and at >900°C (exposed to butane torch). And we implemented impact tests at -196°C, 25°C and 1000°C using a steel ball and analyzed the ball tracks. The ball tracks were identical for all cases as observed by SEM and 3-D mapping that suggested unvarying viscoelastic properties across this 1200°C temperature range. We interpret that the thermal stability stems from energy dissipation through the zipping and unzipping of carbon nanotubes at contacts. Quantitatively, the viscoelastic properties by DMA showed that the CNT material possessed similar stiffness (storage modulus 1MPa), higher dissipation ability (loss modulus (0.3MPa) and damping ratio (0.3) than silicone rubber at room temperature. Further DMA characterization from -140°C to 600°C demonstrated temperature invariant frequency stability (0.1-100Hz), the same level of reversible deformation (critical strain 5%) and fatigue resistance (1,000,000 cycles, 100Hz).

1:51PM B28.00008 Understanding Chiral-Selective Growth of Carbon Nanotubes: In-Situ Raman Studies of Individual Single Walled Carbon Nanotube Growth , RAHUL RAO, DAVID LIPTAK, TONYA CHERUKURI, DAYLOND HOOPER, Air Force Research Laboratory, BORIS YAKOBSON, Rice University, BENJI MARUYAMA, Air Force Research Laboratory — In-situ Raman scattering has been used to obtain growth kinetics of individual single-walled carbon nanotubes (SWNTs) using a custom designed cold-wall chemical vapor deposition (CVD) chamber coupled to a Raman spectrometer. Raman spectra are collected during SWNT growth and plots of the G band area versus time are fitted to self-exhausting exponential curves, from which we obtain SWNT growth rates and catalyst lifetimes (time constant). Chiral index assignments are made for several individual SWNTs via analysis of the radial breathing modes. The growth rate of the SWNTs is shown to be proportional to the chiral angle. In addition we find a positive correlation between SWNT length (obtained from SEM analysis) and the growth rate. This confirms the model put forth by Ding *et al.* [1] which links SWNT growth rate to the chiral angle. A growth model based on our results illuminates an as-yet unexplained distribution in the chiral yield of typical CVD-grown nanotubes as being driven by chiral-selective growth kinetics. 2:03PM B28.00009 Dislocation Dynamics in Multishell Carbon Nano-Onions[1] , TRAIAN DUMITRICA, EVGENIYA AKATYEVA, University of Minnesota, JIANYU HUANG, Sandia National Laboratories — Graphite has long served as a model material to understand dislocations. An early work on natural graphite provided factual evidence for the existence of screw dislocations. Recently, synthetic carbon nanostructures began to be explored in order to understand dislocations at the nanoscale. Here we study the 1/2<0001> edge dislocation in nested multishell carbon onions [1]. We report in situ electron microscopy observations of dislocation dissociation and annihilation processes in individual nanometer-sized carbon onions. Essential for these processes is the counterintuitive motion of the 1/2<0001> edge from the outer surface to the inner region, which cross-links or unlinks a large number of shells. The correlation with atomistic simulations and analysis of the energy, which separates the strain and edge components, indicates that this inward glide originates in the reduction of edge with each inwards glide step, an effect specific to the spherical topology.

Monday, March 21, 2011 11:15AM - 2:15PM –
Session B29 GQI: Advances in Ion Trap Quantum Computation C148

11:15AM B29.00001 Trapped ion arrays for quantum simulation[1] , RICHART SLUSHER, Georgia Tech Research Institute — Trapped ions have been used to demonstrate a broad range of quantum information processes with high fidelity[2] and are an obvious choice for quantum simulations. Several quantum simulations have already been demonstrated with ions.[3,4] The present goal is to simulate quantum systems that cannot be achieved with classical computation using more than 20 ions. It is challenging to assemble more than 20 ions in suitable arrays for quantum simulation of arbitrary model systems. Present ion trap based quantum simulations with up to 20 ions are now in progress. This talk describes ion trap micro-fabrication techniques and designs that have the potential to increase the number of coupled ions to the range between 50 and 100 ions. High precision ion traps are fabricated using silicon VLSI techniques on silicon wafers with aluminum electrodes.[5] At the Georgia Tech Research Institute we are designing, fabricating and testing ion trap arrays that will contain and accurately control at least 50 ions in linear chains of equally spaced ions. Large numbers of equally spaced ions have recently been shown[6] to be stable in anharmonic trap potentials that are easily obtained in the micro-fabricated traps. The limits on quantum simulation accuracy due to errors in the ion trap parameters will be discussed.

11:51AM B29.00002 Laser-induced charging of microfabricated ion traps , GUANG HAO LOW, MIT, SHANNON X. WANG, sxwang@mit.edu, NATHAN LACHENMYER, YUFEI GE, PETER HERSKIND, ISAAC L. CHUANG, MIT — Microfabricated ion traps are promising candidates for realizing large-scale quantum computers, but small trap sizes leads to increased sensitivity of the trapped ions to surface effects, including localized charging of the trap electrodes. Laser-induced charging on microfabricated ion traps is studied by monitoring the ion micromotion over a period of up to 20 minutes that a laser is incident on the trap. The ion is trapped 100 μm above the metal surface and the trap is operated at 6K. The lasers used are at 405, 460, and 674 nm, which are relevant atomic transitions in Sr+ ions, and the typical intensity at the trap is 10^{35} photons/sec. The ion's micromotion signal is related to the number of charges created on the trap. A wavelength and material dependence of the charging behavior is observed: lasers at lower wavelengths cause more charging, and aluminum exhibits more charging than copper or gold. We describe the charging dynamic based on a rate equation approach.

12:03PM B29.00003 Superconducting microfabricated ion traps , SHANNON X. WANG, YUFEI GE, JAROSLAW LABAZIEWICZ, MIT, ERIC DAULER, MIT Lincoln Laboratory, KARL BERGGREN, ISAAC L. CHUANG, MIT — We fabricate superconducting ion traps with niobium and niobium nitride and trap single ^{88}Sr ions at cryogenic temperatures. The superconducting transition is verified and characterized by measuring the resistance and critical current using a 4-wire measurement on the trap structure, and observing change in the rf reflection. The lowest observed heating rate is 2.1(3) quanta/sec at 800 kHz at 6 K and shows no significant change across the superconducting transition, suggesting that anomalous heating is primarily caused by noise sources on the surface. This demonstration of superconducting ion traps opens up possibilities for integrating trapped ions and molecular ions with superconducting devices.

12:15PM B29.00004 Microfabricated surface trap for scalable ion-photon interfaces , PETER HERSKIND, SHANNON WANG, MOLU SHI, YUFEI GE, MARKO CETINA, ISAAC CHUANG, MIT — The combination of high-finesse optical mirrors and ion traps is attractive for quantum light-matter interfaces, which represents an enabling resource for large-scale quantum information processing. We report on a scalable approach to ion-photon interfaces based on a surface electrode ion trap microfabricated on top of a highly reflective mirror. An aperture in the central electrode, directly below the ion, allows the mirror to interact with the ion. The integration of such mirrors is scalable as several mirror apertures may be added with no additional overhead for fabrication. Furthermore, the design provides a path for reaching the strong coupling regime of Cavity QED, where an ion-cavity system can be realized by adding a small concave mirror above the trap mirror. The quality of the mirror is not significantly compromised in the course of fabrication and we have measured an increase in losses for light at 422 nm at the level of 100 ppm. The functionality of the mirror has also been verified by light collection from, and imaging of, the ion 169 ± 4 μm above the mirror. Despite its proximity, we find that the presence of the mirror does not perturb the trap. Trapping is stable with laser cooled ion lifetimes of several hours and we observe only minimal sensitivity to laser-induced charging. Furthermore, through operation of the trap in a cryostat at 15 K the heating rate of the ion is a the level of only 0.1 quanta/ms.

12:27PM B29.00005 Ion crystal transducer for strong coupling between single ions and single photons , LUCAS LAMATA, Max-Planck-Institut fuer Quantenoptik, DAVID LEIBRANDT, National Institute of Standards and Technology, ISAAC CHUANG, Center for Ultracold Atoms, Department of Physics, MIT, IGNACIO CIRAC, Max-Planck-Institut fuer Quantenoptik, MIKHAIL LUKIN, ITAMP, Harvard-Smithsonian Center for Astrophysics, and Department of Physics, Harvard University, VLADAN VULETIC, Center for Ultracold Atoms, Department of Physics, MIT, SUSANNE YELIN, ITAMP, Harvard-Smithsonian Center for Astrophysics, and Department of Physics, University of Connecticut — A quantum interface between single photons and single ions in an ion crystal is proposed. The coupling between single photon and single particle is collectively enhanced via a collective internal ion state and a phonon state. Applications for this scheme include single-photon generation, a memory for a quantum repeater, and a deterministic photon-photon or photon-ion entangler.

12:39PM B29.00006 Temperature driven structural phase transition for trapped ions , ZHE-XUAN GONG, GUIN-DAR LIN, LU-MING DUAN — A Wigner crystal formed with trapped ion can undergo structural phase transition, which is determined only by the mechanical conditions on a classical level. Instead of this classical result, we show that through consideration of quantum and thermal fluctuation, a structural phase transition can be solely driven by change of the system's temperature. We determine a finite-temperature phase diagram for trapped ions using the renormalization group method and the path integral formalism, and propose an experimental scheme to observe the predicted temperature-driven structural phase transition, which is well within the reach of the current ion trap technology.

12:51PM B29.00007 Differential Stark shift measurement of clock states of Yb+ using an optical frequency comb , QUDSIA QURAISHI*, DAVID HAYES, DAVID HUCUL, DZMITRY MATSUKEVICH, SHANTANU DEBNATH, SUSAN CLARK, CHRIS MONROE, JQI, Univ of Maryland Dept of Physics and NIST — Quantum information processing with trapped ions has traditionally involved state preparation, manipulation (eg. quantum gates) and detection using CW lasers. Quantum gates implemented with ions typically involve optical Raman transitions between two atomic levels. An optical frequency comb, emitted by a pulsed laser, is an excellent tool for bridging atomic frequency differences. Previously, we demonstrated quantum gates and separately, ultrafast spin manipulation, using pulsed lasers [1,2]. Unlike the CW case, employing pulsed lasers has the marked advantage of both low spontaneous emission and low AC Stark shifts, because the high powers available from pulsed lasers allow for larger detunings from optical resonance. Here, we show both experimentally and theoretically the scaling of the differential Stark shift with detuning (6 THz to 20 THz) of the Raman fields, achieving values of 10^{-3} of the Rabi frequency. [1] D. Hayes, et al., Phys. Rev. Lett. 104, 140501 (2010) [2] W. C. Campbell, et al., Phys. Rev. Lett. 105, 090502 (2010). *Currently NRC postdoc with SEDD, ARL, Adelphi, MD. Support: DARPA OLE under ARO contract, IARPA under ARO contract, NSF PIF Program, NSF PFC at JQI and *IC Postdoc administered by the NGA.

1:03PM B29.00008 "Tack" ion trap for efficient photon collection.[1] , CHEN-KUAN CHOU, GANG SHU, NATHAN KURZ, THOMAS NOEL, JOHN WRIGHT, BORIS BLINOV, University of Washington — Trapped, laser-cooled atoms and ions produce intense fluorescence of the order 10^7 – 10^8 photons per second. Detection of this fluorescence enables the efficient measurement of the quantum state of qubit based on the trapped atoms. Thus, it is desirable to collect a large fraction of the (isotropically emitted) photons to make the detection faster and more reliable. Additionally, efficient fluorescence collection can improve the speed and fidelity of remote ion entanglement and quantum gates. Refractive and reflective optics, as well as optical cavities, and, recently, bare multimode optical fibers have all been used to collect the trapped ion fluorescence with up to 10% efficiency. Here we show a novel ion trap design that incorporates a high numerical aperture metallic spherical mirror as the integral part of the trap itself (the RF electrode) which enables up to 35% solid angle collection of trapped ion fluorescence. The movable central needle-shaped electrode of this "tack" trap allows precise placement of the ion at the focus of the spherical mirror. We also study the properties of the images formed by the spherical mirror and comment on possible methods for aberration correction. Owning to the simplicity of its design, this trap structure can be adapted for mircofabrication and integration into more complex trap architectures.

[1]Supported by National Science Foundation and IARPA

1:15PM B29.00009 Towards laser cooling of a LC-resonator via trapped ions , SOENKE MOELLER, NIKOS DANIILIDIS, UC Berkeley, BOYAN TABAKOV, University of New Mexico, AARON BRADLEY, HARTMUT HAEFFNER, UC Berkeley — We will discuss our experimental progress towards coupling strings of trapped ions to an LC-resonator. The goal of our experiments is to cool the resonant mode of a superconducting high-quality resonant circuit to ultra-low temperatures. By continuously laser cooling a crystal of ions coupled to the circuit, energy is removed from the resonator. For quality factors on the order of 10^5, the time-scale of the environment-to-mode coupling, i.e. the time for the resonant mode of the LC-resonator to thermally equilibrate, can be on the order of a second. Thus, engineering an ion-resonator coupling of 10$\sim$kHz results in a reduction of the electronic temperature by four orders of magnitude as compared to the ambient temperature of the resonator. The expected temperatures below 1mK are extremely low approaching even the vibrational ground state of the oscillator mode, enabling novel quantum electronics applications in the solid state.

1:27PM B29.00010 Micro-Fabricated Surface Electrode Y-Junction Ion Traps , DAVID MOEHRING, MATTHEW BLAIN, ROBERT COOK, KEVIN FORTIER, RAYMOND HALTLI, CLARK HIGHSTRETE, DANIEL STICK, CHRIS TIGGES, Sandia National Laboratories — We will present results of the design, operation, and performance of two different Y-Junction surface ion micro-traps fabricated at Sandia. Recent progress in the testing of the micro-traps will be highlighted, including the successful shuttling of single and multiple ions, ion-chain splitting and recombination, and the validation of simulations with experiments. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

1:39PM B29.00011 Emergent effective spin models in ion-trap-based quantum simulators[1] , CHENG-CHING JOSEPH WANG, Georgetown University, UMD AND JQI COLLABORATION — We show how effective spin models emerge from the interaction of laser light with the ions in a linear Paul trap. It has been shown that quantum Ising models can be studied by adiabatic state evolution in a transverse magnetic field which is ramped from large to small values. The standard proof involves and adiabatic elimination of the phonons in the Lamb-Dicke regime. We discuss here that such an elimination can be problematic due to the inherent entanglement between the spins and the phonons. If the magnetic field is ramped sufficiently fast, one can show that all quantum state probabilities measured along the Ising field axis are independent of the phonons. But if the field is ramped more slowly, then the phonons and spins become entangled. Nevertheless, the main effects are to change the spin entanglement of the quantum states rather than the probabilities of the different states in the wavefunction. We present numerical evidence to illustrate these points.

[1]This work was supported under ARO grant number W911NF0710576 with funds from the DARPA OLE Program.

1:51PM B29.00012 Individual addressing of trapped ions using a MEMS beam steering system , TAEHYUN KIM, CALEB KNOERNSCHILD, EMILY MOUNT, STEPHEN CRAIN, RACHEL NOEK, DANIEL GAULTNEY, PETER MAUNZ, JUNGSANG KIM, Duke University — Implementation of single-qubit and two-qubit quantum gates in a long linear chain of trapped ions generally requires the manipulation of qubits stored in individual ions using a set of laser beams. Individual addressing has been demonstrated with acousto-optic and electro-optic deflectors, by using the Zeeman shift due to a magnetic field gradient, and by separating the ions. Microelectromechanical system (MEMS) technology offers an alternative approach using micromirrors to focus laser beams on individual ions. Advantages of this approach are its broadband optical performance and scalability to more beams and multiple dimensions. We report progress towards integrating a MEMS beam steering system with an Yb ion trap experiment. The MEMS system will direct an ultraviolet beam with waist of $\sim$1.5μm at the ions across a 20μm range. For a designed ion separation of 4um this allows addressing up to 5 ions. The far-detuned laser will induce an AC Stark shift on a single ion in the chain, and the induced phase shift can be measured by Ramsey spectroscopy.

2:03PM B29.00013 Scalable micro-scale optics for planar ion traps , TRUE MERRILL, Georgia Institute of Technology, HARLEY HAYDEN, CHIEN-SHING PAI, Georgia Tech Research Institute, RACHEL NOEK, JUNGSANG KIM, Duke University, CURTIS VOLIN, Georgia Tech Research Institute — Efficient collection of fluorescence from atomic ions is required for fast high-fidelity measurement in ion trap quantum information processing. Conventional multi-element lens stacks can achieve photon collection efficiencies as high as 5%, however these systems typically have restricted field-of-view and are not generally scalable to image large arrays of ions. We report the development and fabrication of planar traps with integrated micro-scale spherical mirrors with an expected 15% collection efficiency. The mirror shape is controlled with a combination of silicon wet-processing and polishing techniques while maintaining a surface roughness below $\sigma_{RMS} < 10$ nm. The design allows for multiple integrated mirrors in a single chip allowing for the simultaneous measurement of many ions over a 10 mm object space.

Monday, March 21, 2011 11:15AM - 2:15PM –
Session B30 DCMP: Graphene: Transport and Correlations C147/154

11:15AM B30.00001 Magnetoconductance Oscillations in High-Mobility Suspended Bilayer and Trilayer Graphene , WENZHONG BAO, ZENG ZHAO, HANG ZHANG, GANG LIU, PHILIP KRATZ, LEI JING, JAIRO VELASC, DMITRY SMIRNOV, CHUN NING LAU, DEPARTMENT OF PHYSICS, UNIVERSITY OF CALIFORNIA, RIVERSIDE, RIVERSIDE, CA 92521 TEAM, NATIONAL HIGH MAGNETIC FIELD LABORATORY, TALLAHASSEE, FL 32310 COLLABORATION — We observed pronounced magnetoconductance oscillations on suspended bilayer and trilayer graphene devices with mobilities up to 270,000 cm^2/Vs. For bilayer devices, we observe conductance minima at all integer filling factors n between 0 and -8, as well as a small plateau at n=1/3. For trilayer devices, we observe features at n=-1, -2, -3 and -4, and at n$\sim$0.5 that persist to 4.5K at B=8T. All of these features persist for all accessible values of Vg and B, and could suggest the onset of symmetry breaking of the first few Landau (LL) levels and fractional quantum Hall states.

11:27AM B30.00002 Novel Excitonic Effects in Graphene and Bilayer Graphene[1] , LI YANG, Department of Physics, Washington University in St. Louis — Through first-principles calculations with many-body effects included, we have revealed unique excitonic effects in the high-frequency regime (10 $\sim$ 20 eV) of optical spectra of graphene and bilayer graphene (BLG). Despite their different symmetries, the parallel σ and π* bands result in enhanced excitonic effects in such two-dimensional semimetals; one narrow resonant exciton is discovered to form an isolated peak below the prominent absorption continuum with a surprisingly large binding energy, 270 meV in graphene and 80 meV in BLG. Moreover, because of its extremely weak resonant character, this exciton exhibits a bound electron-hole wave function.

[1]Computational resources are provided by Lonestar of Teragrid at the Texas Advanced Computing Center.

11:39AM B30.00003 Metal-insulator transitions in graphene , MARIO AMADO, Universidad Complutense de Madrid, Spain, ENRIQUE DIEZ, Universidad de Salamanca, Spain, FRANCESCO ROSSELLA, VITTORIO BELLANI, Universita degli Studi de Pavia, Italy, DAVID LOPEZ-ROMERO, CT-ISOM Universidad Poletcnica de Madrid, Spain, DUNCAN MAUDE, Laboratoire national des champs magnetiques intenses, Grenoble, France — We investigate the metal-insulator quantum phase transitions that appear in the quantum Hall effect, namely the plateau-insulator and plateau-plateau transitions We have performed magnetotransport experiments with the magnetic field as the driving parameter in the temperature range from 4K up to 230K and magnetic fields up to 28T. The analysis of the temperature dependence of the Hall and longitudinal resistivity reveals the non-universality of the critical exponent for the metal-insulator transition when varying the density of carriers. We also find relevant discrepancies with recent works concerning the value of the critical exponent of the plateau-plateau transition.

11:51AM B30.00004 Conductivity of Coulomb interacting massless Dirac particles in graphene[1]

, VLADIMIR JURICIC, Lorentz-Instituut for Theoretical Physics, Universiteit Leiden, The Netherlands, OSKAR VAFEK, National High Magnetic Field Laboratory and Department of Physics, Florida State University, USA, IGOR HERBUT, Department of Physics, Simon Fraser University, Canada — The ac conductivity of the Coulomb interacting Dirac fermions in graphene is considered in the collisionless regime using a variant of the dimensional regularization with the spatial dimension $D = 2 - \epsilon$ for $\epsilon > 0$. We show that this regularization procedure preserves the Ward-Takahashi identity associated with the charge conservation [1], and as such it can serve as a consistent regularization of the entire interacting field theory. As a consequence of the explicitly preserved $U(1)$ gauge symmetry, the dimensional regularization yields the same result for the Coulomb correction to the conductivity when calculated using the current-current and the density-density correlators, which is, nevertheless, different than the ones previously reported in the literature. References: [1] V. Juricic, O. Vafek, and I. F. Herbut, ArXiv:1009.3269 (Phys. Rev. B, in press).

12:03PM B30.00005 Plasma Excitations of Dressed Dirac Electrons in Graphene[1]

, OLEKSIY ROSLYAK, Hunter College, CUNY, DANHONG HUANG, AFRL, Kirkland Airforce Base, ANDRII IUROV, GODFREY GUMBS, Hunter College, CUNY — The dispersion relation for the collective plasma excitations of optically dressed Dirac electrons in single and double graphene layers is calculated in the random-phase approximation. The presence of circularly polarized light gives rise to an energy gap ϵ_g between the conductance and valence bands. The value of ϵ_g may be adjusted by varying the frequency and intensity of the light which could be sizable compared to that which is generated by spin-orbit coupling or sub-lattice symmetry breaking. We present numerical results for the dispersion relation for plasma excitations for various energy gaps and separation between graphene layers. The induced ϵ_g opens up a gap in the particle-hole continuum thus allowing plasmon excitations of short wave-length. An optical and acoustic phonon-like modes are obtained in the double layer configuration. Those are very sensative to the induced energy gap and symmtry breaking between the layers.

[1]This work was supported by contract # FA 9453-07-C-0207 of AFRL and the Air Force Office of Scientific Research (AFOSR).

12:15PM B30.00006 Variational approach to the excitonic phase transition in graphene[1]

, FERNANDO SOLS, Universidad Complutense de Madrid, JAVIER SABIO, FRANCISCO GUINEA, ICMM-CSIC (Madrid) — We analyze the Coulomb interacting problem in undoped graphene layers by using an excitonic variational ansatz. By minimizing the energy, we derive a gap equation which reproduces and extends known results. We show that a full treatment of the exchange term, which includes the renormalization of the Fermi velocity, tends to suppress the phase transition by increasing the critical coupling at which the excitonic instability takes place.

[1]Supported by MICINN (Spain), FIS2008-00124 and FIS2010-21372.

12:27PM B30.00007 First-principles study of polarization in graphene

, PRIYAMVADA JADAUN, YUGUI YAO, LEONARD F. REGISTER, QIAN NIU, SANJAY BANERJEE, The University of Texas at Austin — The emergence of polarization in monolayer graphene is investigated using first-principles calculations. We try to understand electronic polarization calculated using Berry phase technique as well as ionic polarization when in-plane symmetry is broken within the graphene lattice. The effect of underlying substrate as well as stress on this symmetry breaking is also explored.

12:39PM B30.00008 Graphene K and K' States at the Dirac Point

, LAWRENCE SNYDER, CHRISTOPHER WELLS, The University at Albany - SUNY, Chemistry Department — The graphene band structure states at the K and K' points and the Fermi level, the Dirac point, computed when a (1x1) unit cell is employed, fall at the gamma point when a (3x3) unit cell is employed. These states at the gamma point of the Brillouin zone for the (3x3) unit cell have a zero phase factor and are conveniently represented as molecular orbitals of pi electrons. These states are illustrated and discussed.

12:51PM B30.00009 Edges states and anomalous Aharonov-Bohm-type oscillation in anti-dot lattice graphenes formed by nanoporous alumina template mask

, J. HARUYAMA, T. SHIMIZU, J. NAKAMURA, Aoyama Gakuin University, T. MATSUI, H. FUKUYAMA, Tokyo University — Edge states of graphene with a zigzag structure theoretically have extremely high electronic density of states (EDOS), electron localization, and polarized spin transport as well [1]. However, few studies have reported on the experimental observation of edge states and related quantum phenomena. Here, we report on the nonlithographic and low-damage fabrication of honeycomb-like nanopore arrays (anti-dot lattice) on thin multilayered graphenes utilizing nanoporous alumina template masks [2]. We confirm the presence of high EDOS at the edges of the nanopores using STM observation. We find periodic magnetoresistance oscillations with two different periods over a wide magnetic field range (anomalous Aharonov-Bohm-type effect [3]) (e.g., high fields at where the diameter of cyclotron-motion electrons is smaller than diameter of the nanopore). These findings clearly suggest the presence of localized electrons and edge states at the nanopore edges of graphene.

1:03PM B30.00010 Snake orbits in graphene underneath an array of $Ni_{0.80}Fe_{0.20}$ nano-dots

, ADAM NEAL, JIANGJIANG GU, TONY LOW, PEIDE YE, Purdue University — The existence of snake orbits in 2DEG formed at AlGaAs/GaAs heterojunction is theoretically predicted and experimentally demonstrated by creating a spatially inhomogeous magnetic field [1]. Due to its ambipolar nature, graphene opens up new possibilities to investigate snake orbits and other exotic phenomena by simply creating a p-n junction in a homogenous magnetic field. We have fabricated periodic arrays of $Ni_{0.80}Fe_{0.20}$ nano-dots on graphene with the dot diameter of 80 nm or 150 nm and the period of 160 nm or 300 nm, respectively. A quasi-periodic magneto-resistance oscillation is observed in the low-temperature magneto-transport measurement. We ascribe it to Aharonov-Bohm oscillations induced by snake orbits of carriers underneath the nano-dots. Due to the high work-function of $Ni_{0.80}Fe_{0.20}$, it is possible to generate local circular n-p and p–p junctions underneath the nanodots, which form the snake orbits of carriers in an external applied magnetic field. Dependence of these oscillations on temperature and carrier density and simulation work on snake orbits will be presented.

1:15PM B30.00011 Metal Electrode Effect on Electronic Transport through Graphene

, CHENG GONG, WEICHAO WANG, GEUNSIK LEE, BIN SHAN, KYEONGJAE CHO, Department of Materials Science and Engineering, The University of Texas at Dallas — Metal-graphene contact is one of key issues in graphene-based device applications. In this work, electronic transport through metal/graphene/metal end-contact structures with zigzag interface is investigated by first-principles non-equilibrium Green's function method. Double-dips transmission characteristics in Palladium/Graphene/Palladium are observed with a common positive dip and varied negative dips for graphene of different lengths. Transmission through the structure is suppressed by mode mismatch among different carbon localities perturbed by interface hybridization, yet intensities of the suppression at two dips are featured by distinctive channel potential profiles. Finite transmissions at Fermi level are attributed to both evanescent and propagating modes. This study benefits the understanding of the origins of contact resistance at metal/graphene interfaces.

1:27PM B30.00012 Casimir Interaction Between Graphene and Planar Systems[1] , DAVID DROSDOFF, LILIA WOODS, University of South Florida — Casimir forces become increasingly important as systems become miniaturized. Such fluctuation forces are studied between graphene, a potential future substitute for silicon based electronics, and other materials. Because graphene is one atomic layer thick, the Casimir force is relatively weak. Yet its singular electronic properties give rise to an attraction between graphene layers in the order of a factor of $\alpha \approx 1/137$ times smaller than the interaction between two ideal metal plates. For the case of the interaction between graphene and metamaterials, a strong reduction in the Casimir attraction or even repulsion may be found if the metamaterial is mostly magnetic in nature. Metamaterials with strong magnetic responses in the optical range may soon be possible as the rapid development of metamaterials continue. Other graphene configurations with metals and metamaterials are also studied.

1:39PM B30.00013 Hot electron dynamics and Schwinger mechanism in graphene[1] , MENG-CHIEH LING, JÖRG SCHMALIAN, Ames Laboratory and Iowa State University — We investigate the nonlinear dc conductivity of graphene by explicitly solving the Boltzmann equation with relaxation and particle-hole pair production contributions and obtain the non- equilibrium electronic distribution function. First, by considering isotropic elastic electron-phonon scattering, we show that, in the limit of weak external electric field one recovers Ohm's law, while above a threshold field $E = (k_B T)/(ev_F\tau)$ the dc conductivity varies as the inverse of the external electric field. In particular, we obtain an explicit form for the scaling of the conductivity with respect to E/T. We then investigate how this result is affected by the Schwinger mechanism, which leads to particle-hole creation and, consequently, to interband transitions.

1:51PM B30.00014 Band structures of bilayer graphene superlattices , SI WU, MATTHEW KILLI, ARUN PARAMEKANTI, University of Toronto — We have studied the electronic band structures of bilayer graphene (BLG) superlattices. In BLG, there are two distinct types of superlattice modulations - chemical potential modulations and electric field induced gap modulations. We have solved energy bands for one- and two-dimensional superlattices for both kinds of modulations. We found, in particular, for a 2D superlattice with gap modulation, that the energy gap is one order smaller than that in a uniform electric field. The problem of a single charged impurity in gated BLG is also studied. Implications of our results on transport experiments are discussed.

2:03PM B30.00015 Giant inelastic tunneling in epitaxial grapheme mediated by localized states , KEES FLIPSE, KEVIN RUIT VAN DE, Eindhoven University of technology, JIRI CERVENKA, Academy of Sciences of the Czech Republic — Local electronic structures of nanometer-sized patches of epitaxial grapheme and its interface layer with SiC(0001) have been studied by atomically resolved scanning tunneling microscopy and spectroscopy. Localized states belonging to the interface layer of the graphene/SiC system show to have essential influence on the electronic structure of grapheme. Giant enhancement of inelastic tunneling, reaching 50% of the total tunneling current, has been observed at the localized states on a nanometer-sized graphene monolayer surrounded by defects.

Session B31 DMP: Focus Session: van der Waals Bonding in Advanced Materials: Applications to Systems and Behaviors C145

11:15AM B31.00001 Physisorbed molecules: How their frictional and diffusive properties impact lubricity[1] , JACQUELINE KRIM, North Carolina State University — Friction and its consequences are of great concern from both a national security and quality-of-life point of view, and the economic impact of energy efficiency, wear, and manufacturing cannot be underestimated [1]. Lubrication schemes for many macroscopic applications have been solved, but an era of science and engineering is emerging where control of mechanical and electrical systems at the atomic level will be required [2]. A fundamental understanding of the dissipative and frictional properties of weakly adsorbed films, which are ubiquitous in these systems, is key to a vast range of emerging applications. This talk will begin with a discussion of how diffusive and frictional properties of adsorbed atoms and molecules governed by van der Waals interactions can be measured experimentally [3]. Selected example of how atomic scale mobility in physisorbed materials, even at very low coverage, can directly impact friction, tribological performance and/or device viability will then be presented, for systems spanning Micro- and Nano- ElectroMechanical Systems to avalanches in granular materials [4,5].

11:51AM B31.00002 Edge-dependent Static Friction of Adsorbed van der Waals Islands[1] , NICOLA VARINI, Udine Univ., Int. School Adv. Stud. (SISSA), CNR-IOM DEMOCRITOS, FURIO ERCOLESSI, Udine Univ., UGO TARTAGLINO, ANDREA VANOSSI, Int. School Adv. Stud. (SISSA), CNR-IOM DEMOCRITOS, ERIO TOSATTI, Int. School Adv. Stud. (SISSA), CNR-IOM DEMOCRITOS, ICTP — Rare gas islands adsorbed through van der Waals forces on metal surfaces do not slide freely, but exhibit static friction in QCM experiments. Static friction appears, unexpectedly, even for incommensurate and defect-free crystal surfaces, where sliding should be frictionless. Via atomistic simulations of Kr islands on Au(111), we show that the island edges may be the ultimate culprits. Adsorbate sliding requires the flow of solitons - tiny density and corrugation modulations with the beat periodicity between the two periodicities. For an island, we find an edge-originated energy barrier that blocks the soliton flow, keeping the island pinned. As the static friction force is reached, the barrier vanishes at one point on the edge, and new solitons enter the island, which becomes depinned. Unsurprisingly, we find that low surface corrugation and high temperature facilitate this edge depinning. However, the island's thermal expansion is large and leads to changeable commensurability upon heating, which gives rise to the possibility of re-entrant static friction.

12:03PM B31.00003 Why viscosities of Ne and Kr monolayers are so different on the Pb(111) surface[1] , RUQIAN WU, YANNING ZHANG, University of California, Irvine, V. BORTOLANI, Università di Modena e Reggio Emilia, Italy — Adsorption and segregation of Ne and Kr monolayers on the Pb(111) surface are examined through density functional calculations to understand the puzzling experimental observations of different tribological properties of these two rare gases. Theoretical results reveal weak but non-negligible interaction between rare gas and Pb(111), manifested as charge polarization and orbital intermixing. Because of its large atomic size, orbital polarizability and wave function extension, Kr binds with Pb(111) more strongly than does Ne. The activation energy of Kr segregation from the ground state hcp site to the metastable fcc site is 3.8 meV, substantially larger than that of Ne, 2.1 meV. This explains the drastic difference between the viscosities of Ne and Kr over Pb(111), observed at low temperatures using a quartz-crystal microbalance technique.

12:15PM B31.00004 Tribological Characterization of Nanoclustered Lead Films , KEELEY M. STEVENS, JACQUELINE KRIM, North Carolina State University — For thin films of Pb on Ti, a system which does not wet, it is known that when studying coverages below the percolation transition measurement of surface friction via a sliding gas monolayer is an effective probe of electronic structure for the isolated lead nanoclusters.[1] This technique is capable of studying superconductors as they pass through the transition temperature. Motivated by on-going reports of quantum size effects in thin lead films grown on Si(111)[2] and Cu(001),[3] we examine the issue of nitrogen adsorption[4] onto such nanostructured films. Funding provided by NSF DMR.

12:27PM B31.00005 van der Waals bonded materials: vanadium pentoxide bulk structure , ELISA LONDERO, ELSEBETH SCHROEDER, Chalmers University of Technology — In this work we present a computational study of the layered oxide structure of vanadium pentoxide (V_2O_5) using the vdW-DF functional (M. Dion et al., Phys.Rev.Lett. **92**, 246401 (2004); T. Thonhauser et al., Phys. Rev. B **76**, 125112 (2007); K. Lee et al., Phys. Rev. B **82**, 081101 (2010)) which has proven to be able to capture the essential van der Waals interactions across matter separated by charge voids. We show that these forces play a substantial role for the description of the lattice constants and cohesion of this compound. In addition we document and handle a sensitivity to numerical noise in the evaluation of some exchange versions used with nonlocal correlation.

12:39PM B31.00006 Stacking and Registry Effects in Layered Materials: The Case of Hexagonal Boron Nitride , LEEOR KRONIK, NOA MAROM, Weizmann Institute of Science, JONATHAN BERNSTEIN, Tel Aviv University, JONATHAN GAREL, Weizmann Institute of Science, ALEXANDRE TKATCHENKO, Fritz Haber Institut, ERNESTO JOSELEVICH, Weizmann Institute of Science, ODED HOD, Tel Aviv University — The interlayer sliding energy landscape of hexagonal boron nitride (h-BN) is investigated via a van der Waals corrected density functional theory approach. It is found that the main role of the van der Waals forces is to anchor the layers at a fixed distance, whereas the electrostatic forces dictate the optimal stacking mode and the interlayer sliding energy. A nearly free-sliding path is identified, along which band gap modulations of 0.6 eV are obtained. We propose a simple geometric model that quantifies the registry matching between the layers and captures the essence of the corrugated h-BN interlayer energy landscape. The simplicity of this phenomenological model opens the way to the modeling of complex layered structures, such as carbon and boron nitride nanotubes. Reference: Marom et al., Phys. Rev. Lett. 105, 046801 (2010).

12:51PM B31.00007 van der Waals binding and band structure effects in graphene overlayers and graphane multilayers[1] , PER HYLDGAARD, JOCHEN ROHRER, Chalmers University of Technology — We study graphene formation (by selective Si evaporation) and adhesion on SiC surfaces as well as stacking and binding of graphane multilayers [1] using a number of versions of the van der Waals Density Functional (vdW-DF) method [2] and plane-wave density functional theory calculations. For the graphene/SiC systems and for the graphane multilayers we document that the bonding is entirely dominated by van der Waals (vdW) forces. At the same time we find that dispersive forces acting on the layers produce significant modifications in the graphene and graphane band structure. We interpret the changes and discuss a competition between wave function hybridization and interaction with the charge enhancement (between the layers) that results from density overlap.

1:03PM B31.00008 Noble gas adsorption on carbon nanotubes: insight from a van der Waals density functional study , DE-LI CHEN, WISSAM AL-SAIDI, KARL JOHNSON, University of Pittsburgh — Adsorption of nobel gases (Ar, Kr, Xe) on metallic and semiconducting carbon nanotubes (CNTs) is investigated using the van der Waals density functional (vdW-DF) developed by the Lundqvist and Langreth groups. Standard local and semi-local density functional methods do not describe nonlocal dispersive forces and fail in these systems. We found that the noble gases are underbound or even unbound with the generalized gradient approximation, while the bonding distance is underestimated at the local density approximation level of theory. In contrast, the vdW-DF approach gives considerable improvement in the description of the adsorption energies. We found no difference in the adsorption between the metallic and semiconducting nanotubes, indicating that the adsorption energies for rare gases on carbon nanotube are not strongly influenced by differences in the electronic structure of the nanotubes. The adsorption energies predicted from classical potentials are smaller than those from vdW-DF calculations by about 10-35%.

1:15PM B31.00009 Water droplet distributions in pure and functionalized single walled carbon nanotubes , CALLEN JOHNSON, The University of Tulsa, SUPRIYO GHOSH, XENIA TOMBOKAN, Bruker Corporation, PARAMESWAR HARI, The University of Tulsa, BRUKER CORPORATION TEAM, UNIVERSITY OF TULSA TEAM — In this study we investigated water droplet distribution in (1-2 nm diameter and 30 μs long) single walled carbon nanotubes (SWCNT) using time domain nuclear magnetic resonance (NMR). Annealing SWCNTs at 400°C resulted in a carbon nanotube with closed ends. We attached various amounts of water on the annealed SWCNT samples and measured the NMR spin-spin relaxation (T_2) distribution profile. The T_2 distributions were analyzed using the inverse Laplace transform to estimate the amount of water attached to the SWCNT. We performed NMR measurements on water distributions in pure CNT and functionalized CNT with OH and COOH radicals. The T_2 distribution curves for pure and functionalized SWCNTs show significant difference in water attachment. We also studied water distribution profile with the SWCNTs annealed at 800°C. Annealing at 800°C opens the ends of the SWCNTs. T_2 distribution curves at 400°C and 800°C will be compared to obtain the amount of free water attached on the outer and inner surface of pure and functionalized SWCNTs.

1:27PM B31.00010 How do hybrid functionals, dispersion interactions and quantum nuclei affect the structure of liquid water? , ZHAOFENG LI, ROBERT A. DISTASIO JR., ROBERTO CAR, Princeton University, XIFAN WU, Temple University — We report *ab-initio* molecular dynamics simulations of liquid water at STP and at the volume corresponding to experimental equilibrium density. These simulations are based on the hybrid functional PBE0 for the electrons and include approximate dispersion interactions according to Ref [1]. Nuclear quantum corrections were included as estimated by Ref [2]. We find that all of these components are important to significantly improve the agreement of the simulated structure with recent experimental analyses based on neutron and X-ray diffraction[3] and on NMR experiments. 1:39PM B31.00011 Density, structure and dynamics of water: the effect of Van der Waals interactions[1] , MARIVI FERNANDEZ-SERRA, JUE WANG, Stony Brook University, GUILLERMO ROMAN, Universidad Autonoma de Madrid, EMILIO ARTACHO, University of Cambridge, JOSE SOLER, Universidad Autonoma de Madrid — We present a DFT AIMD study of liquid water using several GGA functionals as well as the van der Waals density functional (vdW-DF) of Dion et al. [PRL 92, 246401(2004)]. As expected, we find that the density of water is grossly underestimated by GGA functionals. When a vdW-DF is used, the density improves drastically and the experimental diffusivity is reproduced without the need of thermal corrections. We analyze the origin of the density differences between all the functionals. We show that the vdW-DF increases the population of non-H-bonded interstitial sites, at distances between the first and second coordination shells. However, it excessively weakens the H-bond network, collapsing the second coordination shell. This structural problem is partially associated to the choice of GGA exchange in the vdW-DF. We show that a different choice for the exchange functional is enough to achieve an overall improvement both in structure and diffusivity. Jue Wang et al. J. Chem. Phys, 133, (2010).

1:51PM B31.00012 Van der Waals Density Functional Simulations of Liquid Water[1] , JUN WU, CUI ZHANG, GIULIA GALLI, FRANCOIS GYGI, University of California Davis, Davis, CA95616 — We compare two versions of van der Waals density functionals (DRSLL [1], LMKLL [2]) in electronic structure computations of weakly bonded systems. The functionals are implemented in the Qbox code [3] and are verified by reproducing published binding energies and equilibrium separations of several weakly bonded dimers. Vibrational frequencies of the water monomer and dimer computed using the above van der Waals functionals are not improved compared to PBE results. We present results of molecular dynamics simulations of liquid water using the DRSLL and LMKLL functionals and compare radial distribution functions with corresponding results obtained with GGA functionals.

Session B32 DMP: Focus Session: Optical Properties of Nanostructures and Metamaterials II

C144

11:15AM B32.00001 ABSTRACT WITHDRAWN –

11:27AM B32.00002 Optical Properties of Metal-Dielectric-Metal (MDM) Nanoantennas , BHUWAN JOSHI, Kent State University, XUEJIN WEN, Ohio State University, KAI SUN, University Of Michigan, WU LU, Ohio State University, QI-HUO WEI, Kent State University — We present a new design of plasmonic nanoantennas and study their optical properties. The nanoantennas consist of two metal blocks (cuboids or cylinders) stacked vertically with a dielectric spacer. The results from numerical simulations show that such plasmonic nanoantennas exhibit various cavity resonance modes which produce sharp peaks in the near field spectra and leave dips in the far field scattering spectra. Nanofabrication and characterization of these nanoantennas will also be presented in the talk.

11:39AM B32.00003 Designing broadband plasmonic nanoantennas for ultrasensing , ZHENHUAN YI, KAI WANG, DMITRI V. VORONINE, ANDREW TRAVERSO, ALEXEI SOKOLOV, Institute for Quantum Science and Engineering, Texas A&M University, College Station, TX 77843 — Various designs of broadband plasmonic nanoantennas made of gold and silver nanospheres are considered and optimized for ultrasensitive spectroscopic applications. The simulated nanostructures show a broadband optical response which may be tuned by varying the size, position and composition of nanospheres. Near-field enhancement in nanoantenna hot spots is analyzed and compared with previous literature results in the case of a fractal plasmonic nanolens. Broadband plasmonic nanoantennas may allow detecting ultrasmall concentrations of toxic materials and may be used for decoding DNA and for ultrafast nanophotonics applications.

11:51AM B32.00004 Optical nanoantennas: controlled emission of single photon sources , NIEK VAN HULST, ICFO - the Institute of Photonics Sciences (Barcelona) — Nanoscale quantum emitters are key elements in quantum optics and sensing. However, efficient optical excitation and detection of such emitters involves large solid angles, due to their omnidirectional interaction with freely propagating light and due to limits of diffraction. Optical nanoantennas offer both nanoscale localization and efficient interaction. Here we focus on the control of the interaction of single photon emitters (molecules, quantum dots) with radiation through metal nanorod antennas. First a novel analytical model is presented, which shows the continuous evolution of the properties of optical antennas as they become increasingly bound, i.e. plasmonic. The model accurately describes the complete emission process, the radiative decay rate, quantum efficiency, and angular emission, moreover gives a quantitative description of the gradual emergence of sub-radiant, super-radiant, and dark modes. Next we investigate experimentally the coupling of a single quantum dot to a nanorod of increasing length. The angular luminescence of the quantum dot is detected through increasingly higher order antenna modes. Simultaneously the emission is strongly polarized and enhanced. Direct confrontation with theory allows to determine the coupling efficiency of the quantum dot to the antenna. Finally, we present unidirectional emission of a single emitter by coupling to a nanofabricated Yagi-Uda antenna. A quantum dot is placed in the near field of the antenna so that it drives the resonant feed element of the antenna. The resulting quantum-dot luminescence is strongly polarized and highly directed into a narrow forward angular cone. The directionality of the quantum dot can be controlled by tuning the antenna dimensions. Thus our results show the potential of optical antennas to communicate energy to, from, and between nano-emitters.

A.G.Curto et al., Science 329, 930 (2010)

12:27PM B32.00005 Plasmon-mediated polarization-tuneable enhancement of optical absorption in a polymer film[1] , EDWARD J. OSLEY, PAUL G. THOMPSON, CLAUDIU G. BIRIS, NICOLAE C. PANOIU, PAUL A. WARBURTON, University College London — We have fabricated and characterized arrays of nanoscale apertures displaying polarization-tuneable localized surface plasmon (LSP) resonances in the infrared. Arrays of asymmetric cruciform apertures were milled in a gold film using a focused ion beam and subsequently coated with Poly(methyl methacrylate) (PMMA). The aperture geometry is designed so that for a certain polarization state of the incident wave the LSP resonance occurs at the same wavelength as the C=O bond absorption peak in PMMA. The nanostructured film results in an order of magnitude increase in the absorption in PMMA by comparison with a continuous film. By changing the in-plane electric-field polarization of the incident light the LSP resonance shifts away from the PMMA absorption peak, allowing us to quantify the role of plasmonic field-focussing on infrared optical absorption in the polymer film. Numerical simulations show that the increased optical absorption is due to the field enhancement both inside the apertures as well as in their close proximity. We will discuss how this technique may be applied to studies of plasmon-mediated field focussing in other materials including photovoltaic materials.

[1]Work supported by EPSRC

12:39PM B32.00006 Plasmonic-molecular resonance coupling , JIANFANG WANG, The Chinese University of Hong Kong — Localized plamsons have been widely used to enhance optical signals. The plasmon enhancement requires optically active species to be close to the metal surface. The presence of active species can affect the plasmon resonances. Understanding the plasmon-molecule interactions is of importance for both enhancing optical signals and developing plasmon shift-based sensors. We have studied the resonance coupling between Au nanocrystals (NCs) and dyes. The coupling strength can be tuned by varying NC plasmon wavelength. The maximum plasmon shift reaches above 120 nm, which is about 10 times larger than that caused by the local index increase. The plasmon shift decays rapidly as the dye-NC spacing is increased. In addition, the coupling strength is strongly dependent on the molecular properties but independent on the NC shape and size. We have further measured the resonance coupling on single Au NCs. The resonance coupling reveals a unique three-band structure. These single-particle studies will greatly help in understanding the fundamental aspects of the resonance hybridization and designing various plasmon-enhanced spectroscopies.

12:51PM B32.00007 ABSTRACT WITHDRAWN –

1:03PM B32.00008 Advanced Material Models for Nano-Plasmonic Systems via Discontinuous Galerkin Methods , KURT BUSCH, Karlsruhe Institute of Technolgy, Karlsruhe, Germany — Nano-Plasmonic systems offer a tremendous potential for the controlled delivery and extraction of electromagnetic energy to and from tiny objects such as molecules and quantum dots in their immediate vicinity. In view of the increasing sophistication of fabrication and spectroscopic characterization, quantitative computational approaches face challenges that go well beyond the usual description of metals as linear dispersive materials. These challenges include the development of material models that describe the (potentially) strongly nonlocal and nonlinear optical response of such metallic nano-structures themselves as well as the strongly modified light-matter interaction that is mediated by them. This talk reports on the progress of applying the Discontinuous-Galerkin Time-Domain (DGTD) method to the quantitative analysis of nano-plasmonic systems using advanced material models. This includes the efficient modeling of complex geometric features via curvilinear elements, the improvement of the time-stepping scheme via tailored low-storage Runge-Kutta schemes, and the incorporation of optically anisotropic media. In addition, this talk reports on recent results regarding the development and application of advanced material models that are based on a hydrodynamic description of the metal's conduction electrons. By coupling the Maxwell equations to this treatment of the free electrons as a plasma in a confined geometry one is able to capture nonlocal and nonlinear effects and to analyze their consequences.

1:39PM B32.00009 Suppression of Landau Damping in Metal Nanostructures via Quantum Size Effect[1] , XIAOGUANG LI, University of Tennessee-Knoxville, DI XIAO, Oak Ridge National Laboratory, ZHENYU ZHANG, Oak Ridge National Laboratory, University of Tennessee-Knoxville, University of Science and Technology of China — Using the matrix random phase approximation, we study the tunability of localized surface plasmon resonance in small metal nanostructures, where the Landau damping is the dominant dissipation channel and the intrinsic limit to plasmonics technique. We find that the linewidth of plasmon can be effectively suppressed due to the quantization of electron-hole pair energy in various highly confined geometries, where the strength of Landau damping oscillates as the scale of system. Moreover, beyond a classical surface scattering picture, the oscillatory effect can be illustrated with an electron-hole pair description, which can be used to understand many other properties of plasmon. Our results show the possibility to control the Landau damping and therefore should be able to stimulate more efforts on future plasmonics of small nanostructures.

1:51PM B32.00010 Excitation of electromagnetic modes in spheres[1] , RAUL GARCÍA-LLAMAS, Universidad de Sonora, LUIS RAMIREZ-RODRIGUEZ, Posgrado en Física, Universidad de Sonora — A study of the excitation of whispering gallery modes (WGM) in non-dispersive dielectric micro sphere is presented. The Near-Field intensity behavior of the nano-jets, sub-wavelength volume regions, is presented as a function of the radii of the sphere in resonant and off-resonant conditions. A similar study is presented for nano metallic sphere.

Session B33 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides: Electronic Conduction and Defects C143/149

11:15AM B33.00001 Conduction at different ferroelectric domain walls in $BiFeO_3$, SAEEDEH FAROKHIPOOR, CHRISTOPHE DAUMONT[1], BEATRIZ NOHEDA, Zernike Institute for Advanced Materials, University of Groningen — $BiFeO_3$ (BFO) is, at room temperature, a rhombohedrally distorted, ferroelectric perovskite. There are eight possible polarization directions (or domains) and three different types of domain walls, namely, 180° (ferroelectric) and 109° and 71° (ferroelectric and ferroelastic) domain walls. Recent works have shown that the domain walls of BFO can display functionalities different from those of the domains, generating photocurrents [1], inducing exchange bias [2] and displaying conductivity at room temperature [3]. Conduction has been reported at 180° and 109° domain walls[3] and it was proposed that the reduction of the band gap, associated with the suppression of ferroelectric distortions, at domain walls was responsible for the observed conduction[3]. It is, however, not yet clear if and how other (extrinsic) mechanisms affect the conductivity at the walls. In order to help clarifying the origin of domain wall conductivity, we have performed temperature, thickness and orientation dependent local conductivity measurements in BFO thin films. The results will be discussed in this presentation.

[1]Present address: THALES-CNRS (France)

11:27AM B33.00002 Electronic Transport properties of ultra-thin $BiFeO_3$, DIPANJAN MAZUMDAR, Center for Materials for Information Technology, University of Alabama, Tuscaloosa, AL 35487, OLEG MRYASOV, VILAS SHELKE, Center for Materials for Information Technology, University of Alabama, Tuscaloosa AL 35487, STEPHEN JESSE, ARTHUR BADDORF, SERGEI KALININ, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge Tennessee., ARUNAVA GUPTA, Center for Materials for Information Technology, University of Alabama, Tuscaloosa AL 35487 — We have investigated the electronic transport properties of rhombohedral (R) and the nearly-tetragonal (T) phase of $BiFeO_3$ using beyond density functional techniques, and combined with nanoscale I-V transport measurements. Using Quasi-particle GW approximation, we show the R and T phase to have significantly different electronic structures. We find that the T phase has significantly lower effective mass at the conduction band edge compared to the R phase leading to a lower effective barrier height for tunnel electrons (0.38 eV vs 3.6 eV). We therefore anticipate that tunnel devices with T phase BFO to have significantly lower resistances. Local transport measurements performed on ultra-thin BFO R phase are consistent with this inference. Tunneling measurements on the tetragonal phase films are also presented.

11:39AM B33.00003 Oxygen vacancies in lanthanum aluminate ($LaAlO_3$) , JOSHUA SAYRE, NICOLA SPALDIN, University of California, Santa Barbara — Oxygen vacancies can affect the properties of an oxide in various manners such as increasing its ion or electronic conductivity, changing its lattice constant or causing dielectric breakdown. The aim of this research is to investigate structural changes and consequent changes in properties caused by oxygen vacancies in a model complex oxide, lanthanum aluminate, $LaAlO_3$. We use density functional theory with the generalized gradiant approximation (GGA) and within the VASP package to calculate the structure and properties of representative oxygen vacancy profiles. We find that the presence of oxygen vacancies modifies the pattern of rotations of the oxygen octahedra. We discuss the implications of our results for understanding the correlation between epitaxial strain in oxide thin films and intrinsic defect profiles.

11:51AM B33.00004 Defect-Induced Electronic Structures and Formation Energies of Vacancy Complexes in $SrTiO_3$, JIYEON KIM, CHOONG H. KIM, ROKYEON KIM, JAEJUN YU, Center for Strongly Correlated Materials Research, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea — Recently defect induced ferroelectricity in $SrTiO_3$ has been reported at room temperature. Strontium-oxygen vacancies were suggested as a possible source of electric polarization regarding to the existence of mid-gap states. To understand the detailed electronic structures induced by defects and their formation energies, we carried out density-functional-theory calculations for various defects such as Sr, Ti, O, Sr-O, Sr-O- O vacancies. We employed the LDA+U method as implemented in the VASP code to describe the d-orbital occupation at the Ti- site due to the presence of oxygen vacancy. A complex of Sr-O-O vacancies is found to contribute to the localized electronic states in the band gap and its formation energy is small enough to form easily under the poor oxygen limit. We conclude that the vacancy-complex defects play a crucial role in determination of the physical properties of $SrTiO_3$ thin films.

12:03PM B33.00005 Quasiparticle electronic structure calculations of F centers in $SrTiO_3$ perovskite , CHANDRIMA MITRA, ALEX DEMKOV, University of Texas at Austin — Among the broad class of oxides, ABO_3 perovskites have attracted a lot of attention in the recent past due to its beneficial material properties. $SrTiO_3$ is one such example of this class of compounds. It shows a wide range of properties from being ferroelectric to exhibiting superconducting properties in doped $SrTiO_3$. The anomalous dielectric properties in this material make it a potential candidate for technological applications. However, being a semicovalent oxide, the complexities in its electronic structure have hindered a proper characterization of the system. For instance, the intrinsic excitonic luminescence, in this system, is not well understood and there is no general agreement as to whether it is caused by defects or due to self trapped excitons. This calls for an accurate theoretical description of the electronic levels as well as the various defect states in this material. In this work we present results for quasiparticle GW calculations of pure as well as *defective* $SrTiO_3$ containing oxygen vacancies which form F centers in these compounds. From a quasiparticle description of the system excitonic properties of $SrTiO_3$ will be examined.

12:15PM B33.00006 Charge transition levels of oxygen vacancies in monoclinic hafnia[1] , MANISH JAIN, University of California at Berkeley and Lawrence Berkeley National Laboratory, JAMES R. CHELIKOWSKY, University of Texas at Austin, STEVEN G. LOUIE, University of California at Berkeley and Lawrence Berkeley National Laboratory — We perform electronic structure calculations on oxygen vacancies in hafnia using a combined density functional theory (DFT) and GW formalism. This formalism corrects for the error in calculating formation energy and charge transition levels using standard DFT. While the formalism is, in principle, exact; in previous calculations of this kind, one makes several approximations to make the calculation tractable. We assess the impact of these approximations on the charge transition levels of the oxygen vacancy in hafnia. In particular, we examine the assumption that the quasiparticle wavefunctions are the same as DFT wavefunctions for the defect states. We show that this assumption can lead to erroneous results in this system and present the charge transition levels without making use of this assumption. We also explore the possibility that these defects are negative U centers.

12:27PM B33.00007 ABSTRACT WITHDRAWN –

12:39PM B33.00008 Disproportionation and comproportionation reactions of resistive switching in polycrystalline NiOx films , FOREST S.-S. CHIEN, YI-TA WU, GUAN-LONG LAI, Department of Physics, Tunghai University, Y.H. LAI, Department of Chemistry, Tunghai University — The NiO_x thin film exhibit excellent bistable unipolar resistive switching, which has strong potential in nanoscale nonvolatile-memory applications. The underlying mechanism of NiOx resistive switching is still in debate. We studied the chemical bonding states of Ni 2p and O 1s at high/low resistance spots by focused X-ray photoemission spectroscopy. The disproportionation and comproportionation reactions of $3NiO \leftrightarrow Ni + Ni_2O_3$, accounts for the resistive switching of NiO_x. The calculated Gibbs energy of the reaction indicates the reversibility of the reaction thermochemically. The dynamic breathing of the filaments with switching was observed by conducting atomic force microscopy.

12:51PM B33.00009 The effect of oxygen migration for random resistance access memory in oxide-based devices[1] , ZHAOLIANG LIAO, Louisiana State University & Institute of Physics, Chinese Academy of Sciences, PENG GAO, YANG MENG, HONGWU ZHAO, XUEDONG BAI, DONGMIN CHEN, Institute of Physics, Chinese Academy of Sciences — The observed electric field induced resistance switching in metal oxide thin films is generally thought to arise from the creation or annihilation of oxygen defects. By depositing different kinds of metal electrodes on $Pr_{0.7}Ca_{0.3}MnO_3$ and CeO_2 thin films to construct sandwiched devices, we found that the devices can be categorized into two groups with different switching behaviors, depending on the Gibbs free energy of oxidation of the top electrodes with respect to that of underneath metal oxide. *In-situ* TEM measurements show a structure change with an applied electric field. Our analysis indicates that the structure change is related to the oxygen migration driven by external electric field. Therefore, it suggests that not only the oxygen defects but also their migration play important roles in the functionality of oxide-based devices

1:03PM B33.00010 Conduction and Loss Mechanisms in Flexible Oxide-Based Memristors , J.L. TEDESCO, N. GERGEL-HACKETT, L. STEPHEY, A.A. HERZING, M. HERNANDEZ-MORA, C.A. HACKER, J. OBRZUT, L.J. RICHTER, C.A. RICHTER, National Institute of Standards & Technology — In order to study the conduction and loss mechanisms behind their operation, flexible sol-gel based memristors were fabricated with differing oxide film thicknesses and device sizes. XPS, TEM, EELS, and VASE measurements indicated the oxide was amorphous TiO_2, with a significant fraction of organic material. Analysis of the bias and sweep rate dependence of the devices suggested the switching mechanism was induced by charge flow in the memristor and not by the electric field. Further analysis of the I-V curves indicated that once the memristors were switched into the high-current "ON" state, conduction through them generally became ohmic. Once such memristors were cut to yield two smaller devices, there was typically only one device that remained ohmic, indicating that localized conduction pathways caused switching in the flexible memristors. There was a shift in the capacitance-frequency and conductance-frequency measurements following switches between the "ON" and "OFF" states of the devices, indicating that an additional dielectric loss mechanism was present in these films that was not present in ordinary TiO_2 films. This loss mechanism is attributed to dipoles in the organic constituents of the films that are by-products of the sol-gel process.

1:15PM B33.00011 Capacitive network near the metal insulator transition in Vanadium Dioxide , J.G. RAMIREZ, E.J. PATINO, Universidad de los Andes, R. SCHMIDT, Universidad Complutense de Madrid, A. SHARONI, Bar-Ilan University, M.E. GOMEZ, Universidad del Valle, I.K. SCHULLER, University of California-San Diego — Recent infrared spectroscopy and transport measurements in nano-scaled junction of VO2 have revealed the existence of phase separation into metallic and insulating phases. Here we present Impedance spectroscopy measurements performed in high quality Vanadium dioxide (VO_2) thin films for the first time. This technique allows distinguishing between the resistive and capacitive response of the VO_2 films and provides the dielectric properties across the metal-insulator transition (MIT). The film capacitance exhibits an unusual increase close to the MIT which implies the formation of a capacitor network produced by the nanoscale phase separation of metallic and insulating phases. This work has been supported by AFOSR, COLCIENCIAS, CENM and Ramon y Cajal Fellowship.

1:27PM B33.00012 Substitution site for Zn in $LiNbO_3$ from detailed EXAFS analysis[1] , FRANK BRIDGES, BRAD CAR, UCSC, JAIME CASTILLO, Universidad Tecnologica d la Mixteca, MICHAEL KOZINA, SCOTT MEDLING, UCSC — We report detailed EXAFS studies of Zn doped $LiNbO_3$, at the Zn and Nb K-edges, as a function of dopant and as a function of temperature. For this material there exist several models concerning the substition site(s) for Zn. Our data are only consistent with Zn substitution on the Li site. Any substitution on the Nb site is very small. Further as the Zn concentration changes from 5-9% the EXAFS r-space function for the Zn K-edge changes very little, a slight amplitude reduction consistent with increased local disorder for increasing Zn concentration. Our detailed analysis shows that the nearest O neighbors to Zn are slightly pulled inward while the nearst metal atoms - Nb - are pushed away. We cannot tell if there are vacancies on the Li sites because Li is a very weak backscatterer, and the amplitude of the rather long Zn-Li peak is very low. We discuss and compare our results with previous proposed models and with recent calculations for other defects that suggest that many +2 dopants substitute at the Li site.

1:39PM B33.00013 Structure and Magnetic Properties of Electron Doped $YMnO_3$, TIAN YU, PENG GAO, TREVOR TYSON, New Jersey Institute of Technology — Combined local and long range structural measurements were conducted on the electron doped ferroelectric $Y_{1-x}Zr_xMnO_3$ system. Doping by Zr is found to maintain the hexagonal structure for a large range of x-values. The location of Zr in the lattice is identified and changes in structure with doping are followed. These details of the local structure are examined by x-ray diffraction and x-ray absorption spectroscopy and compared with detailed magnetic studies to correlate the impact of electron doping and atomic structure on the magnetic order in these systems. This work is supported by DOE Grant DE-FG02-07ER46402.

1:51PM B33.00014 First-principles calculations of Ti and O NMR chemical shift tensors in ferroelectric perovskites[1] , DANIEL PECHKIS, ERIC WALTER, HENRY KRAKAUER, College of William and Mary — Complementary chemical shift calculations were carried out with embedded clusters, using quantum chemistry methods, and with periodic boundary conditions, using the GIPAW approach[2] within the Quantum Espresso package.[3] Compared to oxygen chemical shifts, $\hat{\delta}$(O),[4] cluster calculations for $\hat{\delta}$(Ti) were found to be more sensitive to size effects, termination, and choice of gaussian-type atomic basis set, while GIPAW results were found to be more sensitive to the pseudopotential construction. The two approaches complemented each other in optimizing these factors. We show that the two approaches yield comparable chemical shifts for suitably converged simulations, and results are compared with available experimental measurements.

2:03PM B33.00015 Electrical Breakdown in Lightning Arrestor Connector (LAC) Devices , HAROLD P. HJALMARSON, KENNETH KAMBOUR, Sandia National Laboratories, ANDREW C. PINEDA, U.S. Air Force Research Laboratory — Lightning arrestor connector (LAC) devices protect electronic devices by providing a conductive path to ground for electrical power surges caused by lightning. Such devices consist of an insulating material between electrodes. This insulation region is composed of an air gap and a high permittivity dielectric. In this presentation, the physics of the phenomena active in the early stages of the flow of transient electrical current will be described. The conditions that lead to thermal breakdown of the dielectric will also be discussed.–Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

Session B34 DMP GMAG: Focus Session: Interfaces in Complex Oxides - Spectroscopy and Growth C141

11:15AM B34.00001 Strain-modulated asymmetric orbital–lattice interactions in correlated oxide heterostructures[1] , J. CHAKHALIAN, Univeristy of Arkansas, J. RONDINELLI , JIAN LIU, B. GRAY, M. KAREEV, E.J. MOON, J. COHN, M. VARELA, S.G. ALTENDORF, F. STRIGARI, B. DABROWSKI, L.H. TJENG, P.J. RYAN, J.W. FREELAND — Artificial structuring of quasi-two dimensional correlated electron thin films and heterointerfaces offers an arena to discover innovative functionalities by harnessing electronic and orbital degrees of freedom. To harness this potential understanding of how structurally linked correlated electronic responses are modified through epitaxial constraints at the substrate–film hetero-interface is clearly required. We use a suite of advanced experimental probes along with ab-initio calculations to show how compressive and tensile bi-axial strain lead to unusual asymmetrical orbital responses. Microscopic studies based on resonant X-ray spectroscopies reveal that the asymmetry leads to a new ground state with a ligand hole density and chemical bond covalency that is modulated by the sign of the epitaxial constraint at the interface.

11:27AM B34.00002 Structural effects on the electronic properties of epitaxially strained $RNiO_3$ thin films , I.C. TUNG[1], Department of Materials Science and Engineering, Northwestern University, JIAN LIU, B. GRAY, J. CHAKHALIAN, Department of Physics, University of Arkansas, J. RONDINELLI, P. RYAN, J.W. KIM, Advanced Photon Source, Argonne National Laboratory, M.J. BEDZYK, Department of Materials Science and Engineering, Northwestern University, J.W. FREELAND, Advanced Photon Source, Argonne National Laboratory — Since the metal–insulator (MI) transition is a hallmark of strongly correlated materials, understanding the behavior of the MI transition of $RNiO_3$ (R=rare earth) thin films subjected to confinement, lattice misfit and broken symmetry at the interface in the ultra-thin limit is fundamentally and technologically important [1]. Here we present a study of the effect of the lattice symmetry with epitaxial strain in thin films of $LaNiO_3$ and $NdNiO_3$ grown on $SrTiO_3$(001) substrates by pulsed laser deposition. A combination of x-ray diffraction, soft x-ray absorption spectroscopy, and temperature-dependent resistivity has been applied to elucidate structural and electronic properties of the samples. Work at the Advanced Photon Source, Argonne is supported by the U.S. Department of Energy, Office of Science under Contract No. DE-AC02-06CH11357.

[1]Advanced Photon Source, Argonne National Laboratory

11:39AM B34.00003 Orbital engineering near La_2NiO_4-La_2CuO_4 superlattice interfaces[1] , S. SMADICI, J.C.T. LEE, J. MORALES, P. ABBAMONTE, University of Illinois at Urbana-Champaign, IL 61801, G. LOGVENOV, A. GOZAR, I. BOZOVIC, Brookhaven National Laboratory, NY 11973 — Orbital states of transition metal oxides present the opportunity of adjusting material properties to a specific purpose (orbital engineering). A comparison of the resonant soft x-ray reflectivity of La_2NiO_4-La_2CuO_4 superlattices at Ni L and Cu L edges shows different spatial distributions of the occupation of Ni $d_{x^2-y^2}$ and $d_{3z^2-r^2}$ orbitals in the LNO layers. This modulation of the Ni valence is possible through a pronounced modulation of the density of oxygen interstitial dopants within the structure which does not follow exactly the structure itself. This is the first observation of orbital engineering in a 214 oxide.

[1]This work was supported by Grants DE-FG02-06ER46285, DE-AC02-98CH10886, MA-509-MACA, DE-FG02-07ER46453 and DE-FG02-07ER46471.

11:51AM B34.00004 Orbital Control in single unit cell LaNiO3/LaAlO3 superlattices , J.W. FREELAND, Argonne National Laboratory, J. LIU, B. GRAY, M. KAREEV, University of Arkansas, J.W. KIM, P.J. RYAN, Argonne National Laboratory, R. PENTCHEVA, University of Munich, J. CHAKHALIAN, University of Arkansas — Oxide heterostructures built from strongly correlated electron materials offers unique opportunity to generate new ground-states by altering the balance of competing energies in the system. In pursuit of rational control of orbital polarization, we present a combined experimental and theoretical study of single unit cell $LaNiO_3/LaAlO_3$ superlattices[1]. Polarized x-ray absorption spectra show a distinct asymmetry in the orbital response under tensile vs. compressive strain. A splitting of orbital energies $\sim$100 meV with octahedral distortions is found for the case of compressive strain which is much smaller than the $3d$ bandwidth. In sharp contrast, for tensile strain, no splitting is found although a strong orbital polarization is still present. Density functional theory calculations of the electronic properties reveal that the asymmetry results from a combination of strain effects and altered covalency in the bonding across the interfacial apical oxygen to the Al site, leading to the opening of a pseudogap in the heterostructure for tensile strain. Work at Argonne, including the Advanced Photon, is supported by the U.S. Department of Energy, Office of Science, and Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357. [1] J.W. Freeland et. al. arXiv:1008.5618

12:03PM B34.00005 Realistic DMFT calculations for nickelate superlattices , M.J. HAN, Columbia University, XIN WANG, University of Maryland, CHRIS A. MARIANETTI, ANDREW J. MILLIS, Columbia University — We present phase diagram, photo-emission and RIXS (resonant inelastic X-ray scattering) spectra, orbital polarization, and Fermi surface plots for LaNiO3/LaXO3 superlattice (X=Al, Ga,...) obtained from DMFT (dynamical mean-field theory) calculation based on a realistic multi-band tight-binding model derived from DFT (density functional theory) calculations and in particular including oxygen orbitals. Our results indicate that heterostructuring is unlikely to produce one band model physics and point toward a new view of metal-insulator transition of this system. This work is supported by ARO via grant No. W911NF0910345-56032PH.

12:15PM B34.00006 Conductivity enhancement of ultrathin $LaNiO_3$ films in superlattices

JUNWOO SON, JAMES M. LEBEAU, S. JAMES ALLEN, SUSANNE STEMMER, University of California, Santa Barbara — The transport properties of heterostructures with Mott materials, such as $LaNiO_3$, have been predicted to exhibit unusual phenomena not present in the bulk. Prior studies have shown that ultrathin $LaNiO_3$ films exhibit strongly localized behavior, whereas thicker films remain metallic. Here, we report on epitaxial $[SrTiO_3(3\text{ u.c.})/LaNiO_3(4\text{ u.c.})]_n$ superlattices on (001) $(LaAlO_3)_{0.3}(Sr_2AlTaO_6)_{0.7}$ (LSAT) substrates (u.c. = unit cell). X-ray diffraction and Z-contrast imaging confirm sharp interfaces. The sheet resistance of the superlattices is explored as a function of temperature and number of bilayers. All superlattices with more than 2 layers were metallic whereas 4 u.c. $LaNiO_3$ films and a single 4 u.c. $LaNiO_3$/3 u.c. $SrTiO_3$ bilayer were both insulating. The sheet resistance of superlattices decreases with n. Possible models for the electrical characteristics will be discussed. The first model attempts to describe the sheet resistance with conduction through parallel-connected $LaNiO_3$ layers and conductive interfacial layers. The second model is based on coupling of layers, each of which is near the percolation threshold for a metal-insulator transition, and explains the difference in conductivity of single layers and superlattices without invoking interfacial layers.

12:27PM B34.00007 Electric-Field Control of the Metal-Insulator Transition in Nickelate Thin Films

RAOUL SCHERWITZL, PAVLO ZUBKO, University of Geneva, IGNACIO GUTIERREZ-LEZAMA, SHIMPEI ONO, ALBERTO MORPURGO, University of Geneva, GUSTAU CATALAN, CIN2, JEAN-MARC TRISCONE, University of Geneva — The rare-earth perovskite nickelates ($RNiO_3$) are a fascinating family of compounds displaying a sharp temperature-driven metal-insulator (MI) transition with resistance changes of several orders of magnitude. From a fundamental point of view, these materials present an ideal system to study MI transitions since, in contrast to most oxides, a complete evolution from itinerant to localized behavior can be achieved without doping. From a technological point of view, the nickelates are just as exciting, as the large changes and thermal hysteresis in resistance may find uses in various electronic applications, particularly if the MI transition could be tuned using an electric field. We discuss the electric field control of the MI transition in $NdNiO_3$. The electric double layer technique was used in order to obtain very large charge carrier density modulations (exceeding 10^{15} cm^{-2}), enabling us to reversibly tune the transition temperature by more than 50 K and to achieve electro-conductivities as high as 60000% [1].

12:39PM B34.00008 Interface Structures in Ferromagnetic $LaMnO_3$-$SrMnO_3$ Superlattices

AMISH SHAH, Arizona State University, QUENTIN RAMASSE, SuperSTEM Laboratory, UK, STEVEN MAY, ANAND BHATTACHARYA, Argonne National Laboratory, XIAOFANG ZHAI, JAMES ECKSTEIN, JIAN-MIN ZUO, University of Illinois at Urbana-Champaign, JOHN SPENCE, Arizona State University — We have investigated the interfaces of $LaMnO3_{2n}$-$SrMnO3_n$ (LMO/SMO) superlattices. Charge density calculations have predicted a leakage of Mn e_g electrons from LMO into SMO.[1] For n=1, these electrons are expected to be distributed throughout all films in the superlattice, while for $n > 3$, the electrons are expected to be localized within a few layers near the interfaces. Using aberration corrected STEM coupled with EELS, we probed a $LMO_{11.8}$-$SMO_{4.4}$ superlattice at high spatial resolution to examine interfacial states. We find that the LMO on SMO interface is structurally sharper than SMO on LMO interfaces. Extra interfacial states above the Fermi level are localized to 1 unit cell of the sharp LMO/SMO interface while the states are weak or absent at the rougher SMO/LMO interfaces. The same interfaces that have extra states have an enhanced ferromagnetic moment at low temperatures.[2]

GIBLIN, ISIS Facility, Rutherford Appleton Laboratory, Chilton, Oxfordshire, OX11 0QX, United Kingdom., T. NAKAMURA, K. KODAMA, Japan Synchrotron Radiation Research Institute, SPring-8, 1-1-1 Kouto, Sayo, Hyogo 679-5198, Japan, S. OKAMOTO, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831-6071, USA — We show evidence of induced magnetism resulting from the electronic (charge) or orbital reconstruction occurring at the interface. We show a novel form of Ti magnetism at the interface between $SrTiO_3$ (STO) and $LaMnO_3$ (LMO) [1] as evidenced by evidenced by a strong XMCD signals at Ti and Mn edges. The magnetic alignment (ferromagnetic or antiferromagnetic) of Ti and Mn moments can be tuned by structural parameters.

1:03PM B34.00010 Orbital Reflectometry and the Electronic Structure of Oxide Interfaces

EVA BENCKISER, Max Planck Institute for Solid State Research, Heisenbergstraße 1, 70569 Stuttgart — The occupation of d-orbitals has a key influence on the physical properties of transition-metal (TM) oxides.[1] Due to the strong hybridization with neighboring oxygen ions, the electronic structure is very sensitive to changes in the TM-oxygen bond distances induced by strain and/or by the chemical bonding to other ions with different electronic configuration. Both effects might be important in oxide heterostructures,[2] but thus far it has been difficult to probe atomic-scale modulations of the orbital occupation in a quantitative manner.[3] We present results from polarized soft x-ray resonant reflectivity, which demonstrate that it is possible to derive quantitative, spatially resolved orbital polarization profiles. We show that this method is sensitive enough to resolve differences of $\sim 3\%$ in the occupation of Ni e_g orbitals in adjacent atomic layers of a $LaNiO_3$-$LaAlO_3$ superlattice, and the experimental findings are in good agreement with electronic-structure calculations. The possibility to quantitatively correlate theory and experiment on the atomic scale opens up new perspectives for orbital physics in oxide heterostructures.

1:39PM B34.00011 Source oxidation problem in oxide-MBE environment and its solution

NAMRATA BANSAL, YONG-SEUNG KIM, SEONGSHIK OH[1], Rutgers University — Maintaining stable fluxes for multiple source elements is a challenging task when the source materials have significantly different oxygen affinities in a complex-oxide MBE environment. Although this problem has been known to the complex oxide MBE community since the late 1980s, a detailed study and solution is still lacking. Here, using Sr as a test source, because of its easy oxidation and popularity in complex oxides, we investigated the source-oxidation problem in a number of different conditions. We found that the source oxidation was less for higher flux rates, unmelted source shape, and extended port geometry. The extended port geometry was also found to eliminate the flux transient, usually observed in a standard port, after opening the source shutter. Furthermore, a crucible aperture insert scheme was found to be very effective in suppressing the source oxidation. In this scheme, a disk-shaped aperture was mounted inside the crucible and we found that it blocks most of the oxygen species coming to the source. However, the depth of the aperture disk was critical for its performance. We will discuss how these configurations suppress source oxidation and lead to significantly enhanced stability of Sr-flux in harsh oxidation conditions.

1:51PM B34.00012 Growth of SrTiO3(110) film with oxide molecule beam epitaxy[1] , JIANDONG GUO, ZHIMING WANG, FANG YANG, JIAGUI FENG, FENGMIAO LI, Institute of Physics, Chinese Academy of Sciences — In the past decade, a tremendous amount of evidence has shown that thin films, superlattices and heterointerfaces of oxides display a rich diversity of glamorous properties that is related, but not identical to that in the bulk. To understand the underlying physical mechanism, it is essential to construct the oxide heterostructures under control with atomic precision. We have studied the $SrTiO_3$(110) surface that bears intrinsic instability of reconstruction in addition to the broken symmetry due to the surface polarity, which provides us an additional degree to tune the properties of the epitaxial material by manipulating the termination layer of the substrate. Beyond the termination, we are able to tune the stability of a series of surface reconstructions and realize the reversible phase transitions between them. By applying the knowledge to the homoepitaxy, we develop an easy method to coordinate the metal evaporation sources with required flux rate ratio precisely during the oxide MBE growth. We further simplify the growth by controlling the shutter of the Sr source. The atomically well defined grown surface is characterized by scanning tunneling microscopy.

2:03PM B34.00013 Oxygen Doping Study of Cuprate/Manganite Thin-Film Heterostructures[1] , HAO ZHANG, University of Toronto, J.Y.T. WEI, University of Toronto and Canadian Institute for Advanced Research, WEN HE GONG, Brockhouse Institute for Material Research, McMaster University, GIANLUIGI A. BOTTON, Canadian Centre for Electron Microscopy — Recent studies of thin-film heterostructures comprising superconducting cuprates and ferromagnetic manganites have revealed a range of novel physical phenomena. These phenomena are believed to involve complex interfacial interactions between competing order parameters [1], and appear to be highly sensitive to carrier doping [2]. To further examine these phenomena, we carry out a systematic oxygen-doping study of cuprate/manganite multilayer thin films, grown epitaxially by pulsed laser-ablated deposition. Our samples are characterized by electrical transport and magnetization measurements, as well as x-ray diffraction and several microscopy probes including SEM and TEM. We also make cation substitution in the cuprate layer, in order to study the effects of carrier doping across the interface.

Monday, March 21, 2011 11:15AM - 2:15PM –
Session B35 DCMP: Topological Insulators: Theory I C140

11:15AM B35.00001 Classification of Gapped Topological Phases in 1D Interacting System , XIE CHEN, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA, ZHENG-CHENG GU, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, CA 93106, USA, XIAO-GANG WEN, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA — Topological phases exist in quantum many-body systems beyond the usual symmetry breaking understanding of phase and phase transition. While a full classification of topological insulators and superconductors has been given for non-interacting fermions, the question of what phases exist for strongly interacting systems and how to identify them seems hard. Here we give a full classification of 1D gapped phases with possible topological and symmetry breaking order in both spin and fermion systems, based on the local unitary equivalence relation between short-range correlated matrix product states, which represent well the class of 1D gapped ground states. We find that in certain symmetry classes, the classification result for non- interacting systems is changed when strong interaction is allowed. Understanding about 1D system also allows us to obtain some simple results for topological phases in higher dimensions when certain symmetries are present.

11:27AM B35.00002 Classification of topological insulators and superconductors using KR theory , ABHISHEK ROY, University of Illinois, Urbana-Champaign — Kitaev's periodic table[1] provided a classification of topological insulators and superconductors. The classes are indexed by dimension and symmetries. We present a method of arriving at the table using KR theory. This gives a unified and systematic method of constructing model Hamiltonians for each class, as well as those for boundaries and defects. We motivate the formulae for the topological invariants and explain the diagonal periodicity in the invariants.

[1]A. Kitaev, Proceedings of the L.D.Landau Memorial Conference Advances in Theoretical Physics, June 22-26, 2008

11:39AM B35.00003 The classification of topological insulators and superconductors , CHING-KAI CHIU, MICHAEL STONE, TAYLOR HUGHES, University of Illinois at Urbana-Champaign — We use the process of band crossings during quantum phase transitions to explain the periodic table of topological insulators and superconductors. This is achieved by showing how irreducible representations of the real and complex Clifford algebras are related to the 10 Altland-Zirnbauer symmetry classes of Hamiltonian matrices which are associated with time reversal, particle-hole, and chiral symmetries. The representation theory not only reveals why a unique topological invariant $(0, Z_2, Z)$ exists for each specific symmetry class and dimension, but also shows the interplay between quantum phase transitions, topologically protected boundary modes, and topological invariants.

11:51AM B35.00004 Chern Numbers Hiding in Time of Flight Images[1] , INDUBALA SATIJA, ERHAI ZHAO, PARAG GHOSH, George Mason university, NOAH BRAY-ALI, Joint Quantum Institute, National Institute of Standard and Technology — Since the experimental realization of synthetic magnetic fields in neural ultracold atoms, transport measurement such as quantized Hall conductivity remains an open challenge. Here we propose a novel and feasible scheme to measure the topological invariants, namely the chern numbers, in the time of flight images. We study both the commensurate and the incommensurate flux, with the later being the main focus here. The central concept underlying our proposal is the mapping between the chern numbers and the size of the dimerized states that emerge when the two-dimensional hopping is tuned to the highly anisotropic limit. In a uncoupled double quantum Hall system exhibiting time reversal invariance, only odd-sized dimer correlation functions are non-zero and hence encode quantized spin current. Finally, we illustrate that inspite of highly fragmented spectrum, a finite set of chern numbers are meaningful. Our results are supported by direct numerical computation of transverse conductivity.

12:03PM B35.00005 Topological Nature of Phonon Hall Effect[1] , LIFA ZHANG, JIE REN, JIAN-SHENG WANG, BAOWEN LI, National University of Singapore — We provide a topological understanding on phonon Hall effect in dielectrics with Raman spin-phonon coupling. A general expression for phonon Hall conductivity is obtained in terms of the Berry curvature of band structures. We find a nonmonotonic behavior of phonon Hall conductivity as a function of magnetic field. Moreover, we observe a phase transition in phonon Hall effect, which corresponds to the sudden change of band topology, characterized by the altering of integer Chern numbers. This can be explained by touching and splitting of phonon bands.

12:15PM B35.00006 Effects of Metallic Contacts on Topological Insulator Surface States , JIMMY HUTASOIT, TUDOR STANESCU, West Virginia University — We study the effect of the coupling between a time-reversal invariant topological insulator and a metal. The coupling of the surface states to the metal is studied both numerically, using a tight-binding model, and analytically within a two-dimensional effective theory. The original surface state described by a massless Dirac fermion acquires a non-trivial spectral profile upon interaction with the metal. This results in the broadening of the surface modes and a shift in the position of the Γ- point, which may sink into the valence band at strong coupling.

12:27PM B35.00007 Spin active scattering at the interface between a metal and a topological insulator , ERHAI ZHAO, George Mason University, CHUN ZHANG, National University of Singapore, MAHMOUD LABABIDI, George Mason University — We present theoretical results for the spin-active scattering and local spectrum at the interface between a metal and a three-dimensional topological band insulator. We show that there exists a critical incident angle at which complete (100%) spin flip reflection occurs and the spin rotation angle jumps by π. We discuss the origin of this phenomena, and systematically study the dependence of spin-flip and spin-conserving scattering amplitudes on the interface transparency and metal Fermi surface parameters. The interface spectrum contains a well-defined Dirac cone in the tunneling limit, and smoothly evolves into a continuum of metal induced gap states for good contacts. We also investigate the complex band structure of Bi_2Se_3.

12:39PM B35.00008 Floquet Topological Insulator in Semiconductor Quantum Wells , NETANEL LINDNER, GIL REFAEL, California Institute of Technology, VICTOR GALITSKI, University of Maryland — Topological phase transitions between a conventional insulator and a state of matter with topological properties have been proposed and observed in mercury telluride - cadmium telluride quantum wells. We show that a topological state can be induced in such a device, initially in the trivial phase, by irradiation with microwave frequencies, without closing the gap and crossing the phase transition. We show that the quasi-energy spectrum exhibits a single pair of helical edge states. The velocity of the edge states can be tuned by adjusting the intensity of the microwave radiation. We discuss the necessary experimental parameters for our proposal. This proposal provides an example and a proof of principle of a new non-equilibrium topological state, Floquet topological insulator, introduced in this paper. arXiv:1008.1792

12:51PM B35.00009 A study of localized states in topological insulators , KUN WOO KIM, TAMAR PEREG-BARNEA, GIL REFAEL, California Institute of Technology — Perturbative and Semiclasscial approaches are employed to find the localized state of the toplogical insulators both on sample edges and defects in the bulk. The models used are massive Dirac with either one or two valleys. The topology is provided by the mass term which has either a momentum dependence or a different sign on the two Dirac points. A semiclasscial Hamiltonian is deduced by following a certain classical path and the Hamilton-Jacobi equation determines the dynamics. Our semiclassical results reproduce the lattice model's chiral edge modes and allow us to investigate impurity bound states. These bound states also appear in a T-matrix calculation.

1:03PM B35.00010 Zero modes in the bulk of the Topological Insulators induced by disorder or dislocations , DAVID SCHMELTZER, City College of New York — The enigma of the finite conductivity which comes from the bulk of the Topological Insulators (T.I.) is solved by showing that domain walls in the T.I. bind protected zero modes. We consider two scenarios: a)-Dislocations: -We solve the massive Dirac equation (which corresponds to the T.I. in four and two dimensions) in a curved space generated by the coordinates transformation induced by a single dislocation or a single disclination. We examine the condition for the protected zero modes caused by Torsion and Curvature. b) Disorder:-We use the Keldish formalism to study the effect of disorder and interaction of the T.I. We identify an effective Non-Linear Sigma model with a Maxweell and Chern-Simon term which correspond to the different phases: regular metal, regular insulator, topological insulator and protected metals.

1:15PM B35.00011 Zero energy modes in heterostructures , TUDOR PETRESCU, STEPHAN RACHEL, KARYN LE HUR, Physics Department, Yale University — Zero energy gapless modes have been realized in 1-dimensional domain walls of 2-dimensional systems. In the case of single- or bi-layer graphene, such a quantum wire can be realized by inverting the sign of the gap across a one dimensional interface, without time-reversal symmetry breaking. With the experimental realization of artificial graphene, previously unrealistic additional terms in the Hamiltonian such as staggered potential or artificial gauge fields can be exploited towards the same goal. We classify these terms and study the interplay of disorder effects and boundary conditions.

1:27PM B35.00012 Protected Entanglement Spectrum in Disordered Topological Insulators , EMIL PRODAN, Yeshiva University, TAYLOR HUGHES, University of Illinois at Urbana-Champaign, ANDREI BERNEVIG, Princeton University — The topological insulating phase is robust against disorder. However, the phase diagram of a topological insulator, more precisely the boundary between the trivial and topological phases, can be strongly reshaped by the disorder. It is therefore important to devise methods that can efficiently map the extent of the topological phase in the presence of disorder. This talk will describe two such methods and presents several applications. First, it is shown that, in the topological phase, the entanglement spectrum remains extended while in the trivial phase it becomes localized, in the presence of disorder. The localized/delocalized character of the entanglement spectrum has a clear signature in the level statistics, which can be used to efficiently map the boundary between topological and trivial phase. The second method is based on efficient real space calculations of the bulk invariants that do not involve twisted boundary conditions. In fact, it is shown that both methods involve only data encoded in the ground states of the systems.

1:39PM B35.00013 Theory of Inversion Symmetric Topological Insulators , TAYLOR HUGHES, University of Illinois at Urbana-Champaign, EMIL PRODAN, Yeshiva University, B. ANDREI BERNEVIG, Princeton University — We analyze translationally-invariant insulators with inversion symmetry that fall outside the current established classification of topological insulators. These insulators exhibit no edge or surface modes in the energy spectrum and hence they are not edge metals when the Fermi level is in the bulk gap. However, they do exhibit protected modes in the entanglement spectrum localized on the cut between two entangled regions. There is a direct connection between the inversion eigenvalues of the Hamiltonian band structure and the mid-gap states in the entanglement spectrum. We also analyze the linear response of these insulators and provide examples of when the inversion eigenvalues determine a non-trivial charge polarization, a quantum Hall effect, an anisotropic 3D quantum Hall effect, or a magneto-electric polarization.

1:51PM B35.00014 Topological Properties of Insulators with Inversion Symmetry , ARI TURNER, YI ZHANG, ROGER MONG, ASHVIN VISHWANATH, UC Berkeley — There are many phases of insulators with inversion symmetry (with no other symmetry required). In particular, certain inversion parities cannot change unless there is a phase transition. I will show how to use these parities to classify phases of topological insulators and explain which combinations of these parities have physical consequences (e.g. for the magnetoelectric effect). Many of these results can be derived by pictorial arguments using the entanglement spectrum.

2:03PM B35.00015 Computing topological invariants without inversion symmetry , ALEXEY SOLUYANOV, DAVID VANDERBILT, Rutgers University — We consider the problem of calculating the weak and strong topological indices in noncentrosymmetric time-reversal (T) invariant insulators. In 2D we use a gauge corresponding to hybrid Wannier functions that are maximally localized in one dimension. Although this gauge is not smoothly defined on the two-torus,[1] it respects the T symmetry of the system and allows for a definition of the Z_2 invariant in terms of time-reversal polarization.[2] In 3D we apply the 2D approach to T-invariant planes. We illustrate the method with first-principles calculations on GeTe and HgTe under [100] and [111] strain. Our approach is different from the one suggested previously by Fukui and Hatsugai[3] and should be easier to implement in *ab initio* code packages. Time permitting, we will also discuss methods for decomposing the band space into T-paired Chern subspaces, and for carrying out a general construction of a Wannier representation for Z_2 insulators.

Monday, March 21, 2011 11:15AM - 2:15PM –
Session B36 GERA: Photovoltaics: Novel Approaches and System Issues C142

11:15AM B36.00001 Surpassing the classical light-trapping limit in thin film solar cells , JEREMY MUNDAY, DENNIS CALLAHAN, HARRY ATWATER, California Institute of Technology — We describe a methodology for designing thin film solar cells that have light-trapping intensity and absorption enhancements that exceed the classical, ergodic light-trapping limit. From thermodynamic arguments, Yablonovitch and Cody determined the maximum absorption enhancement in the ray optics limit for a bulk material to be $4n^2$, where n is the index of refraction of the absorbing layer. Stuart and Hall expanded this approach to study a simple waveguide structure; however, for the waveguide structures they considered, the maximum absorption enhancement was $< 4n^2$. Using a combination of analytical and numerical methods, we describe why these structures do not surpass the ergodic limit and show how to design structures that can. We present here a physical interpretation in terms of the waveguide dispersion relations and optical density of states. We further describe the necessary criteria for surpassing the classical limit and provide examples of waveguide structures with absorption enhancements in excess of $4n^2$.

11:27AM B36.00002 Resonance shifting: A simple, all-optical method for circumventing the reabsorption problem in luminescent concentrators , NOEL GIEBINK, GARY WIEDERRECHT, Argonne National Lab, MICHAEL WASIELEWSKI, Northwestern University — Luminescent concentrators (LSCs) were developed over three decades ago as a simple route to obtain high concentration ratio for photovoltaic cells without tracking the sun. In principle, high concentration ratios >100 are possible for commonly used chromophores. In practice, however, there is typically an overlap between the chromophore absorption and emission spectra that, although small, ultimately leads to unacceptable reabsorption losses, limiting the concentration ratio to ∼10 and hence the utility of LSCs to date. We introduce a simple, all-optical means of avoiding reabsorption loss by "resonance shifting" from a bilayer cavity that consists of an absorber/emitter waveguide lying upon a low refractive index layer supported by a transparent substrate. Emission is evanescently coupled into the substrate at sharply defined angles and hence, by varying the cavity thickness over the device area, the original absorption resonance can be avoided at each bounce, allowing for extremely low propagation loss to the substrate edges and hence an increase in the optical concentration ratio. We validate this concept for absorber/emitter layers composed of both a typical luminescent polymer and inorganic semiconductor nanocrystals, demonstrating near-lossless propagation in each case.

11:39AM B36.00003 Computational Design of All-Carbon Photovoltaics , MARCO BERNARDI, JEFFREY C. GROSSMAN, Massachusetts Institute of Technology, GROSSMAN GROUP TEAM — We employ ab-initio computational approaches to study interfaces between different carbon nanomaterials (graphene nanoribbons, carbon nanotubes, graphene fragments) with different structures and surface chemistries. The presence of suitable type-II band alignment at these interfaces and significant light-absorption in the visible and infrared make all-carbon heterojunctions appealing as the active material in next-generation flexible photovoltaic devices, particularly given their greatly enhanced stability compared with polymer-based cells. Results for a wide range of carbon nanomaterials interfaces will be presented, and we will discuss possible applications of such a technology, extending the analysis to the thin-film device scale.

11:51AM B36.00004 Continuum and KMC simulations of realistic bulk heterostructure solar cell photovoltaic devices , KANOKKORN PIMCHAROEN, DANIEL OLDS, PHILLIP DUXBURY — Design of novel solar cell architectures is significantly assisted by reliable continuum device models, and computational methods capable of solving these models in one, two and three dimensions. We are developing computational methods for these models and are validating them using Kinetic Monte Carlo simulations in the same morphologies. We present simulations using idealized morphologies to test approximations in the continuum models, and we present results for bulk heterostructure morphologies deduced by refining digital nanostructures to experimental neutron relectometry and small angle scattering data. In particular we discuss the ability of one dimensional device models to capture the physics of photovoltaic response of realistic bulk heterostructures.

12:03PM B36.00005 Computational Materials Design for High Efficiency Photovoltaic Solar Cells and Transparent Conducting Sulfides , HIROSHI KATAYAMA-YOSHIDA, YOSHIMASA TANI, KAZUNORI SATO, Osaka University — Based on the first-principles electronic structure calculations we propose computational materials design for high efficiency and low price (In free) solar cell materials based on CuInSe2. Firstly, to avoid the use of In, we try to substitute In by Zn and Sn, or by Ga. The electronic structure calculations are performed by using the KKR-CPA method. To calculate band gap energy correctly, we use self interaction corrections proposed by Filippetti et al. It is found that the direct band gap does not collapse and there appears no deep impurity state in the gap, thus it should be possible to avoid In without any deterioration of photovoltaic effect. From the calculations of mixing energy, we predict that the present system favors the spinodal decomposition and we can expect the formation of nano-wire by two dimensional spinodal nano-decomposition. When the nano-wires are formed, we can expect Type 2 band alignment between host material and the nano-wires. Due to this band alignment, efficient electron hole separation is expected leading to highly efficient photovoltaic effect. As an extension of the present design, we also propose a new class of n-type and p-type transparent conducting sulfides with the negative activation energy for the application of high-efficiency photovoltaic solar-cells.

12:15PM B36.00006 Efficient Black Silicon Solar Cells with Multi-Scale Surface Texture , FATIMA TOOR, WILLIAM NEMETH, MATTHEW PAGE, QI WANG, HOWARD BRANZ, HAO-CHIH YUAN, National Renewable Energy Laboratory — A nanostructured, density-graded surface layer can replace conventional quarter-wavelength coatings as the anti-reflection layer in photovoltaics. If the layer is comprised of structures smaller than the wavelength of the incident light and the density is graded across more than about half the wavelength of the light, reflection is strongly suppressed (H. M. Branz et al., APL **94** 2009). We developed an inexpensive liquid etch technique for silicon to produce "black Si" based upon this physics. However, the problem of high carrier recombination within this nanostructured layer must be overcome to improve beyond the present best solar cell with its confirmed 16.8% black silicon sunlight-to-electricity conversion efficiency (H-C. Yuan et al., APL **95** 2009). In this work, we combine the black Si layer with conventional KOH-etched pyramidal surface texture (Y. Xiu et al., Langmuir **24** 2008) at micron-scale. Pyramids contribute anti-reflection based on geometric optics. Combining the pyramids with nanostructures only 100 nm deep provides reflectivity below 2% across a wavelength range from 350 – 1000 nm. To-date, we have obtained a solar cell efficiency of 17% with a V_{oc} of 613 mV, J_{sc} of 35 mA/cm^2 and fill-factor of 78%. These cells have improved blue response compared to the best planar black Si cells.

12:27PM B36.00007 Scalability of Nanocoax PV Architecture , MICHAEL J. NAUGHTON, ZHIFENG REN, KRIS KEMPA, Boston College — The radial junction nanocoax-based nanowire solar architecture offers the prospect of high conversion efficiency with thin film PV, due to enhanced light trapping and ultrathin absorbers. We critique the potential applicability of this structure for various PV media.

12:39PM B36.00008 Physical effects of ultrathin photovoltaic junctions , T. KIRKPATRICK, K. KEMPA, M.J. NAUGHTON, Boston College — Hot carrier photovoltaic cells have potential to increase conversion efficiency beyond the Shockley-Queisser limit. In addition to implementing selective energy filters into the device in order to extract the hot carriers at elevated energies beyond the band edges, a possible requirement, of particular importance for non-crystalline material, is that the device also be constructed ultrathin in order to extract the hot carriers as usable energy on time scales of less than one picosecond, after which thermalisation sets in. Ultrathin amorphous silicon p-i-n junctions have been shown to extract hot carriers as usable energy at fixed short circuit current density for p- and n- region thicknesses of 5 nm, and i-layer thickness less than 50 nm [Appl. Phys. Lett. **95**, 233121 (2009)]. Physical effects on device performance in ultrathin cells, such as optical absorption, scattering, band structure, and transport are discussed.

12:51PM B36.00009 Amorphous Silicon-Carbon Nanostructure Solar Cells , MARIA SCHRIVER, UC Berkeley, WILL REGAN, MATTHIAS LOSTER, ALEX ZETTL — Taking advantage of the ability to fabricate large area graphene and carbon nanotube networks (buckypaper), we produce Schottky junction solar cells using undoped hydrogenated amorphous silicon thin films and nanostructured carbon films. These films are useful as solar cell materials due their combination of optical transparency and conductance. In our cells, they behave both as a transparent conductor and as an active charge separating layer. We demonstrate a reliable photovoltaic effect in these devices with a high open circuit voltage of 390mV in buckypaper devices. We investigate the unique interface properties which result in an unusual J-V curve shape and optimize fabrication processes for improved solar conversion efficiency. These devices hold promise as a scalable solar cell made from earth abundant materials and without toxic and expensive doping processes.

1:03PM B36.00010 Prediction of enhanced photovoltaic performance of amorphous silicon solar cells with filled nanopores , JEFFREY GROSSMAN, JOO-HYOUNG LEE, Massachusetts Institute of Technology — We propose a novel hybrid structure for improving the efficiency of thin-film amorphous silicon solar cells. Using $ab\ initio$ calculations, we demonstrate that nanoporous, amorphous silicon (pa-Si), when filled with polythiophene (PT) inside the pores, forms a staggered gap (type II) heterojunction at the interfaces, where both the highest occupied and the lowest unoccupied molecular orbitals of PT are positioned in energy higher than those of pa-Si. Furthermore, we find that while the absorption coefficient (α) of pa-Si is significantly reduced from that of bulk amorphous Si (a-Si), inclusion of PT recovers α to the values of a-Si and even higher at thicknesses of $\sim 1\mu$m. These results suggest that such a hybrid material, which from a manufacturing standpoint may be substantially easier to scale up than nanowire-based approaches, could greatly enhance the hole mobility in the active layer, which is one of the main reasons for poor efficiency in a-Si solar cells.

1:15PM B36.00011 Optimizing materials for photon-enhanced thermionic emission , JARED SCHWEDE, DANIEL RILEY, IGOR BARGATIN, SAMUEL ROSENTHAL, ROGER HOWE, NICHOLAS MELOSH, ZHI-XUN SHEN, Stanford University — We recently described a novel process for solar energy harvesting called photon-enhanced thermionic emission (PETE) based on a semiconductor cathode and a low-workfunction anode separated by a vacuum gap. Previous work explored the limiting theoretical efficiency of a PETE device, which was shown to exceed the Shockley-Queisser limit on single-junction photovoltaic cells, and described experiments that showed strong evidence the PETE effect. In this presentation, I will describe challenges for making the PETE process efficient, some of which were encountered in these proof-of-concept measurements. I will also describe experimental paths to overcoming these challenges and improving efficiency.

1:27PM B36.00012 Optimization and Characterization of Nanostructured Surfaces for Photon-Enhanced Thermionic Emission and Photoemission cathodes , DANIEL RILEY, VIJAY NARASIMHAN, JOEL JEAN, IGOR BARGATIN, JARED SCHWEDE, ZHI-XUN SHEN, ROGER HOWE, NICK MELOSH, Stanford University — In the cathode of an energy converter based on photon-enhanced thermionic emission (PETE) photoexcited carriers may need to encounter the emissive surface numerous times before having sufficient thermal energy to escape into vacuum and therefore should be confined close to the surface. However, in a traditional planar geometry, a thin cathode results in incomplete light absorption. Nanostructuring has the potential to increase light capture and boost emission by decoupling the lengths associated with photon absorption and electron emission. Nanostructures may complicate the properties of the emissive surface; therefore, the effect of nanostructuring on emission efficiency needs to be studied. _We have recently reported preliminary theoretical results from a suite of simulation tools to capture the full photoemission process: photon absorption, carrier transport within the active material, and electron ballistics following emission. In this work we use the simulation suite to optimize nanostructures for applications including PETE-based solar energy converters, photodetectors and electron sources. The samples are then characterized, and the emission efficiency measured in an ultra-high vacuum test chamber under application-centric conditions.

1:39PM B36.00013 Design and characterization of transparent thin film nanostructure device , UDAY TRIVEDI, UTPAL JOSHI — Indium tin oxide (ITO) is one of the most widely used transparent conducting oxides (TCO) because of its electrical conductivity and optical transparency.We have grown "all oxide" transparent $p-n$ junction thin film nanostructure device by using chemical solution deposition and e-beam evaporation onto SiO_2 substrate. The oxide $p-n$ junction was characterized by GIXRD, AFM, UV-Vis. spectroscopy and I-V measurements. Combined GIXRD and AFM confirm phase pure, mono-disperse 30 nm NiO and ITO nanocrystallites. More than 70% optical transparency is achieved across 160 nm thick $p-n$ junction. The forward bias current is greater than the reverse bias current by approximately a factor of 10^4 in the measured voltage s weeping range. A small leakage current as low as 12 nA was observed at a reverse bias of –5 V. Previously, Tonooka and co-authors [3] reported the average turn on voltage of their n-ZnO / p-Cu-Al-O diode $\sim$ 0.5 V, which is higher than our p-NiO/n-ITO diode. This is mainly because of the large variations in the carrier concentrations as well as larger lattice mismatch between the oxides forming the $p-n$ junction. The observed optical and electrical properties of oxide transparent diode are attributed to the heteroepitaxial nature and carrier diffusion at the junction interface.

1:51PM B36.00014 Interface properties of chalcopyrite heterocontacts , CHRISTIAN PETTENKOFER, ANDREAS HOFMANN, EIKE JANOCHA, CARSTEN LEHMANN, Helmholtz-Zentrum Berlin, E-I4 TEAM — Interface properties of heterocontacts determine the device performance of thin film solar cells. We investigated well defined chacopyrite interfaces and heterocontacts of MBE grown samples by electron spectroscopy to obtain informations on the morphology and electronic properties of the contact phases. In particular CuInSe2 and CuInS2 (001) and (112) surfaces were grown by MBE and studied with respect to contact formation to ZnO, ZnS and ZnSe. Due to Cu back diffusion into the bulk even for stoichiometric samples Cu poor interfaces were observed giving rise to interdiffused Zn3In2X6 (X=S,Se) layers in the contact plane. Band alignments obtained fort the prepared heterocontacts will be compared to models given by Mönch and Wei et al. The influence of contact preparation on the properties of the interface will be discussed in detail.

2:03PM B36.00015 Effects of Back Contact Materials on Substrate Configuration CdTe Solar Cells[1] , NATHAN G.F. REAVER, KRISTOPHER WIELAND, ALVIN D. COMPAAN, Dept. of Physics & Astronomy, University of Toledo — Substrate configuration CdTe photovoltaics has the potential to provide both a reduction in the production costs and improved power to mass ratio. In this study the effect of copper placement in the cells, sequence of $CdCl_2$ treatment, and the effect of back contact material on cell performance was examined. Cells were deposited on a Mo coated conductive substrate, on stainless steel or on TCO coated glass, using RF magnetron sputtering. Three different back contacts were used, copper-gold as used in superstrate configuration cells, Sb_2Te_3, and ZnTe:N. Cells were measured using a solar simulator at one sun to obtain current density vs. voltage curves and cell efficiencies. The structure that gave the best performance was stainless steel/Mo/Sb_2Te_3/CdTe/CdS/ZnO/ZnO:Al, with the best cell having an efficiency of 5.34%.

Session B37 DMP: Focus Session: Graphene Growth, Characterization, and Devices: Devices and Contacts C146

11:15AM B37.00001 BN / Graphene / BN RF Transistors , HAN WANG, MIT, THITI TAYCHATANAPAT, Harvard University, ALLEN HSU, PABLO JARILLO-HERRERO, TOMAS PALACIOS, MIT — In this work we demonstrate the first BN/graphene/BN transistor for high frequency RF applications. This sandwich structure allows a significant improvement in the mobility of graphene, which reaches more than 18,000 cm^2/Vs at room temperature. Graphene field effect transistors (GFETs) have been fabricated with L_{DS}= 800 nm and L_G=300 nm. The minimum conduction point of these devices is very close to zero, a result of the negligible substrate doping to the graphene. A current density in excess of 1 A/mm and DC transconductance above 200 mS/mm are achieved for both electron and hole conductions. RF characterization is performed for the first time on this device structure and initial results show a current-gain cut-off frequency f_T=10 GHz. These experimental results have been combined with simulations of the small-signal model to study the scaling potential of these GFETs for high frequency applications. The impact of the access resistances (R_s, R_d), the capacitances (C_{gs}, C_{gd}, C_{ds}), and the transconductance (g_m) on the frequency performance of the GFETs has also been studied. Finally, the fabricated devices have been compared to GFETs fabricated with SiO_2 substrate and Al_2O_3 gate dielectrics. The improved performance obtained by the BN/graphene/BN structure is very promising to enable the next generation of high frequency RF electronics.

11:27AM B37.00002 Bilayer graphene $p-i-n$ tunnel junction controlled by modulated top gate[1] , HISAO MIYAZAKI, SONG-LIN LI, KAZUHITO TSUKAGOSHI, NIMS-MANA, JST-CREST, AKINOBU KANDA, Univ. of Tsukuba, JST-CREST — Ambipolar nature of graphene enables us to set charge polarity for electric transport to be p-type or n-type. We fabricated a bilayer graphene (BLG) with spatially modulated p-type and n-type regions. The spatial modulation was introduced by a pair of gate electrodes; a uniform back (substrate) gate and a top gate with stepwise geometry. The gate electric field between the top and back gate also induces band gap in the BLG. As a result, an insulating region is inserted between the p- and n-regions, realizing a $p-i-n$ junction. The current through the junction showed nonlinearity as a function of the source-drain bias. We identified that the origin of nonlinearity is the tunnel current between the p- and n-regions. The nonlinearity reflects the density of states singularity at the edge of the conduction and the valence band in BLG with the band gap. This observation appends another evidence for electric-field-induced band gap in BLG.

[1]This work was supported in part by a Grant-in-Aid for Scientific Research (No. 21241038) from MEXT of Japan, and by the FIRST Program JSPS.

11:39AM B37.00003 Rectification at the graphene and multi-layer-graphene / semiconductor interface from room temperature up to 900K[1] , SEFAATTIN TONGAY, University of Florida, Nanoscience Institute for Medical and Engineering Technology, TODD SCHUMANN, ARTHUR F. HEBARD, University of Florida, Department of Physics — We report on the formation of Schottky diodes on GaN and SiC using a graphite/graphene electrode as a semimetal contact to the semiconductor. The GaN (SiC) /graphene Schottky barriers display rectifying behavior over a wide temperature range with ideality constant close to unity, implying thermionic emission is the dominant transport across the interface. The diodes display larger breakdown voltages (more than 20V) compared to conventional metal junctions (5V). Advantageously, graphite/graphene is stable up to high temperatures and does not diffuse into the semiconductor. We find that these diodes are stable and rectifying up to 900K and are superior to typical metal Schottky diodes reported for the same semiconductors. High temperature measurements are interesting since graphite semimetal contact starts behaving as Boltzmann gas at temperatures well above Fermi energy (T>>280K). Our results imply that graphene based junctions fabricated on conventional semiconductors are good candidates for both high and low temperature devices.

11:51AM B37.00004 Complementary-like semiconducting graphene logic inverters , SONG-LIN LI, HISAO MIYAZAKI, KAZUHITO TSUKAGOSHI, National Institute for Materials Science, Japan, AKINOBU KANDA, University of Tsukuba, Japan — The application of graphene as a post-silicon channel material is an interesting but challenging topic due to its metallic nature and low switching ratio. It is expected that the condition would change if a sizeable band gap is introduced. Here we report the electrical characteristics of the first semiconducting graphene-based logic inverters. Free of doping, the *p*- and *n*- branches in the bipolar graphene transistors are delicately used as the complementary components required in logic devices. Within perpendicular electric fields, large transport band gap (> 100 meV) and high switching ratio (~ 200 at 77 K) are obtained in bilayer graphene channels. Besides, a simple and high capacitive-efficiency top gate with natural alumina dielectric ($\sim 0.9\,\mu F/cm^2$) is adopted and the operating bias is lowered within 2 V. For the first time, > 1 voltage gain are extracted from graphene inverters. Voltage gain up to 8 and 2 are achieved at liquid-nitrogen and room temperatures, respectively. Importantly, a match between input and output voltage levels is realized, indicating the potential for direct cascading between multiple devices for future large-scale integration.

12:03PM B37.00005 Ferroelectric gating of CVD graphene devices[1] , GUANGXIN NI, YI ZHENG, National University of Singapore, KUI YAO, Institute of Material Research and Engineering (IMRE), BARBAROS ÖZYILMAZ, National University of Singapore, DEPARTMENT OF PHYSICS, NATIONAL UNIVERSITY OF SINGAPORE, 2 SCIENCE DRIVE 3, SINGAPORE 117542 TEAM, NANOCORE, NATIONAL UNIVERSITY OF SINGAPORE, 4 ENGINEERING DRIVE 3, SINGAPORE 117576 TEAM, INSTITUTE OF MATERIAL RESEARCH AND ENGINEERING (IMRE), 3 RESEARCH LINK, SINGAPORE 117602 COLLABORATION, NUS GRADUATE SCHOOL FOR INTEGRATIVE SCIENCES AND ENGINEERING, SINGAPORE 117597 TEAM — The recent availability of large area graphene has opened up new possibility in graphene research. We will first discuss experiments, where graphene on the ferroelectric substrate PZT allows the fabrication graphene field effect transistors (GFETs) and graphene memory within ± 1 V operating voltage with maximum doping exceeding 10^{13} cm^{-2}. Ferroelectric substrates may also be of importance for large scale applications. Graphene's exceptional optical and mechanical properties make it suitable also for transparent conductors (TCs). While chemical doping has been proven to be an efficient approach to achieving ultra-low sheet resistance, some challenges remain. Here we propose an alternative way to obtain low sheet resistance of graphene using ferroelectric gating.

12:15PM B37.00006 Electrical noise in graphene FETs , NAN SUN, KRISTOF TAHY, GERALD ARNOLD, DEBDEEP JENA, HUILI XING, STEVEN RUGGIERO, University of Notre Dame, DEPARTMENT OF PHYSICS TEAM, DEPARTMENT OF ELECTRICAL ENGINEERING COLLABORATION — We report on the low-frequency electrical noise measured in graphene FETs. Samples were created by e-beam lithography using both exfoliated graphene and epitaxial graphene films on SiC. The observed 1/f noise varies as a function of gate bias, where the noise amplitude follows Hooge's empirical relation ($S_V \sim 1/N$), and the noise spectrum deviates from 1/f behavior at low carrier densities. We discuss this behavior in the context of a model including random telegraph noise generated by slow traps.

12:27PM B37.00007 Development of epitaxial graphene based electronics , WALT DE HEER, Georgia Institute of Technology — Epitaxial graphene (EG) has demonstrated a great potential for novel electronic devices [1]. In micron-sized structures graphene is essentially a gapless semimetal, consequently reasonable on-to-off rations can be achieved, but digital electronics is precluded. There are essentially two methods to introduce a bandgap in graphene. One is to make very small structures [1], and the other is to chemically modify the graphene itself [2]. Electron beam lithography is not commercially viable and the graphene is severely degraded by this method. Graphene's conductivity depends on the doping density. For interconnects, reliable methods need to be developed to highly dope graphene without deteriorating the mobility. Furthermore, metallic interconnects are required for all but the simplest structures and they need to be incorporated without defeating graphene's favorable properties. Finally, in the more distant future, EG device architectures that rely on wave properties of the electrons that go beyond diffusive electronics are envisioned [1]. These will require interconnected, nanoscopic graphene structures. An overview and perspective of these issues will be given. I will present new directions, involving multilayer epitaxial graphene, interconnect schemes, non-conventional patterning methods (templated graphene growth [3] and related methods), as well as methods to chemically modify and dope EG.

1:03PM B37.00008 Metal selection criteria for enhancing electrical conductance of metal-graphene junctions , MARCELO KURODA, Univ. of Illinois - IBM T.J. Watson, J. TERSOFF, IBM T.J. Watson R.C., DENNIS NEWNS, IBM T.J. Watson, GLENN MARTYNA, IBM T.J. Watson R.C. — We study from first principles the electrical conductance of a junction formed by graphitic films in between metal electrodes. We find that for some metals the junction conductance decays exponentially with the number of graphene layers (thickness of the film) while for others it saturates. These different behaviors are attributed to the presence/absence of Fermi-level states in the metal electrode that couple to those of the graphitic thin film. We also find that the bonding between the metal and graphene atoms at the interface has a significant contribution which is dominant for sufficiently thin films. The study may be proven useful for the design and optimization of epitaxially grown electrical contacts.

1:15PM B37.00009 Influence of Metal Contact on the Operation and Scalability of Graphene Field-Effect-Transistors , PEI ZHAO, University of Notre Dame, QIN ZHANG, CMOS and Novel Devices Group, National Institute of Standards and Technology, DEBDEEP JENA, University of Notre Dame, SIYURANGA O. KOSWATTA, IBM Research Division, T. J. Watson Research Center — We explore the effects of metal contacts on the operation and scalability of 2D Graphene Field-Effect-Transistors (GFETs) using detailed numerical device simulations based on the non-equilibrium Green's function formalism at the ballistic limit. Our treatment of metal/graphene (M/G) contacts captures: (1) the doping effect due to the shift of the Fermi level in graphene contacts, (2) the density-of-states (DOS) broadening effect inside the graphene contacts, and (3) the Metal-Induced-States inside the graphene channel. Our results confirm the asymmetric transfer characteristics in GFETs due to the doping effect by metal contacts. Furthermore, the DOS broadening effect will increases the on-current at higher M/G coupling strengths. Finally, with scaling of the channel length, influence on the minimum current in the off-state is also discussed.

1:27PM B37.00010 Flexible and Transparent Field Emission Devices based on Graphene-Nanowire Hybrid Structures , MUHAMMAD ARIF, KWANG HEO, BYUNG YANG LEE, Department of Physics and Astronomy, Seoul National University, Seoul, Korea, DAVID H. SEO, SUNAE SEO, Semiconductor Devices Lab., Samsung Advanced Institute of Tech., Yongin-Si, Gyeonggi-do, Korea, JIKANG JIAN, Department of Physics, Xinjiang University, Xinjiang 830046, P. R. China, SEUNGHUN HONG, Department of Physics and Astronomy, Seoul National University, Seoul, Korea — Recent developments in wafer scale synthesis and transfer of graphene have made it possible to fabricate electrodes for versatile flexible devices. However, a flexible and transparent graphene-based field emission device has not been explored yet. Herein, we report the fabrication of flexible and transparent field emission devices based on graphene-nanowire hybrid structures. In this work, we successfully grew vertically-aligned Au nanowires on graphene surface using an electrochemical method and utilized it as a cathode. We also utilized a graphene electrode for an anode resulting in a transparent and flexible field emission device. Our field emission devices can be bent down to 22 mm radius of curvature without any significant change in its field emission currents. This flexible and transparent field emission device based on graphene-nanowire hybrid structures will utilized for various applications such as field emission displays, x-ray tubes, and pressure sensors.

1:39PM B37.00011 CVD grown graphene field-effect device arrays with water top gate , BEI WANG, B. KOGER, J. ZHU, Physics Department, The Pennsylvania State University, JUN ZHU TEAM — We synthesize single-layer graphene sheets by chemical vapor deposition (CVD) on copper foil. Large sheets are transferred to Si/SiO_2 wafers using poly(methyl methacrylate) (PMMA). Raman spectroscopy of transferred graphene shows the signatures of high-quality graphene with a very small D band. Graphene field-effect device arrays are fabricated using conventional photolithography. A thin SiO_2 film is deposited on top of the finished devices as the last step. We employ two methods of field effect gating. Gate sweeps of the SiO_2 back gate show large initial hole doping. When a droplet of water is deposited on the device and used as a top gate, the majority of devices show a Dirac point of $\sim$0.3 V and bipolar behavior. The water top gate injects charges much more efficiently than the 290nm SiO_2 back gate. The mobility of the devices is estimated to be a few thousand cm^2/Vs. We discuss transport properties and potential applications of these device arrays.

1:51PM B37.00012 Graphene p-n Junctions via Molecular Functionalization , REN-JYE SHIUE, Academia Sinica, HUNG-CHIEH CHENG, CHIA-CHANG TSAI, YIT-TSONG CHEN, National Taiwan University, WEI-HUA WANG, Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan — An essential challenge in graphene-based electronics is to engineer the carrier type and density and still preserve the transport properties of graphene. We report an experimental investigation of graphene $p-n$ junctions via molecular functionalization. By developing a generic scheme for the chemical functionalization, we have shown that an effective and uniform chemical doping of graphene can be achieved by non-covalent modification of the molecules. The effectiveness and uniformity of the modification is systematically confirmed by optical microscopy, surface potential measurement, and Raman spectroscopic imaging. Furthermore, the chemical doping by molecules is utilized to fabricate the graphene $p-n$ junctions. The transport characteristics of the graphene $p-n$ junctions are investigated by transport and magnetotransport measurements. The signatures of the graphene $p-n$ junctions are presented with high carrier mobility, energy splitting of Dirac points, and non-conventional quantum Hall effect.

2:03PM B37.00013 Device fabrication progress on epitaxial graphene on SiC , YIKE HU, ZELEI GUO, RUI DONG, CLAIRE BERGER, WALT DEHEER, Georgia Tech — Epitaxial graphene on SiC has been demonstrated to be a viable route toward electronic device fabrication. While a top gate is required to locally change doping density and carrier type, specifically for field effect transistors graphene devices, back gating is relevant to globally change carrier and to address the graphene layer at the SiC-graphene interface. Here we report result on back-gating and top-gating epitaxial graphene grown on SiC by the confinement controlled sublimation method. Post-patterning treatments of graphene devices are also discussed.

Monday, March 21, 2011 11:15AM - 2:15PM –
Session B38 DCP: Earle K. Plyler Prize Session I: Spectroscopy A130/131

11:15AM B38.00001 Earle K. Plyler Prize for Molecular Spectroscopy Talk: Coherent Ultrafast Multidimensional Spectroscopy of Molecules; From NMR to X-rays , SHAUL MUKAMEL, University of California, Irvine — Multidimensional spectroscopic techniques which originated with NMR in the 1970s have been extended over the past 15 years to the optical regime. NMR spectroscopists have developed methods for the design of pulse sequences that resolve otherwise congested spectra, enhance selected spectral features and reveal desired dynamical events. The major experimental and computational advances required for extending these ideas to study electronic and vibrational motions on the femtosecond timescale will be surveyed. The response of complex molecules and semiconductor nanostructures to sequences of optical pulses provides snapshots of their structure and dynamical processes. Two-dimensional correlation plots of the signals show characteristic cross-peak patterns which carry information about hydrogen bonding, secondary structure fluctuations of proteins and amyloid fibrils, and coherent and incoherent energy and charge transfer in photosynthetic complexes. Double quantum coherence signals that are induced by correlations among electrons or excitons allow the visualization of correlated wavefunctions. Future extensions to the attosecond regime using xray pulses will be discussed. Since core excitations are highly localized at selected atoms, such signals can monitor the motions of valence electron wavepackets in real space with atomic spatial resolution. Common principles underlying coherent spectroscopy techniques for spins, valence electrons, and core electronic excitations, spanning frequencies from radiowaves, infrared, ultraviolet all the way to hard X-rays will be discussed.

11:51AM B38.00002 Photoelectron spectroscopy of solvated electrons in liquid tetrahydrofuran and methanol microjets , ALEXANDER SHREVE, University of California, Berkeley — Solvated electrons are an important species in radiation chemistry, biology, and other areas. As the simplest quantum solute, solvated electrons are a critical benchmark to test our understanding of solvation in general. Furthermore, when formed in cells, they are highly reactive and may lead to irreversible damage. It is, therefore, important to understand the energetics associated with electron solvation. To this end, we have undertaken a series of studies directly probe electron vertical binding energies (VBEs) in solvents introduced to vacuum through liquid microjets. Solvated electrons are generated following the excitation of the charge-transfer-to-solvent (CTTS) precursor state of iodide from a millimolar concentration salt included in the solution, detached to vacuum, and measured with our field-free time-of-flight spectrometer. Here we present preliminary results of the measurement of the VBE of electrons solvated in bulk tetrahydrofuran and methanol.

12:03PM B38.00003 The Solvated Electron in Acetonitrile , STEPHANIE DOAN, ARTHUR BRAGG, BENJAMIN SCHWARTZ, Dept. Chem. & Biochem., UCLA — The nature of solvated electrons in liquid acetonitrile is of great interest as it appears that excess electrons in this solvent are stabilized in two forms, a dipole-bound (DB) electron (i.e. a typical solvated electron) and a valence-bound electron (VB) electron (e.g. a solvated CH3CN dimer anion). Previous work has suggested that these two species are in equilibrium and can interconvert. We performed 3-pulse transient hole-burning experiments aimed at better understanding the nature of the VB and DB electrons. We found that photoexcitation of VB electrons produces an increased population of DB electrons, but that exciting DB electrons does not produce VB electrons. This suggests a significant asymmetry in the solvent motions that accompany photoexcitation of the electron: it is easier for a DB electron to relax back into the solvent location from which it came than for the local solvation structure to change enough to create a VB electron, whereas excitation of a VB electron disrupts the local solvent structure to the point where the excited electron can relax into the bulk solvent rather than back to the molecules on which it initially resided.

12:15PM B38.00004 Dynamics of electron solvation in $I^-(CH_3OH)_n$ clusters ($4 \leq n \leq 11$) , RYAN YOUNG, University of California, Berkeley — The dynamics of electron solvation following excitation of the charge-transfer-to-solvent (CTTS) precursor state in iodide-doped methanol clusters, $I^-(CH_3OH)_{n=4-11}$ are studied with time-resolved photoelectron imaging (TRPEI). This excitation produces a $I\cdots(CH_3OH)_n^-$ cluster that is unstable with respect to electron autodetachment, and whose autodetachment lifetime increases monotonically from ~800 fs to 85 ps as n increases from 4-11. The vertical detachment energy (VDE) and width of the excited state feature in the photoelectron spectrum show complex time dependences during the lifetime of this state. The VDE decreases over the first 100-400 fs, then rises exponentially to a maximum with a $\sim$ 1ps time constant, decreasing by as much as 180 meV with timescales from 4-10 ps. The early dynamics are assigned to electron transfer from the iodide to a localized portion of the methanol cluster, while the longer-time changes in VDE are attributed to solvent reordering, possibly in conjunction with ejection of neutral iodine from the cluster. Changes in the observed width of the spectrum largely follow those of the VDEs; the dynamics of both are attributed to the major rearrangement of the solvent cluster during relaxation. The relaxation dynamics are interpreted as a reorientation of at least one methanol molecule and the disruption and formation of the solvent network in order to accommodate the excess charge.

12:27PM B38.00005 Vibronic Enhancement of Exciton Sizes and Energy Transport in Photosynthetic Complexes , ANDREW MORAN, JORDAN WOMICK, BRANTLEY WEST, STEPHEN MILLER, University of North Carolina — This talk investigates the impact of vibronic couplings on the electronic structures and relaxation mechanisms of two cyanobacterial light harvesting proteins, allophycocyanin (APC) and c-phycocyanin (CPC). Both APC and CPC possess three pairs of pigments (i.e., dimers), which undergo electronic relaxation on the sub-picosecond time scale. Electronic relaxation is approximately 10 times faster in APC than in CPC despite the nearly identical structures of their pigment dimers. Femtosecond laser spectroscopies conducted in conjunction with a Frenkel exciton model find that photo-induced electronic relaxation in these two proteins is understood on the same footing only when the vibronic couplings in high-frequency modes are properly taken into account. In addition to incorporating high-frequency intramolecular modes in the spectral density, we simulate electronic relaxation dynamics using a model in which the excitons delocalize in a vibronic basis. General implications of the present findings for energy transport in artificial systems (e.g., crystalline organic semiconductors) are discussed.

12:39PM B38.00006 Nonlinear Coherent Optical Imaging for Biomedicine: The Quest for Ultimate Sensitivity , SUNNEY XIE, Harvard University — Recent advances in nonlinear coherent optical imaging, particularly stimulated Raman scattering microscopy, have allowed highly sensitive label-free imaging of living cells and organisms based on molecular spectroscopy. Using the ultimate sensitivity of nonlinear optical microscopy, the detection of a single-molecule absorption signal at room temperature has been achieved. These unprecedented sensitivities offer exciting possibilities for biomedicine.

1:15PM B38.00007 Optical Control of Conjugated Oligomer Planarity , SERGEI TRETIAK, Los Alamos National Laboratory, JENNY CLARK, Cavendish Laboratory, University of Cambridge, GUGLIELMO LANZANI , Lanzani — Using a sequential photo-excitation mechanism we observe the ultrafast conformational planarization of a large fluorene oligomer at $\sim$ 60fs timescale. Novel non-adiabatic excited state molecular dynamics (NA-ESMD) framework incorporating quantum transitions has been used to rationalize this phenomenon. Simulation show the ultrafast relaxation of the photoexcited wavepacket toward the lowest electronic excited state along the torsional coordinate. The process effectively 'locks' the oligomer into a planar state within 100 fs, with excess energy being dissipated into other vibrational modes. Ultrafast control of molecular conformation, as demonstrated here, could have impacts for molecular conformational switches for memory or molecular electronics.

1:27PM B38.00008 Using 2D Fourier-transform spectroscopy to separate homogeneous and inhomogeneous line widths of heavy- and light-hole excitons in weakly disordered semiconductor quantum wells , STEVEN CUNDIFF, ALAN BRISTOW, TIANHAO ZHANG, MARK SIEMENS, JILA, NIST and University of Colorado, RICHARD MIRIN, NIST-Boulder — Optical two-dimensional Fourier-transform spectroscopy is used to study the heavy- and light-hole excitonic resonances in GaAs quantum wells with weak structural disorder. Homogeneous and inhomogeneous broadening contribute differently to the two-dimensional resonance line shapes, allowing separation of homogeneous and inhomogeneous line widths. The heavy-hole exciton exhibits more inhomogeneous than homogeneous broadening, whereas the light-hole exciton shows the opposite. This situation arises from the interplay between the length scale of the disorder and the exciton Bohr radius, which affects the exciton localization and scattering. Utilizing this separation of line widths, excitation-density-dependent measurements reveal that many-body interactions alter the homogeneous dephasing, while disorder-induced dephasing is unchanged.

1:39PM B38.00009 Oxygen atom roaming and multiple dissociation pathways of NO_3 , MICHAEL GRUBB, MICHELLE WARTER, KURT JOHNSON, SIMON NORTH, Texas A&M University — The role of nitrate radical (NO_3) photolysis in atmospheric has long been known, but mysteries remain regarding the mechanism of the dissociation. In particular, the NO + O_2 channel has proven to be a challenge both theoretically and experimentally. High resolution velocity map ion imaging studies reveal that there are two distinct mechanisms to form the NO + O_2 products. Additionally, the dominant of these mechanisms appears to be the non-traditional state "roaming" mechanism recently identified in formaldehyde dissociation. The roaming mechanism involves large amplitude motion associated with a frustrated radical dissociation before roaming oxygen atom abstraction to form O_2. The identification of roaming in the NO_3 reaction may imply the widespread importance of this type of mechanism in atmospheric chemistry.

1:51PM B38.00010 First Principle Simulations of the Infrared Spectrum of Liquid Water using Hybrid Density Functionals , CUI ZHANG, DAVIDE DONADIO, FRANCOIS GYGI, GIULIA GALLI, Univeristy of California, Davis — We report on calculations of the infrared spectrum (IR) of liquid water carried out using first principle molecular dynamics and the hybrid functional PBE0. We find results in much better agreement with experiment than those obtained using semi-local, gradient corrected exchange correlation functionals. In particular the description of the IR stretching band is greatly improved and in good accord with recent measurements. When adopting the PBE0 functional, substantial improvement is also found in the description of the structural properties of the liquid, consistent with a smaller average number of hydrogen bonds, and a reduced molecular dipole moment, as revealed by our analysis of maximally localized Wannier functions. Finally the average electronic gap of the liquid is increased by 60% with respect to PBE, when computed at the PBE0 level of theory, and is in fair agreement with experiment. Work supported by NSF/OCI-0749217.

2:03PM B38.00011 Nonequilibrium Mixed Quantum-Classical simulations of Hydrogen-bond Structure and Dynamics in Methanol-d Carbon tetrachloride liquid mixtures and its spectroscopic signature , KIJEONG KWAC, EITAN GEVA — Liquid mixtures of methanol-d and carbon tetrachloride provide attractive model systems for investigating hydrogen-bond structure and dynamics. The hydrogen-bonded methanol oligomers in these mixtures give rise to a very broad hydroxyl stretch IR band ($\sim$150 cm^{-1}). We have employed mixed quantum-classical molecular dynamics simulations to study the nature of hydrogen- bond structure and dynamics in this system and its spectroscopic signature. In our simulations, the hydroxyl stretch mode is treated quantum mechanically. We have found that the absorption spectrum is highly sensitive to the type of force fields used. Obtaining absorption spectra consistent with experiment required the use of corrected polarizabile force fields and a dipole damping scheme. We have established mapping relationships between the electric field along the hydroxyl bond and the hydrogen-stretch frequency and bond length thereby reducing the computational cost dramatically to simulate the complex nonequilibrium dynamics underlying pump-probe spectra.

Monday, March 21, 2011 11:15AM - 2:15PM –

Session B39 DBP DPOLY DCP: Focus Session: Single Molecule Biophysics II: Novel Single Molecule Approaches to Biology A124/127

11:15AM B39.00001 Single-image molecular analysis for accelerated fluorescence imaging , YAN MEI WANG, University of Washington — We have developed a new single-molecule fluorescence imaging analysis method, SIMA, to improve the temporal resolution of single-molecule localization and tracking studies to millisecond timescales without compromising the nanometer range spatial resolution [1,2]. In this method, the width of the fluorescence intensity profile of a static or mobile molecule, imaged using submillisecond to milliseconds exposure time, is used for localization and dynamics analysis. We apply this method to three single-molecule studies: (1) subdiffraction molecular separation measurements, (2) axial localization precision measurements, and (3) protein diffusion coefficient measurements in free solution. Applications of SIMA in flagella IFT particle analysis, localizations of UgtP (a cell division regulator protein) in live cells, and diffusion coefficient measurement of LacI in vitro and in vivo will be discussed.

11:51AM B39.00002 Super-resolution imaging of multiple fluorescent proteins with highly overlapping emission spectra in living cells , MUDALIGE GUNEWARDENE, University of Maine, FEDOR SUBACH, Albert Einstein College of Medicine, TRAVIS GOULD, Yale University , GREGORY PENONCELLO, MANASA GUDHETI, University of Maine, VLADISLAV VERKHUSHA, Albert Einstein College of Medicine, SAMUEL HESS, University of Maine — Diffraction limits resolution in far field microscopy. Single molecule localization based superresolution imaging has surpassed such limitations and is rapidly gaining popularity, yet limited availability of cell-compatible photoactivatable fluorescent probes with distinct emission spectra have impeded simultaneous visualization of multiple molecular species in living cells. We introduce PAmKate, a monomeric far-red photoactivatable fluorescent protein (PAFP), which has facilitated simultaneous imaging of three PAFPs in biological samples with fluorescence photoactivation localization microscopy (FPALM). Successful probe identification was achieved by measuring the fluorescence emission intensity in two distinct spectral channels spanning approximately 100 nm of the visible spectrum. Raft-, non-raft- and cytoskeleton- associated proteins were simultaneously imaged in both live and fixed fibroblasts co-expressing Dendra2-hemagglutinin, PAmKate-transferrin receptor and PAmCherry1-β-actin chimeras, revealing evidence for specific interactions between membrane proteins and membrane-associated actin structures.

12:03PM B39.00003 Single-image diffusion coefficient measurements of proteins in free solution , SHANNON KIAN ZAREH, MICHAEL DESANTIS, JONATHAN KESSLER, YAN MEI WANG, Washing University in St. Louis, Physics department — Diffusion coefficient measurement of biomolecules is important for particle size determination, reaction rate characterization, and molecular dynamics investigation. Here we present a simple and fast method for determining diffusion coefficient of nanometer- and sub-nanometer-sized fluorophores, such as GFP, in free solution by analyzing their single fluorescence images with sub-millisecond exposure times. In this method, the standard deviation (SD) of a diffusing molecule's intensity profile is used to determine its diffusion coefficient. Our SD vs. diffusion coefficient expression is consistent with our simulation and experimental measurement results, rendering this sub-millisecond-long method to be an improvement of at least 100-fold in temporal resolution over current diffusion coefficient measurement methods, such as single-particle-tracking and FCS.

12:15PM B39.00004 Quantifying kinetics and dynamics of DNA repair proteins using Raster-scan Image Correlation Spectroscopy , SALIM ABDISALAAM, University of Texas at Arlington/UT Southwestern Medical Center, MILAN POUDEL, DAVID CHEN, UT Southwestern Medical Center, GEORGE ALEXANDRAKIS, University of Texas at Arlington/UT Southwestern Medical Center — DNA double strand breaks are potentially dangerous lesions as their incomplete repair may lead to carcinogenesis. In this study the confocal Raster scan Image Correlation Spectroscopy technique is used to study kinetics and dynamics of double stand break repair proteins after γ-irradiation of mammalian cells. Diffusion and binding constants were obtained by fitting with different physical models. Results were compared to ones obtained by creating high density DNA damage with a laser and subsequently performing Fluorescence Recovery after Photobleaching over the damage area. This work presents similarities and differences in double strand break repair response between γ-irradiation versus laser damage. This is of importance to answering the question of whether the popular use of laser induced DNA damage is a sufficient surrogate for predicting the radiation treatment response of cancer cells.

12:27PM B39.00005 Overview of single-molecule methods including high-force, force-fluorescence, and dual-trap studies for probing molecular and cellular machinery , MATTHEW LANG, Vanderbilt University — High force optical trapping, including double trap geometry and simultaneous visualization with single molecule fluorescence imaging enables a wide range of measurement capabilities applicable for probing molecular and cellular machinery. A series of single molecule measurement methods will be presented. Force-fluorescence microscopy enables visualizing amyloid fibers while physically probing their structures including direct unfolding and rupture of fibers with a high force optical trap. Force spectroscopy is employed to probe the strength of single peptide aptamer bonds. A dual-trap geometry allows for direct tracking of unfolding and translocation machinery of the biological motor ClpXP. Force fluorescence microscopy directly visualizes T-cell activation. Automation and flexibility in our instruments coupled with advances in physical assay design strategies are leveraged to access a broad set of molecular and cellular measurement targets.

1:03PM B39.00006 ABSTRACT WITHDRAWN –

1:15PM B39.00007 3D single molecule tracking in thick cellular specimens using multifocal plane microscopy[1] , SRIPAD RAM, E. SALLY WARD, University of Texas Southwestern Medical Center, RAIMUND J. OBER, University of Texas at Dallas — One of the major challenges in single molecule microscopy concerns 3D tracking of single molecules in cellular specimens. This has been a major impediment to study many fundamental cellular processes, such as protein transport across thick cellular specimens (e.g. a cell-monolayer). Here we show that multifocal plane microscopy (MUM), an imaging modality developed by our group, provides the much needed solution to this longstanding problem. While MUM was previously used for 3D single molecule tracking at shallow depths ($\sim$ 1 micron) in live-cells [1], the question arises if MUM can also live up to the significant challenge of tracking single molecules in thick samples. Here by substantially expanding the capabilities of MUM, we demonstrate 3D tracking of quantum-dot labeled molecules in a $\sim$10 micron thick cell monolayer. In this way we have reconstructed the complete 3D intracellular trafficking itinerary of single molecules at high spatial and temporal precision in a thick cell-sample.

1:27PM B39.00008 Single Molecule Analysis of Serotonin Transporter Regulation Using Quantum Dots , JERRY CHANG, Vanderbilt University, IAN TOMLINSON, MICHAEL WARNEMENT, ALESSANDRO USTIONE, ANA CARNEIRO, DAVID PISTON, RANDY BLAKELY, SANDRA ROSENTHAL — For the first time, we implement a novel, single molecule approach to define the localization and mobility of the brain's major target of widely prescribed antidepressant medications, the serotonin transporter (SERT). SERT labeled with single quantum dot (Qdot) revealed unsuspected features of transporter mobility with cholesterol-enriched membrane microdomains (often referred to as "lipid rafts") and cytoskeleton network linked to transporter activation. We document two pools of surface SERT proteins defined by their lateral mobility, one that exhibits relatively free diffusion in the plasma membrane and a second that displays significantly restricted mobility and localizes to cholesterol-enriched microdomains. Diffusion model prediction and instantaneous velocity analysis indicated that stimuli that act through p38 MAPK-dependent signaling pathways to activate SERT trigger rapid SERT movements within membrane microdomains. Cytoskeleton disruption showed that SERT lateral mobility behaves a membrane raft-constrained, cytoskeleton-associated manner. Our results identify an unsuspected aspect of neurotransmitter transporter regulation that we propose reflects the dissociation of inhibitory, SERT-associated cytoskeletal anchors.

1:39PM B39.00009 Casein Kinase 2 Reverses Tail-Independent Inhibition of Kinesin-1[1] , JING XU, ZHANYONG SHU, PREETHA ANAND, BABU REDDY, SILVIA CERMELLI, THOMAS WHISENANT, UC Irvine, STEPHEN KING, University of Missouri-Kansas City, LEE BARDWELL, LAN HUANG, STEVEN GROSS, UC Irvine — Kinesin-1 is a plus-end microtubule-based molecular motor, and defects in kinesin transport are linked to diseases including neurodegeneration. Kinesin can auto-inhibit via a direct head-tail interaction, but is believed to be active otherwise. In contrast, this study uncovers a fast but reversible inhibition distinct from the canonical auto-inhibition pathway. The majority of the initially active kinesin (full-length or tail-less) loses its ability to bind/interact with microtubule, and Casein Kinase 2 (CK2) reverses this inactivation (up to 4-fold) without altering kinesin's single motor properties. Motor phosphorylation is not required for this CK2 -mediated kinesin activation. In cultured mammalian cells, knockdown of CK2 level, but not kinase activity, was sufficient to decrease the force required to stall lipid droplet transport, consistent with a reduction in the number of active motors. We propose that CK2 forms a positive regulating complex with the motor. This study provides the first direct evidence of a protein kinase positively regulating kinesin-transport, and uncovers a pathway whereby inactive cargo-bound kinesin can be activated.

1:51PM B39.00010 Asymmetric Friction and Directed Movement of Brownian Motors , OLEG ANDREEV, University of Rhode Island, VLADISLAV MARKIN, University of Texas Southwestern Medical Center, URI TEAM, UTSMC TEAM — It is assumed that a Brownian motor is a system that can rectify thermal fluctuations into directed movement. The intriguing question is how this is achieved: what is the mechanism for transferring random pulses from the environment into directed movement. A number of models have been proposed, which, in general, assume the existence of an "asymmetric flashing potential" that makes the motor's diffusion predominately in one direction. In this work, we introduce a model of Brownian motors based on asymmetric friction rather than on asymmetric flashing potential. We show that asymmetric friction can break the symmetry of a molecule's "random walk" by changing the step size depending on direction. Our model assumes the presence of a symmetrical Brownian force (Gaussian function, average force is 0), an isotropic viscous force, which is proportional to the velocity value but opposite in direction, and an asymmetric friction force, whose value depends on the direction. We present a mathematical model that explains the directed movement for several Brownian motor types.

2:03PM B39.00011 GSK-3 regulates transport of kinesin-1 driven cargos *in vivo* , CHRISTINA LEIDEL, Department of Physics, University of Texas at Austin, CAROLE WEAVER, LUKASZ SZPANKOWSKI, LAWRENCE S.B. GOLDSTEIN, HHMI, Department of Cellular and Molecular Medicine, School of Medicine, Univeristy of California, GEORGE T. SHUBEITA, Department of Physics, University of Texas at Austin, CENTER FOR NONLINEAR DYNAMICS, DEPARTMENT OF PHYSICS, UNIVERSITY OF TEXAS AT AUSTIN COLLABORATION, HHMI, DEPARTMENT OF CELLULAR AND MOLECULAR MEDICINE, UNIV. OF CALIFORNIA COLLABORATION — The Glycogen Synthase Kinase 3 (GSK-3) has been linked to many aspects of the development of Alzheimer's disease and was proposed to play a role in the transport of the Amyloid Precursor Protein (APP) by kinesin-1 motors. Using *Drosophila* embryos and larvae with altered GSK-3 expression, we characterize motor transport of cargos including APP and lipid droplets using DIC microscopy, high-resolution video tracking, fluorescence, and *in vivo* stall force measurements with optical tweezers. By comparing cargo velocities and run lengths we find that GSK-3 is a required negative regulator of *in vivo* transport. Stall force measurements on lipid droplets reveal that enhanced transport under conditions of reduced GSK-3 is a result of a larger number of active motors hauling the cargo. Our findings have implications on the use of GSK-3 inhibitors in treatment of Alzheimer's disease.

Session B40 DBP: Lipid Bilayers and Biological Membranes: Dynamics and Thermodynamics

A122/123

11:15AM B40.00001 Correlating Anomalous Diffusion with Membrane Obstacle Structure Using Single Molecule Tracking and AFM[1] , MICHAEL SKAUG, MARJORIE LONGO, ROLAND FALLER, UC Davis — Anomalous diffusion has been observed abundantly in the plasma membrane, but the underlying mechanisms are still unclear. In general, it has not been possible to directly image the obstacles to diffusion in membranes, so the dynamics of diffusing particles are used to deduce the obstacle characteristics. We present a supported lipid bilayer system in which we characterized the anomalous diffusion of lipid molecules using single molecule tracking, while at the same time imaging the obstacles to diffusion with atomic force microscopy. To explain our experimental results, we performed lattice Monte Carlo simulations of tracer diffusion in the presence of the experimentally determined obstacle configurations. We correlate the observed anomalous diffusion with obstacle area fraction, fractal dimension and correlation length. We further discuss our results in the context of confinement models and the generating stochastic process.

[1]Supported by NSF grant CBET 0506602

11:27AM B40.00002 Tracking single Kv2.1 channels in live cells reveals anomalous subdiffusion and ergodicity breaking , AUBREY WEIGEL, BLAIR SIMON, MICHAEL TAMKUN, DIEGO KRAPF, Colorado State University — The dynamic organization of the plasma membrane is responsible for essential cellular processes, such as receptor trafficking and signaling. By studying the dynamics of transmembrane proteins a greater understanding of these processes as a whole can be achieved. It is broadly observed that the diffusion pattern of membrane protein displays anomalous subdiffusion. However, the mechanisms responsible for this behavior are not yet established. We explore the dynamics of the voltage gated potassium channel Kv2.1 by using single-particle tracking. We analyze Kv2.1 channel trajectories in terms of the time and ensemble distributions of square displacements. Our results reveal that all Kv2.1 channels experience anomalous subdiffusion and we observe that the Kv2.1 diffusion pattern is non-ergodic. We further investigated the role of the actin cytoskeleton in these channel dynamics by applying actin depolymerizing drugs. It is seen that with the breakdown of the actin cytoskeleton the Kv2.1 channel trajectories recover ergodicity.

11:39AM B40.00003 Studies of molecular diffusion in single-supported bilayer lipid membranes at high hydration by quasielastic neutron scattering[1] , M. BAI, A. MISKOWIEC, S.-K. WANG, H. TAUB, U. Mo., F.Y. HANSEN, Tech. U. Denmark, T. JENKINS, M. TYAGI, D.A. NEUMANN, NIST, S.O. DIALLO, E. MAMONTOV, K.W. HERWIG, ORNL — Bilayer lipid membranes supported on a solid surface are attractive model systems for understanding the structure and dynamics of more complex biological membranes that form the outer boundary of living cells. We have recently obtained quasielastic neutron spectra from single-supported bilayer lipid membranes using the backscattering spectrometer BASIS at the Spallation Neutron Source. Protonated DMPC membranes were deposited onto SiO_2-coated Si(100) substrates and characterized by AFM. Analysis of their neutron spectra shows evidence of a relatively broad Lorentzian component that we associate with bulk-like water above a freezing temperature of ∼267 K. At lower temperatures, the spectra differ qualitatively from that of bulk supercooled water, a behavior that we attribute to water bound to the membrane. We also find evidence of a narrow Lorentzian component that we tentatively identify with a slower motion (time scale ∼1 ns) associated with conformational changes of the alkyl tails of the lipid molecules.

[1]Supported by NSF Grant No. DMR-0705974.

11:51AM B40.00004 Studies of molecular diffusion in single-supported bilayer lipid membranes at low hydration by quasielastic neutron scattering[1] , A. MISKOWIEC, M. BAI, M. LEVER, H. TAUB, U. Mo., F.Y. HANSEN, Tech. U. Denmark, T. JENKINS, M. TYAGI, D.A. NEUMANN, NIST, S.O. DIALLO, E. MAMONTOV, K.W. HERWIG, ORNL — We have extended our investigation of the quasielastic neutron scattering from single-supported bilayer lipid membranes to a sample of lower hydration using the backscattering spectrometer BASIS at the SNS of ORNL. To focus on the diffusive motion of the water, tail-deuterated DMPC membranes were deposited onto SiO_2-coated Si(100) substrates and characterized by AFM. Compared to a sample of higher hydration, the dryer sample does not have a step-like freezing transition at ∼267 K and shows less intensity at higher temperatures of a broad Lorentzian component representing bulk-like water. However, the broad component of the "wet" and "dry" samples behaves similarly at lower temperatures. The dryer sample also shows evidence of a narrow Lorentzian component that has a different temperature dependence than that attributed to conformational changes of the alkyl tails of the lipid molecules in the wet sample. We tentatively identify this slower diffusive motion (time scale ∼1 ns) with water more tightly bound to the membrane.

[1]Supported by NSF Grant No. DMR-0705974.

12:03PM B40.00005 Diffusion in Single Supported Lipid Bilayers , C.L. ARMSTRONG, McMaster Univeristy, Hamilton, Canada, M. TRAPP, Institut de Biologie Structurale, Grenoble, France, M.C. RHEINSTÄDTER, McMaster University, Hamilton, Canada — Despite their potential relevance for the development of functionalized surfaces and biosensors, the study of single supported membranes using neutron scattering has been limited by the challenge of obtaining relevant dynamic information from a sample with minimal material. Using state of the art neutron instrumentation we have, for the first time, modeled lipid diffusion in single supported lipid bilayers.[1] While we find that the diffusion coefficient for the single bilayer system is comparable to a multi-lamellar lipid system, the molecular mechanism for lipid motion in the single bilayer is a continuous diffusion process with no sign of the flow-like ballistic motion reported in the stacked membrane system. In the future, these membranes will be used to hold and align proteins, mimicking physiological conditions enabling the study of protein structure, function and interactions in relevant and highly topical membrane/protein systems with minimal sample material.

[1]C.L. Armstrong, M.D. Kaye, M. Zamponi, E. Mamontov, M. Tyagi, T. Jenkins and M.C. Rheinstädter, Soft Matter Communication, 2010, Advance Article, DOI: 10.1039/C0SM00637H

12:15PM B40.00006 Membrane stress relaxation by transbilayer cholesterol exchange , MARK L. HENLE, L. MAHADEVAN, Harvard University — Fusion and fission events in the cell membrane play a crucial role in many biological processes, yet the mechanism for inducing the membrane bending deformations required for such events remains poorly understood. In particular, standard membrane elastic models predict a problematically high energy barrier for the strongly curved "neck" region formed during fusion and fission. These models assume that the exchange of lipids between membrane leaflets is negligible. While this is valid for phospholipids, other amphiphilic molecules such as cholesterol undergo rapid flip-flop between leaflets. Such exchange can relax bending stresses in the membrane: By flipping from the compressed to the expanded leaflet, cholesterol can reduce the energy required to bend the membrane. In this talk, we present a coarse-grained energetic model (derived from a simple microscopic description of the membrane) for a two-component lipid bilayer that contains a lipid species that can undergo rapid transbilayer exchange. Using this model, we show that lipid flip-flop dramatically reduces the energetic barriers encountered during membrane fusion and fission events and also plays an important role in determining the deformations induced by external forces such as osmotic pressure.

12:27PM B40.00007 Ethanol enhances collective dynamics of lipid membranes , MARTIN KAYE, MAIKEL RHEINSTADTER, McMaster University, Hamilton, Ontario, Canada — Lipid bilayers have long been considered simple homogeneous passive barriers. However, there is a growing consensus that bilayer composition and properties impact their role in membrane function. One molecule which participates in lipid bilayers is ethanol. Ethanol is principally known to increase membrane permeability, serving as a model drug enhancer. While bilayer permeability was thought to depend solely on structural properties such as the area per lipid, this may be supported by thermal fluctuations in the bilayer core. Thermal motion results in the formation of small voids in the hydrocarbon chains, which may play a role in the transport small molecules through the membrane core. In both inelastic neutron scattering experiments and molecular dynamics simulations we find evidence for a new low-energy dynamic mode in the fluid phase of DMPC bilayers immersed in a 5% water/ethanol solution [1]. The molecular motion associated with this phonon corresponds to coherent displacements of the carbon atoms in the lipid tails both in, and partially normal to, the plane of the membrane. This finding supports the possibility of a fluctuation supported trans-membrane transport process in lipid bilayers.

[1] "Ethanol enhances collective dynamics of lipid membranes", M. D. Kaye, M. Tarek, K. Schmalzl, M. C. Rheinstädter, submitted to Physical Review Letters

12:39PM B40.00008 Vesicle Shape Transformations Driven by Active and Spontaneous Lipid Flip-flop , THOMAS POWERS, Brown University, ELNAZ BAUM-SNOW, University of Connecticut Health Center — The lipid composition of cell membranes is created and maintained in part by flippases, enzymes that translocate lipid molecules from one layer of the bilayer membrane to the other. We study how lipid translocation can affect membrane shape, using a cylindrical vesicle as a simple model system. For a short pulse of flippase activity, in which a fraction of lipids are flipped from one layer to the other, we calculate the fraction of flipped lipids that makes the cylinder unstable to a periodic modulation in its radius, as well as the growth rate of perturbations of different wavenumber. We also study the cases of continuous flippase activity and spontaneous flip-flop.

12:51PM B40.00009 *In vitro* approach to the mechanics of lipid membrane area regulation: vesicle absorption and tube formation , MARGARITA STAYKOVA, DOUGLAS HOLMES, CLARKE READ, HOWARD A. STONE — We have designed an experimental approach that allows us to study the response of supported lipid bilayers to cycles of biaxial expansion and compression. We observed that the bilayer effectively adjusts its area during dilatational or compressive strains in order to reduce its tension. For example, if there is a sufficient lipid reservoir in the form of attached vesicles, then a lipid bilayer may accommodate strains tens of times larger than the critical strain for rupture by expanding its area. Additionally, upon compression the bilayer reduces its area by expelling lipid tubes out of its plane. These observations offer new insights into how cells regulate their surface area in response to various mechanical stimuli, i.e. during physiological volume changes, locomotion, cyclic expansion and compression of the uro- and the alveolar- epithelium, etc.

1:03PM B40.00010 Structural Phase Diagram for Multi-lamellar Tubular Deformations of Lipid Mesophases , LOBAT TAYEBI, ATUL PARIKH, University of California, Davis — Stable multi-lamellar cylindrical tubules protrude readily from concentrated mass of amphiphilic molecules in response to a variety of external stresses. Using energetic considerations, we have developed an phase diagram, predicting various types of morphologies of equilibrium multilamellar tubular deformations that stabilize for a broad range of their bending rigidity and surface tension values. Tubular morphologies are described in terms of core radius(rc) and number of lamellae(N). Results of the calculations reveal that emergent tubular morphologies can be classified into three major classes: (1) thin tethers (small rc and low N); (2) solid tubes (high N); and (3) hollow tubes (large rc and and low N). Experimental validation of these predictions is obtained in experiments involving hydration of dry stack lipids Here, tubular deformations, referred to as myelin figures, of all predicted morphologies form in separate populations. Furthermore, the phase diagram also sheds light on a long-standing question of the determinants of the thickness of such myelin figures.

1:15PM B40.00011 Biomembranes that respond to specific triggers by phase separating , MATTHEW LEROUX, MATTHEW FRANTES, VERNITA GORDON, Center for Nonlinear Dynamics and Department of Physics, University of Texas at Austin — Lipid membranes are widely used as models for the cell membrane and for applications such as encapsulation, delivery, and controlled release. We have recently found that when membranes adhere nonspecifically, the adhesion site favors the nucleation and growth of more-ordered lipid phases. The physics behind this, which works by suppressing membrane fluctuations, should be applicable to specifically-adhering membranes as well. This will allow better experimental models for cell adhesion, which is mediated by transmembrane proteins and associated with lipid heterogeneities, and also indicates a new category of pathways for making 'smart,' responsive materials out of lipid membranes. We are transforming our previous, non-specifically adhering systems into membranes that specifically adhere to a surface via binder molecules. We will determine the thresholds for forming ordered phases as a function of binder stiffness, length, and density, compatibility of the binder structure with the molecular packing of lipids in these phases, and membrane properties such as bending modulus and proximity to a phase transition.

1:27PM B40.00012 Lipid domains in supported SM-Chol membranes measured by GISANS[1] , MIKHAIL ZHERNENKOV, MANISH DUBEY, Los Alamos National Laboratory, BORIS TOPERVERG, Ruhr-Universität Bochum, JAROSLAW MAJEWSKI, MICHAEL FITZSIMMONS, Los Alamos National Laboratory — Cell membranes are known to contain regions (called lipid domains, or rafts) described as sphingolipid-cholesterol assemblies which also may contain a subset of membrane proteins. Currently, the main point of discussion is the methodology to study lipid domains and their sizes. We report on Grazing Incidence Small Angle Neutron Scattering (GISANS) measurements of lipid domains in supported sphingomyelin(SM)-cholesterol(Chol) bilayers in a fully aqueous environment. The model bilayers SM:Chol(2:1), SM:Chol(1:2), and a pure SM were deposited using Langmuir-Blodgett/Langmuir-Schaefer technique at a surface pressure of 10 mN/m and measured at 25 $^{\circ}$C. First measurements revealed short range inhomogeneities of the order of 100 Å in both binary systems. The control measurement of a pure SM bilayer exhibited nearly no GISANS indicating an absence of lipid domains in the SM bilayer. This observation is consistent with the notion that a single component system studied below the liquid-gel transition temperature will not produce lipid domains.

[1]Work was supported by DOE-BES.

1:39PM B40.00013 Structure of the Stern layer in Phospholipid Systems[1] , SWETA VANGAVETI, Iowa State University, ALEX TRAVESSET, Iowa State University and Ames lab — The structure of the Stern layer in Phospholipid Systems results from a subtle competition of salt concentration, ionic valence, specific ionic-phospolipid interactions and pH. It becomes very challenging to develop a rigorous theory that encompasses all these effects, yet its understanding is extremely relevant for both model and biological systems, as the structure of the Stern layer determines the interactions of phospholipids with proteins or electrostatic phase separation (rafts). In this talk we will present our theoretical model for the Stern Layer and discuss how all these effects are included. Particularly emphasis is made to Phosphoinositides and Phosphatidic acid.

[1]This work is supported by grant NSF DMR-0748475.

1:51PM B40.00014 Modeling Signal Transduction and Lipid Rafts in Immune Cells , ASHOK PRASAD, Dept. of Chemical and Biological Engr, Colorado State University — Experimental evidence increasingly suggests that lipid rafts are nanometer sized cholesterol dependent dynamic assemblies enriched in sphingolipids and associated proteins. Lipid rafts are dynamic structures that break-up and reform on a relatively short time-scale, and are believed to facilitate the interactions of raft-associated proteins. The role of these rafts in signaling has been controversial, partly due to controversies regarding the existence and nature of the rafts themselves. Experimental evidence has indicated that in several cell types, especially T cells, rafts do influence signal transduction and T cell activation. Given the emerging consensus on the biophysical character of lipid rafts, the question can be asked as to what roles they possibly play in signal transduction. Here we carry out simulations of minimal models of the signal transduction network that regulates Src-family kinase dynamics in T cells and other cell types. By separately treating raft-based biochemical interactions, we find that rafts can indeed putatively play an important role in signal transduction, and in particular may affect the sensitivity of signal transduction. This illuminates possible functional consequences of membrane heterogeneities on signal transduction and points towards mechanisms for spatial control of signaling by cells.

2:03PM B40.00015 Calcium-mediated rigidity in PIP2 lipid domains , WOUTER G. ELLENBROEK, Dept. of Applied Physics, Eindhoven Univ. of Technology and Dept. of Physics & Astronomy, Univ. of Pennsylvania, ANDREA J. LIU, Dept. of Physics & Astronomy, Univ. of Pennsylvania — In lipid mixtures containing the highly negatively charged lipid PIP2 (a crucial component in cell membrane mechanics) multivalent ions such as calcium can drive the formation of PIP2-rich domains by mediating attractions between the lipids. Although the existence of ion-mediated attractions is well known in macromolecular systems, their form is poorly understood because they result from strong correlations between the charged molecules and ions. Within a numerical model of a lipid monolayer, we analyze the mechanics of PIP2-rich domains. We show that they are liquid-like at moderate values of the PIP2-charge but rigid at higher PIP2-charge. We use a recently introduced method to extract the effective pair interaction between the charged lipids in the many-body system, in which the calcium ions and remaining lipids are integrated out.

Monday, March 21, 2011 11:15AM - 2:15PM –

Session B41 DPOLY DBP: Focus Session: Supramolecular Self-Assembly–Controlling Network and Gel Formation I A115/117

11:15AM B41.00001 Bio-mimetic metal-ligand crosslinks yield self-healing polymer networks with near-covalent elastic moduli , NIELS HOLTEN-ANDERSEN, University of Chicago, MATTHEW HARRINGTON, Max Planck Institute for Colloids and Interfaces, HENRIK BIRKEDAL, University of Aarhus, BRUCE LEE, PHILLIP MESSERSMITH, Northwestern University, HERBERT WAITE, University of California, Santa Barbara , KA YEE LEE, University of Chicago — Growing evidence supports a load-bearing role for metal-polymer interactions in biological protein networks. In particular, the strength of the coordinate bonds in metal-ligand coordination complexes combined with their capacity to reform after breaking has been proposed as a source of the high toughness and potential self-healing in certain natural materials. Some of the highest stabilities among metal-ligand coordination complexes are found between Fe3+ and catechol ligands at alkaline pH where the tris-catecholato-Fe3+ stoichiometry prevails, yet the effect of such crosslinks on material properties has not been fully characterized due to the low solubility of Fe3+ at high pH. Inspired by the pH jump experienced by marine biomaterials during secretion, we have developed a simple method to control catechol-Fe3+ inter-polymer crosslinking via pH. The resulting gels display elastic moduli (G') that approach covalently crosslinked gels as well as self-healing properties.

11:27AM B41.00002 Controlling Mechanical Properties of Bis-leucine Oxalyl Amide Gels , WILLIAM CHANG, DANIEL CARVAJAL, KENNETH SHULL, Northwestern University — is-leucine oxalyl amide is a low molecular weight gelator capable of gelling polar and organic solvents. A fundamental understanding of self-assembled systems can lead to new methods in drug delivery and the design of new soft material systems. An important feature of self-assembled systems are the intermolecular forces between solvent and gelator molecule; by changing the environment the gel is in, the mechanical properties also change. In this project two variables were considered: the degree of neutralization present for the gelator molecule from neutral to completely ionized, and the concentration of the gelator molecule, from 1 weight percent to 8 weight percent in 1-butanol. Mechanical properties were studied using displacement controlled indentation techniques and temperature sweep rheometry. It has been found that properties such as the storage modulus, gelation temperature and maximum stress allowed increase with bis-leucine oxalyl amide concentration. The results from this study establish a 3-d contour map between the gelator concentration, the gelator degree of ionization and mechanical properties such as storage modulus and maximum stress allowed. The intermolecular forces between the bis-leucine low molecular weight gelator and 1-butanol govern the mechanical properties of the gel system, and understanding these interactions will be key to rationally designed self-assembled systems.

11:39AM B41.00003 4D Structural Dynamics of Sheared Collagen Networks[1] , RICHARD AREVALO, DANIEL BLAIR, JEFFREY URBACH, Georgetown University — Soft biopolymer networks undergo substantial bulk stiffening when subject to shear strain. This nonlinear rheological signature has been observed for a wide range of semiflexible and stiff biopolymers, but the underlying geometric fiber rearrangements have not been measured and the resulting stress propagation through the network has not been experimentally assessed. We apply steady shear strains to collagen gels adhered to a thin elastic polyacrylamide gel substrate embedded with fluorescent displacement markers, while simultaneously imaging the three-dimensional network with a coupled confocal-rheometer. We observe dramatic network realignment towards the shear gradient driven by the nonaffine stretching, buckling, and rotation of constituent fibers and simultaneously measure stress inhomogeneities at the collagen-polyacrylamide interface. These observations elucidate the physical mechanisms governing strain-stiffening and our recent observation of the system-size dependence of this effect.

11:51AM B41.00004 Molecular Dynamics Modeling of Actin Network Formation , RONALD PANDOLFI, PETER BECICH, UC Merced, LAM NGUYEN, FSU, LINDA HIRST, UC Merced — Actin filaments are ubiquitous and critical in cellular functions. The polymer protein F-actin is a semi-flexible filament that forms networks in the presence of binding proteins (i.e. α-actinin, filamin, fascin). Molecular dynamics modeling and simulation of the formation of these networks has revealed the dependence of network structure on the ratio of G-actin monomers to cross-linkers, cross-linker shape, and filament length. In this study we focus on the effects of filament length on the assembled system. Comparative experimental work informs the accuracy of the modeled systems. Fourier analysis of the simulated networks allows quantitative characterization of the network structure.

12:03PM B41.00005 Polyelectrolyte-Surfactant Complexes: A New Class of Organogelators , KEVIN CAVICCHI, YUQING LIU, The University of Akron, GUSTAVO GUZMAN, Universidad Nacional de Colombia — Polyelectrolyte-surfactant complexes (PE-SURFs) are a class of polymers generated by neutralizing a polyelectrolyte with an oppositely charged surfactant. It has been found that PE-SURFs composed of polystyrene sulfonate and long chain alkyl dimethyl amines act as good organogelators for a range of hydrophobic, organic solvents. Thermo-reversible organogels are formed by heating and cooling PE-SURF/solvent solutions. The gel transition temperature is influenced by the degree of polymerization, the length of the alkyl side-chain, the solubility parameter of the solvent, and the concentration of the gelator. Freeze-drying and scanning electron microscopy characterization of the resultant xerogels shows the formation of rod- and plate-like network morphologies depending on the system parameters. This behavior is consistent with gelation driven by the self-assembly of the amphiphilic PE-SURFs into micellar networks.

12:15PM B41.00006 Self-Assembly of DNA–Block Copolymer Micelles , WEI QU, Northwestern University, XUAN JIANG, HAI-QUAN MAO, Johns Hopkins University, ERIK LUIJTEN, Northwestern University — Cationic–hydrophilic block copolymers have been developed as a potential carrier for use in gene delivery, displaying good transfection efficiency and biocompatibility. The cationic blocks effectively condense the DNA into a core surrounded by a protective and stabilizing corona formed by the hydrophilic blocks [Jiang *et al.*, J. Control. Release **122** 297–304 (2007)]. Although the DNA condensation induced by the cationic blocks can be understood from energetic considerations, the formation of micelles with distinct morphologies is more complicated, as it involves several competing interactions. We employ computer simulations to model this interplay of driving forces. By correlating our simulation results with experimental observations, we provide an understanding of the self-assembly process and determine the key structural and experimental parameters that influencing the morphology of the DNA–block copolymer micelles.

12:27PM B41.00007 LL37-DNA complexes and auto-immune diseases , FAN JIN, University of California, Los Angeles, LORI K. SANDERS, University of Illinois, Urbana -Champaign, WUJING XIAN, University of California, Los Angeles, MICHEL GILLIET, University of Texas, Houston, GERARD C. L. WONG, University of California, Los Angeles, DEPARTMENT OF IMMUNOLOGY, UNIVERSITY OF TEXAS, HOUSTON COLLABORATION — LL37 is an alpha-helical host defense peptide in humans. Recent work has shown that Toll-like receptor-9 (TLR9), an intracellular receptor in plasmacytoid dendritic cells (pDCs) of the immune system that normally responds to pathogen nucleic acids, can be pathologically triggered by self DNA in the form of DNA-LL37 complexes. Synchrotron small-angle x-ray scattering (SAXS) measurements reveal an unanticipated form of self-assembly between DNA and this positively charged macroion. We examine the generality of this with other macroions, and propose a new geometric criterion for immune cell activation.

12:39PM B41.00008 Stiffness of DNA nanotubes: insights for the design of dsDNA materials , PAUL WEITEKAMP, Physics Department, UCSB, DANIEL SCHIFFELS, Physics Department, U Munich, ALEX ITEEN, DEBORAH FYGENSON, Physics Department, UCSB — DNA is increasingly used as a material in the design and construction of elaborate structures with nanoscale precision and functionalities. Whether self-assembled from tiles of short, synthetic oligomers or woven from purified genomic strands, most DNA nanostructures are based on parallel arrays of double-stranded DNA (dsDNA) held together by Holliday junction-like cross-links. There is considerable evidence that the double-helices thus intertwined are largely B-form in structure, but the mechanical integrity of the resulting nanostructures has gone largely unexplored. Here we present a systematic study of the stiffness of DNA nanotubes varying parameters such as helix number, cross-link density and strand complexity. We find stiffness is a useful reporter of structural quality for nanotubes and extract design principles for optimizing mechanical integrity of dsDNA materials.

12:51PM B41.00009 Peptide assemblies: from cell scaffolds to immune adjuvants[1] , JOEL COLLIER, University of Chicago — This talk will discuss two interrelated aspects of peptide self-assemblies in biological applications: their use as matrices for regenerative medicine, and their use as chemically defined adjuvants for directing immune responses against engineered antigens. In the first half of the presentation, the design of peptide self-assemblies as analogues for the extracellular matrix will be described, with a focus on self-assemblies displaying multiple different cell-binding peptides. We conducted multi-factorial investigations of peptide co-assemblies containing several different ligand-bearing peptides using statistical "design of experiments" (DoE). Using the DoE techniques of factorial experimentation and response surface modeling, we systematically explored how precise combinations of ligand-bearing peptides modulated endothelial cell growth, in the process finding interactions between ligands not previously appreciated. By investigating immune responses against the materials intended for tissue engineering applications, we discovered that the basic self-assembling peptides were minimally immunogenic or non-immunogenic, even when delivered in strong adjuvants. -But when they were appended to an appropriately restricted epitope peptide, these materials raised strong and persistent antibody responses. These responses were dependent on covalent conjugation between the epitope and self-assembling domains of the peptides, were mediated by T cells, and could be directed towards both peptide epitopes and conjugated protein antigens. In addition to their demonstrated utility as scaffolds for regenerative medicine, peptide self-assemblies may also be useful as chemically defined adjuvants for vaccines and immunotherapies.

1:27PM B41.00010 Multiscale peptide self-assembly , JUSTIN BARONE, DEVIN RIDGLEY, Virginia Tech — Here, we demonstrate a hierarchical peptide self-assembly process from the nanometer to the micrometer scale. The process begins by mixing a short hydrophobic peptide and a longer α-helix peptide. Cross-β nanostructures spontaneously form that then aggregate into nanometer fibrils and then micron-sized fibers. FT-IR and Raman spectroscopy show unraveling of α-helices and packing of aliphatic side groups as the major events leading to β-sheet and large fiber formation. A thermodynamic model is presented that uses conformational change and hydrogen bond formation to describe free energy change.

1:39PM B41.00011 Intermolecular Hydrogen Bonding in Peptide and Modified Jeffamine Organogels , DANIEL SAVIN, ADAM RICHARDSON, School of Polymers and High Performance Materials, University of Southern Mississippi — In these studies, we present two systems whereby supramolecular assembly results in rigid organogels. First, a series of AB diblock copolymers consisting of poly(Lysine(Z)) (P(Lys(Z)) blocks were synthesized and found to form stable, rigid organogels in THF (ca. 1 - 1.5 wt.% solutions) and chloroform at room temperature. In these systems, the protecting group on the P(Lys) side-chains remains intact and gel formation results from the assembly of the solventphobic P(Lys(Z)) chains through intermolecular beta-sheet formation. The non-peptide block was found to have an effect on organogel properties due to interfacial frustration, which disrupts H-bonding. Second, Jeffamine polymers were modified in a facile way to incorporate intermolecular H-bonding groups to yield networks able to gel various solvents as well as mineral and canola oil. We present the physical and rheological properties of the organogels produced.

1:51PM B41.00012 Designing responsive peptide hydrogels using peptide-responsive polymer conjugates , ALBERTO SAIANI, School of Materials, The University of Manchester, ANTON MASLOVSKIS, ALINE MILLER, School of Chemical Engineering, The University of Manchester — Self-assembly represents a simple and efficient route to the construction of large, complex structures. Peptide self-assembly in particular offers the possibility to design new functional bio-materials that find application in drug delivery and tissue engineering. The β-sheet motif is are of particular interest as short peptides can be designed to form β-sheet rich fibres that entangle and consequently form hydrogels. These hydrogels can be functionalised using specific biological signals and can also be made responsive through the use of enzymatic catalysis and/or conjugation with responsive polymers. In this presentation we will focus on the design of the latter using peptide-responsive polymer conjugates. The main objective is to create hydrogels possessing an internal transition resulting from the conjugation with the responsive polymer in the gel state that can be used as a trigger for example the release of a drug.

2:03PM B41.00013 Stimuli-Responsive Peptide-based Triblock and Star Copolymers , JACOB RAY, SANDEEP NAIK, ASHLEY JOHNSON, JACK LY, DANIEL SAVIN, School of Polymers and High Performance Materials, University of Southern Mississippi — Stimuli-responsive copolymers demonstrate diverse aggregation behavior in aqueous solution. In general, the molecular architecture and the balance of hydrophilic and hydrophobic volumes influence morphology. This study involves polypeptide-based ABA linear triblock and AB2 star copolymer (which structurally resemble phospholipids) amphiphiles. Model systems for this study are poly(L-lysine)-b-poly(propylene oxide)-b-poly(L-lysine) (KPK) triblocks and poly(L-glutamate) (PE) based star copolymers. Extensive studies with KPK systems have resulted in morphological transitions by modifying pH, and we hypothesize that a change in individual chain conformation is the driving force for these transitions. Preliminary results for PE-based star copolymers with various hydrophobic moieties suggest polymersome (vesicle) formation. Light scattering (dynamic and static) and TEM were used to determine aggregate size and morphology as a function of pH; furthermore, circular dichroism (CD) spectroscopy was used to measure helix-to-coil transitions of the polypeptide blocks.

Session B42 DPOLY: Polyelectrolytes, Conformations, Assembly, and Dynamics A302/303

11:15AM B42.00001 Scaling behavior of single chain dimension of polystyrene sulfonate[1] , QINGBO YANG, JIANG ZHAO, Institute of Chemistry, Chinese Academy of Sciences — Scaling behavior of single chain of polystyrene sulfonate (PSS-) has been studied by fluorescence correlation spectroscopy. The scaling power index of the hydrodynamic radius of the PSS- single chain in aqueous solutions was found to depend on the salt condition in the solution and a systematic investigation on salt concentration and salt valency has been conducted. The results clearly demonstrate the change in conformation of PSS- chain due to its interaction with the counterions.

[1]Project supported by National Natural Science Foundation of China (NSFC).

11:27AM B42.00002 Bridging induced by multivalent counterions in polyelectrolyte brush , NICOLAS LAUGEL, ROBERT FARINA, Lawrence Berkeley National Lab, PHILIP PINCUS, Materials Research Laboratory, University of California in Santa Barbara, MATTHEW TIRRELL, Dept of Bioengineering, University of California in Berkeley — When the counterions of a polyelectrolyte brush are multivalent, significant changes in its behavior are observed. One example is its shrinkage at values of ionic strengths where osmotic pressure would be expected to keep chains extended. This effect could be explained through the existence of a bridging phenomenon, with the multivalency of each counterion enabling attractive interactions with more than one polymeric charge at a time. Here we present a variational and phenomenological free energy model in a description of the charged brush as an homogeneous layer subject to classical energy contributions related to both chains and counterions. Two mean-field order parameters are introduced to describe counterion condensation and bridging. The model predicts an abrupt collapse of the brush height upon very fine changes in values of the parameters value which is reminiscent of the experimentally observed behavior.

11:39AM B42.00003 Collapse of single polyelectrolytes in a.c. electric fields , CHUNDA ZHOU, ROBERT RIEHN, NC State University — Experimental and theoretical studies of single polyelectrolyte molecules under alternating electric fields have concluded that stretching is the near-universal response. We confined fluorescently stained λ-DNA (48.5 kbp, $\approx$16 μm contour length) in TBE buffer solution in 500 nm x 10 μm microchannels and applied alternating electric fields ranging from 0 kV/cm to about 2 kV/cm. We observed that DNA molecules collapsed under these conditions, in contrast to the literature reports. We observed single molecules with a fluorescence microscope, and analyzed the radius of gyration of each molecule in each frame. The threshold of the electric field at which DNA molecules start to collapse depends on both the concentration of TBE buffer solutions and the frequencies of the alternating electric fields. In particular, the critical electric field for collapse increases as the frequency increases. In our experiment, DNA molecules were suspended in 0.25x TBE, 0.5x TBE, 1x TBE and 2x TBE buffer solution, and the frequency was 100 Hz, 200 Hz, 300 Hz, 450 Hz, 675 Hz or 800 Hz. The critical electric field ranged from 0.5 kV/cm to 1.5 kV/cm. We believe the phenomenon is due to aggregation of density fluctuations within the polymer coil, which is not described in traditional homogeneous coil models.

11:51AM B42.00004 Conformation of Randomly Sulfonated Pentablock Ionomers in Dilute Solution: Molecular Dynamic Simulation Study , DIPAK ARYAL, DVORA PERAHIA, Clemson University, GARY S. GREST, Sandia National Laboratories — As part of our efforts to define the factors that control the structure and dynamics of structures ionic polymers, the conformation of a pentablock copolymer that consists of randomly sulfonated polystyrene, an ionomeric block, bound to poly-ethylene-r-propylene end caped by poly-t-butylstyrene has been studied in dilute solutions using molecular dynamic simulations. Multi-block copolymers offer a means to tailor several properties into one molecule, taking advantage of their rich phase diagram together with unique properties of specific blocks. We varied the solvent quality for the different blocks and followed the changes in conformation. The spatial configuration of the pentablock as well as the dynamics of the polymer was studied. We find that, independent on the solvent, the higher the sulfonation level, the lower R_g. The static and dynamic structure factors were calculated and compared in an implicit poor solvent, water and a common solvent. These data are compared with results obtained from neutron scattering.

12:03PM B42.00005 Polyelectrolyte Dendrimer Conformations from Mean Field Theory , THOMAS LEWIS, VENKAT GANESAN, University of Texas at Austin — The unique architecture of dendrimers has led to research in a wide array of applications including drug delivery. It is widely accepted that non-charged dendrimers exhibit a dense-core radial density profile in order to balance entropic and excluded volume forces. The use of polyelectrolyte dendrimers in drug delivery has been suggested as a way to attain internal cavities within the dendrimer, which can be tuned by varying salt concentration and pH of the solution. In order to gain insight into the equilibrium behavior of both annealed and quenched polyelectrolyte dendrimers, we have developed and numerically solved a Self-Consistent Field Theory approach for charged dendrimer molecules in an implicit solvent. We then use this method to examine the effects of pH, salt concentration, and generation number upon the conformations of these molecules.

12:15PM B42.00006 Controlling the swelling and wettability of weak polyelectrolyte brushes , RICHARD GURTOWSKI, BENXIN JING, ELAINE ZHU, University of Notre Dame — Weak polyelectrolytes (PE) of tunable ionization shows great potential as "smart" polymer materials for diverse applications from drug delivery to energy storage. However, the conformational dynamics of surfaced-tethered weak PE chains remain inadequately understood due to the complexity of their dynamic charge states in response to solvation and surface immobilization conditions. In this work, we investigate the wetting and swelling characteristics of poly(2-vinyl pyridine) (P2VP) brushes grafted to a gold substrate by AFM and water contact angle measurements. We observe the collapse of P2VP brushes, accompanied with increased surface hydrophobicity, as increasing solution pH across a critical transition pH, which is considerably lower than the pKa of free P2VP chains in bulk solution. Surprisingly, the broadness of the transition pH range shows a strong dependence with brush thickness, but not grafting density, suggesting a distribution of chain ionization along grafted P2VP brushes. We further manipulate P2VP brush structures by applying ac-electric fields across the brushes to make tunable and switchable polymer surfaces.

12:27PM B42.00007 Light- and pH Switchable Supramolecular Nanoparticles through Electrostatic Self-Assembly , FRANZISKA GROEHN, University Erlangen-Nuremberg, IMMANUEL WILLERICH — Supramolecular structures that can respond to external triggers are of high interest for example for nanotechnology or drug delivery. Recently we have introduced an approach to electrostatic self-assembly for the formation of supramolecular particles in solution: polyelectrolytes and multivalent stiff organic counterions build well-defined and stable nano-objects. In addition to electrostatics, secondary interactions between counterions such as pi-pi stacking directs the association. Aggregates with narrow size distribution and varying shape such as spheres, cylinders, vesicles and networks result. PH-responsive assemblies can be repeatedly switched "on" and "off" through pH. Furthermore, light is an elegant, non-invasive stimulus offering possibilities for new functional nanostructures. By electrostatic self-assembly, supramolecular particles can be built the size of which can be triggered by light. For example, assemblies of dendrimer macroions and divalent azobenzene counterions can respond to light with a size increase from 30 nm to 165 nm radius. Detailed characterization by static and dynamic light scattering, AFM, SANS and zeta-potential measurements as well as thermodynamic studies yield insight into driving forces and structural control in the self-assembly process.

12:39PM B42.00008 Tunable morphologies from charged diblock copolymers , MONOJOY GOSWAMI, BOBBY SUMPTER, Oak Ridge National Laboratory — Molecular Dynamics (MD) simulations are carried out to understand the physical aspects of different bulk morphologies formed in charged diblock copolymers. It has been seen that the bulk morphologies formed by charged block copolymers, 75 vol % fluorinated polyisoprene (FPI) - 25 vol% sulfonated polystyrene (PSS) with 50% sulfonation are substantially different from their diblock counterparts. In this study we show how the bulk morphologies change from the uncharged diblock counterparts and also how morphology can be tuned with volume fraction of the charged block and with a change in dielectric constant. A physical understanding based on the underlying strong electrostatic interactions between the charged block and counterions is obtained. The 75/25 diblock shows hexagonal morphologies with the minority blocks (PSS) forming the continuous phase due to charge percolation and the FPI blocks arranged in hexagonal cylinders. Some long-range order can be sustained even by changing the dielectric of the medium. Diverse and atypical morphologies are readily accessible by simply changing the number distribution of the charges on PSS block.

12:51PM B42.00009 Finite size effects in polyelectrolyte adsorption: A simulation study , MARIA SAMMALKORPI, PAUL R. VAN TASSEL, Dept. of Chemical Engineering, Yale University — In recent experiments, we have uncovered conditions where polyelectrolyte adsorption to a conducting surface may become continuous in the sense of scaling linearly with time over hours [1]. This discovery of continuous layer growth offers an enticing possibility of nanoscale thin film growth in a single step process, but also brings forth questions of the underlying mechanisms. Here, we present a molecular Monte Carlo simulation study aimed at understanding mechanistically the continuous adsorption process and, more broadly, polyelectrolyte adsorption in general. Our system consists of two parallel polymer chains composed of charged tangent spheres above a surface of variable dielectric discontinuity between the substrate and the solution, and spherical counterions and salt ions. We find that counter ion correlations act to enable the formation of stable polymer-polymer binding and aggregation. We discuss the sensitivity of the attractive regime to a Coulombic coupling parameter and to finite ion size, and the implications of finite size effects and charge distribution both in the polyelectrolytes and in the ions, and implications to experimental observations. [1] A. P. Ngankam and P. R. Van Tassel, Proc. Nac. Acad. Sci. 104, 1140-1145 (2007); C. Olsen and P. R. Van Tassel, J. Colloid and Interface Science 329, 222-227 (2009).

1:03PM B42.00010 Thermal Properties of Linearly and Exponentially Growing Layer-by-Layer Assemblies , AJAY VIDYASAGAR, JODIE LUTKENHAUS, Texas A&M University — Polyelectrolyte multilayer thin films have received significant attention for assembling various nanostructured coatings, but their thermochemical properties are challenging to measure. Here, we present results regarding the thermochemical properties of two different "model" layer-by-layer (LbL) assemblies. The LbL process involves alternate deposition of positively and negatively charged polymers resulting in interpenetrating networks of layers with fine structural control. Films may grow linearly or exponentially, and each type of growth is expected to give varied internal structure. Poly(allylamine hydrochloride)/poly(styrene sulfonate) (PAH/PSS) multilayers assembled without (or with) added salt are selected as the linear (or exponential) "models." Other systems explored include hydrogen bonding and PAH/poly(acrylic acid) multilayers. In general, linear growth takes place due to charge overcompensation leading to thinner films than exponential growth, where interdiffusion of polyelectrolytes is a major driving force forming much thicker films. Calorimetry and ellipsometry were used to determine glass transition and crosslinking temperatures. A standing hypothesis is that linear (or exponential) growth is observed for glassy (or rubbery) multilayers. The aim of this work is to understand the origin of linear versus exponential growth in polyelectrolytes with respect to their thermal properties.

1:15PM B42.00011 Polyelectrolyte gel dynamics during volume phase transitions , MITHUN MITRA, JING HUA, MURUGAPPAN MUTHUKUMAR, University of Massachusetts, Amherst — We will address the dynamics of the elastic modes of a polyelectrolyte gel near the first-order volume phase transition. The role of the neutralizing plasma on the modulus of the polyelectrolyte gel will be discussed.

1:27PM B42.00012 Field theoretic simulations of the interfacial properties of complex coacervates , ROBERT RIGGLEMAN, University of Pennsylvania, GLENN FREDRICKSON, University of California, Santa Barbara — Many biological processes and emerging technologies, such as wet adhesives and biosensors, rely on the association between oppositely charged polyelectrolytes. Such association is driven not only by the electrostatic interactions between the polyelectrolytes, but there is also a substantial entropy gain associated with counterion release upon complexation. In some cases, the association between oppositely charged polymers can lead to a solid precipitate while others can result in a fluid phase rich in polyelectrolytes (coacervate phase) coexisting with a polyelectrolyte-dilute solvent phase. For many of the applications seeking to exploit coacervation, characterization of the interface between the solvent phase and the coacervate is of paramount importance. In this talk, we will present the results of field-theoretic simulations for a coarse-grained polyelectrolyte model that exhibits complex coacervation. Our simulations sample the fully-fluctuating fields in three-dimensions and provide a detailed characterization of the interface between the solvent and the coacervate phase for symmetric polyelectrolytes (where both the polycations and the polyanions carry identical charge densities) as a function of salt concentration and strength of the electrostatic fields. Finally, we characterize the interfacial properties for a select set of asymmetric conditions.

1:39PM B42.00013 Electrohydrodynamics of polyelectrolytes using Lattice-Boltzmann simulations without electrostatics , OWEN A. HICKEY, JAMES L. HARDEN, University of Ottawa, CHRISTIAN HOLM, University of Stuttgart, GARY W. SLATER, University of Ottawa — In computer simulations of polyelectrolyte electrophoresis, the effects of long-ranged hydrodynamics are often ignored due to the high computational cost. However, the hydrodynamic interactions often play a key role in the physics and can lead to some surprising phenomena. We present hybrid Molecular Dynamics simulation methods to study the electrohydrodynamics of polyelectrolytes using a Lattice-Boltzmann (LB) fluid. By applying a local slip between the monomer beads and the LB fluid we are able to reproduce realistic dynamics for free solution electrophoresis as well as the correct stall force for a polyelectrolyte subject to an electric field. Simulations also demonstrate how a net-neutral object, such as a block polyelectrolyte, can have a non-zero net force due to hydrodynamic interactions and that the force can even be perpendicular to the applied electric field.

1:51PM B42.00014 Thermophoresis of a polyelectrolyte[1] , JENNIFER KREFT PEARCE, AUDREY HAMMACK, ANDREW LASTER, JAMES LEE, SETH NORMAN, University of Texas at Tyler — Thermophoresis, the migration of a species due to a temperature gradient, has been shown to be a possible mechanism for manipulating molecules in microfluidic devices. The mechanism governing thermophoresis is complex making a molecule's Soret coefficient (S_T) and its dependence on different physical factors hard to predict. We experimentally investigate thermophoresis of a polyelectrolyte. For sufficiently high average temperatures, two forms of the molecule are present. We measure the Soret coefficient of both and find that one has positive S_T and the other negative. We also investigate the dependence of S_T on co-dissolved ionic species, specifically NaOH and NaCl.

2:03PM B42.00015 Charge transport in confined ionic liquids[1] , JOSHUA SANGORO, CIPRIAN IACOB, WYCLIFFE KIPNUSU, FRIEDRICH KREMER, University of Leipzig — Charge transport and glassy dynamics in neat and polymerized ionic liquids confined in nanoporous silica are investigated in a wide frequency and temperature ranges by a combination of Broadband Dielectric Spectroscopy and Pulsed Field Gradient Nuclear Magnetic Resonance (PFG NMR). By applying the Einstein-Smoluchowski relations to the dielectric spectra, diffusion coefficients are obtained in quantitative agreement with independent PFG NMR. The impact of geometrical confinement as well as the pore wall-ionic liquid interactions on the overall ionic mobility is explored for diverse categories of ionic liquids. The results are discussed within the framework of dynamic glass transition assisted charge transport in ionic liquids.

[1]Financial support from the Deutsche Forschungsgemeinschaft under the DFG SPP 1191 Priority Program on Ionic Liquids is gratefully acknowledged.

Session B43 DMP DPOLY GERA: Focus Session: Polymers for Energy Storage and Conversion – Nanoscale Structure in Polymer-based Photovoltaics A306/307

11:15AM B43.00001 Association of P3HT and PCBM in solution , TOMEK KOWALEWSKI, Carnegie Mellon University — This abstract not available.

11:51AM B43.00002 Organic solar cells: a theoretical study of the effects of polymer side-chains , NICOLAS BERUBE, HELENE ANTAYA, MICHEL COTE, Universite de Montreal — Organic photovoltaic cells received a great interest in the last few years as they offer an environmentally clean and low-cost solution to the world's rising energy needs. One of the main problems limiting the efficiency of an organic solar cell device is the strong binding energy of the excitons, typically situated about a few hundreds of meV, which is ten to one hundred times more than in inorganic devices. Another limiting factor can be the misalignment of the the HOMO (Highest Occupied Molecular Orbital) and the LUMO (Lowest Unoccupied Molecular Orbital) energy level of the different components of the solar cell. In this presentation, we will discuss how different modifications on organic polymers' side-chains can affect and improve their electronic properties. Our calculations, based on density-functional theory using the B3LYP functional, indicate a HOMO and LUMO lowering of more than 1 eV in various organic polymers like poly-isothianaphtene (pITN) and poly-thienothiophene (pTT), and various side-chains like aldehyde-based ones. Preliminary calculations on oligothiophenes also show a lowering of the exciton binding energy.

12:03PM B43.00003 Perylene Diimide Based "Nanofabric" Thin Films for Organic Photovoltaic Cells[1]

, AUSTIN CARTER, JUNE HYOUNG PARK, Dept. of Physics, The Ohio State University, YONG MIN, Dept. of Chemistry, The Ohio State University, ARTHUR EPSTEIN, Dept. of Physics and Chemistry, The Ohio State University — We report progress in using a perylene diimide (PDI) nanofabric as an effective electron accepting nanostructure for organic photovoltaics (OPV). A key challenge in OPV continues to be the recovery of electrons after charge separation due to the relatively poor mobility of C60 and related materials. A series of PDI compounds and complexes have been synthesized and used to fabricate nanofibers and thin films using solution and vacuum deposition techniques. Overlaping PDI-based nanofibers form a fast electron-transporting "nanofabric" that has been characterized (AFM, PL, UV-vis, etc.) and can be blended with electron donating materials. A solution-processible OPV configuration containing a nanofabric heterojunction (FHJ) of poly(3-hexylthiophene) and the PDI nanofabric was investigated. We observed a significant improvement in power-conversion efficiency due in part to expansion of the interfacial area and the presence of high mobility electron pathways to the LiF/Al electrode.

12:15PM B43.00004 Influence of Annealing and Blending of Photoactive Polymers on Their Crystalline Structure

, MATTHIAS A. RUDERER, STEFAN M. PRAMS, MONIKA RAWOLLE, QI ZHONG, PETER MUELLER-BUSCHBAUM, TU Muenchen, Physik-Department LS E13, Chair of Functional Materials, James-Franck-Str. 1, 85747 Garching (Germany), JAN PERLICH, STEPHAN V. ROTH, HASYLAB at DESY, Notkestr. 85, 22603 Hamburg (Germany) — Thin photoactive polymer films of poly(3-octylthiophene-2,5-diyl) (P3OT) and poly(2,5-di(hexyloxy)cyanoterephthalylidene) (CN-PPV) are investigated. With X-ray reflectivity measurements, linear concentration-thickness dependence is found for both. Grazing incidence wide-angle X-ray scattering (GIWAXS) is used to probe the crystallinity of thin films and to determine characteristic length scales of the crystalline structure. Moreover, the orientation of the crystalline parts regarding the substrate of both the homopolymer and the blended films is probed with GIWAXS. Temperature annealing is found to improve the crystallization for both homopolymers. In addition, reorientation of the predominant crystalline structures takes place. Blending both polymers reduces or even suppresses the crystallization during spin coating as well as temperature annealing. Absorption measurements complement the structural investigations [1].

12:27PM B43.00005 ABSTRACT WITHDRAWN –

12:39PM B43.00006 Bio-Inspired electro-photonic structure for organic and dye sensitized solar cells[1]

, RENE LOPEZ, Department of Physics and Astronomy, University of North Carolina at Chapel Hill, Chapel HIll, NC, 27599 — A major challenge in solar cell technology dwells in achieving an efficient absorption of photons with an effective carrier extraction. In all cases, light absorption considerations call for thicker modules while carrier transport would benefit from thinner ones. This dichotomy is a fundamental problem limiting the efficiencies of most photovoltaics. One pathway to overcome this problem is to decouple light absorption from carrier collection. We present solutions to this problem applying bio-inspired nanostructures to two different types of systems: organic photovoltaic (OPV) and dye sensitized solar cells (DSSC). For OPV devices based on poly-3-hexylthiophene:[6,6]-phenyl-C61-butyric acid methyl ester (P3HT:PCBM), we describe a 2-D photonic crystal geometry that enhances the absorption of polymer-fullerene photonic cells $\sim$ 20% relative to conventional planar cells. Remarkably, the photonic crystal cell offers the possibility to increase photocurrents by improvements in optical absorption and carrier extraction simultaneously, and particularly through the excitation of photonic resonant modes near the band edge of organic PV materials. We also present an optical method to extract charge transport lengths from device photoactive layers. For DSSCs we introduce a new structural motif for the photoanode in which the traditional random nanoparticle oxide network is replaced by vertically aligned bundles of oxide nanocrystals. We have used a pulsed laser deposition system to ablate titanium oxide targets to obtain the porous and vertically aligned structures for enhanced photoelectrochemical performance. Absorption studies show that in optimized structures for titanium oxide, there is a 1.4 times enhancement of surface area compared to the best sol-gel films, Incident-Photon-Conversion-Efficiency values are better than 3 times thicker sol-gel films, and $\sim$ 92% Absorbed-Photon-Conversion-Efficiency values have been observed when sensitizing with the N3 dye (Ru(dcbpyH)2(NCS)2). The direct pathways provided by the vertical structures appear to indeed provide for enhanced collection efficiency for carriers generated throughout the device.

1:15PM B43.00007 The Poly(3-hexylthiophene) / ZnO (10-10) interface: structure and energetics

, JIE JIANG, SOHRAB ISMAIL-BEIGI, Yale University — The poly(3-hexylthiophene) (P3HT) polymer on ZnO system is of significant interest for hybrid nanoscale solar energy research and applications. Using density functional theory and periodic supercells, we study the P3HT/ZnO interface where sulfur atoms on the P3HT side chains are used to anchor the polymer onto the ZnO (10-10) surface. We discuss the structure and energetics of the binding modes for low and high polymer coverage. We then apply the Frenkel-Kontorova model to study the likely polymer structures in practice (e.g. dislocation formation to release strain energy). We end with a discussion of the band energy alignment across the interface.

1:27PM B43.00008 Photovoltaic Device Performance Enhancement by Interfacial Decoration of Bulk-Heterojunctions with Semiconducting Nanocrystals

, THEODORE J. KRAMER, IOANNIS KYMISSIS, IRVING P. HERMAN, Columbia University — We have developed a facile method for decorating the donor-acceptor interface of organic bulk-heterojunctions (BHJs) with semiconducting nanocrystals (NCs). Using nano-scale phase separation of a poly(3-hexylthiophene)/polystyrene copolymer blend, followed by selective removal of the polystyrene, we are able to expose a nano-scale network of poly(3-hexylthiophene) [P3HT] fibers. These fibers are subsequently decorated with cadmium selenide (CdSe) NCs prior to back filling the structure with thermally evaporated C_{60}. Optical characterization techniques have confirmed that NCs located at the donor-acceptor interface show enhanced charge transfer to the surrounding medium compared to NCs randomly dispersed in similar BHJs. Photovoltaic (PV) devices made using this technique show improved external efficiencies compared to similar planar PV structures. This technique provides an elegant mechanism for improving the performance of organic BHJs by tailoring their spectral absorption using semiconducting NCs.

1:39PM B43.00009 Semiconducting Nanocomposites via Directly Grafting Conjugated Polymer onto Quantum Rods

, LEI ZHAO, XINCHANG PANG, ZHIQUN LIN, NANOFM TEAM — Nanocomposites of poly(3-hexylthiophene) (P3HT)-cadmium selenide (CdSe) nanorod (NR) were synthesized by directly grafting P3HT onto bromobenzylphosphonic acid (BBPA) functionalized CdSe NR, dispensing with the need for ligand exchange chemistry. The grafting was accomplished by Heck coupling as well as a newly developed catalyst-free click reaction. The resulting P3HT-CdSe NR nanocomposites possess a well-defined interface, thereby significantly promoting the dispersion of CdSe within the P3HT matrix and facilitating the electronic interaction between them. The success of grafting was confirmed by the NMR and DLS, and the occurrence of charge transfer at P3HT/CdSe NR interface was demonstrated by the UV-vis absorption and photoluminescence (PL) measurements as well as the time-resolved PL study. Similar grafting density was yielded using these two methods. The nanocomposites prepared by the catalyst-free click reaction was found to exhibit a faster charge transfer. To the best of our knowledge, this is the first study of grafting conjugated copolymer directly onto the elongated semiconductor nanomaterials. As such, it provides insight into rational design and fabrication of organic-inorganic nanohybrid solar cells with improved power conversion efficiency.

1:51PM B43.00010 Directed assembly of core-shell hybrid nanomaterials for polymer photovoltaics[1] , SHANJU ZHANG, CANDICE PELLIGRA, LISA PFEFFERLE, CHINEDUM OSUJI — The creation of large-area aligned nanohybrid films/arrays remains a challenge in the fabrication of ordered heterojunction photovoltaics. We demonstrate a bottom-up approach based on the directed assembly of lyotropic inorganic-organic core-shell nanohybrids. Semiconductor nanowires are prepared by solvothermal synthesis. Diameter and length of the nanowires are controlled by various reaction parameters. Core-shell nanohybrids are prepared by grafting conjugated polymers onto the nanowires. Effect of the nanowire diameter on the polymer coating is demonstrated. We show that high aspect ratio nanohybrids spontaneously form nematic phases in liquid media. These systems show isotropic, bi-phasic and nematic phases on increasing concentration in reasonable agreement with Onsager's theory for rigid rods. Suspensions are readily processed to produce films with large-area monodomains. With a decrease of nanowire diameter, the polymers in the nanohybrids tend to form ordered crystalline layers, in which the conjugated backbone is aligned along the nanowire long axis. The corresponding optoelectronic properties are discussed.

2:03PM B43.00011 Interconnected and nano-perforated lamellar sheets of metal oxides produced using novel block copolymer templates , PAUL ZAVALA-RIVERA, KEVIN CHANNON, VINCENT NYUGEN, EASAN SIVANIAH, NATARAJ SANNA KOTRAPPANAVAR, University of Cambridge, S.A. AL-MUHTASEB, Qatar Univeristy — Recently, our group has investigated the development of a novel bicontinuous nanostructure using block copolymers. This has lead to the creation of various bicontinuous, mesoporous, and interconnected metal oxides sheets. The high surface area produced by the 3D nanostructure has shown a considerable improvement in efficiency in the method of preparation. The main transformations from polymer scaffold to inorganic matrices produced by our group include the use of oxide of titanium, and a number of other sol-gel transformations. The application of these nanostructures is shown in the development of photovoltaic devices. We highlight future applications in electronic, memory, energy storage and production devices.

Session B44 DPOLY: Physics of Copolymers I A309

11:15AM B44.00001 Controlling Cellular Endocytosis at the Nanoscale , GIUSEPPE BATTAGLIA, The Krebs Research Institute, Department of Biomedical Science, University of Sheffield, Sheffield, UK — One of the most challenging aspects of drug delivery is the intra-cellular delivery of active agents. Several drugs and especially nucleic acids all need to be delivered within the cell interior to exert their therapeutic action. Small hydrophobic molecules can permeate cell membranes with relative ease, but hydrophilic molecules and especially large macromolecules such as proteins and nucleic acids require a vector to assist their transport across the cell membrane. This must be designed so as to ensure intracellular delivery without compromising cell viability. We have recently achieved this by using pH-sensitive poly(2-(methacryloyloxy)ethyl-phosphorylcholine)- co -poly(2-(diisopropylamino)ethyl methacrylate) (PMPC-PDPA) and poly(ethylene oxide)-co- poly(2-(diisopropylamino)ethyl methacrylate) (PEO-PDPA) diblock copolymers that self-assemble to form vesicles in aqueous solution. These vesicles combine a non-fouling PMPC or PEO block with a pH-sensitive PDPA block and have the ability to encapsulate both hydrophobic molecules within the vesicular membrane and hydrophilic molecules within their aqueous cores. The pH sensitive nature of the PDPA blocks make the diblock copolymers forming stable vesicles at physiological pH but that rapid dissociation of these vesicles occurs between pH 5 and pH 6 to form molecularly dissolved copolymer chains (unimers). We used these vesicles to encapsulate small and large macromolecules and these were successfully delivered intracellularly including nucleic acid, drugs, quantum dots, and antibodies. Dynamic light scattering, zeta potential measurements, and transmission electron microscopy were used to study and optimise the encapsulation processes. Confocal laser scanning microscopy, fluorescence flow cytometry and lysates analysis were used to quantify cellular uptake and to study the kinetics of this process in vitro and in vivo. We show the effective cytosolic delivery of nucleic acids, proteins, hydrophobic molecules, amphiphilic molecules, and hydrophilic molecules without affecting the viability of cells or even triggering inflammatory pathways. Finally we show how size, surface chemistry and surface topology of the vesicles affect their interaction with the cell membrane and hence their cellular uptake.

11:51AM B44.00002 Microphase Separation in Block-Random Copolymers of Styrene and Hydrogenated Isoprene[1] , BRYAN S. BECKINGHAM, Princeton Univesity, RICHARD A. REGISTER, Princeton University — The capacity to synthesize block-random copolymers, which are block copolymers with one or more random copolymer blocks, allows for continuous tuning of the interblock segregation strength, χ, through the composition of the random copolymer. The ability to tune χ effectively decouples the block copolymer molecular weight from its order-disorder transition temperature. By lithium-initiated anionic polymerization with added triethylamine, we synthesize near-monodisperse and near-symmetric block-random copolymers of styrene and isoprene: PI-PSrI (50% wt. styrene). In comparison to PS-PI diblock copolymers, the number of unfavorable segmental contacts in the disordered state is decreased and hence the effective interblock χ is reduced. Isoprene-hydrogenated derivatives of these block-random copolymers exhibit microphase separation into well-ordered lamellae and display sharp thermally-induced order-disorder transitions via small-angle x-ray scattering. The observed reduction in χ, as gauged by the molecular weight required to achieve a desired T_{ODT}, matches well with the mean field prediction.

12:03PM B44.00003 Micellization kinetics of diblock copolymers in a homopolymer matrix: A self-consistent field study[1] , RAGHURAM THIAGARAJAN, DAVID MORSE, Department of Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, MN 55455 — Self-consistent field theory is used to calculate free energy barriers and reaction rates for the spontaneous association and dissociation of micelles formed of block copolymers in a homopolymer matrix. The barriers are prohibitively large for copolymers of typical molecular weights when the unimer (free surfactant) concentration is near the equilibrium critical micelle concentration. As a result, polymeric micelles normally cannot reach true thermodynamic equilibrium. The rates of association and dissociation are, however, sensitive to unimer concentration, making it possible to form or destroy micelles at observable rates in sufficiently highly supersaturated or subsaturated solutions, respectively, even when both reactions are suppressed near the equilibrium CMC. The barrier to disassociation is particularly sensitive to unimer concentration, and vanishes when the unimer concentration is only slightly (e.g., tens of percent) below the equilibrium CMC.

12:15PM B44.00004 Manipulating the structural conformation of block copolymer micelles using co-solvent mixtures , ELIZABETH G. KELLEY, THOMAS P. SMART, MILLICENT O. SULLIVAN, THOMAS H. EPPS, III, Department of Chemical Engineering, University of Delaware — The internal structure of poly(butadiene-*b*-ethylene oxide) (PB-PEO) block copolymer micelles was manipulated through the use of co-solvent mixtures. In aqueous solutions, the PB-PEO block copolymers self-assembled into monodisperse, spherical micelles with well-defined PB cores surrounded by PEO coronas. The addition of tetrahydrofuran (THF) to the micelle solution improved the solvent quality for the PB block and resulted in the swelling of the micelle cores. The average micelle size decreased with increasing THF content as shown by dynamic light scattering, small angle X-ray scattering, and cryogenic transmission electron microscopy. The distribution of PB in the micelles was studied using nuclear magnetic resonance spectroscopy and small angle neutron scattering. Finally, the spherical micelles disassembled in co-solvent mixtures containing greater than 72 vol% THF. This result was consistent with phase behavior studies of PB homopolymer, which indicated that PB is soluble in water-THF mixtures up to a similar THF solution composition.

12:27PM B44.00005 Molecular Exchange in Ordered Diblock Copolymer Micelles[1] , SOO-HYUNG CHOI, TIMOTHY LODGE, FRANK BATES, University of Minnesota — Previously, molecular exchange between spherical micelles in dilute solution (1 vol% polymer) was investigated using time-resolved small-angle neutron scattering (TR-SANS). As the concentration of spherical micelles formed by the diblock copolymers increases, the micelles begin to overlap and eventually pack onto body-centered cubic (BCC) lattice. In this study, concentrated, ordered micelles (15 vol% polymers) prepared by dispersing isotopically labeled poly(styrene-*b*-ethylene-*alt*-propylene) in an isotopic squalane mixture was investigated to understand the micellar concentration dependence of the molecular exchange. Perfectly random mixing of isotopically labeled micelles on the BCC lattice was confirmed by SANS patterns where the interparticle contribution vanishes, resulting in an intensity that directly relates to the exchange kinetics. The measured molecular exchange process for the concentrated, ordered system is qualitatively consistent with the previous observations, but the rate is more than an order of magnitude slower than that for the dilute, disordered system.

12:39PM B44.00006 Kinetics of Pressure Jump for Block Copolymer Phase Transition in Selective Solvent , YONGSHENG LIU, RAMA BANSIL, Boston University, MILOS STEINHART, Institute of Macromolecular Chemistry, CZ Republic — Synchrotron based time-resolved small angle x-ray scattering (SAXS) was used to study the kinetics of the order-disorder transition (ODT) in a 30% (w/v) solution of a diblock copolymer of poly(styrene – isoprene) (SI 18-12) in diethyl phthalate, a selective solvent for the PS block using pressure jump methods. Time resolved pressure jump SAXS experiments were done to study the kinetics of disorder to BCC phase transition and the reverse transition. The results show that the ODT temperature increases at about 20C/kbar with pressure. Analysis of Percus-Yevik model following pressure jumps and pressure ramps will be presented. The analysis shows that core radius of micelles are independent of pressure, but hard sphere radius increases with pressure.

12:51PM B44.00007 Transition Behavior of Hydrogen Bonding mediated Block Copolymer complex , SUDHAKAR NAIDU, HYUNGJU AHN, HOYEON LEE, DU YEOL RYU, Yonsei University, YONSEI UNIVERSITY TEAM — We have investigated transition behavior for block copolymer (BCP) complexes composed of a lamella-forming polystyrene-block-poly(2-vinylpyridine) (PS-b-P2VP) and phenyl acetamide derivatives. Influence of small molecules on transition temperatures such as order-to-disorder transitions (ODT) were analyzed by by in-situ small angle x-ray scattering (SAXS) and depolarized light scattering (DPLS). The importance of the availability for H-bonding mediation to control over transition behavior for BCP mixtures with the functional molecules was shown by changing the annealing temperatures. Non-covalent interactions between the nitrogen units of P2VP block and small molecules enhances nonfavorable segmental interactions between two block components, leading to a significant increase in d-spacing for BCP mixtures.

1:03PM B44.00008 Phase Behavior of Binary Mixtures of Block Copolymers having Hydrogen Bonding , SUNG HYUN HAN, JIN KON KIM, Pohang University of Science and Technology — The phase behavior of binary mixtures of high molecular weight polystyrene-*block*-poly(2-vinyl pyridine) (PS-*b*-P2VP) and low molecular weight polystyrene-*block*-poly(4-hydroxystyrene) (PS-*b*-PHS) copolymers was investigated by using small angle X-ray scattering and transmission electron microscopy. Both block copolymers exhibited lamellar microdomains. When the weight fraction of PS-*b*-PHS in the blend was less than 0.1, lamellar microdomains are maintained. However, with increasing amount of PS-*b*-PHS, the microdomains are transformed to hexagonally-packed cylindrical microdomains, and body-centered cubic spherical microdomains. This is attributed to the hydrogen bonding between P2VP and PHS blocks.

1:15PM B44.00009 Highly Localized Optically Induced Melting Transitions in Block Copolymers , AZAR ALIZADEH, EUGENE BODEN, XIALEI SHI, VICTOR OSTROVERKHOV, DANIEL BRUNNELLE, VICKI WATKINS, CHARLES KERBAGE, MATTHEW MISNER, BRIAN LAWRENCE, GE GLOBAL RESEARCH, NISKAYUNA, NY 12309 TEAM — Semi-crystalline block copolymers are well known to exhibit confined crystallization and/or melting phase transitions in sub-50 nm domains. Confined crystallization within these nano-domains is favored under the following conditions: 1) the crystallizable block forms discrete spherical or cylindrical domains; 2) the glass transition temperature of the matrix block is above the crystallization and melting temperatures of the crystallizable minority block; and 3) the block constituents form a strongly segregating system, such that the phase separation dominates the crystallization process. Here we report on optically induced highly localized crystalline-to-amorphous phase transitions in a composite medium comprised of a semi-crystalline block copolymer and a heat generating dye. We use an optical probe-pump and a Bragg reflective grating to both induce and detect the optically induced phase transitions in these block copolymers. We show that extremely fast and localized melting in these block copolymers can be achieved by exposing the samples to very short (5-20 ns) pulses of light. This study provides a new insight on the timescale of melting transitions in polymeric materials.

1:27PM B44.00010 Self-Assembly of Lamellar Microphases in Linear Gradient Copolymer Melts[1] , NICHOLAS B. TITO, Dartmouth College, SCOTT T. MILNER, The Pennsylvania State University, JANE E. G. LIPSON, Dartmouth College — The ability to create 'designer copolymers' with tunable properties by tailoring their monomer composition has garnered recent interest in their molecular self-assembly. Here we investigate lamellar microphases in linear gradient binary copolymer melts using a variety of techniques, including solutions of self-consistent field equations, scaling theory, and analysis of the strong-segregation limit. The Flory scaling theory predicts the scaling of the equilibrium lamellar width L_{eq} as a function of comonomer incompatibility as characterized by χ. From the strongly segregated limit there are conformational fluctuations, and it is the tradeoff between the entropic effect of these relative to repulsive comonomer interactions that determines L_{eq}. We discover that $L_{eq}\ /R_g \quad \sim (\chi N)^{1/6}$; remarkably, this is the same result as for symmetric diblock copolymers, although for quite different physical reasons.

[1]Work supported by the National Science Foundation and the Petroleum Research Fund.

1:39PM B44.00011 Kinetics and Dynamics of HEX to Gyroid Transition of a Diblock Copolymer in Selective Solvent , JULIAN SPRING, YONGSHENG LIU, RAMA BANSIL, Boston University — Synchrotron based time-resolved small angle x-ray scattering (SAXS) was used to study the kinetics of the formation of a gyroid phase in solutions of a poly (styrene -isoprene) diblock copolymer in dimethyl phthalate, a selective solvent for the polystyrene block. From temperature ramp measurements on an 80% (w/v) sample, a hexagonally-packed cylinders (HEX) phase was identifed below 95 C,while a gyroid formed above 95C. The kinetics of the transitions from HEX to gyroid was examined using temperature jump and ramp experiments over the temperature range of 50-150C. In addition, x-ray photon correlation spectroscopy was used to study the dynamics of the HEX and Gyroid phases, as well as the transition regime. Analysis of the time evolution of the Bragg peaks to follow the kinetics of the transition between these phases will be presented, in addition to analysis of the dynamics of this sample throughout the phase space under investigation. The formation of the Gyroid structure was also modeled using Molecular Dynamics (MD) simulations, and the results of these simulations will also be presented.

1:51PM B44.00012 Dynamics of Cloud Point Transitions in Dilute Solutions of Gradient Copolymers with Prescribed Gradient Strengths , KEITH GALLOW, YUEH-LIN LOO, Princeton University — We have investigated dilute solutions of gradient copolymers comprising hydroxyethyl methacrylate and dimethylaminoethyl methacrylate with different gradient strengths undergoing their cloud point transitions. The gradient strength defines the maximum difference in instantaneous compositions along the polymer backbone. Isothermal dynamic light scattering tracks the fractions of unimers and aggregates with which the half times characterizing this transition can be quantified. We find the temperature dependence of this transition to depend on gradient strength, ranging from -2.22 decades/$^\circ$C for a random copolymer to -0.75 decades/$^\circ$C for a gradient copolymer of comparable molecular weight and overall composition but a gradient strength of 0.52. The progressively shallower temperature dependence of this transition with increasing gradient strength suggests of a nucleation and growth mechanism of aggregate formation.

2:03PM B44.00013 Effect of Macromolecular Architecture on the Morphology of Polystyrene/Polyisoprene Block Copolymers , CALEB DYER, The University of Tennessee, PARASKEVI DRIVA, Oak Ridge National Laboratory, SCOTT SIDES, Tech-X Corporation, BOBBY SUMPTER, JIMMY MAYS[1], MARK DADMUN[2], Oak Ridge National Laboratory, FENG ZUO, FRANK BATES, University of Minnesota — The molecular architecture of branched block copolymers has been shown to dramatically effect morphological behavior. A study of four polystyrene/polyisoprene block copolymers with varying architecture (branched $PSPI_2$, PS_2PI, PS_2PI_2, and linear PSPI), and constant composition and molecular weight is presented. The morphologies of each sample were determined using SCFT simulations and, experimentally using SAXS and TEM. The PS_2PI_2miktoarm star exhibits the same morphology as the lineardiblock but with a reduction in the domain size. The PS_2PI and $PSPI_2$ copolymers demonstrated different morphologies from the diblock copolymer, a result of the architectural asymmetry. The results were then compared to Milner's theoretical predictions and found to be in good agreement. These results, therefore, provide detailed insight into the effect of copolymer architecture on the morphological behavior of block copolymers.

Session B45 DAMOP GQI: Optomechanics at the Quantum Limit A310

11:15AM B45.00001 Sideband cooling micromechanical motion to the quantum ground state , JOHN TEUFEL, NIST Boulder, TOBIAS DONNER, JILA, University of Colorado and NIST, DALE LI, NIST Boulder, KONRAD LEHNERT, JILA, University of Colorado and NIST, RAYMOND SIMMONDS, NIST Boulder — Accessing the full quantum nature of a macroscopic mechanical oscillator first requires elimination of its classical, thermal motion. The flourishing field of cavity opto- and electromechanics provides a nearly ideal architecture for both preparation and detection of mechanical motion at the quantum level. We realize such a system by coupling the motion of an aluminum membrane to the resonance frequency of a superconducting, microwave circuit. By exciting the microwave circuit below its resonance frequency, we damp and cool the membrane motion with radiation pressure forces, analogous to laser cooling of trapped ions. The microwave excitation serves not only to cool, but also to monitor the displacement of the drum. A nearly shot-noise limited, microwave Josephson parametric amplifier is used to detect the mechanical sidebands of this microwave excitation and quantify the thermal motion of the oscillator as it is cooled with radiation pressure forces to its quantum ground state.

11:27AM B45.00002 Cavity Cooling of A Mechanical Resonator in Amorphous Systems[1] , LIN TIAN, University of California, Merced — The quantum backaction force generated by a cavity coupled with a mechanical resonator can be exploited to achieve sideband cooling of the mechanical mode. By applying a red-detuned driving, the quantum ground state of the mechanical mode can be reached in the resolved-sideband regime, which has recently be demonstrated in experiments. However, in many of these materials, surface defects or adsorbates can couple with the mechanical mode and impair the cavity cooling. These defects can be treated as quantum two-level system (TLS). The mechanical vibration changes the local strain tensor and generates coupling with the TLS via the deformation potential. In this work, we study the cavity cooling of the mechanical mode in the presence of a TLS. By applying the adiabatic elimination technique widely used in quantum optics, we derive the cooling master equation for the resonator-TLS system in the eigenbasis of this system. Our results show that the stationary phonon number depends non- monotonically on the energy of the TLS. We also show that the cooling depends strongly on the decoherence rate of the TLS.

[1]This work is supported by the DARPA/MTO ORCHID program through AFOSR, NSF-DMR-0956064, NSF-CCF-0916303, and NSF COINS program.

11:39AM B45.00003 Quantum Interactions of a Torsional Nanomechanical Resonator with a Single Spin[1] , BRIAN D'URSO, SHONALI DHINGRA, University of Pittsburgh — While the motions of macroscopic objects may ultimately be governed by quantum mechanics, the distinctive features of quantum mechanics can be hidden by thermal excitations and coupling to the environment. We present a system consisting of a torsional nanomechanical resonator with quantum behavior introduced to the system by coupling the resonator with a single spin through a uniform external magnetic field. The spin originates from a nitrogen vacancy (NV) center in a diamond nanocrystal which is positioned on the resonator. The quadratic coupling is maximized by utilizing a low moment of inertia resonator and an avoided level crossing. This coupling results in quantum non-demolition (QND) measurements of the resonator and spin states, enabling a bridge between the quantum and classical worlds. Furthermore, it provides a high-fidelity readout of the NV center spin and a potential means of observing the discrete states of the resonator. We will describe the potential for these measurements and report on the experimental progress made towards observing this coupling in the torsional resonator-NV system.

[1]This work is funded by a DARPA Young Faculty Award.

11:51AM B45.00004 Characterization of an oscillator's mechanical impedance using photon pressure , PAUL WILKINSON, GORDON SHAW, JON PRATT, NIST Physical Measurements Lab — In recent years, there has been much progress in coupling optical cavities to mechanical oscillators, especially in the pursuit of the quantum ground state of a macroscopic oscillator. Photon pressure due to reflection is of particular interest, and such experiments must be carefully designed to minimize competing contributions. Typically, such unwanted contributions are estimated or modeled. We describe an experimental approach to place an upper bound on unwanted contributions. A fiber coupled superluminous light emitting diode is modulated at an optical power of 6.5 mW rms, driving a highly reflective cantilever at a displacement of over 10 nm rms at resonance (Q=4900) in vacuum (10-5 Torr). The optomechanical transfer function is measured and fit to a simple harmonic oscillator model. The stiffness of the oscillator determined from the fit (k=16.6 +/- 1.3 N/m) is found to be in good agreement with that obtained by calibration against our SI-traceable nanoindenter (k=17.4 +/- 0.5 N/m). We characterize the modal stiffness, mass, and dissipation of the first two eigenmodes of our oscillator with SI traceability. The quantitative agreement in our experiment indicates that our oscillator is actuated by photon pressure, and that all other contributions to the force must sum to less than 11%.

12:03PM B45.00005 Multi-stability in an optomechanical system with two-component Bose-Einstein condensate[1] , YING DONG, Department of Physics and Astronomy, and Rice Quantum Institute, Rice University, Houston, Texas 77251-1892, USA, JINWU YE, Department of Physics, The Pennsylvania State University, University Park, PA 16802, USA, HAN PU, Department of Physics and Astronomy, and Rice Quantum Institute, Rice University, Houston, Texas 77251-1892, USA — We investigate a system consisting of a two-component Bose-Einstein condensate interacting dispersively with a Fabry-Perot optical cavity where the two components of the condensate are resonantly coupled to each other by another classical field. The key feature of this system is that the atomic motional degrees of freedom and the internal pseudo-spin degrees of freedom are coupled to the cavity field simultaneously, hence an effective spin-orbital coupling within the condensate is induced by the cavity. The interplay among the atomic center-of-mass motion, the atomic collective spin and the cavity field leads to a strong nonlinearity, resulting in multi-stable behavior in both matter wave and light wave at the few-photon level.

12:15PM B45.00006 Optomechanical down-conversion , SIMON GROEBLACHER, SEBASTIAN HOFER, WITLEF WIECZOREK, MICHAEL VANNER, University of Vienna, Austria, KLEMENS HAMMERER, Leibniz University Hannover, Germany, MARKUS ASPELMEYER, University of Vienna, Austria — One of the central interactions in quantum optics is two-mode squeezing, also known as down-conversion. It has been used in a multitude of pioneering experiments to demonstrate non-classical states of light and it is at the heart of generating quantum entanglement in optical fields. Here we demonstrate first experimental results towards the optomechanical analogue, in which an optical and a mechanical mode interact via a two-mode squeezing operation. In addition, we make use of the fact that large optomechanical coupling strengths provide access to an interaction regime beyond the rotating wave approximation. This allows for simultaneous cooling of the mechanical mode, which will eventually enable the preparation of pure initial mechanical states and is hence an important precondition to achieve the envisioned optomechanical entanglement.

12:27PM B45.00007 Photothermally induced dynamics in partially coated loaded microcantilevers , SHOMEEK MUKHOPADHYAY, UMAR MOHIDEEN, University of California, Riverside — Cooling of microcantilevers in a Fabry-Perot cavity either by radiation pressure or using the photothermal effect has attracted significant attention lately. We present ongoing experimental results on partially coated microcantilevers which are either loaded (gold sphere) or have a coating only at the tip. In particular, we will compare the results with that of recent work on fully coated cantilevers.

12:39PM B45.00008 Micro-optomechanical trampoline resonators[1] , BRIAN PEPPER, DUSTIN KLECKNER, UC Santa Barbara, PETRO SONIN, EVAN JEFFREY, University of Leiden, DIRK BOUWMEESTER, UC Santa Barbara, University of Leiden — Recently, micro-optomechanical devices have been proposed for implementation of experiments ranging from non-demolition measurements of phonon number to creation of macroscopic quantum superpositions. All have strenuous requirements on optical finesse, mechanical quality factor, and temperature. We present a set of devices composed of dielectric mirrors on Si_3N_4 trampoline resonators. We describe the fabrication process and present data on finesse and quality factor.

[1]The authors gratefully acknowledge support from NSF PHY-0804177 and Marie Curie EXT-CT-2006-042580.

12:51PM B45.00009 Proposal for detecting measurement-induced entanglement between remote mechanical oscillators , KJETIL BORKJE, ANDREAS NUNNENKAMP, STEVEN M. GIRVIN, Yale University — In optomechanical systems where an optical cavity mode interacts with a mechanical oscillator, the light leaking out of the cavity has sidebands at the mechanical frequency. The photon statistics of these sidebands contain information about the mechanical oscillator. We consider driving two similar optical cavities, containing one mechanical system each, in such a way that the mechanical oscillators are laser cooled close to the ground state. When the output fields of the two cavities are made indistinguishable by combining them on a beamsplitter, the detection of sideband photons can lead to measurement-induced entanglement between the two non-interacting mechanical oscillators. We show how this short-lived entanglement between remote mechanical oscillators can be verified through measurements of higher-order coherences of the optical output field.

1:03PM B45.00010 Investigation of radiation pressure shot-noise in a microwave circuit optomechanical system , JENNIFER HARLOW, JILA, University of Colorado and NIST, JOHN TEUFEL, RAYMOND SIMMONDS, NIST, KONRAD LEHNERT, JILA, University of Colorado and NIST — We examine the possibility of measuring the radiation pressure shot-noise of microwave light. When the motion of a nanomechanical oscillator is coupled to the microwave energy stored in a resonant circuit, the oscillator experiences a radiation pressure force. That force must have a random component associated with the quantum nature of the microwave field, a mechanical manifestation of the microwave photon. The variance of this random component increases with increasing circuit excitation power. Until recently, reaching powers where radiation pressure shot-noise would dominate over other random forces was unfeasible due to relatively weak optomechanical coupling and technical power limitations of microwave circuits. However, the recent advent of a mechanical oscillator coupled strongly to a microwave circuit [1] will enable exploration of this regime. We discuss the most favorable circuit parameters and measurement strategy for studying radiation pressure shot-noise.

1:15PM B45.00011 Levitated Quantum Nano-Magneto-Mechanical Systems , MAURO CIRIO, JASON TWAMLEY, GAVIN K. BRENNEN, Centre for Engineered Quantum Systems, Macquarie University, Sydney Australia, GERARD J. MILBURN, Centre for Engineered Quantum Systems, University of Queensland, Brisbane, Australia — Quantum nanomechanical sysems have attracted much attention as they provide new macroscopic platforms for the study of quantum mechanics but may also have applications in ultra-sensitive sensing, high precision measurements and in quantum computing. In this work we study the control and cooling of a quantum nanomechanical system which is magnetically levitated via the Meissner effect. Supercurrents in nano-sized superconducting loops give rise to a motional restoring force (trap), when placed in an highly inhomogenous magnetic field and can yield complete trapping of all translational and rotational motions of the levitated nano-object with motional oscillation frequencies $\nu \sim 10 - 100$MHz. As the supercurrents experience little damping this system will possess unprecendented motional quality factors, with $Q_{motion} \sim 10^9 - 10^{13}$, and motional superposition states may remain coherent for days. We describe how to execute sideband cooling through inductive coupling to a nearby flux qubit, cooling the mechanical motion close to the ground state.

1:27PM B45.00012 Measurement of Casimir force with transparent conducting oxides , ALEXANDR BANISHEV, CHIA-CHENG CHANG, UMAR MOHIDEEN — The Casimir force plays an important role in micro- and nano electro mechanical systems (MEMS and NEMS) fabrication, because it can easily exceed the electrostatic forces used for actuating the systems at small electrode separation distances. The reduction of the Casimir force in devices is a complicated problem that needs to be scientifically investigated to open opportunities for the full exploitation of MEMS and NEMS technology. One of the ways to tune the Casimir force is to properly choose the materials of which the interacting surfaces are made. According to the Lifshitz theory, the interaction between two objects depends on their dielectric permittivity. In that case the transparent dielectrics attract less than reflective materials. This can be used to decrease the Casimir force when the design requires a smaller short range interaction. To achieve low Casimir forces and avoid uncontrolled electrostatic forces as present in dielectrics, transparent but conductive materials can be used. An ideal choice is conductive Indium Oxide such as very low doped Indium Tin Oxide (ITO). In this report we present the results of the Casimir force using transparent electrodes such as Indium Tin Oxide coated SiO_2 plate.

1:39PM B45.00013 Precision measurements of the Casimir force at Low temperatures[1] , RODRIGO CASTILLO-GARZA, UMAR MOHIDEEN, Physics and Astronomy Dept. UC Riverside — We will present research involving the precision measurement of the Casimir force at low temperatures. The role of material losses in this force and its incorporation into the Lifshitz theory remains unresolved. The Casimir force results from the modification of the zero point photon spectrum due to the presence of boundaries. The problem arises when the Casimir force is calculated at non zero temperature, where the role of thermal photons have to be included to that of the zero point photons. We plan to address this problem by measuring the Casimir force for different materials as a function of the temperature. Currently we are involved in making precision measurements of the Casmir force at 6K, 77K, and 300K with a micro cantilever based system that we have designed and built at UC-Riverside. The high sensitivity of this instrument will provide us with the resolution to advance our understanding of the interactions of both virtual photons and real photons when confined to a semi-infinite cavity made out of real metals. The constructed apparatus will also provide a deeper understanding of the role vacuum fluctuations play when the cavity constituents are made of a combination of dielectric, superconductor, and metal surfaces.

1:51PM B45.00014 Strong interactions of single atoms and photons near a dielectric boundary[1] , N.P. STERN, D.J. ALTON, T. AOKI, H. LEE, E. OSTBY, K.J. VAHALA, H.J. KIMBLE, California Institute of Technology, Pasadena, CA 91125, USA — Quantum control of strong interactions between a single atom and photon has been achieved within the setting of cavity quantum electrodynamics (cQED). To move beyond proof-of-principle experiments involving one or two conventional optical cavities to more complex scalable systems that employ $N > 1$ microscopic resonators requires localization of atoms on distance scales ~ 100 nm from a resonator's surface where an atom can be strongly coupled to a single intracavity photon while at the same time experiencing significant radiative interactions with the dielectric boundaries of the resonator. As an initial step into this new regime of cQED, we use real-time detection and high-bandwidth feedback to select and monitor motion of single Cesium atoms through the evanescent field of a microtoroid[2]. Direct temporal and spectral measurements coupled with simulations reveal both the significant role of Casimir-Polder attraction and the manifestly quantum nature of the atom-cavity dynamics, here in a regime of strong coupling, setting the stage for trapping atoms near micro- and nano-scopic optical resonators.

2:03PM B45.00015 Distinct single photons strongly interacting at a single atom in a waveguide , PAVEL KOLCHIN, RUPERT F. OULTON, XIANG ZHANG, University of California at Berkeley — We propose a waveguide QED system where two distinct single photons can interact strongly. The system consists of a single ladder-type three level atom coupled to a waveguide. We show that the nonlinear interaction can be tremendously enhanced by the strong coupling of the cascade atomic transitions to the waveguide mode simultaneously. As a result, a control photon tuned to the upper transition induces a π phase shift and tunneling of a probe photon tuned to the otherwise reflective lower transition. Waveguide QED schemes could be an alternative to high quality cavities or dense atomic ensembles in quantum information processing.

C1.00001 POLYMERS AND SOFT MATTER I –

C1.00002 Helical Ordering in Chiral Diblock Copolymers – the Effect of Chirality , WEI ZHAO, SUNG WOO HONG, GREGORY GRASON, THOMAS RUSSELL, University of Massachusetts Amherst — Introducing molecular chirality into the segments of block copolymers can influence the nature of the resultant morphology. Such an effect was found for poly(styrene-b-L-lactide) (PS-b-PLLA) diblock copolymers where hexagonally packed PLLA helical microdomains (H* phase) form in a PS matrix. However, molecular ordering of PLLA within the helical microdomains and the transfer of chirality from the segmental level to the morphological scale is still not well understood. We used a coarse-grained model to describe the interactions between segments of chiral blocks, and calculated the bulk morphologies of chiral AB diblock copolymers using self-consistent field theory (SCFT). We also performed in situ grazing incidence small angle x-ray scattering experiments to investigate the formation of the helical microdomains by changing solvents. Experiments confirmed that the H* phase is a kinetically trapped, metastable morphology below the melting point of PLLA block, while the SCFT explores the range of thermodynamic stability of helical structures in the phase diagram of chiral block copolymer melts.

C1.00003 ABSTRACT WITHDRAWN –

C1.00004 Crystallization of a Cyanurate Trimer in Nanopores , YUNG P. KOH, SINDEE L. SIMON, Texas Tech University — Nanoconfinement is known to depress the melting temperature through the well-known Gibbs-Thompson equation. Less well studied is the influence of nanoconfinement on crystallization kinetics. In this work we investigate crystallization of a cyanurate trimer using differential scanning calorimetry. The material shows cold crystallization and melting in the bulk state. Under the nanoconfinement of controlled pore glasses (CPG), cold crystallization and melting shift to lower temperatures, following the shift in the glass transition temperature. More importantly, however, the crystallization kinetics slow down and no crystallization occurs in 13 nm-diameter pores. Isothermal crystallization studies indicate that the Avrami exponent is approximately 2.0 for both bulk and nanoconfined samples. The time scale for crystallization is over one order of magnitude longer for samples confined in 50-nm pores in spite of the fact that samples were crystallized the same distance from T_g.

C1.00005 Chemical Composition Distribution of Partially Brominated Polystyrenes , WAYNE POWERS, Rensselaer Polytechnic Institute, YOUNG KUK JHON, JAN GENZER, North Carolina State University, CHANG RYU, Rensselaer Polytechnic Institute, RENSSELAER POLYTECHNIC INSTITUTE TEAM — Interaction chromatography has been employed to estimate the chemical composition distribution of partially brominated polystyrenes. In particular, random blocky and truly random partially brominated polystyrenes (b-PBrxS and r-PBrxS) differ in the dispersity of their chemical composition distributions, because of the limited accessibility of styrene segments for the bromination at temperature below theta temperature. First, the adsorption-based IC technique was used to fractionate b-PBrxS and r-PBrxS of the same average mole fraction of bromine. Then, these fractions were reinjected, and the peak position of each fraction was analyzed. In addition, the average chemical composition of each brominated polystyrene fraction has been analyzed separately via neutron activation analysis (NAA). The results of this analysis clearly supports that the chemical composition distribution b-PBrxS is narrower than that of r-PBrxS.

C1.00006 Controlled Orientation of Block Copolymer Microdomains on Modified Solid Surfaces , WEIYIN GU, SUNG WOO HONG, THOMAS RUSSELL, University of Massachusetts-Amherst — The interfacial interactions between block copolymers (BCP) and a substrate are important for the self-assembly of BCPs in thin films, especially in terms of orientation of BCP microdomains. A simple, rapid, and robust technique for controlling the alignment of BCP microdomains on modified surfaces is described. End-functionalized poly(styrene-b-ethylene oxide)s (PS-b-PEOs) with different block ratios were end-grafted onto Si substrates creating BCP brushes. Thin films of cylindrical forming PS-b-PEO were prepared on the surface of anchored BCP brushes and thermally annealed. When the fraction of styrene, f, of the anchored BCP was 1, no features were observed in thin film of a PS-b-PEO placed on the surface of the anchored brush due to preferential interaction of the PS block with the brush. When f was varied from 0.3 to 0.7, hexagonally packed cylindrical microdomains oriented normal to the substrate were formed having long range lateral ordering.

C1.00007 Studies on Morphology of PCPDTBT/Fullerene Bulk Heterojunction Organic Photovoltaics , YU GU, THOMAS RUSSELL, University of Massachusetts-Amherst — Low-bandgap conjugated polymer, poly[2,6-(4,4-bis(2-ethylhexyl)-4H-cyclopenta[2,1-b;3,4-b']-dithiophene)-alt-4,7-(2,1,3-benzothiadiazole)] (PCPDTBT), has been used in the active layer of the bulk heterojunction (BHJ) solar cells. Though PCPDTBT has a desirable bandgap, the power conversion efficiency (PCE) of the corresponding solar cells is still lower than the expectation. Grazing incidence wide angle X-ray scattering (GI-WAXS) showed that PCPDTBT is amorphous. Dynamic secondary ion mass spectrometry (DSIMS) and small angle neutron scattering (SANS) confirmed that PCPDTBT and [6,6]-phenyl C61-butyric acid methyl ester (PCBM) were uniformly distributed in the active layers. It is likely that the intimate mixing of the two components leads to a recombination of the free charges and the relatively low PCE. With additives, like 1,8-diiodooctane, the crystallinity of PCPDTBT increases and the PCBM segregates, which leads to improved device performances.

C1.00008 Morphology Evolution of Molecular Weight Dependent P3HT: PCBM Solar Cells , FENG LIU, DIAN CHEN, ALEJANDRO BRISENO, THOMAS RUSSELL, UMASS-Amherst — Effective strategies to maximize the performance of bulk heterojunction (BHJ) photovoltaic devices have to be developed and understood to realize their full potential. In BHJ solar cells, the morphology of the active layer is a critical issue to improve device efficiency. In this work, we choose poly(3-hexyl-thiophene) (P3HT) and phenyl-C61-butyric acid methyl ester (PCBM) system to study the morphology evolution. Different molecular weight P3HTs were synthesized by using Grignard Metathesis (GRIM) method. In device optimization, polymer with a molecular weight between 20k-30k shows the highest efficiency. It was observed that the as-spun P3HT: PCBM (1:1) blends do not have high order by GISAXS. Within a few seconds of thermal annealing at 150 $^\circ$ the crystallinity of P3HT increaased substantially and the polymer chains adopted an edge-on orientation. An-bicontinous morphology was also developed within this short thermal treatment. The *in situ* GISAXS experiment showed that P3HT of high molecular weight was more easily crystallized from a slowly evaporated chlorobenzene solution and their edge-on orientation is much more obvious than for the lower molecular weight P3HTs. DSC was used to study the thermal properties of P3HTs and P3HT: PCBM blend. The χ of P3HT-PCBM was also calculated by using melting point depression method.

C1.00009 Elimination of branching in beta-hairpin self-assembling peptides , SAMEER SATHAYE, DARRIN POCHAN, Department of Materials Science and Engineering, University of Delaware, DARRIN POCHAN RESEARCH GROUP TEAM — Nanoscale fibril self-assembly in (VK)4VDPPT (KV)4-NH2 peptides is initiated by intramolecular peptide folding into a beta-hairpin conformation. Once folded, the peptides undergo intermolecular bilayer formation due to hydrophobic collapse of hydrocarbon valine side chains, all located on one face of respective folded beta-hairpins. Subsequent intermolecular hydrogen bonding between folded hairpins leads to fibril formation. A physically crosslinked network structure is formed due to fibrillar entanglement and defects in hydrophobic collapse that nucleate branching points. We attempt to design "lock and key" specificity in the hydrophobic faces of the folded beta-hairpins so that only 1-d fibril formation can occur without any branching. The success of the new peptide designs to rid the system of branching and characteristics of the networks afforded by new peptide sequences and blends thereof will be discussed by various characterization techniques such as Rheological Characterization, Circular Dichroism (CD), Transmission Electron Microscopy (TEM) and Small Angle Neutron Scattering (SANS).

C1.00010 Theory of Nanoparticle Interactions Mediated by Reversibly Binding Polymer Chains , STEPHANIE TRITTSCHUH, GREGORY GRASON, University of Massachusetts Amherst — In stable polymer-nanoparticle composites, particles must be compatibilized with the polymer matrix to overcome entropically- driven, short-range depletion forces that drive particle aggregation. One strategy is to incorporate end-functional groups to polymers that reversibly bind to particle surfaces via donor- acceptor type interactions, such as hydrogen bonding. The addition of reversibly binding chain ends introduces a new length scale for the effective interaction between two particles due to the possibility of inter-particle bridging conformations available to chains at small particle-particle separations. We use self- consistent field theory to explore the effective pairwise particle potential in a melt of reversibly associating chains and examine how changing particle size, chain length and binding affinity shapes the free energy of interaction and alters higher-order inter-particle organization in nanocomposites.

C1.00011 Thio-amide functionalized polymers via polymerization or post-polymerization modification

, ALI OZCAM, NC State University, ADAM HENKE, IVA STIBINGEROVA, JIRI SROGL, Institute of Organic Chemistry and Biochemistry, JAN GENZER, NC State University — Decreasing supplies of fresh water and increasing population necessitates development of advanced water cleaning technologies, which would facilitate the removal of water pollutants. Amongst the worst of such contaminants are heavy metals and cyanides, infamous for their high toxicity. To assist the water purification processes, we aim to synthesize functionalized macromolecules that would contribute in the decontamination processes by scavenging detrimental chemicals. Epitomizing this role thio-amide unit features remarkable chemical flexibility that facilitates reversible catch-release of the ions, where the behavior controlled by subtle red-ox changes in the environment. Chemical tunability of the thio-amide moiety enables synthesis of thio-amide based monomers and post-polymerization modification agents. Two distinct synthetic pathways, polymerization and post-polymerization modification, have been exploited, leading to functional thioamide-based macromolecules: thioamide-monomers were copolymerized with N-isopropylacrylamide and post-polymerization modifications of poly(dimethylaminoethyl methacrylate) and poly(propargyl methacrylate) were accomplished via quarternization and "click" reactions, respectively.

C1.00012 Charged triblock copolymer self-assembly into charged micelles

, YINGCHAO CHEN, KE ZHANG, JIAHUA ZHU, KAREN WOOLEY, DARRIN POCHAN, DEPARTMENT OF MATERIAL SCIENCE AND ENGINEERING UNIVERSITY OF DELAWARE TEAM, DEPARTMENT OF CHEMISTRY TEXAS A&M UNIVERSITY COLLABORATION — Micelles were formed through the self-assembly of amphiphlic block copolymer poly(acrylic acid)-block-poly(methyl acrylate)-block-polystyrene (PAA-PMA-PS). Importantly, the polymer is complexed with diamine molecules in pure THF solution prior to water titration solvent processing-a critical aspect in the control of final micelle geometry. The addition of diamine triggers acid-base complexation between the carboxylic acid PAA side chains and amines. Remarkably uniform spheres were found to form close-packed patterns when forced into dried films and thin, solvated films when an excess of amine was used in the polymer assembly process. Surface properties and structural features of these hexagonal-packed spherical micelles with charged corona have been explored by various characterization methods including Transmission Electron Microscopy (TEM), cryogenic TEM, z-potential analysis and Dynamic Light Scattering. The forming mechanism for this pattern and morphology changes against external stimulate such as salt will be discussed.

C1.00013 Examining the Role of Structure on Charge Transport of Polymer Semiconductors

, KIARASH VAKHSHOURI, Chemical Engineering Department, The Pennsylvania State University, ENRIQUE GOMEZ — Charge carrier mobility in conjugated semi-crystalline polymers depends critically on the crystallinity, orientation of the crystals, and connectivity between ordered regions. However, the complex interplay between these morphological parameters is not fully understood. By varying the thermal annealing parameters and casting solvents, we have systematically studied charge transport within poly(3-hexylthiophene) and poly(2,5-bis(3-alkylthiophen-2-yl) thieno[3,2-b]thiophene) as a function of the crystallinity. It is found that the crystallinity itself does not always correlate with the charge mobility. Our hypothesis is that the crystallization kinetics can alter the number of tie chains, thereby affecting charge transport in semi-crystalline polymer semiconductors.

C1.00014 Towards quantitative structure-function relationships for organic solar cells

, DEREK KOZUB, Department of Chemical Engineering, The Pennsylvania State University, KIARASH VAKHSHOURI, ENRIQUE GOMEZ — Organic solar cells belong to a class of devices where the morphology of the active layer has a large impact on device performance. However, characterization of the morphology of organic semiconductor mixtures remains a challenge. We have utilized Grazing Incidence Small Angle X-Ray Scattering (GISAXS), Resonant Soft X-ray Scattering (RSOXS), and Energy Filtered Transmission Electron Microscopy (EFTEM) to characterize the morphology of polythiophene/fullerene mixtures as a function of processing conditions. GISAXS and RSOXS have been used to determine the domain spacing within the active layer, whereas EFTEM has been used to generate images with high contrast between domains. Furthermore, these techniques have been useful in guiding our attempts to control the nucleation of crystals and perturb the structure of the active layer. By comparing our morphological data with device data, we are developing structure-function relationships relevant to organic solar cells.

C1.00015 Polarization Controlled Photomechanical Behaviors of Polydomain Azobenzene Liquid Crystalline Polymer Networks[1]

, TIMOTHY WHITE, KYUNG MIN LEE, VINCENT TONDIGLIA, HILMAR KOERNER, RICHARD VAIA, TIMOTHY BUNNING, Air Force Research Laboratory — We report the polarization controlled photomechanical behaviors of azobenzene liquid crystalline polymer networks (azo-LCNs) as a function of crosslink density and temperature. High modulus, glassy polydomain azo-LCNs were synthesized by copolymerizing RM257 and 2-azo, initiated by 1 wt% of the inorganic photoinitiator Irgacure 784. Crosslinking density of azo-LCNs increases from 2.09 mol/dm^3 to 7.24 mol/dm^3 with curing time from 1-120 min. Storage modulus and loss tangent of azo-LCNs also increase with crosslinking density. All azo-LCNs are glassy at room temperature. To increasing temperature, E' begins to decrease through T_g to a level dependent on the crosslinking density, and eventually reaching a rubbery plateau region. Interestingly, the bidirectional (forward and reverse) bending angles of the polydomain azo-LCN cantilevers at equilibrium decrease with increasing temperature and crosslinking density. Absorption and bending behaviors of the azo-LCNs with various thicknesses, concentrations and molecular structure of azobenzene monomer will be discussed.

[1]Authors acknowledge support from AFRL/RX and AFOSR

C1.00016 Effects of Sequence Distribution, Concentration and pH on Gradient and Block Copolymer Micelle Formation in Solution

, STEPHEN MARROU, JUNGKI KIM, CHRISTOPHER WONG, JOHN TORKELSON, Northwestern University — Gradient copolymers are a relatively new class of materials with a gradual change in comonomer composition along the copolymer chain length, which have exhibited unique material properties in comparison to random and block copolymers. Here we extend this architecture to amphiphilic systems that form micelles in solvent, as the effect of a nonuniform comonomer sequence distribution is expected to strongly influence critical aggregation phenomena. Utilizing pyrene as a fluorescence probe, we determined that gradient copolymers present an intermediate critical aggregation concentration in comparison to analogous block and random copolymers. The effect of gradient architecture on a pH-sensitive copolymer was also investigated, concluding that gradient sequencing significantly impacts the solubility and critical aggregation pH when compared to block and random copolymers of similar composition, providing further evidence that gradient architectures introduce a powerful means of tuning properties between block and random copolymers.

C1.00017 Temperature dependence of ionic association of lithium triflate in acetate solutions

, DHARSHANI BOPEGE, Department of Physics and Astronomy, University of Oklahoma, Norman, OK 73019, USA, MATT PETROWSKY, ROGER FRECH, Department of Chemistry and Biochemistry, University of Oklahoma, 101 Stephenson Parkway, Norman, OK, 73019, USA, J.M. FURNEAUX, Department of Physics and Astronomy, University of Oklahoma, Norman, OK 73019, USA — Ion transport is studied in polymer and organic liquid electrolytes due to the importance of these systems in rechargeable battery applications. We have used Fourier Transform Infrared Spectroscopy (FTIR) to study the temperature dependence of ionic association in solutions of lithium trifluoromethanesulfonate ($LiCF_3SO_3$, LiTf) dissolved in propyl, hexyl, octyl, and decyl acetates. The IR Spectra were recorded for three salt concentrations (0.1, 0.2, 0.5 mol kg^{-1}) from 0 °C to 80 °C. Two spectral bands were analyzed at each temperature: the CF_3 symmetric bend (δ_s) in the 740-780 cm^{-1} region and the carbonyl stretch in the 1660-1800 cm^{-1} region. Relative intensities of these bands were calculated by a curve fitting procedure. Three different LiTf ionic species were observed in the $\delta_s(CF_3)$ region. The carbonyl band due to coordination with Li ion appears at a lower frequency (1714 cm^{-1}) than the pure carbonyl band (1744 cm $^{-1}$).

C1.00018 Organic Molecules and Network Polymers of Intrinsic Microporosity: Structural Characterization via X-ray Scattering and Simulations[1] , AMANDA G. MCDERMOTT, LAUREN J. ABBOTT, Penn State University, ANNALAURA DEL REGNO, University of Manchester, KADHUM J. MSAYIB, BADER S. GHANEM, RUPERT TAYLOR, MARIOLINO CARTA, NEIL B. MCKEOWN, Cardiff University, PETER M. BUDD, FLOR R. SIPERSTEIN, University of Manchester, CORAY M. COLINA, JAMES RUNT, Penn State University — Like polymers of intrinsic microporosity (PIMs), organic molecules of intrinsic microporosity (OMIMs) are glassy solids featuring a large concentration of pores smaller than 2 nm and large internal surface area as measured by gas sorption experiments. OMIMs are oligomers designed to fill space inefficiently, consisting of several rigid segments joined at one vertex to produce concave faces. Both X-ray scattering patterns and simulations provide insight into the packing geometry and short-range order of these molecules. We also discuss the interpretation of scattering patterns from two- and three-dimensional network PIMs.

C1.00019 Methyl Methacrylate Polymerization in Nanoporous Matrix: Reactivity and Molecular Weight , HAOYU ZHAO, SINDEE SIMON, Texas Tech University — The influence of nanoconfinement on the free radical polymerization of methyl methacrylate is investigated. Nanoporous controlled pore glass (CPG) is used as a nanoconfining matrix for the polymerization. The reaction is followed by measuring heat flow as a function of reaction time during isothermal polymerization using differential scanning calorimetry (DSC). Preliminary results indicate several interesting effects for polymerization in 110 nm diameter pores: the induction time increases under nanoconfinement, the effective reaction rate constant increases, the effective activation energy is unchanged, and the gel effect or autoaccleration occurs at earlier times after induction. The latter result concerning the gel effect is presumably due to the decrease in diffusivity under nanoconfinement which results in a decrease in the termination rate of free radicals. The cause of the longer induction times and accelerated reaction rates just after induction are under investigation. The influence of nanoconfinement on molecular weight will also be examined.

C1.00020 The Dynamic Heat Capacity of the Potential Energy Landscape of a Simple Chain Model , JONATHAN BROWN, JOHN MCCOY, New Mexico Tech — The dynamic heat capacity of a simple (bead-spring) polymeric model glassformer was computed using molecular dynamics simulations by sinusoidally driving the temperature, and recording the resultant energy. The underlying potential energy landscape of the system was probed by taking a time series of particle positions and quenching them with an energy minimization routine. This shows that the long time relaxation of the model glassformer is the direct result of the dynamics of the potential energy landscape.

C1.00021 Characterization of the Morphology and Rapid Expansion of Swellable Organically Modified Silica , LILIANNA E. CHRISTMAN, AMANDA LOGUE, The College of Wooster, Department of Physics, PAUL L. EDMISTON, The College of Wooster, Department of Chemistry, SUSAN Y. LEHMAN, The College of Wooster, Department of Physics, Wooster OH 44691 — Swellable organically modified silica (SOMS) is a novel sol-gel derived material. SOMS is hydrophobic and selectively absorbs non-polar liquids and immediately swells 5 to 6 times upon absorption. SOMS can be used to remove organic contaminants from water; the contaminant can then be recovered and the SOMS reused. We have investigated the SOMS swelling behavior of neat organic liquids usng macroscopic measurements of the force exerted during expansion and through atomic force microscopy (AFM) of the surface. A powdered SOMS sample was placed in a cylinder with an adjustable piston. Solvent percolated into the cylinder and the piston gradually moved to allow expansion while measuring the force using a load cell. During expansion the SOMS exerted forces up to 150 N per gram of material. AFM shows the surface of the SOMS is textured with cauliflower-like features. In unswollen SOMS, these globules have length scales of a few hundred nanometers, while for SOMS swollen in a solvent the features expand to several micrometers.

C1.00022 ABSTRACT WITHDRAWN –

C1.00023 Self-assembly of PtBA-P3HT multi-arms star-like block copolymer at the air/water interface , LEI ZHAO, XINCHANG PANG, CHAOWEI FENG, ZHIQUN LIN, NANOFM TEAM — A novel PtBA-P3HT multi-arm star-like diblock copolymer (BCP) was synthesized via a combination of atom transfer radical polymerization, quasi-living polymerization and click reaction. The self-assembly of PtBA-P3HT multi-arm star-like BCP at the air/water interface was systematically explored using the Langmuir Blodgett (LB) technique. The hydrophobic star-like BCP has 21 arms, with PtBA as the core and P3HT as the shell. At the air/water interface, the BCP molecules gradually assembled into domains composed of bundle-like structures under surface pressure, and finally formed the network structure in a way controlled by PtBA chain folding and P3HT chain stacking. The photoluminescence measurement showed that the formation of P3HT bundle in LB film led to enhanced luminescence due to the reduced inter-chain coupling.

C1.00024 Glassy dynamics of polymers in thin films and monomolecular layers , MARTIN TRESS, EMMANUEL U. MAPESA, University of Leipzig, ANATOLI SERGHEI, Universite Lyon 1, FRIEDRICH KREMER, University of Leipzig — The glassy dynamics of nanometer thin polymer layers supported on a solid substrate was investigated by Braodband Dielectric Spectroscopy (BDS). The thickness was systematically reduced finally resulting in randomly distributed polymer coils. Highest priority was put on an appropriate sample preparation including an annealing procedure for sufficient long time at elevated temperatures in inert atmosphere to avoid effects due to remaining solvent and chemical degradation. Further, detailed checks of the surface topology by atomic force microscopy (AFM) were performed to verify stability of the samples during the whole measurement. The dynamics is compared to the bulk to trace changes due to the impact of the interface and to give a length scale for the interfacial interactions.

C1.00025 Confinement-Induced Ordering in Dewetting of Polymer Blend Film[1] , MU WANG, XIAO-CHUN CHEN, RU-WEN PENG, GUO-BIN MA, DAJUN SHU, Department of Physics, Nanjing University — Dewetting and phase separation of polymer blend film on a periodically modified substrate can generate unique microstructures. Despite external perturbations in previous studies, polymer film remained continuous with the boundary locating at infinity. It is interesting to investigate dewetting and phase separation process in a confined geometry, such as a fishnet-like environment, where unique self- organization process is anticipated. We report here an effect that polymer blend film of polystyrene(PS) and poly (methylmethacrylate)(PMMA) may evolve to a perfectly ordered droplet array on a periodically excavated silicon substrate, and each droplet possesses a PS kernel surrounded by PMMA cofferdam. The formation of regular pattern depends on initial thickness of polymer film and interstitial separation of microholes on substrate, and a scaling has been revealed. Our observation demonstrates a confinement-induced ordering in dewetting of polymer blend film, and suggests a budget and convenient approach to generate regular polymer microstructures over a large area.

[1]Project supported by NSF of China and MOST of China under Grant Nos. Nos. 50972057, 10874068, 11034005, and 61077023 and 2010CB630705.

C1.00026 Synthesis of polymer brushes by surface-initiated controlled radical polymerization in the presence of free initiators. A Monte Carlo investigation , SALOMON TURGMAN-COHEN, JAN GENZER, North Carolina State University — Simultaneous controlled radical polymerization from free and surface-grafted initiators is studied by means of computer simulations. We model "truly living" reactions by neglecting chain termination and chain transfer. We study the competition between bulk- (i=b) and surface-initiated (i=s) polymers by monitoring the rates of polymerization ($d<N>_i/dt$), the average molecular weight ($<N>_i$), and the polydispersity index (PDI_i) while varying the initiator grafting density (σ), the fraction of surface based polymers (η), and the initial number of free monomers (I_o). We find that $d<N>_B/dt > d<N>_S/dt$ and that $d<N>_S/dt$ decreases with increasing σ. The difference in polymerization rates between the bulk and surface polymerizations results in polymer populations with different $<N>$; this has implications for the experimental determination of σ and $<N>_S$. Although η affects $<N>_S$ and $<N>_B$, it does not influence the PDI. At a specific $<N>_i$, the PDI_i has a value independent of η. In addition, $PDI_S > PDI_B$; this difference increases with increasing σ. We therefore conclude that polymerization conditions that yield bulk polymers with low PDI do not guarantee the same PDI for the surface-initiated polymers.

C1.00027 Directed Dewetting of Thin Polymer Films[1] , SUCHANUN MOUNGTHAI, TRANG PHAM, GUS RAJAENDRAN, GILA STEIN, Univ. of Houston — We present a simple route to generate arrays of microscale polygons by directed dewetting of polystyrene thin films on topographic pre-patterns.[2] Silicon wafers are patterned with arrays of ca. 10 μm wide hexagonal holes using photolithography and wet etching. Patterned substrates are coated with thin films of polystyrene and heated above the glass transition temperature to promote dewetting. The dewetting process is monitored *in-situ* with optical microscopy, and final droplet structures are also imaged with atomic force microscopy. The mechanism of polygon formation is driven by Rayleigh instability; Formation rates and final polygon size are controlled by temperature/viscosity, film thickness, and the geometry of the topographic pre-pattern.

C1.00028 Reaction-Diffusion Processes in Ultrathin Films of Photoresist[1] , GINUSHA PERERA, GILA STEIN, Univ. of Houston — Projection lithography is the primary technology used for patterning semiconductor devices. High-throughput manufacturing requires imaging materials (resists) that are highly sensitive to radiation, and this demand is satisfied through a process termed chemical amplification (CA). CA resists are comprised of a polymer resin (reactant) and photoacid generator (catalyst); a coupled reaction-diffusion mechanism drives image formation, where image resolution is limited by slow diffusion of the acid catalyst. There is evidence that thin film reaction rates deviate from the bulk behavior, and current models for image formation do not capture such effects. We demonstrate that X-Ray Diffraction can measure spatial extent-of-reaction in ultrathin films of a nanopatterned poly(4-hydroxystyrene-co-tertbutylacrylate) CA resist. The feedback acquired is used to construct predictive models for the coupled reaction-diffusion processes that incorporate the physics of confined polymers.

C1.00029 Mechanical properties determination of PDMS films on hard substrate using atomic force microscopy , WENWEI XU, TODD SULCHEK, The George W. Woodruff School of Mechanical Engineering, Georgia Institute of Technology — Mechanical properties of PDMS thin films adhering on hard substrate were investigated using Atomic Force Microscope (AFM) with a spherical tip. Simulation was implemented using finite element method and was compared to the experiments. The effect of the hard substrate on the mechanical response of the PDMS film becomes significant when the indentation depth exceeds 45% of the sample thickness. This relationship was also verified by comparing Hertz model to the experiments in the whole indentation range. Hertz model is not applicable in the large deformation region because the large deformation violates the assumption on which the Hertz model is based. The point wise Young's modulus as a function of indentation was obtained using Hertz model and also identified the effect of the hard substrate on mechanical responses. Furthermore, the point wise Young's modulus in the linear elasticity region decreases with increasing film thickness, until the sample is thick enough and its modulus reaches that for bulk PDMS. In the point wise Young's modulus plot, the Young's moduli at small indentations were several orders of magnitude higher than those in the linear elasticity region; this phenomenon has been observed in previous research and was also studied in our experiments.

C1.00030 Anisotropic Surface and Interfacial Instabilities in Nanoimprinted Polymer Bilayers , DAE UP AHN, ZHENG ZHANG, YIFU DING, University of Colorado — We illustrate the spontaneous formation of hierarchical polymer patterns driven by surface/interfacial instabilities at mobile and corrugated polymer-polymer interface. Upon thermal annealing of polystyrene (PS) films deposited on (and also confined in) topographic patterns of poly(methylmethacrylate) (PMMA), the PS/PMMA bilayers underwent a sequential event of morphological changes encompassing uniform pattern decay, simultaneous capillary breakup, anisotropic coarsening, and Rayleigh instabilities. Particularly, depending on the geometry of the bilayer pattern, the simultaneous capillary breakup has occurred in different modes. The morphological evolutions and structure formations are unique to the current system, and are drastically different from the polymer film dewettings on a planar surface, a chemically patterned surface, or a topographically patterned rigid surface. Thus, we demonstrate that the direct participations of the viscous topographic interface in the instabilities or assemblies offer a unique strategy to achieve a rich spectrum of highly anisotropic hierarchical structures.

C1.00031 Modification of Silicon Oxide Surfaces with Thermally Annealed Polystyrene Films , STEVEN KALAN, KEVIN CAVICCHI, ALAMGIR KARIM, University of Akron — The modification of silicon with a native oxide surface has been accomplished by annealing thin films of anionically polymerized polystyrene spun-coat from solution at elevated temperature followed by dissolving the film in solvent to leave a thin layer of adsorbed polymer that persisted even after prolonged desorbing in solvent even at elevated temperature. It was found by water contact angle analysis of the samples after washing with organic solvent that annealing is a key step to adsorption of a thin layer of polystyrene on the film surface. X-ray reflectivity analysis also demonstrated that the thickness of the adsorbed layer is proportional to the molecular weight of the polymer. However, the contact angle showed a non-monotonic dependence on molecular weight. The further modification of these surfaces by ultraviolet/ozone treatment will be discussed. This is a novel surface treatment method as it performed with a polystyrene polymer without any additional chemical functionality through straight-forward vacuum annealing and washing with organic solvent.

C1.00032 A closer look on the thermo-responsive behavior of ultrathin pNIPAM films - relating interfacial molecular transitions to macroscopic properties , PATRICK KOELSCH, VOLKER KURZ, Karlsruhe Institute of Technology, STEFAN ZAUSCHER, Duke University — The thermo-responsive behavior of thiol-modified poly(N-isopropylacrylamide) (pNIPAM) films immobilized on gold were probed by in situ broadband sum-frequency generation (SFG) spectroscopy, ellipsometry and capturing bubble contact angle. The pNIPAM films were prepared by atom transfer radical polymerization using a nitro-biphenyl-thiol-SAM on a polycrystalline gold surface as a substrate. Macroscopic properties of the film during the lower critical solution temperature (LCST) are tracked in detail by ellipsometry and capturing bubble contact angle allowing us to measure the thickness and water content within the film as well as the surface energy. These results are correlated with data acquired by in situ SFG spectroscopy, an intrinsic surface specific method probing LCST dynamics on a molecular scale.

C1.00033 Non-Contact Measurements of Stiffness in Confined PS Films by Fluorescence and XPCS

, CHRISTOPHER EVANS, Northwestern University, SURESH NARAYANAN, ZHANG JIANG, Argonne National Lab, JOHN TORKELSON, Northwestern University — Fluorescence is used to detect stiffness in confined polystyrene (PS) films through the intensity ratio (I3/I1) of the dye molecule pyrene. Free-standing PS films show a softening (an increase in I3/I1) when the film thickness decreases below 400 nm, and a stiffening (a decrease in I3/I1) below thicknesses of 200 nm. Silica- and PDMS-supported PS films show no softening but report stiffening for films less than 200 nm thick, a result not in accord with the Tg reductions seen for PS on silica. X-ray photon correlation spectroscopy (XPCS) also reports stiffening in PS on silica through the relaxation times of capillary waves at the polymer surface. A two order of magnitude increase in relaxation time is observed for small in-plane wavevectors (q) in a 30 nm PS film compared to a 120 nm film. Bilayer films of PS supported on various bulk underlayers studied by XPCS indicate that lower substrate modulus leads to faster PS surface relaxation times. These are the first reported non-contact measurements related to stiffness in confined PS on silica.

C1.00034 Interfacial Structure, Dynamics, and Transport of Polyelectrolyte Membrane Materials for Fuel Cells

, CHRISTOPHER SOLES, K. PAGE, S. EASTMAN, S. KIM, S. KANG, National Institute of Standards and Technology; Polymers Division, J. DURA, NIST Center for Neutron Research, NATIONAL INSTITUTE OF STANDARDS AND TECHNOLOGY; POLYMERS DIVISON TEAM, NIST CENTER FOR NEUTRON RESEARCH COLLABORATION — Polymer electrolyte membranes (PEM) fuel cells show promise for a wide range of applications both in the transportation sector and for stationary power production due to their high charge density and low operating temperatures. While the structure and transport of bulk PEMs have been studied extensively, little is known about these materials at interfaces and under confinement, as they exist within the membrane electrode assembly (MEA). Using neutron/ x-ray reflectivity and polarization-modulation infrared reflection-absorption spectroscopy, we have studied the polymer-substrate interfacial structure, swelling, and water transport as function of humidity, surface chemistry, and film thickness. The interfacial structure is highly dependent upon the substrate surface chemistry and the swelling/water diffusivity are suppressed when the PEM is confined to a thin film. This new information will enable researchers to more accurately model the performance of the MEA as current simulations typically rely on bulk property values to predict water and proton transport under these conditions.

C1.00035 Large and Reversible Plasmon Tuning using Ultrathin Responsive Polymer film[1]

, SRIKANTH SINGAMANENI, SAIDE NERGIZ, Washington University in St. Louis — We demonstrate reversible linear and branched aggregation of gold nanoparticles adsorbed on an ultrathin responsive polymer ((poly(4-vinyl pyridine), P4VP) film. P4VP is a weak cationic polymer, which exhibits a reversible coil to globule transition with change in external pH. Atomic force microscopy revealed that in the coiled state (below the isoelectric point of the polymer) of the polymer chains, gold nanoparticles adsorbed on the polymer layer existed as primarily individual nanoparticles. On the other hand, lowering the pH caused the polymer chains to transition from coil to globule state, resulting in aggregation of the nanoparticles into linear and branched chains. Reversible aggregation of the nanoparticles results in a dramatic change in the optical properties of the metal nanostructures. Apart from the large redistribution of the intensity between the individual (530 nm) and coupled (650 nm) plasmon bands, the coupled plasmon band exhibits a shift of nearly 60 nm with change in external pH. The pH triggered aggregation of the nanoparticles and the dramatic change in the optical properties associated with the same can form an excellent platform for colorimetric sensing.

C1.00036 Mechanical Properties of Nanofibers Revealed by Interaction with Streams of Air

, YINAN LIN, DANIEL CLARK, DARRELL RENEKER, The University of Akron — Measurements of mechanical properties of electrospun nanofibers are needed for process control [1] and for design of structures that are durable, conformal and hierarchical. A new method, complementing measurements made on miniature mechanical testing devices [2], was developed. Electrospun nanofibers were captured directly between two steel rods that functioned "grips." Tensile deformation was applied by separating grips. The stress information was revealed by the deflections of the nanofibers caused by forces from broad streams of air, flowing perpendicularly to the fibers, at measured velocities. Glints of reflected light that revealed the contour of the deflected nanofibers were recorded with a camcorder. Image analysis of the shapes of the nanofibers was combined with scanning electron microscopy measurements of the diameter of the ends to evaluate the mechanical properties. Stress strain curves and hysteresis loops of selected ultrathin electrospun fibers were obtained. Direct comparisons of mechanical properties were made for a wide range of polymers.

C1.00037 Structural Characterization of Nanopatterned Surface Gratings with Grazing Incidence X-Ray Scattering

, ELAINE CHAN, DONG HYUN LEE, DMITRY VORONOV, HOWARD PADMORE, Lawrence Berkeley National Laboratory, TING XU, University of California, Berkeley, THOMAS RUSSELL, University of Massachusetts Amherst, ALEXANDER HEXEMER, Lawrence Berkeley National Laboratory — The fabrication of surface gratings with periodic, nanoscale features is a promising route for templating nanopatterned thin film materials with macroscopic lateral order. These materials can be utilized for constructing novel and improved micro- and opto-electronic devices and x-ray optical elements. To characterize the structural features of the grating substrates and templated thin films, grazing incidence x-ray scattering (GISAXS) is becoming an increasingly desirable and emerging technique because the method provides sufficiently high sensitivity. We investigate herein the structural features of gratings with sawtooth topologies using GISAXS. We characterize the GISAXS patterns of gratings prepared from silicon and sapphire substrates, and examine the emergence of specific features that appear for varying sawtooth aspect ratio and at different incident angle values. These features are further analyzed using theoretical calculations where feasible. In this manner we demonstrate the utility of GISAXS for characterizing the structures of nanopatterned surfaces.

C1.00038 Thermal Programmed Desorption of $C_{32}H_{66}$

, M. CISTERNAS, Pontificia Univ. Catolica de Chile, V. DEL CAMPO, Univ. Tecnica Federico Santa Maria, Chile, A.L. CABRERA, U.G. VOLKMANN, Pontificia Univ. Catolica de Chile, F.Y. HANSEN, Technical Univ. Denmark, H. TAUB, Univ. of Missouri-Columbia — Alkanes are of interest as prototypes for more complex molecules and membranes. In this work we study the desorption kinetics of dotriacontane C32 adsorbed on SiO_2/Si substrate. We combine in our instrument High Resolution Ellipsometry (HRE) and Thermal Programmed Desorption (TPD). C32 monolayers were deposited in high vacuum from a Knudsen cell on the substrate, monitorizing sample thickness *in situ* with HRE. Film thickness was in the range of up to 100 Å, forming a parallel bilayer and perpendicular C32 layer [1]. The Mass Spectrometer (RGA) of the TPD section was detecting the shift of the desorption peaks at different heating rates applied to the sample. The mass registered with the RGA was AMU 57 for parallel and perpendicular layers, due to the abundance of this mass value in the disintegration process of C32 in the mass spectrometers ionizer. Moreover, the AMU 57 signal does not interfere with other signals coming from residual gases in the vacuum chamber. The desorption energies obtained were ΔE_{des}=11,9 kJ/mol for the perpendicular bilayer and ΔE_{des} = 23,5 kJ/mol for the parallel bilayer.

C1.00039 Molecular dynamics simulations of dotriacontane films supported on a SiO_2 surface

, SEBASTIAN GUTIERREZ, Pontificia Universidad Catolica de Chile, RAUL ARAYA, TOMAS PEREZ-ACLE, Universidad de Chile, MARIA JOSE RETAMAL, ULRICH G. VOLKMANN, Pontificia Universidad Catolica de Chile — Dotriacontane ($C_{32}H_{66}$, C32) films supported on SiO_2 surfaces were studied using very high-resolution ellipsometry, atomic force microscopy (AFM) and x-ray reflectivity techniques. For almost complete layers a model was proposed [1] in which the C32/SiO_2 interfacial region is characterized by a parallel bilayer and perpendicular layers on top. Recent AFM measurements performed on samples forming sea-weed like structures, showed that for these particular perpendicular "fractal like" layers the heights are lower than the all-trans length of dotriacontane (42.5 Å). To gain insights on the internal molecular ordering and layering of C32 supported on SiO_2 surfaces, we used all-atom molecular dynamics to simulate C32 films at different temperatures. Our results confirm the presence of the parallel bilayer suggesting the existence of a mixed layer on top, formed by molecules with both parallel and perpendicular segments. These findings suggest a different molecular architecture for sea-weed like structures of dotriacontane supported on SiO_2.

C1.00040 Fabricating Stable Superhydrophobic Hierarchical Polyelectrolyte Multilayer Films by Layer-by-Layer Assembly and Nanolithography

, XIAYUN HUANG, NICOLE ZACHARIA — Recent experiment shows that wetting can be controlled by not only the chemical nature but geometrical structure of the surface also. Even for a hydrophilic surface, it can transit into hydrophobic one when manipulating the roughness of surface. It is also of interest to determine if superhydrophobic surfaces can be created from hydrophilic multilayer films because multilayer is easy to be coated on any place by layer-by-layer assembly. Here, we used water-soluble polycations, PAH (poly(allylamine)), and polyions, SPS (sodium poly(styrene sulfonate)), to form polyelectrolyte multilayers. By nanoimprint lithography and in-situ growth of inorganic patterns in between these polyelectrolyte multilayers, we can include some micro-sized and nano-sized structures for different generations. When controlled introducing micro-sized and nano-sized hierarchical structures into multilayers, we can learn how the surface roughness increasing superhydrophobic properties from geometry view fundamentally.

C1.00041 Adhesion of Nanoparticles[1]

, JAN-MICHAEL CARRILLO, University of Connecticut, ELIE RAPHAEL, ESPCI, ANDREY DOBRYNIN, University of Connecticut — We have developed a new model of nanoparticle adhesion which explicitly takes into account the change in the nanoparticle surface energy. Using combination of the molecular dynamics simulations and theoretical calculations we have showed that the deformation of the adsorbed nanoparticles is a function of the dimensionless parameter $\beta \propto \gamma (GR)^{-2/3} W^{-1/3}$, where G is the particle shear modulus, R is the initial particle radius, γ is the polymer interfacial energy, and W is the particle work of adhesion. In the case of small values of the parameter β <0.1, which is usually the case for strongly cross-linked large nanoparticles, the particle deformation can be described in the framework of the classical Johnson, Kendall, and Roberts (JKR) theory. However, we observed a significant deviation from the classical JKR theory in the case of the weakly cross-linked nanoparticles that experience large shape deformations upon particle adhesion. In this case the interfacial energy of the nanoparticle plays an important role controlling nanoparticle deformation. Our model of the nanoparticle adhesion is in a very good agreement with the simulation results and provides a new universal scaling relationship for nanoparticle deformation as a function of the system parameters.

C1.00042 ABSTRACT WITHDRAWN –

C1.00043 Pressure Mapping Within a Tribological Contact with Fluorescence Imaging

, MOURAD CHENNAOUI, JANET WONG, Imperial College London, London, UK — In many lubricated applications from gears to MEMS, the operating pressure must be known in order to achieve optimum performance and design. However, due to the small length scale that exists at the tribological contact, placing sensors is unpractical to allow direct pressure measurement. Instead, the pressure is often inferred from indirect techniques such as film thickness measurements, photo-elasticity or the use of micro-transducers. Although these methods lead to good pressure approximations, they generally involve calibrations on well-defined setups. The results obtained can be difficult to interpret or suffer from limited spatial resolutions. In this work, fluorescent molecules in a lubricating fluid are used as probes for in-situ pressure measurements. The change in the probe's photophysical behaviour with pressure is utilised to quantitatively correlate the pressure distribution in a tribological contact such as the one found in elastohydrodynamic lubrication regimes.

C1.00044 Thermal Properties of specific Nonconjugated Conductive Polymers studied using Differential Scanning Calorimetry

, GURUDUTT TELANG, SAPANA SHRIVASTAVA, MRINAL THAKUR, Photonic Materials Research Laboratory, Auburn University, AL 36849 — Differential scanning calorimeter (DSC) has been used to measure the thermal properties of nonconjugated conductive polymers, poly(β-pinene) and trans-1,4-polyisoprene before and after doping with iodine. The measurements have been made over the temperature range of -50 °C to 110°C. The heat capacity of poly(β-pinene) has been observed to increase upon iodine doping. The T_g of undoped poly(β-pinene) and the T_m of undoped trans-1,4-polyisoprene have been measured and were found to be 77 °C and 60 °C respectively. After doping the T_g and T_m transitions were not clearly observable. X-ray diffraction studies have shown the γ-phase crystal structure for trans-1,4-polyisoprene film in the undoped state. These results will be discussed considering the molecular and nano-structures of these materials before and after doping.

C1.00045 Complex fluids with robustly tunable optical properties: experiments and theory[1]

, T. CONG, S.N. WANI, A.S. SANGANI[2], R. SURESHKUMAR[3], Syracuse University, Syracuse, NY, 13244, U.S.A., SYRACUSE UNIVERSITY TEAM — Fluids with tunable optical properties are of fundamental and practical interest. They can be easily processed to manufacture thin films and interfaces for applications such as molecular detection and light trapping in photovoltaics. We use solution phase self-assembly to uniformly distribute various metallic nanoparticles to produce stable suspensions with localized, multiple wavelength or broad-band optical properties. Their spectral response can be robustly modified by varying the species, concentration, size and/or shape of the nanoparticles. Spectral behavior for finite particle concentrations can be predicted by an effective medium theory developed in this work. Structure, rheology and optical properties of these plasmonic suspensions as well as their potential application to high efficiency photovoltaics design will be discussed.

C1.00046 Exploiting redox chemistries to manipulate structure and electrical conductivity in polymer acid-doped polyaniline , JACOB TARVER, JOLINE FAN, YUEH-LIN LOO, Department of Chemical and Biological Engineering, Princeton University — Template synthesis of polyaniline on poly(2-acrylamido-2-methyl-1-propanesulfonic acid) yields electrostatically stabilized particles that can be aqueously dispersed and cast into thin films; electrical conductivity in these films scales with inter-particle connectivity. Previous research has shown that solvent annealing with dichloroacetic acid (DCA) induces structural rearrangement of polymer chains and consequently enhances the electrical conductivity by up to two orders of magnitude (from 0.4 to 40 S/cm). Alternatively, the electrostatic interactions between polyaniline and its template can be neutralized through chemical reduction with hydrazine monohydrate, after which the polymer undergoes extensive structural rearrangement; subsequent exposure to nitric oxide leads to reassociation of polyaniline and its polymer acid dopant. Enhanced conductivity is observed following this chemical redox process, and is attributed to extensive polymer chain relaxation and concurrent elimination of the particulate nature of template-synthesized polyaniline.

C1.00047 Electromagnetic transport in magnetorheological elastomer composites[1] , DARIN ZIMMERMAN, KOFI ADU, RICHARD BELL, TIMOTHY HOOPER, GARY WEISEL, The Pennsylvania State University, Altoona College — We present systematic measurements of the electron transport properties and optical response of gold-coated-iron (Au/Fe)-elastomer composite materials. By mixing micron-sized Au/Fe particles with silicone-based liquid elastomer, we produce two types of magnetorheological elastomer composites (MREs): those in which the particles are aligned by an external magnetic field prior to elastomer hardening and those in which the particles are left in random arrangement. By applying modest external stress or an external magnetic field to the two types of post-hardened MREs, we control the transport properties and optical response and observe significant differences in their behavior.

C1.00048 Solution Structures of Poly(3-alkylthiophene)[1] , KAIKUN YANG, LIWEI HUANG, NARAYAN CH DAS, HOWARD WANG, State University of New York, Binghamton — Small angle neutron scattering has been used to understand the solution structure of regioregular and regiorandom alkyl-derived polythiophenes, with alkyl side groups varying from 4 to 10 carbons. While poly(3-octylethiophene) (P3OT) remain coil conformations in solution, poly(3-butylthiophene) (P3BT) and poly(3-dodecylthiophene) form gel networks. However, poly(3-hexylthiophene) (P3HT) forms rod-like aggregates over large length scales. At elevated temperatures, all structures dissolve to coil solutions. A temperature dependent study shows that the aggregates (coils, rods and gels) are thermally reversible. The solution structure is reflected in the morphology of as-prepared films cast from the same P3HT solution stored for various time. In general, roughness and large rod-like features in as-cast films increase with storage time. Those long 1D aggregates may form in solution and is responsible for the eventual gelation of P3HT solution, render it useless for casting films for applications.

C1.00049 Generation of conductivity through transfer charge properties, for polyesters and polyamides with characteristic functional groups , CARMEN GONZALEZ, LUIS HERNAN TAGLE, CLAUDIO A. TERRAZA, Pontificia Universidad Catolica de Chile, ANDRES BARRIGA, Universidad de Chile, A.L. CABRERA, ULRICH G. VOLKMANN, Pontificia Universidad Catolica de Chile — Electro-optic properties of σ-conjugated polymers, as polysilylene; are associated with electron conjugation in the silicon atom, which allows a significant delocalization of electrons along of the chain. Thus, the conductivity is intimately connected to the mobility of charge carriers, which in turn depends on the structure and morphology of the system. We report the characterization of polyesters (PEFs) and polyamides (PAFs). Film thicknesses were obtained by ellipsometry. The vibration frequencies of the groups were determined by FT-IR and corroborated by Raman spectroscopy. Structural information was obtained from X-Ray diffraction (XRD). The structural and surface morphology were studied by scanning electron microscope (SEM). Electrical conductivity of the polymers was measured before and after exposure to iodine vapor, for films of different thicknesses. Morphological differentiation was studied by energy dispersive microscopy (EDX), showing a regular distribution of iodine within the polymer. Preliminary conductivity measurements showed adverse effects when oxidation of the polymer films is induced These effects are related to a certain grade of disorder within the system

C1.00050 Structural symmetry breaking of silicon containing polymers and their relation with electrical conductivity and Raman active vibrations , ALEJANDRO CABRERA, CARMEN GONZÁLEZ , LUIS TAGLE, CLAUDIO TERRAZA, ULRICH VOLKMANN, Pontificia Universidad Catolica de Chile, ANDRÉS BARRIGA, Universidad de Chile, ESTEBAN RAMOS, MAXIMILIANO PAVEZ, Pontificia Universidad Catolica de Chile — The incorporation of silicon into the polymeric main chain or side groups can provide an enhancement in chemical, physical and mechanical properties. We report an efficient method for the synthesis of polymers containing silicon in the main chain, from the polycondensation reactions of four optically active carboxylic diacid. The solubility of the polymers, the molecular weight, the glass transition and the thermal stability were studied by standard techniques. Raman spectroscopy was used to probe the conformation of stretching modes as function of the temperature. The conductivity measurements indicated that the alignment of the molecules is a crucial parameter for electrical performance. When the polymers were exposed to iodine, charge transfer increased their mobility and decreased their optical band gaps. These novel properties highlight the possibility to generate alternative active opto-electronics polymers.

C1.00051 Structural Disorder and Thermal Properties of the Alpha' Phase of Poly(l-Lacitc Acid) , JEFFREY KALISH, SHAW LING HSU, University of Massachusetts - Amherst — Poly(lactic acid) samples rich in alpha' or alpha crystals have been characterized using spectroscopic and thermal methods. Cryogenic infrared and Raman spectroscopy were used to probe the differences in chain conformation and packing. Compared to the alpha crystal, the alpha' crystal has weakened specific carbonyl and methyl interactions. Experimental spectroscopic analysis in conjunction with simulation studies have shown that the alpha' crystal has uniform chain conformational disorder. This disorder in chain conformation and packing leads to different crystalline forms with varying stabilities. The difference in thermal stability was quantified by measuring enthalpic change at melting for both crystalline forms by extrapolation of the glass transition as well as by using small molecule extrapolation. Equilibrium melting enthalpy was determined to be 57 J/g for alpha' and 96 J/g for the alpha crystal. The transformation from the less stable alpha' to the more stable alpha phase has been characterized. This analysis provides an explanation for the double melting peaks usually found in the PLLA samples.

C1.00052 Influence of graphene on the crystallization behavior of polyethylene , SHAN CHENG, CHRISTOPHER LI, Drexel University — Recent work on polyethylene(PE)/carbon nanotube nanocomposites demonstrates that CNTs can significantly alter PE crystallization. Graphene, a 2D counterpart of CNT, is an excellent candidate for fabricating polymer nanocomposites. We herein report the influence of graphene on crystallization behavior of PE. High density polyethylene (HDPE) was first crystallized in dilute solution in the presence of dispersed single or few-layer graphene sheets. Epitaxial growth of polyethylene on the basal plane of graphene sheets was observed using transmission electron microscopy. PE/graphene nanocomposites with various graphene loading were then fabricated. Both non-isothermal and isothermal crystallization behavior of these nanocomposites were studied using a differential scanning calorimeter. Multiple melting peaks of the nanocomposite were correlated to homo- and heterogeneous nucleation of PE crystallites. Crystallization kinetics was studied using Avrami equation. The results were compared with cabon nanotube/PE system and the difference will be discussed.

C1.00053 Crystallization effects of carbon nanotubes on semicrystalline isotactic polypropylene[1] , GEORGI GEORGIEV, Assumption College, SCOTT SCHOEN, DEVIN IVY, PEGGY CEBE, Tufts University, ASSUMPTION / TUFTS TEAM — When carbon nanotubes are introduced in isotactic polypropylene (iPP) materials the iPP crystals assemble in a fibrillar instead of spherulitic arrangement. We study the effects of concentration and isothermal vs nonisothermal treatments on the rate of crystal formation. Those nanocomposites provide means of controlling the crystal orientation in polymer materials by aligning the nanotubes and creating materials with novel properties. We used Differential Scanning Calorimetry (DSC) as our primary method of investigation due to its ability to give detailed data on the phase transitions of iPP nanocomposites with low concentrations of CNTs (0-5 percent). We analyzed the crystallization of each sample in the DSC at a range of cooling rates (10-20C/minute). We found that increased concentrations of CNTs speed up the nanocomposites' crystallization and decrease the crystal size distribution.

C1.00054 Structure and dynamics of solvent-free polymer grafted nanoparticles: A computational study , ALEXANDROS CHREMOS, ATHANASSIOS PANAGIOTOPOULOS, Chemical and Biological Engineering, Princeton University — The structure and dynamics of solvent-free polymer-grafted nanoparticles have been investigated using molecular dynamics simulations. A basic coarse-grained model was used, where the nanoparticle is represented as a single smooth particle with bead- spring polymer chains attached to it. Motivated by the recent advances in nanoparticle ionic materials and nanoparticle organic hybrid materials, we use our model to explore the behavior of these systems over a wide range of parameters and gain insights of their structure and transport properties. In particular, we find that the chain length variation can change the softness of the nanoparticles, so for short chains the system exhibits rich structural characteristics while for long chains display (dilute) liquid-like characteristics. Additionally, we find that by increasing the softness of the particles the structural relaxation of the system becomes less sensitive to temperature variation, indicating a change from the hard-spheres to soft particles. The results confirm the experimental observations that changing the chain length the system can display behavior that spans from glasses to liquids.

C1.00055 A new method to measure the optical trapping energy of nanoparticles , JOSEPH JUNIO, Lehigh University, JACK NG, Hong Kong Univeristy Science and Technology, JOEL COHEN, University of the Pacific, ZHIFANG LIN, Fudan University, H. DANIEL OU-YANG, Lehigh University — A novel method is described for measuring the potential energy of nanoparticles in an optical trap by trapping an ensemble of particles with a focused laser beam. The mechanical force balance between repulsive osmotic and confining gradient-force pressures determines the single-particle trapping potential independent of interactions between the particles. The ensemble nature of the measurement permits evaluation of single-particle trapping energies much smaller than k_BT. Energies obtained by this method are compared with those of single-particle methods as well as with theoretical calculations based on classical electromagnetic optics.

C1.00056 Spontaneous asymmetry in coated spherical nanoparticles in solution and at liquid-vapor interfaces , J. MATTHEW D. LANE, GARY S. GREST, Sandia National Laboratories — Nanoparticles in solution are often stabilized with functional coatings to prevent aggregation. We'll present recent simulations results showing that small spherical nanoparticles produce highly asymmetric coating arrangements, when coated with simple polymer chains. These coatings are not symmetric even when extremely uniform grafting arrangements and full coverages are employed. I will also discuss the geometric properties which dictate the coating shape. When particles are placed in an anisotropic environment, such as the liquid/vapor interface, the asymmetric coatings are amplified and oriented by the surface. Particle shape and its responsive behavior is seen to strongly influence interactions. Implications and examples of controlled self-assembly will be presented.

C1.00057 ABSTRACT WITHDRAWN —

C1.00058 Controlled Evaporative Self-Assembly of Hierarchical Polymer Stripes with Ordered Nanochannels , WEI HAN, MYUNGHWAN BYUN, LEI ZHAO, Iowa State University, JAVID RZAYEV, The State University of New York, ZHIQUN LIN, Iowa State University — A toluene solution of a bottlebrush block copolymer, polystyrene-polylactide (PS-PLA), was confined in a "cylinder-on-flat" geometry, from which the consecutive "stick-slip" motion of the contact line of the PS-PLA solution was effectively regulated as the solvent evaporated, thereby forming gradient stripes at the microscopic scale. Upon subsequent solvent vapor annealing, hierarchically organized structures of PS-PLA were produced in which the lamellar nanodomains normal to the substrate were obtained within the stripes. After mild removal the PLA component, channels at the nanoscale wrere formed with the stripes. This facile approach of combining controlled evaporative self-assembly with subsequent vapor annealing opens up a new avenue to rationally organize and engineer self-assembling building blocks into functional materials and devices in a simple, cost-effective and controllable manner.

C1.00059 Supercritical carbon dioxide induced surface melting/recrystallization process in ultrathin PEO films[1] , NAISHENG JIANG, Stony Brook University, MITSUNORI ASADA, Kuraray Co., Ltd., PETER GIN, SO KING LAM, MAYA ENDOH, Stony Brook University, SUSHIL SATIJA, NIST, TAD KOGA, Stony Brook University — Crystallization of polymeric materials in nanoconfined geometries has attracted considerable attention in the past decade. In this talk, we will show the novel effects of supercritical carbon dioxide as a plasticizer in order to control the melting/crystallization behavior of semicrystalline polymer thin films. Poly(ethylene oxide) (PEO) thin films with thickness of 10nm-100nm were used for this study. In-situ neutron reflectivity technique was utilized to study the swelling behavior of deuterated PEO films in $scCO_2$ at T=50 $^\circ$C, showing the clear evidence of the surface melting phenomenon even below the bulk melting temperature (65 $^\circ$C). The surface structures before and after exposure at the different CO_2 process conditions were then investigated in air by using atomic force microscopy and grazing incidence x-ray diffraction. The results clearly showed that $scCO_2$-induced re-crystallization from the amorphous state via pressure quench results in various surface crystalline structures, depending on temperature, pressure, quench rates, and the film thickness.

C1.00060 ABSTRACT WITHDRAWN —

C1.00061 Highly Swollen Porous Microstructures in Polyelectrolyte Multilayers , CHUNGYEON CHO, JEREMY KAISER, NICOLE ZACHARIA — We investigated the creation of porous morphologies from polyelectrolyte multilayers (PEMs) consisting of linear poly(ethylenimine) and poly(acrylic acid), and poly (allylamine hydrochloride) and poly (acrylic acid) as a function of pH and immersion time under post-base assembly treatment. The porous transition is linked to the neutralization of the polycations electrolytes as well as ionization of PAA by the exposing LbL films to high pH. This causes PEMs to undergo spinodal decomposition, creating pores and an increase in film thickness. By using reactive wet stamping technique, we were able to locally cause porosity changes under high pH conditions in the LbL films. Further investigation of the mechanical properties of patterned LbL films was done by performing nano-indentation analysis. The results showed clear difference of physical properties such as hardness and modulus between stamped and unstamped regions based on porous transition.

C1.00062 Morphological Change of Poly(4-*tert*-butylstyrene-*block*-4-*tert*-butoxystyrene) in a Wide Range of Segregation Strength Though Hydrolysis Reaction

, SITI SARAH ABDUL RAHMAN, DAISUKE KAWAGUCHI, YUSHU MATSUSHITA, Department of Applied Chemistry, Nagoya University, Japan — Morphological change of symmetric poly(4-*tert*-butylstyrene-*block*-4-*tert*-butoxystyrene)s (BO) upon hydrolysis reaction was investigated by transmission electron microscopy and small-angle X-ray scattering. Segregation strength, χN (χ: interaction parameter, N: degree of polymerization), which governs the chain dimension, was gradually tuned since poly(4-*tert*-butoxystyrene) (O), a non-polar polymer, can be converted into poly(4-hydroxystyrene) (H), a polar one, through hydrolysis. Samples with different molecular weights and conversion rates of O into H, f_Hs, were prepared. Domain spacing of the lamellar structure, D, increased as f_H increases where it abruptly increased at a critical f_H, indicating that the chain stretched perpendicularly to the lamellar interface. The degree of chain stretching compared to a random coil, D/D_0s (D_0: correlation length at f_H=0), were scaled by χN. Three regimes can be distinguished in the plot of (D/D_0) vs. χN: (I) the weak segregation regime with $D/D_0 \sim$1 that associates with the scaling behavior of $D \sim N^{0.55}$, (II) the intermediate segregation regime with the scaling behavior of $(D/D_0) \sim (\chi N)^{0.34}$, and (III) the strong segregation regime with $D/D_0 \sim$2.3 which corresponds to $D \sim N^{0.67}$.

C1.00063 Frustrated ABC Linear Block-Random Copolymer with a Semicrystalline End Block[1]

, BRYAN S. BECKINGHAM, RICHARD A. REGISTER, Princeton University — The solid-state structure of semicrystalline block copolymers is set either by block incompatibility or by crystallization of one or more blocks. A variety of solid-state morphologies may be observed depending on the block interaction strength, ranging from spherulitic to confined crystallization within preexisting microphase-separated domains. Linear triblock copolymers, polybutadiene-*b*-polyisoprene-*b*-poly(isoprene-*r*-styrene) (A-B-C), are synthesized via lithium-initiated anionic polymerization in cyclohexane. After polymerization of the butadiene block, triethylamine is added to facilitate the random styrene/isoprene copolymerization while also increasing the vinyl content of the polyisoprene block. Selective hydrogenation of the diene units with a Ni-Al catalyst yields a semicrystalline polyethylene endblock, with a frustrated block sequence: $\chi_{BC} > \chi_{AB} >> \chi_{AC}$. For a polymer with block molecular weights of 30-14-14 kg/mol, small-angle x-ray scattering reveals the formation of a well-ordered lamellar melt from which crystallization of the hydrogenated polybutadiene (polyethylene) block proceeds.

C1.00064 Self-Consistent Field Modeling of Diblock Copolymers in Selective Solvents[1]

, RAGHURAM THIAGARAJAN, DAVID MORSE, Department of Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, MN 55455 — The purpose of my poster is to study the driving forces behind the self-assembly of a diblock copolymer AB, consisting of a solventphilic block (B) and a solventphobic block (A), in selective solvents (S). Micellar transformations between spherical, cylindrical, and bilayer curvatures for a model system are tracked using self-consistent field modeling, in real space, in the dilute regime. The transition from a concentrated regime, $\phi_{\rm AB} \sim 1$, to a dilute regime, $\phi_{\rm AB} \sim 0$, is studied. Phase portrait for the concentrated regime is generated using periodic self-consistent field modeling. The unbinding transition, as seen in the periodic counterpart of self-consistent field theory, is compared with the transformations observed in the dilute regime. The two phase regions in the dilute regime are mapped out for the inverted phases as well.

C1.00065 Synthesis and Characterization of Tapered Block Copolymers

, WEI-FAN KUAN, RAGHUNATH ROY, JONGKEUN PARK, THOMAS EPPS, University of Delaware, Newark, DE 19716 — Tapered block copolymers offer the opportunity to manipulate copolymer segregation strength independent of molecular weight and chemical constituents, which allows the design of materials with improved mechanical properties while retaining the desired phase separated structures. In this work, we focus on the synthesis and characterization of poly(isoprene-*b*-isoprene/styrene-*b*-styrene-*b*-styrene/methyl methacrylate-*b*-methyl methacrylate) [P(I-IS-S-SM-M)] tapered triblock copolymers. P(I-IS-S) tapered diblock copolymers are synthesized using living anionic polymerization and treated as macroinitiators for activator regenerated by electron transfer (ARGET) atom transfer radical polymerization (ATRP). ARGET ATRP is employed to make the SM tapered interface and M block, enabling synthesis of tapered triblocks with low polydispersity ($M_w/M_n <$ 1.2). These materials self-assemble into well-defined nanoscale architectures depending on segment volume fractions and taper dimensions.

C1.00066 Gelation of Copolymers Photo-crosslinked by Pendant Benzophenones

, SCOTT CHRISTENSEN, RYAN C. HAYWARD, University of Massachusetts - Amherst — Copolymers containing pendant benzophenone (BP) groups provide a simple and powerful route to crosslinkable polymer films. While the solution state photo-chemistry of BP is well established, and crosslinking of polymers blended with BP has been studied in detail, the process of crosslinking by covalently attached BP has received comparatively little attention. We have prepared copolymers of BP with several different monomers, and studied gelation as a function of BP content and degree of photochemical conversion. We seek to understand the influence of polymer chemistry on crosslinking efficiency, to guide choices of materials for photo- crosslinkable polymer films and to provide a route for tailoring morphology in polymer blends.

C1.00067 Understanding the phase behavior and equilibration kinetics of PDMS-containing block copolymers

, CHARLOTTE STEWART-SLOAN, EDWIN THOMAS, Massachusetts Institute of Technology — Block copolymers containing both PDMS and an olefin are of interest because they combine high chi parameters which allow for strong segregation on small length scales with a differential etch resistance to oxygen plasma. In order to understand the phase behavior and how it is affected by thermal treatments, low molecular weight diblocks of PS-PDMS and PI-PDMS were examined at different temperatures using synchrotron radiation. The movement and changes in intensity of the peaks present in the SAXS patterns at different temperatures after long equilibration times provides information about the equilibrium structures present in these materials and the evolution of these patterns over time allows insight into structural kinetics. The ODT was determined for three different compositions and the structure equilibration on heating and cooling were investigated. Of particular interest is the evolution of structure at room temperature after high temperature treatment.

C1.00068 Cloud Point Depression in Dilute Solutions of HEMA/DMAEMA Copolymers with Prescribed Composition Profiles and Gradient Strengths

, KEITH GALLOW, Princeton University, YOUNG JHON, JAN GENZER, North Carolina State University, YUEH-LIN LOO, Princeton University — We have synthesized a random copolymer and gradient copolymers of hydroxyethyl methacrylate and dimethylaminoethyl methacrylate whose instantaneous compositions vary linearly and according to hyperbolic tangent (Tanh) functions along the backbones, all having similar molecular weights and overall compositions. The cloud point of the dilute solution of the random copolymer is 20.0°C; the transparent-to-turbid transition occurs over 1.0°C. Dilute solutions of linear gradient copolymers exhibit cloud point depressions of up to 3.5°C and transition breadths of 1-3°C compared to that of the random copolymer. The cloud points of dilute solutions of gradient copolymers with Tanh composition profiles are further suppressed by as much as 9.0°C compared to that of the random copolymer. Our observations demonstrate the importance of monomer sequence distribution in altering the macroscopic solution properties of copolymers.

C1.00069 High area density etching mask for data storage industry based on the block copolymer self-assembly[1]

, XIAODAN GU, THOMAS RUSSELL, University of Massachusetts Amherst, BIN ZHANG, DORSEY PAUL, Western Digital Inc., UNIVERSITY OF MASSACHUSETTS TEAM, WESTERN DIGITAL INC. TEAM — The application of block copolymer as etching mask for data storage industry was investigated. Higher area density silicon oxide pillars from block copolymer template were generated on the media substrate over several inch square areas. Thin film of PS-b-PVP was spin coated and solvent annealed to generate cylindrical micro-domain normal to surface. The film was then reconstructed in the ethanol alcohol to generate the porous cylindrical micro-domain. Polydimethylsiloxane (*PDMS*) was then spin coated onto the porous film surface. The film was heated to facilitate the movement of PDMS into the pores, and then etched with fluorine and oxygen plasmas to remove the polymeric material, leaving only silicon oxide pillars. The effect of pore diameter on the size and quality of silicon oxide pillar was investigated. Larger pores generated higher quality pillars. Areal densities from 0.5 to 2 Teradots per inch square were achieved. The silicon oxide produced had a good ion-etch resistance, enabling pattern transfer the pillar pattern to underlying magnetic media.

C1.00070 Orientation Control of Block Copolymer Films on Rough Substrates Prepared by E-beam Lithography

, YOUNGWOO CHOO, HYO SEON SUH, HYUN-MI KIM, MYUNG RAE CHO, YUN DANIEL PARK, KI-BUM KIM, Seoul National University, KOOKHEON CHAR — Several researches on the perpendicularly oriented BCP thin films induced from the underlying substrates with surface roughness have been reported. In the present study, we investigated the effect of each roughness factor, such as period or depth of the roughness, on the orientation of BCP thin films. In order to control such roughness factors systematically, we introduced various lithographic techniques. The hydrogen silsesquioxane (HSQ) patterns with controlled period and depth were prepared by the Atomic Image Projection E-beam Lithography (AIPEL), which were realized by adjusting lithographic parameters of AIPEL. In addition, we also prepared silicon oxide patterns using ordinary e-beam lithography. The line width and period of patterns were finely tuned during the E-beam writing while the depth of the patterns was modified by the reactive ion etching on the patterned substrates. On the substrates with specified roughness, we deposited symmetric PS-*b*-PMMA diblock copolymers and observed the effect of individual roughness factors on the orientation of BCP thin films.

C1.00071 Architectural Effects in Thin Films of Poly(styrene-b-methyl methacrylate) Copolymers[1]

, NIKHILA MAHADEVAPURAM, THAI VU, GILA STEIN, Univ. of Houston — Block copolymer self-assembly offers a simple route to generate nanostructures over large areas. Control over domain orientation is critical for nanopatterning; typically, the lower-surface energy constituent will segregate at the air interface and drive a parallel orientation of cylindrical or lamellar domains. Recent works by Khanna et al.[2] and Matsen[3] suggest that molecular architecture can affect surface energetics and domain orientations. We compared the thin film ordering of lamellar poly(styrene-b-methyl methacrylate) (PS-PMMA) diblock copolymers with PMMA-PS-PMMA triblock copolymers. Films that ranged in thickness from $t = L_0 - 5L_0$ were cast on neutral substrates, annealed under vacuum at 220°C for 2 days, and then measured with grazing-incidence small-angle X-ray scattering. The triblock copolymers adopt a perpendicular domain orientation near the film surface for all thicknesses considered, while the perpendicular domain orientation was only stable for diblock copolymers when $t \leq L_0$. However, triblock thin films contain defects in the film interior that limit their utility.

C1.00072 From blood dialysis to desalination: A one-size fits all block copolymer based membrane system

, NATARAJ SANNA KOTRAPPANAVAR, Univeristy of Cambridge, PAUL ZAVALA-RIVERA, KEVIN CHONNON, University of Cambridge, SHAHEEN S.A. ALMUHTASEB, Qatar University, EASAN SIVANIAH, University of Cambridge, UNIVERSITY OF CAMBRIDGE TEAM, QATAR UNIVERSITY COLLABORATION — Asymmetric membrane with ultrahigh selective self-assembled nanoporous block copolymer layer were developed successfully on polyimide (PI) support, which demonstrated excellent thermal, chemical and mechanical stability. Membranes with specific nano- structural architectures and optimized cascades of block assemblies on the top selective skin have been used largely for separation of colour from aqueous streams, wastewater treatment, desalination, blood filtration and gas separation with dense layer transformation. A consistent and reliable method of membrane preparation and measuring separation performance has been adopted. A homologous series of ethylene oxide oligomers covering a large range was used to characterise MWCO of Membrane and were able to provide many points to give a comprehensive description of the membrane performance in the nanofiltration range.

C1.00073 Circular Patterns over Large Areas from The Self-Assembly of Block Copolymers Guided by Shallow Trenches

, SUNG WOO HONG, XIAODAN GU, University of Massachusetts Amherst, JUNE HUH, Yonsei University, SHUAIGANG XIAO, Seagate Technology, THOMAS RUSSELL, University of Massachusetts Amherst — We report the fabrication of ultra-dense circular nanoarrays of block copolymer (BCP) microdomains over macroscopic areas. These arrays were generated by the directed self-assembly of BCPs on the topographically patterned substrates, where the trenches with circular shape are patterned on a flat substrate. The width of circular trench and the distance between circular trenches are varied for commensurability issues, and difference BPCs are used to demonstrate the generality of this strategy. When a commensurability condition is satisfied, BCPs on the topographically patterned substrates undergo a grapho-epitaxial self-assembly with solvent annealing, resulting in an areal density amplipication of the circular patterns over large areas. The methodology described here may provide an easy approach to high densities of circularly shaped nanopatterns for data storage applications.

C1.00074 Poly (2-vinyl naphthalene-b-acrylic acid) (P2VN-b-PAA) block copolymer pattern formation, alignment and pattern transfer by reactive ion etching (RIE)

, XIN ZHANG, CHRISTOPHER METTING, R.M. BRIBER, SANG HAK SHIN, BEN JONES, Department of Materials Science and Engineering, University of Maryland, College Park, MD 20742 — P2VN-b-PAA (Mn=30.8-b-24 kDa) lamellar block copolymer was examined for use as a pattern transfer template due to the potential large dry etching contrast between the blocks. As-spun films have a micelle or vertically oriented cylindrical morphology depending on the spinning solvent. Vapor annealing with acetone, a poor solvent for P2VN-b-PAA, resulted rapid reordering to a vertically oriented lamellar morphology within 5 minutes for films <50 nm thick. Films between 30 to 50 nm thick were spin coated onto oxide wafers with interdigitated electrodes to examine if an electric field would align the morphology. The lamellae aligned normal to the electrodes within 1 hour by electric field assisted acetone vapor annealing at field strengths as low as 1V/micron. CF_4 plasma dry etching contrast as high as 1:3.8 (P2VN:PAA) for homopolymer blanket films was measured. The block copolymer pattern was transferred to the silicon substrate in two steps using CF_4 followed by SF_6 RIE.

C1.00075 Methods for Self-Assembly of Rod-Coil Diblock Copolymer Thin Films , SAMANTHA COLLINS, AMANDA KAMPS, MICHAEL FRYD, RUSSELL COMPOSTO[1], SO-JUNG PARK[2], University of Pennsylvania — Long range order in diblock copolymer (BCP) thin films can be induced by solvent annealing. First, thin films of semiconducting BCPs were spin-coated onto base-treated and hydroxyl-terminated silicon substrates. These BCP films were then solvent vapor annealed in inert, solvent-saturated atmosphere. Structure was investigated as a function of substrate end group, film thickness, and solvent annealing duration, and an optimized ordering condition was found. Film thickness was varied to direct the morphology perpendicular to the substrate for potential photovoltaic device applications. Second, BCP thin films were processed by novel thermal gradient annealing as an alternative route to directing long range order in the films. The effect of thermal gradient steepness and temperature range on ordering was analyzed for the optimized thickness determined by solvent annealing.

C1.00076 Nanopatterns in a confined triblock copolymer , JUMI LEE, YEONGMIN JEON, Dankook University, JAEUP KIM, Ulsan Institute of Science and Technology, JUNHAN CHO, Dankook University — Ordered structures in thin films of ABC triblock copolymers are studied experimentally and theoretically in order to be applied to fabrication of nanoscale electronic devices. A field-theoretic simulation method based on the self-consistent field theory is used to generate useful nanopatterns starting with a random configuration of compositions. The main parameters for the phase stability, such as Flory interaction parameters, total chain size, compositions, film thickness, and surface interactions, are considered as controllable variables in the present analysis. By using some typical triblock copolymers, nanopatterns observed in experiments are comparable with those in the simulation.

C1.00077 Hierarchical assembly of coil-rod-coil peptide-based copolymers , NANDULA WANASEKARA, CASEY JOHNSON, LASHANDA KORLEY, Department of Macromolecular Science and Engineering, Case Western Reserve University, Cleveland, OH — Coil-rod-coil block copolymers have been shown to exhibit an array of morphologies, from crystalline lamellae, to novel, three-dimensional tetragonal lattices, depending upon coil length and molecular weight. We have been motivated by recent advances in controlled polymerization techniques and the opportunity to develop bio-inspired copolymer motifs to explore the hierarchical self-assembly of coil-rod-coil peptide-based copolymers with variations in peptidic rod length. Thin films were characterized using atomic force microscopy, x-ray scattering and thermal analysis techniques showing random sphere-like nanostructures with alpha-helix peptide secondary structure. Our goal is to utilize these materials to engineer the interface of hierarchically-designed, nature-inspired elastomers.

C1.00078 Enhanced stability of self-assembled polymer nanostructures by molecular crosslinking , MARK STOYKOVICH, IAN CAMPBELL, BRIAN PEREA, University of Colorado-Boulder — Self-assembled nanostructures of block copolymers have attracted interest for applications in next generation lithography and advanced materials synthesis. Many of these applications require mechanically and chemically robust nanostructures that cannot be achieved by simple diblock copolymer materials alone. Here we have investigated a method to stabilize block copolymer nanostructures after self-assembly in thin films by incorporating cross-linking molecular components within the self-assembled domains. Polymer blends consisting of a majority symmetric PS-block-PMMA copolymer and equal amounts of PS and PMMA homopolymers were prepared and determined to form lamellar phase morphologies. The PS and PMMA homopolymers were synthesized with a small fraction of glycidyl methacrylate monomer which served as the cross-linking agent in the blends. These nanostructures exhibit enhanced solvent and thermal stability, and have been demonstrated for the fabrication of three-dimensional multilayer structures.

C1.00079 Local segmental dynamics of cis-1,4-polybutadiene, polypropylene, and polyethylene terephthalate via molecular dynamics simulations , DAVID WHITLEY, DAVID ADOLF, University of Leeds, UK — NPT molecular dynamics simulations of cis-1,4-polybutadiene, polypropylene, and polyethylene terephthalate have been performed. The simulation pressure was 1 atmosphere for all systems, with all simulation temperatures being well above each polymer's glass transition temperature. The trajectories have been analysed via autocorrelation functions (ACFs) of chord vectors spanning different numbers of chain backbone bonds. Inverse Laplace transformations of these ACFs using the CONTIN algorithm afforded the corresponding distributions of relaxation times (DRTs) for the simulated dynamics. All DRTs illustrated a peak on fast time scales corresponding to short length scale segmental motion and a peak at longer time scales corresponding to longer length scale relaxations. An intermediate peak between the fast and slow peaks appears as the relaxation dynamics of longer chord vectors are analysed. The temperature dependence of the relaxation dynamics has also been investigated.

C1.00080 Coarse-grained modeling of polystyrene at different concentrations using the Iterative Boltzmann Inversion technique , BESTE BAYRAMOGLU, ROLAND FALLER, UC Davis — We present systematic coarse-graining of several polystyrene models and test their performance under confinement and eventually in brush systems. The structural properties of a dilute polystyrene solution, a polystyrene melt and a confined concentrated polystyrene solution at 450K, 1 bar were investigated in detail by atomistic molecular dynamics simulations of these systems. Coarse-graining of the models was performed by Iterative Boltzmann Inversion Technique (IBI), in which the interaction potentials are optimized against the structure of the corresponding atomistically simulated systems. Radial distribution functions, bond, angle and dihedral angle probability distributions were calculated and compared to characterize the structure of the systems. Good agreement between the simulation results of the coarse-grained and atomistic models was observed.

C1.00081 Identifying Entanglement States of Ring Polymers Using Knot Polynomials , JIAN QIN, SCOTT MILNER, ChE at Penn State University — Melts of ring polymers have fixed topologies in the absence of ring opening or reconnecting operations. We identify the topological states by recognizing how rings are knotted with each other, which can be achieved by computing knot invariant polynomials. We used this idea to count the entanglement states of ring polymers, prepared with off-lattice Monte Carlo simulations, in which the system topology is allowed to change by various ring rebridging moves. We project polymer configurations to obtain crossing diagrams, and use algorithms based on knot theory to compute the Jones invariant polynomial. We studied both aperiodic and periodic systems, to estimate the surface effects on entanglements. For the periodic case, we extended the algorithm for aperiodic knots to deal with periodic patterns. These tools enable us to accumulate the probability distribution of topological states for rings of different lengths, from which we determined the entanglement length by identifying the topological entropy as k_B per entanglement strand.

C1.00082 Conformation of a Lennard-Jones Chain in Explicit Solvent: A Solvation Potential Approach[1] , SHISHIR ADHIKARI, MARK TAYLOR, Dept. of Physics, Hiram College, Hiram, OH — The conformation of a polymer chain in solution is intrinsically coupled to the chain's local solvent environment. In much of the theoretical work on polymers in solution the effects of solvent are treated implicitly and explicit chain-solvent coupling is ignored. Although a formally exact treatment of chain-solvent coupling can be constructed, the required many-body solvation potential is not practical to compute. Following on our work with hard-sphere and square-well chain-in-solvent systems [1] here we show that for Lennard-Jones (LJ) systems this many-body solvation potential can be made tractable via an "exact" decomposition into a set of two-site potentials. We use these exact short chain results, combined with the pure solvent potential of mean force, to construct approximate two-site solvation potentials for long LJ-chains. Monte Carlo simulations for full chain-in-solvent systems verify the accuracy of our solvation potential mapping across the full LJ-solvent phase diagram.

C1.00083 Differential AC/scanning chip nanocalorimeter for in-situ measurements of vapor deposited glasses , MATHIAS AHRENBERG, University of Rostock, KATIE WHITAKER, University of Wisconsin-Madison, HEIKO HUTH, University of Rostock, MARK D. EDIGER, University of Wisconsin-Madison, CHRISTOPH SCHICK, University of Rostock, UNIVERSITY OF ROSTOCK TEAM, UNIVERSITY OF WISCONSIN-MADISON TEAM — We use nanocalorimetry to investigate the formation of extraordinarily stable glasses prepared by vapor deposition. For that purpose we've built a vapor deposition chamber that allows in-situ characterization of vapor-deposited organic molecules down to liquid nitrogen temperature. The use of commercially available nanocalorimeter sensors permits us to measure the temperature at the sample position directly via heater resistivity. The calibration of this method was done with the frequency dependence of the dynamic glass transition temperature of low molecular glass formers such as toluene over a broad frequency range. This was applied to investigate vapor deposition of glass formers as a function of time as well as vapor deposited samples as a function of temperature.

C1.00084 An apparatus for in situ x-ray scattering studies of polymer melts during homogenous uniaxial extensional flow , WESLEY BURGHARDT, RUINAN MAO, Northwestern University — In situ x-ray scattering methods have been broadly applied to study the structural dynamics of polymers and other complex fluids under flow, and can provide deep insights into the microstructural origins of complex non-Newtonian flow characteristics. Most studies in this vein have employed either homogenous shear flow, or processing flows such as fiber spinning which are complicated by inhomogenous deformation histories and/or nonisothermal operation. Here we present the design and implementation of a new apparatus for in situ x-ray scattering studies of polymer melts during homogenous uniaxial extensional flow. The experiment is based on the commercially-available SER extensional flow fixture, which employs two counter- rotating drums to deform a sample strip of polymer melt. This fixture has been incorporated into a custom-fabricated convection oven designed to facilitate x-ray access to the sample, and operation in a typical synchrotron beam line environment. Preliminary data on extensional flow induced orientation of ordered block copolymers will be used to illustrate the capabilities of this device.

C1.00085 Differential dynamic optical microscopy for the characterization of soft matter: liquid crystal dynamics, volume phase transition of hydrogels, and phase transition of binary mixtures , BEOM-JIN YOON, JUNG OK PARK, MOHAN SRINIVASARAO, School of Materials Science and Engineering, Georgia Institute of Technology, Atlanta, GA 30332, MICHAEL H. SMITH, L. ANDREW LYON, School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA, 30332 — The structure and dynamics of soft matter were studied by differential dynamic optical microscopy. One can retrieve q-space information through image processing and Fourier analysis, even when the feature sizes in real space image are too small to be resolved or even visible in an optical microscope. The temporal sequence of real space images were Fourier transformed, and analyzed for the temporal and spatial fluctuations of power spectrum. Here, we present the results on liquid crystal dynamics and their elastic properties, volume phase transition of hydrogels when their dimensions are sub-micron, and critical opalescence of binary mixtures (water/2,6-lutidine).

C1.00086 Fast Off-Lattice Monte Carlo Simulations with Soft Potentials , JING ZONG, DELIAN YANG, Colorado State University, YUHUA YIN, Nankai University, XINGHUA ZHANG, QIANG (DAVID) WANG, Colorado State University — Fast off-lattice Monte Carlo simulations with soft repulsive potentials that allow particle overlapping give orders of magnitude faster/better sampling of the configurational space than conventional molecular simulations with hard-core repulsions (such as the hard-sphere or Lennard-Jones repulsion).[1] Here we present our fast off-lattice Monte Carlo simulations ranging from small-molecule soft spheres and liquid crystals to polymeric systems including homopolymers and rod-coil diblock copolymers. The simulation results are compared with various theories based on the same Hamiltonian as in the simulations (thus without any parameter-fitting) to quantitatively reveal the consequences of approximations in these theories.

[1] *Q. Wang and Y. Yin*, **J. Chem. Phys., 130**, 104903 (2009).

C1.00087 Kinetic Control for the Morphological Transition of Block Copolymer Micelle Complexes , MISOOK LEE, JINKEE HONG, KOOKHEON CHAR, Seoul National University — The morphology of charged block copolymer micelle complexes, consisting of crew-cut poly(styrene-b-acrylic acid) (PS-b-PAA) and poly(styrene-b-4vinyl pyridine) (PS-b-P4VP) micelles, was controlled by pH of aqueous solvent. The charge densities of corona block segments (PAA and P4VP blocks) dispersed in water were sensitive functions of solution pH. The high pH region (pH $>$ 5.5) is particularly interesting in the present case due to the formation of spherical micelle clusters since the degree of ionization of P4VP blocks is negligible while PAA blocks are fully charged in this regime. These spherical clusters were then slowly transformed into different morphologies when the solution pH was adjusted to the range allowing both of the corona blocks to be oppositely charged. The morphological transitions of micelle blends were also monitored by varying experimental parameters such as blending ratio, blending sequence, and the content of co-solvent when coupled with the effect of solution pH. The present study demonstrates that the kinetic pathway for the formation and transformation of micelle complexes at various solution pH is significantly important for the morphological evolution involving charged micelles.

C1.00088 Multigeometry micelles made from self-assembly of block copolymer mixtures via kinetic control , JIAHUA ZHU, University of Delaware, SHIYI ZHANG, YUN LIN, KE ZHANG, Texas A&M University, CAROLINE MIESCH, TODD EMRICK, University of Massachusetts-Amherst, KAREN WOOLEY, Texas A&M University, DARRIN POCHAN, University of Delaware — Multicompartment/multigeometry micellar structures, due to segregation of unlike hydrophobic domains trapped within the same micelle core, have been produced via self-assembly of block copolymer mixtures in tetrahydrofuran/water solution. The mixture is composed of two/or more block copolymers with distinctive hydrophobic blocks but the same poly(acrylic acid) (PAA) hydrophilic block. By taking advantage of the complexation in the hydrophilic corona between the acid side chains of the PAA block and added organoamine molecules, unlike hydrophobic blocks are trapped in the same micelle core and, consequently, locally segregate into compartments. Through designed kinetic pathways, block copolymer design and mixing ratios, both micelle compartment size and shape could be controlled to form multicompartment spheres, sphere-cylinder hybrid micelles and multicompartment cylinders. New mixtures using PAA-containing block copolymers with additional hydrophilic blocks or end-group functionalization produce multigeometry/multicompartment micelles with patterned surfaces in addition to multicompartment cores.

C1.00089 Nanocomposites Consisting of Nanoparticles with Multidentate PS Brushes Mixed with PS Matrices , HYEMIN LEE, SANGHYUK WOOH, JAEHOON LIM, Seoul National University, MATTHIAS ZORN, RUDOLF ZENTEL, Johannes Gutenberg University of Mainz, KOOKHEON CHAR, Seoul National University — In order to prevent massive phase separation of nanoparticles (NP) in a polymer matrix, the relevant hybridization of NPs with polymer matrices has proven to be an effective method for the high performance of nanocomposites in applications. The surface of inorganic (gold or QD) NPs of various size was modified with polystyrene (PS) polymer brushes, poly(styrene)-block-poly(cysteamine methyl disulfide), by the ligand exchange procedure. The disulfide groups in the PS brushes act as anchoring blocks for NPs. Different PS brushes were prepared with different total molecular weights and mole fractions of disulfide moieties. Compared with NPs dispersed in PS without disulfide anchoring groups, NPs anchored with PS brushes through disulfide groups were uniformly distributed within PS matrices. The dispersion of NPs within a polymer matrix was found to be influenced by the total molecular weight of PS brushes as well as the number of anchoring disulfide groups. Furthermore, the effect of the ratio between relative size of NP and the radius of gyration of a polymer brush as well as the grafting density of PS brushes anchored onto NPs on the NP distribution within a polymer matrix is discussed.

C1.00090 Controlling the Self-Assembly of Inorganic Nanoparticles within Conjugated Rod-Coil Block Copolymers , BRYAN MCCULLOCH, RACHEL SEGALMAN, University of California - Berkeley — Blends of conjugated polymers and inorganic nanoparticles have been investigated for numerous applications however optimization relies on precise control over the nanoscale morphology. We have designed a conjugated rod-coil block copolymer consisting of poly(3-(2'-ethyl)hexylthiophene)-b-poly(2-vinyl pyridine) (P3EHT-b-P2VP) which self assembles into controllable morphologies. Inorganic nanoparticles reside within the P2VP domain due to the favorable interactions between P2VP and the nanoparticle surface as well as the exclusionary effects of the liquid crystalline P3EHT. The nanoparticle location can be tuned by altering nanocrystal surface chemistry. These findings are used to develop a comprehensive understanding of the self assembly processes in conjugated rod-coil block copolymer nanocomposites.

C1.00091 Experimental and computational studies of finite-size effects in nanocomposites , M.P. ROMAN, Dept. of Physics, NC State University, Raleigh, NC 27695, E.W. SKAU, D.R. STEVENS, L.N. DOWNEN, T.J. HOFFMAN, L.I. CLARKE — Polymeric nanocomposites are formed when a nanometer-sized particle is embedded within a supporting matrix. Such composites can also be nanostructured - that is, shaped so that characteristic sample length scales may be similar to at least one dimension of the embedded particle [1]. This is particularly true for long aspect-ratio particles such as nanotubes where the length of the particle can approach or exceed the thickness of a thin nanocomposite film or a nanofiber diameter. In these cases, the formation of a particle network (for instance, for mechanical or electrical conductivity enhancement) is affected. We present experimental electrical conductivity and 3-D continuum Monte-Carlo simulation results on such finite-sized percolation effects, which can occur whenever any dimension of the sample is less than ca. 10 times the longest dimension of the particle.

C1.00092 Nanoparticle Surface Functionalization for Improved Dispersion in Network Composites , ADAM RICHARDSON, OLIVIA MCNAIR, GREGORY STRANGE, MARK EARLY, DANIEL SAVIN, School of Polymers and High Performance Materials, University of Southern Mississippi — Incorporation of inorganic nanoparticles into crosslinked networks has resulted in greater toughening behavior with lower filler content compared to traditional composites. The characteristics that provide these desirable qualities are also responsible for their poor dispersion and, consequently, limiting wide commercial use. This work aims to demonstrate how excellent dispersion can be obtained easily and efficiently in different networks through nanoparticle surface modification. Both epoxy/Jeffamine and thiol-ene based networks were examined with differing molecular weight and chemical functionality tethers. The aggregation behavior of nanocomposite samples were monitored optically and using TEM. Thermomechanical properties were studied using DSC, DMA and MTS. The Tg was dependent on both nanoparticle incorporation and functionality. Toughening was observed in some, but not all, cases.

C1.00093 Effect of Metal-Dielectric Interface on Capacitor Functions of Ag-Polymer Nanocomposites at Low Frequency (< 1 MHz) , ATAUR CHOWDHURY, University of Alaska Fairbanks, ABHIJIT BISWAS, University of Notre Dame, ILKER BAYER, Italian Institute of Technology — Metal-dielectric interfaces greatly influence the capacitor functions of nanodielectric composites. Nanodielectric composites of silver in PMMA were fabricated by electron-beam-assisted vapor phase codeposition at ambient temperature ($\sim 35^\circ$ C) in high vacuum. The fabricated samples containing 15- 65% silver reveal unique interfacial structure as studied by X-ray and atomic force microscopy. The capacitance of the as prepared samples were measured with an Agilent LCR meter at frequencies ranging from 20 Hz to 1 MHz. All nanodielectric composites show similar capacitor characteristic with a capacitor density of about 2.0 nF at 20 Hz to about 0.2 nF at 1 MHz., revealing continuous decrease in capacitor density with increasing frequency. This continuous decrease is a direct result of the interface between the silver granules and the dielectric material. This behavior, however, is in clear contrast with our recent study of BTO-PMMA nanocomposites (A. Biswas, et al., NNL, Vol. 1, 111-118, 2009), which show a stable capacitor function over a wide frequency range (20-80 MHz).

C1.00094 A Robust Model for Predicting Charge Mobility in a Random CNT Composite Sample , JOSHUA BROWN, Louisiana Tech University, PEDRO DEROSA, Louisiana Tech University/Grambling State University — Experimental results have shown that Carbon Nanotube (CNT) concentrations have significant impact on the conductivities of CNT polymer composites. Two charge transport mechanisms have previously been observed in these composites: covalent hopping and tunneling. Using these mechanisms as a foundation a robust Monte Carlo simulation has been realized. The simulation first creates a CNT composite sample under different initial conditions such as concentration, tortuosity and length. The charge mobility of the sample is then predicted under an applied electric field for CNT concentrations below and above the percolation threshold.

C1.00095 Effect of Single-Walled Carbon Nanotubes on Glass Transition Behavior in Polystyrene , BRIAN GRADY, University of Oklahoma, WARREN FORD, ABHIJIT PAUL, Oklahoma State University — Our group previously investigated (Macromolecules, 2009, 42, 6152) the effect of nanotube addition on the glass transition temperature (Tg) and the heat capacity change at the glass transition (Delta Cp). Tg increased with nanotube addition by $\sim 7^\circ$C at 1 wt% added nanotubes, while the delta Cp had the same qualitative behavior, but with a $\sim$20% decrease instead of an increase. We have extended this work to polymer grafted-to nanotubes, with polystyrene molecular weights of 2800, 15,000 and 50,000 g/mol; the weight fractions of grafted chains were approximately the same. For the two higher grafting densities, Tg showed the same qualitative behavior but quantitatively the increase in Tg was closer to 9°C. Composites with 50 K grafted nanotubes were statistically identical in terms of the Tg and Delta Cp, although the latter at high nanotube concentrations (20 wt%) did show some anomalous behavior. The decrease in Delta Cp for composites made with the nanotubes having the highest grafting density was linear with added grafted nanotubes to a maximum of a $\sim$35% decrease. Delta Cp for the materials made with 15 K grafted nanotubes showed either a small decrease, or no change in Delta Cp.

C1.00096 Deformation and fracture of Coarse-grained Model of Filled Rubber Composites , KATSUMI HAGITA, National Defense Academy, HIROSHI MORITA, AIST, MASAO DOI, University of Tokyo, HIROSHI TAKANO, Keio University — We presented a result of coarse-grained Molecular Dynamics simulation of filled polymer melts with Sulfur-crosslink under deformation based on the Kremer-Grest Model. Under uni-axial deformation (extension) by setting Poisson's ratio to less than 0.5, facture of this polymer nanocomoposites occurs due to volume increase for increasing the strain. In order to study facture behavior, we use the original Lennard Jones potential formula (with attractive part) as interaction between polymers. The size of simulation box under periodic boundary conditions (PBC) is set to about 133nm. We put 2048 fillers, 5120 polymer chains of 1024 particles, and many crosslink into the PBC box. Due to the crosslink, all polymer chains are connected to one network gel. One filler consists of 320 particles of the C320 fullerene structure. A repulsive force from the center of the filler is applied to the particles of C320 in order to make a sphere whose diameter is about 7nm. We can observe the fracture occurs due to void created near surface of fillers for the case that interaction between polymer and filler is relatively non- attractive. Various cases of Poisson's ratio and interaction between polymer and filler are examined.

C1.00097 SEMICONDUCTORS —

C1.00098 Photocatalytic Activity of TiO_2 Thin Films Obtained by the Sputtering RF in Wastewater

, JAIRO ARMANDO CARDONA BEDOYA, WILMER ASMED SANCHEZ VELANDIA, MIGUEL IBAN DELGADO ROSERO, ALEX ENRIQUE FLORIDO CUELLAR, Universidad del Tolima, Facultad de Ciencias, Depto. de Física, ORLANDO ZELAYA ANGEL, JULIO G. MENDOZA ALVAREZ, Centro de Investigación y de Estudios Avanzados, IPN, Depto. de Física — The photocatalytic activity of TiO_2 thin films in wastewater, under an UV irradiation, is studied. The films were prepared on corning glass substrates by the sputtering RF technique. We present evidence on the photocatalytic degradation, carried out by advanced oxidation processes (AOPs) in domestic wastewater pretreated with UASB (upflow anaerobic sludge blanket) reactors. TiO_2 films were illuminated with ultraviolet light during a time of 4 hours ($\lambda \cong 264$ nm). We could see the effect of degraded operation in the absorbance measurement using UV-VIS spectrophotometry. The results show an increased rate of degradation of the wastewater by 30% compared to the values reflected biologically treated wastewater by anaerobic reactors.

C1.00099 Afterglow Study of ZnS:Cu,Co Water-soluble Nanoparticles and Potential Applications

, LUN MA, WEI CHEN — ZnS:Cu,Co water-soluble afterglow particles with average size of 4 nm have been prepared by using simple wet chemistry method. The X-ray diffraction pattern of the nanoparticles shows a cubic zinc blende structure as the synthesis temperature is low comparing with solid state reactions. The nanoparticles have two photoluminescence emission peaks. The blue emission is from sulfur defects (vacancies), while the green emission is from Cu^{2+} luminescent center which also contributes to the particle's afterglow. The presence of co-dopant Co^{2+} is critical to perform the afterglow of these nanoparticles. The afterglow intensity and decay vary on different $Cu^{2+}$and Co^{2+} doping levels. Further conjugation of ZnS:Cu,Co nanoparticles and photosensitizers presents a new method for deep cancer treatment in photodynamic therapy. The successful afterglow observation from water-soluble nanoparticles may find many new applications in biological imaging, detection and treatment.

C1.00100 Characterization of GaN grown on tilt-cut γ-$LiAlO_2$ by molecular beam epitaxy

, WEN-YUAN PANG, IKAI LO, YU-CHI HSU, CHENG-HUNG SHIH, CHIA-HO HSIEH, Department of Physics, National Sun Yat-Sen University, Kaohsiung, Taiwan, MING-CHI CHOU, Department of Materials and Optoelectronic Science, National Sun Yat-Sen University, Kaohsiung, Taiwan — The non-polar GaN film is a potential candidate for high-efficient optoelectronic devices. This study reports on the characterization of GaN grown on tilt-cut γ-$LiAlO_2$ by plasma-assisted molecular beam epitaxy. The (100) γ-$LiAlO_2$ substrate was tilt-cut about the angle of 11 degree to in-plane. It was found that the GaN thin film tilts to match the atoms of (100) γ-$LiAlO_2$. The basal plan stacking fault and the interface between substrate and thin film have been investigated by transmission electron microscopy. In addition, the characteristics of GaN films for different growth temperatures were studied by X-ray diffraction, scanning electron microscopy, and photoluminescence measurements. From the full width at half maximum of X-ray rocking curve, we found that the quality of GaN film can be improved by tuning the growth temperature. The crystal structure, film surface, and optical properties of the samples will be discussed, as well.

C1.00101 Characterization of M-plane GaN film grown on β-$LiGaO_2$ (100) by plasma-assisted molecular beam epitaxy

, CHIA-HSUAN HU, IKAI LO, CHENG-HUNG SHIH, WEN-YUAN PANG, YING-CHIEH WANG, Department of Physics, National Sun Yat-Sen University, Kaohsiung, Taiwan, MITCH M.C. CHOU, Department of Materials and Optoelectronic Science, National Sun Yat-Sen University, Kaohsiung, Taiwan — Lithium gallate ($LiGaO_2$) has an orthorhombic crystal structure that can be described as a wurtzite-like structure. The **M**-plane basis of GaN wurtzite structure is nearly matched to the selected lattice axes of pseudo-hexagonal $LiGaO_2$. **M**-plane GaN thin films have been grown on β-$LiGaO_2$ (100) substrates by plasma-assisted molecular-beam epitaxy in our group. Pure **M**-plane GaN crystal films have been verified by the measurements of x-ray diffraction, micro-Raman scattering, polarization-dependent photoluminescence and atomic force microscopy. The measurements of x-ray diffraction and micro-Raman scattering exhibited the evidences of large compressive stress on the **M**-plane GaN thin films. Based on experimental results, we showed that the large compressive stress is the major source leading to the peeling of **M**-plane GaN thin film off substrate after thermal recycles.

C1.00102 Effect of substrate induced strains on the magnetic and ferroelectric properties of epitaxial bilayer thin films of lead zirconate titanate and cobalt ferrite[1]

, DEVAJYOTI MUKHERJEE, TARA DHAKAL, ROBERT HYDE, PRITISH MUKHERJEE, HARIHARAN SRIKANTH, SARATH WITANACHCHI, University of South Florida — Epitaxial bilayer thin films of cobalt ferrite (CFO) and lead zirconium titanate (PZT) were deposited on MgO (100) and $SrTiO_3$ (STO) (100) substrates by pulsed laser deposition. The structural properties were characterized using X-ray diffraction and atomic force microscopy. The magnetic properties were measured at 10 K and 300 K in both parallel and perpendicular magnetic fields. The CFO-PZT bilayers showed enhanced or reduced magnetization compared to the single layer CFO films depending on the substrate of deposition. The ferroelectric properties of the CFO-PZT bilayers showed enhanced polarization compared to PZT single layer films on both types of substrates. A strain compression-relaxation mechanism was proposed in order to explain the structure-property relationships in the CFO-PZT bilayers.

[1]This work was supported by NSF (Grant Nos. DMI-0217939 and DMI-0078917) and DOD (Grant No. W81XWH-07-1-0708).

C1.00103 Photochemical synthesis of porous silicon thin films[1]

, OLIVIA SKEEN, TONI SAUNCY, Angelo State University — Porous silicon thin films were produced by photochemical synthesis with a solution of hydrofluoric acid (HF) and the oxidizer cobalt nitrate ($Co[NO_3]_2$). An 11mW HeNe laser was used during synthesis to produce the local electric field necessary for the formation of the porous matrix on the surface of the crystalline silicon substrate. Substrates used were n-type (Antimony), and p-type (Boron). Samples prepared with variations in process time from 15 minutes to 5 hours were examined using photoluminescence, SEM and Raman spectroscopy. Results indicate that the presence of the oxidizer during synthesis enhances the intensity and persistence of p-Si photoluminescence when compared with samples prepared using only HF. In addition, post process analysis reveals that the porous layer on the samples is present only on samples processed for less than 4 hours.

C1.00104 Bipolar resistive switching in $Ba_{0.5}S_{r0.5}Co_{0.2}Fe_{0.8}O_3$ thin films

, ZHONGWEN XING, Dept. of Materials Science and Engineering, Nanjing University, NAIJUAN WU, ALEX IGNATIEV, Center for Advanced Materials and Department of Physics, University of Houston — Five-component perovskite Ba0.5Sr0.5Co0.2Fe0.8O3 (BSCFO) thin films are reported to have polarized electrical-pulse-induced resistance (EPIR) change at room temperature. Such an EPIR change is attributed to a combined effect of the resistance change of the Schottky barrier and the oxygen ion/vacancy movement near the interface. In the BSCFO, the lower threshold voltage of the electric pulse that leads to nonvolatile resistive changes is close related to its higher oxygen permeability.

C1.00105 Effect of spin-orbit interaction on the ballistic transport properties of nanowires

, SHEEHAN AHMED, RYAN BRENNAN, Fordham University, GODFREY GUMBS, Hunter College, CUNY, ANTONIOS BALASSIS, Fordham University, DANHONG HUANG, Air Force Research Laboratory, Kirtland Air Force Base — We calculated the effects of spin-orbit interaction (SOI) on the energy bands, ballistic conductance (G) and the electron-diffusion thermoelectric power ($S_{\rm d}$) of a nanowire by varying the temperature, electron density and width of the wire. We used the effective mass approximation in a model for the quasi-1D electron system that includes a Rashba potential lateral confinement of the 2DEG and a quasi-square potential well confinement transverse to the 2DEG. Both terms (α and β) give rise to SOI coupling which affects significantly the band structure obtained from numerical solutions of a pair of coupled equations. Comparing our model with the already published work where harmonic confinement was employed to describe the transverse confinement, we found that the energy bands are different and, in addition to crossing effect of the transverse energy bands, there is also anticrossing for specific values of the wavevector k_y along the wire. The β-term of the Hamiltonian causes a displacement and a deformation of the transverse energy band structure which is more pronounced for large values of the wave vector.

C1.00106 Investigation of first principle thermoelectric properties of compound semiconductor

, CEM SEVIK, ALPER KINACI, TAHIR CAGIN, Artie McFerrin Dept of Chemical Engineering, Laboratory of Computational Engineering of Nanomaterials Texas A&M University, College Station, TX, TEXAS A&M UNIVERSITY TEAM — We analyze relevant electronic and transport properties of several different compound semiconductors, Cu_2ZnSnX_4, (X = S, Se, Te), $Cu_2CdSnSe_4$, and Cu_3SbM_3, (M = Se, S) to assess their potential as thermoelectric materials. Using density functional theory and Boltzmann transport equations, we determine Seebeck coefficients, conductivities, and power factors for each compound. To assess their potential application as thermoelectrics, we calculated a simple measure: "maximum" thermoelectric figure of merit, ZT_{max} at experimentally amenable doping levels. We compared this with results for other well known bulk thermoelectrics (Bi_2Te_3 and $SrTiO_3$). However, our calculations indicate that it is not possible to reach ZT values higher than 1, so that these materials to be competitive with other materials for power generation and refrigeration applications.

C1.00107 Transport Anisotropy of Epitaxial VO_2 films grown on (100) TiO_2

, SALINPORN KITTIWATANAKUL, Department of Physics, University of Virginia, JIWEI LU, Department of Materials Science and Enginieering, University of Virginia, STUART WOLF, Department of Physics, University of Virginia — Vanadium dioxide (VO_2) exhibits a metal semiconductor transition (MST) at 340 K. This transition is accompanied by the abrupt change in the electrical conductivity, optical transmittance and reflectance in infrared region, which can be used in the electronic devices such as temperature sensors and electric switches. In this study, Reactive Bias Target Ion Beam Deposition was used for epitaxial VO_2 thin film growth on TiO_2 (100) substrates. The out-of-plane and the in-plane XRD scans have been performed to confirm the single phase VO_2 and the epitaxial relationship between the film and the substrate. The hall bars along the in-plane c-axis and b-axis of R-VO_2 were fabricated via the photolithographic process. It is found that the maximum conductivity was parallel to c-axis, while the minimum conductivity was parallel to b-axis. The conductivity anisotropy persisted through the metal semiconductor transition. The conductivity anisotropy ratio σ_c/σ_b was found to be $\sim$16.2 at 300 K, much larger than that of single crystal VO_2. The temperature dependent anisotropy of the carrier concentration and the mobility is to be discussed.

C1.00108 Transport Characteristics of Amorphous Borocarbides: A Variable Range Hopping Treatment

, NASEER DARI, DONALD PRIOUR, JR, University of Missouri, Kansas City — We calculate the temperature dependent conductivity of amorphous borocarbide materials within a variable range hopping framework. We study the impact of disorder on borocarbide transport characteristics by beginning with a regular rombahedral lattice of periodically placed icosahedral arrangements of boron and carbon atomic species. A self consistent numerical procedure is used to calculate the charge occupancy factors. Three dimensional lattices containing several hundred icosahedral clusters are considered; disorder is introduced in the form of random translational displacements of the icosahedral cages. In addition, we use stochastic rotations about three independent randomly selected axes to implement orientational disorder for each of the icosahedral clusters. We find the sensitivity to random lateral displacements of the boron-carbon icosahedra to be on the order of 5%, whereas the effects of even appreciable orientational disorder appears to be negligible within the assumptions of our model. In sum, we find temperature and the density of icosahedral clusters to have the strongest effect on the conductivity, while the transport characteristics are largely robust with respect to the introduction of disorder.

C1.00109 Temperature dependent adsorption and dissociation of water molecules on the Si(001)-(2×1) surface

, JA-YONG KOO, Korea Research Institute of Standards and Science, YONG-SUNG KIM, HANCHUL KIM, SANG-YONG YU — The dissociative adsorption of water molecules on the Si(001)- (2×1) surface was studied up to 850 K by scanning tunneling microscopy (STM). A water molecule is dissociated into on-dimer (OD) and inter-dimer (ID) configurations and the population ratio n_{ID}/n_{OD} changes from $\sim$5 at room temperature to $\sim$0.5 above 500 K. A quantitative analysis was made by considering the flipping motion of Si dimers to overcome the discrepancy between the experiment and theoretical estimations from the model of simple energy barrier. The flipping motion of Si dimers plays a dominant role in the dissociation of water molecules on the Si (001)-(2×1) surface.

C1.00110 Asymmetric Double Quantum Dot Energy States in a Quantizing Magnetic Field

, NORMAN HORING, SPENCER HORTON, SINA BAHRAMI, Stevens Inst. Tech. — This work is concerned with electron states and propagation in a two-dimensional asymmetric quantum double-dot system embedded in a two dimensional host sheet subject to Landau quantization. The two dots are represented by two Dirac delta function potential terms of differing depths each of which would support just one subband state if the other were absent, if there were no magnetic field. The integral equation for the Schrodinger Green's function for this double-dot system is solved exactly in closed form in terms of the infinite sheet Green's function for two dimensional electrons subject to Landau quantization with no quantum dots. The dispersion relation for the double dot subband energies is formulated and examined by analyzing the frequency poles of the Green's function with Landau-quantization-like splintering of the levels by the magnetic field. The effects of the asymmetry in regard to the potential well depths are analyzed as functions of the well-depth difference and dot-separation.

C1.00111 Core level XAS study on high pressure solids

, MIN WU, JIANZHONG JIANG, Zhejiang University, JOHN TSE[1], University of Saskatchewan — We investigated the K and L-edge core level X-ray absorption spectra of solid CO2 and Silica (SiO2) under high pressure, using methods based on pseudopotentials and all-electron Bethe-Salpeter Equation. A comparison of the calculated spectra with both methods is present. We found that the calculated Si K and L-edge spectra of quartz and stishovite are in good agreement with experiment. Particularly, the origin of the second peak in the O K-XAS observed in compressed silica which is often used as an indication of six-fold coordinate is explained. Preliminary calculations show both the full core hole and no core hole approximations failed to reproduce quantitatively the observed C and O K-edge XAS.

[1]corresponding author

C1.00112 An Ab Initio Study of Hydrogenation induced Metallization of SiC001 (3x2)

, JAMES WESTOVER, ABDELKADER KARA, University of Central Florida — We will present results for the band structure of hydrogenated Silicone Carbide (001) (3x2) surface with various levels of hydrogenation. These band structures were obtained using density functional theory with a generalized gradient exchange correlation function. Further, the calculations reveal the following scenario. Initially, Hydrogen atoms saturate all the dangling bonds of the surface dimers. This in turns allows for the subsequent H atoms to bind with Si atoms in the second layer. Those new bonds for the appropriately hydrogenated surface cause a "metallization" of the surface. Hydrogenation beyond that brings the system to its semiconducting state.

C1.00114 Electron affinities of d1 transition metal chloride clusters and onset of super halogen behavior

, SWAYAMPRABHA BEHERA, JORLY JOSEPH, PURUSOTTAM JENA, VCU — Geometry, electronic structure, and electron affinity of d1 transition metal chloride clusters (MCl_n, M = Sc,Y, La; n = 1–5) have been calculated using density functional theory. Chlorine atoms are chemically bound in all cases except for MCl_5. The electron affinities of MCl_n (n = 1–3) are small and increase only marginally as a function of n until the valence of the metal atom is consumed. Beyond this, they rise sharply and reach a value of 5.96, 6.03 and 5.90 eV for $ScCl_4$, YCl_4 and $LaCl_4$, respectively and remain high for n = 5. MCl_n, (n = 4,5) clusters, therefore, behave as superhalogens. Results are compared with available experimental data

C1.00115 Calculation of the Electronic Structure for the AlGaAs Quantum Well

, CHIN-SHENG WU, Yuan Ze University — Quantum wells are important in semiconductor lasers because they allow some degree of freedom in the design of the emitted wavelength through adjustment of the energy levels. We apply the various the well width w and barrier height V in order to match the device information made by Willander. Solving the Schrödinger equation with exchange- correlation energy and effective mass of electrons for a finite potential will produce values of the energy levels within the well. Alternating GaAs-AlGaAs layers produce high and low energy gaps. The result is the generation of quantum wells. The electrons in the donor section AlGaAs diffuse into the low band gap GaAs section, where is free of impurity atoms, therefore the effective mass of electrons reduces and the mobility increases. Dispersion relations in conduction band and valence band are applied for the effective mass approximation. Because of the presence of quantum wells the electrons have discrete energies and these appear as peak in the absorption measurements.

C1.00116 Carrier cooling and Auger heating in Si doped InN thin films

, Y.-G. ZENG, D. -J. JANG, C.-F. TZEN, Department of Physics, National Sun Yat-sen University, M.-E. LEE, Department of Physics, National Kaohsiung Normal University, L.-W. TU, Department of Physics, National Sun Yat-sen University — Silicon doped InN thin films grown on sapphire substrates by plasma-assisted molecular beam epitaxy have been studied using time-resolved photoluminescence (TRPL) upconversion technique. The back ground carrier densities vary from 6.2×10^{18} to 1.27×10^{20} cm^{-3}. The carrier temperature curves, derived from the TRPL at different time delay, indicate that the hot carriers lost most of their excess energy within the first 10 ps after photoexcitaiton. For low doping densities, the carrier cooling curves can be explained by carriers releasing excessive energy through the carrier–LO-phonon interaction. The extracted effective phonon emission times decreased as the photoexcited carrier concentration reduced. The radiative and nonradiative decay rates were obtained with the TRPL signals and the nonlinear dependence of the PL intensity on the carrier concentration. The derived radiative recombination rates were consistent with the theoretical predications. The Auger recombination was found to increase with the doping concentration. The reduced carrier cooling rates for large doping densities can be accounted for by the Auger heating occurred during carrier relaxation.

C1.00117 Radiative and nonradiative recombination rates of Si:InN thin films

, S.-F. WANG, D. -J. JANG, C.-F. TZEN, Department of Physics, National Sun Yat-sen University, M.-E. LEE, Department of Physics, National Kaohsiung Normal University, L.-W. TU, Department of Physics, National Sun Yat-sen University — Silicon doped InN thin films with background carrier densities vary from 6.2×10^{18} to 1.27×10^{20} cm^{-3} were investigated by time-resolved photoluminescence (TRPL) upconversion technique. The radiative and nonradiative decay rates as a function of carrier density were derived from the TRPL signals. The Shockley-Read-Hall, radiative recombination, and Auger recombination coefficients were obtained by fitting the derived decay rates with the rate equation. The defect density can be determined from the differences of doped and undoped carrier densities. We found that the SRH coefficient is proportional to the defect density. The capture cross sections, determined from the SRH coefficient, defect density, and thermal velocity, were $1.5\sim3.0\times10^{16}$ $cm.^2$ The radiative decay times determined from the rate equation were compared with those determined by a model developed by Gourdan and Lavallard, which is recently used to determine radiative lifetimes of InN by several reports. We found the discrepancy of radiative lifetimes determined by these two approaches is attributed to the large nonradiative recombination rates in these samples.

C1.00118 Differential reflectance study of InN

, M.-S. WANG, D. -J. JANG, Department of Physics, National Sun Yat-sen University, M.-E LEE, Department of Physics, National Kaohsiung Normal University, L.-W TU, Department of Physics, National Sun Yat-sen University — Time-resolved differential reflectance (TRDR) of Si:InN thin films grown on sapphire substrates by plasma-assisted molecular beam epitaxy were investigated. The background carrier densities of $4.4\times10^{18}\sim1.27\times10^{20}$ cm^{-3} were measured by van der Pauw Hall geometry for undoped and Si doped InN thin films. The energy of the degenerated pump and probe beams were tuned from 1.37 to 1.65 eV. All the signals were measured at room temperature. The intensity and the temporal position of the TRDR peak intensity increase with the pumping intensity and show trivial dependence on photoexcitation energy. The TRDR intensity exhibits single-exponentially decay for photogenerated carrier density up to 6×10^{18} cm^{-3}. For higher excited carrier density, two decay times must be employed to describe the decay behavior. The rate equation includes the Shockley-Read-Hall, radiative, and Auger recombination were used to fit the decay rate. While the Auger recombination is insignificant for low photoexcitation, it becomes the dominated recombination mechanism within 10 ps for high photoexcitaiton. The dominated recombination mechanism for different pumping energy will be discussed.

C1.00119 Precision Bandgap Control of Titanium Dioxide Nanoparticles by Ultrasonication

, ROBBY FLAIG[1], LESTER LAMPERT, JORGE CAMACHO, JAMES HAMILTON, University of Wisconsin-Platteville — TiO2 is a commonly used material in many areas of industry including photocatalysis and pigments. Band gap narrowing and particle size are engineered with a high level of control. We report precision bandgap control by ultrasonication in novel stable solvent systems in which unmodified TiO2 can be suspended. The effects of ultrasonication in these unique solvent systems are monitored by optical band gap (UV-Vis), scanning electron microscopy (SEM), atomic force microscopy (AFM), and x-ray diffraction (XRD).

C1.00120 Seung-Nelson representation for singular thin sheets[1]

, THOMAS WITTEN, JIN WANG, University of Chicago — We extend the popular Seung-Nelson model [1] to better study thin elastic sheets with singular or multi-scale structures, which are common phenomena in thin sheets [2]. Because it requires a uniform distribution of lattice points over the simulated sheets, the original model is ill-equipped to study these singular structures. Our extended model retains the essence of the original one, but it allows lattice points to be concentrated as needed in regions of large curvatures. We will compare the two methods by applying them to study the energy of the core region of a developable cone [3].

C1.00121 Hamiltonian monodromy , CHEN CHEN, JOHN DELOS, MEGAN IVORY, SETH AUBIN, College of William and Mary — We say that a system exhibits monodromy if we take the system around a closed loop in its spectrum space, and we find that the system does not come back to its original state. We report a method for experimental realization of a newly discovered dynamical manifestation of monodromy by investigating the behavior of atoms in a trap. The trapping potential has long range attraction to and short range repulsion from the center. Calculations include two parts. First we consider atoms as classical particles for which we can choose any desired set of initial conditions. As was shown previously for different systems, when we take the system around a monodromy circuit, a loop of initial conditions evolves into a topologically different loop. Second, we incorporate the limitations that would appear in experimental implementation. The atoms have a range of initial angles, initial angular momenta, and initial energies. Our work shows how real atoms can be driven by real forces around a monodromy circuit, and thereby shows how one can observe dynamical monodromy in a laboratory. Finally, we extend classical dynamical monodromy to quantum dynamical monodromy by examining wave function evolution under comparable conditions.

C1.00122 The complete interpretation of the fractions in quantum Hall effect , KESHAV SHRIVASTAVA, University of Malaya — We propose that the modified cyclotron energy is given by $(h/2\pi)\omega_c(1/2)g(n+1/2)$ so that the fractional charge is given by the angular momentum with both signs of spin, $j = l \pm$ s. In addition to the (i) principal fractions given by (1/2)g our theory with effective charge e*=(1/2)ge, has (ii) resonances at $\nu_1 - \nu_2$ and (iii) two-particle states at $\nu_1 + \nu_2$ and there are (iv) clusters with spin >1/2, where ν is a filling factor. This theory explains all of the 101 fractions and full graphene series. The fractional charges of graphene [2] are also explained. The series also explains the even denominators for S=0,1,2, . . . , as in electron clusters. The S=0, L=0, corresponds to half filled Landau level. S=1/2, L=0 with negative sign before s in j gives the zero-energy state. All of the predicted fractions agree with the data.

C1.00123 Trial Wavefunctions and Ground State Energies of Some Non-Laughlin Correlated Quantum Hall Systems , JOHN QUINN, University of Tennessee — In the lowest Landau level (LL0), incompressible quantum liquid (IQL) states occur at the Laughlin-Jain sequence of filling factors $\nu = n(2pn \pm 1)^{-1}$, where n and p are positive integers. In all of these states, Laughlin correlations (avoidance of pair states with the largest repulsion) are the cause. In the first excited Landau level (LL1), IQL states occur at $\nu' = \nu - 2 = 1/2$. This state and daughter states of Laughlin quasiparticles with $\nu_{QE} = 1/3$ cannot be caused by Laughlin correlations. Paired states described by the Moore-Reed Pfaffian wavefunction and by a novel wavefunction with different pairing correlations are studied as candidate wavefunctions. The energy of each of these states is evaluated analytically for an arbitrary pair pseudopotential $V(L_2)$, where L_2 is the pair angular momentum. Explicit results are derived for a six particle system. The generalization to N particle systems is proposed and compared for both trial functions.

C1.00124 Density functional study of the effects of doping and stoichiometry on gallium diffusion in gallium arsenide , J.T. SCHICK, Villanova Univ., C.G. MORGAN, Wayne State Univ. — Previous experimental [1-4] and theoretical [5,6] work on the properties of diffusion of gallium within gallium arsenide has produced some results that are apparently at odds with each other. We present results of a wide theoretical survey of the point defects that form in this material with special attention paid to the formation and diffusion of excess-gallium-related point defects. In this study we applied density functional theory in the local density approximation [7]. Diffusion was examined through the use of the nudged elastic band method [8]. After considering the accuracy of the approximations used, the calculations yield information compatible with the experimental situation and capable of shedding light on areas of apparent disagreement.

C1.00125 Investigation of Mg- and Si- doped AlN epilayers by Transmission Electron Microscopy , BO CAI, Department of Physics, Brooklyn College of CUNY, NY 11210, M.L. NAKARMI — Aluminum nitride (AIN) has emerged as a promising deep ultraviolet (UV) material for the development of optoelectronic devices operating in deep UV region. Low dislocation density AIN on sapphire substrate has been achieved by metal organic chemical vapor deposition technique. Doping in AIN is very crucial in order to use it in active devices. Silicon and magnesium are usually used for n- and p- type doping in III-nitride materials. We report on microstructure analysis of Mg- and Si- doped AIN epilayers by transmission electron microscopy (TEM). The samples were grown on low dislocation density AIN/sapphire templates. Cross section and plan view TEM images were taken to characterize the threading dislocations in these samples during the growth process. High resolution TEM images are also taken to study the detailed nature of the dislocations, and their generation and propagation. The TEM images will be compared with the undoped AIN epilayers to investigate the effect of doping in the generation/annihilation of threading dislocations. Implications of our finding for the applications in deep UV optoelectronic devices will be discussed.

C1.00126 Spin transport and spin minibands in a magnetic superlattice: dependence on geometrical and physical parameters[1] , NAMMEE KIM, JINWOO KIM, HEESANG KIM, Soongsil University — We have studied the spin miniband structure and the ballistic spin-polarized transport through a magnetic superlattice, formed by inhomogeneous magnetic field in a semiconductor nanowire. Based on the transfer matrix theory and the Bloch's theorem, we calculate the energy dispersion having spin miniband and minigap due to Bloch periodicity and spin dependent ballistic conductance for various geometrical and physical parameters. It is shown that full spin polarization in the ballistic conductance of the system occurs clearly for each spin, and that the fully spin polarized range for each spin can be enhanced by modulation of geometrical and physical parameters.

[1]This work was supported by the Korea Research Foundation (NRF, grant No. 20100021328).

C1.00127 Magnetocurrent of a multiferroic resonant tunneling diode[1] , NAMMEE KIM, HEESANG KIM, Soongsil University — We study the resonant tunneling magnetoresistance of a multiferroic resonant tunneling diode, which is hybridized of ferroelectric double barriers and a ferromagnetic quantum well. Magneto-current is calculated, focusing on its dependence on ϕ, the angle between an external magnetic field and the spontaneous magnetic field in the diluted magnetic semiconductor quantum well, by using the non-equilibrium Green's function method. The magneto-current varies from zero to 440%, and the spin polarization of the current varies from zero to 1 by changing the angle ϕ. We also perform controlling of the transmission energy level by reversing the direction of dipole polarization in ferroelectric barriers. Therefore, the magneto-current and its current spin polarization through this multiferroic resonant tunneling diode can be manipulated either by the direction of the external magnetic field in the diluted magnetic semiconductor quantum well or by the direction of the dipole polarization in ferroelectric barriers. This study shows the possible application of this structure to a multiferroic spin device to control the amount of current and spin polarization of current through it.

C1.00128 Effect of disorder on the Curie temperature of GaMnN and InMnN diluted magnetic semiconductors

, AHMAD ALSAAD, Department of Physical Sciences, Jordan University of Science and Technology, Irbid-Jordan — The critical Curie temperatures of GaN, InN, CrN, and MnN diluted magnetic semiconductors and those of ordered and disordered diluted (Ga,Mn)N and (In,Mn)N magnetic semiconductors are investigated by using the classical Heisenberg model within the mean field approximation with the structural parameters are obtained from first principles total energy calculations. We show that Curie temperature depends on the Mn and Cr concentrations. Our calculations on these systems have shown that above room-temperature can be observed. Ferromagnetic stability in GaN, InN, CrN, and MnN is systematically studied. Our results indicate that 3d Mn and Cr impurities in GaN and InN favor the ferromagnetic state rather than the spin-glass phase. The mechanism behind this behavior is discussed and explained in details.

C1.00129 Spin resolved transverse electron focusing in wide leads due to diffuse collimation in InSb/InAlSb two-dimensional electron gases

, L.F. COHEN, A.M. GILBERTSON, Imperial College, A. KORMÁNYOS, C.J. LAMBERT, Lancaster University, M. FEARN, T. ASHLEY, QinetiQ, S.A. SOLIN, Washington University in St. Louis — Using the transverse electron focusing geometry, we report spin-resolved cyclotron motion in an InSb two-dimensional electron gas (2DEG). A zero field spin spitting[1] causes electrons from different spin subbands to have slightly different cyclotron radii in external field which manifest as a splitting in the first focusing peak.[2] Traditionally in focusing experiments, electrons are emitted and collected via quantum point contacts that host only a few open channels. We show that spin resolved electron focusing is observable in $wide$ leads with many open channels due to diffuse collimation of ballistic electrons emitted into the bulk 2DEG region. The results are compared to a semiclassical model[3] from which a Rashba-type spin-orbit coupling parameter of $\alpha = 5x10^{-11}$ eVm is deduced at 2 K. We compare these results to values determined from the beating of Shubnikov-de Haas oscillations.[4] We also present ballistic transport results extending over 3 μm.

C1.00130 Spin-orbit coupling in InAs-based wurtzite quantum wells[1]

, J.Y. FU, POLIANA H. PENTEADO, J. CARLOS EGUES, University of Sao Paulo — By folding down the 8×8 Kane model, accounting for the s-p_z orbital mixing, we derive an effective Hamiltonian for the conduction electrons. In this derivation, we consider the renormalization of the spinor component of the conduction band wave function. In addition to the Rashba-type term arising from the bulk inversion asymmetry of the wurtzite lattice, we obtain the usual linear in momentum Rashba term induced by the structural inversion asymmetry of the well. We also find a new Rashba-like contribution, proportional to the well profile only and not to its derivative. We self-consistently calculate the spin-orbit coupling parameters for single and double wurtzite InAs-based wells with two subbands. By gating the structures, we find that the new Rashba term shows a distinctive voltage dependence as compared to that of the usual Rashba coupling. Finally, for the double-well case, we find that both the intersubband spin-orbit coupling and the Dresselhaus term for each subband show a resonant behavior for the symmetric configuration of the well.

C1.00131 2D Waveguides as spin devices: spin-orbit and lead effects[1]

, LILIA MEZA-MONTES, Instituto de Fisica BUAP — Straight waveguides with different shapes have been proposed as devices to control the spin polarized transport, with Rahsba spin-orbit interaction as the mechanism to induce spin mixing. Several theoretical approaches have been applied, mostly based on transfer-matrix method. Here, the Schroedinger equation is solved by means of the Finite-Element Method,finding good agreement with previous calculations. It is known that positions of the leads influence the ballistic transport in this sort of cavities due to changes in the spatial symmetry. The role of the lead positions on the transmission and, in turn on the spin polarization, will be discussed for several geometries. The linear Dresselhaus interaction is taken into account to consider zincblende structure. Implications for quantum dots is also addresed.

C1.00132 First principles calculations of magnetic properties of Gd-doped ZnSiN[1]

, J. RUFINUS, Science Division, Widener University, Chester, PA 19013 — Diluted metal-doped chalcopyrite compounds have recently attracted a great attention due to some experimental confirmations on their ability to achieve high temperature ferromagnetism. Such a material would likely play a role in building future spintronic devices. First principles calculations of the magnetic properties of Gd-doped $ZnSiN_2$, a semiconductor chalcopyrite, have been performed using the density functional theory within generalized gradient approximation. Our results show, independent of the substitutional sites, the lowest energy structure is ferromagnetic.

C1.00133 Zitterbewegung-induced Spin Resonance in Quantum Wires[1]

, MARCO O. HACHIYA, Instituto de Fisica de Sao Carlos, Universidade de Sao Paulo, 13560-970 Sao Carlos, SP, Brazil, GONZALO USAJ, Instituto Balseiro and Centro Atomico Bariloche, Comision Nacional de Energia Atomica, 8400 San Carlos de Bariloche, Argentina, J. CARLOS EGUES, Instituto de Fisica de Sao Carlos, Universidade de Sao Paulo, 13560-970 Sao Carlos, SP, Brazil — Recently, the *Zitterbewegung* in quantum wires was proposed theoretically by Schliemann *et al.* [1]. This effect is characterized by an oscillatory motion in the position and spin components of an electron wave packet injected along the quantum wire with spin-orbit coupling. We investigate the *Zitterbewegung* evaluating time dependent expectation value for the spin operators. Here we consider the *Zitterbewegung* in a multi-band quantum wire with both the Rashba and Dresselhaus spin-orbit interactions. We find that an external magnetic field perpendicular to the quantum wire can be used to tune the probability of spin flip, i.e., the resonance condition. A possible experimental scenario to observe this effect is proposed using injection via a quantum point contact.

C1.00134 Deep level transient spectroscopic study of oxygen-implanted ZnO single crystal[1] , ZIRAN YE, GUANGWEI DING, JINCHENG FAN, CHI CHUNG LING, The University of Hong Kong — ZnO single crystal samples were implanted by oxygen with the energy of 150keV. After the pretreatment of hydrogen peroxide [1], Schottky contacts were fabricated with Au film deposited by thermal evaporation. Deep level defects were studied by deep level transient spectroscopy (DLTS). The activation energy of the 0.29eV deep trap was observed in the as-implanted sample and samples anneal at 350 °C , 650 °C and 750 °C. Three peaks were identified in the DLTS spectra of the 900 °C sample, with the activation energies of 0.11eV, 0.25eV and 0.37eV respectively. The thermal evolutions of the deep levels up to the temperature of 1200 °C were also investigated.

C1.00135 ABSTRACT WITHDRAWN –

C1.00136 Observation of defects in $CuInSe_2$ by 300kV aberration corrected scanning transmission electron microscope , AKANE TAKESHITA, TAKAYUKI TANAKA, Tokyo Institute of Technology, TADAHIRO KUBOTA, Honda R&D Co., Ltd., HIDETO MIYAKE, Mie University, HIDETAKA SAWADA, YUKIHITO KONDO, Japan Electron Optics Laboratory, YOSHIFUMI OSHIMA, Osaka University, YASUMASA TANISHIRO, KUNIO TAKAYANAGI, Tokyo Institute of Technology — Vacancies (V_{Cu}, V_{In}) and substitutional atoms (In_{Cu}, Cu_{In}) in $CuInSe_2$ crystal, which is the key semiconductor material for thin film solar cell applications, were directly observed by 300kV aberration-corrected high angle annular dark field scanning transmission electron microscope (HAADF-STEM). The atomic columns of Cu, In and Se were independently observed from $CuInSe_2$ [100] crystal zone axis by HAADF-STEM. Some In and Cu columns showed reduced and increased intensities from that of column without defect, respectively. On the other hand, no defects in Se columns were observed. The intensity analysis suggests In substitution of Cu site (In_{Cu}) and Cu substitution of In site (Cu_{In}). The concentrations of Cu and In substitutions were evaluated based on comparison with the multi-slice calculation.

C1.00137 LaF3:Ce/CdTe nanocomposites for radiation detection application , MINGZHEN YAO, UT Arlington, PACIFIC NORTHWEST NATIONAL LABORATORY TEAM — Radiation detection demands new scintillators with high quantum efficiency, high energy resolution, and short luminescence lifetimes. Nanocomposites consisting of quantum dots and Ce^{3+} doped nanophosphors may be able to meet these requirements. Here, we report the luminescence enhancement of LaF_3:Ce/CdTe nanocomposites which were synthesized by a wet chemistry method. The results show that CdTe luminescence in LaF_3:Ce/CdTe nanocomposites is enhanced about five times. Energy transfer, light reabsorption, and defect passivation are the likely reasons for the luminescence enhancement

C1.00138 Determination of property in semiconductors , CARLOS FIGUEROA, Depto de IIS Unison, RAÚL RIERA, DIFUS Unison, MARTÍN MOLINAR — In this work it is doing a comparative study of the most conventional semiconductors in electronics, such as silicon (Si), germanium (Ge) and gallium arsenide (GaAs). We present the mathematical development of the magnitude that determines the intrinsic semiconductor property, which is the concentration of charge carriers, and is discussed in each case with respect to temperature variation. On the other hand, in the case of extrinsic semiconductors is calculated potential barrier of a pn junction. The task to make in this work is to use the intrinsic concentration of each material and their respective potential barrier to verify their behavior in relation to temperature. In the case of reverse bias generates a graphical output capacitance associated with these quantities. It is also used matlab to solve the transcendental equation that defines the relationship between voltage, resistance and current of a semiconductor diode bias. These demonstrations and concepts are important because they govern the operation of basic electronic devices and can characterize the differences between the Si, Ge and GaAs.

C1.00139 SURFACES, INTERFACES AND THIN FILMS –

C1.00140 Modeling the Self- and Directed-assembly of Viruses on Surfaces , DANIEL SULLIVAN, Colorado School of Mines, GEORGE GILMER, Lawrence Livermore National Laboratory, CRISTIAN CIOBANU, Colorado School of Mines — The exploitation of naturally self-assembling viruses has received much attention recently in regards to fabrication of nanomaterials and devices. Formation of dense viral mono- and multilayers as well as viral immobilization via chemospecific surface functionalization can be studied by modeling viruses as colloidal particles. We use a modified Lennard-Jones (LJ) potential, characterizing each colloid as an integrated collection of LJ particles, to describe intercolloidal and colloid-surface interactions. By carefully selecting the LJ interaction parameters and performing molecular dynamics simulations, we are able to replicate experimentally observed behavior of viruses on both strongly and weakly interacting surfaces in our surrogate colloidal system. Kinetic properties of the computational system are monitored and we find them to be in good agreement with predictions based on experimental data. We provide a basis for further investigation into the capabilities and limitations of modeling self-assembly of viral systems of technical interest using classical molecular dynamics.

C1.00141 Silicon Nanoparticle Formation Analysis and Optical Properties[1] , DANIEL FRASIER, GREG SPENCER, ANUP BANDYOPADHYAY, WIM GEERTS, Texas State University-San Marcos — In this study, the formation of silicon nanoparticles by thermal annealing of an initial silicon-on-insulator (SOI) structure is being performed. The SOI samples are synthesized by thermal oxidation of Si (100) wafers followed by magnetron and ion beam sputtering of a thin Si top layer. The thermal anneals are performed in a rapid thermal anneal system at temperatures ranging from 600 °C to 900 °C under atmospheric pressure of Ar gas. The nanoparticle formation process is being studied as a function of the thermal anneal maximum temperature, anneal time, and Si layer thickness. The annealed samples are measured by atomic force microscopy to determine the resulting nanoparticle size distributions and synthesis details. Electron microscopy is also being used for physical analysis in addition optical properties being studied through Effective Medium Approximations (EMA) proposed in the Lorentz-Lorenz (LL), Maxwell-Garnett (MG), and Bruggeman methods. Results for these experiments as well as comparisons with the work of others will be presented.

[1]Supported in part by NSF IGERT.

C1.00142 A study of the structure and dynamics of the interface between a nanoparticle and a surface: the case of Cu and Ag , JAMES BORRELLI, JAMES WESTOVER, ABDELKADER KARA, University of Central Florida — We performed a Molecular Dynamics study using the Embedded Atom Method for interatomic potentials for silver and/or copper nanoparticles projectiles incident on Ag and/or Cu (100) surfaces. Nanoparticles in the range of 1 to 2 nm in diameter were used with incident energies ranging from 50 to 500 meV/atom; while the surface temperature is kept at a temperature ranging between 300 and 700K. After collision and thermalization, distributions of nearest neighbor distances show a variety of values that reflect the strength of the local bonding. Using a Real Space Green's Function approach, we have determined the vibrational densities of states and the corresponding thermodynamical functions for a limited number of cases. Results for the vibrational dynamics show a strong effect at the high frequency end of the densities reflecting the stiffness of the bond at the interface. Results for the vibrational enery, entropy, lattice heat capacity as well as Debye temperatures will be presented.

C1.00143 Cluster growth driven by long range de-wetting interactions in thin films , ADI CONSTANTINESCU, LEONARDO GOLUBOVIC, West Virginia University, ARTEM LEVANDOVSKY, University of California Riverside — Long range de-wetting inteactions acting across thin films, such as the van der Waals forces, may drive the formation of large clusters (tall multi-layer islands). We study, by analytic arguments and simulations, the growth of these clusters within a unified model explicitly incorporating de-wetting interactions. The ultimate cluster growth scaling laws at long times are universal: Short and long range de-wetting interactions yield the same coarsening exponents. However, long range de-wetting interactions introduce a long lasting early-time scaling behavior characterized by a slow growth of the cluster height/lateral size aspect ratio (i.e., a time-dependent Young angle). This stage of cluster evolution is characterized by effective coarsening exponents that we calculate from our simulations and from an analytic approach.

C1.00144 Insights in to hetero diffusion and growth: A DFT Study , H. YILDIRIM, SUBRAMANIAN SANKARANARAYANAN, JEFF GREELEY, Argonne National Laboratory — We report the results of first principles calculations performed to study heteroatom diffusion on the terraces and step edges of fcc(001) surfaces on a series of 3d, 4d and 5d transition metals. For each adsorbate-substrate pair, we report the most stable adsorption sites and the corresponding adsorption energies. The corresponding terrace diffusion barriers are also reported, and periodic trends in the barrier heights are related to differences in adsorbate adsorption energies, cohesive energies of both adsorbate and substrate, and the differences in bond length/strength. Diffusion barriers and mechanisms at the step edges are also reported. Finally, insights into the possibility of 2D vs. 3D growth for each studied system are discussed via the calculated Ehrlich-Schwoebel barriers.

C1.00145 Initial growth of CrAs on GaAs(001)-c(4×4)α[1] , KAZUMA YAGYU, SHIGERU KAKU, JUNJI YOSHINO — CrAs is a ferromagnetic material which has a hexagonal structure. It is, however, predicted by first-principles calculation that zincblende (ZB) CrAs shows ferromagnetism and has a halfmetaric electronic structure [1-3]. Although ferromagnetism of a CrAs epitaxial film was confirmed so far, its crystal structure is still unclear. It turned out that ferromagnetism originated at the interface. In this study, initial growth of CrAs film has been investigated with scanning tunneling microscopy at 80 K. CrAs was grown on a GaAs(001)-c(4×4)α surface by means of exposing Cr as well as As_4 atoms at 250° C, followed by annealing at the same temperature. Randomly grown CrAs islands were observed form larger islands in proportion to the annealing time. Dimer structure which is similar to that of the substrate was confirmed on the surface of CrAs islands. This means that a CrAs island may have a ZB structure. The detailed structure and electric state of CrAs islands are discussed in the presentation.

C1.00146 Effect of deposition temperature on the properties of ZnO thin films , ALI ER, ASHRAF FARHA, Old Dominion University, YUKSEL UFUKTEPE, Cukurova University — The effect of deposition temperature on the surface morphology of zinc oxide thin films prepared by spray pyrolysis has been studied. The surface morphology of the films was studied by using X-ray diffraction (XRD), scanning electron microscopy (SEM) and atomic force microscopy (AFM). The effects of substrate temperature during deposition on the structure with optical properties of ZnO thin films were determined. Surface parameters were calculated and compared for different thin films. It showed that the films were polycrystalline with hexagonal wurtzite structure and c-axis was perpendicular to the substrate. The grain size of the films changed from 240 to 440 nm with different substrate deposition temperatures. It was found that growth temperature has significantly affected the morphological (grains size, surface roughness) as well as optical properties of ZnO films.

C1.00147 ABSTRACT WITHDRAWN –

C1.00148 Investigation of Chemical Reactivity at the Co/CuO interface by X-ray Photoelectron Spectroscopy[1] , J. EDMONDSON, Y. JUDIE, A. CHOURASIA, TAMU-Commerce — The technique of x-ray photoelectron spectroscopy has been utilized to investigate the chemical reactivity between cobalt and copper oxide at the Co/CuO interface. Thin films of copper (about 15 nm) were deposited on silicon substrates by the e-beam method. Such samples were oxidized in an oxygen environment in a quartz tube furnace at 400 ° C. The formation of CuO was checked by the XPS spectral data. Thin films of cobalt were then deposited on these CuO samples. The cobalt 2p, oxygen 1s and copper 2p regions were investigated by XPS. The magnesium anode (energy = 1253.6 eV) has been used for this purpose. The spectral data show chemical reactivity at the Co/CuO interface. The samples were annealed afterwards in air at 400 ° C. The spectral data were recorded at different take-off angles. Diffusion of copper through the cobalt overlayer with the formation of CuO is observed in the annealed samples.

[1]Supported by Organized Research, TAMU-Commerce

C1.00149 High resolution scanning tunneling microscope (STM) image of $SrTiO_3$(100)-$\sqrt{5} \times \sqrt{5} - R26.6°$ surface , ICHIRO SHIRAKI, Interdisciplinary Graduate School of Medical and Engineering, University of Yamanashi, Japan, KAZUSHI MIKI, National Institute for Materials Science (NIMS), Japan, SHUHENG PAN, Department of Physics, University of Houston, Houston, Texas — $SrTiO_3$(100)-$\sqrt{5} \times \sqrt{5} - R26.6°$ surfaces were studied by scanning tunneling microscope (STM) in ultra-high vacuum conditions at room temperatures. STM images with truly atomic resolution in filled states, which have never been reported, were successfully obtained. The atomic arrangement in $\sqrt{5} \times \sqrt{5}$ unit cell is clearly seen. It is currently assumed that Ti and its fourfold site O atoms were separately imaged with varying bias voltages, which indicates that TiO_2 plane is a basic plane of $\sqrt{5} \times \sqrt{5}$ surface superstructures. The dI/dV images simultaneously taken with topographic images were also obtained in filled states. Comparing our experimental results with the previous works, especially a theoretical study of O-vacancy model [1] and an experimental and theoretical study of Sr adatom model [2], possible structures on $\sqrt{5} \times \sqrt{5}$ surfaces will be discussed.

C1.00150 Molecular-scale Structure of Pentacene at Functionalized Electronic Interfaces , SOON-JOO SEO, Chungbuk National University, GUOWEN PENG, MANOS MAVRIKAKIS, ROSE RUTHER, ROBERT HAMERS, PAUL EVANS, University of Wisconsin-Madison, HEE JAE KANG, Chungbuk National University, GUOWEN PENG AND MANOS MAVRIKAKIS COLLABORATION, ROSE RUTHER AND ROBERT J. HAMERS COLLABORATION, PAUL G. EVANS TEAM, HEE JAE KANG TEAM — A dipolar interlayer can cause dramatic changes in the device characteristics of organic field-effect transistors or photovoltaics. We have conducted a series of experiments in which different molecular linkages are placed between a pentacene thin film and a silicon substrate. Interface modifications with different linkages allow us to predict the nature of tunneling through pentacene on modified Si surfaces with different dipole moment. The molecular-scale structure and the tunneling properties of pentacene thin films on modified Si (001) with nitrobenzene and styrene were examined using scanning tunneling spectroscopy. Electronic interfaces using organic surface dipoles can be used to control the band lineups of a semiconductor at organic/inorganic interfaces. Our results can provide insights into the charge transport characteristics of organic thin films at electronic interfaces.

C1.00151 Chemisorption of Anthracene on Cu(110) , JERONIMO MATOS, ABDELKADER KARA, University of Central Florida — We use density functional theory (PBE) to calculate the adsorption of an Anthracene molecule on Cu(110). Anthracene adsorbs at a height of 2 Å above the surface and has a binding energy of 562 meV/molecule. We also found noticeable changes in the atomic and electronic structures of both the molecule and the substrate. The molecule is bent while the surface atoms experience a buckling. The dz^2 state of the copper atoms that are directly under carbon atoms presents new states near the Fermi level. These effects, in addition to a change in the work function, classify this system as chemisorption. We also determined the barrier for diffusion along the Cu(110) channel to be 77 meV.

C1.00152 A low friction coefficient between graphane coated surfaces , CAN ATACA, Department of Physics, Bilkent University, Ankara, Turkey, 06800, HASAN SAHIN, UNAM-Material Science and Nanotechnology, Bilkent University, Ankara, Turkey, 06800, SALIM CIRACI, Department of Physics, Bilkent University, Ankara, Turkey, 06800; UNAM-Material Science and Nanotechnology, Bilkent University, Ankara, Turkey, 06800 — Using first-principles calculations, we investigate the electronic properties and stability of recently synthesized 2D hydrocarbon in honeycomb structure, namely graphane. Varios charge analysis result that in graphane geometry negatively charged carbon atoms are sandwiched between positively charged hydrogen atoms bound from both sites. In addition high frequency vibration modes associated with C-H bonds are well separated from the rest of the spectrum. The repulsive interaction between two graphane layers due to mainly strong Coulomb interaction serves as if a boundary lubricant and prevents the sliding graphane surfaces from being closer to each other even under high normal forces. As a result, calculated lateral force variation generated during sliding has small magnitude under high constant loading forces. Superlow friction observed earlier between diamondlike carbon-coated surfaces can be understood strong and stiff carbon-carbon and carbon-hydrogen bonds which do not favor energy dissipation.

C1.00153 Tribological Properties of Atmospheric Pressure Plasma Polymerized Silica-like Films , BING HAN, JAMES BOERIO, University of Cincinnati — Thin silica-like films were deposited on ferrotype plate and polycarbonate (PC) substrates with an atmospheric pressure plasma jet using hexamethyldisiloxane (HMDSO) as the precursor. It was found that the thickness and properties of the film were sensitive to the flow rate of the precursor, the deposition distance, and the radio frequency power Residual methyl groups were incorporated into the film when the distance between the nozzle of the plasma jet and the substrate was increased, or when the RF power used in deposition was decreased. This was confirmed by an increase in Si-CH_3 peak intensity in the Fourier transform infrared spectroscopy spectra of the films. The atomic compositions and chemical bonding of HMDSO-air plasma-polymerized SiO_xC_y were analyzed by X-ray photoelectron spectroscopy. Low precursor flow rates produced smoother, more continuous, and more uniform films than high precursor flow rates. Low precursor flow rates produced films with atomic composition of Si:O:C=1:2.37:0.2. The deposited films presented mainly inorganic characteristics without adding oxygen or argon gas to the ionization gas mixture, as is common in the literature. Scratch resistance of the films was measured using a scratch tester with a diamond indenter under progressive load. Post scratch image and surface morphology of the substrate and the film was obtained by scanning electron microscopy and atomic force microscopy.

C1.00154 Diamagnetic Levitation Cantilever System for the Calibration of Normal Force Atomic Force Microscopy Measurements[1] , JAHN TORRES, Brown University/ Naval Undersea Warfare Center, JIN-WOO YI, Korean Institute of Science and Technology, COLIN MURPHY, Naval Undersea Warfare Center, KYUNG-SUK KIM, Brown University — In this presentation we report a novel technique for normal force calibration for Atomic Force Microcopy (AFM) adhesion measurements known as the diamagnetic normal force calibration (D-NFC) system. The levitation produced by the repulsion between a diamagnetic graphite sheet and a set of rare-earth magnets is used in order to produce an oscillation due to an unstable mechanical moment produced by a silicon cantilever supported on the graphite. The measurement of the natural frequency of this oscillation allows for the calculation of the stiffness of the system to three-digit accuracy. The D-NFC response was proven to have a high sensitivity for the structure of water molecules collected on its surface. This in turns allows for the study of the effects of coatings on the structure of surface water.

C1.00155 Modeling of charged particles trajectories in order to optimize the design of a new, higher resolution, Time of flight- Positron Annihilation Induced Auger Electron Spectroscopy (TOF PAES) System[1] , PRASAD JOGLEKAR, L. LIM, SUMAN SATYAL, SUSHANT KALASKAR, K. SHASTRY, ALEX WEISS[2], U T Arlington — Time of Flight Positron Annihilation Induced Auger Electron Spectroscopy (TOF PAES) is a surface analytical technique with high surface selectivity. TOF PAES is used to study elemental composition, surface defects, and various energy loss mechanisms. Positrons incident on the sample surface at low energies can be trapped in an image-potential well just above the surface Prior to annihilation. Consequently it is possible to use positron annihilation related signals to selectively probe the top-most atomic layer. This poster presents the results of modeling of the charge particle beam transport system performed in connection with the optimization of the the design of the new TOF-PAES system currently under construction at U T Arlington. The system will incorporate a 2 m long drift tube in order to achieve better energy resolution than our previous TOF-PAES system design which used a 1 m long drift tube

C1.00156 Coherent x-ray surface scattering applied to Pt (001)[1]

, MICHAEL S. PIERCE, DANIEL HENNESSY, KEE-CHUL CHANG, Materials Science Division, Argonne National Laboratory, VLADIMIR KOMANICKY, Faculty of Science, Safarik University, ALEC SANDY, JOSEPH STRZALKA, Advanced Photon Source, Argonne National Laboratory, HOYDOO YOU, Materials Science Division, Argonne National Laboratory — Scattering using highly coherent light provides information about the very small scale, but over a very large area suitable for an ensemble measurement. We have used coherent x-ray diffraction to study the surfaces Pt (001) single crystal surfaces at high temperature in vacuum and compare them with earlier measurements of Au (001) in similar conditions. Both metals possess a temperature dependent quasi-hexagonal surface reconstruction. The speckled scattering patterns can be quantitatively compared against each other to determine how quickly configuration is changing, even when the macroscopically the system appears in equilibrium. We have been able to obtain measurements of the dynamic temperature dependent surface processes for these two different systems. For Pt (001) we have also directly observed step-flow motion of the terraces, obtaining step-edge velocity as a function of temperature. Our results point to two very different mechanisms at work in lifting the surface reconstruction at high temperature in vacuum.

C1.00157 Ion neutralization as a probe to study electronic dynamics on clean and nanostructured surfaces[1]

, HEE SUK LEE, RYAN O'CONNELL, ANDREW SCHMITZ, JOHN SHAW, HIMADRI CHAKRABORTY, Northwest Missouri State University — Resonant charge transfer in ion-surface collisions is a classic tool to explore the surface electronic structure. Using the Crank-Nicholson propagation [1] we solve the time-dependent Schroedinger equation to simulate electrons' motion during the interaction of a H^- anion with clean, nanostepped, and nanolayered metal surfaces. Ion survival from a clean surface is found to depend adiabatically on the metal band gap, but for the fast (diabatic) ion-speed perpendicular to the surface interactions with image states dominate [2]. For larger distance of ion's closest approach, however, the image interaction intrudes the adiabatic region. For the stepped surfaces, conversely, the survival is found to depend on the ion speed parallel to the surface from super-lattice sub-band effects, resulting in rich structures in the survival probability. Electrons that populate a nanolayered surface, in contrast, are found to modify the Shockley surface state and image states by inducing standing waves in the direction perpendicular to the surface.

C1.00158 Electronic structure of oxygen di-vacancies on the (110) surface of rutile

, WILLIE MADDOX, BRANDEN KAPPES, CHRISTIAN CIOBANU, Department of Engineering, Colorado School of Mines — We report the results of electronic structure calculations for the reduced surface of rutile (110). We have performed density functional theory calculations in the framework Hubbard-corrected generalized gradient approximation (GGA+U) to investigate the electronic signatures of single and di-vacancies on rutile (110) slabs, both neutral and positively charged. We have also carried out Bader charge analysis to evaluate the charge transfer that occurs upon the reduction of the rutile surface. We observe n-type character for the neutral systems and p-type character for the positive slabs. For U=3 eV, we observe mid-gap states for the neutral system, while for U=6 eV, we observe mid-gap states for the positively charged system as well. Bader analysis shows that the atoms associated with mid-gap states are those that experience a larger charge transfer. The dependence of the band gap on the U parameter was also investigated, and the results were compared with experimental observations in the literature for both electronic properties and for structural atomic relaxations.

C1.00159 ABSTRACT WITHDRAWN –

C1.00160 Electronic structure of alkali/Si(111):B semiconducting interfaces

, LAURENT CHAPUT, ANTONIO TEJEDA, CEDRIC TOURNIER-COLLETTA, YANNICK FAGOT-REVURAT, LUIS CARDENAS, BERTRAND KIERREN, DANIEL MALTERRE, IJL, UMR CNRS 7198, Nancy Universite, France, PATRICK LEFEVRE, FRANCOIS BERTRAN, AMINA TALEB-IBRAHIMI, Synchrotron-SOLEIL, Cassiopee Beamline, France — We have evidenced by LEED and STM a novel $2\sqrt{3} \times 2\sqrt{3}$ surface reconstruction for K, Rb and Cs on Si(111):B.[1] The $2\sqrt{3}$ charge ordering occurring mainly in Si dangling bonds has been evidenced by high resolution photoemission measurements on core levels whereas the k-dependent photoemission spectral function agrees with the $2\sqrt{3}$ symmetry establishing a full gap higher than 1 eV.[2] These results will be discussed in the light of ab initio calculations giving evidence for strong atomic distortions associated with a possible full charge ordering in dangling bonds, in connection to a large energy gap,[3] which is compatible with a bi-polaronic scenario.

C1.00161 Scanning Tunneling Spectroscopy Observation of New Type of Resonances on the Dense Pb Overlayer on the Si(111)

, SHIN-MING LU, H.Y. CHOU, Institute of Physics, Academia Sinica, Nankang, Taipei 115, Taiwan, Y.P. CHIU, Department of Physics, National Sun Yat-Sen University, Kaohsiung 804, Taiwan, W.B. SU, P.H. CHU, C.L. JIANG, C.S. CHANG, Institute of Physics, Academia Sinica, Nankang, Taipei 115, Taiwan, H.L. HSIAO, Department of Physics, Tunghai University, Taichung 407, Taiwan, TIEN T. TSONG, Institute of Physics, Academia Sinica, Nankang, Taipei 115, Taiwan — We use scanning tunneling spectroscopy (STS) to investigate the electronic structures of the dense Pb overlayers of 1×1, $\sqrt{7}\times\sqrt{3}$ and stripe incommensurate (SIC) phases grown on the Si(111) surface. Although their atomic structures are all very different, very surprisingly the STS spectra of these three phases show a nearly identical oscillatory feature with two resonance peaks. These resonances are not the common quantum-well states but the energy bands originating from the dominant 1×1 potential in these phases. However, the local electronic states found by STS on the $\sqrt{7}\times\sqrt{3}$ and SIC phase exhibit that the resonances can be affected locally by the superstructures of two phases. It reflects that there exists a weak additional one-dimensional periodic potential on the $\sqrt{7}\times\sqrt{3}$ phase and the SIC phase is of the local variation of the work function.

C1.00162 Effect of substrate strain on the charge dynamics of $Nd_{0.5}Sr_{0.5}MnO_3$ investigated by pump-probe technique , MUNKHBAATAR PUREVDORJ, J.S. KIM, Institute of Photonics and Information Technology, Chonbuk National University, Korea, H.Y. HWANG, Department of Advanced Material Science, University of Tokyo, Japan, K. MYUNG-WHUN, Institute of Photonics and Information Technology, Chonbuk National University, Korea — We present the polarization and time dependent transmittance of $Nd_{0.5}Sr_{0.5}MnO_3$ (NSMO) thin films grown on $SrTiO_3$ (STO) (100) and STO (110) substrates. We used the normal transmission technique and the pump-probe technique for the measurement. While the transmittance of NSMO film on STO (100) is isotropic, the transmittance of NSMO on STO (110) measured with the electric field parallel to [-110] direction (E//[-110]) is larger than that of E//[100]. The time dependent transmittance change of NSMO film on STO (100) shows a sharp increase near the zero time delay and exponential decreases as the time delay between the pump and the probe pulse increases. The transmittance change of NSMO film on STO (110) shows almost the same time dependence. The time dependent transmittance change of NSMO film on STO (100) shows no significant polarization direction dependence, however the magnitude of time dependent transmittance change of NSMO on STO (110) is different depending on the polarization direction. The mechanism of the polarization dependence of transmittance change and the polarization direction independent relaxation will be discussed in terms of the substrate strain and its effect on the charge dynamics.

C1.00163 Angular Distributions and Total Yields of Bi Sputtered by 20 keV He^+, Ne^+ and Ar^+ , NARESH DEOLI, LUCAS PHINNEY, JOSE PACHECO, DUNCAN WEATHERS, University of North Texas, IBMAL TEAM — The angular distributions of neutral atoms sputtered from the surface of solid Bi by normally incident 20 keV He^+, Ne^+ and Ar^+ ions have been measured. The sputtered atoms were collected on pure aluminum foils under ultrahigh vacuum conditions, and the collector foils were subsequently analyzed using heavy ion Rutherford backscattering spectroscopy. The angular distributions obtained were integrated to determine the total sputtering yields of Bi for the different incident ions. Details of the measurements and data analysis are presented.

C1.00164 Segregation of impurities at γ' (L12) / γ (fcc) interfaces in a Ni-based superalloy , DE NYAGO TAFEN, MICHAEL GAO, National Energy Technology Laboratory, 1450 Queen Ave SW, Albany, OR 97321, USA; URS Corporation, P.O. Box 1959, Albany, OR 97321, USA — One of the most technologically advanced energy conversion devices is the gas turbine used in aerospace jet engines and gas- fired land-based turbines for electricity generation, fabricated from Ni-based superalloys. However, these materials lack of long- term mechanical and microstructure stability, which is largely due to an excessive coarsening of γ' that can cause substantial loss of creep resistance and mechanical instability at high temperatures. Theoretical prediction of the creep rate of these important compounds is very imperative, but yet is extremely challenging. Interfacial energy is one of the most important factors that control the coarsening kinetics of these important phases. It indirectly determines the creep resistance of the alloy through the coarsening rate of the strengthening precipitate phase. In this talk, we will present the results of various γ'/γ interfaces of a Ni-based superalloy obtained using DFT calculations. Then, we will discuss the segregation of impurities at these interfaces. Minor alloying elements in superalloys can alter the interfacial energy between γ and γ', and change the strength behavior of the alloy. Alloying elements or impurity species can segregate to interfaces. A favorable segregation would result in enhancing the interfacial cohesion and thus lower the energy.

C1.00165 METALS —

C1.00166 Structural properties of nanometric HfN/VN superlattices[1] , P. PRIETO, Excellence Center for Novel Materials, M. VILLAREAL, C. ESCOBAR, J.C. CAICEDO, G. CABRERA, Thin Film Group, Universidad del Valle, L. YATE, J. ESTEVE, A. LOUSA, Department de Fisica Aplicada i optica, Universitat de Barcelona — HfN and VN systems have broadly been used as protective hard and anticorrosive coatings. [HfN/VN]n multilayered were deposited on silicon substrates by two target-r.f. magnetron sputtering with alternatively changing the sputtering plasma composition between pure Hf and V elements under a reactive mixture Ar/N_2. HfN/VN bilayer period varied from nanometric range (15 nm) to higher nanometric range (600 nm) values. Structural, morphological and stoichiometric of the coatings were analyzed by high angle and low-angle X-ray diffraction, X-ray photo electron spectroscopy (XPS), secondary ion mass spectrometry (SIMS), atomic force microscopy (AFM) and cross sectional transmission electron microscopy (TEM). We determined multilayer period, Λ, and individual layer thicknesses. We found a cube-on-cube epitaxial growth structure with an epitaxial relationship between layers inside each columnar crystallite given by $(111)[100]_{HfN}//(200)[100]_{VN}$.

C1.00167 Synthesis and Characterization of Multifunctional Epitaxial Metal-oxide Films[1] , JIE XIONG, JUNYI ZHAI, GUIFU ZOU, Los Alamos National Laboratory, HAIYAN WANG, Texas A&M University, LI YAN, MUJIN ZHUO, YINGYING ZHANG, Los Alamos National Laboratory, BOWAN TAO, YANRONG LI, University of Electronic Science and Technology of China, J.L. MACMANUS-DRISCOLL, University of Cambridge, QUANXI JIA, Los Alamos National Laboratory — Transition metal-oxides have attracted great attention due to their versatile properties. Multilayers, and/or artificial superlattices, are especially interesting since these architectures usually exhibit unique physical properties in comparison with single phase thin films. Furthermore, the lattice strains and the coupling in the multilayered systems can strongly affect the films' growth and their physical properties. We have grown and characterized different multilayered metal-oxide thin films using laser molecular beam epitaxy (MBE). Specifically, we have prepared $[(BiFeO_3)_n/(La_{0.7}Sr_{0.3}MnO_3)_n]_m$ and $[(BiFeO_3)_n/(BiMnO_3)_n]_m$ superlattices and strained $BiFeO_3$ $(BFO)_{0.5}$: $BiMnO_3$ $(BMO)_{0.5}$ films. We have systematically investigated the strain states on the magnetic properties of these multilayer films.

[1]This work was supported by the U.S. Department of Energy and the Center for Integrated Nanotechnologies. J. X. acknowledges the support from National Science Foundation of China under Grant Nos. 50902017.

C1.00168 Origin of interfacial gap states in Ga_2O_3 layer grown on GaAs surface and interface passivation by F and Gd , WEICHAO WANG, K. XIONG, Department of Materials Science & Engineering, The University of Texas at Dallas, ROBERT M. WALLACE, KYEONGJAE CHO, Department of Materials Science & Engineering and Department of Physics, The University of Texas at Dallas — III-V compound semiconductors are potential candidates to replace Si as the channel of future high performance n-MOSFETs. However, the poor III-V/dielectric interface quality leads to low performance of device operations. Prior to any high-k deposition on III-V, a passivated III-V surface could help to obtain a high quality high-k/III-V interface. We examine the native oxides of Ga_2O_3 on GaAs with density functional theory to determine the origin of gap states and propose possible ways to passivate the interface. Ga_2O_3 molecular species is gradually added in first principles molecular dynamics until one monolayer formed on the top of GaAs at 700 K within 3 ps. During the growth process, O atoms tend to diffuse into GaAs, and Ga-Ga dimer forms as well. The interface states originate from the Ga dangling bonds, Ga-Ga dimers and under-coordinated Ga suboxides Based on the understanding of the origin of the gap states, F and Gd are proposed to remove the gap states.

C1.00169 Crystal Growth of MoO_2 and $K_xMoO_{2-\delta}$[1] , B.S. DE LIMA, C.A.M. DOS SANTOS, L.M.S. ALVES, S.S. BENAION, A.D. BORTOLOZO, Departamento de Engenharia de Materiais - Escola de Engenharia de Lorena - USP, M.R. ANDREETA, Instituto de Fisica de São Carlos - USP, J.J. NEUMEIER, Department of Physics - Montana State University — During the last years our group has searched for new quasi-one- dimensional (1D) conductors, which led to the discovery of $K_xMoO_{2-\delta}$. The electrical resistivity of this compound is well described by a power law in temperature [1]. In this presentation, progress on the crystal growth of $K_xMoO_{2-\delta}$ will be discussed. Crystal growth of the parent compound MoO_2 utilizes chemical vapor transport (CVT) with iodine as transport agent. Crystal growth of $K_xMoO_{2-\delta}$ by CVT was carried out using high purity K_2MoO_4, MoO_3, and Mo powders which were mixed in appropriate amounts ($0 \leq x \leq 0.25$) and sealed with I_2 in quartz tubes, followed by heat treatment in temperature gradients from 750 to 950^{o}C for 100 h. The crystals were characterized by X-ray diffraction, scanning electron microscope (SEM), Raman spectroscopy, electrical resistance and magnetization measurements.

C1.00170 Induced Magnetic Behavior and Anomalous X-ray Fluorescence Spectra of Thermally Tailored Copper , PATRICK BRADLEY, CLAIRE CHANENCHUK, CHRIS NAGEL, Continuum Energy Technologies — When a high purity (>99.98 wt%) copper ingot was melted, subjected to high temperature thermal cycling including rapid electromagnetic field oscillation (thermally tailored), the resultant solidified metal exhibited unexpected magnetic regions with unique spectroscopic behavior. A high-resolution magnetic microscope was used to provide current density imaging with resultant surface mapping of magnetic fields of the magnetically active regions on the copper ingot. Energy-dispersive, X-ray fluorescence (XRF) analysis of the magnetic regions exhibited energy emissions inconsistent with the known starting composition of the material. An analysis of the magnetic field and XRF data shows them both to be a result of the tailoring process and eliminates the possibility of causation by impurities accumulated during the process.

C1.00171 Crystal structure and electrical properties of the $Bi_{2-y}Sr_yIr_2O_7$ α-pyrochlore solid solution , CARLOS COSIO-CASTANEDA, GUSTAVO TAVIZON, Facultad de Quimica, PABLO DE LA MORA, Facultad de Ciencias, UNAM, FRANCISCO MORALES, Instituto de Materiales — In this work we report the synthesis and crystal structure of the $Bi_{2-y}Sr_yIr_2O_7$. From structural Rietveld refinements we show that in this system the local geometry of the IrO_6 passes from a trigonal antiprism (y<0.4); a regular octahedron (y=0.5), reaching a new trigonal antiprism at the end compositions (y>0.5). Experimentally, this is a metallic system with a conductivity that decreases as a function of the Sr content in the (10-300 K) low temperature range. By means of electronic structure calculations, using WIEN2k to study $Bi_2Ir_2O_7$ and two hypothetical compounds, $BiSrIr_2O_7$ and h-$BiSrIr_2O_7$, we show that a) the main contribution to conductivity come from the shift of the oxygen towards the Ir atoms; b) the lattice imperfections (random occupation of Sr) and lattice vibrations are responsible for the drop of the electrical conductivity, and c) the IrO_6 local geometry (and crystal field configuration, t_{2g}^5 $e_g^0/e_g^4a_{1g}^1b_{2g}b_{1g}$ change), this last one does not seem to affect the electrical conductivity.

C1.00172 Effect of Temperature, Pressure and Precursor flux ratios on InSb Thin film Growth: Morphology and Properties , SAMUEL MENSAH, ALEXANDER VOGEL, JOERG WITTEMANN, JOHANNES DE BOOR, VOLKER SCMHIDT, Max-Planck Institute of Microstructure Physics — We have investigated the growth of InSb thin films on InAs and GaAs substrates by Chemical Beam Epitaxy (CBE). Raman spectroscopy measurements show that the optical properties of the grown layers is not greatly affected even when varying the growth conditions over a wide range (varying the V/III flux ration between 1 and 10, growth temperature between 390-480°C). The lattice mismatch between the layers and substrates, results in regions of no growth during the deposition of InSb layers. To circumvent this problem, the growth process is preceded by a 10 mins exposure of the substrates to TMIn. This step eliminates the regions of no growth. Our results show that at constant pressure, the growth rate decreases with increasing temperature and with increasing V/III flux ratio. A much slower response was observed for increasing antimony partial pressure. The lattice mismatch between the layer and substrate give rise to stacking fault and twins. A decrease in particle size from 34.89 to 9.95nm was observed for increasing flux ratio and an increase from11.31 to 32.68nm for increasing temperature. Evidence of Raman spectroscopy results confirms the crystalline nature of the deposited films. Details of our results will be presented at the meeting.

C1.00173 Growth of thin, transparent and high quality phase pure hBN films , MUHAMMAD SAJJAD, XIOAN ZHANG, PETER FENG, University of Puerto Rico — A simple approach using pulse laser deposition technique was made in order to obtain multi layers transparent hexagonal boron nitride films at low substrate temperature (700 °C) with iron nano-particles as catalyst. The catalyst helped in creating reactive species of boron and nitrogen to react quickly and formed h-BN base layer. The formation of film layers were studied systematically with increasing amount of catalyst keeping same experimental conditions and steps. Transparent and ultra thin base layer was obtained using small amount of catalyst. However, with increasing amount of catalyst, few more layers were formed on the base layer which affected the transparency of the films. Therefore, it was revealed that with optimized amount of catalyst helped in nucleating ultra thin transparent layers of BN with clear variation in atomic wall layers, sharp edge of the film, shape and surface smoothness. Scanning Electron Microscopy was used to analyze the surface images of hBN thin films whereas Energy Dispersive X-Ray spectroscopy (EDS) verified dominance of boron and nitrogen in the structure. The crystalline structure of the films was analyzed with Raman spectroscopy and XRD technique.

C1.00174 Magnetic and thermodynamic properties of Americium-II: An *Ab Initio* Study[1] , JIANGUANG WANG, LI MA, ASOK RAY, University of Texas at Arlington — Hybrid density functional theory based method has been used to study the structural, magnetic, electronic, and thermodynamic properties of Americium-II. Non-magnetic, ferromagnetic (FM), and anti-ferromagnetic (AFM) configurations without and with spin-orbit coupling (SOC) have been considered. The experimental NM ground state configuration is indeed obtained for Am-II at a level of 40% HF exchange with SOC and the computed structural properties and electronic density of states are in good agreement with experimental observations. The importance of SOC is found to be significant. The phonon related properties of Am-II are presented for the NM ground state configuration and the computed heat capacity and entropy are in good agreement with the experimental measurements. The lattice constant, bulk modulus, heat capacity, and entropy of Am-II are predicted to be 9.44 a.u., 21.7 GPa, 24.3 $JK^{-1}mol^{-1}$, and 55.7 $JK^{-1}mol^{-1}$, respectively.

[1]This work is partially supported by the Welch Foundation, Houston, Texas (Grant No. Y-1525) and by the Department of Energy.

C1.00175 Characterization of Doped $CeCoIn_5$, A.R. TREAT, Boston College, J.C. COOLEY, Los Alamos National Laboratory, C.P. OPEIL, Boston College — Department of Physics, Boston College, Chestnut Hill, Massachusetts 02467. Los Alamos National Laboratory, Los Alamos, New Mexico 87545. $CeCoIn_5$ is an unconventional, d-wave, heavy fermion superconductor with a critical temperature of ∼2.3K. The physical properties of doped samples of $CeCo_{1-x}M_xIn_5$, where M is Fe, Cr, Rh, Ru, Ir, Mn, Ni, V, or Cu for $x \leq 0.03$, are characterized. Resistivity, magnetoresistance, and magnetization are measured in a temperature range 5 - 300K and magnetic field up to 9 Tesla; the magnetization is measured using a capacitive cantilever magnetometer. The effect of the dopants on resistivity and magnetization, with regard to percentage x present in the sample, provides valuable insight into the character of the parent material $CeCoIn_5$. Implications of magnetic, diamagnetic, and non-magnetic doping of $CeCoIn_5$ will be discussed.

C1.00176 A Universal Relation between Heat Conduction and Diffusion[1]

, SHA LIU, BAOWEN LI, National University of Singapore — We rigorously prove a useful equality relating the heat current autocorrelation function and the mean square displacement of the energy diffusion. From this equality, we are able to recover the existing theories for normal diffusion and normal heat conduction. Moreover, we are also able to obtain a connection between anomalous diffusion and anomalous heat conduction. We are results are applicable to all isotropic systems with any dimension.

[1]This work is supported by the Grants No. W-144-000-222-646 of NUS

C1.00177 Study of the angular-dependence of the L-alpha and L-beta radiation produced by 0-15 kev photons incident on Au targets of various thicknesses

, SEBASTIAN REQUENA, SCOTT WILLIAMS, Angelo State University — We report the results of experiments involving the L-alpha and L-beta x-ray lines produced by 0-15 keV bremsstrahlung incident on gold targets of various thicknesses at forward-scattered angles ranging from 20 to 160 degrees. Previous reports [1, 2] have shown the L-beta peaks to be isotropic and the L-alpha peaks to be anisotropic due to the symmetry/asymmetry associated with the orbital being filled during the transition. The relative intensities are compared to the predictions of the Monte Carlo code, PENELOPE.

C1.00178 Hexagonal motifs on the Ir(100) surface reconstructions from a first-principles study

, WAN-SHENG SU, National Center for High-Performance Computing, Tainan 741, Taiwan, FENG-CHUAN CHUANG, Department of Physics, National Sun Yat-Sen University, Kaohsiung 804, Taiwan, KEN-MING LIN, TSAN-CHUEN LEUNG, Department of Physics, National Chung Cheng University, Chia-Yi 621, Taiwan — The hexagonal motifs of the Ir(100) surface overlayer are examined by using first-principles calculations. The studied hexagonal motifs are formed on the Ir(100) surface overlayer with (5x1), (8x1), (12x1), and (14x1) periodicities. Our results showed that the unstrained (5x1) phase is the most stable phase, which is consistent with not only previous theoretical calculations but also experimental findings. Further analysis on the strain-induced phase transition among various hexagonal reconstructions is presented. Such a phenomenon can be further qualitatively elucidated by analyzing the computed average standard deviation of angles.

C1.00179 An *Ab Initio* Study of FCC $Pu_{1-x}Ga_x$[1]

, KINJAL GANDHA, ASOK RAY, Department of Physics, University of Texas at Arlington — As is known, the addition of a few atomic percent of Ga stabilizes the fcc δ – phase of Pu at room temperature. In this work, conventional and hybrid density functional theory have been used to study the electronic, geometric, and magnetic structure properties of $Pu_{1-X}Ga_x$with varying Ga concentrations in the fcc δ phase. The calculations have been performed using the all-electron full-potential linearized augmented plane wave plus local orbitals basis method and the *WIEN2k* software. Each compound has been studied at the non-magnetic, ferromagnetic, and anti-ferromagnetic configurations with and without spin-orbit coupling (SOC) and full geometry optimizations. The ground state structures are found to be anti-ferromagnetic with a contraction of the lattice constants from pure δ-Pu. The obtained lattice parameters are in satisfactory agreement with experimental data.

C1.00180 Spectroscopic ellipsometry of NTO/ultrathin Cu/NTO films

, JUN WOO PARK, HYUNG KEUN JANG, HOSUK LEE, HOSUN LEE, JUN-HYUK PARK, HAN-KI KIM, Kyung Hee University, BO HYUN KONG, HYUNG KOUN CHO, Sungkyunkwan University — NTO/Cu/NTO/glass thin films were grown using sputtering deposition. The thickness of the Cu film (t) varied between 1.5 nm and 50 nm. The ellipsometric angles (Ψ, Δ) of the NTO/Cu/NTO/glass thin films were measured by using spectroscopic ellipsometry. The thicknesses and dielectric functions of the Cu films in the NTO/Cu/NTO/glass were estimated by using a multi-layer model analysis with the parametric optical constant and Drude models. Transmission electron microscopy measurements showed that the Cu layers evolved from aggregates of Cu nanoparticles to coalesced Cu thin films as the Cu film thickness increased. According to sheet resistance data, the Cu films thinner than 8 nm were aggregations of Cu nanoparticles that were not well-connected and the Cu films thicker than 8 nm were above the percolation threshold. From the Drude model, the plasmon frequency (ω_p) and the electron relaxation time (τ) were estimated and were found to increase with increasing film thickness. We obtained the second derivatives of the dielectric function spectra that were composed of several peaks near 1.5, 2.1, 2.5, 3.5, and 4.3 eV, and attributed to interband transitions. The peak energies (except 1.5 eV) matched to the band structure calculations found in the literature.

C1.00181 Magnetic properties of $Mn_{11}Si_{19}$ and Mn_4Si_7 in their bulk and powdery states

, KIYOTAKA HAMMURA, Hitachi Cambridge Laboratory, HARUHIKO UDONO, TOMOSUKE AONO, Ibaraki University, ISAO OHSUGI, Salesio Polytechnic, ELISA DE RANIERI, Hitachi Cambridge Laboratory, KEN-ICHI YAJIMA, YUSUKE UJIIE, Ibaraki University — The purpose of this paper is to determine by experiment whether $Mn_{11}Si_{19}$ and Mn_4Si_7 in their bulk and powdery states have a finite magnetic moment or not. High quality bulk samples for both were prepared using the temperature gradient solution growth method. Powery samples for both were prepared by pounding bulk crystals in a mortar. Magnetisation measurements were carried out using both SQUID system and Kerr rotation system. SQUID measurements revealed that $Mn_{11}Si_{19}$ has finite magnetism while Mn_4Si_7 does not in their bulk states. It was also confirmed that Mn_4Si_7 became magnetic and $Mn_{11}Si_{19}$ exhibited a distinctive hysteresis, in their powdery state. The enhancement of magnetism in their powery states implied that the surface of the samples was to a great extent linked to its magnetism.

C1.00182 Polarization-dependent optical excitations in AB-stacked graphite

, CHIH-WEI CHIU, YUAN-CHENG HUANG, FENG-LIN SHYU, MING-FA LIN — The band structure of AB-stacked graphite exhibits two pairs of parabolic bands, where the band-edge states induce the peaks and shoulders in the density of states and in the joint density of states (JDOS). The dipole matrix element M^{cv} plays an important role in the relationship between the spectral function A(ω) and JDOS. It is strongly dependent on the polarization directions $\hat{\mathbf{E}}$ of the laser beams, showing a anisotropic property. The optical excitations do not fully reflect the special structures of JDOS. For $\hat{\mathbf{E}}$ on the graphene plane, A(ω)$'$s are isotropic and include one sharp peak and some shoulders. As for $\hat{\mathbf{E}}$ along the stacking direction, A(ω) is much weaker, and only shows a broadened peak. The spectra contrast sharply with those of AA-stacked graphite.

C1.00183 Correlation effect investigations on the Magneto-optical Kerr Spectra of Co-based Heusler alloys from first principles[1]

, MIYOUNG KIM, Division of Energy System Research, Ajou University, HANJO LIM, JAE IL LEE, Dept of Physics, Inha University — Here, we report our *ab-initio* calculational results on the electronic structures and magneto-optical (MO) properties of the ferromagnetic Co_2MnX full Heusler alloys. Employing the +U corrections for the transition metal $3d$ bands in addition to the local density approximation (LDA), we investigate the correlation effect on the MO spectra in polar geometry as well as the detailed electronic structures using FLAPW [1] method. Results show that the correlation effect results in a blue-shift of the peak positions and large enhancement of the low energy MO spectra, which are attributed to the increased t_{2g}-e_g splitting of spin minority Co and Mn $d-$bands indicating the suppression of diagonal elements of optical conductivity at energy region of 1$\sim$2 eV where the interband transitions are forbidden.

[1]This work is supported by Korean Research Foundation Grant by MOEHRD (KRF 2007-412-J04001) and also by Basic Science Research Program through the National Research Foundation of Korea (NRF-2010-0005387).

C1.00184 Theoretical Study of tip apex electronic structure in Scanning Tunneling Microscope[1]

, HEESUNG CHOI, MIN HUANG, Department of Materials Science & Engineering and Department of Physics, The University of Texas at Dallas, JOHN RANDALL, Zyvex Lab, KYEONGJAE CHO, Department of Materials Science & Engineering and Department of Physics, The University of Texas at Dallas — Scanning Tunneling Microscope (STM) has been widely used to explore diverse surface properties with an atomic resolution, and STM tip has played a critical role in controlling surface structures. However, detailed information of atomic and electronic structure of STM tip and the fundamental understanding of STM images are still incomplete. Therefore, it is important to develop a comprehensive understanding of the electronic structure of STM tip. We have studied the atomic and electronic structures of STM tip with various transition metals (TMs) by DFT method. The d-electrons of TM tip apex atoms show different orbital states near the Fermi level. We will present comprehensive data of STM tips from our DFT calculation. Verified quantification of the tip electronic structures will lead to fundamental understanding of STM tip structure-property relationship. This work is supported by the DARPA TBN Program and the Texas ETF.

C1.00185 Exchange constants and spin waves of MnV_2O_4 from first principles DFT calculations

, RAVINDRA NANGUNERI, SERGEY SAVRASOV, University of California, Davis — We present results of DFT calculations of exchange constants of the magnetic spinel MnV_2O_4. The starting point is the one-particle eigenfunctions of the Kohn-Sham auxiliary Hamiltonian as a function of the self-consistent, converged charge density. Using linear response and perturbation theory, the exchange constants between the magnetic ions Mn and V are calculated in both the collinear and non-collinear, orbital-ordered phases of the spinel. The collinear exchanges have exchange constants proportional to the unit matrix, which means they are isotropic. On the other hand, the non-collinear exchanges have unequal diagonal elements and in addition have off-diagonal elements, revealing anisotropic magnetic interactions. The anisotropy is traced to the orbital-order and non-collinear spin structure of the low-temperature ground-state. We find that the interactions between the V atoms can sometimes be anti-ferromagnetic. The V atoms are located at the vertices of a corner-sharing tetrahedral lattice, commonly known as a pyrochlore lattice. AFM interactions on such a lattice are geometrically frustrated because all pair-wise bond energies cannot be simultaneously minimized with a classical spin configuration. It has been experimentally found that as the temperature is lowered, MnV_2O_4 undergoes a transition from a paramagnet with a cubic symmetry structure phase to a ferrimagnetic with cubic symmetry phase at 56 K.

C1.00186 Comparative Studies of Constitutive properties of Nanocrystalline and Bulk Iron During Compressive Deformation

, XIAOHUI YU, JIANZHONG ZHANG, LIPING WANG, YUSHENG ZHAO — We present a comparative study of mechanical properties of bcc nano-crystalline iron and microncrystalline iron by in-situ high-pressure synchrotron x-ray diffraction under tri-axial compression. For nano-Fe with a starting high dislocation density of 10^{16} m^{-2}, the peak broadening is almost reversible upon unloading from 8.6 GPa to ambient pressure, indicating that no additional dislocations are built up during compressive deformation inside grains, at grain boundaries or twin boundaries. Furthermore, an orientation dependent surface strain is found to be stored in the surface layer of the bcc nano Fe, which is in agreement with the core-shell model of the nano crystals. For micron-Fe, a significant and continuous peak sharpening and the associated work softening were observed after the sample is yielded at pressures above 2.0 GPa, which can be presumably attributed to a pressure-induced dislocation annihilation. This finding/interpretation supports the hypothesis that the annihilation of dislocations is one of the dominant mechanisms underlying the plastic energy dissipation. The determined yield strength of 2.0 GPa for nano-Fe is more than 15 times higher than that for micron-Fe (0.13 GPa), indicating that the nano scale grain-size reduction is a substantially more effective strengthening mechanism than the conventional carbon infusion in iron.

C1.00187 Density functional study of the mechanical properties in single-layered graphene sheet[1]

, JORGE TAPIA, FRANCIS AVILES, RICARDO PEON, FI-UADY, GABRIEL CANTO, CICORR-UAC, MMS-NM TEAM — By means of the density functional theory, we studied the structural and mechanical properties (the Young's modulus, shear modulus and Poisson's ratio) of single-layered graphene sheets (SLGS). The calculations were performed with a linear combination of atomic orbitals method using pseudopotentials and the generalized gradient approximation for the exchange-correlation potential. The uniaxial stress is applied along the one preferential direction for the range of $\pm$10% in the unitary deformation. We found that the bond lengths between carbon atoms in SLGS are larger than the experimental value of graphite and the mechanical properties showed good agreements with the data available in the literature.

[1]This research was supported by SEP under Grants: PROMEP/103.5/07/2595, PROMEP/103.5/08/2971 and CONACYT under Grants: No. 82497 and No. 60534.

C1.00188 The morphological evolution and migration of inclusions in thin-film interconnects under electric loading

, YINFENG LI, Department of Engineering Mechanics, Shanghai Jiaotong University and Division of Engineering, Brown University, XI WANG, ZHONGHUA LI, Department of Engineering Mechanics, Shanghai Jiaotong University — The paper reports the result of an investigation into electromigration-driven morphological evolution of inclusions in finite scale thin-film interconnects using a phase field method. In examples, two types of inclusion defect are simulated and discussed. The results show that the morphological evolution and migration of inclusion is proportional to the electric field strength applied on thin-film interconnects. It is also seen from the result that the inclusion with anisotropic diffusion interface will move faster than one with isotropic interface under the identical electric field, and the one with anisotropic diffusion interface may evolves into an irregular shape with protuberance.

C1.00189 Calculation of the Peierls barrier of screw dislocations in bcc metals and its dependence on stress

, ROMAN GROGER, Institute of Physics of Materials, Academy of Sciences of the Czech Republic, VACLAV VITEK, Department of Materials Science and Engineering, University of Pennsylvania — Plastic deformation of bcc metals at low temperatures is governed by thermally activated glide of $1/2\langle 111\rangle$ screw dislocations over Peierls barriers. Thermodynamic models of the dislocation glide depend on the shape of the Peierls barrier and its changes under stress. Atomistic simulations provide only the maximum slope of the Peierls barrier and, therefore, its overall shape as well as the path of the dislocation are generally unknown. We introduce a new approach by which the Peierls barrier and its changes under stress can be calculated if a suitable set of constraints is imposed to prevent the dislocation from falling into the nearest potential minima. The state of the system at any point along the path is described by the position of the intersection of the dislocation with the perpendicular $\{111\}$ plane. Hence, both the Peierls barrier and the transition path are obtained directly. This is a clear advantage over the currently used approach, where one calculates the path of the system of N atoms through the space of $3N$ degrees of freedom. We compare the results of these two approaches by employing the Finnis-Sinclair potential for tantalum.

C1.00190 Hydrogen Segregation in Crystalline Palladium and Effects on Mechanical Properties

, HIEU PHAM, AMINE BENZERGA, TAHIR CAGIN, Texas A&M University — Calculations of tensile strength and tensile modulus were carried out to investigate the effects of hydrogen interactions, diffusion and segregations in palladium single crystal, high-vacancy crystal and bicrystal, by using the embedded atom method. Elevated temperature, hydrogen absorption and defects such as vacancy and grain boundary (GB) individually induce a loss in mechanical strength of palladium in a monotonous manner. The hydrogen-induced mechanical degradation was noticed at the grain boundary, as well as in bulk. The failure induced by hydrogen in palladium up to x_H=0.1 is plastic rather than brittle, even around grain boundary region, by formation of dislocations. At high H absorption, the global hydrogen concentration is a dominant factor over crystal defects. However, a high-angle grain boundary such as $\sum$5 (2 1 0) provides a great driving force for diffusion and tendency for physical trapping of hydrogen. Therefore, the existence of grain boundary makes materials more susceptible and easily exposed to high hydrogen absorption and segregation. Also, our simulation shows that hydrogen maintains the highest localization at GB in the vicinity of ambient temperatures; and this finding coordinates with experimental observation that hydrogen embrittlement are generally observed at room temperatures.

C1.00191 Atomic analyzis and photocurrent studies of isolated sub-100 nm diameter silicon nanowires

, DIDIER STIEVENARD, CNRS - ISEN, TAO XU, ISEN, BRUNO GRANDIDIER, CNRS - ISEN, YANNICK LAMBERT, ISEN, CHRISTOPHE KREMINSKY, CNRS - ISEN, ABDELLATIF AKJOUJ, YAN PENNEC, BAHRAM DJAFARI-ROUHANI, Universite de Lille 1, WANGHUA CHEN, RODRIGUE LARDE, EMMANUEL CADEL, PHILIPPE PAREIGE, CNRS INSA Universite de Rouen, PHYSICS GROUP TEAM, PHYSICS OF MATERIALS GROUP TEAM — n-doped Si NWs were synthesized by the vapor-liquid-solid mechanism using the chemical vapor deposition (CVD) technique.The nanowires were grown to a nominal length of 10 μm with a diameter ranging typically from 60 to 110 nm. Atom Probe Tomography analyzes evidence a gradient of concentration of the phosphorous atom dopants, inducing a built-in potential accros the nanowires. Photocurrent on isolated nanowires was performed with a monochromator source. Depending on the light energy and on the nanowire diameters, we measure various absorption thresholds. Calculations have been performed on a periodic array of wires of varying diameters and with different periodicity by using a Finite Difference Time Domain (FDTD) method. The results evidence a clear dependence of the optical absorption with the nanowire diameters. This work was supported by DGA REI contract N°2008.34.0031.

C1.00192 Raman Study of the Verwey Transition in Magnetite (Fe_3O_4) at High Pressure and Low Temperature: Effect of Aluminum Doping

, Z. SHIRSHIKOVA, L. GASPAROV, Department of Physics, University of North Florida, V. STRUZHKIN, A. GAVRILIUK, Geophysical Laboratory, Carnegie Institution of Washington, H. BERGER, EPFL, CH-1015 Lausanne, Switzerland — Raman spectra of pure and doped magnetite provide a set of markers allowing one to study how the Verwey transition in magnetite changes with the change of pressure. At ambient pressure Verwey transition temperature, Tv, of the single crystals of magnetite, Fe3O4, is determined to be 123K. High-pressure experiment indicates strong dependence of the change of pressure vs. change in the Verwey transition temperature on the amount of impurities: for pure Fe_3O_4 the change is -0.2 GPa/K; for doped iron, $Fe_{2.98}Al_{0.02}O_4$, the change is -0.09 GPa/K. Aluminum-doped magnetite ($Fe_{2.98}Al_{0.02}O_4$) where Al substitutes Fe^{+2} and Fe^{+3} atoms, represents a 2% aluminum doping, which shifts the Verwey transition temperature to T_v=118.5K. The rate with which the Verwey temperature decreases with pressure is further discussed based on the molar specific heat measurements.

C1.00193 INSTRUMENTATION AND MEASUREMENTS –

C1.00194 Design and Construction of a Radio Telescope for Undergraduate Research[1]

, CHRISTOPHER STATHIS, Ithaca College — Radio telescopes provide a practical and economical alternative to optical observatories for astrophysics research and education at primarily undergraduate physics and astronomy institutions. Ithaca College is in the testing phase of development for a low cost, flexible frequency band radio telescope which I have developed as the research component of my undergraduate thesis. I have constructed a three-stage low noise superheterodyne radiometer on custom printed circuit boards for signal detection, which is mounted on a 3 meter parabolic antenna. Data collection and signal processing is achieved using custom software written in MATLAB. We are currently performing preliminary drift continuum observations of the Sun and Milky Way at Ku band frequencies. We expect that the receiver can also be easily adapted to measure spectral emission of neutral hydrogen and OH masers at L band. I present my design methods for the radiometer and printed circuit boards, including measured noise characteristics and SPICE simulations, as well as an overview of applied signal processing methods and a discussion of observable celestial sources.

[1]Dr. Bruce G. Thompson and Dr. Matthew Price, Research Advisors, Ithaca College

C1.00195 Synthesis and characterization of ZnO nanostructures for sensor application[1]

, XIAOYAN PENG, JIN CHU, University of Puerto Rico, BOQIAN YANG, University of Massachusettes, PETER FENG, University of Puerto Rico, FENG TEAM — ZnO nanostructures including nanoparticles (diameter about 50nm), nanorods (diameter about 150 nm and length about 1-1.5μm) and nanoparticles (diameter $\sim$ 20 nm) were prepared onto Si (100) substrates using both r.f sputtering and PLD technique, respectively. Thermal annealing was performed at 800 ^{o}C in atmosphere for 2 hours to improve the qualities of ZnO crystalline structures. X-ray diffraction, electron scanning microscope and Raman scattering have been used to characterize all these nanostructured samples After synthesis and initial characterizations, the ZnO nanostructure-based field effect transistor sensors have been designed, fabricated, and tested. High sensitivity (few PPM), quick time response (less than 1 second) of the newly designed sensors have been achieved. Experimental data indicate that the sensitivity of the sensor highly relies on the operating temperature.

[1]This work is partially supported by NSF-DMR (0706147)

C1.00196 Doped and functionalized ZnO nano films and their applications for gas sensors[1]

JIN CHU, XIAOYAN PENG, PETER FENG, University of Puerto Rico, FENG TEAM — We demonstrate efficient gas sensors using Cu-doped ZnO nanowires and Li atoms-modification of ZnO nanorods. Various Cu-doped ZnO nanowires were synthesized on Si substrates by plasma sputtering at 300 °C with deposition duration of 30 minutes, while Li-coated ZnO nanorods were prepared by coating Li on the surface of the as-grown nanorods. Raman and EDX data indicated that the obtained ZnO nanowires and nanorods have wurtzite structure with Cu-doping concentration of 1 wt.% and ZnO nanorods with Li-coated concentration of 3 wt.%, respectively The sensing properties were examined by being exposed to H_2, N_2 and CH_4 gases with a home-made system that can facilitate the detection of the resistance change and the control of gas flow as well as temperature. The sensitivities of both samples increased with the operating temperature from RT to 200 °C and signal intensity of the sensor increased with gas concentration at each type of gas. Experimental data indicates that both types of samples-sensors showed highly sensitive to H_2 and selectivity against N_2 and CH_4. However, the response time for Li-coated ZnO nanorods-based sensor is less than 1 second, much quicker than that for Cu-doped ZnO nanowires-based sensors.

[1]This work is partially supported by NSF-DMR(0706147)

C1.00197 First-principles study of γ-ray detector materials : heavy alkali metal compounds[1]

HOSUB JIN, JUNG-HWAN SONG, ARTHUR J. FREEMAN, BRUCE W. WESSELS, MERCOURI G. KANATZIDIS, Northwestern University — In an effort to find good candidate materials for γ-ray detectors, alkali metal based chalcogenide semiconductors containing heavy elements were investigated. We performed ab- initio density functional theory calculations using the highly precise full-potential linearized augmented plane wave (FLAPW) method[2] to estimate their electronic characteristics. The state-of-the-art screened-exchange LDA scheme was adopted to correct the underestimation of the band gap in the LDA method. Several candidate materials for γ- ray detectors such as $Cs_2Cd_3Te_4$ and $Cs_2Hg_6S_7$ were suggested based on the electronic properties like band gaps, effective masses, absorption coefficients, and work functions. Lattice degrees of freedom such as static dielectric constants and bulk modulus were also calculated, and are reported.

C1.00198 ZSM-5, Y, and Mordenite Zeolites as Sensing Materials for Ethanol Vapor

ANUVAT SIRIVAT, INTIRA YIMLAMAI, The Petroleum and Petrochemical College, Chulalongkorn University — The effects of the framework type, the charge balancing cation type, and the Si/Al ratio of ZSM-5, Y, and Mordenite zeolites on the electrical conductivity responses towards ethanol vapor have been investigated. All zeolites were characterized using XRD, FT-IR, SEM, TGA, BET, and NH_3-TPD techniques. For the effect of the framework type, H^+Y has a higher electrical conductivity sensitivity value than that of H^+MOR because of a greater pore volume and available surface area. For the effect of the charge balancing cation, all NH_4^+ZSM-5 zeolites (Si/Al = 23, 50, 80, 280) show negative responses, whereas the H^+Y zeolites (Si/Al = 30, 60, 80) and the H^+MOR zeolites (Si/Al = 30, 200) show positive responses. These differing behaviors can be traced to the interactions between ethanol molecules and the reactive sites of the zeolites. For the effect of Si/Al ratio, the electrical conductivity sensitivity towards the ethanol decreases with increasing Si/Al ratio or decreasing Al content, and there is a lesser degree of interaction between ethanol molecules and the active sites of the zeolites. The interactions between the ethanol molecules and the zeolites were investigated through infrared spectroscopy.

C1.00199 Apparatus for the analysis of surfaces in gas environments using Positron Spectroscopy[1]

SUMAN SATYAL, LAWRENCE LIM, PRASAD JOGLEKAR, SUSHANT KALASKAR, KARTHIK SHASTRY, ALEXANDER WEISS — Positron spectroscopy performed with low energy beams can provide highly surface specific information due to the trapping of positrons in an image potential surface state at the time of annihilation. Here we present design details of a new positron beam system for the analysis of surfaces gas environments. The new system will employ differential pumping to transport the positrons most of the way from the source to the sample under high vacuum. The positrons will then be transported through a thin gas layer surrounding the sample. The positrons will be implanted into the sample at energies less than ∼10 keV ensuring that a large fraction will diffuse back to the surface before annihilation. The Elemental content of the surface interacting with the gas environment will then be determined from the Doppler broadened gamma spectra.

C1.00200 High-resolution X-ray Emission Spectroscopy as a Microprobe Imaging Modality[1]

JOSEPH PACOLD, GERALD SEIDLER, BRIAN MATTERN, MATTHEW HAAVE, University of Washington, ROBERT GORDON, Simon Fraser University, University of Washington — Hard x-ray microprobe beamlines at third generation light sources have made significant impacts in several fields of science and technology. Such facilities permit rapid 2-dimensional studies of multiphase materials on submicron length scales using a variety of pixel-by-pixel imaging modalities (e.g., x-ray diffraction, x-ray absorption near edge fine structure, or x-ray fluorescence). Here, we aim to expand hard x-ray microprobe imaging modalities to include high-resolution x-ray emission spectroscopy (XES). When performed at 1-eV resolution, such measurements can provide quite direct atomic-level information on ionic valence, spin, and local electronic and chemical environment. Ongoing work in our research group has improved the efficiency of XES via the development of a new type of compact and inexpensive x-ray spectrometer design, the "miniature x-ray spectrometer" or "miniXS" paradigm. We will report preliminary 2-dimensional XES studies of planar multiphase materials, with specific applications to samples of interest for geophysics and catalysis science.

[1]Supported by the U.S. Department of Energy Office of Basic Energy Sciences

C1.00201 Measurements of chemical bonds using diffraction of electronic waves traveling through crystals[1]

ROBERT LANNING, CRISTIAN BAHRIM, Department of Physics, Lamar University — We propose a simple and intuitive procedure for discovering the atomic arrangement and the chemical bonds in transparent crystals using the diffraction of light or electronic waves by crystals. This study can help to improve methods of optical imaging, electronic microscopy, microbiology, and crystallography. Using fundamental principles of quantum mechanics, we also explain the formation of electronic wave packets when a free electronic beam passes through the atoms of a solid target. The atoms in solids act as the narrow slits of a diffraction grating producing a Fourier transform of the sinusoidal waves associated to free electrons incident on the solid target. Such a model allows measuring the chemical bonds within 1% precision. This research project was done under a NSF-DUE-sponsored program, called STAIRSTEP [1], which was designed to engage STEM undergraduate students in high-quality research in several fields of science including physics, at Lamar University.

C1.00202 Negative thermal expansion in Prussian Blue analogs , S. ADAK, H. NAKOTTE, L. DAEMEN, LANSCE (Lujan Center), LANL — While many Prussian Blue (PB) analogs are known to display negative thermal expansion (NTE), few have been studied in detail. Not all compounds in this family exhibit NTE. Because it is possible to systematically vary ion size and charge in these materials, they represent an interesting playground to study NTE and possible correlations with electronic and crystal structures. By contrast with many silicates displaying NTE and in which tetrahedral units are linked with apical oxygens, the octahedral units in PB compounds are linked with a linear cyanide ligand. This introduces more degrees of freedom in the (mostly) cubic PB structures compared to the silicates. Polycrystalline samples of PB analogs, $M_2^{II}[Fe^{II}(CN)_6]$ and $M_2^{III}[A^{III}(CN)_6]_2$*(M = Mn, Co, Ni, Cu, Zn; A = Cr, Fe, Co)* were synthesized via standard chemical precipitation. Variable temperature X-ray powder diffraction patterns were collected *in-situ* in the range 300-123 K to study the T-dependence of the lattice parameter and to obtain an average coefficient of thermal expansion (CTE). Lattice parameters were extracted using the Rietveld refinement technique with the General Structure Analysis System (GSAS) software. The determined average CTEs, for the compounds showing NTE behavior, are in the range -4.9 x $10^{-6}K^{-1}$ to -39.5 x 10^{-6} K^{-1} while the CTEs for the other materials showing positive TE behavior are in the range 5.9 x $10^{-6}K^{-1}$ – 59.2 x 10^{-6} K^{-1}.

C1.00203 New Approach to Image Aerogels by Scanning Electron Microscopy , FRANCISCO SOLÁ, FRANCES HURWITZ, NASA Glenn Research Center, JIJING YANG, Carl Zeiss SMT Inc. — A new scanning electron microscopy (SEM) technique to image poor electrically conductive aerogels is presented. The process can be performed by non-expert SEM users. We showed that negative charging effects on aerogels can be minimized significantly by inserting dry nitrogen gas close to the region of interest. The process involves the local recombination of accumulated negative charges with positive ions generated from ionization processes. This new technique made possible the acquisition of images of aerogels with pores down to approximately 3nm in diameter using a positively biased Everhart-Thornley (E-T) detector. Well-founded concepts based on known models will also be presented with the aim to explain the results qualitatively.

C1.00204 Three-axis positional drift correction in scanning probe microscopy[1] , NATHAN D. FOLLIN, CHRISTOPHER J. MUSALO, MATTHEW L. TRAWICK, Department of Physics, University of Richmond, Richmond, VA — Positional drift in scanning probe microscopy can cause image distortion and metrological errors of tens of nanometers or more. It can arise from thermal drift, due to thermal expansion of materials in the sample and microscope while scanning, or from piezo creep, particularly along the z axis. We present a technique for correcting positional drift errors in all three axes. Our method works by comparing each scanned topographical image to a second, partial scan, taken immediately afterwards, on which the fast and slow scan axes have been reversed. We model the positional distortion as a low-order polynomial function in three dimensions, searching for the set of correctional coefficients that minimizes the difference between the two scans. Using this technique we have successfully reduced positional errors from 50 nm to 0.5 nm in the z axis, and from 40 nm to 2 nm (about half of a single pixel) in the xy plane.

C1.00205 Three Electrode Control of the NanoDeposition of Gold Nanoparticles With Atomic Force Controlled Capillary Electrophoresis , AARON LEWIS, TALIA YESHUA, MILA PALCHAN, Hebrew University of Jerusalem, YULIA LOVSKY, HESHAM TAHA, Nanonics Imaging Ltd. — Controlled deposition of the metallic features such as nanoparticles with high spatial accuracy has a great interest in different applications such as surface plasmons, surface enhanced Raman scattering (SERS), nanophotonics and nano biophysics. Lithography based scanning probe microscopy techniques have been shown as a potential methodology for accurate and localized deposition of material in the nanometer scale. Here we report an accurate deposition of high resolution features of single gold nanoparticles using Three Electrodes and atomic force microscopy (AFM) controlled capillary based fountain pen nanolithography. In this methodology three electrodes are attahced one on the outside of the metal coated glass probe, one on the inside of the hollow probe in the solution contained in the capillary and a third electrode on the surface on which the writing is to take place. The three electrodes provide electrical pulses for accurate control of the deposition and retraction of the liquid from the surface. We will demonstrate depositing of single gold nanoparticle with size of 1.2nm onto surfaces such as semiconductors.

C1.00206 Have some large structures? Try small-angle neutron scattering (SANS) , LISA DEBEER-SCHMITT, KATHY BAILEY, NSSD, ORNL, LILIN HE, GEORGE WIGNALL, YURI MELNICHENKOV, NSSD,ORNL, KEN LITTRELL, NSSD, ORNL — The small-angle neutron scattering (SANS) beam line, CG-2, has been in operation since 2007. CG-2 has been optimized so that structures from 0.5 to 200 nm can be thoroughly investigated. HFIR's cold source places the flux at CG-2 among the best in the world. Along with high flux, many varied sample environments can easily be integrated into the beam line which gives the user a versatile temperature range from 1.5 K to 1000 K. In addition there are two cryomagnets (horizontal 4.5 T and vertical 7 T), pressure cells and load frames available to users allowing for the availability of multiple configurations of experimental setups. Due to all the above equipment and the flux at CG-2, there have been many diverse and intriguing scientific developments. One such outcome is the study of flux-line lattices found in Type-II superconductors including the highly touted iron pnictides. Besides superconductors, other science studied on CG-2 ranges from molecular self-assembly and interactions in complex fluids to phase separation to grain growth and orientation in metallurgical alloys.

C1.00207 Characterization and Modeling of Off-Specular Neutron Scattering for Analysis of Two Dimensional Ordered Structures , CHRISTOPHER METTING, University of Maryland, BRIAN MARANVILLE, PAUL KIENZLE, NIST Center for Neutron Research, ROBERT BRIBER, University of Maryland, JOSEPH DURA, CHUCK MAJKRZAK, NIST Center for Neutron Research — The University of Maryland along with NIST Center for Neutron Research (NCNR) and the NSF funded DANSE project are currently developing off-specular neutron reflectometry modeling software for fitting scattering data from multilayer samples. The software includes a robust sample representation scheme for easy development of various models. Theory functions are being calculated using a variety of approximations. The suite of approximations allows for the evaluation of each calculation's usefulness in representing the scattering data. In this presentation we describe corrections made to a purely Born approximation that capture dynamical scattering and resolution effects seen in measured data. We then show modeled data taken on the Advanced Neutron Diffractometer/Reflectometer (AND/R) at the NIST Center for Neutron Research (NCNR) from a sample of gold pillars using a substrate modified Born approximation, and compare it to a model which uses a purely Born approximation.

C1.00208 On-demand Control of Micro Quartz Resonator in Scanning Probe Microscopy[1] , JUNGHOON JAHNG, WONHO JHE, BONGSU KIM, Physics and Astronomy, Seoul National University — We demonstrate generalized theoretical analysis and experimental realization of active feedback control for the self-oscillating quartz tuning-fork (QTF) which is a widely used probe for sensing applications in scanning probe microscopy. In this work, we present the damping control, feedback cooling, resonance control and nonlinear dynamics for the QTF by implementing active feedback control scheme. Finally, we suggest the prospect of several novel applications in scanning probe microscopy by using the active feedback control of QTF such as increasing the force sensitivity, reducing the thermal noise and modulating the resonance of the sensor.

C1.00209 Low Temperature Scanning Probe Microscope(LT-SPM) operating in a Cryogen-Free Cryostat, 1.5-300K , OZGUR KARCI, NanoMagnetics Instruments Ltd, MUNIR DEDE, NanoMagnetics Instruments Ltd., YURY BUGOSLAVSKY, RENNY HALL, Cryogenic Limited, AHMET ORAL, Sabanci University, NANOMAGNETICS INSTRUMENTS LTD. TEAM, CRYOGENIC LIMITED TEAM, SABANCI UNIVERSITY TEAM — We present the design of a Low Temperature Scanning Probe Microscope(LT-SFM) operating in a vibration-free cryogen-free cryostat. A 0.5W ultra now noise Pulse Tube cryocooler is integrated into the cryostat with a 9T magnet. Stick slip coarse approach mechanism is used to bring the sample in to close proximity of the sample. The sample can be moved in XY directions within 3 mm range, while the position is measured with capacitive encoder with 3μm accuracy. An improved fiber interferometer with $\sim$12fm/$\sqrt{}$Hz noise level is used to detect cantilever deflection. The resonance of the cantilever controlled by a digital Phase Locked Loop (PLL) integrated in our Control Electronics with 5mHz frequency resolution. We can achieve $\sim$1nm resolution in AFM mode & $<$10nm resolution in MFM mode. Results from different imaging modes; non-contact AFM, MFM, Piezoresponse, Conductive AFM etc. will be presented.

C1.00210 A 129 GHz dynamic nuclear polarizer in a wide-bore superconducting magnet[1] , LLOYD LUMATA, RICHARD MARTIN, ASHISH JINDAL, CRAIG MALLOY, A. DEAN SHERRY, UT Southwestern Medical Center, MARK S. CONRADI, Washington University in St. Louis, MATTHEW MERRITT, UT Southwestern Medical Center — Dynamic nuclear polarization via fast dissolution method has allowed production of solutions containing highly-polarized nuclei (>10,000-fold enhancement of the room-temperature liquid-state NMR signal) of bio-molecules for *in vitro* and *in vivo* metabolic nuclear magnetic resonance spectroscopy (MRS) and imaging (MRI). Here we present the construction and use of a 129 GHz dynamic nuclear polarizer in a 4.6 T wide-bore superconducting magnet. The relatively large bore (150 mm) of the superconducting magnet allows the use of a cryostat separate from the magnet and routing of the microwaves such that the waveguide does not have to be removed before dissolution. A 100 mW microwave source operating at 129 GHz was used to irradiate the samples. The cryostat has a 10-liter liquid Helium capacity which lasts for 10-12 hrs of continuous operation. Base temperature of 1.15 K is achieved with a 450 m^3/hr roots blower pump. Preliminary results will be discussed.

C1.00211 Diffuse Reflectance Spectroscopy and Colorimetry as a Diagnostic Tool for Acanthosis Nigricans , BENSACHEE PATTAMADILOK, Henry Ford Health System, SUNEETHA DEVPURA, Wayne State University, ZAIN U. SYED, PRANITA VEMULAPALLI, MARSHA HENDERSON, Henry Ford Health System, STEVEN J. REHSE, Wayne State University, ILTEFAT HAMZAVI, BASSEL H. MAHMOUD, HENRY W. LIM, Henry Ford Health System, RATNA NAIK, Wayne State University — The purpose of this study was to quantify skin color changes due to Acanthosis Nigricans, a disorder common among prediabetic and obese individuals. The non-invasive optical technique diffuse reflectance spectroscopy (DRS) was used to determine skin melanin, oxyhemoglobin and deoxyhemoglobin content through the measured absorption spectrum. Colorimetery was used to measure skin color based on the standard Tristimulus values (L*, a*, and b*). Data was obtained from eight patients, spanning eight months of treatment. Measurements were obtained from lesion tissue on the neck and healthy skin was used as a control. L*, a* and b* values showed significant differences between lesion and normal controls, whereas melanin was the only parameter which showed statistical significant differences in DRS measurements. Future work will use more sensitive chemometric methods to increase diagnostic accuracy based on the raw spectra of the DRS.

C1.00212 Toward contrast-enhanced, optically-detected NMR spectroscopy[1] , CARLOS MERILES, DANIELA PAGLIERO, Department of Physics, City College of New York - CUNY — Optical detection of Nuclear Magnetic Resonance (NMR) takes place via a two-step process that relies on the interaction between optical photons and electrons on the one hand, and the hyperfine coupling between electrons and nuclear spins on the other. The latter depends on the material system under consideration while the former is dominated by the difference between the illumination and optical transition wavelengths. Here we use optical Faraday rotation to monitor nuclear spins in real time after resonant radio-frequency excitation at high-magnetic field. Comparison between inductively and optically detected NMR spectra in model sample fluids indicates that each of these mechanisms can lead to alternate forms of spectral contrast. Extension of these findings may find application in solvent suppression protocols, sensitivity-enhanced NMR of metalloproteins, or the characterization of molecular orbitals in diamagnetic systems.

C1.00217 Collective states of interacting Yang-Lee anyons in 1D: the golden chain's twin

, EDDY ARDONNE, Nordita, JAN GUKELBERGER, ETH Zurich, ANDREAS LUDWIG, UCSB, SIMON TREBST, Microsoft Station Q, MATTHIAS TROYER, ETH Zurich — Collective states of interacting non-Abelian anyons have recently been studied mostly in the context of exotic quantum Hall states. In this talk we will further expand this line of research and present certain non-unitary generalizations of the original golden chain model. In particular, we introduce the notion of Yang-Lee anyons, discuss their relation to the 'Gaffnian' quantum Hall wave function, and describe an elementary model for their interactions. A one-dimensional version of this model can be fully understood in terms of an exact algebraic solution and numerical diagonalization. We discuss the gapless phases of these models, and comment on the physical implications of the non-unitarity of their underlying critical theories.

C1.00218 Long-range in a system of thermal brownian particles[1]

, ALEXANDRO HEIBLUM, Posgrado Ciencias Fisicas, Universidad Nacional Autonoma de Mexico, FRANCISCO SEVILLA, Instituto de Fisica, Universidad Nacional Autonoma de Mexico, VICTOR DOSSETTI, Instituto de Fisica, Benemerita Universidad Autonoma de Puebla — We present a model that exhibits an order-disorder phase transition in two spatial-dimensions. The model considers a collection of N thermal Brownian particles moving in a square of length L subjected to periodic boundary conditions and to velocity-alignment forces. The alignment force affects only the velocity direction in a way that it makes it equal to the velocity direction of the nearby group. Our results contrast with those obtained from the well known model of Vicsek *et al.* [Phys. Rev. Lett. **75**, 1226 (1995)] where such a transition occurs out of equilibrium.

[1]We acknowledge support from PCF-PAEP and PAPIIT-IN117010

C1.00219 Long-range order in a system of thermal Brownian particles[1]

C1.00220 Investigating Low Dimensional Chaos with Nearly Elastic Spheres

, ALEX SABEY, COREY LAFONTAINE, JEFFREY OLAFSEN, Department of Physics, Baylor University — An experimental and numerical study of the dynamics in a system which is prone to chaotic motion is implemented via a shaking plate and two nearly elastic particles. Confined to move in the vertical direction, one spherical particle is driven by the shaking plate while the other sphere is driven by collisions with the first. The motion of the two particles and the plate were captured with a relatively high speed ($\sim$340 fps) CCD camera via image analysis algorithms written in IDL. Measurements of position, velocity, acceleration, and energy and are used to formulate a thorough description of the system. The experimental results are compared to those of a numerical simulation to explore phase space for chaotic orbits of the two trajectories as well as phase synchronization between the particles and the plate. A thorough investigation of the phase space to describe the low dimensional system as well as to examine the dynamics for phase synchronization between the two particles will be presented.

C1.00221 Simulation studies of diffusion limited ballistic growth of particles from a surface[1]

, STEPHEN M. KUEBLER, Department of Chemistry & The College of Optics and Photonics, University of Central Florida, Orlando, ANIKET BHATTACHARYA, Department of Physics, University of Central Florida, Orlando — Motivated by electroless deposition of metals on polymeric surfaces we plan to study evolving morphologies of deposited particles from a surface using Monte Carlo simulation in continuum which shares characteristics of both diffusive and ballistic behavior. In the proposed model we assume that the particles residing at the surface of a growing pattern are capable of attracting particles those are within a certain range. Once one of these seed particles attracts a particle it transfers its attractive characteristics to the newly adsorbed particle which then acquires this characteristics for further growth. The motion of the particles in the bulk is diffusive. However, once they are within the range of an "active" particle they move ballistically along a straight line and gets adsorbed to a cluster unless hindered by other particles on its way. We plan to report the characteristics of the evolving patterns as a function of density of the diffusive particles, the range of the attractive particles, and the speed of ballistic moves.

C1.00222 Intermittency and ergodicity breaking in a system of interacting self-propelled particles[1]

, FRANCISCO J. SEVILLA, Instituto de Fisica, Universidad Nacional Autonoma de Mexico, VICTOR DOSSETTI, Instituto de Fisica, Benemerita Universidad Autonoma de Puebla — A comprehensive dynamical model for cooperative motion of self-propelled particles [Dossetti et al. Phys. Rev. E 79, 051115 (2009)], that combines velocity alignment interactions, spatial interactions, and angular noise, is studied. The noise considered in this model comes about nonlinear with correlations that decay in time, leading to a unique collective behavior. In particular, for a certain arrangement of the parameters, the system develops intermittent behavior and some sort of ergodicity breaking. In this work, we characterize these phenomena by studying the distributions of time intervals between turbulent bursts and changes between metastable states, respectively.

C1.00223 Non-Equilibrium Statistical Dynamics of River Network Evolution[1] , XU-MING WANG, School of Physics and Electric Informantion, Ningxia University, PING ZHANG, JIE HUO, RUI HAO, School of Physics and Electric Informantion, Ningxia University — According to the erosion rule in a natural process, a Langevin Equation describing the prolongation of river channel is defined. The determinate prolongation is given by consideration of the characteristics of the early stage in the development of a river channel. The random growth (diffusion) is expressed by the fluctuations of the related stochastic variables or factors. A Fokker-Planck equation that describes the evolution of the distribution of the channel length is derived from this Langevin Equation. The solution presents the transition probability and exceedence probability with a Power-Exponent function which indicates that the channel length distributes in a complicated way. The details show that there exists a critical time, before which river network is developing and marked by exponent distribution., and beyond which river network is developed and marked by power distribution. On the basis of Hack's law, the transition probability of river's area and the corresponding exceedence probability are obtained. They are in excellent agreement with them obtained by field observations.

C1.00224 Introduction to the Mu-bit , FLORENTIN SMARANDACHE, University of New Mexico, Gallup Campus, V. CHRISTIANTO, Sciprint.org — Mu-bit is defined here as 'multi-space bit'. It is different from the standard meaning of bit in conventional computation, because in Smarandache's multispace theory (also spelt multi-space) the bit is created simultaneously in many subspaces (that form together a multi-space). This new 'bit' term is different from multi-valued-bit already known in computer technology, for example as MVLong. This new concept is also different from qu-bit from quantum computation terminology. We know that using quantum mechanics logic we could introduce new way of computation with 'qubit' (quantum bit), but the logic remains Neumann. Now, from the viewpoint of m-valued multi-space logic, we introduce a new term: 'mu-bit' (from 'multi-space bit).

C1.00225 Stochastic Phase Decoupling in Dynamical Networks , WILLIAM SULIS, McMaster University — Network models and their theories play a central role in the understanding of complex systems, in particular complex social systems such as societies and organizations. An important problem is to understand how agent attributes become organized within the connectivity structure of a network. The effective matching of agent attributes is important for the expression of functionality by a network. The creation of static networks relative to some control parameter has been extensively studied and gives rise to order-disorder phase transitions. This paper extends this work to dynamic networks. Several models of dynamic networks are created relative to two control parameters and their associated stochastic phase transitions are examined. Under conditions of weak coupling between the control parameters, it is shown that the relevant stochastic phase transitions become decoupled from one another, each qualitatively distinct and dependent on a single (distinct) control parameter.

C1.00226 Range of spectral exponents in rigor-state muscle fibers – a 1/f noise family affair? , CAROLINE RITZ-GOLD, Center for Biomolecular Studies, Fremont CA 94536 — Using EPR spectroscopy, we have followed changes in crossbridge state in rigor-state muscle fibers as a function of time. These observed changes were of two types – erratic fluctuations taking place on multiple time scales, and slowly-relaxing transients in response to substrate analog. For both types of change, the resulting power spectra had a 1/f-like power-law form with spectral exponents ranging from near 0 (white noise) to around 2 (brown noise). The average exponent was around 1 (pink noise). This observed broad range of spectral exponents is similar to that seen in the extended-family model of 1/f noise processes – a model that includes members ranging from white noise to pink to brown (JM Halley, Trends. Ecol. Evoln. 11, 33, 1996). Properties of this extended family model include self-affinity, long correlation times (memory), and non-stationarity (JM Halley & P Inchausti, Fluct. Noise. Lett 4, R1, 2004). We conclude that the broad range of spectral exponents observed in rigor-state muscle fibers reflects a type of underlying 1/f process. However, this particular type of process is unusual in that, although produced by a single biological source (rigor muscle fibers), it appears to include not just one but all of the members of the extended 1/f noise family – from white to pink to brown.

C1.00227 Self organization of social hierarchy in competitive societies , TAKASHI ODAGAKI, Tokyo Denki University, RYO FUJIE, Kyushu University — We investigate self organization of social hierarchy in a competitive society where all individuals have rights to participate in fighting. The winning probability of an individual against an opponent depends on the difference of their wealth. We introduce cost to participate in the fighting and show that the emergence of the hierarchical society depends strongly on the ratio of the cost to the reward for the winner. We show numerically and analytically that the phase transition occurs in two steps for most values of the ratio. Furthermore, we determine the phase diagram as a function of the ratio and the probability of participating in fighting. We show that there are four different phases in the parameter space, one egalitarian phase and three distinct hierarchical phases

C1.00228 Fermi Acceleration in a Periodically Driven Fermi-Ulam Model , O.F. DE ALCANTARA BONFIM, University of Portland — The dynamics of a particle bouncing between two harmonically vibrating walls is analyzed in the context of the static wall approximation. Fermi acceleration is observed for a wide range of the ratio between the frequencies of the oscillating walls and their relative phases. However, no acceleration is observed if the frequency ratio is an integer. In the phase versus frequency-ratio diagram, the region in which Fermi acceleration is observed is separated by an upper and lower boundary. At the lower boundary, after a large number of collisions the particle average velocity increases with the square-root of the number of collisions (n) with the walls. Between the lower and upper boundaries, the particle average velocity behaves as $V(n) \sim n^{\beta}$, with β in the interval [0.5, 1.0]. Below and near the lower boundary, the average particle velocity initially grows with the number of collisions until it eventually reaches a plateau. In this region, for a fixed frequency ratio, the velocity of the particle exhibits scaling properties over a range of the relative phases of the vibrating walls. Inelastic collisions with the walls cause suppression of the Fermi acceleration inside the previously accelerating region and lead to the particle velocity exhibiting scaling properties with respect to changes in the coefficient of restitution.

C1.00229 Moment ratios and dynamic critical behavior of a reactive system with several absorbing configurations[1] , WAGNER FIGUEIREDO, MARCELO FREITAS DE ANDRADE, Departamento de Física - UFSC - Brazil — We determine the critical behavior of a reactive model with many absorbing configurations. Monomers A and B land on the sites of a linear lattice and can react depending on the state of their nearest-neighbor sites and temperature of the catalyst. We consider that monomers of the type A are allowed to react with nearest-neighbor monomers A or B, but reactions between monomers B are forbidden. Besides the temperature of the catalyst, we also include lateral interactions between pairs of nearest-neighbor monomers. We employ Monte Carlo simulations and finite-size scaling arguments to calculate the moments of the order parameter of the model as a function temperature. Some ratios between pairs of moments are independent of temperature and are in the same universality class of the Contact Process. We also find the dynamical critical exponents of the model and we show that they are in the direct percolation universality class whatever the values of temperature.

C1.00230 Simulating Electroweak Baryogenesis in the Standard Model , ANDREW BLAIKIE, R. MIKE WINTERS, The College of Wooster, DEVA O'NEIL, Bridgewater College — One explanation for the abundance of matter over anti-matter in the universe is Electroweak Baryogenesis, which proposes that an excess of baryons was created during the electroweak phase transition, when particles first acquired mass. This transition, which occurred about one-tenth of a nanosecond after the Big Bang, proceeded through bubble nucleation, with the walls of the "bubbles" expanding until the electroweak symmetry was broken everywhere in space. We modeled this process in Mathematica using the Standard Model. Although current mass limits for the Higgs boson rule out Electroweak Baryogenesis in the Standard Model, our simulation can provide the basis for modeling more sophisticated scenarios. We used the sonification software SuperCollider to create an audio representation of the growth of the bubbles.

C1.00231 Shannon's entropy decreases spontaneously in certain isolated systems , SATORU SATO, Dept. of Network and Multi-Media Engineering, Kanto Gakuin University — In this study, we present an isolated system in which the Shannon's entropy decreases spontaneously. Of course physical entropy must increase in an isolated system according to the second law of thermodynamics. But Shannon's entropy which depends on the view point of an observer can decrease in certain isolated systems entailed by the increase of the physical entropy. As Shrödinger said in his famous book "entropy, taken with the negative sign, is itself a measure of order"[1]. However, the order of living organisms is not just the decrease of the physical entropy itself, but something in larger scale, for example proteins. This fact suggests that the formation of order does not necessarily involve the emission of physical entropy from the view point of information theory.

[1] E. Shrödinger, WHAT IS LIFE?, first published 1944

C1.00232 Trajectory Analysis for Inelastic Gravitational Billiards , ANDY YOST, JEFFREY OLAFSEN, Department of Physics, Baylor University — We present an analysis for an experiment [1] involving the motion of a gravitational billiard undergoing inelastic collisions with a sloped boundary. The inelastic particle is set into ballistic motion within three types of boundary shapes: parabolic, hyperbolic, and wedge geometries. The two-dimensional experimental cell is oriented vertically with respect to gravity and motion is maintained by horizontal shaking. Trajectories for various boundary shapes, shaking frequencies, and amplitudes are analyzed to determine regions of periodic and chaotic behavior. The shaking is provided by a DC-motor and armature that allows for control of both the shaking amplitude and frequency. Comparison of the experimental results to numerical methods provides a sensitive test of the velocity dependence of the coefficient of restitution. The trajectories may also be examined to extract a Lyapunov exponent for the motion.

C1.00233 Nonlinear dynamics of an electronic model of one-way coupling in one and two dimensions , AARON DOUD, BARBARA BREEN, JAMIE GRIMM, ANDREW TANASSE, STUART TANASSE, University of Portland, JOHN LINDNER, KATSUO MAXTED, The College of Wooster — One-way or unidirectional coupling is a striking example of how topological considerations – the parity of an array of multistable elements combined with periodic boundary conditions – can qualitatively influence dynamics. Here we introduce a simple electronic model of one-way coupling in one and two dimensions and experimentally compare it to an improved mechanical model and an ideal mathematical model. In two dimensions, computation and experiment reveal richer one-way coupling phenomenology: in media where two-way coupling would dissipate all excitations, one-way coupling enables soliton-like waves to propagate in different directions with different speeds.

C1.00236 Finite-Size-Scaling at the Jamming Transition: Corrections to Scaling and the Correlation Length Critical Exponent[1] , STEPHEN TEITEL, University of Rochester, DANIEL VÅGBERG, Umeå University, DANIEL VALDEZ-BALDERAS, MICHAEL MOORE, University of Manchester, PETER OLSSON, Umeå University — We carry out a finite size scaling analysis of the jamming transition in frictionless bi-disperse soft core disks in two dimensions. We consider two different jamming protocols: (i) quench from random initial positions, and (ii) quasistatic shearing. By considering the fraction of jammed states as a function of packing fraction for systems with different numbers of particles, we determine the spatial correlation length critical exponent $\nu \approx 1$, and show that *corrections to scaling* are crucial for analyzing the data. We show that earlier numerical results yielding $\nu < 1$ are due to the improper neglect of these corrections.

[1]Supported by DOE Grant No. DE-FG02-06ER46298, Swedish Research Council Grant No. 2007-5234, a grant from the Swedish National Infrastructure for Computing (SNIC) for computations at HPC2N and the University of Rochester Center for Research Computing.

C1.00237 Response of Jammed Ellipsoid Packings , ZORANA ZERAVCIC, Lorentz Institute, Leiden University and James Franck Institute and Department of Physics, University of Chicago, ANDREA LIU, Department of Physics and Astronomy, University of Pennsylvania, SIDNEY NAGEL, James Franck Institute and Department of Physics, University of Chicago — We investigate the nature of the jamming transition for packings of spheroids by examining the elastic moduli as a function of the aspect ratio of the particles ε and the compression. Irrespective of the particle aspect ratio, both shear modulus G and bulk modulus B show the same scaling as a function of compression as is found for packings of spheres. Moreover, for any value of ε, G is proportional to the excess of the coordination number above that found at the jamming threshold; this recovers the result for frictionless spheres at $\varepsilon = 1$. Our results imply a new diverging length scale associated with the loss of rigidity of these spheroid packings. The critical behavior of ellipsoid packings is an extension of that found for spheres.

C1.00238 A new solution to the statistics of hard elongated objects , MOHAMMAD H. ANSARI, Institute for Quantum Computing, IQC and University of Waterloo — We propose a formalism that helps to study elasticity of hard elongated objects (e.g. needles, rectangles, ellipses, etc) analytically. For this aim, we introduce an approximation to the exact model that simplifies the Gibbs free energy to be solved analytically and then extract some formulations for a collective number of Gibbs related physical quantities. Interestingly, this formalism reproduces the numerical results of the exact model. The simplicity and the accuracy of this formalism allows to study some previously unknown properties of of elongated objects in different compressions, such as the elasticity coefficients of objects with curved boundary shapes. Moreover we introduce a new quantity, i.e. the mean inverse distance, and investigate how it behaves under different compressions.

C1.00239 Multiscale Modeling of Biomimetic Self-Healing Materials , GERMAN KOLMAKOV, AMY SCARBROUGH, CHET GNEGY, ISAAC SALIB, Chemical Engineering Department, University of Pittsburgh, KRZYSZTOF MATYJASZEWSKI, Department of Chemistry, Carnegie Mellon University, ANNA BALAZS, Chemical Engineering Department, University of Pittsburgh — We use a hybrid computational approach to examine the self-healing behavior of polymeric materials composed of soft nanogel particles crosslinked by a network of both stable and labile bonds. The latter are highly reactive and therefore, can break and readily reform. To capture the multiscale structure of the material, we take advantage of the multi-level Hierarchical Bell Model (mHBM) where the labile crosslinks are organized into M levels of interconnected elements, each of them represents a number of bonds that lie in parallel and is described by a single-level HBM. We vary the number of hierarchical levels M and the number of labile bonds in each element to determine optimal conditions for improving strength and toughness of the material. We also compare the properties of the multiscale material with those for the gel, in which only single-level interconnections are presented. This study takes its inspiration from biological systems that show remarkable resilience in response to mechanical deformation.

C1.00240 (BNL/DoE-hyped) "Self-Organized-Criticality"(SOC) is Merely Newton's(1687) Third Law of Motion F = ma REdiscovery: LONG PRE-"Bak"!!! , P.R.E. BAK, I. C1.00241 Deformation of Entangled Random Fiber Networks , CATALIN PICU, GOPINATH SUBRAMANIAN, Rensselaer Polytechnic Institute — The mechanics of random fiber networks which are not bonded or cross-linked but are subjected to topological constrains imposed by the excluded volume of the fibers is studied by means of a computational model. The fibers do not cross, have linear constitutive behavior in the axial and bending deformation modes and interact with each other frictionally. The system-scale response is highly-non-linear (power law) and hysteretic. The system exhibits a rich dynamics in response to imposed deformation, characterized by intermittency and spatial and temporal correlations of localized deformation (fiber-fiber sliding events). The role of friction in defining the overall system response is discussed.

C1.00242 Study of Transient Nuclei near Freezing , MASAHARU ISOBE, Nagoya Institute of Technology, BERNI ALDER, Lawrence Livermore National Laboratory — The molasses tail in dense hard core fluids is investigated by extensive event-driven molecular dynamics simulation through the orientational autocorrelation functions. Near the fluid- solid phase transition, there exist three regimes in the relaxation of the pair orientational autocorrelation function, namely the kinetic, molasses (stretched exponential), and diffusional power decay. The density dependence of both the molasses and diffusional power regimes are evaluated and the latter compares with theoretical predictions in three dimensions. The largest cluster at the freezing density of only a few sphere diameter in size persist for only about 30 picoseconds ($\sim 2.8 \times 10^{-11}$[s]). The most striking observation through the bond orientatinal order parameter is the dramatic increase of the cluster size as the freezing density is approached.

C1.00243 COMPLEX STRUCTURED MATERIALS I —

C1.00244 From 2D graphene to 1D graphene nanoribbons: dimensional crossover signals in the structural thermal fluctuations , ARIEL DOBRY, Instituto de Física Rosario (Argentine), SEBASTIÁN COSTAMAGNA, International School for Advanced Studies (Italy) and tituto de Física Rosario (Argentine) — I this work, by analyzing the thermal excited rippling in the graphene honeycomb lattice, we find clear signals of an existing dimensional crossover from 2D to 1D while reducing one of the dimensions of the graphene layer. Trough a joint study, using montecarlo atomistic simulations and analytical calculation based, we find that the normal-normal correlation function $G(q)$ does not change the power law behavior valid on the long wavelength limit, however the system size dependency of the quadratic out of plane displacement h^2 shows a breakdown of its corresponding scaling law. In this case we show that a new scaling law appear which correspond to a truly 1D system. On the basis of these results, and having explored a wide number of realistic systems size, we conclude that narrow nanoribbons presents strongest corrugations than the square graphene sheets. This result could have important consequences on the electron transport properties of freestanding graphene systems.

C1.00245 Properties of anisotropically etched graphene devices , C.M. REYNOLDS, A. ROBERTS, A.S. SANDHU, B.J. LEROY, University of Arizona — Mechanically exfoliated graphene on a SiO2 substrate was etched using a solution of nickel nanoparticles. Using an atomic force microscope, etch lines 10 nm in width were observed. In addition, etch lines made angles of only 60 and 120 degrees and did not cross one another indicating that the etching occurs along a crystallographic edge. This resulted in structures such as equilateral triangles and nanoribbons as narrow as 35 nm wide. We have investigated these devices using Raman spectroscopy and scanning tunneling spectroscopy to determine the quality of the crystallographic edges and the local electronic properties.

C1.00246 Anisotropy and edge roughness scattering in the thermal conductivity of graphene nanoribbons[1] , ZLATAN AKSAMIJA, IRENA KNEZEVIC, University of Wisconsin-Madison — We present a calculation of the thermal conductivity of graphene nanoribbons, based on solving the Boltzmann transport equation with the full phonon dispersions, a momentum-dependent model for edge roughness scattering, as well as three-phonon and isotope scattering. The interplay between strong edge roughness scattering and the anisotropy of the phonon dispersions results in thermal conduction that strongly depends on the chiral angle of the nanoribbon. A minimum occurs in the armchair direction and a maximum is attained in zig-zag nanoribbons. We also show that both the thermal conductivity and the amount of armchair/zig-zag anisotropy depend strongly on the width of the nanoribbon and the rms height of the edge roughness, with smallest and most anisotropic thermal conductivities occuring in narrow GNRs with rough edges. We conclude that physical width of the nanoribbon and the rms roughness of its line edges can be used along with angular direction as parameters to tailor the value of the thermal conductivity.

[1]This work has been supported by the Computing Innovation Fellows Project (NSF award No. 0937060 to the Computing Research Association, sub-award CIF-146 to the University of Wisconsin) and by the AFOSR YIP program (award No. FA9550-09-1-0230).

C1.00247 Electro-Mechanical Actuation of Carbon Nanotube Yarns, Sheets, Composites , JIYOUNG OH, MIKHAIL KOZLOV, The Alan G. MacDiarmid NanoTech Institute, University of Texas at Dallas, MEI ZHANG, Florida State University, SHAOLI FANG, RAY BAUGHMAN, The Alan G. MacDiarmid NanoTech Institute, University of Texas at Dallas — We report preparation of highly conductive carbon nanotube yarns and sheets. The materials aim at such applications as electronic textiles, electro-mechanical actuators, and conductive coatings. The electro-mechanical response of the specimens was measured using custom made force transducer operating in an isometric mode. The measurements were carried out at room temperature in aqueous and organic electrolytes; square-wave potential of variable amplitude was applied with a potentiostat. It was found that the maximum isometric stress generated by nanotube actuators could be as large as 12 MPa. This approaches the stress generation capability of commercial ferroelectrics and is significantly larger than that of natural muscles. A variety of applications of the materials is discussed.

C1.00248 Convenient growth of millimeter-long, few-walled carbon nanotube forests , RAQUEL OVALLE-ROBLES, XAVIER LEPRO, MARCIO LIMA, RAY BAUGHMAN, NanoTech Institute University of Texas at Dallas, NANOTECH INSTITUTE TEAM — We report the efficient growth of 3 mm long, few-walled carbon nanotube (FW-CNT) forests by chemical vapor deposition on Si substrates. High yields (nearly 90%) of FW-CNTs were grown in a continuous and controlled way in 3 hours without resorting to water-assisted growth. TEM and SEM images of 1 and 3 mm long FW-CNTs show that the forests are comprised of mostly carbon double walled nanotubes and single walled nanotubes having large diameters. The number of walls was controlled by the catalyst thickness (ranging from 0.2 to 0.6 nm) and nanotube length was controlled by adjustment of gas pressures (ethylene, hydrogen and argon), temperature and residence time. The Al_2O_3 buffer layer was critically important for this controlled synthesis.

C1.00249 Super acid processing of Single walled carbon nanotube (SWNT): effect of SWNT aspect Ratio on Macroscopic properties , NATNAEL BEHABTU, ANSON MA, DMITRI TSENTALOVICH, COLIN YOUNG, MATTEO PASQULI, Rice University — Single walled carbon nanotubes are exceptional building blocks that combine great mechanical, electrical and thermal properties with low density. A number of processing techniques have been proposed to manufacture macroscopic articles made purely of carbon nanotubes. Superacid processing is the most flexible and promising of all since it allows dissolution of a wide range of carbon nanotube materials, including hundreds of micron long carpets. Here we show how SWNT aspect ratio influences the rheology (both shear and extensional) of SWNT/super acid solution. The longest SWNT ($\sim$10 microns as measured by cryo-TEM) are able to form stable, highly aligned fibrils under elongational flow. Fibrils thus made can be recovered and further characterized. These fibrils have some of the lowest resistivity of SWNT based material to date (160 μm-cm). These materials can also be processed into conducting and transparent films via dip coating and vacuum filtration. Films made with the longest SWNT gave a sheet resistance of 150 Ohm/sq at 90% transparency. We have also mixed long SWNT at high concentration (10 wt%) and, as expected, they form liquid crystalline solution. Surprisingly, we find that the viscosity of highly concentrated solution is not a function of the aspect ratio of the constitutive molecules (unlike dilute solutions). This allows for the high concentration solutions to be successfully spun into neat SWNT fibers.

C1.00250 Development of Side-gated Carbon Nanotubes for Terahertz Studies[1] , CHRIS MCKITTERICK, JOEL CHUDOW, DANIEL SANTAVICCA, DANIEL PROBER, Yale, PHILIP KIM, Columbia — The single-walled carbon nanotube is a truly one-dimensional conductor. The currently accepted theory describing propagation of electrons in the nanotube is Luttinger liquid theory, which predicts collective charge modes moving at a velocity greater than the Fermi velocity. By modeling the carbon nanotube as a transmission line, this propagation velocity can be determined from the standing wave resonances in the system. Due to the high resistance of carbon nanotubes, a length on the order of one micron must be used, resulting in resonances which occur at terahertz (THz) frequencies. These resonances can be measured using the heating of the nanotube electron system [1]. To avoid the use of a conducting substrate that absorbs THz, we use a side gate. We describe the development of nanotube samples with side gates for the proposed THz experiment.

C1.00251 Understanding the emission current limiting step in the carbon nanotube based polymer composite cathodes , DAVID CAREY, THOMAS CONNOLLY, RICHARD SMITH, University of Surrey — Carbon nanotube (CNT) based electronic applications often make use of the intrinsically high electrical conductivity of the nanotubes for charge transport. One attractive area for the exploitation of nanotubes is to combine their high electrical conductivity with their high aspect ratio leading to the development CNT based cathodes. In the presence of an electric field the field lines concentrate on the tip of nanotube and the resultant high local electric field (few V/nm) can result in electron tunneling (Fowler – Nordheim tunneling) from the tip and emission. Embedding a nanotube in a polymer matrix opens up the possibility of a large area and a solution processable way to produce cathodes [1]. We have studied the factors that control the rate limiting step for electron transport in functionalized CNTs in polyvinyl alcohol composites. We demonstrate excellent emission and current transport for nanotube volume fractions down to as low as 1 vol.% and that in the range from 1 vol.% to 7 vol.% the threshold field for emission does not significantly depend on nanotube content. Key to good emission is the ability to disperse the nanotubes efficiently.

C1.00252 In-Air Growth of Carbon Nanotubes[1] , CHRISTOPHER HUYNH, RYAN LU, AYAX RAMIREZ, SPAWAR SYS CEN PAC, DEBJYOTI BANERJEE, Texas A&M University, SSCPAC/TAMU COLLABORATION — Carbon nanotubes were fabricated using catalytic metal growth methods in air. Their microstructures were characterized using scanning electron microscopy and micro Raman spectroscopy. The results indicate non-aligned carbon nanotubes. In-air growth would facilitate implementation of wide-area growth of carbon nanotubes in a variety of DoD and commercial applications.

[1]Supported by ONR.

C1.00253 Molecular dynamics simulations of oxide memory resistors (memristors) , ALEXANDER BRATKOVSKY, Hewlett-Packard Laboratories, Palo Alto, S.E. SAVELIEV, A.S. ALEXANDROV, Loughborough U, UK, R.S. WILLIAMS, Hewlett-Packard Laboratories, Palo Alto — Reversible bipolar nano-switches that can be set and read electronically in a solid-state two-terminal device are very promising for applications. We have performed molecular- dynamics simulations that mimic systems with oxygen vacancies interacting via realistic potentials and driven by an external bias voltage. The competing short- and long-range interactions among charged mobile vacancies lead to density fluctuations and short-range ordering, while illustrating some aspects of observed experimental behavior, such as memristor polarity inversion. The simulations show that the "localized conductive filaments" and "uniform push/pull" models for memristive switching are actually two extremes of one stochastic mechanism [1].

C1.00254 The electrical and magnetic properties of C-doped ZnO film , DONG HAK KIM, JOON WON PARK, DAEYOUNG LIM, Kyung Hee University — The theoretical explanation on the room temperature ferromagnetism (RTF) in ZnO:C is based on the C incorporation at the O-site and the consequent exchange interaction between the localized C2p spins and valence-band holes. Here, we investigated the C incorporation site and the electrical properties of C-doped ZnO films grown by pulsed laser deposition (PLD) at both an oxygen rich and a poor conditions. Contrary to the theoretical explanations, all the C-doped ZnO films exhibited n-type conductivity. Furthermore, most of the carbons were not incorporated at the O-site, but rather at the interstitial or Zn site, or formed C clusters. Our experimental results indicate that the defect-induced ferromagnetism mechanism can better explain most of the observed RTF in the PLD grown ZnO:C films.

C1.00255 Molecular Simulations of Graphene-Based Electric Double-Layer Capacitors[1] , RAJA K. KALLURI, DEEPTHI KONATHAM, ALBERTO STRIOLO, The University of Oklahoma, School of Chemical, Biological and Materials Engineering — Towards deploying renewable energy sources it is crucial to develop efficient and cost-effective technologies to store electricity. Traditional batteries are plagued by a number of practical problems that at present limit their widespread applicability. One possible solution is represented by electric double-layer capacitors (EDLCs). To deploy EDLCs at the large scale it is necessary to better understand how electrolytes pack and diffuse within narrow charged pores. We present here simulation results for the concentrated aqueous solutions of NaCl, CsCl, and NaI confined within charged graphene-based porous materials. We discuss how the structure of confined water, the salt concentration, the ions size, and the surface charge density determine the accumulation of electrolytes within the porous network. Our results, compared to data available for bulk systems, are critical for relating macroscopic observations to molecular-level properties of the confined working fluids.

C1.00256 Capture and release of carbon dioxide by carbon nanotubes via temperature cycling[1] , DENIZ RENDE[2], NIHAT BAYSAL[2], Yeditepe University, RAHMI OZISIK, Rensselaer Polytechnic Institute — Carbon nanotubes (CNTs) received remarkable attention since they were shown to possess many unique properties as well as being effective and stable adsorbent materials that make them potentially useful for gas storage and separation of various gas mixtures. In this study, the effect of temperature variations on carbon dioxide (CO_2) capture via single walled carbon nanotubes (SWNTs) and multi walled carbon nanotubes (MWNTs) were investigated with molecular dynamics simulations. SWNTs of type (10,10), (15,15), and (20,20) and MWNTs formed from the combination of these were simulated. The temperature was varied between 300 and 360 K. The results suggest that absorption of CO_2 into the CNTs were directly related to the internal volume of the nanotube, but the cross-sectional area of the tube entrance had a significant effect on the number of CO_2 molecules retained. The number of CO_2 molecules collected in CNTs gradually decreases with increasing temperature. Separate simulations were performed to understand the potential use of CNTs as thermal pumps to collect/discharge CO_2 molecules via temperature cycling.

C1.00257 Half-Metallic Sandwich Molecular Wires with Negative Differential Resistance and Sign-Reversible High Spin-filter Efficiency , LU WANG, XIN YAN, JING ZHOU, JING LU, ZHENGXIANG GAO, State Key Laboratory for Mesoscopic Physics and Department of Physics, Peking University, Beijing 100871, P. R. China, XINGFA GAO, SHIGERU NAGASE, Department of Theoretical and Computational Molecular Science, Institute for Molecular Science, Okazaki 444-8585, Japan, STEFANO SANVITO, School of Physics and CRANND, Trinity College, Dublin 2, Ireland, YUTAKA MAEDA, Department of Chemistry, Tokyo Gakugei University, Tokyo 184-8501, Japan, TAKESHI AKASAKA, Center for Tsukuba Advanced Research Alliance, University of Tsukuba, Ibaraki 305-8577, Japan, WAI-NING MEI, Department of Physics, University of Nebraska at Omaha, Omaha, Nebraska 68182-0266 — Using density functional theory and non-equilibrium Green's function method, we construct organometallic nanowires that consist of Fe or V atoms sandwiched between composite molecules (Cp*FeCp*, where Cp* is $C_5(CH_3)_5$). For the first time, we demonstrate that half-metallicity, negative differential resistance, and sign-reversible high spin-filter capability can coexist remarkably in one organometallic nanowire (FeCp* wire). This renders FeCp* wire promising in electronics and spintronics.

C1.00258 An investigation on work-function enhancement in multilayer graphene , ABBAS EBNONASIR, BRANDEN B. KAPPES, CRISTIAN V. CIOBANU — Using density functional theory calculations, we perform a detailed analysis of the electronic properties of multilayer graphene on a generic substrate. A range of the possible substrate effects is simulated by systematically changing the interlayer distance between the first two graphene layers and leaving the other layers at the nominal graphite spacing. We find that the work function on the graphite-like side varies with the number of layers and with the distance between the first two layers, and we analyze the charge transfer distribution and the surface dipole moment as a function of the distance between the first two graphene layers. We correlate our results with reported experimental observations and provide possible explanations of pronounced work-function variations.

C1.00259 Scanning Tunneling Microscopy Study of Grain Boundaries in Graphene Grown by Chemical Vapor Deposition on Copper Foil , JUSTIN KOEPKE, DAVID ESTRADA, JOSHUA WOOD, ERIC POP, JOSEPH LYDING, University of Illinois at Urbana-Champaign — There have been few scanning tunneling microscopy studies of graphene grown by CVD on Cu [1] and no atomic scale studies of the electronic properties of the films' grain boundaries. We present the electronic nature of grain boundaries in polycrystalline graphene grown by CVD on Cu foil and transferred to SiO2 substrates. These grain boundaries are continuous across large protrusions and wrinkles in the graphene and other surface topography. We observe misorientation angles of approximately 7°, 23°, and 30° across the grain boundaries and standing wave patterns adjacent to the grain boundaries with a decay length on the order of 1 nm. The spectroscopy shows enhanced conduction in empty states at the grain boundaries. The graphene is grown on 1.4 mil copper foil by CVD. After growth the graphene was transferred onto a SiO_2/Si substrate using PMMA and $FeCl_3$. Raman spectroscopy and atomic force microscopy are used to characterize the roughness and quality of the graphene. The sample was degassed in the UHV-STM system at 600 – 700 °C for 24 hours.

C1.00260 CVD graphene growth on different substrates[1] , P. HÄBERLE[2], A. CORTES, C. CELEDON, V. DEL CAMPO, UTFSM — Graphene growth on solid substrates have the advantage of growing high quality epitaxial graphene. In this sence it is important to choose substrates and precursors having in mind the final application and an efficiency if the process. In this work we grow graphene by CVD on three different substrates, changing temperatures and precursor concentration. For graphene growth on copper foil we heat the sample up to 1000 ° C in the presence of a hydrogen and acethylene flux. The same process is performed for graphene growth on copper oxide thin films. These thin films (∼400 nm) are prepared by conventional sputtering on SiO_2 substrates and the reduced inside the preparation chamber. The advantage of this process is that copper undergoes a dewetting process during graphene growth, so at the end we have graphene suported on the SiO_2 substrate. To monitor graphene growth we use Raman spectrometer. For graphene growth on Ru(0001) we heat the substrate, temperature between 840°C and 1000°C in ultra high vacuum (UHV). We introduce ethylene in the vacuum chamber and cool down the sample. To monitor graphene growth we use Low Energy Electron Diffraction.

C1.00261 Controlling the Thermal Decomposition of Silicon Carbide into Graphene[1] , DAVID TORRANCE, TIEN HOANG, DAVID MILLER, BAIQIAN ZHANG, WALT DE HEER, PHILLIP FIRST, Georgia Institute of Technology — The quality of epitaxial graphene films grown by thermal decomposition of silicon carbide depends on experimental control of the net silicon desorption rate. Such control has been previously demonstrated by three techniques: tight confinement within an induction furnace, growth in 1-atm Ar buffer gas, or introduction of a silane overpressure. Our goal is to study the physics of these methods. We have constructed an all-graphite UHV induction furnace with maximum temperature over 1700° C and gas handling that allows process gas pressures from UHV to 1 atm. Sample holders with different orifices are used to vary the furnace confinement. Our initial systematic measurements of the effect of Ar buffer gas pressure establish that the silicon sublimation rate is adequately described by a 1D diffusion model with geometry-dependent parameters.

[1]Supported in part by the NSF, and the NRI-INDEX

C1.00262 Large area growth of single layer graphene on the C-face SiC , BAIQIAN ZHANG, MING RUAN, MICHAEL SPRINKLE, YIKE HU, JOHN HANKINSON, School of Physics, Georgia Institute of Technology, CLAIRE BERGER, School of Physics, Georgia Institute of Technology; Institut Néel, CNRS, Grenoble, France, WALT A. DE HEER, School of Physics, Georgia Institute of Technology — High quality graphene, from monolayer to many layers are consistently grown on the carbon terminated face of 4H-SiC, using the confinement controlled sublimation growth method in an induction furnace. Here we show large area monolayer graphene grown on silicon carbide substrates with this method. C-face 1cmx1cm SiC samples were graphitized by carefully controlling silicon sublimation. Ellipsometry measurements demonstrate an essentially uniform high quality graphene layer over the entire surface. The SiC chip is entirely covered by monolayer graphene, with less that 5% of bi-layer region. The thickness homogeneity is confirmed by photoemission electron microscopy, Raman spectroscopy, Atomic force microscopy (AFM). We also present transport measurements on single graphene layer C-face sample.

C1.00263 Micellization and phase transitions in a triblock copolymer-D_2O system[1] , HOSANNA ODHNER, Bryn Mawr, ALISON HUFF, KELLY PATTON, D.T. JACOBS, The College of Wooster, BRYNA CLOVER, University of Maryland, College Park, SANDRA GREER[2], University of Maryland and Mills College — The triblock copolymer ("unimer") of PPO-PEO-PPO (commercially known as 17R4) has hydrophobic ends and a hydrophilic center. When placed in D_2O at lower concentrations and temperatures, only a network of unimers exists. However, at higher concentrations or temperatures, micelles of different geometries can form. We have measured the micellization line marking the transition from only unimers to some micelles, as well as a one- to two-phase transition at higher temperatures. This second transition is an Ising-like, LCST critical point, based on the shape of the coexistence curve. We find the LCST to not correspond to the minimum of the cloud point curve, which indicates polydispersity as described by Sollich.

C1.00264 INSULATORS AND DIELECTRICS —

C1.00265 The T_g of polycyanurate in cylindrical nanoporous confinement , SIYANG GAO, SINDEE SIMON — The glass transition behavior of materials under nanoconfinement is often different than their behavior in the bulk. A leading explanation is that enhanced mobility at free surfaces or neutral interfaces results in depressions in Tg, whereas attractive interfaces result in increases in Tg. In this work, we examine the Tg of a polycyanurate using differential scanning calorimetry for both material confined in cylindrical nanopores and for freely-standing nanocylinders. Preliminary results using an alumina nanofilter for the confining matrix indicate that the Tg depression for the supported and freely standing nanocylinders are similar. The implications of the results will be discussed.

C1.00266 Band Alignment of atomic layer deposited HfO2 on clean and N passivated Germanium surfaces , ABDUL RUMAIZ, Brookhaven National Laboratory, JOSEPH WOICIK, NIST, GABRIELLA CARINI, PETER SIDDONS, Brookhaven National Laboratory, ERIC COCKAYNE, NIST, PATRICK LYSAGHT, SEMATECH, DANIEL FISCHER, NIST — Hard x-ray photoelectron spectroscopy (HAXPES) has been used to study the band alignment between atomic layer deposited (ALD) HfO2 on clean Ge (100) and nitrogen treated Ge (100) surfaces. The position of the valence-band maximum was determined by convolving theoretically calculated density of states from first-principles calculations and comparing with experimental valence-band data. The valence-band offset was found to be 3.2 ± 0.1 and 3.3 ± 0.1 eV for the samples grown on clean and N passivated Ge, respectively. The oxide charge however shows a significant increase between the two samples. The small change in the band offset between the two systems strongly indicates negligible contribution of the interface to the conduction/valence-band barrier and the band alignment of the heterojunctions.

C1.00267 Spectroscopic Ellipsometry of Gadolinium Gallium Oxide Multilayers , KALEB GILBERT, KUNAL BHATNAGAR, STEVE JACKSON, Angelo State University, RAVI DROOPAD, WILHELMUS GEERTS, Texas State University — The dielectric parameters of Gadolinium Gallium Oxide (GGO) multilayer structures have been investigated with spectroscopic ellipsometry and modeled with a simplified modeling technique. The GGO thin films are of varying thickness and the simple four parameter model was effective in determining consistent values for the dielectric constants of this important high k dielectric material. Ellipsometric data was collected in two different acquisition configurations to insure the merit of the model. The model is further confirmed by the determination of film thickness values within an acceptable range when compared with those reported by the sample grower. The dielectric parameters are then used to determine the band gap of GGO.

C1.00268 The existence of an isopermitive point of water at low frequencies , HILDA MERCADO, ABRIL ANGULO, Cinvestav-Monterrey — Water has been studied extensively since the last past century and it continues to be a subject of great interest because it has special properties and a relevant role in biological functions. One of the most used techniques to study water is the dielectric spectroscopy. Normally, the studies with this method are carried out at frequencies higher than 1 MHz. We have studied the relative permittivity of water at low frequencies (100 Hz to 1 MHz), and we found that this varies strongly as a function of the frequency. In addition, we found a specific frequency where this parameter is independent of temperature and we called it the isopermitive point. Below this point the relative permittivity increase with temperature, above, it decreases. Our explanation of this behavior is that water can be considered as a system of two species: dipoles and ions. The first obey the Maxwell-Boltzmann statistics, while the second causes the Maxwell-Wagner-Sillars effect. At the isopermitive point the effect of both mechanisms in the relative permittivity compensate each other.

C1.00269 An *Ab Initio* Study of rare gases in uranium dioxide[1] , LI MA, ASOK RAY, University of Texas at Arlington — Hybrid density functional theory has been used to study the stability and behavior of rare gases (He, Ne, Ar, Kr and Xe) in uranium dioxide. The calculations have been performed using the all-electron full-potential linearized augmented plane wave plus local orbitals basis (FP-L/APW+lo) method. Three insertion sites are considered: the octahedral interstitial position and the oxygen and uranium substitution sites. The defect formation energy, the optimized lattice constants and the volume variation induced by gaseous atom incorporation, and the electronic structure are studied for each rare gas in anti-ferromagnetic UO_2 phase without and with spin-orbit coupling (scalar vs. "full" relativistic). The results indicate that the lattice constants and formation energies increase with the increase of the radius of the rare gases. The octahedral interstitial position is the most favorable occupation site. All incorporation energies are found to be positive implying an exothermic process.

[1]This work is partially supported by the Welch Foundation, Houston, Texas (Grant No. Y-1525) and by the Department of Energy.

C1.00270 Ab initio study of adatom adsorption on topological insulator thin film , KYUNG-HWAN JIN, Department of Physics, Pohang University of Science and Technology, SEUNG-HOON JHI, Department of Physics and Division of Advanced Materials Science, Pohang University of Science and Technology — Recently topological insulator has attracted great attention due to its intriguing electronic and transport properties. Topological insulator has bulk energy gap but conducting surface states which are chiral with a linear energy-momentum relation. These surface states are robust against external perturbations as they are protected by the time reversal symmetry. We studied the electronic structure of topological insulator Bi_2Te_3 thin film and investigated how it is modified upon the adsorption of single atomic impurities using first-principles calculations. We chose nitrogen (N), oxygen (O), sodium (Na) and cobalt (Co) atoms to study their adsorption on top of Bi_2Te_3surface. We investigated the effect of non-magnetic and magnetic impurities on the surface states, and the band splitting due to the inversion symmetry-breaking by the Rashba field.

C1.00271 Phonons in Bi2Te3 and Bi2Se3 Thin Films[1] , SHANG-FEN REN, Illinois State University, WEI CHENG, Beijing Normal University — Bi2Te3 and Bi2Se3 are topological insulators attracted great research attention in recent years. In this research, some of calculated results on phonons in Bi2Te3 and Bi2Se3 bulk and single quintuple thin films are presented. The effects of spin-orbit couplings on phonon properties in these materials are discussed. Some features of Raman observations of these materials are explained.

C1.00272 Performance of the spin- and angle- resolved photoemission spectrometer with highly efficient VLEED spin detector , K. MIYAMOTO, T. OKUDA, A. KIMURA, H. MIYAHARA, K. KURODA, H. NAMATAME, M. TANIGUCHI, Hiroshima univ. — Because of the growing scientific interests in the spin-related exotic materials such as topological insulators, spin- and angle- resolved photoemission with much improved efficiency is strongly desired. In this report, we present the current status of a new SARPES with significantly improved energy- (ΔE) and angular resolutions ($\Delta\theta$), which is under construction at beam line BL-9B in Hiroshima Synchrotron Radiation Center. The system consists of high performance hemispherical analyzer (VG-Scienta R-4000) and highly efficient spin detector based on very low energy electron diffraction of Fe(001)p(1x1)-O, which has 100 times higher efficiency than conventional Mott spin detector. Owing to the high efficiency of the detector, the highest ΔE and $\Delta\theta$ have been improved to be 7.5 meV and 0.37^o. Moreover, high-resolution ARPES measurement ($\Delta E \sim 2$meV, $\Delta\theta \sim 0.2^o$) and Fermi surface mapping in the sample temperature range from 8K to room temperature can be efficiently performed by hemispherical analyzer equipped with multi-channel detector and motorized 5 axis goniometer. These features of the SARPES enable us to observe detailed spin-dependent band structures of topological insulators very precisely and efficiently.

C1.00273 Statistics of Josephson vortices in topological superconductors , EYTAN GROSFELD, University of Illinois, ADY STERN, Weizmann Institute of Science — In recent years there has been an intensive search for Majorana fermions in condensed matter systems. Predicted to be localized on cores of vortices in certain non-conventional superconductors, their presence is known to render the exchange statistics of bulk vortices non-Abelian. In this talk I will present novel results regarding the persistence of Majorana zero modes into insulating barriers, providing a way to coherently and effectively manipulate them. A method to probe the Majorana modes will be presented.

C1.00274 Van der Waals epitaxial growth and transport properties of Bi2Se3 thin films[1] , JIAN-HAO CHEN[2], JACK HELLERSTEDT, WILLIAM CULLEN, MICHAEL FUHRER, Dept. of Physics, Materials Research Science and Engineering Center and Center for Nanophysics and Advanced Materials, Univ. of Maryland, College Park — Thin films of Bi_2Se_3 with high carrier mobility are grown with van der Waals epitaxy method in ultra-high vacuum environment on single crystal Sapphire (0001) and single crystal $SrTiO_3$ (111) surfaces. *Ex-situ* transport measurement revealed weak-antilocalization-like behavior at small out-of-plane magnetic field (B_o) and non-linear Hall conductance versus Bo. The carrier concentration of the Bi_2Se_3 can be substantially tuned with applied electric field through the $SrTiO_3$ substrate.

[2]Present address: Department of Physics, UC Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA

C1.00275 Electronic properties at the interface in oxide $BiFeO_3$/Nb-doped $SrTiO_3$ semiconductor , YU-TING CHEN, YA-PING CHIU, MIN-CHUAN SHIH, Department of Physics, National Sun Yat-sen University, Kaohsiung, 804, Taiwan, ROC, JAN-CHI YANG, Department of Materials Science and Engineering, National Chiao Tung University, HsinChu, 300, Taiwan, ROC, YI-CHUN CHEN, Department of Physics, National Cheng Kung University, Tainan 70101, Taiwan, ROC, YING-HAO CHU, Department of Materials Science and Engineering, National Chiao Tung University, HsinChu, 300, Taiwan, ROC — In oxide systems, the interface of the heterojunctions had attracted much attention due to the interesting properties of the low-dimensional electron confinement. In this work, by using cross-sectional scanning tunneling microscopy, the direct and local information of structural and electronic properties across the$p-n$ heterojunction in the multiferroic $BiFeO_3$ films grown on Nb-doped $SrTiO_3$ substrate was investigated. Spectroscopy analysis of the point-to-point electronic properties allows us to realize how the asymmetrically electronic band alignment is formed at the interface. Further analysis of the evolution of the potential field across the interface also reveals that surface charge states, spontaneous polarization, and the $p-n$ contact contribute to the formation of the build-in field pointing from $BiFeO_3$ films to Nb-$SrTiO_3$ semiconductors.

C1.00276 Size dependent anomalous dielectric behavior in nanoparticle Gd_2O_3 : SiO_2 glass composite system , SUDIP MUKHERJEE, YU-HSING LIN, TING-HUI KAO, C.C. CHOU, H.D. YANG, Department of Physics and Center for Nanoscience and Nanotechnology, National Sun Yat-Sen University, Kaohsiung, 804 Taiwan — Gd_2O_3 (0.5 mol%) nanoparticles have been synthesized in a silica glass matrix by the sol-gel method at calcination temperatures of 700 °C and above. Compared with the parent material SiO_2, this nano-glass composite system shows enhancement of dielectric constant and diffuse phase transition along with magnetodielectric effect around room temperature. Observed conduction mechanism is found to be closely related to the thermally activated oxygen vacancies. Magnetodielectric behavior is strongly associated with magnetoresistance changes, depending on the nanoparticle size and separation. Such a material might be treated as a potential candidate for device miniaturization.

C1.00277 Study of field-dependent coupling of mixed phases in highly-strained BFO by impedance spectrum , JHIH-WEI CHEN, Dept. of Physics, National Cheng Kung University, YI-CHUN CHEN, H.J. CHEN, W.I. LIANG, YING-HAO CHU — In this study, we investigated the dielectric mechanism of highly-strained BFO epitaxial films with Tetragonal (T)-like and rhombohedral (R)-like monoclinic phases. The ratio of R-like BFO to T-like BFO is controllable by varying the film thickness through the relaxation of substrate stress. The impedance spectrum of T-like and R-like samples showed conducting-system dispersive (CSD) peaks at 20 kHz and 6.7 MHz, respectively. By contrast, the T+R-BFO had an additional dielectric-system dispersive (DSD) mechanism at relatively low frequency of 4.2 kHz. Moreover, the distribution range of relaxation time for this mechanism depended on the switching history, implying that the mechanism is related to the ferroelastic interaction between the two monoclinic phases. This result suggested intermediate states through phase transformation will reduce energy barrier for polarization switching. The effect of interfacial capacitance between sample and electrode was also discussed.

C1.00278 Monoclinic phase transition in stress-induced BiFeO3 epitaxial films , YEN-CHIN HUANG, Department of Physics, National Cheng Kung University, Y.C. CHEN, C. CHENG, K.I. LIN, J.S. HWANG, W.I. LIANG, H.J. CHEN, Y.H. CHU — Material system near morphotropic phase boundary usually attracted a lot of attention due to their unique physical properties. The key issue of the mechanism is to reveal the coupling between the multiple phases or the intermediate states during phase transformation. Recently, highly-strained multiferroic BiFeO3 (BFO) films had been reported to possess a particular isosymmetric boundary between tetragonal(T) and rhombohedral(R) phases. In this study, we investigated the as-grown state of mixed-phase BFO and the evolution of phases under external stimulus. Through first principle study and Raman measurement, we found the mixed phase BFO films at room temperature included two monoclinic phases, MA(Cm) and MC (Pm). When the temperature was increased to about 420 K, MC phase transformed to a R-like phase. The MA and the R-like phase coexisted until 620 K; after that, the R-like phase disappeared while the MA lasted to higher temperatures. This result showed the possible path of transition near the morphotropic phase boundary.

C1.00279 Tunnel electroresistance in ferroelectric tunnel junctions , A. CHANTHBOUALA, A. CRASSOUS, V. GARCIA, K. BOUZEHOUANE, S. FUSIL, J. GROLLIER, C. DERANLOT, Unite Mixte de Physique CNRS/Thales, France, X. MOYA, N. MATHUR, University of Cambridge, UK, M. BIBES, A. BARTHELEMY, Unite Mixte de Physique CNRS/Thales, France — In tunnel junctions with a ferroelectric barrier, large resistance changes can arise upon switching the ferroelectric polarization direction. This tunnel electroresistance (TER) effect has recently been observed by scanning probe techniques on electrode/barrier bilayers (e.g. LSMO/$BaTiO_3$), yielding giant TER values in the 50000% range at room temperature. Beside their fundamental interest to elucidate the interplay between electrostatic effects, changes in the interfacial density of states, piezoelectricity and quantum-mechanical tunneling, ferroelectric tunnel junctions undoubtedly present a great potential for application as memory devices with simple, non-destructive readout and low-power write operations. We will present our progress towards the realization of solid-state ferroelectric tunnel junctions and discuss their potential as next-generation non-volatile memories.

C1.00280 Structural and Magnetic Study of $YCrO_3$ Doped with Calcium[1] , EDUARDO VERDIN, Departamento de Física, Universidad de Sonora, México, FRANCISCO MORALES, RAUL ESCAMILLA, ROBERTO ESCUDERO, Instituto de Investigaciones en Materiales, UNAM, México, ALEJANDRO DURAN, Centro de Nanociencias y Nanotecnologia, UNAM, Ensenada, B. C. México — In recent years there has been much interest in multiferroic materials. The coupling between ferromagnetic and ferroelectricity on the same material is important from both basic science and applications. Here we address the behavior observed in $YCrO_3$ doped with Ca. The pure material presents a ferroelectric transition at about 473 K, and ferromagnetism at about 140 K. The magnetic transition is due to canted spins, so ferromagnetism and antiferromagnetism coexist. In this presentation we will show the studies on Ca doped $YCrO_3$. We show that Ca does not affect the magnetic transition (T_N), but the dielectric behavior is strongly affected by the increase of the electrical conductivity (σ_{ac}) in the range of 35 to 200 °C.

[1]Thanks to DGAPA-UNAM through project no. IN112909.

C1.00281 Surface magnetization of a multiferroic with linear M-to-P coupling: The case of $FeTiO_3$, JAMES GLASBRENNER, KIRILL BELASHCHENKO, University of Nebraska-Lincoln — A multiferroic material with linear coupling between the magnetization **M** and electric polarization **P** could serve as an electric switch of magnetization. However, for applications it is necessary to couple its magnetization to a proximate ferromagnet through exchange bias at the interface. Symmetry considerations indicate that multiferroics with linear **M**-to-**P** coupling should also have a boundary magnetization, which is not directly coupled to **P** but is rather determined by the surface normal direction. This magnetization can present an obstacle for electric switching of exchange bias. Here we investigate the (001) surface magnetization of $LiNbO_3$-type $FeTiO_3$ using first-principles PAW calculations with spin-orbit coupling. The surface magnetization appears through spin canting of the surface moments. This canting is found for different surface terminations and compared with the bulk behavior.

C1.00282 Impact of Step Defect on Surface States of Topological Insulators , DEGANG ZHANG, C.S. TING, Texas Center for Superconductivity and Department of Physics, University of Houston, Houston, TX 77204 — Recent topological insulators have attracted much attention in the condensed matter community due to the existence of surface states. The Dirac-cone topological surface states, which preserve time-reversal symmetry, are produced by strong spin- orbit coupling. In recent STM experiments, the modulations of local density of states (LDOS) induced by a step defect were observed. In this work, we investigate electron tunneling in the presence of $\delta(x)$ or $\delta(y)$ potential on the surface of topological insulators in the framework of quantum mechanics and calculate the LDOS near the δ potential. The STM experiments could be interpreted by an additional spin torque term in the wave function. We also figure out the oscillatory features of the LDOS produced by the $\delta(x)$ and $\delta(y)$ potentials, respectively.

C1.00283 Current-Induced Spin Polarizations in Surfaces of Topological Insulators , TETSURO MISAWA, Tokyo Institute of Technology, SHUICHI MURAKAMI, Tokyo Institute of Technology, PRESTO, Japan Science and Technology Agency — Topological Insulators (TI) have gapless conducting states on their surfaces, which are largely spin-split. Former studies have showed that in spin-orbit coupled systems, current can induce a spin polarization. In this research, we calculate the response of the TI surface state to the dc electric field, that is, transverse conductivity and the induced in-plane spin polarization in the presence of delta-function impurities using Kubo formula. Additionally, in Bi_2Te_3, the shape of Fermi surface is warped to be 6-fold rotationally symmetric; thereby the transport properties are modified. In this warped Fermi surface, we predict that the current induces a component of spin polarization perpendicular to the surface as a nonlinear response. This out-of-plane polarization may be easier to detect than in-plane polarization. Using the 6-fold rotational symmetry, we discuss the nonlinear response of spin accumulation to the current and its implications on Bi_2Te_3. We also study another non-linear effect, the inverse Faraday effect, where the oscillating electric field induces the dc spin polarization.

C1.00284 GENERAL PHYSICS I —

C1.00285 Blowpipe Mineralogy for Physics/Environment: Highest-Possible-Tc SuperConductor (Beyond: (but via!!!) MgB2, Cuprates, Pnictides) Quest; BOTH PERMANENT FOREVER Carb-IDES SOLID-State Sequestration AND Drought(s)-Elimination , KURT SEGLER, WENDELL WILLIAMS, EDWARD SIEGEL, FLYING-WATER — Detailed are old blowpipe new applications: charcoal-block reduction of borates to yield ("N-NW" of MgB2) Overhauser-[PR 35,1,411(1987); Intl.J.Mod.Phys.1, 2 & 4, 927(1987)]-"land" predicted high-EST-POSSIBLE Tc SC ∼ "LiD2"; very-early: Siegel[Phys.Stat.Sol.(a)11,45(1972);Semiconductors.and Insulators 5: 39,47,62(1979)] carb-IDES SOLID-state phase-TRANSITIONED CHEMICALLY-REDOX"-REACTED STABLE PERMANENT LONG-term NOT "CO2" BUT C-sequestration: PROFITABLE "Grab and Sell" TRUMPS "cap and trade"!!!; Mott alloying/vertical metal-insulator transitions in "borax-(GLASS)-beads"; and very-earlySiegel [3rd Intl.Conf.Alt.Energy (1980)-vol.5/p.459!!!] "FLYING-WATER" Hindenberg-effect (H2-UP;H2O-DOWN) via Hydrogen-maximal-Archimedes-buoyancy "chemical-rain-in-pipelines", only via Siegel proprietary "magnetic-hydrogen-valve"(MHV): Renewables-Hydrogen-Water flexible versatile agile scaleable retrofitable integrated operating-system for PERMANENT drought(s)-elimination FOREVER!!!

C1.00286 Consciousness can reduce the voltage of the output signal of solar cell , DAYONG CAO, Beijing Natural Providence Science & Technology Development Co., Ltd — When the sun's light radiate on the solar cell, it can produce the output signal as the pho- tocurrent. We use the Data Acquisition Modules to record the voltage of the output signals. The v1 is voltage of the photocurrent of solar cell1; The v2 is the one of solar cell2. And these two solar cells stay side by side. When we record the voltages from the morning to the noon, the voltages will go up, and the v1 is bigger than the v2 during this time. But in other experi- menter, not only sun's light ratiade on two solar cells, but also consciousness act on two solar cells. Not only I can use consciousness to reduce the growth voltage of the output signals, but also can change the v1 to be littler than the v2. The experiment was conducted on Sep. 2010. When light of lamp radiate on two solar cells, I can reduce v1, at the same time, can augment v2. These experiments had been finished in Los Angeles, Oct. 26th. And the experiment show that the consciousness active function differ from the passive function of conditioned reflex (of Pavlov). There is the physical system of the mass, energy, space and time-MEST; There is the spirited system of the mind, consciousness, emotion and desire-MECD; the information system is the code system. We can use the consciousness change the electron-structure of solar cell by the interaction of the information.

C1.00289 Horizons and Phase Space , RICHARD KRISKE, University of Minnesota — This author has previously suggested that the CMBR may not be entirely due to the generalized Red-Shift, but may be due to the curvature of the Universe in that the time dimensional axis would gradually tilt away from the observer at great distances in the same way that the height dimension tilts away from the observer on the surface of the Earth. There is a well known theory used by navigators that uses Euclidean Geometry to gauge this effect on the surface of the Earth, but when used in 4 space this method lacks the height needed to calculate the distance to the horizon in that the height is the time dimension. A similar height like variable can be found in QED however in the phase that is calculated from the Lagrangian. This author is suggesting that QED needs to be corrected in adding an additional phase that comes about from information conveyed in the wave-function at the time it is created giving it information about the direction of the time dimension which is rotated as the wave function moves and ultimately changes the frequency of the photon. This is field information that resembles current theories.

C1.00290 Interface Defect States and Charge Transport Properties in Low-Cost Photovoltaic Devices made from Scalable Deposition Methods[1]

, ANDREW MARIN, DAVID MUNOZ-ROJAS, DIANA IZA, TALIA GERSHON, JUDITH MACMANUS-DRISCOLL, University of Cambridge — Electrochemical deposition and Atmospheric Atomic Layer Deposition (AALD) are high-throughput, scalable methods that can be used to produce low-cost transition metal oxides for photovoltaic devices. Previous work by our group has used electrochemical deposition to fabricate ZnO/Cu_2O cells, however the performance of these cells is limited by poor Cu_2O transport properties and recombination at interface states. AALD has been shown to produce much smoother films of Cu_2O but little work has been done to characterize the electrical properties of these films. Similarly little work has been done to show the ability of AALD to reduce interface defect states. In this investigation, we use impedance spectroscopy and illuminated solar cell performance to examine the electrical properties of Cu_2O films and ZnO/Cu_2O photovoltaic devices. We also show how AALD can deposit seed layers for further improved electrochemical deposition.

[1]The authors would like to thank the Gates-Cambridge Trust and the International Copper Association.

Monday, March 21, 2011 2:30PM - 5:30PM –

Session D1 DCMP: New Developments in Quantum Criticality Ballroom A1

2:30PM D1.00001 Quantum critical points and novel phases in heavy fermion metals[1]

, QIMIAO SI, Rice University — Quantum criticality arises from competing interactions of correlated systems that favor rivaling ground states. It not only influences physical properties over a wide temperature and parameter ranges, but also gives rise to a plethora of new quantum phases. Magnetic heavy fermion metals represent a prototype system in this context, and have in particular provided the setting to study local quantum criticality that involves not only order-parameter fluctuations but also a Kondo breakdown [1]. Surprisingly, recent theoretical and experimental developments have revealed some unusual phases proximate to the heavy-fermion quantum critical points, thereby opening up an entirely new frontier on the relationship between quantum criticality and novel phases [1]. I will summarize the relevant recent experiments [2] and discuss them within the framework of a global phase diagram that was put forward several years ago [3] and has recently been discussed more extensively [4,5]. Our theoretical studies emphasize the interplay between two effects. One is the Kondo screening and its breakdown, and the other is the fluctuations in the quantum magnetism of local moments alone. The insights gained from these studies of the well-defined quantum criticality in heavy fermions may have broader relevance. Such implications will be discussed, in particular on the interplay between metallic antiferromagnetism, electronic localization and unconventional superconductivity.

3:06PM D1.00002 Two-dimensional Confinement of Heavy Fermions in Artificial Superlattices[1]

, HIROAKI SHISHIDO, Research Center for Low Temperature and Materials Sciences, Kyoto University, Kyoto, Japan — Low dimensionality and strong electron-electron Coulomb interactions are both key parameters for novel quantum states of condensed matter. A metallic system with the strongest electron correlations is reported in rare-earth and actinide compounds with f electrons, known as heavy-fermion compounds, where the effective mass of the conduction electrons are strikingly enhanced by the electron correlations up to some hundreds times the free electron mass. To date the electronic structure of all heavy-fermion compounds is essentially three-dimensional. We realized experimentally a two-dimensional heavy fermion system, adjusting the dimensionality in a controllable fashion. We grew artificial superlattices of $CeIn_3(m)/LaIn_3(n)$, in which m-layers of heavy-fermion antiferromagnet $CeIn_3$ and n-layers of a non-magnetic isostructual compound $LaIn_3$ are stacked alternately, by a molecular beam epitaxy [1]. By reducing the thickness of the $CeIn_3$ layers, the magnetic order was suppressed and the effective electron mass was further enhanced. The Néel temperature becomes zero at around $m = 2$, concomitant with striking deviations from the standard Fermi liquid low-temperature electronic properties. Standard Fermi liquid behaviors are, however, recovered under high magnetic field. These behaviors imply new "dimensional tuning" towards a quantum critical point. We also succeeded to fabricate artificial superlattices of a heavy fermion superconductor $CeCoIn_5$ and non-magnetic divalent Yb-compound $YbCoIn_5$. Superconductivity survives even in $CeCoIn_5(3)/YbCoIn_5(5)$ films, while the thickness of $CeCoIn_5$ layer, 2.3 nm, is comparable to the c-axis coherence length $\xi_c \sim$2 nm. This work has been done in collaboration with Y. Mizukami, S. Yasumoto, M. Shimozawa, H. Kontani, T. Shibauchi, T. Terashima and Y. Matsuda.superconductivity is realized in the artificial superlattices.

3:42PM D1.00003 Universal Signatures of Metamagnetic Quantum Criticality[1]

, FRANZISKA WEICKERT, Los Alamos National Laboratory, MPA-CMMS, Los Alamos, NM, 87545, USA — The continuous quest for quantum critical materials is inspired by the exotic phases and unusual phenomena that can be observed close to a zero-temperature instability. An appealing realization of such a critical point is found in metamagnetic materials where the magnetization shows a finite step at a certain magnetic field that becomes more pronounced at low temperatures. The most striking advantages of this kind of quantum criticality are that the critical point is i) symmetric in the associated thermodynamic phase diagram and not accompanied by a symmetry-breaking ordered phase and ii) the tuning parameter magnetic field H can be adjusted continuously and makes a very detailed and comprehensive study of this so called quantum critical end-point (QCEP) possible. In the presented talk the qualitative features of a field-driven QCEP are discussed, which result from very basic thermodynamic relations and the two general assumptions that i) the differential magnetic susceptibility diverges at the critical field H_c by definition and ii) the QCEP has Ising symmetry. We present real examples of metamagnetic systems, where the characteristics can be found experimentally. Particular emphasis will be placed on the well-known intermetallic material $CeRu_2Si_2$. We argue that a QCEP is approximately realized in this compound and confirm our claims by the combination of new high-resolution thermal expansion, magnetostricion and specific heat results. Very similar behavior was found recently on the prominent material $Sr_3Ru_2O_7$ whose metamagnetic quantum criticality is masked by the appearance of a phase proposed to be of nematic electronic nature. We believe that our work will facilitate and promote the experimental identification of further metamagnetic systems for quantum criticality in the future.

4:18PM D1.00004 Quantum criticality and confinement effects in an Ising chain in transverse field

, RADU COLDEA, University of Oxford — The Ising chain in transverse field is one of the key paradigms for the theory of continuous zero-temperature quantum phase transitions. We have recently realized this system experimentally by applying strong magnetic fields to the quasi- 1D, low-exchange Ising ferromagnet CoNb2O6 to drive it to its quantum critical point where the spontaneous long-range magnetic order is suppressed by magnetic field [1]. Using high-resolution single-crystal neutron scattering we have probed how the spin dynamics evolves with the applied field and have observed a dramatic change in the character of spin excitations at the quantum critical point, from pairs of domain-wall (kink) quasiparticles in the magnetically-ordered phase, to sharp spin-flip quasiparticles in the paramagnetic phase. The weak, but finite couplings between the chains significantly enrich the physics by stabilizing a complex structure of two-kink bound states due to mean-field confinement effects. In zero field the rich spectrum of bound states can be quantitatitively understood following McCoy and Wu's analytic theory of weak confinement [2]. Just below the critical field the energies of the two lowest bound states approach the "golden ratio" as predicted by Zamolodchikov's E8 scaling limit solution of the off-critical Ising model in a weak longitudinal field [3].

4:54PM D1.00005 Strange metals and quantum phase transitions from gauge/gravity duality

, HONG LIU, MIT — Metallic materials whose thermodynamic and transport properties differ significantly from those predicted by Fermi liquid theory, so-called non-Fermi liquids, include the strange metal phase of cuprate superconductors, and heavy fermion systems near a quantum phase transition. We use gauge/gravity duality to identify a class of non-Fermi liquids. Their low-energy behavior is governed by a nontrivial infrared fixed point which exhibits non-analytic scaling behavior only in the temporal direction. Some representatives of this class have single-particle spectral functions and transport behavior similar to those of the strange metals, with conductivity inversely proportional to the temperature. Such holographic systems may also exhibit novel "magnetic instabilities", where the quantum critical behavior near the transition involves a nontrivial interplay between local and bulk physics, with the local physics again described by a similar infrared fixed point. The resulting quantum phase transitions do not obey the standard Landau-Ginsburg-Wilson paradigm and resemble those of the heavy fermion quantum critical points.

Monday, March 21, 2011 2:30PM - 5:30PM –

Session D2 DCMP: Topological Surface States Ballroom A2

2:30PM D2.00001 Visualizing surface states of topological insulators using spectroscopic mapping with the scanning tunneling microscope[1]

, PEDRAM ROUSHAN, Princeton University — In topological insulators, the spin texture of the surface states makes them distinct from conventional two-dimensional electron states, and leads to novel properties for these states. These surface states are expected to be immune to localization and to overcome barriers caused by material imperfections. We have used scanning tunneling microscopy and spectroscopy to study the topological surface states in $Bi_{0.9}Sb_{0.1}$, *Sb,* and Bi_2Te_3. By mapping the interference of the surface states scattering off random alloying disorder in $Bi_{0.9}Sb_{0.1}$, we have demonstrated that despite strong atomic scale disorder, backscattering between states of opposite momentum and opposite spin is absent, resulting from the spin texture [1]. Furthermore, we have measured the transmission and reflection of topological surface states of *Sb* through atomic terraces [2]. In contrast to Schottky surface states of noble metals, these surface states penetrate such barriers with high probability. To examine the possibility of disorder induced localization, we investigated the surface states of Bi_2Te_3 in the presence of local defects. In the presence of magnetic dopants, we have observed an interference pattern throughout a broad range of energies, even in the region of linear dispersion near the Dirac point [3]. We discuss the results of a statistical analysis of these patterns which can help to learn about the tendency toward localization for these surface states and how this trend is affected as the energy is tuned to the Dirac point. *Work was done in collaboration with J. Seo, H. Beidenkopf, L. Gorman, Y. S. Hor, C. Parker, D. Hsieh, and A. Richardella, M. Z. Hasan, R. Cava, and A. Yazdani.

3:06PM D2.00002 STM and STS studies of electronic states near macroscopic defects in topological insulators[1]

, ZHANYBEK ALPICHSHEV, Stanford University — Bi_2Te_3 and Bi_2Se_3 have been argued recently to be three-dimensional (3D) topological insulators (TI), exhibiting a bulk gap and a single, non-degenerate Dirac fermion surface band topologically protected by time-reversal symmetry. In this talk we will discuss the physics of topological insulators. We will show that Scanning tunneling spectroscopy (STS) studies on high-quality Bi_2Te_3 and Bi_2Se_3 crystals exhibit perfect correspondence to ARPES data, hence enabling identification of different regimes measured in the local density of states (LDOS). Unique to Bi_2Te_3, we will discuss observations of oscillations of LDOS near a step. Within the main part of the surface band we found that the oscillations are strongly damped, supporting the hypothesis of topological protection. At higher energies, as the surface band becomes concave, oscillations appear which disperse with a particular wave-vector that results from an unconventional hexagonal warping term in the surface-state-band Hamiltonian [1]. For both systems, a bound state was observed in the bulk gap region that runs parallel to the edge of the defect and is bound to it at some characteristic distance. An expression that fits the data, and provides further insight into the general topological properties of the electronic structure of the surface band near strong structural defects, can be obtained using the full three-dimensional Hamiltonian of the system.

3:42PM D2.00003 Theory of Topological Insulators and Superconductors: Application to Cux-Bi2Se3

, LIANG FU, Harvard Univ — This abstract not available.

4:18PM D2.00004 Investigation and manipulation of the electronic properties of magnetically doped topological insulators[1] , KE HE, Institute of Physics, Chinese Academy of Sciences — Topological insulator (TI) is characterized by gapless surface/edge states which are protected by time reversal symmetry (TRS). Magnetic order in or adjacent to a TI can break its TRS, and thus result in various exotic phenomena, e.g. magnetic monopole, quantum anomalous Hall effect, and topological magneto-electric effect. Combining angle-resolved photoemission spectroscopy, scanning tunneling microscopy/spectroscopy, and transport measurement, we have investigated the electronic structures and properties of Bi2Se3 family three dimensional TIs doped with magnetic impurities. Gap opening at the Dirac surface states induced by magnetic impurities has been observed, suggesting the formation of long range magnetic order in the TIs. The Dependences of the gap size on impurity concentration, chemical potential and real space position and the (anomalous) Hall effect of the magnetically doped TIs have been systematically studied, the result of which reveals the nature and mechanism of the magnetic order. The present studies pave the road to the realization of the novel properties predicted in magnet/TI heterostructures.

[1]This work was supported by NSFC and MOST of China.

4:54PM D2.00005 Theory of surface phenomena in topological insulators , MARCEL FRANZ, University of British Columbia — Recently discovered topological insulators (TIs) are materials with bulk bandgap and robust gapless surface states protected by topological invariants that characterize their bulk band structure. After a brief introduction to the physics of TIs I will describe recent theoretical advances in understanding the behavior of surface electrons in the presence of both magnetic and non-magnetic impurities, surface steps, as well as magnetic and superconducting coating. The key property of the topological surface states – absence of backscattering from non-magnetic defects – leads to a number of features that stand in a stark contrast to the physics of ordinary non-topological states. Among these are vastly enhanced transmission through crystal steps, absence of quasiparticle interference patterns caused by non-magnetic impurities and formation of a gap in the presence of magnetic impurities.

Monday, March 21, 2011 2:30PM - 5:30PM –

Session D3 DMP GERA: Materials for Energy Ballroom A3

2:30PM D3.00001 Material tradeoffs in direct thermal to electric energy conversion systems , ALI SHAKOURI, Baskin School of Engineering, University of California, Santa Cruz — Thermoelectric devices allow direct conversion of heat into electricity without any moving parts. However the energy conversion efficiency has been limited due to parasitic Joule heating in the thermoelectric material as well as the heat leakage from the hot to the cold junction mainly through phonons. Using thermionic emission over heterostructures and electron energy filtering, high Seebeck coefficient and high electrical conductivity can be achieved simultaneously. Embedded nanoparticles can also be used to scatter mid and long wavelength phonons and reduce the lattice thermal conductivity with small impact on electrical transport. While the tradeoff in material properties can be reduced with nanoengineered structures, the overall efficiency/cost tradeoff has not been analyzed in detail. In a waste heat recovery system, in addition to the thermoelectric device, the heat sink and the electrical and thermal resistances have to be co-optimized. A recent analytic theory is reviewed which shows the potential of thermoelectric waste heat recovery in a wide range of applications. Co-optimization of the thermoelectric module with the heat sink will permit minimizing the amount of material used in the system and reduce the overall energy payback. Optimization of the thermoelectric system in maximum output power regime, which is important in many practical applications, lead to interesting conclusions about the asymmetric role of thermal resistances with hot and cold reservoirs.

3:06PM D3.00002 Photophysics of Strongly Confined Multiexcitons from the Perspective of Lasing and Solar Energy Conversion[1] , VICTOR KLIMOV, Los Alamos National Laboratory — Using semiconductor nanocrystals one can produce extremely strong spatial confinement of electronic wave functions not accessible with other types of nanostructures. One consequence of this effect is a significant enhancement in carrier-carrier interactions that lead to a number of novel physical phenomena including ultrafast mutiexciton decay due to Auger recombination and efficient generation of multiple electron-hole pairs by single photons via carrier multiplication. In this talk, I will discuss the implications of ultrafast Auger decay for lasing applications of the nanocrystals and describe several recent approaches developed in our group for resolving this problem by engineering carrier-carrier interactions in various types of heterostructured particles. I will also review the current status of carrier-multiplication research including experimental challenges in studies of this phenomenon, the role of extraneous effects, the competing energy relaxation channels, and applications of carrier multiplication in solar photovoltaics.

[1]This material is based upon work within the Center for Advanced Solar Photophysics, an Energy Frontier Research Center of the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences.

3:42PM D3.00003 Engineering Interfaces for Photovoltaic Energy Conversion , STACEY BENT, Stanford University — Dye-sensitized solar cells (DSSCs) and the related quantum dot-sensitized solar cells (QDSSCs) show promise as inexpensive, efficient next-generation photovoltaic technologies. A typical cell design consists of a sensitizer chemisorbed to a nanoporous TiO_2 substrate; the sensitizer absorbs a photon and an excited electron is injected into the TiO_2 where it diffuses to the anode. However, many devices suffer from a high rate of electron-hole recombination at the interface between TiO_2 and the hole conductive material, leading to reduced conversion efficiency. In this work we explore whether a passivating layer at the interface can improve efficiency by acting as a barrier against electron recombination. We have studied both organic and inorganic approaches to modifying the interfacial properties in DSSC and QDSSC devices. In studies of CdS-based QDSSCs, a series of organic self-assembled monolayers were formed at the interface, and their effect on CdS uptake and resulting optoelectronic and device properties was investigated. In DSSCs, nanoscale inorganic dielectric films of different thicknesses were applied to the interface using atomic layer deposition prior to dye absorption. The effect on device performance was measured experimentally and compared with predictions from kinetic models. The results of these investigations will be discussed in the context of the ability of interface engineering to improve photovoltaic energy conversion.

4:18PM D3.00004 Experimental and Theoretical Studies on Phonon Mean Free Path in Thermoelectric Materials[1] , GANG CHEN, MIT — Nanostructured thermoelectric materials have shown improved thermoelectric figure of merit due to reduced phonon thermal conductivity. To design nanostructures that effectively scatter phonons via interface and boundary scattering, it is important to know the phonon mean free path of thermoelectric materials in their bulk form. In this talk, we will present recent progress in experimental and theoretical investigation of phonon mean free path in thermoelectric materials. On the experimental side, we extend an optical pump-and-probe technique to measure contributions of phonons with different mean free paths to thermal conductivity via systematically changing the size of the heated regions. On the theoretical side, we apply first-principle calculations to extract anharmonic force constants, and compute the phonon relaxation time due to phonon-phonon scattering. We will present experimental and theoretical results obtained on silicon, half-heuslers, etc, and their implications to thermoelectric materials.

[1] This work is supported partially by S3TEC, a DOE BES funded EFRC, and by JSPS Excellent Young Researchers Overseas Visit Program.

4:54PM D3.00005 Progress in Materials for Solar Energy Conversion , EICKE WEBER, Fraunhofer-Institut fr Solare Energiesysteme ISE — This abstract not available.

Session D4 DCOMP DAMOP: Simulations Meet Experiments on Ultracold Quantum Gases

Ballroom A4

2:30PM D4.00001 Pairing states of a one-dimensional spin imbalanced Fermi gas accross a Feshbach resonance , ADRIAN FEIGUIN, University of Wyoming — A description of the BCS-BEC crossover in one dimension that properly accounts for the coexistence of fermions and bound pairs can be achieved in the framework of the Bose-Fermi resonance model, in which two fermions in an open channel couple resonantly to a diatomic molecule in the closed channel. In the case of a gas with spin imbalance, pairing correlations consistent with a phase of the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) type dominate a wide parameter range on the BCS side of the resonance. In the BEC regime, the FFLO correlations are suppressed, leading to a Bose-Fermi mixture consisting of a conventional bosonic superfluid in the molecular channel immersed into a gas of fermions that is either partially or fully polarized. I will present results of a comprehensive numerical study of this model using the density matrix renormalization group method, and determine the dependence of the critical polarization on filling and detuning. [F. Heidrich-Meisner, A.E. Feiguin, U. Schollwoeck, W.Z werger, Phys. Rev. A81, 023629 (2010)]

3:06PM D4.00002 Quantum Simulations with Ultracold Bosons in Optical Lattices and Superlattices , STEFAN TROTZKY, Ludwig-Maximilians-Universitat Munchen — Ultracold quantum gases in optical lattices have opened a new window for understanding strongly correlated many-body systems. They especially allow for ab-initio tests of fundamental condensed matter theories. In the presentation, I will discuss several examples, where static phases and non-equilibrium evolutions of ultracold quantum gases are compared to theoretical simulations. Among the examples that will be discussed are the measurement of the critical temperature for superfluidity in the vicinity of the quantum phase transition from a superfluid to a Mott insulator and the observation of a reentrant phase transition between superfluid and Mott insulating phases in a columnar superlattice. Finally, I will report on experimental and theoretical results that shed light on the question how isolated, strongly interacting quantum systems, can locally appear as if the system has equilibrated globally.

3:42PM D4.00003 Trapping, cooling and probing fermionic atoms into the Mott and Neel states[1] , JEAN-SEBASTIEN BERNIER[2], College de France and Ecole Polytechnique — A new form of quantum condensed matter physics has emerged from the study of ultra-cold fermionic atoms in optical lattices. Experiments have recently reached the incompressible Mott regime. Detailed comparison to theory and computational studies at intermediate temperatures have validated the concept of optical lattice emulation of many-body fermionic systems. Cooling these systems deeper into the quantum degenerate regime, and devising new spectroscopic probes to investigate physical issues of interest such as quasiparticle properties, are key challenges in this context. The presentation will be based in part on the following references: L. De Leo, C.Kollath, A.Georges, M.Ferrero and O.Parcollet Phys. Rev. Lett. 101, 210403(2008); J.-S. Bernier et al. Phys. Rev. A 79, 061601 (2009); R. Jördens et al. Phys. Rev. Lett. 104, 180401 (2010); J.-S. Bernier et al., Phys. Rev. A 81, 063618 (2010); L. De Leo et al., arXiv:1009.2761

[1]Collaboration with J.S. Bernier, L. De Leo and C.Kollath is especially acknowledged. Work supported in part by CNRS, the "Triangle de la Physique" and the DARPA-OLE program.

[2]In collaboration with Antoine Georges, College de France and Ecole Polytechnique.

4:18PM D4.00004 Generalized Thermalization in Integrable Systems[1] , MARCOS RIGOL, Georgetown University — Once only of theoretical interest, integrable models of one-dimensional quantum many-body systems can now be realized with ultracold gases. The possibility of controlling the effective dimensionality and the degree of isolation in the experiments have allowed access to the quasi-1D regime and to the long coherence times necessary to realize integrable models. In general, in integrable quantum systems that are far from equilibrium, observables cannot relax to the usual thermal expectation values. This is because of the constraints imposed by the non-trivial set of conserved quantities that make these systems integrable. Experimentally, relaxation of an observable to a non-thermal expectation value was recently observed in a cold-atom system close to integrability. At integrability, it is natural to describe the observables after relaxation by an updated statistical mechanical ensemble: the generalized Gibbs ensemble (GGE), which is constructed by maximizing the entropy subject to the integrability constraints. In recent studies, the GGE has been found to accurately describe various observables in the steady state of integrable systems, but a microscopic understanding of its origin and applicability remains elusive. In this talk, we review some of the early results on this topic and discuss the justification of the GGE based on a generalized view of the eigenstate thermalization hypothesis, which was originally introduced to explain thermalization in nonintegrable systems. **References:**

4:54PM D4.00005 A quantitative analysis of small atomic systems , LODE POLLET, ETH Zurich — Ultracold atoms in an optical lattice provide a unique toolbox for emulating the prototypical models of condensed matter physics. Before the optical lattice system can be trusted as a quantum simulator however, it needs to be validated and benchmarked against known results, for which quantum Monte Carlo simulations are ideally suited. In this talk, an overview of recent numerical studies of ultracold bosonic and fermionic systems in an optical lattice will be given, starting with a full comparison based on experimental time-of-flight images of bosons in an optical lattice and ab-initio simulations. Next, the advantages of single-site resolution detection tools will be highlighted. Finally, the temperature and entropy in present experiments on fermions in an optical lattice will be estimated, and the full thermodynamics on approach to the Neel temperature will be presented. Nearest-neighbor spin-spin correlations are shown to be useful for thermometry.

Monday, March 21, 2011 2:30PM - 5:30PM –

Session D5 FIAP: Industrial Physics Forum: Frontiers in Physics

Ballroom C1

2:30PM D5.00001 Controlling how atoms respond to ultra-intense x-ray radiation[1] , LINDA YOUNG, Argonne National Laboratory — With the advent of the Linac Coherent Light Source, the world's first hard x-ray free electron laser, an era of exploration using ultrafast, ultra-intense x-ray pulses has arrived. One can deposit 100,000 x-ray photons into one square Angstrom within 100 fs, producing an electric field strength that exceeds that binding the electron in a hydrogen atom. How does matter respond under these conditions? Using neon atoms, we investigated the electronic response as the x-ray interaction is tuned from the outer to the inner shell. At photon energies above all inner-shell edges, fully stripped neon is produced via six-photon absorption. The route to bare neon proceeds through photoejection of 1s electrons that produces hollow atoms and an intensity-induced x-ray transparency. X-ray transparency can be induced in all atomic, molecular and condensed matter systems. Going beyond non-resonant x-ray atom interactions, we investigated the atomic response at inner-shell resonances and find evidence for x-ray induced Rabi cycling. These investigations provide a framework for understanding ultra-intense x-ray interactions with matter.

[1]Work supported by DOE, Office of Basic Energy Sciences.

3:06PM D5.00002 Scanning Tunneling Microscopy of Dirac Fermions at mK Temperatures , JOSEPH STROSCIO, NIST — Since the beginning of the last century new frontiers in physics have emerged when advances in instrumentation achieved lower experimental operating temperatures. Notable examples include the discovery of superconductivity and the integer and fractional quantum Hall effects. New experimental techniques are continually adapted in order to meet new experimental challenges. A case in point is scanning tunneling microscopy (STM) which has seen a wealth of new measurements emerge as cryogenic STM instruments have been developed in the last two decades. In this talk I describe the design, development and performance of a scanning probe microscopy facility operating at a base temperature of 10 mK in magnetic fields up to 15 T [1]. The microscope is cooled by a custom designed, fully ultra-high vacuum (UHV) compatible dilution refrigerator (DR) and is capable of in-situ tip and sample exchange. Sub-picometer stability at the tip-sample junction is achieved through three independent vibration isolation stages and careful design of the dilution refrigerator. The system can be connected to, or disconnected from, a network of interconnected auxiliary UHV chambers used for sample and probe tip preparation. Current measurements are focusing on Dirac fermions in graphene and in topological insulators. The history of the fractional quantum Hall states in semiconductor heterostructures suggests that studying graphene at lower temperatures and higher magnetic fields may reveal new quantum phases of matter. Scanning tunneling spectroscopy of graphene at mK temperatures reveals the detailed structure of the degenerate Landau levels in graphene, resolving the full quartet of states corresponding to the lifting of the spin and valley dengeneracies [2]. When the Fermi level lies inside the four-fold Landau manifold, significant electron correlation effects result in enhanced valley splitting and spin splitting. New many-body states are observed at fractional filling factors of 7/2, 9/2, and 11/2.

3:42PM D5.00003 Topological materials and their potential applications , SHOUCHENG ZHANG — In this talk I shall give a brief introduction on the physics of the recently discovered topological materials and discuss their potential applications.

4:18PM D5.00004 The Hottest Liquid on the Planet , BARBARA JACAK, Department of Physics and Astronomy, Stony Brook University — We generally expect high temperature matter to act like a gas. However, nature sometimes holds surprises. Collisions of heavy nuclei at very high energies produce a plasma of quarks and gluons which is a strongly coupled liquid. Its vanishingly small shear viscosity to entropy density ratio means it flows essentially without resistance, making it one of the most "perfect" liquids known. Astoundingly, a key tool for theoretical study of the dynamics of this novel liquid arises from the duality of string theory with black holes. I will describe how this liquid is studied, what we've learned about its properties at the Relativistic Heavy Ion Collider in the U.S. and at the Large Hadron Collider in Switzerland, as well as what we haven't figured out yet. I'll also discuss how the quark gluon plasma relates to other strongly coupled systems such as dusty plasmas, cold atomic gases, and strongly correlated condensed matter.

4:54PM D5.00005 Ultracold polar molecules , DEBORAH JIN, NIST, JILA, Univ. of Colorado — Ultracold quantum gases are model systems for studying many-body quantum physics. For example, superfluidity in ultracold Fermi gases of atoms realizes an electrically neutral analog of superconductivity. Recently, enormous progress has been made toward the goal of creating a new type of quantum gas where the constituent particles are polar molecules rather than atoms. In addition to new internal degrees of freedom of the particles, polar molecules introduce the possibility of long-range dipole-dipole interactions, which make the system fundamentally different from atom gases, which have short-range, or contact, interactions. I will discuss recent experimental work on a trapped gas of ultracold fermionic polar molecules.

Monday, March 21, 2011 2:30PM - 5:30PM –

Session D6 DBP DPOLY DCMP: Physics of Proteins I: Unifying Principles and Concepts

Ballroom C2

2:30PM D6.00001 Protein Dynamics , HANS FRAUENFELDER, Los Alamos National Laboratory — Proteins combine properties of solids, liquids, and glasses. Schrödinger anticipated the main features of biomolecules long ago by stating that they had to be solid-like, but able to assume many different conformations. Indeed proteins can assume a gigantic number of conformational substates with the same primary sequence but different conformations. The different substates are described as craters in a very-high-dimensional energy landscape. The energy landscape is organized in a hierarchy of tiers, craters within craters within craters. Protein motions are pictured as transition between substates - jumps from crater to crater. Initially we assumed that these jumps were controlled by internal barriers between substates, but experiments have shown that nature selected a different approach. Proteins are surrounded by one to two layers of water and are embedded in a bulk solvent. Structural motions of the protein are controlled by the alpha fluctuations in the solvent surrounding the protein. Some internal motions most likely involving side chains are controlled electrostatically by beta fluctuations in the hydration shell. The dynamics of proteins is consequently dominated by the environment (H. Frauenfelder et al. PNAS 106, 5129 (2009). One can speculate that this organization permits exchange of information among biomolecules. The energy landscape is not just organized into two tiers, alpha and beta, but cryogenic experiments have revealed more tiers and protein more properties similar to that of glasses. While proteins function at ambient temperatures, cryogenic studies are necessary to understand the physics relevant for biology.

3:06PM D6.00002 Engineering electron tunneling in natural and artificial proteins[1] , P.L. DUTTON, Johnson Research Foundation, Department of Biochemistry and Biophysics, University of Pennsylvania, Philadelphia, PA 19104 — Experimental investigation of oxidoreductases has revealed their naturally selected electron tunneling engineering that underlies oxidative and reductive catalysis. This engineering is relatively simple, which allows us to design artificial oxidoreductases from scratch, without the unnecessary complexity found in natural proteins. We have constructed a simple, four α-helix protein bundle protein framework that can be manipulated to support a range of cofactor and substrate binding, and redox and light driven actions. For example, by controlling water access and mobility, this framework can support hemoglobin-like oxygen transport without anything resembling a globin fold. The same framework provides a clear path to artificial proteins designed to catalyze single or multi electron tunneling coupled to chemistry.

[1]In collaboration with C.C. Moser, Johnson Research Foundation, Department of Biochemistry and Biophysics, University of Pennsylvania.

3:42PM D6.00003 The Physical Mechanism of Proton Transfer in Proteins , AIHUA XIE, Department of Physics, Oklahoma State University, Stillwater, OK 74078 — Proteins are able to perform an enormous variety of functions, while using only a limited number of underlying processes. One of these is proton transfer. The physical mechanism of proton transfer has been extensively studied, using a variety of experimental and computational methods. However, it remains unclear what determines the direction and rate of proton transfer reactions in proteins. We have developed and applied a new approach to this long-standing problem by integrating structural dissection, energy landscape, first principle calculation (quantum theory), and molecular dynamics simulation. Our proof of concept study reveals key structural elements that control the direction and rate of proton transfer in proteins. The results are of predictive power and can be generally applied to different proteins.

4:18PM D6.00004 Frustration and the Functional and Folding Landscape of Proteins , PETER WOLYNES, University of California, San Diego — The energy landscape for folding is funnel-like and largely correlates topology directly with energetics. Thus many of the "excited states" important for function are ensembles of structures in which entropy balances partial unfolding energy costs. I will discuss such spectra for cytochrome c. Another way of achieving low free energy excitations is via frustration which entails deviations from the simple funnel landscapes responsible for setting the overall protein shape. I will discuss interesting examples of the consequences of frustration for binding, allostery and for membrane protein systems.

4:54PM D6.00005 Dynamics and mechanism of water-protein interactions , DONGPING ZHONG, The Ohio State University — Water-protein interactions are essential to biology and such interactions are not static but dynamic in nature. With femtosecond spectroscopy and site-directed mutagenesis, we have systematically investigated protein surface hydration dynamics and the actual time scales of their fluctuations. These new results are significant to understanding the physics of protein dynamics at the most fundamental level.

Monday, March 21, 2011 2:30PM - 5:30PM –

Session D7 GSNP: From Molecular Control to Spatiotemporal Patterns in Bacteria and Beyond

Ballroom C3

2:30PM D7.00001 Bacterial strategies for chemotaxis response , MASSIMO VERGASSOLA, CNRS/Institut Pasteur — Bacteria respond to chemical cues by performing a biased random walk that enables them to migrate towards attractants and away from repellents. Bias is achieved by regulating the duration of the bacterial runs as a function of the environment, inferred from the history of chemoattractant detections experienced by the bacterium. This time-signal is processed using a time convolution function that can be assayed measuring the response of the bacterium to short pulses of chemoattractant. The convolution constitutes an elementary form of memory, which is encoded at the molecular level by the processes of (de-)methylation and (de-)phosphorylation of the underlying biochemical network. While the latter is being characterized in detail, the functional reasons shaping the bacterial chemotactic response are largely unknown. We show that the chemotactic response observed experimentally is the strategy that ensures the highest minimum (MaxiMin) uptake of chemoattractant, in any field thereof. The consequence is that adaptation of the chemotactic bacterial system appears to be evolutionary driven by the need to cope with space-time environmental fluctuations rather than the extension of the dynamic range of response.

3:06PM D7.00002 Arrested phase separation in reproducing bacteria: a generic route to pattern formation? , JULIEN TAILLEUR, University of Edinburgh — In this talk I will present a generic mechanism by which reproducing microorganisms can form stable patterns. This mechanism is based on the competition between two separate ingredients. First, a diffusivity that depends on the local population density can promote phase separation, generating alternating regions of high and low densities. Then, this is opposed by the logistic law for birth and death of microorganisms which allows only a single uniform density to be stable. The result of this contest is an arrested nonequilibrium phase separation in which dense droplets or rings become separated by less dense regions, with a characteristic steady-state length scale. I will illustrate this mechanism by considering a model of run-and-tumble bacteria, for which a density dependent diffusivity can stem from either a decrease of the swim speed or an increase of the tumbling rate at high density. No chemotaxis is assumed in this model, yet it predicts the formation of patterns strikingly similar to those believed to result from chemotactic behavior.

3:42PM D7.00003 A tunable sequential and periodic pattern formed by coupling cell motility with density , JIANDONG HUANG, The University of Hong Kong — The ability of living organisms to form patterns is an untapped resource for synthetic biology. We aim to generate unique patterns by rewiring the genetic circuitry controlling cell motility. Specifically, E. coli cells are programmed to regulate their movement by sensing local cell density. Interesting patterns are formed by newly engineered cells. An engineered low-density mover strain spreads outwards and autonomously forms a sequential and periodic pattern. Moreover, we build a theoretical model that satisfactorily fits our current experimental data, and also predicts some parameters which may significantly affect the pattern formation. The study of this self-organized spatial distribution of cells may help us to probe the principles underlying the formation of natural biological patterns, and to prepare for future engineering of biological structures.

4:18PM D7.00004 Self-organized biological patterns driven by growth and expansion , TERENCE HWA, Center for Theoretical Biological Physics, UC San Diego — The reaction-diffusion (RD) model, involving the diffusion of two types of morphogens ("activator" and "inhibitor") whose interaction stimulates their own synthesis, is an established paradigm to explain the autonomous generation of space-filling patterns in biology. Starting from random initial perturbations, the RD model typically generates patterns via the development of finite-wavelength dynamical instabilities in confined geometries. In this talk, I will describe examples where elements of the RD model, together with the open, expanding geometries offered by growing biological systems, give rise to novel strategies to generate well-defined patterns in space and time.

4:54PM D7.00005 Deadly competition between sibling bacterial colonies , AVRAHAM BE'ER, University of Texas at Austin, CNLD — As a result of stress due to nutrient limitation or antibiotics, competing individual bacteria within a single colony may lyse sibling cells to release nutrients (cannibalism) or DNA (fratricide). However, we have recently shown that competition is not limited to individuals, but can occur at the colony level [A. Be'er et al., PNAS 106, 428 (2009); A. Be'er et al., PNAS 107, 6258 (2010).] In response to the presence of an encroaching sibling colony, *Paenibacillus dendritiformis* bacteria secrete a lethal protein, lysing cells at the interface between the colonies. Analysis of the proteins secreted by these competing sibling colonies, combined with a mathematical model, shows how colonies maintain their growth by self-regulating the secretion of two proteins: subtilisin (a well-known growth promoter), and Slf (a previously unknown protein, which is lethal). The results also explain why a single colony is not inhibited by its own secretions.

Monday, March 21, 2011 2:30PM - 5:30PM –

Session D8 GMAG: Spin Currents Ballroom C4

2:30PM D8.00001 Spin Currents in Silicon[1] , IAN APPELBAUM, University of Maryland, College Park — I will discuss the results of our recent spin injection experiments using long-distance non-degenerate undoped (and n-type doped) Si devices. We have a unique capability to recover the details of electron transport on a sub-ns timescale through a "Larmor clock" transformation of spin precession data, despite using only quasistatic current measurements. I suggest that this is potentially a new tool for probing non-equilibrium phenomena in semiconductors, revealing both intrinsic and extrinsic materials properties through sensitivity to subtleties of the bandstructure and impurity spectrum.

[1]Supported by ONR and NSF.

3:06PM D8.00002 Spin Hall Effects in Ferromagnet-Semiconductor Heterostructures , MUN K. CHAN, University of Minnesota — The effect of spin-orbit coupling on charge transport has long been studied in the form of the anomalous Hall effect in ferromagnets. Charge current in a ferromagnetic channel is intrinsically spin polarized, and asymmetric transverse scattering of spin-up and spin-down electrons due to spin-orbit coupling leads to charge accumulation on the channel edges. Recent breakthroughs in the ability to inject and detect non-equilibrium spin populations in non-ferromagnetic materials have opened up new avenues to study related phenomena. Of particular interest is the spin Hall effect (SHE) in which an ordinary charge current induces a transverse spin current. The resultant spin accumulation at the channel edges was first detected optically [Y. K. Kato *et al.*, Science 306, 1910 (2004) ; J. Wunderlich *et al.*, Phys. Rev. Lett. 94, 047204 (2005)]. We report on an all-electrical measurement of the SHE in Fe/n-In$_x$Ga$_{1-x}$As heterostructures. The edge spin accumulation is detected with spin-sensitive Fe/Schottky tunnel barrier contacts. We investigate the bias and temperature dependence of the SHE and successfully determine the skew and side-jump contributions [E. S. Garlid *et al.*, Phys. Rev. Lett. 105, 156602 (2010)]. Additionally, we have studied the inverse spin Hall effect (iSHE), in Fe/n-GaAs devices. Spin current injected into n-GaAs by a biased Fe/Schottky contact results in a spin-dependent Hall voltage. The iSHE signal is an order of magnitude larger than that expected from SHE measurements in the same heterostructure. Temperature dependence, nuclear magnetic resonance, and field cycling measurements show conclusively that the iSHE is coupled to the dynamically polarized nuclear spins. We have therefore discovered a new contribution to spin Hall effects: the hyperfine coupling. Work done in collaboration with E.S. Garlid, Q.O. Hu, C.J. Palmstrøm, and P.A. Crowell. Funding provided by NSF DMR 0804244, ONR MURI, and NSF MRSEC and NNIN programs.

3:42PM D8.00003 Electrostatically Manipulated Ballistic Spin Currents[1] , MARK JOHNSON, Naval Research Laboratory — Two decades ago Datta and Das published a remarkable paper [1] concerning spin polarized ballistic electron currents in a semiconductor channel and the Rashba spin orbit interaction. They predicted that the source-drain conductance of a spin-injected Field Effect Transistor (spin FET) would oscillate periodically as a function of monotonically increasing gate voltage. We have observed Datta Das oscillations using spin-FETs with ferromagnetic metal electrodes as source and drain [2]. The channel is composed of a high mobility InAs single quantum well heterostructure with strong spin-orbit interaction. The source-drain length is less than the electron mean free path at T=1.8 K. Using the nonlocal geometry, diffusive carriers are removed at a remote ground and the channel conductance is dominated by a current of spin polarized ballistic electrons. A conductance that oscillates as a function of gate voltage is observed. The oscillation amplitude is calibrated from the lateral spin valve magnetoresistance. The spin-orbit interaction parameter is determined from beats in Shubnikov-de Haas data. Thus, the fit to theory has no adjustable parameters other than a small phase factor. Finally, we compare the temperature dependence of the oscillation amplitude with that of the carrier mean free path. The importance to Spintronics, which proposes the use of both spin and charge as state variables, is the demonstration that carrier spin orientation can be modulated by voltage, a parameter normally associated with charge.

[1]In collaboration with H.C. Koo, J. Eom, S.H. Han and J. Chang. I acknowledge support from ONR.

4:18PM D8.00004 Logic Devices Based on Spin Current[1] , BEHTASH BEHIN-AEIN[2], Purdue University — The need to find low power alternatives to digital electronics circuits has led to increasing interest in alternative switching schemes like the magnetic quantum cellular automata that store information in nanomagnets which communicate through their magnetic fields. A recent proposal called all spin logic (ASL) proposes to communicate between nanomagnets using spin currents which are spatially localized and can be conveniently routed. In this talk we present a model for ASL devices that is based on established physics and is benchmarked against available experimental data. We investigate switching energy- delay of ASL devices and provide frameworks that allow simple comparisons with charge based devices like CMOS and can help to determine possible use of ASL in future logic implementation. Expected scaling of switching energy-delay of ASL devices as magnets are downscaled while retaining their stability against thermal fluctuations will be presented.

4:54PM D8.00005 Optical detection of spin currents[1] , HUI ZHAO, Department of Physics and Astronomy, University of Kansas — Extensive efforts are currently being devoted to developing spintronics. Several techniques have been developed to generate pure spin currents in many materials and structures. However, there is still no method available that can be used to directly detect pure spin currents, which carry no net charge current and no net magnetization. Currently, studies of pure spin currents rely on measuring the induced spin accumulation with optical techniques or spin-valve configurations. I will discuss observation of a second-order nonlinear optical effect of pure spin currents that can be used for the non-invasive, non- destructive, and real-time imaging of pure spin currents. This effect is caused by a subtle imbalance of the Faraday rotation of electrons with opposite spin orientations [1]. In our experiment, a transient pure spin current was injected in a GaAs crystal by a quantum interference and control technique using a pair of phase-locked ultrafast laser pulses. Second- harmonic generation of an ultrafast probe pulse with a central wavelength of 1760 nm was observed [2]. We systematically studied the second-harmonic power as a function of the probe delay, probe position, spin current density, and carrier density. All the observations are consistent with a second- order nonlinear optical effect induced by the pure spin current. Since this effect does not rely on optical resonances, it can be used to detect pure spin currents in a wide range of materials with different bandstructures. Furthermore, the control of nonlinear optical properties of materials with pure spin currents may have potential applications in photonics integrated with spintronics.

Monday, March 21, 2011 2:30PM - 5:30PM –

Session D9 DFD: Patterns, Nonlinear Dynamics followed by General Fluid Dynamics D220

2:30PM D9.00001 Rayleigh Bénard Convection-A Case Study on Pattern Formation , HIRA SIDDIQUI, RUDOLF FRIEDRICH, WWU Muenster, Germany — Spiral turbulence in Rayleigh-Benard convection is studied numerically in the framework of generalized Swift Hohenberg equations. The model equation consist of an order parameter equation for the temperature field coupled to an equation for the mean flow field. In contrast to the earlier work, nonlinearities in the dynamics of the mean flow are retained leading to a two dimensional Navier-Stokes equation coupled to a Swift-Hohenberg equation. We present the numerical investigations of nonlinear effects due to the interaction of nonlinear two dimensional flows and the pattern forming process.

2:42PM D9.00002 A simple approach to localized convection , H. PLEINER, Max Planck Inst. for Polymer Research, Germany, M.G. CLERC, Univ. de Chile, Santiago de Chile, J. MARTINEZ-MARDONES, Pont. Univ. Catolica de Valparaiso, Chile, L.M. PEREZ, Dep. Ingeneria Metalurgica, Univ. de Santiago, Chile, D. LAROZE, Max Planck Institute for Polymer Research, Mainz and Inst. de Alta Investigacion, Univ. de Tarapaca, Arica, Chile — Localized structures can be found in many different (dissipative) driven systems [1], an example being stationary and traveling convection structures in the thermal instability of binary fluids. Here, the special localized structure is a convective state between two quiescent, conductive ones, and can been interpreted as a pinning phenomenon close to a stationary sub-critical bifurcation. Generally, localized structures are described by using higher dimensional, complex amplitude or phenomenological prototype (e.g. Swift-Hohenberg) equations or by direct numerical integration of the hydrodynamic equations. Here we show, using the binary mixture convection in porous media as an example, that the analytically derived one-dimensional amplitude equation amended by non-adiabatic (non-resonant) terms important close to convection fronts, well describes localized convection states, in particular the slanted homoclinic bifurcation diagrams.

2:54PM D9.00003 The dynamics of cracks in torn thin sheets , YOSSI COHEN, ITAMAR PROCACCIA, Department of Chemical Physics, The Weizmann Institute of Science, Rehovot 76100, Israel — The stress field near the tip of a crack due to a mode III shear tearing of a thin plate of elastic material has a universal form but with a non-universal amplitude known as the Stress Intensity Factor. All the non-universal aspects of the stress distribution are collected in the Stress Intensity Factor which depends on everything, including the crack length, the boundary conditions and the history of the loads that drive the crack evolution. Although the equations of elasticity for thin plates are well known, there remains the question of selection of a path for a propagating crack. We invoke a generalization of the principle of local symmetry to provide a criterion for path selection and demonstrate the qualitative agreement of our results with the experimental findings. We also analyze the nature of the singularity at the crack tip with and without the nonlinear elastic contributions. Finally we present an exact analytic results for the stress intensity factor to the linear approximation for the crack developing in thin sheets.

3:06PM D9.00004 Chaotic Plume-Like Bursts in Rimming Flows , GABRIEL SEIDEN, VICTOR STEINBERG, Weizmann Institute of Science — We report a detailed experimental investigation of chaotic, plume-like bursts observed in rimming flows of polymer solutions within a partially filled horizontal cylinder. In particular, we investigate the attractive interaction between adjacent plumes and the effect of rotation rate and polymer concentration on the statistics of these unique bursts. A comparison is also made between the Newtonian and non-Newtonian cases.

3:18PM D9.00005 Cracks formation during blood drop evaporation , BENJAMIN SOBAC, DAVID BRUTIN, Université de Provence, UNIVERSITÉ DE PROVENCE TEAM — We firstly presented the pattern formation occurring when drops of whole blood desiccate in a recent publication [1]. The phenomena presented evidence to involve lots of physical field such as surface chemistry, haematolology, fluid mechanics, heat transfer, colloids science... All these mechanisms are acting together and produce an axisymetric and reproducible pattern. Dried cellular components are segregated and deposited by a capillary flow. During the evaporation, the system is slowly drying and cracks when stresses are too important leading to the final pattern observed. In this presentation, we will present the mechanisms involved in the formation of crack patterns. The phenomenon presented here with red blood cells as the main colloids involved is very similar to the drying of drop of nanoparticules [2]. We will explain the common point and the differences encountered.

3:30PM D9.00006 ABSTRACT WITHDRAWN –

3:42PM D9.00007 Pattern formation and coarsening in crystalline membranes , DANIEL A. VEGA, ALDO D. PEZZUTTI, Dep. de Física- IFISUR- Universidad Nacional del Sur - CONICET — We study through a Brazovskii-Helfrich Hamiltonian the process of defect formation, annealing and coarsening of two dimensional crystalline membranes. In good agreement with the cosmological model of Kibble and Zurek, proposed to determine the density of topological defects at the onset of a symmetry breaking phase transition, we found that the collision of orientationally uncorrelated domains produces a structure of grains with an average density of topological defects controlled by the temperature of the quench. The strain field of the dislocations and disclinations generated during the phase separation process can induce the buckling of the membrane, slowing down the Lifshitz-Safran mechanism of coarsening observed in flat systems.

3:54PM D9.00008 Pattern formation in ternary lipid membranes with composition-deformation coupling , MATTHEW DEMERS, Northwestern University Department of Applied Mathematics, FRANCISCO SOLIS, MONICA OLVERA DE LA CRUZ, Northwestern University Department of Materials Science — We study patterns formed in three-component lipid membranes, where composition is coupled to shape via differences in spontaneous curvature. The system is examined in the strong segregation regime. System morphology is determined by the competition of bending energy, surface tension, and line tension. We will present the phase behavior as determined by numerical minimization, as well as analytic solutions for select cases.

4:06PM D9.00009 Supercavitating flow past an elastic curvilinear hydrofoil[1] , YURI ANTIPOV, Louisiana State University — A nonlinear inverse fluid-structure interaction problem is considered. The obstacle is a curvilinear elastic hydrofoil, and the cavity formed behind is modeled according to the single-spiral-vortex model by Tulin. First, the model for a rigid polygonal supercavitating hydrofoil is solved by the method of conformal mappings. The mapping function is expressed through the solutions of two Riemann-Hilbert problems. To identify the vertices of the polygon where the jets break away from the foil, the Brillouin-Villat separation condition is applied. The unknown parameters of the conformal mapping are computed on solving a system of transcendental equations. Next, by increasing the number of vertices of a regular N-polygon, the cavitation problem for a circular arc is solved, pressure on the foil is defined, and a boundary- value problem for a thin shell subject to normal loading is stated. The elastic problem is solved exactly for an arc with clamped ends, and the new hydrofoil profile is determined. Finally, a new cavitation problem for the deformed foil is stated and solved. Numerical experiments reveals the presence of two thin partial cavities near the foil ends.

4:18PM D9.00010 Drag calculations using the inviscid Euler equations alone , GALEN GISLER, PGP/University of Oslo — Recently Hoffman and Johnson[1] have proposed a new resolution of d'Alembert's Paradox, the problem that inviscid potential flow predicts zero drag on a body, in contrast to observations. They reject the commonly accepted resolution, that drag results from the very thin viscous boundary layer between the no-slip condition on the surface of the body and the free-flowing fluid. Instead they argue that drag results from turbulence in the body's wake, even if free-slip is assumed. They used a finite-volume code to verify their conclusions. While their calculations look promising, and offer prospects for calculation of rather more complex flows at modest resolution, it is desirable to perform independent verification. I will present independent tests of the Hoffman-Johnson resolution using a finite-volume Euler-equation code, studying the dependence of the inferred drag on meshing style and resolution.

4:30PM D9.00011 Dynamics of induced dipole ER fluid: a continuous energetic approach , JIANWEI ZHANG, WENFENG LI, JIAXI LI, Dept. of Physics, Tongji University, Shanghai, China — We studied dynamics of Electrorheological (ER) fluid by continuum induced dipole fluid method [1]. We found that the velocity profile of ER fluid increases in high shear-rate region and solid particles are separated from colloid in high electric field. These findings demonstrated the breakdown of Bingham fluid model under high shear-rate and high electric field. Our continuum approach describes ER fluid's behaviors under most conditions. We also found that the shift of maximum shear stress under different electric field follows the same trend as that of the maximum static stress. This indicates that the static and dynamic stresses are both dominated by the same energetic process. A connection between micro-particles' structures and macro-dynamic properties under varying conditions is established by our continuum method. Our studies probe the physics of induced dipole ER fluid.

4:42PM D9.00012 Velocity fluctuations in steadily sedimenting suspensions , K. VIJAY KUMAR[1], SRIRAM RAMASWAMY, CCMT, Department of Physics, Indian Institute of Science, Bangalore 560012 — The simplest model of a homogeneous suspension steadily sedimenting under gravity at low Reynolds number indicates that the velocity fluctuations should diverge with the system size. This is, however, not seen in experiments. We improve on a previously described coarse-grained model proposed for this problem by identifying certain crucial missing terms in the equations of motion. These terms are allowed by symmetry considerations and can be generated by a mechanism which is natural in the dynamics of low Reynolds number sedimentation. A dynamical renormalization group calculation of our model leads to the conclusion that these extra terms are always relevant. If these terms are stabilizing, this suggests a natural mechanism for suppressing fluctuations in sedimenting suspensions. We analyze the properties of the critical point where these extra terms vanish.

[1]Present Address: Departments of Mechanical Engineering & Materials Science and Physics, Yale University, New Haven, CT 06511

4:54PM D9.00013 Stabilization of toroidal droplets using viscoelastic media , EKAPOP PAIRAM, ALBERTO FERNANDEZ- NIEVES, School of Physics / Georgia Tech Team — We inject a viscous liquid through a needle into another rotating viscous liquid to generate toroidal droplets. These droplets are unstable and undergo a transformation into spherical droplets driven by surface tension: They either break ala Rayleigh-Plateau or grow fatter to become a single spherical droplet depending on the aspect ratio of the torus. By replacing the outer phase with a viscoelastic fluid with a non-zero yield stress we can stabilize these and other non-zero genus droplets. We will examine this stabilization mechanism and present criteria to effectively prevent the break-up of these droplets.

5:06PM D9.00014 Iron chemistry at aqueoues interfaces by near edge X-ray spectroscopy[1] , DAVID VAKNIN, WENJIE WANG, ALEX TRAVESSET, Ames Laboratory, and Department of Physics, Iowa State University, Ames, Iowa 50011, IVAN KUZMENKO, X-ray Science Division, Advanced Photon Source, Argonne National Laboratory, Argonne, IL 60439 — Employing synchrotron X-ray absorption near-edge spectroscopy (XANES) combined with X-ray fluorescence (XF) and reflectivity (XR) techniques, we monitor the state of ferrous and ferric iron as it binds to charged carboxylic and phosphate groups. By subphase pH manipulation, arachidic acid and dihexadcyl phosphate monolayers can provide a range of surface charge density from nearly charge-neutral to a fully charged monolayer to which iron ions are attracted from solutions. Analysis of our results from fluorescence show that the driving forces attracting Fe^{3+} and Fe^{2+} to the interface originate from chemical interactions and electrostatic, respectively. XANES shows that the electronic and geometric structure of iron complexes at interface are different from those in the bulk. Moreover, the XANES results demonstrate that valence state and bonding of the interfacially bound Fe^{3+} and Fe^{2+} are practically indistinguishable. This, we argue, is due to the versatility of iron ions in behaving as electron acceptors (Fe^{3+}) or as donors (Fe^{2+}).

[1]Supported by the Office of BES, U.S. Department of Energy Cont. No. DE-AC02-07CH11358.

5:18PM D9.00015 Interfacial microrheology in viscoelastic membranes , GOPAL SUBEDI, KENNETH W. DESMOND, ERIC R. WEEKS, Emory University — Prior studies on interfaces using microrheology have typically been applied to interfaces with only a surface viscosity component and not an elastic one. We are extending the application of interfacial microrheology to viscoelastic lipid monolayers. We use a DPPC and cholesterol lipid monolayer in a Langmuir trough as a model system. The Langmuir trough gives us the flexibility to control the concentration and thus the phase of the monolayer. The microrheology technique allows us to measure the rheology at specific concentrations or in situations as the concentration is changed. The microrheology technique employs video microscopy to record the diffusive motion of micron size spheres placed at the interface. Since the diffusive motion of the microspheres is dominated by the interfacial rheology of the monolayer, the recorded motions of the microspheres are used to infer the rheological properties of the interface. We hope to extend our understanding of viscoelastic interfaces with the study.

Monday, March 21, 2011 2:30PM - 5:30PM –
Session D10 SPS: SPS Undergraduate Research II D221

2:30PM D10.00001 The ^{11}C Project:Measurement of Root Exudation at Elevated CO2 Levels in Low and High Nutrient Solutions , VERIDA LEANDRE, North Carolina AT SU, CALVIN HOWELL, Duke Univ. — Understanding the plant kingdom's mechanisms of resource management in variable environments is integral to predicting how plants will respond to an increase in atmospheric CO_2. The goal of this study is to determine the effects of changing nutrient conditions on the root exudation of barley plants at elevated CO_2 levels. The ^{11}C group at the Triangle Universities Nuclear Laboratory (TUNL) tags various species of plants with short-lived positron-emitting radioisotopes in order to analyze metabolite transport in response to changes in the environment. ^{11}C is produced at TUNL using a tandem Van de Graaff particle accelerator, then transported from TUNL to the Duke Univ. Phytotron (100m) where plants are labeled with ^{11}C in a growth chamber. The chamber allows researchers to control the light intensity, air temperature, humidity and concentration of CO_2 in the air. The plant absorbs $^{11}CO_2$ in a leaf that is placed inside a cuvette through which radioactive $^{11}CO_2$ gas flows. The sugars in the labeling leaf are tagged with ^{11}C and translocated throughout the plant similar to ^{12}C. Scintillation detectors are used to track the tagged sugars as they are translocated through the plant and exudated from the root into the nutrient solution or $^{11}CO_2$ gas is respired by the root. The labeling system, detector arrangement, electronics and data analysis will be described and preliminary results will be presented.

2:42PM D10.00002 A One Dimensional Stochastic Susceptible-Infectious-Recovered Model and its Variations: a Hamiltonian Approach , ALI HAMED, Washington and Lee University, DIA'A BISHARAT, MOHAMAD AMINE, IRINA MAZILU, Washington and Lee — The spread of an infectious disease is a random process, and a stochastic approach to the problem is justified. The susceptible-infectious-recovered model (SIR) describes the evolution of three types of individuals (in a small community) which undergo an infection and recovery mechanism. The model (and its variations) predicts the number of infected individuals over a certain period of time, gives an estimate of the maximum possible number of infected people, and predicts how long the disease will be threat to the examined community. Using a quantum mechanical approach, we investigate four variations of the original SIR model and compare our analytical findings with the computer simulation results. We also calculate correlations between infected and recovered individuals, and find a good agreement between theory and computer simulations.

2:54PM D10.00003 Exploring a Parasite-Host Model with Monte Carlo Simulations , NYLES BREECHER, JIAJIA DONG, Hamline University — We explore parasite-host interactions, a less investigated subset of the well-established predator-prey model. In particular, it is not well known how the numerous parameters of the system affect its characteristics. Parasite-host systems rely on their spatial interaction, as a parasite must make physical contact with the host to reproduce. Using C++ to program a Monte Carlo simulation, we study how the speed and type of movement of the host affect the spatial and temporal distribution of the parasites. By drawing on mean-field theoretics, we find the exact solution for the parasite distribution with a stationary host at the center and analyze the distributions for a moving host. The findings of the study provide rich behavior of a non-equilibrium system and bring insights to pest-control and, on a larger scale, epidemics spreading.

3:06PM D10.00004 Optical design of a robotic TV camera probe for minimally invasive abdominal surgery[1] , SUSANNA TODARO, Harvey Mudd College, WEIYI HE, DENNIS KILLINGER, University of South Florida — Minimally invasive techniques are a promising new field of surgery; however, they limit the surgeon's access points and maneuverability. In order to increase the number of access points in minimally invasive abdominal surgery, a proposed implantable medical probe braces to the abdominal wall and provides illumination and video signal. The probe is cylindrical, about 25 mm long and 10 mm in diameter. A ring of LEDs on the end of the probe illuminates the tissue, and the resulting image is focused onto an HD video detector. It was necessary to apply beam-shaping reflectors to collimate the light onto a small target area, to avoid illuminating areas not picked up by the video. These reflectors were designed and simulated using the optical ray tracing software TracePro. Two LED chip geometries and three types of reflector geometries were analyzed, and the parameters for each geometry were optimized. For the straight-edged reflectors, the intensity patterns and optimization were compared to experimental results. Although parabolic reflectors produced the best collimation, cone reflectors with a 20-degree half-angle produced significant collimation at a much cheaper price.

3:18PM D10.00005 Developing a Procedure for the Characterization of Mechanical Properties of Collagen Gels[1] , CHRISTOPHER CHAMBERS, Northern Arizona University, HEATHER LOVELADY, GARRETT MATTHEWS, University of South Florida — The characterization of bulk mechanical properties of type I collagen gels is critical to understanding the role of collagen in the extracellular matrix (ECM), and developing biocompatible devices for use in the human body. Understanding the mechanical properties of the gel state of collagen can lead to the ability to adjust these properties for multiple uses. Here, we examined the Young's modulus of the synthesized gels. This project used a microrheological approach to discover these properties. Gels were first formed using a known process and magnetic microspheres were embedded in the gel prior to formation. An optical microscope was fitted with a magnetic chamber used to drive the embedded beads in two modes, an oscillatory motion and a pulse motion. Tracking software was modified and used to analyze the motion of the beads recorded with a CCD camera on the microscope. These techniques should be sufficient to obtain a reliable value for the Young's modulus of collagen gels, as well as other similar materials.

3:30PM D10.00006 ABSTRACT WITHDRAWN –

3:42PM D10.00007 Does Thioflavin-T Detect Oligomers Formed During Amyloid Fibril Assembly[1] , CHRISTOPHER PERSICHILLI, Rensselaer Polytechnic Institute, SHANNON E. HILL, JASON MAST, MARTIN MUSCHOL, University of South Florida — Recent results have shown that oligomeric intermediates of amyloid fibril assembly represent the main toxic species in disorders such as Alzheimer's disease and type II diabetes. Thioflavin-T (ThT) is among the most commonly used indicator dyes for mature amyloid fibrils *in vitro*. We used ThT to monitor amyloid fibril formation of lysozyme (HEWL), and correlated ThT fluorescence to concurrent dynamic light scattering and atomic force microscopy measurements. Specifically, we tested the ability of ThT to discern among oligomer-free *vs.* oligomeric fibril assembly pathways. We found that ThT fluorescence did not detect oligomer growth; however, fluorescence increases did coincide with the formation of monomeric filaments in the oligomer-free assembly pathway. This implies that ThT fluorescence is not generally suitable for the detection of oligomeric intermediates. The results further suggest different internal structures for oligomeric *vs.* monomeric filaments.

[1]This research was supported, in part, by funding through the Byrd Alzheimer's Institute (ARG-2007-22) and the BITT-Florida Center of Excellence for M.M., an NSF-REU grant (DMR-1004873) for C. P. and an NSF-IGERT fellowship for S.H.

3:54PM D10.00008 The Design and Fabrication of Bismuth Hall Effect Biosensors , A.J. SIGILLITO, University of Dallas, M. RUDOLPH, V. SOGHOMONIAN, J.J. HEREMANS, Virginia Tech — Because of their high sensitivity, accuracy, and low cost, the use of Hall biosensors promises to be an effective diagnostic technique that may aid in the early diagnosis of diseases. In this research, Hall sensors were fabricated from thermally evaporated bismuth thin films. The bismuth films were deposited under high vacuum onto heated Si/SiO_2 substrates using a two layer deposition technique. The films varied in thickness from 60 nm to 75 nm and were etched into Hall bar geometries using photolithography and wet chemical etching. Magnetoresistance and Hall measurements were taken from 4 K to 300 K. The data indicate that the sensors may be characterized using a two carrier model with high mobility, low density holes and low mobility, high density electrons. Additionally, the sensors were exposed to magnetite nanoparticles and characterized using atomic force microscopy. The results will be reported. This research was funded by the National Science Foundation (NSF Grant DMR-0851662).

4:06PM D10.00009 EPR Study of Lithium Borovanadate and Lithium Silicate Glasses , BIKESH DAHAL, D. BLANE BAKER, William Jewell College, STEVE FELLER, Coe College — Lithium borovanadate and lithium silicate samples with varying molar ratios were prepared using both roller quenching and plate quenching methods. Electron paramagnetic resonance EPR spectra of those samples show that resolution of the hyperfine structure lines(hfs) depend on their molar ratio. When the molar ratio (K) is less than 0.5 in the borovanadate system, the hyperfine structure lines are well resolved and defined. However, when the molar ratio becomes greater than 0.5; the spectra starts to get less resolved; at molar ratio 0.7 there is no hyperfine resolution. Well resolved samples were modeled by using a modeling program in MATLAB to obtain Hamiltonian parameters. The Hamiltonian parameters that were obtained were $g_{parallel}$, $g_{perpendicular}$, $A_{parallel}$ and $A_{perpendicular}$. The Hamiltonian parameters were calculated to learn about the orientation of V^{4+} ions and electrons in the glass samples. According to our calculation $g_{parallel} < g_{perpendicular} < g_e$ which suggests that crystal field of the V^{4+} ions has a octahedral site with a tetragonal compression in the glass samples.

4:18PM D10.00010 EPR study of radical trapping of RAFT polymerization of Multifunctional Acrylates , AAYUSH REGMI, ASHUTOSH DAHAL, D. BLANE BAKER, William Jewell College, JOHN POJMAN, Louisiana State University, PATRICK BUNTON, William Jewell College — Electron Paramagnetic Resonance (EPR) was used to monitor radical trapping during Reversible Addition-Fragmentation chain Transfer (RAFT) polymerization of acrylate monomers with different degrees of functionality. Monomers used for the study were 1, 6-Hexanidiol Diacrylate (HDODA), Trimethylopropane Triacrylate (TMPTA), and Pentaerythritol Tetracrylate (PETA). X-band EPR spectra were obtained for approximately 0.2 g of samples in a 4 mm quartz tube heated at 50^0C inside the cavity. The trapped radicals' signals were first observed after the samples were heated for 400-500 minutes. Radical density continued to increase for an additional 180 -190 minutes. EPR spectra of RAFT samples of TMPTA and PETA were compared with subsequent spectra produced by traditional free radical polymerization.

4:30PM D10.00011 EPR study of Frontally Polymerized Multifunctional Acrylates[1] , ASHUTOSH DAHAL, AAYUSH REGMI, ANNA THOMA, ALECIA VALENCIA, William Jewell College, VERONIKA VINER, RAFAEL CUETO, Louisiana State University, D. BLANE BAKER, William Jewell College, JOHN POJMAN, Louisiana State University, PATRICK BUNTON, William Jewell College — Electron Paramagnetic Resonance(EPR) study of frontally polymerized Trimethylopropane Trimethacrylate(TMPTMA), Trimethylopropane Triacrylate(TMPTA), 1,6-Hexanidiol Diacrylate(HDODA) and Pentaerythritol Tetracrylate(PETA) was done to determine the absolute radical concentration. Higher radical concentrations were found in the frontally polymerized samples compared to the bulk polymerized samples for TMTPMA and PETA. The concentration of radicals was highest in TMPTMA frontal sample at 8.74 X 10^{-3} moles/kg. The lowest measureable concentration was in the HDODA bulk samples at 0.0266 X 10^{-3} moles/kg. For all frontally polymerized samples high radical concentrations were observed at the point of initiation after which the signal intensity decreased to steady state within a few centimeters down the front. An exponential growth in the radical signal was observed in the mixture of TMPTMA and TMPTA when the concentration of the TMPTMA was increased.

4:42PM D10.00012 First-principles investigation of graphene-metal interfaces[1] , ANDREW ROSS, Saint Anselm College, LYUDMYLA ADAMSKA, YOU LIN, IVAN OLEYNIK, University of South Florida — Epitaxial growth of graphene on Ni(111) substrates is one promising method of large-scale, high-quality graphene wafer production, due to the small lattice mismatch between these two materials. We present results of first-principles density functional theory (DFT) investigation of thestructural, electronic, and magnetic properties of graphene/Ni(111) interfaces relevant to experimental studies of graphene growth on nickel substrates. DFT calculations were performed to identify the favored interface geometries and binding sites for different interface configurations. Additional adlayers of Ni and Cu were either adsorbed on top of the graphene/metal interface, or placed between the graphene and substrate to model processes of metal intercalation. It was also found that the interaction between graphene/Ni(111) and the top Cu adlayer is much weaker compared to that for Ni adlayer. The atomic, electronic, and magnetic properties of these interfaces, including induced magnetic moments in graphene/Ni(111) and Cu,Ni/graphene/Ni(111) systems are also discussed.

4:54PM D10.00013 Growth of Graphene on Metal Substrates[1] , TRAVIS MILLER, Grove City College, JAYEETA LAHIRI, RAFIK ADDOU, MATTHIAS BATZILL, University of South Florida — Graphene, a single layer of graphite, has large potential as an electronic material. For these applications large scale, high quality graphene wafers are required. A promising approach to achieve this is by growth on metal substrates. In this REU project I used Auger electron spectroscopy to study the growth of graphene on Ni(111) and its modification by Cu or Al additions. On pure nickel we found two graphene growth regimes. Below 480 °C graphene grows by converting a surface carbide phase while above 480 °C graphene grows on pure nickel. Addition of copper destabilizes the nickel carbide enabling the growth of graphene in the absence of a carbide at lower temperatures. Finally, aluminum intercalation through the Ni- supported graphene layer was investigated in an attempt to form an ordered Ni-Al alloy underneath the graphene. Surprisingly, we found that this intercalation process already occurs at only 100 °C. Furthermore, the intercalated Al is protected by the graphene against oxidation.

5:06PM D10.00014 Single-Walled Carbon Nanotubes in Epoxy – Investigating Behavior under Strain and Alignment Using Fluorescence Spectroscopy[1] , TAMIKA THOMAS, KENA SENEGAL, SARENA SENEGAL, PAUL WITHEY, Northwestern State University, SERGEI BACHILO, R. BRUCE WEISMAN, Rice University — Single-walled carbon nanotubes (SWCNTs) have been successfully embedded into EPON 862/W epoxy both with and without a surfactant. Applying strain to the nanocomposite permitted the interfacial adhesion between the SWCNT and host to be studied at the single-particle level using near-infrared fluorescence spectroscopy. Load transfer from the host to an embedded CNT is clearly observed as a shift in the nanotube's spectral emission. Loss of adhesion, or slipping, is also detected. Attempts at enhancing CNT-alignment within the nanocomposite will also be discussed. Near-infrared fluorescence imaging and spectroscopy prove to be ideal methods for monitoring the behavior of SWCNTs within nanocomposites, especially at the single-particle level. Much of this work has been carried out by undergraduate physics and chemistry majors.

5:18PM D10.00015 An Ab-initio Study of Folded Armchair Graphene Nanoribbons , ADAM IAIZZI, Ithaca College, NAM LEE, LILIA WOODS, University of South Florida — We present a first principles approach to the characterization of armchair graphene nanoribbons folded along their long axis using density functional theory, along with ultrasoft psuedopotentials and the local density approximation for the exchange-correlation functional. Based on past studies, we anticipate that folding nanoribbons will produces changes in the band structure, possibly turning normally semiconducting nanoribbons into metallic nanowires. We determine the energy required to produce a number of different folded structures from nanoribbons as well as the energy and band structure as a function of width in single-fold structures. Ribbons as narrow as 13 carbon atoms formed stable folded structures.

Session D11 FIAP: Thermal Properties in Semiconductors and Nanostructures D222

2:30PM D11.00001 Thermoelectric Properties of Granular Materials[1] , ANDREAS GLATZ, Argonne National Laboratory, IGOR BELOBORODOV, California State University, Northridge — I will present our recent studies of thermoelectric properties of mono-phasic nanocrystalline semiconductors and metals in the weak coupling regime. The focus is in particular on the thermopower and figure of merit for temperatures less than the charging energy. I will show that the dimensionless figure of merit ZT, which is a measure for the performance of thermoelectric materials, has a maximum at certain temperatures and grain sizes which can be in the range of technological relevant values $ZT > 3$. The talk is based on: Phys. Rev. B **80**, 245440 (2009) and EuroPhys. Lett. **87**, 57009 (2009).

2:42PM D11.00002 Thermal Conductivity Characteristics of Three-Layer Superlattices , JING ZHANG, HUA TONG, NELSON TANSU, Lehigh University — For thermoelectric applications, the thermal conductivity of the material needs to be reduced as low as possible in order to achieve higher thermoelectric efficiency of devices, as the device efficiency depends on the thermoelectric figure of merit ($Z*T$). Both theoretical and experimental data show that the cross-plane thermal conductivity of superlattices is much lower than that of the bulk materials The cross-plane thermal conductivity of three-layer superlattices is calculated by a numerical method, which is developed from the lattice dynamical theory. The phonon mean free path is included into the calculation, thus the minimum thermal conductivity occurs at the crossover of the particle-like model and wave-like model of the phonons. The studies focus on the effect of mass ratio, layer thickness, and mean free paths on the minimum thermal conductivity of the three-layer superlattice design. The minimum thermal conductivity of the three-layer superlattice structure is approximately half of that of the conventional two-layer superlattice structure. This finding indicates that the thermoelectric figure of merit for superlattice structure can further be enhanced by 2 times from the use of the three-layer superlattice design.

2:54PM D11.00003 Lattice thermal conductivity with first-principles anharmonic lattice model , TERUMASA TADANO, YOSHIHIRO GOHDA, SHINJI TSUNEYUKI, Department of Physics, The University of Tokyo — First-principles calculation of lattice thermal conductivity is important to design new devices such as high-efficiency thermoelectric materials. For lattice thermal conductivity calculations of complex materials and nanostructures, non-equilibrium molecular dynamics (NEMD) is more suitable than widely used Boltzmann transport theory. However, a combination of NEMD and FPMD is almost impossible because of its high computational cost, so that NEMD has been performed only with classical model potentials for specific materials. In order to overcome this limitation in materials, we have developed a new methodology for calculating lattice thermal conductivity without relying on any experimental values. In this method, the potential energy of a system is expressed as a many-body anharmonic model, that is, a Taylor expansion of the total energy with respect to displacements of atoms up to 4th order. Parameters of the anharmonic lattice model are determined with Hellmann-Feynman force of FPMD by least-square fitting. We performed thermal conductivity calculations with the anharmonic lattice model combined with NEMD and obtained reasonable agreements with experimental values.

3:06PM D11.00004 Surface roughness and phonon transport in thin Si nanowires: an atomistic study[1] , JESUS CARRETE, LUIS JAVIER GALLEGO, LUIS MIGUEL VARELA, Facultad de Fisica, Universidad de Santiago de Compostela, Spain, NATALIO MINGO, LITEN, CEA-Grenoble, France — Good thermal insulation is much harder to achieve than electrical insulation. Thus, the astonishingly low thermal conductivities recently reported on Si nanowires came as a surprise, since the displayed values were an order of magnitude lower than predicted by the diffuse boundary limit of Casimir's theory. Recent theoretical work has employed the Born approximation to predict a very much enhanced boundary scattering rate that would lead to a thermal conductivity well below the Casimir limit. We present a Green's function calculation that answers the question of whether the Casimir limit to the phonon mean free path can be overcome by roughness. Our results show that the mean free path (MFP) and the thermal conductivity of a nanowire are very close to the Casimir limit for shallow disorder, and can only be pushed below it using very deep surface roughness, well beyond previous estimates. We also explore the limits of the Born approximation in this context using vacancies and isotopic impurities as defects.

3:18PM D11.00005 Quantal Heating of 2D electrons in strong magnetic fields[1] , SERGEY VITKALOV, The City College of New York, New York, NY 10031, USA, ALEXEY BYKOV, Institute of Semiconductor Physics, 630090 Novosibirsk, Russia — Usually heating of conducting electrons by dc electric field increases electron temperature and effects weakly the electron transport. In this report we show that the dc heating of 2D electrons with a quantized spectrum is very peculiar and violates strongly the Ohm's Law [1]. The quantal heating establishes nontrivial electron distribution, which has the same broadening or an effective "temperature" as the unbiased system. The heating reduces significantly the dissipative electron transport, forcing the quantum conductors into a state with zero differential resistance (ZDR). Furthermore an apparent dc driven metal-insulator transition is found, which correlates with the transition into the ZDR state. This interesting correlation is unexpected and is not understood.

3:30PM D11.00006 Light-induced thermodynamic metastability in amorphous silicon , DANIEL QUEEN, JULIE KAREL, FRANCES HELLMAN, University of California, Berkeley, QI WANG, RICHARD CRANDALL, EUGENE IWANICZKO, National Renewable Energy Lab — The efficiency of amorphous silicon photovoltaics is limited due to the generation of dangling bond defects upon light soaking which leads to a decrease in their efficiency known as the Staebler-Wronski Effect. These defects act as recombination centers for photoexcited electron-hole pairs and can be reversibly removed by annealing above 150°C. The electrical properties of these defects are well documented but the mechanism that gives rise to them is still an open question. It is known that hydrogen plays a crucial role in their formation and recovery but it is not clear if hydrogen participates in the defect formation. We present heat capacity data for a-Si:H films grown by the Hot-Wire CVD (HWCVD) technique and a-Si films grown by e-beam evaporationand measured using our MEMS based nanocalorimeter. Both materials have an excess heat capacity observed upon light soaking that is reversibly removed by annealing at 200°C. This excess is found to be independent of H content in the HWCVD films and is present but at a smaller magnitude in the e-beam evaporated a-Si. The lack of dependence on H content and the presence in the e-beam films indicates the light induced metastability is intrinsic to the amorphous silicon matrix.

3:42PM D11.00007 Thermodynamic properties of ZrSiO4 polymorphs from DFT based *ab initio* phonon calculations[1] , JINCHENG DU, MRUNAL CHAUDHARI — Zircon and Reidite are the polymorphs of $ZrSiO_4$minerals that are natural hosts of various radioactive elements in the crust of the earth. Its high permittivity also makes it a promising material for the gate dielectric material in metal-oxide semiconductors. Knowledge of the thermodynamic properties at high temperature and high is very important to consider its application as an effective natural storage for the radioactive wastes and high technology ceramics. These properties are thoroughly studied both computationally and experimentally for zircon, while significantly less attention was paid to reidite in the literature. We report studies of thermodynamic properties of Zircon and Reidite from phonon spectra calculations using *ab initio* based periodic density-functional theory (DFT) calculations. Various thermodynamic properties such as free energy, internal energy, entropy, enthalpy, heat capacity and thermal displacement as a function of temperature are calculated. Phoon dispersion curves and density of states are calculated and compared with the experimental data. Calculated bulk properties agree very well with the experimental data in the literature.

3:54PM D11.00008 Vibrational and thermal properties of ternary semiconductors and their isotopic dependence: chalcopyrite CuGaS2[1] , ALDO ROMERO, CINVESTAV, Unidad Queretaro, M. CARDONA, R. KREMER, R. LAUCK, Max Planck Institute, Stuttgart, A. MUÑOZ, ULL, Spain — The availability of *ab initio* electronic calculations and the concomitant techniques for deriving the corresponding lattice dynamics have been profusely used in the past decade for calculating thermodynamic and vibrational properties of semiconductors, as well as their dependence on isotopic masses. The latter have been compared with experimental data for elemental and binary semiconductors with different isotopic compositions [1]. Here we present theoretical and experimental data for several vibronic and thermodynamic properties of a canonical ternary semiconductor of the chalcopyrite family: CuGaS2 [2]. Among these properties are the lattice parameters, the phonon dispersion relations and densities of states (projected on the Cu, Ga, and S constituents), the specific heat and the volume expansion coefficient. The calculations were performed with the ABINIT and VASP codes within the LDA approximation for exchange and correlation.

4:06PM D11.00009 Temperature dependence of band gap of highly confined CdSe and PbSe nanocrystals , JASON BYLSMA, PRASENJIT DEY, JASON REJMAN, University of South Florida, AARON ZAUBI, SARATH WITANACHCHI, PRITISH MUKHERJEE, DENIS KARAISKAJ, MATTHEW C. BEARD COLLABORATION[1] — We have recorded fluorescence spectra from PbSe and CdSe quantum dots in hexane/toluene respectively between 5K and 300K in order to investigate the temperature dependence of the electronic band gap of these highly confined nanostructures. The band gap for CdSe follows the known blue shift with decreasing temperature (dE/dt = -225 μeV/K). Olkhovets et. al. first reported a red shift of the band gap energy with decreasing temperature for small (d $<$ 4 nm) PbSe and PbS quantum dots [1]. Such behavior would contradict the expected blue shift of the band gap with decreasing temperature. We have measured the temperature dependence of the band gap of PbSe quantum dots for two different diameters below 4 nm and indeed observe a red shift of the band gap with decreasing temperature (dE/dT = 58 μeV/K), which is stronger for the smaller size quantum dots (dE/dt = 82 μeV/K). The origin of this peculiar behavior is not well understood and we are pursuing further theoretical and experimental studies in order to elucidate the mechanism behind it. [1] A. Olkhovets, et. al. Phys. Rev. Lett. 81, 3539 (1998).

4:18PM D11.00010 Temperature and polarization dependent photoluminescence studies of WO_3 and WO_{3-x}single crystals , PRASENJIT DEY, University of South Florida, JUSTIN EASLEY, Massachusetts Institute of Technology, DENIS KARAISKAJ, University of South Florida, SATYEN DEB, National Renewable Energy Laboratory, TED CISZEK, Geolite/Siliconsultant, DANIEL DESSAU, University of Colorado, Boulder — WO_3 is an important material not only due to its interesting electronic properties but also for applications in electrochromics and energy storage. The mechanism behind the electrochromic effect has been debated for several decades.[1] We have studied two WO_3 single crystals, a transparent and a doped WO_{3-x}. A photoluminescence center around 865 nm is observed after sub-band gap excitation at 405 nm with relatively higher intensity in the crystal containing oxygen vacancies. The center appears as a broad transition of 35 nm FWHM and does not follow the band gap energy with temperature. However polarization dependent studies reveal at least two polarization dependent component of the center.

4:30PM D11.00011 Mapping free-carrier diffusion in GaAs with radiative and heat-generating recombination[1] , TIM GFROERER, RYAN CRUM, Davidson College, MARK WANLASS, NREL — We use a tightly focused laser along with optical and thermal imaging to measure the diffusion-driven, free-carrier distribution in a GaAs/GaInP heterostructure. We find that temperature profiles are broader than their luminescence counterparts. This observation is consistent with how the underlying recombination mechanisms depend on carrier density: the rate of heat generation should be approximately proportional to the density of carriers, while the radiative rate should scale with the density squared. We show that the square root of the light signal follows the heat profile, giving consistent, independent measurements of the local carrier density.

Session D12 DMP: Focus Session: Dopants and Defects in Semiconductors: Compound Semiconductors II D223/224

2:30PM D12.00001 Defect energy distribution in GaN/AlGaN heterostructures grown in Ga-rich and ammonia-rich conditions[1] , TANIA ROY, YEVGENIY PUZYREV, ENXIA ZHANG, DANIEL FLEETWOOD, RONALD SCHRIMPF, SOKRATES PANTELIDES — We use low-frequency noise measurements to estimate energy distributions of electrical-stress-induced defects in AlGaN/GaN high electron mobility transistors from 85 K to 450 K. The devices were grown under Ga-rich and ammonia-rich conditions using molecular beam epitaxy. The Ga-rich devices show a positive shift in pinch-off voltage and a decrease in gate leakage current with stress under a gate voltage of -3.6 V and a drain voltage of 20 V. These changes in response are associated with hydrogenated Ga vacancies in AlGaN. The ammonia-rich devices show a negative shift in pinch-off voltage and an increase in gate leakage current under the same stress conditions; these changes in device response are caused by N-antisite defects. The excess drain voltage power spectral density of the low frequency $1/f$ noise peaks at $\sim$ 100 K in both device types, which corresponds to a trap energy of 0.2 eV. We attribute this to N-vacancy-related defects, which are also observed in proton damage experiments.

2:42PM D12.00002 Thermal electron capture rate by Fe acceptor in GaN , J. DASHDORJ, M.E. ZVANUT, University of Alabama at Birmingham, T. PASKOVA, K. UDWARY, Kyma Technologies, Inc. — Doping GaN with Fe compensates the main residual impurities such as O and Si to produce semi-insulating substrates. Electron paramagnetic resonance measurements were made on GaN grown by hydride vapor phase epitaxy and doped with 1.5x10^{17} to 1.6x10^{18} cm^{-3} Fe. The Fe^{3+} spectra, angular dependence, and concentrations are consistent with literature and secondary ion mass spectroscopy data. During illumination with photon energies greater than 1.2 eV, the Fe^{3+} signal increased in the lowest doped sample, but decreased in the more highly doped samples. One possible interpretation of the results is that the $Fe^{2+/3+}$ and $Fe^{3+/4+}$ levels are about 1.2 eV below the conduction band. Due to our measurement resolution, the spectral separation between the levels cannot be determined. The time-dependence of the Fe^{3+} signal recovery after removal of 2.64 eV was recorded at temperatures between 3.5 and 297 K. Analysis show that capture rate of electrons by Fe^{3+} decreases from 6x10^{-16} to 5x10^{-17} cm^3/s with an inverse-square-root temperature dependence. The work is supported by the NSF.

2:54PM D12.00003 Direct atomic imaging of Mn in the GaN growth surface: High-density, Two-dimensional, Striped Superstructures[1] , KANGKANG WANG, Ohio University, NOBORU TAKEUCHI, ABHIJIT CHINCHORE, WENZHI LIN, ARTHUR SMITH — A class of novel well-ordered striped superstructures have been observed by depositing submonolayer Mn onto GaN(0001)-"1×1" surface. These superstructures consist of stripe domains along $[1\bar{1}00]_{GaN}$ with various widths, while scanning tunneling microcopy images resolved a common local $\sqrt{3}\times\sqrt{3}$-R30° structure for the stripes. Combined with first-principles calculations, a new two-dimensional structural model is proposed having a dense Mn_xGa_{1-x} surface layer. Mn atomic sites within the GaN surface are directly identified. A spin-induced asymmetry in the Mn electronic structure is revealed in real-space for the narrow stripes. These findings explain the behavior of Mn atoms in the GaN growth surface and herald the development of magnetic nanostructures on GaN surfaces.

[1]This work is funded by Department of Energy and National Science Fundation.

3:06PM D12.00004 Initial Phase of Sub-monolayer Iron Growth on GaN(0001) pseudo-1×1-1+1/12 Surface Studied Using Scanning Tunneling Microscopy and First Principles Theoretical Calculations[1] , WENZHI LIN, NOBORU TAKEUCHI, KANGKANG WANG, ABHIJIT CHINCHORE, MENG SHI, ARTHUR SMITH, Nanoscale and Quantum Phenomena Institute, Department of Physics and Astronomy, Ohio University, HAMAD ALBRITHEN, Physics and Astronomy Department, King Saud University — Iron/gallium nitride bi-layer structures have potential use for spintronic applications. Therefore, we have carried out an investigation of the initial phase of sub-monolayer iron growth on GaN(0001) pseudo-1×1-1+1/12 surface. To begin with, we verified an atomically smooth GaN growth surface with the assistance of *in situ* reflection high energy electron diffraction. STM shows smooth terraces separated by single and double height bilayer atomic steps. About 0.4 ML iron was deposited on the smooth GaN, and the subsequent STM images reveal Fe islands with a height of $\sim$ 2 Å growing in a two-dimensional step-flow mode outward from the GaN step edges of the pseudo-1x1-1+1/12 surface. A clear 6 × 6 structure is observed for the islands. First principles theoretical calculations are being carried out in order to interpret the experimental results.

3:18PM D12.00005 Atomic displacements in proton-irradiated AlGaN/GaN heterostructures , YEVGENIY PUZYREV, 1, TANIA ROY, ENXIA ZHANG, RONALD SCHRIMPF, DANIEL FLEETWOOD, 2, SOKRATES PANTELIDES, 1, DEPARTMENT OF PHYSICS AND ASTRONOMY DEPARTMENT, VANDERBILT UNIVERSITY TEAM, DEPARTMENT OF ELECTRICAL ENGINEERING AND COMPUTER SCIENCE, VANDERBILT UNIVERSITY TEAM — We report results of quantum molecular dynamics calculations of atomic recoils in AlGaN and GaN. The recoil energy required to create defects in a perfect AlGaN/GaN lattice is known to be over 40eV. However, drastic changes in atomic configuration occur when defect atom itself recoils with than 10eV. We show that both N antisite defects and N atoms near Ga vacancy require less than 10 eV to introduce N vacancies, divacancies and N interstitials. This phenomenon leads to additional donors that can account for a positive shift in threshold voltage, observed in our electrical measurements in AlGaN/GaN devices irradiated by 1.8 MeV protons.[1] In addition, divacancies and N vacancies have an electron transition level near the Fermi level in AlGaN which also provides explanation for the experimentally observed increase in 1/f noise after proton irradiation.[2]

3:30PM D12.00006 Nanoscale Potential Fluctuations in (GaMn)AsGaAs Heterostructures: From Individual Ions to Charge Clusters and Electrostatic Quantum Dots , PAUL KOENRAAD, INEKE WIJNHEIJMER, JENS GARLEFF, Eindhoven University of Technology, OLEG MAKAROVSKY, LAURENCE EAVES, RICHARD CAMPION, BRYAN GALLAGHER, University of Nottingham — During growth of the dilute p-type ferromagnetic semiconductor GaMnAs, interstitial manganese is formed when the Mn concentration exceeds 2%. This interstitial Mn acts as a double donor which compensates the free holes that mediate ferromagnetism. Annealing causes out-diffusion of these interstitials, thereby increasing the Curie temperature. Here, we use cross sectional scanning tunneling microscopy and spectroscopy to visualize the potential landscape which arises due to the clustering of interstitial Mn in annealed p-i-n (GaMn)As-GaAs double barrier heterostructures. We map the local minima in the potential landscape, link them to clusters of individual interstitial Mn ions, and show that the ions are doubly charged.

3:42PM D12.00007 Controlled layer-by-layer depth-profiling of GaAs(110) using scanning tunneling microscopy , DAVID GOHLKE, DONGHUN LEE, JAY GUPTA, Department of Physics, Ohio State University — The electronic properties of dopants in semiconductors such as GaAs vary depending on proximity to interfaces. We utilize a low temperature (5K) scanning tunneling microscope to realize a layer-by-layer peeling technique on p-GaAs(110). We apply positive voltage pulses near As vacancies to desorb surface-layer Ga and As atoms. Subsequent motion of the STM tip peels away the first layer from this starting point, fully exposing sections of the subsurface layer. The second and further layers can be readily peeled away by the same technique. This newly created pit allows depth-profiling of subsurface defects with STM. Funded by the Center for Emergent Materials at the Ohio State University, an NSF MRSEC (DMR-0820414). http://www.physics.ohio-state.edu/∼jgupta

3:54PM D12.00008 Time-Resolved Far-Infrared Magnetospectroscopy of Electron Relaxation in GaAs[1] , S.N. GILBERT[2], Vanderbilt Univ., G.L. CARR[3], Brookhaven National Lab — We report time-resolved magnetospectroscopy results for (S-I) GaAs at T∼10K and fields up to 10T. A pulsed Ti:sapphire laser produces photoelectrons with energy ∼10 meV above the conduction band minimum that are subsequently probed by far-infrared transmission spectroscopy. Both free electrons and exciton transitions are observed, including transitions involving Landau levels when the magnetic field is applied. We also observe a time-dependent change in these transitions and discuss a model for the relaxation of a warm (non-equilibrium) distribution of electrons on a ∼500 ps time scale.

4:06PM D12.00009 Tunable control over the ionization state of single Mn acceptors in GaAs with defect-induced band bending[1] , DONGHUN LEE, JAY GUPTA, Dept. of Physics, Ohio State University — The continuous miniaturization of semiconductor devices will ultimately reach a point where control over the properties of single dopants is necessary. Recent STM studies have demonstrated the ability to control the ionization state of single dopants through tip-induced band bending. This change in ionization state appears in STM images as a ring-like feature centered on the dopant, whose diameter depends on voltage, tip-sample distance, and tip termination. Here we demonstrate an additional degree of freedom for controlling the charge state of single Mn acceptors in GaAs by utilizing nearby charged defects which can be positioned with atomic precision. Systematic changes in the ring diameter with the separation between Mn and defect allows us to separately extract contributions from defect-induced and tip-induced band bending. These methods provide non-volatile control over the ionization state of single dopants, even in the absence of probe electrodes or STM tip.

4:18PM D12.00010 Identification of the major cause of endemically poor mobilities in SiC/SiO_2 structures[1] , XIAO SHEN, SOKRATES T. PANTELIDES, Vanderbilt University — Mobility degradation at semiconductor-dielectric interfaces is generally attributed to defects at the interface or inside the dielectric, as is the case in Si/SiO_2 structures. In the case of SiC/SiO_2 structures, a decade of research focused on reducing or passivating interface and oxide defects, but low mobilities have persisted. It is known that during oxidation of Si, Si atoms are emitted into the substrate, but they do not form strongly-bonded complexes and their effects are usually benign. In contrast, during oxidation of SiC, C atoms are emitted into the substrate and they can form strongly-bonded carbon complexes. Here we identify one particular complex that explains a range of experimental defect signatures and electrical measurements. We propose that this complex is a major cause of the poor mobility in SiC/SiO_2 structures.

4:30PM D12.00011 Electronic properties of Si-C interfaces[1] , XIANG-GUO LI, HAI-PING CHENG, Department of Physics, University of Florida, USA — In this work, we report our investigations of interfacial properties of Si-C systems. Electronic properties of Fe-doped carbon on silicon surfaces, Si-Fe-C layered structures and Si-graphene-Si junctions have been studied using first-principles calculations. Charge transfer at the interfaces, densities of states, and magnetization are fully analyzed. These problems are important because recent experiments show that Fe@C-Si materials have giant electro-resistance and magneto-resistance highly sensitive to the external magnetic field. The non-magnetic feature leads to very small magnetic noise. In addition, photovoltaic effects were also observed in some of these systems.

4:42PM D12.00012 Polariton Formation Enhances Lifetimes of Dense Exciton Gasses in Cuprous Oxide by Suppressing Two-Exciton Decay[1] , N. LASZLO FRAZER, Northwestern University, R.D. SCHALLER, Argonne National Lab, Northwestern University, J.I. JANG, SUNY Binghamton, S.E. MANI, J.B. KETTERSON, Northwestern University — Collective excitonic states form at high densities, but in dense gases the long lifetime of excitons in cuprous oxide (Cu_2O) is compromised by two-exciton annihilation processes. Using the picosecond streak camera spectroscopy facility at the Center for Nanoscale Materials at Argonne National Laboratory we directly measured the decay of orthoexciton-polaritons generated by two photon absorption. The two-body decay lifetime is an order of magnitude longer than for excitons uncoupled to photons. The extended lifetime opens opportunities for experiments that manipulate polariton collective states. Unlike time-averaged measurements of two-body processes, streak camera detection shows decay suppression without effects from production efficiency or additional density dependent processes.

4:54PM D12.00013 Ultrafast carrier dynamics in Bi2Se3 thin films , KELIANG HE, LIGUO ZHU, CHEN XIA, BRIAN KUBERA, JIE SHAN[1], Department of Physics, Case Western Reserve University, 10900 Euclid Avenue, Cleveland, OH 44106, U.S.A. — Bismuth Selenide (Bi2Se3), a group V-VI narrow gap layered semiconductor, is a well-known efficient solid thermoelectric material at room temperature. It has recently also attracted much research attention due to its interesting topological properties. The carrier dynamics and charge transport, electron-phonon coupling, and its role in the transport properties in Bi2Se3 are fundamental issues in understanding its thermoelectric and topological properties. In this work, we employ the optical-pump terahertz-probe technique to study the transient photoconductivity in Bi2Se3 thin crystalline films as a function of the pump-probe delay time and the excitation fluence. The photoconductivity spectrum ranging from 0.3 to 1.9 THz reveals both a Drude and a Lorentz contribution. The former is attributed to a free electron response with a scattering time of 0.7 ps; and the latter, with both its amplitude and peak frequency dependent on the carrier density, arises from a coupled LO phonon-plasmon mode. The nature of this mode and its role in transport will be discussed.

5:06PM D12.00014 Oxygen in B_2O_3 covered Czochralski-grown Ge , TOSHINORI TAISHI, Institute of Carbon Science and Technology, Shinshu University, HIDEAKI ISE, YU MURAO, TAKAYUKI OHSAWA, YUKI TOKUMOTO, YUTAKA OHNO, ICHIRO YONENAGA, Institute for Materials Research, Tohoku University — Ge has been regained keen interest in applications of Ge for ultra-fast CMOS and PV devices. High quality Ge crystals should be demanded for realization of such devices with higher performances in these circumstances. Oxygen impurity can be expected to enhance thermo-mechanical stability of Ge crystals due to dislocation locking similar to oxygen in Si. For the purpose, we grew oxygen-enriched Ge crystals by the Czochralski method from B_2O_3 covered melt added with GeO_2 powder in a silica crucible. To evaluate precious knowledge oxygen behavior in Ge, local vibrations of oxygen were evaluated by FT-IR spectroscopy. Concentrations of interstitially dissolved oxygen impurity in the crystals were in the range between 8.5×10^{15} and 5.5×10^{17} cm^{-3} determined from the FT-IR absorption at 855 cm^{-1} originating in local vibration of Ge-O_i-Ge quasi-molecules. Absorption peaks relating to GeO_x, SiO_x and Si-Oi-Si were not detected in the as-grown crystals. By prolonged annealing at 350_C, an absorption peak developed at 780 cm^{-1}, indicating formation of oxygen related thermal donors. Such donors disappeared by annealing at 550_C.

Session D13 GSNP: Statistical and Nonlinear Physics: General D225/226

2:30PM D13.00001 Stability and dynamical properties of Cooper-Shepard-Sodano compactons , ANDRES CARDENAS, New York University, BOGDAN MIHAILA, Los Alamos National Laboratory, FRED COOPER, Santa Fe Institute, AVADH SAXENA, Los Alamos National Laboratory — Extending a Pade approximant method used recently to study the properties of compactons in the Rosenau-Hyman (RH) equation [see B. Mihaila et al. Phys. Rev. E 81, 056708 (2010)], we study the numerical stability of single compactons of the Cooper-Shepard-Sodano (CSS) equation and their pairwise interactions. The CSS equation has a conserved Hamiltonian which has allowed several approaches for studying analytically the nonlinear stability of the solutions. We study three different compacton solutions and find they are numerically stable. Similar to the collisions between RH compactons, the CSS compactons reemerge with the same coherent shape when scattered. The time evolution of the small-amplitude ripple resulting after scattering depends on the values of the parameters characterizing the corresponding CSS equation. The simulation of the CSS compacton scattering requires a much smaller artificial viscosity to obtain numerical stability than in the case of RH compacton propagation.

2:42PM D13.00002 Pair Correlations for Charges in a Harmonic Trap , JEFFREY WRIGHTON, JAMES DUFTY, University of Florida, HANNO KÄHLERT, TORBEN OTT, PATRICK LUDWIG, MICHAEL BONITZ, Christian-Albrechts-Universität zu Kiel — A classical system of N identical charges in a harmonic trap exhibits both shell structure and orientational ordering due to Coulomb correlations. The shell structure can be reproduced accurately using approximate correlations from the bulk OCP [1]. Here we report additional relationships between correlations in the trap and those for the bulk OCP: 1) pair correlations calculated without reference to their location in the trap agree with those of the bulk OCP, 2) orientational pair correlations among particles within a shell are represented by those of the bulk OCP, when Euclidean distance is replaced by arc length (qualitative agreement using 3D OCP; quantitative agreement using 2D OCP). At stronger coupling, the correlations induce an ordering within the shells (spherical Wigner crystal). It is shown that the orientational correlations for this phase are described by those for the single sphere Thomson problem, i.e. the Thomson sites represent the "lattice" for the spherical crystal. Finite temperature effects for this phase are described as well. Research supported by DOE award DE-FG02-07ER54946, and by the Deutsche Forschungsgemeinschaft via SFB-TRR24.

2:54PM D13.00003 Quasi-bound state lifetimes and classical periodic orbits in HOCl , ALEX BARR, KYUNGSUN NA, LINDA REICHL, University of Texas at Austin — We use a discrete variable representation together with reaction matrix theory to calculate the quasi-bound states of a Chlorine atom scattering off a diatomic molecule of Hydrogen and Oxygen. The lifetimes of these quasi-bound states are found to vary over six orders of magnitude in a very small energy window. By examining Husimi distributions for various quasi-bound states we show that the longest-lived quasi- bound states are anchored by an island of stability surrounding a stable periodic orbit in the otherwise chaotic classical phase space. This stable periodic orbit, which corresponds to Chlorine rotating around the HO molecule, is responsible for the very long lifetimes of these quasi-bound states.

3:06PM D13.00004 An Infinite Order Phase Transition , PRADEEP KUMAR, University of Florida, AVINASH KHARE, Institute of Physics, Bhubaneshwar, AVADH SAXENA, Los Alamos National Laboratory — An infinite order phase transition, in the sense envisioned by Ehrenfest, must show no singularity in any finite (thermal or mechanical) derivative of the free energy. By considering the infinite p limit of a free energy that we have derived for a p-th order phase transition, we can derive a Landau type free energy. We will discuss the properties of the free energy and identify the features essential for a description of an infinite order phase transition. These include a logarithmic interaction between the fields and a novel dependence on spatial gradients. Contrary to popular belief, since some symmetry is broken at each finite p order, we submit that an infinite order phase transition does not exclude a symmetry being broken. Restricting to one dimension, we solve for domain wall solutions. Finally we show the relationship between an infinite order phase transition and Tachyon condensation. They are both analyzed as the infinite p limit of a class of p enumerated field theories. The mathematical difference being that the free energy for infinite order transition belongs to a potential that is negative (inverted) of the action for tachyon condensation.

3:18PM D13.00005 First Principles Derivation of Fading Models from Wave Chaos Theory , JEN-HAO YEH, University of Maryland — Wave chaos is the study of solutions to linear wave equations in situations where the ray dynamics recovered in the classical limit is chaotic. Fading is the observation of variations in signal strength measured at a receiver due to time-dependent variations in the propagation or multi-path scattering and interference. A quantitative statistical theory of wave chaos - random matrix theory (RMT) - can be applied to predict statistical properties of many quantities, such as the scattering matrix, of a wave chaotic system. Here we started from the statistical model of the scattering matrix [1] to establish a general fading model that includes Rayleigh fading and then combine the RMT fading model with our random coupling model that takes account system-specific features [2-4] to build a more general fading model that includes Rician fading. In the high loss limit, our model agrees with the Rayleigh/Rice models, however, it shows deviation in the limit of low loss. We have performed experiments [3,4] to verify the RMT fading model.

3:30PM D13.00006 Quantum statistical mechanics on infinitely ramified fractals , JOE P. CHEN, Cornell University — I present the thermodynamics of identical particles confined in infinitely ramified, exactly self-similar fractals, such as the Sierpinski carpet (in 2D) and the Menger sponge (in 3D). Recent results from analysis on fractals have established that the heat kernel associated with the Laplacian on such fractals satisfy, in the short-time regime, a scaling relation with exponent $d_S/2$ (where d_S is the spectral dimension) modulated by log-periodic oscillations. I explain how such a scaling affects the partition function, and the resultant thermodynamics associated with blackbody radiation [1], Casimir effect, and electrons in the fractal box.

3:42PM D13.00007 Unified Approach to Quantum and Classical Dualities[1] , EMILIO COBANERA, GERARDO ORTIZ, Indiana University, Bloomington, IN, ZOHAR NUSSINOV, Washington University, St. Louis, MO — We discuss a new systematic and algebraic approach to searching for dualities in quantum systems. By associating "bond algebras" to quantum Hamiltonians we show how dualities can be characterized, recognized as unitary transformations, and mapped to dualities of classical partition functions. Hence our approach unifies classical and quantum dualities and provides a powerful method for determining exact properties of systems of interest. We show how duality transformations can be used always to eliminate gauge symmetries completely, and present a new duality between the Abelian Higgs model and a generalized Kitaev's extended toric code model in *three space dimensions* that illustrate this point. We also show new dualities for Z_p) gauge models.

[1]Phys. Rev. Lett. 104, 020402 (2010)

3:54PM D13.00008 Fluctuation-induced forces in strongly anisotropic critical systems , M. BURGSMÜLLER, H.W. DIEHL, Fakultät für Physik, Universität Duisburg-Essen, 47048 Duisburg, Germany, M.A. SHPOT, Institute for Condensed Matter Physics, 79011 Lviv, Ukraine — Strongly anisotropic critical systems have two (or more) correlation lengths ξ_α and ξ_β that diverge as nontrivial powers $\xi_\alpha \sim \xi_\beta^\theta \to \infty$ upon approaching criticality. We investigate the effective (Casimir-like) forces that are induced between two confining parallel boundary planes at a distance L by fluctuations in such systems at bulk criticality. Two fundamentally distinct orientations of boundary planes must be distinguished: parallel, for which the planes are parallel to all of the available $1 \leq m < d$ α-directions, and perpendicular, for which they are perpendicular to an α-direction, but parallel to all other α- and β-directions. Using a RG approach, we show that universal Casimir amplitudes $\Delta_{\parallel,\perp}^{BC}$, depending on both the large-scale boundary condition (BC) at both plates and the type of surface plane orientation, can be introduced to characterize the asymptotic L-dependence of the critical fluctuation-induced force. This varies as $\mathcal{F} \sim -(\partial/\partial L)\,\Delta_{\parallel,\perp}^{BC}\,L^{-\zeta_{\parallel,\perp}}$, where the proportionality constant is nonuniversal. To corroborate these findings, $O(n)$ ϕ^4 models with m-axial Lifshitz points are investigated below their upper critical dimension $d = 4 + m/2$. Explicit one- and two-loop results for $\Delta_{\parallel,\perp}^{BC}$ are presented for both orientations and periodic or Dirichlet-like boundary conditions, along with large-n results.

4:06PM D13.00009 Multifractality of instantaneous normal modes at mobility edges , TEN-MING WU, Institute of Physics, Natl Chiao-Tung Univ, Hsinchu, Taiwan — In terms of the multifractal analysis, we investigate the characteristics of instantaneous normal modes (INMs) at mobility edges (MEs) of a simple fluid, where the locations of two MEs in the INM spectrum were identified in a previous work (Phys. Rev. E 79, 041105 (2009)). The mass exponents and the singularity spectrum of the INMs are obtained by both the box-size and system-size scalings under the typical average. The INM eigenvectors at a ME exhibit a multifractal nature and the multifractal INMs at each ME yield the same results in generalized fractal dimensions and singularity spectrum. Our results indicate that the singularity spectrum of the multifractal INMs agrees well with that of the Anderson model at the critical disorder. This good agreement provides a numerical evidence for the universal multifractality at the localization-delocalization transition. For the multifractal INMs, the probability density function and the spatial correlation function of squared vibrational amplitudes are also calculated. The relation between probability density function and singularity spectrum is examined numerically, so are the relations between the critical exponents of the spatial correlation function and the mass exponents of the multifractal INMs. All results will be appeared in Phys. Rev. E.

4:18PM D13.00010 Experimental study of memory erasure in a double-well potential , YONGGUN JUN, JOHN BECHHOEFER, Dept. of Physics, Simon Fraser University — We have experimentally demonstrated memory erasure in a time-dependent, double-well potential using a protocol suggested by Dillenschneider and Lutz [PRL 102, 210601 (2009)]. The protocol implements the erasure of information by removing the potential barrier, skewing the potential to one side, and then raising the barrier back. In this context, erasure means that no matter which well the particle started the cycle in, it ends up in a designated well. We implement the potential by placing an overdamped, charged Brownian particle in a feedback trap that uses electrophoresis to generate an arbitrary virtual two-dimensional potential. In a large system, Landauer's principle gives a lower bound for the heat dissipated in the erasure of a single bit (kT ln2). In a small system such as ours, thermal fluctuations allow for occasional violations. We quantify such violations as a function of barrier size and show that while averages are consistent with Landauer's principle, the tail of the distribution of dissipation per cycle—a fraction of trajectories—violates it.

4:30PM D13.00011 Cosmology in One Dimension: Fractal Geometry, Power Spectra and Correlation , BRUCE MILLER, Texas Christian University, JEAN-LOUIS ROUET, Universite d'Orleans — Concentrations of matter, such as galaxies and galactic clusters, originated as very small density fluctuations in the early universe. The existence of galaxy clusters and super-clusters suggests that a natural scale for the matter distribution may not exist. A point of controversy is whether the distribution is fractal and, if so,over what range of scales. One-dimensional models demonstrate that the important dynamics for cluster formation occur in the position-velocity plane. Here the development of scaling behavior and multifractal geometry is investigated for a family of one-dimensional models for three different, scale-free, initial conditions. A possible physical mechanism for understanding the self-similar evolution is introduced. It is shown that hierarchical cluster formation depends both on the model and the initial power spectrum. Under special circumstances a simple relation between the power spectrum, correlation function, and correlation dimension in the highly nonlinear regime is confirmed.

4:42PM D13.00012 ABSTRACT WITHDRAWN –

4:54PM D13.00013 Thermodynamics in a complete description of the Landau diamagnetism , S. CURILEF, F. OLIVARES, F. PENNINI, Universidad Catolica del Norte — We analyze some consequences that come from semiclassical measures as the Wehrl entropy and the Fisher information for the problem of a particle in a magnetic field starting from a complete description of the Husimi function. We discuss in the most complete form (three dimensions)[1] some results related to measures in contrast with the incomplete form (two dimensions)[2,3]. The formulation in two dimensions is sufficient unto itself to explain the problem whenever the length of the cylindrical geometry of the system is large enough. Our semiclassical description constitutes a useful framework to illustrate problems related to size effects, role of boundaries and other typical anomalies derived from the size of the system, which are refereed to two parameters as area and length and they explicitly appear in the form of the limiting temperature and magnetic field. In addition, we discuss that the zero temperature can be achieved only if the length of the system size is large enough, otherwise physical properties strongly depend on the size of the system. Moreover, from the quantization of the quantum Hall effect, we have obtained a family of quantized Wehrl entropies.

5:06PM D13.00014 Newtonian trajectories as a tool for quantum dynamics in an electromagnetic field , FONS BROSENS, University of Antwerpen, WIM MAGNUS, imec-Leuven — In previous studies, we showed that the classical equations of motion provide a solution to quantum dynamics, if appropriately incorporated in the Wigner distribution function, exactly reformulated in a type of Boltzmann equation. However, this earlier work was limited to scalar potentials. In the presence of an electromagnetic field, we now show that this description in terms of classical paths remains valid, despite the fact that the definition of the Wigner distribution function is not gauge invariant. Some analytical results are also presented.

5:18PM D13.00015 The bond problem with an arbitrary percolation radius is solved! , VLADIMIR UDODOV, MARIYA BUREEVA, Katanov Khakas State University, KATANOV KHAKAS STATE UNIVERSITY TEAM — The results of investigations of main characteristics of a one-dimensional percolation theory (percolation threshold, critical exponents of correlation radius and specific heat) are presented for the problem of bonds and sites. It is shown that for a finite-size system the stability condition is fulfilled while the scaling hypothesis is inacceptable for one-dimensional bond problem. The correlation length exponent ν in a one-dimensional problem of bonds has been found to exceed the values of ν in the problem of sites for equal-length chains, and, in general, this exponent was found to be extraordinary large compared to the 2-D and 3-D cases for ordinary phase transitions in macrosystems. The scaling hypothesis is inapplicable to random (disordered) one-dimensional nanostructures containing hundreds of structural elements. The results obtained in this work can be used in modeling hopping conduction in semiconductors at low temperatures and polytype transformations in close-packed crystals. For the first time, using the method of computer simulation, we have solved the bond problem for the model of one-dimensional percolation in finite-size systems of tens of nanometers with an arbitrary percolation radius.

Monday, March 21, 2011 2:30PM - 5:30PM –
Session D14 GSNP: Systems Far From Equilibrium D227

2:30PM D14.00001 Fluctuation Relations for Currents[1] , NIKOLAI SINITSYN, Theoretical Division, Los Alamos National Laboratory, ALEXEI AKIMOV, Department of Chemistry, Rice University, VLADIMIR CHERNYAK, Deparment of Chemistry, Wayne State University, MICHAEL CHERTKOV, Theoretical Division, Los Alamos National Laboratory — We consider a non-equilibrium statistical system on a graph or a network. Identical particles are injected, interact with each other, traverse, and leave the graph in a stochastic manner described in terms of Poisson rates, possibly strongly dependent on time and instantaneous occupation numbers at the nodes of the graph. We show that the system demonstrates a profound statistical symmetry, leading to new Fluctuation Relations that originate from the supersymmetry and the principle of the geometric universality of currents rather than from the relations between probabilities of forward and reverse trajectories.

2:42PM D14.00002 Aging in coarsening ferromagnets with site and bond disorder[1] , HYUNHANG PARK, MICHEL PLEIMLING, Virginia Tech — Aging processes during phase ordering are studied in the random-site and random-bond Ising models in two dimensions through Monte-Carlo simulations. The dynamical correlation length $L(t)$ is numerically determined and the behavior of various two-time quantities is investigated. For both models deviations of $L(t)$ from an algebraic growth law $L(t) \sim t^{1/z}$ are observed. Using the correct form of $L(t)$ a simple scaling picture is recovered for the studied disordered ferromagnets in the coarsening regime. Thus various two-time quantities, as for example the autocorrelation function, the space-time correlation function and the time integrated linear response, show a scaling behavior that is fully consistent with simple aging [1]. The similarities and differences between the site-disordered and the bond-disordered models are discussed.

2:54PM D14.00003 Nonequilibrium phase transition in a driven Potts model with friction[1] , MICHEL PLEIMLING, Virginia Tech, FERENC IGLÓI, Research Institute for Solid State Physics and Optics, Budapest, Hungary, and Szeged University, Hungary, LOÏC TURBAN, University Nancy, France — We consider magnetic friction between two systems of q-state Potts spins which are moving along their boundaries with a relative constant velocity v. Due to interaction between the surface spins there is a permanent energy flow and the system is in a steady state which is far from equilibrium. The problem is treated analytically in the limit $v = \infty$ (in one dimension, as well as in two dimensions for large-q values) and for v and q finite by Monte Carlo simulations in two dimensions. Exotic nonequilibrium phase transitions take place, the properties of which depend on the type of phase transition in equilibrium. When this latter transition is of first order, a sequence of second- and first-order nonequilibrium transitions can be observed when the interaction is varied [1].

3:06PM D14.00004 Aging dynamics for the driven lattice gas[1] , GEORGE L. DAQUILA, UWE C. TÄUBER, Department of Physics, Virginia Tech — We numerically investigate the two-time behavior of the density-density auto-correlation function in driven lattice gases with particle exclusion and periodic boundary conditions in one, two, and three dimensions using precise Monte Carlo simulations. Starting from strongly correlated initial conditions we investigate the relaxation towards the nonequilibrium steady state. We obtain simple aging scaling behavior in one, two, and three dimensions. The simulation data confirm the density auto-correlation aging exponents determined from simple scaling arguments. For the one-dimensional case we connect with the KPZ surface growth model and establish a relation between the density-density and known height-height auto-correlation aging exponents.

3:18PM D14.00005 Effect of size distribution on metastability in magnetic nanoparticles , YOH YAMAMOTO, KYUNGWHA PARK, Virginia Tech, Blacksburg, VA — Magnetic nanoparticles that have been synthesized using various methods have size distributions. This results in distributions in the magnetic anisotropy of magnetic nanoparticles. Considering the particle size distributions, we investigate metastability in magnetic nanoparticles at low temperatures. To model this system, we use a spin $S = 1$ ferromagnetic Blume-Capel model on a square lattice with periodic boundary conditions. The particle size distribution is incorporated in the model such that the uniaxial magnetic anisotropy parameter has a Gaussian distribution. We perform kinetic Monte Carlo simulations of the Blume-Capel model with the Glauber dynamic to explore magnetization relaxation in the regime where a single droplet of flipped spins forms a critical droplet. We present the lifetime of the metastable state as a function of temperature and standard deviation of the magnetic anisotropy distribution as well as a finite-size effect on the lifetime.

3:30PM D14.00006 Phase Diagram for a 2-D Two-Temperature Diffusive XY Model[1] , MATTHEW REICHL, CHARO DEL GENIO[2], KEVIN E. BASSLER, University of Houston — Using Monte Carlo simulations, we determine the phase diagram of a diffusive two-temperature conserved order parameter XY model. When the two temperatures are equal the system becomes the equilibrium XY model with the continuous Kosterlitz-Thouless (KT) vortex-antivortex unbinding phase transition. When the two temperatures are unequal the system is driven by an energy flow from the higher temperature heat-bath to the lower temperature one and reaches a far-from-equilibrium steady state. We show that the nonequilibrium phase diagram contains three phases: A homogenous disordered phase and two phases with long range, spin texture order. Two critical lines, representing continuous phase transitions from a homogenous disordered phase to two phases of long range order, meet at the equilibrium KT point. The shape of the nonequilibrium critical lines as they approach the KT point is described by a crossover exponent $\varphi = 2.52 \pm 0.05$. Finally, we suggest that the transition between the two phases with long-range order is first-order, making the KT-point where all three phases meet a bicritical point.

3:42PM D14.00007 Avalanches in gauge theories , STEFANOS PAPANIKOLAOU, Cornell University — I consider the non-equilibrium behavior of disordered systems which contain a residual gauge symmetry. Remarkably, in this limit each avalanche is a Wilson loop of the associated gauge theory. Such gauge invariant avalanches present interesting critical behavior that we characterize. Also, I show that, when the gauge symmetry is violated, the behavior drastically changes. Finally, the relation of these results to current experimental efforts on spin ice compounds is discussed.

3:54PM D14.00008 A framework for studying biased stochastic dynamics in continuous space[1] , S.M. ALI TABEI, YE TIAN, University of Chicago, MARTIN TCHERNOOKOV, Emory University, AARON DINNER, University of Chicago — Typically in the formalism of large deviation functions the biased dynamics are studied in a discrete space. However, in many realistic stochastic systems dynamics take form in a continuous rather than a discrete space. In recent work it was shown that the biased dynamics for continuous-space models can be calculated using transition path sampling: unbiased trajectories were generated by shooting with the original dynamics from an existing path and then accepted or rejected to obtain the biased path ensemble. Here, we instead develop a way to bias continuous-space dynamics directly in the form of a biased Langevin equation.

4:06PM D14.00009 Measured first-passage-time distributions for a high-dimensional system: noise-induced current switching in semiconductor superlattices[1] , YURIY BOMZE, Duke University, HOLGER T. GRAHN, RUDOLF HEY, Paul-Drude-Institute, Berlin, Germany, STEPHEN W. TEITSWORTH, Duke University — We report the experimental measurement of first-passage-time distributions associated with current switching in weakly-coupled GaAs/AlAs superlattices, in a regime of nonlinear electronic transport where the static current-voltage ($I - V$) curves exhibit multiple branches and bistability. Precision, high bandwidth current switching data are collected in response to sequential steps in applied voltage to a final voltage V_f near to the voltage V_{th} corresponding to the end of a particular branch. For initial state preparation, a double step procedure is used to insure that the system is close to the true metastable state. For a range of V_f values, switching times reveal large stochastic fluctuations driven by internal shot noise. For smaller times ($< 3\mu$s), the switching time distributions show exponential tails, as expected for activated escape from an initial metastable state. However, at larger times (> 10 μs), the distributions exhibit power law tails (with exponent ranging from -2 to -1, and dependent on $|V_f - V_{th}|$). Possible sources for the power law decay include collective effects and the presence of multiple escape trajectories.

4:18PM D14.00010 Non-equilibrium Thermodynamics: Residual Entropy, Internal Variables, Maxwell Relations, and the Prigogine-Defay Ratio , PURU GUJRATI, The University of Akron — We extend a recently formulated [Phys. Rev. E 81, 051130 (2010)] non-equilibrium thermodynamic approach to an inhomogeneous system consisting of many smaller subsystems, each in internal equilibrium; their relative motions result in viscous effects. The correct Gibbs free energy of a subsystem contains the temperature and pressure of the medium, making our approach an extension of the classical non-equilibrium thermodynamics due to de Donder. The additivity of entropy requires quasi-independence of subsystems, so that the energy also becomes additive. We use Gibbs' entropy of the isolated system to derive the entropy for the system even when the latter is out of equilibrium. We use this entropy to discuss the residual entropy when the system is confined to one of the components in the phase space. The approach is extended to include internal variables that cannot be controlled by the observer during non-equilibrium evolution. We then identify the form of non-equilibrium Maxwell relations. We apply our formalism to evaluate the Prigogine-Defay ratio in glasses, which is found to be, in general, different from 1 at the apparent glass transition, as is normally seen in experiments.

4:30PM D14.00011 Generalized Gibbs distribution and energy localization in the semiclassical FPU problem , RAFAEL HIPOLITO, CUNY-College of Staten Island, IPPEI DANSHITA, Tokyo University of Science, VADIM OGANESYAN, CUNY-College of Staten Island, ANATOLI POLKOVNIKOV, Boston University — We investigate dynamics of the weakly interacting quantum mechanical Fermi-Pasta-Ulam (qFPU) model in the semiclassical limit below the stochasticity threshold. Within this limit we find that initial quantum fluctuations lead to the damping of FPU oscillations and relaxation of the system to a slowly evolving steady state with energy localized within few momentum modes. We find that in large systems this state can be described by the generalized Gibbs ensemble (GGE), with the Lagrange multipliers being very weak functions of time. This ensembles gives accurate description of the instantaneous correlation functions, both quadratic and quartic. Based on these results we conjecture that GGE generically appears as a prethermalized state in weakly non-integrable systems.

4:42PM D14.00012 Zero Droplet Stiffness Exponent: Probing Short Range Spin Glasses with Avalanches Induced by Long Range Interactions , GERGELY ZIMANYI, Physics Department, UC Davis, FERENC PAZMANDI — We probe the droplet excitations in short range spin glasses by adding a perturbative long range interaction that decays with distance as a power law: J/r^{σ}. It is shown that if the power law exponent σ is smaller than the spatial dimension d, the perturbation induces large scale avalanches which roll until they force the system to develop a pseudo gap in the excitation spectrum of the stabilities. This makes the perturbative long range interactions relevant for $\sigma < \sigma_c = d$. The droplet theory predicts that the critical exponent σ_c depends on the droplet stiffness exponent as $\sigma_c = d - \theta$. Combining these two results leads to a zero stiffness exponent $\theta = 0$ in the droplet theory of short range spin glasses.

4:54PM D14.00013 Introduction of a new thermodynamic property: "characteristic frequency" , MCKENDREE PEPPER, Chicago Bridge and Iron, and Lamar University, CRISTIAN BAHRIM, Department of Physics, RAFAEL TADMOR, Department of Chemical Engineering, Lamar University — Fluctuations of thermodynamic properties are observed in the critical region of fluids, multiphase regions, and in systems containing a small number of molecules. We describe the dynamics within the vapor-liquid *interfacial region* (IR) of a monatomic fluid in thermal equilibrium using fundamental principles of mechanics and thermodynamics. Our objective is to provide a new dynamic parameter which characterizes thermodynamic systems fluctuating near equilibrium, such as the IR. We call this new property *"characteristic frequency"*. Our model assumes that the IR is (1) a closed thermodynamic system, (2) has a linear response to a driving force generated by a thermodynamic fluctuation, and (3) has a unique characteristic (resonant) frequency. We find that mild oscillations from equilibrium of a thermodynamic system occur at the most probable speed, and that the amplitude of the oscillations depends solely on the partition functions of the vapor and liquid within the IR. Our conclusion is that fluctuating thermodynamic systems at thermal equilibrium can exhibit oscillations analogous to mechanical systems and manifest a similar resonant response as the classical oscillators near their characteristic frequency.

5:06PM D14.00014 An effective Fluctuation Theorem in Bidirectional Single-Electron Counting , YASUHIRO UTSUMI, Mie University, DIMITRY GOLUBEV, MICHAEL MARTHALER, Karlsruhe Institute of Technology, KEIJI SAITO, Graduate School of Science, University of Tokyo, TOSHIMASA FUJISAWA, NTT Basic Research Laboratories, GERD SCHOEN, Karlsruhe Institute of Technology — We investigate the direction-resolved full counting statistics of single-electron tunneling through a double quantum dot system and compare with predictions of the fluctuation theorem (FT) for Markovian stochastic processes. Experimental data obtained for GaAs/GaAlAs heterostructures appear to violate the FT. After analyzing various potential sources for the discrepancy we conclude that the nonequilibrium shot noise of the measurement device influence the tunneling statistics. Taking these modifications into account we show how the FT can be violated due to measurement effects and recovered for fast detection by introducing an "effective temperature."

5:18PM D14.00015 Landauer-Buettiker approach to current-induced forces in nanoelectromechanical systems , SILVIA VIOLA KUSMINSKIY, NIELS BODE, Dahlem Center for Complex Quantum Systems & Fachbereich Physik, Freie Universitaet Berlin, REINHOLD EGGER, Heinrich-Heine Universitaet, Duesseldorf, Germany, FELIX VON OPPEN, Dahlem Center for Complex Quantum Systems & Fachbereich Physik, Freie Universitaet Berlin — We study current-induced forces in nanoelectromechanical systems with coupling between electronic and mechanical degrees of freedom. We focus on the regime where the mechanical motion is slow and Coulomb blockade effects can be neglected. We derive the current-induced forces both in and out of equilibrium and give the conditions under which these forces can be expressed solely in terms of the S-matrix. We pay particular attention to situations with more than one mechanical degree of freedom which are characterized by several qualitatively new features. We apply our general results to some simple examples.

3:06PM D15.00004 Unfolding first-principles band structures[1] , WEI KU, T. BERLIJN, Brookhaven National Laboratory; Stony Brook University, C.-C. LEE, Brookhaven National Laboratory — A general method [1] is presented to unfold band structures of first-principles supercell calculations with proper spectral weight, allowing easier visualization of the electronic structure and the degree of broken translational symmetry. The resulting unfolded band structures contain additional rich information from the Kohn-Sham orbitals, and absorb the structure factor that makes them ideal for a direct comparison with angle resolved photoemission spectroscopy experiments. With negligible computational expense via the use of Wannier functions, this simple method has great practical value in the studies of a wide range of materials containing impurities, vacancies, lattice distortions, or spontaneous long-range orders.

3:42PM D15.00007 Finite-basis correction applied to the optimized effective potential within the FLAPW method , CHRISTOPH FRIEDRICH, MARKUS BETZINGER, STEFAN BLÜGEL, Institut fuer Festkoerperforschung and Institute for Advanced Simulation, Forschungszentrum Juelich and JARA, 52425 Juelich, Germany — The optimized-effective-potential (OEP) method is a special technique to construct local exchange-correlation (xc) potentials from general orbital-dependent xc energy functionals for density-functional theory. Recently, we showed that particular care must be taken to construct local potentials within the all-electron full-potential augmented-plane-wave (FLAPW) approach. In fact, we found that the LAPW basis had to be converged to an accuracy that was far beyond that in calculations using conventional functionals, leading to a very high computational cost. This could be traced back to the convergence behavior of the density response function: only a highly converged basis lends the density enough flexibility to react adequately to changes of the potential. In this work we derive a numerical correction for the response function, which vanishes in the limit of an infinite, complete basis. It is constructed in the atomic spheres from the response of the basis functions themselves to changes of the potential. We show that such a *finite-basis correction* reduces the computational demand of OEP calculations considerably. We also discuss a similar correction scheme for GW calculations.

4:18PM D15.00010 The random phase approximation and beyond: an assessment for molecular binding energies and reaction barrier heights , XINGUO REN, PATRICK RINKE, MATTHIAS SCHEFFLER, Fritz Haber Institute (Berlin), JOACHIM PAIER, Humboldt University (Berlin), ANDREAS GRÜENEIS, GEORG KRESSE, University of Vienna (Vienna), GUSTAVO E. SCUSERIA, Rice University (Houston) — The random phase approximation (RPA) for the correlation energy has become a promising approach for describing electronic systems in various bonding situations. Recent efforts have focused mainly on correcting the general tendency of RPA to underestimate bond strengths e.g. by adding corrections from second-order screened exchange (SOSEX) [1,2] or single excitations (SE) [3]. In this work, we systematically assess the influence of SOSEX, SE and their combinations on the atomization energies of the G2-I molecular set, as well as the chemical reaction barrier heights of the HTBH38/04 and NHTBH38/04 benchmark sets [4]. We find that RPA+SOSEX+SE based on PBE gives the most balanced description. However, for reaction barrier heights standard RPA based on PBE turns out to be better and is surprisingly accurate. The underlying mechanism governing the performance of RPA and its variants in different circumstances will be analysed. [1] A. Grüneis *et al.*, J. Chem. Phys. **131**, 154115 (2009). [2] J. 4:30PM D15.00011 Approximating Densities of States with Gaps[1] , ROGER HAYDOCK, C.M.M. NEX, Department of Physics and Materials Science Institute, University of Oregon — Reconstructing a density of states or similar distribution from moments or continued fractions is an important problem in calculating the electronic and vibrational structure of defective or non-crystalline solids. For single bands a quadratic boundary condition introduced previously [Phys. Rev. B 74, 205121 (2006)] produces results which compare favorably with maximum entropy and even give analytic continuations of Green functions to the unphysical sheet. In this paper, the previous boundary condition is generalized to an energy-independent condition for densities with multiple bands separated by gaps. As an example it is applied to a chain of atoms with s, p, and d bands of different widths with different gaps between them. The results are compared with maximum entropy for different levels of approximation. Generalized hypergeometric functions associated with multiple bands satisfy the new boundary condition exactly.

[1]Supported by the Richmond F. Snyder Fund.

4:42PM D15.00012 A New Boundary Condition for Embedding Atoms in Solids , G.A. BENESH, Department of Physics, Baylor University, Waco, TX 76798-7316, ROGER HAYDOCK, Department of Physics, University of Oregon, Eugene, OR 97403-1274 — Previously, Haydock and Nex [Phys. Rev. B 82, 205114 (2010)] formulated an approximation for embedding a finite discrete system into an infinite substrate by means of a new boundary condition. This boundary condition requires a maximum breaking of time-reversal symmetry (MBTS) in the sense that probability is carried away from the embedding surface at a maximal rate. The MBTS boundary condition has been useful in discrete systems for constructing accurate densities of states and other distributions from moments or continued fractions. In this work, we generalize the approach to the problem of embedding an atom or a cluster of atoms into an infinite solid. The new, continuous MBTS boundary condition has been applied to model systems and to the embedding of a hydrogen atom. Results are presented and compared with other methods.

4:54PM D15.00013 Reference Calculation of Temperature-dependent Behavior of Confined Many-electron Systems[1] , FRANK E. HARRIS, TRAVIS SJOSTROM, University of Florida — Confined many-electron systems at finite temperatures present a major challenge to density functional theory. Very little is known about the free energy behavior over the temperature range of interest, for example, in the study of warm dense matter, and as a result, it is difficult to assess the validity of proposed free energy density functionals. We present preliminary results on a comparatively simple but computationally feasible model, namely thermally occupied Hartree-Fock states for eight one-electron atoms in a box. We discuss the main technical task, evaluation of the required matrix elements, and summarize the results thus far obtained.

[1]We acknowledge support from US DoE Grant DE-SC0002139.

5:06PM D15.00014 Finite-temperature Exchange and Correlation Functionals in Self-Consistent Calculations[1] , T. SJOSTROM, V.V. KARASIEV, S.B. TRICKEY, University of Florida — Density functional theory is being used increasingly to investigate systems at substantial electron temperatures (e.g., warm dense matter, order of 1-10 eV or more). A common approach uses a ground-state (zero-temperature) exchange-correlation (XC) functional with thermal occupancy (Fermi distribution) of the Kohn-Sham states. Various finite-temperature extensions for XC free energy (Sommerfeld expansion, RPA, STLS, classical map) have been proposed, however. All have LDA form. We have implemented several in a pseudopotential code (SIESTA), and also extended them to have the PBE-GGA as the zero-temperature limit. We report equation of state calculations for Li from ambient density and temperature through the warm dense matter regime. Nontrivial variation is found.

[1]We acknowledge support from US DoE Grant DE-SC0002139.

5:18PM D15.00015 Finite Temperature Scaling of the Non-interacting Free Energy Density Functional[1] , J.W. DUFTY, V.V. KARASIEV, S.B. TRICKEY, Physics, Univ. Florida — The non-interacting free energy density functional is central to formulation of orbital-free DFT, yet its construction remains a challenge. Here, exact scaling relations and related bounds are obtained for guidance. First, that free energy is expressed as a functional of one-body reduced density operators that deliver the same average number density. For a one-component Fermion system, this functional has a minimum at the Fermi operator whose external potential assures the chosen number density. This is the formal definition of the non-interacting free energy density functional. The associated entropy and internal energy functionals are identified directly. A unitary transformation generating spatial scaling then determines how these functionals change under density scaling. As an application, these scaling laws are used to obtain inequalities and bounds for functionals at different values of the density and temperature. Relationships to similar recent work at finite temperatures, and the extensive prior zero-temperature results are noted.

Monday, March 21, 2011 2:30PM - 5:30PM –
Session D16 GMAG: Magnetic Imaging and Characterization D173

2:30PM D16.00001 Single Shot Nanoscale Magnetic Imaging at the Linac Coherent Light Source[1] , BENNY WU, TIANHAN WANG, Stanford University, CATHERINE GRAVES, DILING ZHU, WILLIAM SCHLOTTER, JOSHUA TURNER, JOACHIM STOHR, Linac Coherent Light Source, ANDREAS SCHERZ, Stanford Institute for Materials and Energy Science — One of the major challenges of modern magnetism research is the manipulation and control of the magnetization on ultrafast timescales. Using the unprecedented brightness of the Linac Coherent Light Source (LCLS), we have been able to image the nanoscale magnetic worm domain structures in [Co/Pd] multilayer systems with a single x-ray pulse through x-ray Fourier transform holography on the Co L3 absorption edge. We established the threshold fluences for both non-destructive imaging and sample damage. In combination with the femtosecond pulses of LCLS, single shot coherent imaging will enable the observation of nanoscale magnetization dynamics on the sub-picosecond timescale for problems such as ultrafast demagnetization and all-optical magnetization reversal.

[1]This research was funded by the U.S. Department of Energy, Office of Basic Energy Sciences.

2:42PM D16.00002 Magnetic soft X-ray microscopy at 10nm spatial resolution[1] , PETER FISCHER, WEILUN CHAO, MI-YOUNG IM, ERIK ANDERSON, CXRO LBNL Berkeley CA — Magnetic soft X-ray microscopy, which combines high spatial and temporal resolution with elemental specificity by utilizing the specific features of X-ray magnetic circular dichroism effects is a unique and powerful analytical technique to image fast spin dynamics of nanoscale magnetism [1]. The spatial resolution is determined by Fresnel zone plate lenses used as diffractive optics. FZPs are fabricated by state-of-the-art lithography techniques and the challenge is to produce a dense, circular line pattern with a high aspect ratio to achieve high efficiency. Using an overlay technique [2-3], which requires high position accuracy of the e-beam writer, FZPs with 12nm outermost zone width could be fabricated. Implementing this optic at BL 6.1.2 at the ALS in Berkeley CA, we have demonstrated that a 10nm line and space test pattern can be clearly resolved. First magnetic images of a PtCo film with a pronounced perpendicular anisotropy will be presented. Further progress to below 10nm can be anticipated in the near future.

2:54PM D16.00003 New Developments in Magnetic Coherent Diffractive Imaging , ASHISH TRIPATHI, University of California, San Diego, SANGSOO KIM, Argonne National Laboratory, SEBASTIAN DIETZE, ERIK SHIPTON, ERIC FULLERTON, OLEG SHPYRKO, University of California, San Diego, IAN MCNULTY, Argonne National Laboratory — Magnetism at the nanoscale is central to understanding emergent complexity in transition metal oxides and engineered rare earth-transition metal multilayers, and in designing new magnetic data storage and spintronic technology. We study magnetism at the nanoscale here using coherent x-ray diffractive imaging (CXDI), which is a technique with potentially wavelength-limited spatial resolution that can probe deeply beyond surfaces, and potentially on ultrafast timescales using new x-ray laser sources. We look at the domain evolution vs. applied magnetic field over the whole hysteresis loop of a ferrimagnetic GdFe multilayer film using x-rays resonant at the Gd M5 edge for domain contrast. We explore complimentary and return point memory by imaging the multilayer over a large field of view. We lastly explore experimental and algorithmic improvements in CXDI using dichroism as contrast mechanism, as well as new opportunities for ultra-fast, single-shot imaging using a variation on the CXDI approach.

3:06PM D16.00004 Design of a Self-Aligned, 300mK-300K Temperature range Magnetic Force Microscope(MFM) with <10nm Resolution , OZGUR KARCI, NanoMagnetics Instruments Ltd. & Hacettepe University, IVAN KNEZ, Rice University, HILAL ATALAN, NanoMagnetics Instruments Ltd., RUI-RUI DU, Rice University, AHMET ORAL, Sabanci University, NANOMAGNETICS INSTRUMENTS LTD TEAM, HACETTEPE UNIVERSITY TEAM, RICE UNIVERSITY TEAM, SABANCI UNIVERSITY TEAM — We present the design of a self-aligned MFM, operating from 300mK to 300 K. Unique 'Self-Aligned' design uses cantilever alignment chips and eliminates the alignment procedure and sustains the alignment across the full temperature range. The MFM is very compact, 23.6mm OD, and is adopted to fit into Oxford Instruments Heliox TL system. A fiber interferometer with $\sim$12fm/$\sqrt{}$Hz noise level is designed and used to detect cantilever deflection. Stick slip coarse approach mechanism is used to bring the sample in to close proximity of the sample. We can also move the sample in XY directions within 3 mm range, while we measure the position with capacitive encoder with 3μm accuracy. We can also operate the LT-MFM in high magnetic fields. The microscope has been successfully operated between 300mK-300K and we can achieve <10nm resolution. MFM images of 394 Gbpsi Harddisk at 1.5-300K and CoPt Multilayers at 350mK will be presented.

3:18PM D16.00005 Monolithic diamond probes for nanoscale magnetic imaging using single spins in diamond , PATRICK MALETINSKY, SUNGKUN HONG, MICHAEL GRINOLDS, BIRGIT HAUSMANN, RON WALSWORTH, MIKHAIL LUKIN, MARKO LONCAR, AMIR YACOBY, Harvard University — Sensitive detection of magnetic fields at the nanoscale is a challenging problem in biological and physical sciences with great relevance to technological applications. Recent experimental demonstrations have shown the outstanding performance of diamond nitrogen-vacancy (NV) centers in magnetic field sensing [1, 2]. Here, we present a robust experimental realization of a scanning NV-magnetometer that exploits the full coherence properties of the NV-center for magnetic imaging. Our apparatus consists of a combined atomic force (AFM) and optical microscope, where the AFM tip is formed by a high purity diamond nanopillar containing a single NV center at its end. This geometry ensures high spatial resolution, long NV coherence times and waveguiding of NV fluorescence through the pillar, which combine to give maximal magnetic field sensitivity. We demonstrate the performance of our nanoscale magnetometer by imaging various magnetic field sources, including few tens of nm wide domains of a magnetic memory.

[2] Nature 455, 644 (2008)

3:30PM D16.00006 A stroboscopic approach to combining diamond magnetometry with Atomic Force Microscopy , SUNGKUN HONG, MICHAEL GRINOLDS, PATRICK MALETINSKY, MIKHAIL LUKIN, RONALD WALSWORTH, AMIR YACOBY, Harvard University — Nitrogen-Vacancy (NV) defect centers in diamond have been recently considered as a promising candidate for sensitive magnetic field detection[1, 2] with nanometric spatial resolution. Most applications requiring high spatial resolution necessitate stabilizing the NV center in close proximity to the sample of interest, which can be accomplished using standard Atomic Force Microscopy (AFM) techniques[2]. However, the fluctuations associated with AFM tip oscillation set limits to both spatial resolution and magnetic field sensitivity[2]. Here we demonstrate a stroboscopic approach that locks the magnetic signal acquisition to a particular position of the tip. Our approach allows us to reach the sensitivity and spatial resolution given by the intrinsic properties of NV centers.

3:42PM D16.00007 High sensitivity SQUID susceptibility measurements , B. KALISKY, J.R. KIRTLEY, L.C. QIAN, B.L. DWYER, K.A. MOLER, Stanford, J. NGAI, Y. SEGAL, J. REINER, F. WALKER, C. AHN, Yale, A.M. HAMILTON, B. RUTT, A.C. MATIN, Stanford, O.M. AUSLAENDER, Technion, D.A. BONN, R. LIANG, W.N. HARDY, UBC, J.G. ANALYTIS, J.-H. CHU, I.R. FISHER, Stanford — Scanning superconducting quantum interference device (SQUID) sensors have high sensitivity to magnetic flux ($10^{-6}\Phi_0/\sqrt{Hz}$) and magnetic moment ($\sim$ 100 electron spins) under reasonable scanning conditions. In addition, a single turn field coil co-centered with the SQUID sensing loop provides excitation for simultaneous measurement of low field susceptibility, with sensitivity of $\chi \sim 10^{-6}$ at a spatial resolution of a few microns. I will present our recent measurements on several systems which exhibit weak susceptometry signals: thin film paramagnetic LaNiO3 that are (hopefully) the precursors to engineered superconducting films; individual magnetotactic bacteria, which are used as MRI contrast agents; and twinned high critical temperature cuprate and pnictide superconducting samples that may experience variations in the superfluid density at the twin boundary.

3:54PM D16.00008 Magnetic Characterization of Individual Magnetotactic Bacteria , LISA QIAN, Stanford University, BEENA KALISKY, Stanford Unversity, AMANDA HAMILTON, BO DWYER, A.C. MATIN, KATHRYN MOLER, Stanford University — Magnetic nanoparticles 5-50nm in size are of wide interest in the biological and medical fields. In particular, magnetotatic bacteria containing chains of nanoscale magnetite particles show potential for MRI contrast agents and targeting tumors. Magnetic characterization is typically done in large ensembles, where variations in shape and structure cannot be determined and interparticle coupling may cause bulk properties from those of isolated particles. We report the detection and magnetic characterization of individual magnetotatic bacteria using a variable temperature scanning SQUID microscope (SSM). SSM is ideal for this challenge due to its high spin sensitivity, ∼100 mu_B/sqrt(Hz). AC and DC modes of operation allow for direct probing of susceptibility and magnetic moment. We will also discuss calculation techniques used to obtain values for the magnetic moment, anisotropy energy and magnetosome chain length of individual bacteria.

4:06PM D16.00009 Magneto-resistance based First Order Reversal Curve (MR-FORC) analysis of MgO based MTJs , JOSHUA POMEROY, JOHN READ[1], National Institute of Standards and Technology (NIST) — MR-FORC utilizes partial magneto-resistance hysteresis loops to reveal the coercive and interaction field distributions in the free layer of MgO based magnetic tunnel junctions. The interpretation of the FORC diagrams will be discussed with emphasis on the identification of coercive values, the interlayer exchange properties, the magnetic after-effect and a reversible magnetic instability under study.

4:18PM D16.00010 Stress and Depth Dependence of Stochastic Processes in the Barkhausen Effect , DAVID JILES, Iowa State University, Ames, Iowa 50011, LUKASZ MIERCZAK, EUGENE MELIKHOV, Wolfson Centre for Magnetics, Cardiff University, United Kingdom, IOWA STATE UNIVERSITY TEAM, WOLFSON CENTRE FOR MAGNETICS TEAM — Magnetic Barkhausen Noise (MBN) consists of discontinuous stochastic changes in flux density caused by sudden irreversible changes in magnetization as the magnetic field H changes continuously. These changes can be detected at the surface by a magnetometer, which in its simplest form can be in the form of voltage pulses caused in a pickup coil. The amplitude of such pulses has been shown to depend on the microstructure and stress in the material. Propagation of Magnetic Barkhausen emissions in magnetic materials is frequency dependent and therefore information from different depths inside the material is contained in the frequency spectrum of the detected Barkhausen signal at the surface. However the depth dependent information, although present, is difficult to extract from the measurements. Despite this extracting the depth dependent information about material conditions, such as variations in microstructure and/or the presence of residual stress is of a great interest. This work presents a new method for extracting this information from measured MBN signals.

4:30PM D16.00011 Cluster-deposited high-anisotropy magnetic nanoparticles[1] , BALAMURUGAN BALASUBRAMANIAN, RALPH SKOMSKI, XINGZHONG LI, DAVID SELLMYER, Nebraska Center for Materials and Nanoscience and Department of Physics and Astronomy, University of Nebraska, Lincoln, NE-68588 — Magnetic nanoparticles of size less than 10 nm with high magnetocrystalline anisotropy are highly desirable to understand the nanoscale effects on their magnetic properties and create building blocks for modern applications such as ultra-high-density recording media and high-performance permanent magnets. In the present study, monodisperse Co-based nanoparticles with an average particle size of 3 -10 nm, such as YCo_5 and $Co_{1-x}Pt_x$ ($x < 0.2$), were produced using an inert-gas-condensation cluster-deposition system and characterized using XRD, TEM, EDX and SQUID magnetometer. These nanoparticles were directly ordered into high-anisotropy crystal structures during the cluster-aggregation process and exhibit high anisotropic constant of order 10^7 ergs/cm^3. Size-effects on the structural and magnetic properties of YCo_5 and Co_xPt_{1-x} nanoparticles will be discussed.

[1]This work is supported by DOE, ARPA-E, BREM, NSF-MRSEC, and NCMN.

4:42PM D16.00012 Improved evaluation of magnetic nanoparticle susceptibility in hyperthermia, spectroscopy, and imaging[1] , YONG WU, ZHEN YAO, TIMOTHY ATHERTON, LISA BAUER, MARK GRISWOLD, ROBERT BROWN, Case Western Reserve University — Magnetic nanoparticles are becoming increasingly important for both diagnosis (through applications such as MRI and magnetic particle imaging (MPI), which comes from the nonlinear magnetization of nanoparticles and provides images with both high spatial and temporal resolutions) as well as for therapy (through focal heating). Thus understanding and modeling of the magnetic susceptibility of the nanoparticles is critical. In hyperthermia calculations, a constant chord susceptibility approximation is used to get a lower bound estimate of the power dissipated. In later work, this approximation has been adapted to examine the decay effects due to nanoparticle relaxation under oscillating magnetic fields in the MPI modality. We provide in the present paper both analytical and numerical work to understand where it is, or is not, appropriate to make this approximation. In addition, we provide a more general approach that does not rely on the above approximations, and may provide new insight to manufacture optimal nanoparticles for applications.

4:54PM D16.00013 The Spin-Lattice Relaxation of Hyperpolarized ^{89}Y Complexes , ASHISH JINDAL, LLOYD LUMATA, UT Southwestern Med. Cntr., YIXUN XING, UT Dallas, MATTHEW MERRITT, UT Southwestern Med. Cntr., PIYU ZHAO, UT Dallas, CRAIG MALLOY, DEAN SHERRY, ZOLTAN KOVACS, UT Southwestern Med. Cntr. — The low sensitivity of NMR can be overcome by dynamic nuclear polarization (DNP). However, a limitation to the use of hyperpolarized materials is the signal decay due to T_1 relaxation. Among NMR-active nuclei, ^{89}Y is potentially valuable in medical imaging because in chelated form, pH-sensitive agents can be developed. ^{89}Y also offers many attractive features – 100 % abundance, a 1/2 spin, and a long T_1, up to 10 min. Yet, developing new ^{89}Y complexes with even longer T_1 values is desirable. Designing such complexes relies upon understanding the mechanism(s) responsible for T_1 relaxation. We report an approach to hyperpolarized T_1 measurements that enabled an analysis of relaxation mechanisms by selective deuteration of the ligand backbone, the solvent or both. Hyperpolarized ^{89}Y – DTPA, DOTA, EDTA, and deuterated EDTA complexes were studied. Results suggest that substitution of low-gamma nuclei on the ligand backbone as opposed to that of the solvent most effectively increase the ^{89}Y T_1. These results are encouraging for in vivo applications as the presence of bound water may not dramatically affect the T_1.

5:06PM D16.00014 Magnetic Thermal Hysteresis in Dy nanolayers , AJANI ROSS, ALI KOYMEN, University of Texas Arlington — Magnetic thermal hysteresis is observed when the temperature dependent magnetic properties of a material are reliant on the starting point of the measurement. Trilayer samples of pure Dysprosium (Dy) and Gadolinium (Gd) were grown on substrates of glass ($Gd_n/Dy_m/Gd_n$), n and m constitutes the number of layers. We observed magnetic thermal hysteresis in these thin films at low values of constant external magnetic field strengths. The temperature is swept from 20K to 300K at constant field, then back (300K to 20K) under the same field. In these temperature sweeps differences in magnetic moment were observed near the low end of the temperature range. Experiments are being done, currently, to confirm the existence of alternate helicity (AH-state) and helical (H-state) states in these trilayer films, which are believed to be the cause of the observed thermal hysteresis according to theoretical calculations. In addition, the temperature dependence of entropy change for these samples is calculated.

5:18PM D16.00015 Chain formation in a magnetic fluid under the influence magnetic fields. , MATT BARRETT, ANDREAS DESCHNER, McMaster University, JAN EMBS, ETH Zurich & Paul Scherrer Institut, AN-CHANG SHI, MAIKEL RHEINSTADTER, McMaster University — We studied the aggregation of magnetic particles into simple chainlike structures in a Cobalt-based magnetic fluid, exposed to external magnetic fields [1]. The length of chain segments in very strong magnetic fields of up to 2 T was measured using small angle neutron scattering in-situ. Although it was predicted that the chain length can be described by a Langevin function, leading to chains several hundred particles in length, we observe a maximum correlation length of $\sim$ 650 Å, or 4-5 particles. To gain insight into the molecular mechanisms involved, our experiments were complemented by Monte Carlo simulations. We observed that the chains which formed increased in length as the magnetic field increased until reaching equilibrium at 4 particles, in excellent agreement with our experimental findings. We speculate that the interplay between the entropy and energy of the system combined with the particular properties of the magnetic dipole-dipole interaction ultimately decide the length of the particle chains. We observed attractive or repulsive interaction between chain segments depending on their relative position. [1] *"Chain formation in a magnetic fluid under the influence of magnetic fields"*, M. Barrett, A. Deschner, J.P. Embs, A.-C. Shi, M.C. Rheinstädter, submitted to Physical Review Letters.

Session D17 DMP GMAG: Focus Session: Bulk Properties of Complex Oxides - Cobaltites D174

2:30PM D17.00001 Possible link of a structurally driven spin flip transition and the insulator-metal transition in the perovskite $La_{1-x}Ba_xCoO_3$, DESPINA LOUCA, University of Virginia — The intricate nature of the magnetic ground state near the insulator-metal transition (IMT) in $La_{1-x}Ba_xCoO3$ was investigated via neutron scattering. For x less than the critical concentration, x_c $\sim$0.22, a commensurate antiferromagnetic (AFM) phase initially appears. As x approaches x_c, the AFM component continuously weakens while ferromagnetic (FM) order sets in the rhombohedral lattice. The two magnetic phases appear to be growing in different domains and have different ordering temperatures, with the FM order parameter setting in first at higher temperatures while the AFM order parameter occurs at lower temperatures. At x_c, a spin flip to a new FM state occurs while the crystal transforms to an orthorhombic (Pnma) symmetry. The magnetic Pnma phase coincides with the minimum saturation reached in the resistivity. It is proposed that the orbital overlap in the Pnma phase is the most conducive to charge hopping.

3:06PM D17.00002 Phase Control of Magnetic Order in (Y,Lu)$BaCo_4O_7$, JOHN MITCHELL, HONG ZHENG, SEVDA AVCI, Argonne National Laboratory, LAURENT CHAPON, DMITRY KHALYAVIN, ISIS Facility, OMAR CHMAISSEM, Northern Illinois University, ASHFIA HUQ, Oak Ridge National Laboratory — The $RBaCo_4O_7$ (R=Ca, Y, Tb-Lu) provides a novel topology for studying geometric frustration, in which face-sharing tetrahedra of magnetic ions link to form trigonal bipyramids on a Kagomé lattice. Here we describe the structural and magnetic behavior of the Lu member and the solid solution joining Lu to Y as a chemical means to tune between magnetically ordered and disordered ground states. Mean-field models of the generic magnetic phase diagram of $RBaCo_4O_7$ determined recently by our group (D. D. Khalyavin et al. Physical Review B 82, 094401 (2010)) show a variety of magnetic states as a function of two exchange parameters: J_{ab} and J_c, where J_{ab} links Co ions in the Kagomé planes and J_c links Co ions from the Kagome plane to the interleaving triangular layer. Experimentally, we find that $YBaCo_4O_7$ has a long-range ordered antiferromagnetic ground state, while $LuBaCo_4O_7$ appears to be disordered above 2 K. We use the solid solution to interpolate between these endpoints and discuss these results with respect to the mean-field phase diagram.

3:18PM D17.00003 Determination of magnetic moments and orbital occupancy in the spin chain compound $Ca_3Co_2O_6$[1] , JONATHAN DUFFY, MATTHEW BUTCHERS, University of Warwick, JONATHAN TAYLOR, ISIS, STEPHEN DUGDALE, TOM HAYNES, University of Bristol, STEFANO AGRESTINI, MARTIN LEES, University of Warwick — The one-dimensional cobaltate $Ca_3Co_2O_6$ exhibits a number of intriguing phenomena, including several metamagnetic steps as a function of applied magnetic field. Although it has attracted a considerable amount of research, the origin of the magnetism has not yet been fully determined. We report a measurement of the spin density in $Ca_3Co_2O_6$ using magnetic Compton scattering. The bulk spin moment was determined to be 3.78 $\pm$ 0.05μ_B at 7 T, confirming the existence of a large unquenched Co orbital moment of 1.4 $\pm$ 0.1 μ_B. In combination with molecular orbital calculations, the results reveal that double occupation of the $d_{x^2-y^2,xy}$ orbital is responsible for the observed large unquenched orbital moment. Fitting the model to the experimental data shows that there is an induced oxygen moment of 0.8 $\pm$ 0.1 μ_B. Unexpectedly, further comparison with KKR-SPA electronic structure calculations strongly indicates the existence of a Fermi surface.

3:30PM D17.00004 Theory of the carrier concentration-dependent behavior in layered cobaltates , HONGTAO LI, University of Arizona, R. TORSTEN CLAY, Mississippi State University, SUMIT MAZUMDAR, University of Arizona — Layered cobaltates – anhydrous Na_xCoO_2, Li_xCoO_2 and the "misfit" cobaltates $[Bi_2A_2O_4] \cdot [CoO_2]_m$, where A = Ba, Sr or Ca – have attracted wide attention for their 2D layered structure and metallicity (both reminescent of 2D cuprates), and the tunability of the carrier concentration over a wide range. The Co ions form a 2D triangular lattice, and their formal charge in Na_xCoO_2 and Li_xCoO_2 can be tuned from Co^{3+} at $x = 1$ to Co^{4+} at $x = 0$. Charge carriers in all cases are holes, with the carrier concentration given by the fraction of Co-ions that are in the S = 1/2 Co^{4+} state. Experiments have indicated remarkable carrier concentration dependent magnetic susceptibility and thermoelectric power that remains unexplained to date. Specifically, all three systems show weakly correlated behavior at small nonzero x (large carrier concentration), and strongly correlated behavior at large x (small carrier concentration). In this talk we give clear theoretical explanation of the observed carrier concentration dependence within an a_{1g}-only one-band extended Hubbard Hamiltonian. The key to understanding the x-dependence is to have realistic finite on-site correlation U and significant intersite Coulomb interaction V. We present exact numerical results for triangular lattices upto 20 sites, and make detailed comparisons to experiments.

3:42PM D17.00005 Probing the Na atomic order in Na_xCoO_2, x=0.67 and 0.71 by NMR spectroscopy[1] , BEN-LI YOUNG, P.-Y. CHU, J.Y. JUANG, Department of Electrophysics, National Chiao Tung University, Taiwan, G.J. SHU, F.-T. HUANG, M.W. CHU, F.C. CHOU, Center for Condensed Matter Sciences, National Taiwan University, Taiwan — The sodium cobaltate Na_xCoO_2 has a layered structure, consisting of alternating triangular CoO_2 and Na planes. Evidences of Na atomic ordering have been reported at certain Na contents by different diffraction experiments. The Co magnetism, strongly influenced by the Na ordering, gives a unique phase diagram in Na_xCoO_2. In order to investigate the Na ordering and the Co magnetism, we conducted ^{23}Na and ^{59}Co NMR experiments in single crystals Na_xCoO_2 for x=0.67 and 0.71. We found that $Na_{0.67}CoO_2$ does not have well-defined Na structural order. However, the oxygen slightly-deficient sample $Na_{0.67}CoO_{1.98}$ shows a superstructure, as evidenced by the narrow and well-resolved NMR spectrum. As for $Na_{0.71}CoO_2$, Na ordering is also observed. We have tried to solve the Na ordering pattern from our NMR spectra. The results will be discussed and be compared with the existing structural models.

3:54PM D17.00006 Synthesis and anisotropic magnetic and transport properties of cubic $SrCoO_3$ single crystal , YOUWEN LONG, YOSHIO KANEKO, ERATO-MF, JST, Wako 351-0198, Japan, SHINTARO ISHIWATA, Dep. Appl. Phys., Univ. Tokyo, Tokyo 113-8656, Japan, YASUJIRO TAGUCHI, CMRG and CERG, RIKEN-ASI, Wako 351-0198, Japan, YOSHINORI TOKURA, ERATO-MF, JST, CMRG and CERG, RIKEN-ASI, Wako 351-0198, Japan; Dep. Appl. Phys., Univ. Tokyo, Tokyo 113-8656, Japan — Solid state oxides containing transition metals with unusually high valence states exhibit interesting physical properties. However, due to the unstableness of these high valence states, high pressure is often needed to stabilize such high valence states. We were successful in growing a large-size $SrCoO_3$ single crystal by using high-pressure technique. This material shows good metallic behavior with high ferromagnetic Curie temperature about 305 K, and the easy magnetization axis is <111> direction. The spin moment of Co^{4+} ion measured at 2 K and 7 T is about 2.50 μ_B, suggesting an intermediate spin configuration as predicted by theoretical calculations. Although $SrCoO_3$ has a highly symmetric cubic crystal structure (Pm-3m), it exhibits significant anisotropic magnetoresistance at low temperatures.

4:06PM D17.00007 The origin of the temperature dependence of the magnetic susceptibility and the large thermoelectric power in metallic layered cobaltites , IVÁN GONZÁLEZ, Centro de Supercomputación de Galicia, Avda. de Vigo s/n, E-15705 Santiago de Compostela, CAMILO X. QUINTELA, Applied Physics Department, University of Santiago de Compostela, 15782 Santiago de Compostela, Spain, MANUEL BAÑOBRE-LÓPEZ, FRANCISCO RIVADULLA, Physical-Chemistry Department, University of Santiago de Compostela, 15782 Santiago de Compostela, Spain — We perform detailed measurements of the thermoelectric power and the static magnetic susceptibility on metallic Na_xCoO_2 and $Ca_3Co_4O_9$, as representatives of layered Co oxides with a triangular Co-lattice. We propose that the observed large thermoelectric power and the Curie-Weiss temperature dependence of the susceptibility have a common origin related to metallic character of these compounds. Thermoelectric power measurements are compared to Boltzmann transport theory calculations. The Curie-Weiss behaviour of the susceptibility is explained within the framework of the self-consistent renormalization theory for spin fluctuations proposed by Moriya for itinerant magnets. Our results clarify the apparent duality in the localised/itinerant behaviour of the electron spin in these systems and provide a unifying view on the physics of metallic layered cobaltites.

4:18PM D17.00008 TEM imaging and in-situ EELS study of multiple ferroic transitions in LaCoO3[1] , TIANTIAN YUAN, ROBERT KLIE, University of Illinois at Chicago, Department of Physics, NINA ORLOVSKAYA, University of Central Florida — The perovskite oxide LaCoO3 has attracted increasing attention due to its reported room-temperature ferroelastic behavior, and a ferromagnetic transition observed at around 90K in epitaxially strained thin films. To advance our understanding of these nanoscale properties of LaCoO3, a combination of analytical TEM techniques, including the atomic-resolution Z-contrast imaging and electron energy-loss spectroscopy in combination with in-situ cooling experiments have been used to study the relationship of the multiple ferroic transitions in bulk LaCoO3. In particular, we find that the bulk LaCoO3 samples compressed above the coercive stress exhibit ferromagnetic transitions, similar to the ferromagnetic behavior of the epitaxially strained LaCoO3 thin film. While the bulk LaCoO3 samples compressed below the coercive stress do not exhibit any ferromagnetic transitions down to 5K. We will further correlate this ferromagnetic property to the ferroelastic property of LaCoO3, and show how the strain of the LaCoO3 affects the ferromagnetic property of the sample.

4:30PM D17.00009 Magnetocaloric effect across the coupled structural/magnetocrystalline anisotropy transition in $Pr_{1-x}Sr_xCoO_3$ (x=0.3-0.5) , N.S. BINGHAM, M.H. PHAN, H. SRIKANTH, University of South Florida, M.A. TORIJA, C. LEIGHTON, University of Minnesota — Large magnetocaloric effects (MCE) are often observed in materials exhibiting a first order magnetic transition coupled with a crystal structure change. Since the magnetic and structural changes are coupled, it is difficult to decouple the structural entropy contribution from the magnetic entropy contribution to the total MCE. Therefore a clear understanding of the structural entropy change and its field dependence in such materials is lacking. A recent study revealed that $Pr_{1-x}Sr_xCoO_3$ (x>0.35) undergo a coupled structural/magnetocrystalline anisotropy transition at T_A, in addition to the paramagnetic-ferromagnetic transition at T_C. Since the structural change at T_A in PSCO is not associated with any magnetic transition, it is an excellent system for studying the structural entropy change and its contribution to the MCE. We report systematic studies of the MCE in $Pr_{1-x}Sr_xCoO_3$ (x=0.3, 0.35, 0.4, 0.5) compounds. The results show significant entropy change at T_A, whose magnitude can be tuned by controlling the magnetocrystalline anisotropy.

4:42PM D17.00010 Magneto-electronic Phase Separation in $Pr_{1-x}Ca_xCoO_{3-\delta}$: Intrinsic Exchange Spring Magnetism[1] , S. EL-KHATIB, American University of Sharjah, S. BOSE, C. HE, J. KUPLIC, University of Minnesota, M. LAVER, J.A. BORCHERS , Q. HUANG, J.W. LYNN, NIST Center for Neutron Research, J.F. MITCHELL, Argonne National Laboratory, C. LEIGHTON, University of Minnesota — We present a neutron diffraction, small-angle scattering, and magnetometry study of the narrow bandwidth perovskite cobaltite $Pr_{1-x}Ca_xCoO_3$, demonstrating an unusual form of magneto-electronic phase separation where long-range ordered ferromagnetism coexists spatially with short-range ferromagnetism. The two phases have very different coercivities and, remarkably, are strongly exchange coupled. The electronic phase separation thus leads to spontaneous formation of a hard-soft nanocomposite, exhibiting prototypical exchange-spring behavior in the absence of chemical interfaces.

[1]Work at UMN supported by DoE (neutron scattering) and NSF.

4:54PM D17.00011 The nature of magneto-elastic coupling with the isovalent substitution at the B-site in $LaCo_{1-y}B_yO_3$, JUAN YU, DESPINA LOUCA, Physics Department, University of Virginia — The influence of magnetic ion doping on the interplay of the lattice with magnetism in $LaCo_{1-y}B_yO_3$ (B = Ni or Fe, y= 0.1, 0.4) has been investigated via neutron scattering techniques. The substitution of either Ni^{3+} ($3d^7$) or Fe^{3+} ($3d^5$) does not alter the crystal symmetry which remains rhombohedral (R-3c) at all temperatures. With doping, the degree of cooperative octahedral rotations about the (111) axis increases, but it is only with Ni that such a rotation is accompanied by a compression along the trigonal axis. The observed crystal distortion is invoked to break the degeneracy of the magnetic Co^{3+} ions, while maintaining the Co-O bonds at a constant length. The absence of two distinct types of Co-O bond lengths in the local structure with the substitution of Fe^{3+} or Ni^{3+} for Co^{3+} ($3d^6$) is indicative that, unlike in the hole doped cobaltites with Ba^{2+} or Sr^{2+} previously studied, the intermediate spin state of Co is either absent or suppressed. This leaves us to question the origin of the magnetic interactions, which most likely arises from a high-spin state of the Co ion.

5:06PM D17.00012 First Principles Study of Misfit-Layered Calcium Cobaltite Using Fibonacci Approximants[1] , ALEJANDRO REBOLA, ROBERT KLIE, SERDAR OGUT, University of Illinois at Chicago — Cobalt oxides have been the focus of many recent studies due to the wide variety of electrical, magnetic, structural and thermoelectrical properties they exhibit. In this talk we present a first-principles study on the misfit-layered $Ca_3Co_4O_9$. This material can be more accurately described as $[Ca_2CoO_3][CoO_2]_{1.61}$ and consists of two substructures that are incommensurate to each other. Taking into account that the composition ratio is very close to the golden mean (1.6180...), and that this number can be obtained as the limit of the sequence of the ratios of consecutive Fibonacci numbers: 3/2, 5/3, 13/8, . . . , F(n+1)/F(n)..., we model the structure by using supercells of composition $[Ca_2CoO_3]_{F(n)}[CoO_2]_{F(n+1)}$. In this way, structural, electronic, transport and lattice properties can be calculated as a function of cell size. We compute the atomic and electronic structures, defect energetics of a series of rational approximants to $Ca_3Co_4O_9$within the framework of DFT+U, and examine the convergence of such properties with respect to size, thus allowing us to identify the most realistic and smallest structural model for this misfit-layered compound.

[1]This work is in part supported by the US Army Research Office (W911NF-10-1-0147).

5:18PM D17.00013 Complex ferrimagnetic state induced by zigzag oxygen-vacancy stripes in $Sr_3YCo_4O_{10.72}$, D.D. KHALYAVIN, L.C. CHAPON, ISIS facility, Rutherford Appleton Laboratory, E. SUARD, Institut Laue-Langevin, J.E. PARKER, S.P. THOMPSON, Diamond Light Source, A.A. YAREMCHENKO, V.V. KHARTON, University of Aveiro — The nature of high temperature ferromagnetic behaviour in $Sr_3YCo_4O_{10+\delta}$ perovskite has been studied by neutron powder diffraction supplemented with synchrotron X-ray diffraction measurements. The present analysis of the magnetic structure takes into account the complex superstructure formed by oxygen vacancy ordering. These vacancies create zigzag strips in the oxygen-deficient $CoO_{4+\delta}$ layers providing three distinct coordinations for Co ions. The values of the ordered moments were found to be essentially different for the distinct coordinated units and clearly correlate with the coordination number. The symmetry of the superstructure in conjunction with strong antiferromagnetic interactions between neighbour spins results in a net moment whose origin has been the subject of considerable debates.

Session D18 GMAG DMP: Focus Session: Low D/Frustrated Magnetism - Kagome Lattices

D172

2:30PM D18.00001 Highly frustrated magnets: a class of emergent gauge systems , MICHAEL LAWLER, Binghamton University — Condensed matter exhibit a wide variety of exotic emergent phenomena, such as the topological order in the fractional quantum Hall effect, and the "cooperative paramagnetic" response of geometrically frustrated magnets. The classical and quantum dynamics of spins exploring the large configuration space associated with the latter are not well understood analytically. I consider the constrained classical Hamiltonian dynamics of spins exploring such a configuration space as a starting point from which a complete classical and semi-classical description may be reached. The method I employ, introduced by Dirac [1] and now forms the basis of gauge theory, applies to any frustrated system constrained to a continuous set of configurations. Remarkably, in the kagome lattice model I consider as an example, these dynamics are similar to the "topological" (Chern-Simons) dynamics of electrons in the fractional quantum Hall effect and have non-locally entangled edge modes as the only degrees of freedom. In principle, these edge states may be found in any kagome-like Heisenberg antiferromagnets such as Herbertsmithite, the Jarosites, $SrCr_{8-x}G_{4+x}O_{19}$ and $Na_4Ir_3O_8$.

[1] Dirac, P. A. M. *Generalized hamiltonian dynamics.* Can. J. of Math. **2**, 129-148 (1950)

2:42PM D18.00002 Predictions for the ARPES spectral function of kagome antiferromagnetic insulators[1] , SUMIRAN PUJARI, Cornell University, MICHAEL J. LAWLER, Binghamton University, Cornell University — There are now a number of spin liquid candidate materials possibly with exotic spin-1/2 "spinon" excitations. Motivation by these discoveries, we consider the scaling properties of the hole spectral function for the frustrated Kagome Heisenberg antiferromagnet assuming Dirac Spin Liquid(DSL) ground state proposed for Herbertsmithite [2]. We predict a sublinear in energy power law dependence of the ARPES spectral function at certain wave vectors. Using Renormalization group techniques, we show how (gauge) fluctuations of the DSL mean field give an anomalous exponent to spinons[2] and no anomalous exponent to holons thereby leading to the sublinear power law. If this behavior is observed in experiments, they would provide strong evidence for the existence of spinons in highly frustrated magnets.[2]

2:54PM D18.00003 Exact Chiral Spin Liquid with Stable Spin Fermi Surface on the Kagome Lattice[1] , VICTOR CHUA, Department of Physics, University of Texas at Austin, HONG YAO, Department of Physics, University of California, Berkeley, California, GREGORY FIETE, Department of Physics, University of Texas at Austin — We study an exactly solvable quantum spin model of Kitaev type on the kagome lattice. We find a rich phase diagram which includes a topological (gapped) chiral spin liquid with gapless chiral edge states, and a gapless chiral spin liquid phase with a spin Fermi surface. The ground state of the current model contains an odd number of electrons per unit cell which qualitatively distinguishes it from previously studied exactly solvable models with a spin Fermi surface. Moreover, we show that the spin Fermi surface is stable against weak perturbations.

[1]This work is supported in part by NSF grant DMR-0955778 (VC and GAF) at Austin and DOE grant DE-AC02- 05CH11231 (HY) at Berkeley.

3:06PM D18.00004 Quantum criticality in the kagome staircase system $Co_3V_2O_8$ in transverse magnetic field , K. FRITSCH, McMaster Univ., K.C. RULE, Helmholtz-Zentrum Berlin, K.A. ROSS, McMaster Univ., Y. QIU, J.R.D. COPLEY, NCNR NIST, K. KIEFER, K. HABICHT, Helmholtz-Zentrum Berlin, H.A. DABKOWSKA, B.D. GAULIN, BIMR and McMaster Univ. — $Co_3V_2O_8$ (CVO) belongs to the kagome staircase family of orthorhombic materials in which Ising-like Co^{2+}, S=3/2 magnetic moments decorate a stacked and buckled version of the two-dimensional kagome lattice. In zero applied magnetic field, this material displays a complex series of five different magnetically ordered phases below ∼11 K which culminate in a simple ferromagnetic state below Tc∼6 K. Previous inelastic neutron scattering work[1] on this quasi-two-dimensional system showed that the exchange interactions within the kagome planes are rather weak (J∼1.25 meV), making this system an ideal candidate for the study of transverse field-induced quantum critical phenomena as have been observed in $LiHoF_4$ or recently in $CoNb_2O_6$. We have investigated the phase diagram of CVO with the transverse field applied along the stacking direction using magnetization as well as single crystal neutron scattering techniques. We will discuss how the ground state magnetic structure and spin dynamics of CVO evolve upon tuning the transverse magnetic field through the quantum critical point near Hc∼6 T. [1] M. Ramazanoglu et al., PRB 79, 024417 (2009).

3:18PM D18.00005 Herbertsmithite: a slightly less than ideal kagomé antiferromagnet[1] , YUAN WAN, ZHIHAO HAO, OLEG TCHERNYSHYOV, Johns Hopkins University — Herbertsmithite, one of the best realizations of the Heisenberg antiferromagnet on kagomé, shows no signs of magnetic order down to the lowest accessible temperatures and likely possesses a quantum-disordered ground state. A recent site-specific X-ray diffraction experiment [1] shows deviations from the ideal model, most notably in the form of excess copper spins residing outside of kagomé planes. We study the influence of these impurities on the magnetic properties of herbertsmithite, focusing on locally induced Jahn-Teller distortions in kagomé planes and on exchange interactions between the excess spins.

3:30PM D18.00006 Magnetic studies of S=1/2 kagomé lattice single crystals , TIANHENG HAN, MIT, JOEL HELTON, ANDREA PRODI, CLAUDIO MAZZOLI, PETER MULLER, DEEPAK SINGH, JOSE RODRIGUEZ, COLLIN BROHOLM, DANIEL NOCERA, SHAOYAN CHU, YOUNG LEE — The Zn-paratacamite mineral family, $Zn_xCu_{4-x}(OH)_6Cl_2$, presents a promising system for studies of frustrated magnetism on a S=1/2 kagomé lattice. Here we report a new synthesis method, by which high quality single crystals of Zn-paratacamite can be produced. The x = 1 mineral herbertsmithite is a spin-liquid candidate. This compound displays a magnetic susceptibility that is anisotropic at high temperatures. A small anisotropy is observed in specific heat measurements with magnetic field applied in-plane and normal-to-plane. Inelastic neutron scattering has been performed and we will discuss the observed structure factor in the context of various theoretical expectations.

3:42PM D18.00007 Terahertz conductivity of a metal-organic hybrid Kagomé lattice: A candidate spin liquid , DANIEL PILON, ALEX FRENZEL, DANNA FREEDMAN, DANIEL NOCERA, NUH GEDIK, MIT — Recent theoretical studies predict that the optical conductivity of a spin liquid should exhibit power law behavior in frequency at low temperatures. Materials with the Kagomé structure are the most promising candidates for observing spin liquid behavior due to their high degree of magnetic frustration. We have measured the optical conductivity of Cu(1, 3-bdc), a spin-1/2 Kagomé lattice material, in the range 0.5 - 2 THz. We compare these results to the theoretical predictions and comment on the implications for the existence of a spin liquid state in this material.

3:54PM D18.00008 Valence-bond crystal in the extended Kagomé spin-$1/2$ quantum Heisenberg antiferromagnet: A variational Monte Carlo approach , FEDERICO BECCA, CNR, Istituto Officina dei Materiali and SISSA, Trieste, YASIR IQBAL, DIDIER POILBLANC, Laboratoire de Physique Theorique, Universite' de Toulouse — The highly-frustrated spin-$1/2$ quantum Heisenberg model with both nearest (J_1) and next-nearest (J_2) neighbor exchange interactions is revisited by using an extended variational space of projected wave functions that are optimized with state-of-the-art methods. Competition between modulated valence-bond crystals (VBC) proposed in the literature and the Dirac spin liquid (DSL) is investigated. We find that the addition of a $small$ ferromagnetic next-nearest-neighbor exchange coupling $|J_2| > 0.09J_1$ leads to stabilization of a 36-site unit cell VBC, although the DSL remains a local minimum of the variational parameter landscape. This implies that the VBC is not trivially connected to the DSL: instead it possesses a non-trivial flux pattern and large dimerization.

4:06PM D18.00009 Magnetization ramp of the Kagome lattice antiferromagnet , TORU SAKAI, JAEA, SPring-8, HIROKI NAKANO, Graduate School of Material Science, University of Hyogo — Magnetization process of the S=1/2 isotropic Heisenberg antiferromagnet on the Kagome lattice is studied. Data from numerical-diagonalization method up to 39-spin systems, are reexamined from the viewpoint of the derivative of the magnetization with respect to the magnetic field. We find that the behavior of the derivative around the 1/3 height of the magnetization saturation is quite different from the cases of typical magnetization plateaux. The magnetization process of the Kagome-lattice antiferromagnet reveals a new phenomena, which we call the "magnetization ramp." We also compare it with the 1/3 magnetization plateau of the triangular antiferromagnet.

4:18PM D18.00010 Spin dynamics in the hyperkagome compound $Gd_3Ga_5O_{12}$, OLEG PETRENKO, University of Warwick, UK — We present the first neutron inelastic scattering results on the magnetic state of the frustrated hyperkagome compound $Gd_3Ga_5O_{12}$ (GGG) at low temperatures and in applied magnetic field. Our neutron scattering studies reveal a remarkable range of timescales. Short-range spatial correlations appear static within the instrumental resolution (50 μeV). Three distinct inelastic modes are found at 0.04(1), 0.12(2) an 0.58(3) meV at 0.06 K. The application of a magnetic field up to 2.5 tesla reveals disparate behavior of the magnetic excitations. In zero applied field, the lowest and highest energy excitations show spatial dependencies indicative of dimerized short-range antiferromagnetic correlations that survive to high temperatures, comparable to the nearest neighbor exchange interactions. Our results suggest that the ground state of a three dimensional hyperkagome compound differs distinctly from its frustrated counterparts on a pyrochlore lattice and reveal a juxtaposition of cooperative paramagnetism and strong dimerized coupling. These results are surprising since GGG is often classified as a strongly frustrated system with a manifold of connected states for which one would expect a continuum of gapless excitations.

In collaboration with: Pascale Deen, Institut Laue Langevin; G. Balakrishnan, Department of Physics, University of Warwick; B.D. Rainford, Department of Physics and Astronomy, Southampton University; C. Ritter, Institut Laue-Langevin; L. Capogna, Istituto Officina dei Materiali, IOM-CNR; H. Mutka and T. Fennell, Institut Laue-Langevin.

4:54PM D18.00011 Effects of doping on the geometrically frustrated Heisenberg antiferromagnet Gadolinium Gallium Garnet , D.M. SILEVITCH, M.A. SCHMIDT, James Franck Institute/University of Chicago, S. GHOSH, University of California, Merced, G. AEPPLI, University College, London, T.F. ROSENBAUM, James Franck Institute/University of Chicago — Geometric frustration in the Heisenberg antiferromagnet Gadolinium Gallium Garnet (GGG) gives rise to a set of quantum protectorates where clusters of spins decouple from the overall spin liquid state. At 110 mK, there is a partial transition to an ordered AF state. Here, we examine the effect of lightly doping GGG with Nd ions, which partially alleviates the underlying frustration. We examine the size and binding energy of the spin clusters as a function of doping and temperature, and also characterize the suppression of the Neel temperature as the dopant concentration is increased.

5:06PM D18.00012 Electron magnetic resonance studies of the $Pr_3Ga_5SiO_{14}$ and $Nd_3Ga_5SiO_{14}$ kagóme systems , SANHITA GHOSH, Florida State University, SAITI DATTA, HAIDONG ZHOU, National High Magnetic Field Laboratory, MICHAEL HOCH, STEPHEN HILL, Florida State University — In recent years, there has been considerable interest in materials exhibiting magnetic frustration due to their novel ground state properties. $Pr_3Ga_5SiO_{14}$ (PGS) and $Nd_3Ga_5SiO_{14}$ (NGS) have trigonal crystal structures in which the rare earth ions are arranged in corner sharing triangles to form a distorted kagomé lattice. We report high frequency electron magnetic resonance (EMR) measurements on single crystals of NGS and PGS in order to ascertain the nature of their ground states. Both compounds exhibit extremely rich EMR spectra at low temperatures, with a large number of sharp peaks. For each frequency investigated, the peak positions display a strong, systematic dependence on the temperature. However, the usual paramagnetic resonance frequency/field variation is not observed, with the pattern of peaks varying dramatically from one frequency to the next. We thus conclude that the observed spectra correspond to collective excitations associated with finite size ordered clusters that persist on EMR time scales.

5:18PM D18.00013 Valence Bond Crystal on the Hyperkagome Antiferromagnet , EMIL BERGHOLTZ, ANDREAS LAUCHLI, RODERICH MOESSNER, Max Planck Institute for the Physics of Complex Systems — We describe our recent work that indicates that the ground state of the antiferromagnetic spin-1/2 Heisenberg model on the highly frustrated, three-dimensional, hyper-kagome lattice is a valence bond crystal (VBC). Performing a series expansion around an arbitrary dimer covering on the hyper-kagome we find that a ground state with a huge (72 site) unit cell is selected by the quantum fluctuations. The regularity and favorable energetics of our series expansion establishes the VBC as a serious contender to the earlier spin liquid proposals. We find that the ground state supports many, very low lying, excitations in the singlet sector and that the low energy spinful excitations (spinons and triplons) are effectively confined to various emergent lower-dimensional structures. If applicable to the recently studied sodium iridate compound, $Na_4Ir_3O_8$, this scenario has interesting observable implications, such as spatially anisotropic neutron scattering spectra and possibly multiple finite temperature signatures in the magnetic specific heat due to a multi-step breaking of discrete symmetries. Most saliently, here—as for several proposed states for analogous kagome and pyrochlore magnets—one might expect a clearly resolved Ising transition at relatively high temperature.

Monday, March 21, 2011 2:30PM - 5:30PM –
Session D19 GMAG: Low Dimensional Magnetism and Spin Tunneling D170

2:30PM D19.00001 GMAG Student Dissertation Award Talk: Effects of Nanoscale Structure on the Magnetism and Transport Properties of Chromium and Chromium-Aluminum Alloys[1] , ZOE BOEKELHEIDE, University of California, Berkeley — Bulk Cr has an incommensurate spin density wave (ISDW) due to nesting of the Fermi surface which is easily disrupted by perturbation. Thus, the properties of Cr are sensitive to small amounts of dopant atoms, application of pressure, etc. which has been well studied in bulk. We have taken advantage of thin film growth techniques to study the effects of nanoscale structure on the properties of Cr and Cr1-xAlx alloys. The first part of my talk will discuss our research on polycrystalline Cr thin films, where variables such as strain and disorder crucially affect the SDW. We find that Cr thin films can be ISDW like in bulk Cr, or transition to commensurate SDW (CSDW) or mixed depending on deposition conditions and the resulting thin film microstructure. The transport properties are also strongly affected, as quasilocal defect states inside the SDW gap cause resonant scattering. This results in anomalous features such as residual resistivity ranging between 3 and 400 μO -cm and significant resistivity minima at low temperature. Further evidence of quasilocal states inside the SDW gap is seen in the enhanced electronic density of states (DOS) from specific heat measurements of Cr thin films. The second part of my talk will discuss Cr1-xAlx alloys. The addition of Al to Cr causes the ISDW to transition to CSDW for x = 0.03. Cr1-xAlx also exhibits previously unexplained semiconducting behavior for x = 0.15-0.30. I will discuss our ongoing theoretical and experimental research which suggests that a chemically ordered, rhombohedrally distorted Cr3Al structure occurs in nanosized domains and causes a hybridization gap on part of the Fermi surface. The CSDW causes a gap on another part of the Fermi surface, so that the semiconducting behavior can be explained by a combination of structural and magnetic affects.

[1]Supported by the DOE under Contract No. DE-AC02-05CH11231.

3:06PM D19.00002 Suppression of Macrospin Tunneling by Nanomechanical Interference , LORIEN HAYDEN, Department of Physics and Astronomy, University of Missouri, Columbia, ALEXEY KOVALEV, Department of Physics and Astronomy, University of California, Los Angeles, GERRIT BAUER, Kavli Institute of NanoScience, Delft University of Technology, YAROSLAV TSERKOVNYAK, Department of Physics and Astronomy, University of California, Los Angeles — This research considers the quantum dynamics of a nanomechanical resonator coupled to a macrospin of a magnetic nanoparticle. Suppression of macrospin tunneling by nanomechanical interference is demonstrated. By approximating the macrospin molecule as a two level system, the results are extended to the magnetopolariton splitting between resonantly coupled Fock states in which are observed similar interference patterns. The mentioned interference effects should be observable in a single molecule magnet bridged between two leads.

3:18PM D19.00003 Spin Tunneling in a Rotating Nanomagnet , MICHAEL O'KEEFFE, EUGENE CHUDNOVSKY, CUNY Lehman College and Graduate Center, LEHMAN COLLEGE THEORETICAL CONDENSED MATTER PHYSICS TEAM — We study spin tunneling in a magnetic nanoparticle with biaxial anisotropy that is free to rotate about its anisotropy axis. Exact instanton of the coupled equations of motion is found that connects degenerate classical energy minima. We show that mechanical freedom of the particle renormalizes magnetic anisotropy and increases the tunnel splitting.

M. F. O'Keeffe and E. M. Chudnovsky, cond-mat, arXiv:1011.3134.

3:30PM D19.00004 Theory of Raman Scattering in One-Dimensional Quantum Magnets , MASAHIRO SATO, Aoyama Gakuin University, HOSHO KATSURA, Gakushuin University, NAOTO NAGAOSA, University of Tokyo — Raman scattering is one of the powerful tools to study the quantum dynamics of the spin systems, and has been studied for a long term. Conventionally, Raman scattering spectra have been interpreted in terms of the two-magnon processes, from which the exchange coupling can be estimated. However, it is known that the magnon is not a good elementary excitation in low- dimensional quantum spin systems, especially in 1D, and the theoretical studies on the Raman processes in 1D have not been developed compared with those for other electromagnetic processes such as NMR and ESR. Here we have developed a theory for Raman scattering of 1D quantum magnets. We show that Raman spectrum can detect some interesting excitations such as spinon pairs, solitons, etc, depending on the additional interactions to the conventional Heisenberg one and polarization direction of external electromagnetic wave.

3:42PM D19.00005 Surface ferri-magnetism in some antiferromagnetic materials , YONGBIN LEE, Ames Laboratory; Dept. of Physics and Astronomy, Iowa State University, Ames, BRUCE HARMON, Ames Laboratory; Dept. of Physics and Astronomy, Iowa State University, Ames — In an antiferromagnetic material with inversion symmetry the electronic energy bands are spin degenerate because of time reversal symmetry. However, at the surface the inversion symmetry is broken, which opens the possibility of breaking the spin degeneracy and inducing a significant net moment on the surface. As an example of this spin degeneracy breaking, we discuss the electronic structure of antiferromagnetically ordered $BaMn_2As_2$. Unlike the bulk bands, its surface bands can individually possess a net spin polarization. Also the bulk bands in this material have a gap, however the calculated spin polarized surface states cross the Fermi level. Our calculations show that an applied field perpendicular to the surface and along the spin axis induces a significant net surface magnetization, which does not extend significantly into the bulk. - Work at the Ames Laboratory was supported by the US DOE, Basic Energy Science, under contract No. DE-AC02-07CH11358.

3:54PM D19.00006 Spin-orbit interactionsand magnetic field in antiferromagnetic triangular molecular magnets , J.F. NOSSA, M.F. ISLAM, C.M. CANALI, Linnaeus University, M.R. PEDERSON, Naval Research Laboratory — Frustrated triangular molecular magnets such as Cu_3 are characterized by a doubly generate S=1/2 ground-state (GS) with opposite chirality. Recently it has been proposed theoretically [1] and verified by ab-initio calculations [2] that an external electric field can efficiently couple these two chiral spin states, even in the absence of spin-orbit interaction (SOI). SOIs are nevertheless important, since they introduce a splitting in the GS manifold. In this talk we will discuss different schemes on how to evaluate within spin density functional theory the effect of the SOIs on the chiral states. The connection between SOI and the Dzyalozhinsky-Moriya interaction will be discussed. We will also present calculations of the energy dependence on an external magnetic field, whose presence is important to achieve full control of the spin-electric coupling within the manifold of the GS chiral doublets.

4:06PM D19.00007 Real-space imaging of Kondo screening in a two-dimensional Kondo lattice[1] , YING JIANG, YANNING ZHANG, JUEXIAN CAO, RUQIAN WU, WILSON HO, Department of Physics and Astronomy, University of California, Irvine, CA 92697-4575 — Kondo lattice systems exhibit nonuniversal many-body behaviors, mainly resulting from the competition and interplay between onsite Kondo screening and intersite coupling. In reduced spatial dimensions, the many-body correlation effects are expected be to more relevant. We report the realization of a two-dimensional (2D) Kondo lattice formed by self-assembled triplet oxygen molecules on the Au (110)-1×2 reconstructed surface. By mapping the Kondo resonance in the 2D O_2 lattice with a scanning tunneling microscope, the interplay between the intermolecule coupling and the onsite Kondo effect was manifested as the unexpected coexistence of both local and nonlocal Kondo screening at the atomic level. While the latter provides evidence of the collective deconfinement of magnetization in Au, the former shows local hybridization between the Kondo clouds of nearest-neighbor O_2 molecules, as revealed by density functional calculations. These findings may assist in our understanding of the unusual electronic properties in various strongly correlated electron systems, such as heavy fermion compounds and Kondo insulators.

4:18PM D19.00008 Single oxygen and CO molecules on Au(110): what can we learn?[1] , YANNING ZHANG, YING JIANG, WILSON HO, RUQIAN WU, University of California, Irvine — Studies of O_2 and CO molecules on the reconstructed Au (110) surface are crucial for the understanding of unusually high activity of Au nanostructures that are useful in heterogeneous catalysis. Moreover, the O_2/Au system is ideal to probe the Kondo effect using surface science techniques, due to the persisting magnetization of triplet O_2 in physisorption systems. In this work, scanning tunneling microscope (STM) measurements and density functional calculations were performed to investigate the adsorption geometries and physical properties of single O_2 and CO molecules on Au(110). The calculated atomic structures and vibration frequencies are comparable favorably with our STM experimental results at low temperature, allowing efficient establishment of structural models. Interestingly, the O_2 molecule takes a defect site over the Au row, with a tilted geometry. The magnetic moment of O_2 is still as large as 1.9 μ_B, which furthermore induces a pronounced Kondo resonance in a large spatial region. The cloud of Kondo enhancement was found to closely follow the distribution of the calculated spin density at the fermi level, a correlation which is important for the understanding of Kondo effect in molecular systems.

[1]Work was supported by DOE, Basic Energy Science, and NERSC

4:30PM D19.00009 Universal chiral magnetism in low-density 2D Kondo lattice model , DMITRY SOLENOV, DMITRY MOZYRSKY, IVAR MARTIN, Los Alamos National Laboratory — We demonstrate that (quasi-)two-dimensional systems comprised of localized moments and itinerant electrons form non-coplanar magnetic crystal states when the Kondo coupling energy is smaller than the chemical potential. These states arise for fully isotropic local exchange coupling between electrons and magnetic ions and do not require a spin-orbit (Dzyaloshinskii-Moriya) interaction or magnetic field. We give an analytical argument on instability of simple co-planar states and show that the states with non-zero chirality (degree of non-coplanarity) are energetically favorable. Numerical modeling is performed to estimate the ground state configurations.

4:42PM D19.00010 Low temperature magnetic dynamics in one-dimensional Co(II) molecular chains , A. AMJAD, Department of Physics, University of Central Florida, USA, G.M. ESPALLARGAS, J.M. CLEMENTE-JUAN, Instituto de Ciencia Molecular, Universidad de Valencia, Spain, R. KLEMM, E. DEL BARCO, Department of Physics, University of Central Florida, USA, E. CORONADO, Instituto de Ciencia Molecular, Universidad de Valencia, Spain, M. EVANGELISTI, ICMA, CSIC - Universidad de Zaragoza, Spain — We present a low-temperature study of one-dimensional Co-based molecular chains, trans-[$CoCl_2$(3,5-Br_2py)$_2$]. Ac and dc susceptibility experiments show that the cobalt ions tend to form anisotropic ferromagnetic chains, whose properties are dictated by the thermal excitations of 1D domain walls. The observation of anomalies in the hysteresis loops of the sample on increasing the magnetic field sweep rate reveals interesting dynamical effects at the individual chain level. On decreasing the temperature, no evidence for 3D ordering was observed in specific heat measurements, although the magnetization was strongly irreversible below ∼450 mK. Possible sources for this absence of a magnetic phase transition could be the weakness of the interchain interactions, the presence of single-ion anisotropy at skew angles, disordered domains, and lattice defects, etc. These possibilities will be studied both experimentally and theoretically.

4:54PM D19.00011 ABSTRACT WITHDRAWN –

5:06PM D19.00012 Spatial confinement effect on $TbMn_2O_5$ nanorods , CHUN CHUEN YANG, JING HUEI WANG, WEI LUEN HUANG, CHANG YU WENG, Department of Physics, Chung Yuan Christian University, CIH LIAN HONG, YANG YUAN CHEN, Institute of Physics, Academia Sinica, DEPARTMENT OF PHYSICS, CHUNG YUAN CHRISTIAN UNIVERSITY COLLABORATION, INSTITUTE OF PHYSICS, ACADEMIA SINICA COLLABORATION — Series of $TbMn_2O_5$ nanorods were fabricated by hydrothermal method with different annealing temperatures. Three samples which width by length equal to 10(4) nm $\times$ 38(14) nm, 25(6) nm $\times$ 64(18) nm, and 101(25) nm $\times$ 216(54) nm are identified by TEM images, x-ray diffraction, and SAED schemes. Furthermore discovery show that the preferred growth direction is along c axis (length). Ac magnetic susceptibility and specific heat measurements revealed incommensurate ($\sim$41 K) and commensurate ($\sim$38 K) Mn antiferromagnetic ordering peaks are only appeared in 101(25) nm $\times$ 216(54) nm sample. In this case, the small size effect resulted entropy difference of Mn magnetic ordering is 27 % less than bulk one. At 5 K, a small hysteresis loop was also observed in the identical sample and indicated the FM domains occurred. No such magnetic and thermal behaviors were found in another two samples. We believe this is attributing to spatial limitation and distortion caused by low surface-volume ratio. The estimated magnetic correlation length of Mn is in between 25 and 64 nm.

5:18PM D19.00013 Tetrairon(III) Single Molecule Magnet Studied by Scanning Tunneling Microscopy and Spectroscopy , YOUNGTEK OH, HOGYUN JEONG, MINJUN LEE, JEONGHOON KWON, JAEJUN YU, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea, SHARIFUL ISLAM MAMUN, GAJENDRA GUPTA, JINKWON KIM, Department of Chemistry, Kongju National University, Chungnam 314-701, Korea, YOUNG KUK, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea — Tetrairon(III) single-molecule magnet (SMM) on a clean Au(111) has studied using scanning tunneling microscopy (STM) and spectroscopy (STS) to understand quantum mechanical tunneling of magnetization and hysteresis of pure molecular origin. Before the STM studies, elemental analysis, proton nuclear magnetic resonance (NMR) measurement and Energy Dispersive X- ray Spectroscopy (EDS) were carried out to check the robustness of the sample. The STM image of this molecule shows a hexagonal shape, with a phenyl ring at the center and surrounding six dipivaloylmethane ligands. Two peaks are observed at 0.5 eV, 1.5 eV in the STS results, agreeing well with the first principles calculations. Spin-polarized scanning tunneling microscopy (SPSTM) measurements have been performed with a magnetic tip to get the magnetization image of the SMM. We could observe the antiferromagnetic coupling and a centered- triangular topology with six alkoxo bridges inside the molecule while applying external magnetic fields.

Monday, March 21, 2011 2:30PM - 5:30PM –
Session D20 FIAP: Bionanotechnology D168

2:30PM D20.00001 Multifunctional nanoparticles ($Au@SiO_2@Y_2O_3{:}Er^{3+}$) for biological and photonic application[1] , MADHAB POKHREL, JIANHUI YANG, University of Texas at San Antonio, PARESH C. RAY, Jackson State University, DHIRAJ K. SARDAR, University of Texas at San Antonio — Due to plasmon at the surface, the absorption and scattering of electromagnetic radiation by metal nanoparticles are strongly enough. These properties provide the potential of designing multifunctional nanoparticles which are optically active for simultaneous molecular imaging and photothermal cancer therapy. Gold nanorods with suitable aspect ratios can absorb and scatter strongly in the NIR region. In the present work, we have demonstrated the application of multifunctional nanoparticles ($Au@SiO_2@Y_2O_3{:}Er^{3+}$) as contrast agents for both molecular imaging and photo thermal therapy. These multifunctional naoparticles has shown the enhancement in Er^{3+}fluorescence through plasmon interaction and enhancement in Raman spectrum, which made these nanoparticles potential for biosensor for detecting the biological and chemical molecule.

[1]This research is supported by NSF PREM Grant no DMR-0934218.

2:42PM D20.00002 Fundamental Interactions between Deoxyribonucleic Acid (DNA) Oligomers and Au Nanoparticles: Experimental and Theoretical Studies , MOLLESHREE KARNA, Science and Math Academy, Aberdeen High School, Aberdeen, MD 2100, Army Research Lab, Aberdeen Proving Ground, MD 21005, RADHAKRISHNAN BALU, MARK GRIEP, GOVIND MALLICK, Army Research Lab, Aberdeen Proving Ground, MD 21005 — **E**xperimental and theoretical investigations were performed to understand the nature of fundamental interactions between gold nanoparticles (GNPs) and single stranded DNA (ss-DNA). Atomic force microscopic imaging and UV-Visible spectroscopic measurements revealed binding of NPs with ss-DNA under mildly acidic conditions.. *Ab initio* quantum chemical calculations within the framework of density functional theory provided a possible charge transfer pathway from the DNA base guanine to Au atoms and thus characterizing the interaction as electrostatic. The calculations outline the possible effect of the presence of other bases to guanine mediated charge transfer. Specifically, the presence of an adenine base alters the charge localization at the guanine base and thus prevents charge transfer to NPs.

2:54PM D20.00003 Modeling the effect of dynamic surfaces on membrane penetration , REID VAN LEHN, ALFREDO ALEXANDER-KATZ, MIT — The development of nanoscale materials for targeted drug delivery is an important current pursuit in materials science. One task of drug carriers is to release therapeutic agents within cells by bypassing the cell membrane to maximize the effectiveness of their payload and minimize bodily exposure. In this work, we use coarse-grained simulations to study nanoparticles (NPs) grafted with hydrophobic and hydrophilic ligands that rearrange in response to the amphiphilic lipid bilayer. We demonstrate that this dynamic surface permits the NP to spontaneously penetrate to the bilayer midplane when the surface ligands are near an order-disorder transition. We believe that this work will lead to the design of new drug carriers capable of non-specifically accessing cell interiors based solely on their dynamic surface properties. Our work is motivated by existing nanoscale systems such as micelles, or NPs grafted with highly mobile ligands or polymer brushes.

3:06PM D20.00004 Microsphere whispering gallery optical resonators for biomedical microfluidic devices , O. SVITELSKIY, A. DARAFSHEH, D. SUN, V.N. ASTRATOV, University of NC at Charlotte, M. SUMETSKY, OFS Laboratories, NJ 08873 USA, A. LUPU, M. TCHERNYCHEVA, Institut d'Electronique Fondamentale, Université Paris-Sud XI, 91405 Orsay, France — These resonators are potential candidates for broad application range as sensors of various physical quantities, and as key elements for photonic and optomechanical systems. Most of the biomedical applications involve deployment of resonators in fluidic environment. However, closeness of refractive indices of sphere n_s and fluid n_f obstructs excitation of the resonant modes. Moreover, an attempt to increase n_s can deteriorate coupling of light between fiber and sphere. To address these challenges we explore a series of high-Q resonators using a specially developed tapered optical microfiber microfluidic platform. The coupling strength between the cavity and the microfiber taper is shown to depend on the contact position of the microsphere along the taper and on the refractive index contrast between the microsphere and the fluid. We demonstrate that barium titanate glass beads with $n_s \sim 2$ can be suitable for practical tasks.

3:18PM D20.00005 Utilizing nonlinear optical properties in nanoparticles for imaging[1] , BRIAN YUST, NEEMA RAZAVI, DHIRAJ SARDAR, The University of Texas at San Antonio — Optical phase conjugation is a nonlinear effect in which light incident upon a nonlinear medium may be conjugated so that the output signal is in the opposite direction of the input, as seen in four-wave mixing. Recently, we have seen that these nonlinear effects may still be seen in various nanocrystals and nanoparticles. Barium titanate (BaTiO3) is a good candidate for phase conjugation on the nano-scale, because of its large third order susceptibility. BaTiO3 particles of varying size are synthesized through precipitation and hydrothermal methods and analyzed optically and morphologically. The nonlinear absorption, four wave mixing signal in the forward and counter-propagating geometries, and third order susceptibilities are characterized in both the visible and infrared. Possible uses for the unique optical properties of these nanoparticles in imaging, microscopy, and photonics will also be discussed.

[1]This work is supported in part by National Science Foundation PREM Grant No. DMR - 0934218 and UTSA Collaborative Research Seed Grant Program (CRSGP).

3:30PM D20.00006 Gold Nanostars for Photo-Thermal Ablation of Single Neurons[1] , ZURAB KERESELIDZE, Dept. Physics and Astronomy, UTSA, VICTOR ROMERO, CIO, Mexico, WASKAR EGIDO, CHRISTOPHER VALDES, EMMANUEL MICHAELIDES, Dept. Biology, UTSA, XOMALIN PERALTA, MIGUEL JOSE-YACAMAN, Dept. Physics and Astronomy, UTSA, FIDEL SANTAMARIA, Dept. Biology, UTSA — Nanoparticle mediated photo-thermal ablation therapy is a technique for removing cells within a tissue with minimal collateral damage. It works by exciting the surface plasmon resonance of metallic nanoparticles so there is an amplification of the absorption of the incident electromagnetic field which is then transformed into heat and results in photo-thermal ablation. Little is known about its effects at the single-cell level. We fabricated various sized and shaped gold nanoparticles, including nanostars, with a surface plasmon mode in the near infrared. Neurons of mouse cerebellar slices internalize bare nanostars during incubation periods of $<$3 hrs. We imaged the slices and excited surface plasmon mode of the nanostars. Our results show that we are capable of destroying individual nanostar containing cells without affecting the neighbors. Other shapes attach to the cell membrane but are not internalized. Therefore nanoparticles can provide a technique for a neuron single-cell photo-thermal without any functionalization.

[1]NSF PREM (#0934218), UTSA

3:42PM D20.00007 Biochemically Selective Nanoarrays: From Protein-DNA Interactions to Bio-Inorganic Nanoscale Assembly , JUSTIN ABRAMSON, MATTEO PALMA, ALON GORODETSKY, COLIN NUCKOLLS, MICHAEL SHEETZ, SHALOM WIND, JAMES HONE — The ability to control the arrangement of both biomolecules and bio-inorganic structures on surfaces with nanometer resolution is of great interest in the field of nanoscience and nanotechnology. Nanopatterned arrays of biomolecules can offer unmatched sensitivity in molecular diagnostics. Furthermore, templated assembly of bio-inorganic structures at the nanoscale makes possible interesting quantum optical structures, including switchable photonic cavities. Here we describe different strategies to control the immobilization of single- and double-stranded DNA, as well as quantum dots, on nanopatterned surfaces, with features down to the sub-30nm regime. The bio-functional chemistry allows for the formation of non-sterically hindered DNA nanodomains where the dsDNA attached to the nanodots is accessible and maintains its native conformation, as confirmed by restriction enzymes studies at the single molecule level. We will further highlight the broader utility of such nanopatterned surfaces for the self-organization of quantum dots, demonstrating the ability to both biochemically and covalenty assemble single quantum dots on our nanopatterns.

3:54PM D20.00008 Nanoscale open-ended coaxial line proximity sensor array for spatio-temporal impedance imaging[1] , JEFFREY R. NAUGHTON, BINOD RIZAL, MICHAEL J. BURNS, GREGORY MCMAHON, STEPHEN SHEPARD, MICHAEL J. NAUGHTON, Boston College — We describe the development of a dielectric impedance measurement array comprised of open-ended nanoscale coaxial proximity sensors. The device offers the capability of on-chip dielectric impedance tomography for imaging *e.g.* biological cells with $\sim$micron pixel density. Computer simulations of the response of individual pixels and of discrete arrays to changes in dielectric properties of proximate media are presented. Experiments with biological cells on 1st-generation arrays will be discussed.

[1]naughton@bc.edu

4:06PM D20.00009 Nonlinear Optical Properties of ZnO for BioimagingCell and Cell Destruction , BEN URBAN, SAMUDYATHA CHAKKI, University of North Texas, OS SENTHILKUMAR, KASILINGAM SENTHILKUMAR, YASUHISA FUJITA, Shimane University, ARUP NEOGI, University of North Texas — As of recent years nanotechnology has been at the forefront of scientific research. It promises to have a broad range of applications from turning unhealthy foods into health foods, making computers faster and curing cancer. We present results on using nonlinear optical processes of ZnO nano-crystals to detect, track and destroy cells. By incorporating ZnO into a hydrophobic nano-hydrogel matrix with trace amounts of H_2O_2, we can attach antibodies or microRNA for specific cell targeting and, using the heat generating properties of the third order nonlinear process, release H_2O_2 in the cell causing instant cell death. Theoretically, with the appropriate sequence for microRNA or the appropriate antibodies, we could target cancer cells in the body and destroy them. This presentation gives our results until now.

4:18PM D20.00010 Polymeric Nanoelectrodes for Investigating Cellular Adhesion[1] , PREM THAPA, GOVIND PANERU, BRET FLANDERS, Kansas State University — Polyethylene dioxythiophene nano-filaments were grown on lithographic electrode arrays by the recently developed directed electrochemical nanowire assembly technique. These filaments are firmly attached to the electrode but are not attached to the glass substrate. Hence, they behave like cantilevered rods (with one free end). Individual cells of the slime mold *Dictystolium discoideum* initiate contact by extending pseudopods to the nanoelectrodes when cultured on the electrode arrays. Scanning electron micrographs of the interfaces show the contact area to be of the order of 0.1 μm^2. Confocal images reveal the focal adhesions in the cell-electrode contact region. Deflection of the nanoelectrode by an individual cell can be used to measure the force exerted by the cell. Recent results on this innovative force sensing approach will be discussed.

[1]NSF

4:30PM D20.00011 Detecting Lyme disease using antibody-functionalized carbon nanotubes , JENNIFER DAILEY, University of Pennsylvania, Department of Physcs and Astronomy, MITCHELL LERNER, BRETT GOLDSMITH, University of Pennsylvania, Department of Physics and Astronomy, DUSTIN BRISSON, University of Pennsylvania, Department of Biology, A.T. CHARLIE JOHNSON, University of Pennsylvania, Department of Physics and Astronomy — We combine antibodies for Lyme flagellar protein with carbon nanotube transistors to create an electronic sensor capable of definitive detection of Lyme disease. Over 35,000 cases of Lyme disease are reported in the United States each year, of which more than 23 percent are originally misdiagnosed. Rational design of the coupling of the biological system to the electronic system gives us a flexible sensor platform which we can apply to several biological systems. By coupling these antibodies to carbon nanotubes in particular, we allow for fast, sensitive, highly selective, electronic detection. Unlike antibody or biomarker detection, bacterial protein detection leads to positive identification of both early and late stage bacterial infections, and is easily expandable to environmental monitoring.

4:42PM D20.00012 Fluorescence-Based DNA-Nanotube Platform with Single Molecule Resolution , PRAKRIT JENA, ANKUR JAIN, University of Illinois at Urbana-Champaign, DANIEL HELLER, Massachusetts Institute of Technology, MARKITA LANDRY, YANN CHEMLA, University of Illinois at Urbana-Champaign, MICHAEL STRANO, Massachusetts Institute of Technology, TAEKJIP HA, University of Illinois at Urbana-Champaign — We have developed an experimental platform to control and modify the DNA on a DNA-Single Walled Nanotube (SWNT) complex for the purpose of detecting labeled and unlabeled protein-DNA interactions via visible fluorescence. By exploiting the distance-dependent photophysical interaction between organic fluorophores and the surface of a SWNT as the sensing mechanism, fluorophore-conjugated DNA-SWNTs are immobilized and observed using single molecule-total internal reflection microscopy. By analyzing the number of molecules, photobleaching steps and the absolute size of the observed DNA-SWNTs, we have confirmed the presence of a duplex, partial duplex and single-strand DNA scaffold on the SWNT surface using both nucleic acids and proteins as probes. Our approach offers multiple experimental schemes to extend the current use of carbon nanotubes for applications involving the interaction with biologically relevant molecules.

4:54PM D20.00013 Selective Intracellular Activation by Designing pH-Sensitive and Tunable Fluorescent Nanoparticle , KEJIN ZHOU, YIGUANG WANG, XIAONAN HUANG, MILAN POUDEL, GANG HUANG, KATE LUBY-PHELPS, JINMING GAO — Integration of nanotechnology with molecular biology and medical imaging has propelled the development of various nanoscopic imaging probes and targeted therapeutics. Despite great advances, it remains a formidable challenge to create highly biointeractive nanosystems that can respond to subtle changes in physiological stimuli (e.g. pH, enzymes) to achieve desired biological specificity. Here we report a set of robust, pH-activatable micelle nanoprobes with tunable pH transitions in the physiological range. These nanoprobes have a fast fluorescence response ($<$5 ms), up to 55-fold increase of emission intensity between OFF and ON states, and only require $<$0.25 pH unit for activation (vs. 2 pH unit for small molecular dyes). Nanoprobes with different transition pH can be selectively activated in specific endocytic compartments such as early endosomes or lysosomes. This capability allows for the development of pH-activatable imaging probes or nanocarriers that can target specific subcellular organelles for therapy.

5:06PM D20.00014 Formation of Lipid Bilayer Membrane including Ion Channels on Graphene , JUNG YOON CHOI, KYUNG EUN BYUN, SEON NAMGUNG, Seoul National University, HEEJUN YANG, JINSEONG HEO, HYUN-JONG CHUNG, SUNAE SEO, Samsung Advanced Institute of Tech., SEUNGHUN HONG, Seoul National University — Lipid bilayer membrane on a solid electrode has been extensively utilized to study membrane proteins. Recently, graphene has drawn an attention as a transparent and high conductive electrode compatible with biological systems. Herein, we report the successful formation of lipid membrane including ion channels on graphene. In this method, graphene was functionalized by biocompatible molecular layers and utilized as a substrate to support lipid bilayer membrane including ion channels. The functionality of ion channels incorporated in the lipid bilayer membrane was studied via the electrochemical impedance spectroscopy. This lipid membrane-coated graphene structure can be a versatile platform for various applications such as bio-sensing and in vitro drug screening.

5:18PM D20.00015 Aptamer sandwich-based carbon nanotube sensors for single-carbon-atomicresolution detection of non-polar small molecular species , JOOHYUNG LEE, Department of Physics and Astronomy, Seoul National University, Seoul, Korea, MINJOUNG JO, JI-YOUNG AHN, SOYOUN KIM, Department of Biomedical Technology, Dongguk University, Seoul, Korea, TAE HYUN KIM, Department of Chemistry, Soonchunhyang University, Asan, Chungnam, Korea, DONG-KI LEE, Department of Chemistry, Sungkyunkwan University, Suwon, Korea, SEUNGHUN HONG, Department of Biophysics and Chemical Biology, Seoul National University, Seoul, Korea — Portable sensor platforms are crucial for the on-site monitoring of disease-related metabolites, environmental pollutants and food toxicants. However, it is still difficult to build highly-sensitive and selective sensor platforms for small molecular detection. We developed an aptamer sandwich-based carbon nanotube sensor, where aptamers were utilized to capture target molecules as well as to enhance the sensor signals. Using this strategy, we successfully demonstrated the detection of non-polar bisphenol A molecules with a picomolar sensitivity and single-carbon-atomic resolution. Furthermore, by modifying the labeling aptamer with additional biotin, we enhanced the detection limit of our sensors for one hundred times. These results overcome the fundamental limitation of general FET-based sensors and should make a major breakthrough in various applications such as environmental protection and food safety.

Monday, March 21, 2011 2:30PM - 5:30PM –

Session D21 GIMS: Focus Session: Novel Instrumentation & Measurements for Biomedical Research D161

2:30PM D21.00001 Physical principles of genomic regulation through cellular nanoscale structure and implications for initiation of carcinogenesis , VADIM BACKMAN, Northwestern University — Although compelling evidence suggests that cellular nanoarchitecture and nanoscale environment where molecular interactions take place would be expected to significantly affect macromolecular processes, biological ramifications of cellular nanoscale organization have been largely unexplored. This understanding has been hampered in part by the diffraction limited resolution of optical microscopy. The talk will discuss a novel optical microscopy technique, partial wave spectroscopic (PWS) microscopy, that is capable of quantifying statistical properties of cell structure at the nanoscale. Animal and human studies demonstrated that an alteration in the statistical properties of the nanoscale mass density distribution in the cell nucleus (e.g. nuclear nanoarchitecture) is one of the earliest and ubiquitous events in carcinogenesis and precedes any other known morphological changes at larger length scales (e.g. microarchitecture). The talk will also discuss the physical principles of how the alteration in nuclear nanoarchitecture may modulate genomic processes and, in particular, gene transcription.

Work done in collaboration with Hariharan Subramanian, Prabhakar Pradhan, Dhwanil Damania, Lusik Cherkezyan, Yolanda Stypula, Jun Soo Kim, Igal Szleifer, Northwestern University, Evanston, IL, Hemant K. Roy, Northshore University HealthSystems, Evanston, IL

3:06PM D21.00002 3D Cell Culture Imaging with Digital Holographic Microscopy[1] , THOMAS DIMIDUK, Harvard University, KENDRA NYBERG, University of Oregon, DARIELA ALMEDA, Harvard University, EKATERINA KOSHELVA, University of Chigago, RYAN MCGORTY, DAVID KAZ, EMILY GARDEL, DEBRA AUGUSTE, VINOTHAN MANOHARAN, Harvard University — Cells in higher organisms naturally exist in a three dimensional (3D) structure, a fact sometimes ignored by in vitro biological research. Confinement to a two dimensional culture imposes significant deviations from the native 3D state. One of the biggest obstacles to wider use of 3D cultures is the difficulty of 3D imaging. The confocal microscope, the dominant 3D imaging instrument, is expensive, bulky, and light-intensive; live cells can be observed for only a short time before they suffer photodamage. We present an alternative 3D imaging techinque, digital holographic microscopy, which can capture 3D information with axial resolution better than $2\mu m$ in a $100\mu m$ deep volume. Capturing a 3D image requires only a single camera exposure with a sub-millisecond laser pulse, allowing us to image cell cultures using five orders of magnitude less light energy than with confocal. This can be done with hardware costing $\sim \$1000$. We use the instrument to image growth of MCF7 breast cancer cells and p. pastoras yeast.

[1]We acknowledge support from NSF GRFP.

3:18PM D21.00003 Carbogen Enhanced Femto Oximetry Breast Cancer Diagnosis Method with High Specificity , BOGDAN C. MAGLICH, California Science and Engineering Corp., J.K. SHULTIS, C.J. SOLOMON, Kansas State University — As large malignant tumors are oxygen deficient (hypoxic), cancer could be diagnosed *in vivo* and online, by non-invasive measurement of oxygen difference between tumor and adjacent tissue. Computer simulations of noninvasive diagnosis by Femto Oximetry (FO) of hypoxia in 1 cm tumor in 10 cm breast shows that background γ's from non hypoxic tissue will mask hypoxia. To amplify the hypoxic-to-normal O difference, air breathing will be replaced with carbogen (O_2 95%, CO_2 5%) using vasco-constrictive property whereby carbogen breathing increases O in normal tissue, while not in malignant hypoxic tumors. 90% hypoxia will be detectable by FO with specificity 99%. Our method will be tested on R3230 tumors in Fischer rats at UCI.

3:30PM D21.00004 Fractal Analysis of Optical Coherence Tomography of Normal and Malignant Breast Tissue , AMANDA C. SULLIVAN, JOHN P. HUNT, AMY L. OLDENBURG, University of North Carolina at Chapel Hill — Optical coherence tomography (OCT) provides real-time imaging of tissue several mean free photon paths into tissue by heterodyne detection of backscattered light. OCT can potentially be used to rapidly assess tumor margins during breast cancer resection, however, currently it is difficult to differentiate between normal and malignant tissues with OCT. Because cancer is characterized morphologically by increasing disorder, we investigated the fractal dimension of OCT images of normal and cancerous breast tissue. 3D OCT images of 44 specimens were collected, then tissues were histologically processed to independently determine distinct regions of adipose, stroma and cancer. The fractal dimension of each tissue type was then calculated with a one-dimensional box-counting algorithm applied to the OCT axial scans. We found that the fractal dimensions of stromal tissues were significantly higher than those of cancer ($P<10^{-6}$), while those of adipose tissue were significantly lower than those of cancer ($P<10^{-4}$).

3:42PM D21.00005 A new algorithm for detection of apnea in infants in neonatal intensive care units[1] , HOSHIK LEE, College of William and Mary, BROOKE VERGALES, ALIX PAGET-BROWN, CRAIG RUSIN, RANDALL MOORMAN, JOHN KATTWINKEL, University of Virginia, JOHN DELOS, College of William and Mary — Apnea is a very common problem for premature infants: apnea of prematurity (AOP) occurs in $> 50\%$ of babies whose birth weight is less than 1500 g, and AOP is found in almost all babies who are $< 1000\,\mathrm{g}$ at birth. Current respiration detectors often fail to detect apnea, and also give many false alarms. We have created a new algorithm for detection of apnea. Respiration is monitored by continuous measurement of chest impedance (CI). However, the pulsing of the heart also causes fluctuations in CI. We developed a new adaptive filtering system to remove heart activity from CI, thereby giving much more reliable measurements of respiration. The new approach is to rescale the impedance measurement to heartbeat-time, sampling 30 times per interbeat interval. We take the Fourier transform of the rescaled signal, bandstop filter at 1 per beat to remove fluctuations due to heartbeats, and then take the inverse transform. The filtered signal retains all properties except the impedance changes due to cardiac filling and emptying. We convert the variance of CI into an estimated likelihood of apnea.

3:54PM D21.00006 The Suppression of Dominant Acoustic Frequencies in MRI[1] , XINGXIAN SHOU, ROBERT BROWN, Case Western Reserve University — Patient discomfort and brain imaging distortion are serious MRI acoustic noise problems arising from the rapid switching on and off of gradient coils in the presence of the strong Larmor magnetic field. A study is made of dominant frequencies in the acoustic noise spectrum and, motivated by both spring and string ideas, we propose the cancellation of selected frequencies by appropriate gradient pulse sequence design. From both simulations and experiments, vibrations resulting from an impulsive force associated with a ramping up of a gradient pulse are shown to be cancelled upon the application of another impulsive force coming from the appropriately timed ramping down of that pulse. A method for the suppression of multiple-frequency contributions involving a series of gradient pulses with variable timings is developed and confirmed by experiment. Whether we refer to reduction in terms of dB (about 30-40 dB per peak), or to the verdict of a listener, the conclusion is that a marked reduction in sound can be achieved when at least three of the dominant frequency peaks are suppressed. A variety of pulse profiles and timing combinations can be used to attenuate important contributions to the acoustic spectrum.

[1]Supported by the Ohio Third Frontier Program.

4:06PM D21.00007 Linewidth Narrowing for ^{31}Phosphorus MRI of Bones , MERIDETH FREY, SEAN BARRETT, Yale University Physics Dept. — Bone is a particularly challenging tissue to study with conventional MRI given the relatively low water density and wider linewidths of its solid components.[1] Recent fundamental research in quantum computing gave rise to a new NMR pulse sequence that can be used to narrow the broad NMR spectrum of solids.[2] Here we narrow the spectrum of the ^{31}P in natural bone mineral (by a factor of up to 1600x). This technique offers a new route to do high spatial resolution, 3D ^{31}P MRI of bone which complements conventional MRI and x-ray based techniques to study bone physiology and structure. Thus far we have used our pulse sequence to do high spatial resolution (sub-250 μm)^3 3D ^{31}P MRI of *ex vivo* dry bovine cortical bones, wet procine rib bones, and wet rabbit femoral bones at 4T. We have also explored the use of compressive sampling[3] to push imaging time down to less than two hours without distracting artifacts.

4:18PM D21.00008 Linewidth narrowing for ^{31}Phosphorus MRI of cell membranes , SEAN BARRETT, MERIDETH FREY, Yale University Physics Dept., JOSEPH MADRI, MICHAEL MICHAUD, Yale Medical School — Most ^{31}P Magnetic Resonance Spectroscopy studies of tissues try to avoid contamination by a relatively large, but broad, spectral feature attributed to cell membrane phospholipids[1]. MRI using this broad ^{31}P membrane spectrum is not even attempted, since the spatial resolution and signal-to-noise would be poor, relative to conventional MRI using the narrow ^{1}H water spectrum. This long-standing barrier has been overcome by a novel pulse sequence, recently discovered in fundamental quantum computation research[2], which narrows the broad ^{31}P spectrum by $\sim$1000$\times$. Applying time-dependent gradients in synch with a repeating pulse block enables a new route to high spatial resolution, 3D ^{31}P MRI of the soft solid components of cells and tissues. So far, intact and sectioned samples of *ex vivo* fixed mouse organs have been imaged, with (sub-mm)^3 voxels. Extending the reach of MRI to broad spectra in natural and artificial tissues opens a new window into cells, enabling progress in biomedical research.

4:30PM D21.00009 Producing >60,000-fold room-temperature ^{89}Y NMR signal enhancement[1] , LLOYD LUMATA, ASHISH JINDAL, MATTHEW MERRITT, CRAIG MALLOY, A. DEAN SHERRY, ZOLTAN KOVACS, UT Southwestern Medical Center — ^{89}Y in chelated form is potentially valuable in medical imaging because its chemical shift is sensitive to local factors in tumors such as pH. However, ^{89}Y has a low gyromagnetic ratio γ_n thus its NMR signal is hampered by low thermal polarization. Here we show that we can enhance the room-temperature NMR signal of ^{89}Y up to 65,000 times the thermal signal, which corresponds to 10 % nuclear polarization, via fast dissolution dynamic nuclear polarization (DNP). The relatively long spin-lattice relaxation time T_1 ($\sim$500 s) of ^{89}Y translates to a long polarization lifetime. The ^{89}Y NMR enhancement is optimized by varying the glassing matrices and paramagnetic agents as well as doping the samples with a gadolinium relaxation agent. Co-polarization of ^{89}Y-DOTA with a ^{13}C sample shows that both nuclear spin species acquire the same spin temperature T_s, consistent with thermal mixing mechanism of DNP. The high room-temperature NMR signal enhancement places ^{89}Y, one of the most challenging nuclei to detect by NMR, in the list of viable magnetic resonance imaging (MRI) agents when hyperpolarized under optimized conditions.

4:42PM D21.00010 Raman spectroscopy as a diagnostic tool to detect head and neck squamous cell carcinoma in archived tissues , SUNEETHA DEVPURA, Wayne State University, SEEMA SETHI, Pathology, Karmanos Cancer Institute, JAGDISH S. THAKUR, Wayne State University, VAMAN M. NAIK, U of Michigan-Dearborn, RATNA NAIK, Wayne State University — Recently, many spectroscopic techniques are being tried for diagnostic applications. Among them Raman spectroscopy is one of the powerful non-invasive techniques which can differentiate between different biomolecular compositions of tissues on the basis of their vibrational spectra and hence can become an efficient diagnostic tool for detection of cancers. This technique has not yet been explored to study the head and neck squamous cell carcinoma (HNSCC) for archived tissues; here we report its results on HNSCC. Raman spectra were collected from three regions; normal, carcinoma in situ, and carcinoma. The Raman data was analyzed with chemometric methods of principal component analysis (PCA) and discriminant function analysis (DFA). Our preliminary results show that PCA and DFA analysis of Raman spectra can successfully distinguish the pathological states in archived HNSCC tissues. However, large Raman data set from many tissue sections is needed to validate these findings.

4:54PM D21.00011 Optical measurements of mechanical resonances in biological tissues via magnetic nanoparticle interrogation , VASILICA CRECEA, STEVEN ADIE, University of Illinois at Urbana-Champaign, AMY OLDENBURG, University of North Carolina at Chapel Hill, RENU JOHN, Indian Institute of Technology - Hyderabad, STEPHEN BOPPART, University of Illinois at Urbana-Champaign — We present a real-time phase-resolved optical coherence tomography-based technique that interrogates the mechanical properties of tissue phantoms with different elasticities as well as healthy and cancerous rat tissues, via the interaction of high susceptibility iron oxide nanoparticles that reside inside the samples and an external magnetic field. A chirped magnetic field selects the region of natural resonance in the probed samples as evidenced by scatterer displacements measured with nanometer-level sensitivity. This methodology, entitled magnetomotive optical coherence elastography (MM-OCE), which exploits frequency dependent viscoelastic response in biological media, has potential for detecting tissue pathologies.

5:06PM D21.00012 Imaging the Vector Magnetic Field of Magnetospirillum Gryphiswaldense by Optically Detected Magnetic Resonance using Nitrogen-Vacancy Centers in Diamond[1] , RICHELLE M. TEELING, YOUNG WOO JUNG, INHEE LEE, JUSTIN NORTH, ROBIN NAKKULA, ROHAN ADUR, EZEKIEL JOHNSTON-HALPERIN, MICHAEL G. POIRIER, P. CHRIS HAMMEL, The Ohio State University — Nitrogen vacancy centers in diamond are single-spin systems that are stable under ambient conditions with strong optical spin transitions, making them optimal for room-temperature detection of nanoscale magnetic fields using optically detected magnetic resonance (ODMR). We use these ensembles of diamond spins as a scanned probe magnetometer to map the field emitted by Magnetospirillum Gryphiswaldense, in vivo. These bacteria mineralize nanoscale magnetite particles in their internal vesicles. Imaging these living bacteria cells will serve as a strong foundation for the application of our ODMR technique to the medical field, where the bacteria can be used to synthesize functionalized magnetic particles which can be used as biomarkers and targeted drug-delivery systems.

[1]Funding Provided by the Center for Emergent Materials at the Ohio State University, an NSF MRSEC (Award Number DMR-0820414)

5:18PM D21.00013 Sub-Nanoparticle Femto Atometry: Measurement of Genome Lengths of Mammalian Tissues , CHRIS DRUEY, BOGDAN C. MAGLICH, ANNA Z. RADOVIC, California Science & Engineering Corp. — Measurement of porcine and bovine genome length, giga nucleotide base pairs, Gbp, was made by irradiating each tissue for 30' with neutrons of femto DeBroglie $\lambda \sim 10^{-15}$ m, which, unlike nanoparticles, interact only locally with atomic nuclei in nucleotide. O and C atoms were counted via γ rays emitted from (n, n' γ) reaction. By irradiating free dA, dC and T nucleotides for 30' we got response constant: (1,450 $\pm$ 44) γ/O. From 2 measurements we obtained 2.59 $\pm$ .05 and 3.19 $\pm$ .06 Gbp for porcine and bovine, respectively, consistent with 2.7 and 3 Gbp (errors not quoted) obtained by genome sequencing method that took 6 years each.

Monday, March 21, 2011 2:30PM - 5:30PM –
Session D22 DCMP: Metal Insulator Transition in VO2 D163

2:30PM D22.00001 The band structure of VO2 measured by angle-resolved photoemission[1] , LUCA MORESCHINI, Advanced Light Source, YOUNG JUN CHANG, ALS and Fritz-Haber Institut, DAVIDE INNOCENTI, ALS and University of Rome-Tor Vergata, ANDREW L. WALTER, ALS and FHI, YOUNG SU KIM, GEOFFREY GAINES, AARON BOSTWICK, JONATHAN DENLINGER, ELI ROTENBERG, ALS — The origin of the 340K metal-insulator transition (MIT) in VO2 is still under debate. the main reason is that no direct experimental verifications of the electronic structure of VO2 exist up to this point. The quality of the available single crystals is not sufficient for ARPES measurements, so that photoemission is limited to angle-integrated mode. New opportunities are offered by oxide films, on which data of equal or even higher quality have been reported (Saeki *et al.*, PRB 2009). WIth the *in situ* pulsed-laser-deposition (PLD) system available on beamline 7.0.1 at the Advanced Light Source we have grown VO2(001) films on a TiO2 substrate and measured the Fermi surface of the metallic phase. These results will permit a direct comparison with the existing band calculations and open the way to the study of the MIT as a function, e.g., of film thickness or electron doping with Cr.

[1]Work supported by U.S. DOE (DE-AC02-05CH11231 for ALS), the Max Planck Society, and the Swiss National Science Foundation (PBELP2- 125484).

2:42PM D22.00002 Electronic structure of strained vanadium dioxide thin films using soft X-ray spectroscopy , JUDE LAVEROCK, LOUIS PIPER, ANDREW PRESTON, BO CHEN, JAMES MCNULTY, KEVIN SMITH, Boston University, SALINPORN KITTIWATANAKUL, JIWEI LU, STUART WOLF, University of Virginia — Despite over five decades of intense investigation, the origin of the metal-insulator transition (MIT) in VO_2 still presents a challenge to explain. Whether the lattice (Peierls physics) or electron-electron correlations (Mott-Hubbard physics) are responsible for the MIT has been hotly debated; more recently, the general consensus has favored a co-operative description, in which both structural and correlation effects are important and sympathetic to the transition. Key to understanding such a co-operative picture has been the behavior of VO_2 under doping and strain. Here, we report recent soft X-ray measurements of strained VO_2 thin films grown on TiO_2(001) and (110) substrates. We employ X-ray absorption spectroscopy and X-ray emission spectroscopy to probe the changes in both the *unoccupied* and *occupied* partial density of states across the MIT, observing distinct changes in the V $3d$-O $2p$ hybridization. Additionally, the location in energy of the unoccupied $d_{\|}$ state in the insulating phase is found to be dependent on the lattice strain, in agreement with the predictions of recent dynamical mean-field theory calculations. Finally, our results are discussed in the context of the origin of the MIT in VO_2.

2:54PM D22.00003 Scanning Photocurrent Microscopy of VO_2 Nanobeams , CHRISTOPHER MILLER, MARK TRIPLETT, JOEL LAMMATAO, University of California, Davis, KEVIN WANG, DERRICK FU, JUNQIAO WU, University of California, Berkeley, DONG YU, University of California, Davis — Vanadium dioxide (VO_2) is a strongly correlated material that displays a near-room temperature metal-to-insulator transition ($\sim 68^oC$). This transition can be explored at the single domain level in single crystalline VO_2 nanobeams, where the material dimension is smaller than the characteristic domain size. Here we investigate the metal-insulator phase transition and its domain wall physics in single VO_2 nanobeam devices through scanning photocurrent microscopy. This technique, which measures the photocurrent as a function of the local photo-injection position, allows us to determine the band bending direction and the height of the Schottky barriers at each domain wall. Our results may shed light on the charge dynamics in strongly correlated materials and the metal-insulator phase transition mechanism.

3:06PM D22.00004 Conductivity anisotropy in strained VO_2 thin films, probed by THz Time Domain Spectroscopy[1] , MENGKUN LIU, mengkun@buphy.bu.edu, ELSA ABREU, JIWEI LU, KEVIN WEST, SALINPORT KITTIWATANAKUL, WENJING YIN, STUART WOLF, RICHARD AVERITT, 1DEPARTMENT OF PHYSICS, BOSTON UNIVERSITY, BOSTON MA COLLABORATION, DEPARTMENT OF MATERIALS SCIENCE AND ENGINEERING, UNIVERSITY OF VIRGINIA, CHARLOTTESVILLE VA COLLABORATION, DEPARTMENT OF PHYSICS, UNIVERSITY OF VIRGINIA, CHARLOTTESVILLE VA COLLABORATION — We used THz time domain spectroscopy to measure the temperature and polarization dependent far-infrared conductivity of high quality strained VO_2 thin films epitaxially grown on (100) TiO_2 substrates. A large conductivity anisotropy is observed in the metallic phase of our VO_2 films with the conductivity along the rutile axis ∼30 times larger than the orthogonal direction. The MIT temperature also exhibits anisotropy with a value of 360K along the rutile c axis and 340K along the perpendicular direction. Our results are consistent with substrate induced strain modulation of the energy and bandwidth associated with the vanadium 3d orbitals.

[1]We would like to acknowledge sup- port from DOE-BES for this work under grant DE-FG02- 09ER46643, DE-FG02-00ER45799, and ETRI.

3:18PM D22.00005 X-ray induced photoconductivity in Vanadium Dioxide samples , SEBASTIAN DIETZE, JYOTI MOHANTY, MOSES MARSH, JONG WOO KIM, KEVIN WEST, IVAN K. SCHULLER, OLEG G. SHPYRKO, Department of Physics University of California, San Diego — Vanadium Dioxide (VO2) goes through a first-order phase transition at approximately 340K, exhibiting both an insulator to metal transition (IMT) and a structural phase transition (SPT), with a monoclinic (M1) insulating phase at low temperatures and a rutile (R) metallic phase at high temperatures. We show an anomalous behavior of x-ray induced persistent photoconductivity (PPC) well below the temperature induced phase transition in VO2 devices. We present conductivity and X-ray Diffraction (XRD) measurements, revealing a large enhancement of conductivity due to photo-induced carriers. Moreover, with the addition of nominal electric fields, we are able to fully transition into the rutile metallic phase at room temperature. This effect is completely reversible, allowing the monoclinic insulating phase to be recovered via annealing.

3:30PM D22.00006 Electric field-induced breakdown of the Mott insulating state in V2O3 nanostructures , JUSTIN BROCKMAN, Stanford University, LI GAO, NAGAPHANI AETUKURI, BRIAN HUGHES, CHARLES RETTNER, MAHESH SAMANT, KEVIN ROCHE, STUART PARKIN, IBM Almaden Research Center — The origin of the electric field-induced breakdown of the Mott insulating state in vanadium sesquioxide (V2O3) nanostructures is of considerable interest. We have prepared high quality, epitaxial films of V2O3 on (0001)-oriented sapphire substrates by oxygen plasma-assisted thermal evaporation. Lateral, two-terminal nanostructures were patterned by electron beam lithography. The nanostructures displayed strong metal-to-insulator transitions upon cooling to below ∼150K. Modest voltages applied across the devices drive the films into a conducting state. We discuss the role of temperature, applied voltage, device size, and potential Joule heating effects on the switching process, as well as implications for the underlying mechanism involved.

3:42PM D22.00007 Gatability of vanadium dioxide single crystal nanobeams and hydrogen doping[1] , JIANG WEI, HENG JI, DOUGLAS NATELSON, Rice University — Vanadium dioxide is famous for its dramatic metal insulator transition, exhibiting up to 4 or 5 orders magnitude change in conductivity. It is also known to be nongatable, although in the insulating phase it behaves like a semiconductor with 0.5-0.7 eV energy gap. With no sign of gating effects using conventional dielectric materials, such as SiO_2, Al_2O_3 and HfO_2, ionic liquids were used as the gating medium. Ionic liquids form electric double layers (EDL) and could possibly exert an electric field as high as 10^9V/m on the interface of ionic liquid and single-crystal vanadium dioxide nanobeam. No gating effect was observed in the vanadium dioxide device. On the other hand, we found that under positive gate voltage the hydrogen ions originating from trace amounts of water diffuse into the vanadium dioxide crystal, acting as dopants. By controlling the gate voltage and temperature, the insulating phase's conductivity can be reversibly increased up to 2-3 orders magnitude by this process.

3:54PM D22.00008 Dependence of VO_2 thin-film metal-insulator transition on its intrinsic impurities , CHANGHONG CHEN[1], YONG ZHAO, ZHAOYANG FAN, Nano Tech Center and Department of Electrical and Computer Engineering, Texas Tech University — We present variation in strain, metal-insulator transition temperature (T_{MIT}), activation energy (ΔE_a), and charge carrier type in the insulating phase of (011) preferred polycrystalline (Poly-) and multidomain (020) epitaxial (Epi-) VO_2 films grown at different temperature (T_S), to produce variable intrinsic impurities. Both the Poly- and Epi-VO_2behave n-type conductivity when grown at relative low T_S. As T_S increases, acceptor density of impurity increases to alter conductivity from n- to p-type in the Poly-VO_2, while conductive n-type still keeps in the Epi-VO_2 with increased donor density. Moreover, the strain along monoclinic a_m axis dramatically reverses from tensile to compressive in both the Poly- (848 K< T_S <873 K) and Epi-VO_2(873 K< T_S <898 K), and eventually tend to relaxation again in the Poly-VO_2($T_S \geq$898 K) in particular. Consequently, T_{MIT} decreases with increasing the carrier density independent of the conductive type, and low-temperature ΔE_a is associated with the strain. The larger strain leads to higher ΔE_a, while the relaxed strain produces saturated or the minimum ΔE_a in the Poly- or Epi-VO_2.

4:06PM D22.00009 Manipulation of avalanche characteristics in nanoscaled VO_2 devices[1] , SIMING WANG, KEVIN G. WEST, IVAN K. SCHULLER, Department of Physics and Center for Advanced Nanoscience, University of California San Diego, La Jolla CA 92093 — The temperature driven metal insulator transition (MIT) in nanoscaled VO_2 devices occurs through a series of resistance jumps ranging over two decades in magnitude. A power law distribution of the jump sizes, demonstrates that the transition is caused by avalanches across the percolation transition. We investigate the effect of a DC write current on the intrinsic behavior of the MIT transition in nanoscaled VO_2 devices. We find an increase in the maximum resistance jump size by as much as a factor of 10x after application of a DC write current at room temperature. Interestingly, we find no significant changes in the exponent of the power law distribution as a function of an applied DC write current. The observations suggest that the DC current changes the intrinsic properties of the VO_2 thin film and may be related to spatial confinement which leads to an increase in the maximum resistance jump size.[2]

4:18PM D22.00010 stoichiometry engineering of metal-insulator transition in suspended single crystalline vanadium dioxide nanobeams , SHIXIONG ZHANG, IN SOO KIM, LINCOLN J. LAUHON, Department of Materials Science and Engineering, Northwestern University — While the metal-insulator transition (MIT) in VO2 bulk and thin films has been investigated for several decades, recent studies of nanobeams have provided new opportunities to investigate and manipulate the metal-insulator transition and structural domain formation in a correlated manner. We will describe the electrical and structural characterization of suspended single crystal VO2 nanobeams grown/annealed under various conditions. Annealing nanobeams under reducing conditions led to the stabilization of single-crystal rutile nanobeams at room temperature, in some cases suppressing the MIT temperature from 340 K down to below 100 K. Re-annealing under oxidizing conditions led to a recovery of the transition temperature for stoichiometric VO2. Furthermore, growth under oxidizing conditions produced the Mott insulator M2 phase and an intermediate M3. Systematic annealing studies enabled the generation of a pseudo-phase diagram with dimensions of stoichiometry and temperature. The temperature dependence of the electrical resistivity of rutile nanobeams above the transition temperature will also be discussed.

4:30PM D22.00011 Tungsten as a substitutional dopant and its effect on ultrafast switching of vanadium dioxide , JOYEETA NAG, KANNATASSEN APPAVOO, Vanderbilt University, WEIDONG LUO, Lawrence Berkeley National Laboratory and Oak Ridge National Laboratory, GERD DUSCHER, Univeristy of Tennessee, Knoxville and Oak Ridge National Laboratory, SOKRATES PANTELIDES, Vanderbilt University and Oak Ridge National Laboratory, RICHARD HAGLUND, Vanderbilt University — VO_2 undergoes a metal-insulator transition (MIT) at 340K accompanied by a structural change from monoclinic (M1) to tetragonal (R). We have grown W-doped VO_2 films on glass and epitaxially on sapphire substrates and have characterized them by SEM, white light transmission, RBS, XRD, and Z-STEM. These provide direct experimental evidence that W acts as a substitutional dopant in the VO_2 lattice in addition to lowering the transition temperature. From GGA+U, DFT-based simulations we have also calculated the formation energy of substitutional W in VO_2, and relative stability of M1 and R phases before and after doping. Ultrafast pump-probe measurements at 800nm with varying pump fluences show that doped VO_2 switches at substantially lower fluences than undoped VO_2, indicating that the W dopant provides additional conduction-band electrons, thus altering the photo-induced dynamics of the phase transition.

4:42PM D22.00012 Control of the metal-insulator transition in vanadium dioxide nanobeams[1] , JAE HYUNG PARK, SERKAN KASIRGA, University of Washington, JIANG WEI, Rice University, NICHOLAS NOLL, VINCENT ROMA, DAVID H. COBDEN, University of Washington, DEPARTMENT OF PHYSICS TEAM — Single-crystal nanobeams of vanadium dioxide, which are smaller than the characteristic domain size, exhibit a more reproducible and controllable metal-insulator transition (at around 67 degrees C) than bulk samples. We are exploiting this fact to perform systematic studies of the intrinsic properties of the phases involved, the phase transition, and the interphase wall, as well as to control the transition temperature. For these purposes it is necessary to have high quality crystals and to apply uniform strain. We are therefore investigating and improving the procedure of VO2 small-crystal growth by vapor phase transport, while developing experimental techniques in which thin nanobeams can be suspended across adjustable-widths gaps on silicon structures. The latter will enable application of strain purely along the tetragonal c-axis, to tune the transition, while simultaneously carrying out transport, optical and scattering measurements.

4:54PM D22.00013 Electrical properties of vanadium dioxide devices for micro-electronic applications making use of metal-insulator phase transitions[1] , KOEN MARTENS, IULIANA P. RADU, KULeuven - IMEC, SOFIE MERTENS, CHRISTOPH ADELMANN, XIAOPING SHI, HILDE TIELENS, MARC SCHAEKERS, CEDRIC HUYGHEBAERT, SVEN VAN ELSHOCHT, IMEC, STEFAN DE GENDT, MARC HEYNS, KULeuven - IMEC, JORGE A KITTL, IMEC — In principle the metal-to-insulator transition offers prospects for use in an electronic switch. This study investigates the properties of VO_2 test devices to evaluate VO_2's potential use in micro-electronic applications such as a memory, two-terminal selector or transistor device. Vanadium dioxide thin films were produced by thermal oxidation of vanadium and the physical properties of these layers were investigated. Electrical properties of concentric two-terminal vanadium dioxide structures will be discussed such as current-voltage behavior, switching behavior and contact formation to VO_2 with different metals and implications such as Fermi-level pinning and Schottky-type behavior for different metals.

[1]The FWO is acknowledged.

5:06PM D22.00014 Metal-insulator transition mechanism in VO2 under electric bias , YONG ZHAO, JI HAO[1], CHANGHONG CHEN, ZHAOYANG FAN, Nano Tech Center and Department of Electrical and Computer Engineering, Texas Tech University — It is in controversy if metal-insulator phase transition (MIT) of VO_2 can be triggered by electric field/current. In this work, a series of two terminal devices with different gap length, width, and multiple-channel configurations were fabricated on epitaxially grown VO_2 thin films, to study its MIT mechanism under the electric bias. Micro-Raman spectroscopy was used to differentiate the rutile metallic phase from the monoclinic insulator phase. Voltage-current measurements indicated that a temperature-dependent critical current density (J_c) is required to induce MIT. Under the electric bias, the phase transition was observed to be a percolation process until a clear current path (or filament) is formed between the electrodes. Afterwards the pure metallic phase was identified along the current path, while outside of it become pure insulator phase. As current varies, current path width is proportionally changed to keep a constant current density. These observations indicate that a J_c is necessary to maintain the metallic phase current path. Contributions of the current effect and Joule heat effect to the phase transition were discussed.

5:18PM D22.00015 Electric-field-driven phase transition in vanadium dioxide , B. WU, LPEM, ESPCI-ParisTech-CNRS-UPMC, 10 rue Vauquelin, Paris 05, France / National Laboratory for Superconductivity, IOP, CAS, Beijing 100190, P.R.China, A. ZIMMERS, H. AUBIN, LPEM, ESPCI-ParisTech-CNRS-UPMC, 10 rue Vauquelin, Paris 05, France, R. GOSH, Y. LIU, R. LOPEZ, Department of Physics and Astronomy, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina 27599, USA — In recent years, various strongly correlated materials have shown sharp switching from insulator to metallic state in their I(V) transport curves. Determining if this is purely an out of equilibrium phenomena (due to the strong electric field applied throughout the sample) or simply a Joule heating issue is still an open question. To address this issue, we have first measured local I(V) curves in vanadium dioxide (VO_2) Mott insulator at various temperatures using a conducting AFM setup and determined the voltage threshold of the insulator to metal switching. By lifting the tip above the surface (>35nm), we have then measured the purely electrostatic force between the tip and sample surface as the voltage between these two was increased. In a very narrow temperature range (below 360K), a tip height range (below 60nm) and a voltage applied range (above 8V), we observed switching in the electrostatic force (telegraphic noise vs. time and vs. voltage). This purely electric field effect shows that the switching phenomenon is still present even without Joule heating in VO_2.

Monday, March 21, 2011 2:30PM - 5:30PM –

Session D23 DMP: Focus Session: Search for New Superconductors I: Exploring Emergent Phases D165

2:30PM D23.00001 Phase Transitions in CuAs-based $K_xSr_{1-x}Cu_4As_2$ System , BING LV, BERND LORENZ, MELISSA GOOCH, FENG CHEN, LIANGZI DENG, CHING-WU CHU[1], Dept. of Physics and TcSUH, University of Houston — Inspired by the superconductivity with a $T_c \sim 3.5$ K reported by Han et al. in Cu-based $LiCu_2P_2$, the Cu-based compound $SrCu_4As_2$, which has a more complex CuAs layers structure sandwiched by Sr layers, was synthesized and characterized. The magnetoresistance measurements show two anomalies around ∼140K and ∼60K, respectively, which is also consistent with the results of specific heat measurement. Systematically studies of K-doping into $SrCu_4As_2$ system are carefully investigated at ambient and high pressures and no superconductivity has been found in the $K_xSr_{1-x}Cu_4As_2$ system down to 2K, although superconductivity might occur at lower temperature in this system. The overall pressure and doping effects on the magnetic and transport properties of the compounds will be presented and discussed.

2:42PM D23.00002 Synthesis and Characterization of ACu_4Pn_2, with A = alkaline and Pn = As and Sb , L.Z. DENG, BING LV, Y.Y. XUE, C.W. CHU[1], Department of Physics and TcSUH, University of Houston — A large number of the Cu-based layer compounds have been known to exist since the 1970's: some display structures similar to the Fe-based pnictide superconductors, such as the 111 and 122 phases. Unfortunately, other than their structures, reports on their physical properties are generally sparse. Only recently observation of superconductivity with a $T_c \sim 3.5$ K was reported by Han et al. in $LiCu_2P_2$ that displays a 122 structure. It was suggested that a more complex layer structure in pnictides may favor higher T_c as in the case of cuprates. We have therefore examined systematically ACu_4Pn_2 (142), with A = alkaline and Pn = pnictigen which has a more complicated layer substructure than the 1111, 111, 122 or 11 homologues. We have synthesized ACu_4Pn_2, with A = Li, Na, K, Rb and Cs and Pn = As and Sb, some of which were made for the first time. The magnetic, electrical, calorimetric and thermal electric properties were determined at ambient pressure and compared. High pressure was also applied to some of the compounds. The results will be presented and discussed.

2:54PM D23.00003 Superconductivity and Competing Ordered Phase in RuPn (Pn = As, P) , DAIGOROU HIRAI, TOMOHIRO TAKAYAMA, Dept. of Advanced Materials, Univ. of Tokyo, DAISUKE HASHIZUME, AYAKO YAMAMOTO, Riken, HIDENORI TAKAGI, Dept. of Advanced Materials, Univ. of Tokyo — Unconventional superconductivity likely manifests itself when some competing electronic phases are suppressed down to zero temperature such as cuprates and iron-pnictide superconductors. Therefore, the correlated metallic state neighboring a competing electronic ordering can be a promising playground for unconventional superconductivity. Here we report superconductivity emerging adjacent to electronically ordered phases of RuPn (Pn = As, P). We found that RuAs(P) exhibits phase transitions at 240 (265) K, which is discerned as a drop of magnetic susceptibility or a resistivity upturn. Such anomalies can be suppressed by substituting Rh to the Ru site. Accompanied by the disappearance of the electronic order, superconductivity was found to emerge below 1.8 K and 3.8 K for RuAs and RuP, respectively. The superconductivity in Rh substituted RuPn, which neighbors a competing electronic order, might exhibit an exotic pairing state as seen in the unconventional superconductors known to date.

3:06PM D23.00004 Towards New and Higher Temperature Superconductors via Theory Assisted Synthesis[1] , MEIGAN ARONSON, Stony Brook University and Brookhaven National Laboratory — We discuss here a new methodology where electronic structure calculations are integrated with the synthesis of new superconducting materials, with the objective to design and realize new lamellar superconductors with high onset temperatures, and to rigorously test the apparent association of high temperature superconductivity with electron delocalization transitions occurring at quantum critical points. Since lamellar superconductors like the cuprates and iron pnictides are comprised of functional layers where superconductivity resides and charge reservoir layers that determine the electron count in the functional layers, we will use realistic electronic structure calculations to assess which transition metal monopnictides are closest to electron delocalization, and hence optimal for superconductivity. Optical conductivity and photoemission measurements will be used to compare the real and calculated electronic structures. We report initial results on electron and hole doped LaMnPO.

[1]This research is carried out in collaboration with G. Kotliar, D. Basov, and H. Tjeng under the auspices of an NSSEFF fellowship administered by the AFOSR.

3:42PM D23.00005 Gap physics of the doped semiconductor (Ca,F):LaMnPO[1] , J.W. SIMONSON, M.C. ARONSON, Physics and Astronomy Dept., Stony Brook University — Single crystals of $Ca_xLa_{1-x}MnPO$ and $LaMnPO_{1-y}F_y$ (x = 0 to 0.50, y = 0 to 0.40) were synthesized to study the effect of Ca and F doping on LaMnPO, which is isostructural with several recently discovered Fe-based superconductors. The inclusion of F into the lattice was confirmed with single crystal XRD, showing a systematic reduction in unit cell volume with dopant content, in agreement with published accounts of similar compounds. Little change from undoped LaMnPO was observed in the resistivity of Ca doped crystals, while doping with successively higher concentrations of F yielded a systematic enhancement of conductivity. Nonetheless, all resistivity measurements were semiconducting, suggesting that E_F remains pinned within the gap regardless of dopant concentration. Activated behavior was observed, with activation energies falling below 100 meV, substantially less than the 1 eV optical gap. At low temperatures, the resistivity of all compositions exhibited temperature dependence in accord with variable range hopping, suggesting that transport is dominated by disordered and localized states at the Fermi level.

3:54PM D23.00006 Properties of layered iron oxychalcogenides with checkerboard structure[1] , LIANG L. ZHAO, DANIEL WARD, DOUGLAS NATELSON, EMILIA MOROSAN, Department of Physics and Astronomy, Rice University, Houston TX 77005 — The layered iron oxychalcogenides $La_2O_3Fe_2X_2$ (X = S, Se) have a unique checkerboard-like Fe_2OX_2 sublattice. Their Mott insulating behavior makes them promising candidates for novel superconductors. In this talk, we present results on the isostructural $A_2F_2Fe_2OS_2$ (A = Sr, Ba) compounds. Both pure and doped samples are characterized by magnetization, resistivity, heat capacity and Raman spectroscopy measurements. In addition to the previously reported antiferromagnetic transition around $T_N \approx 100$ K, we observed another phase transition in the ordered state, as well as a possible structural phase transition near room temperature. A change in the excitation gap at the high temperature (structural) phase transition is indicated by the temperature dependent resistivity.

4:18PM D23.00008 ABSTRACT WITHDRAWN –

4:30PM D23.00009 Bulk superconductivity in intercalated M_xZrTe_3 (M=Cu, Ni) , XIANGDE ZHU, HECHANG LEI, CEDOMIR PETROVIC, Brookhaven National Laboratory — We report the bulk superconductivity of 3d transition metal (e.g. Cu, Ni) intercalated $ZrTe_3$ single crystals, M_xZrTe_3 (M=Cu, Ni). ZrTe3 shows charge density wave (CDW) transition at T_{CDW}=63K and the CDW nesting vector q_{CDW}=(1/14,0,1/3) (reciprocal space). It is metallic below 300K with an anomaly due to CDW transition and becomes filamentary superconductor below 2 K. The derived superconducting parameters indicate that M_xZrTe_3 are bulk type-II superconductors and can be depicted in the framework of Bardeen-Cooper-Schrieffer (BCS) scenario. Intercalation depresses the CDW transition and enhances the superconductivity.

4:42PM D23.00010 New layered oxuchalcogenide $La_2O_2Mn_2OSe_2$, HECHANG LEI, CEDOMIR PETROVIC, Brookhaven National Laboratory — We report a new $La_2O_2Mn_2OSe_2$ and investigate its physical properties. It is a member of $Ln_2O_2Tm_2OCh_2$ (Ln= rare earth, Tm=Fe, Co, and Ch=S, Se). The structure of these compounds can be described as an alternate stacking of fluorite type $[Ln_2O_2]^{2+}$ or $[A_2F_2]^{2+}$ layers and anti-CuO_2-type $[Tm_2OCh_2]^{2-}$ layers (anti-perovskite type). $La_2O_2Mn_2OSe_2$ is the first manganese-base compound with anti-CuO_2-type layers. It is a ferromagnetic (FM) Mott insulator exhibiting several successive magnetic transitions. The magnetic properties are different from other compounds with this structure.

4:54PM D23.00011 Physical Properties of $CaFe_4As_3$ Single Crystals , AMAR KARKI, YIMIN XIONG, JIANNENG LI, SHANE STADLER, GREGORY MCCANDLESS, JULIA CHAN, RONGYING JIN, Louisiana State University — New compound $CaFe_4As_3$ crystallizes in an orthorhombic structure with Fe_2As_2 layers aligned along b direction but a rectangular cross-section in *ac* plane. The needle-shaped $CaFe_4As_3$ single crystals were grown and are found to undergo two successive phase transitions occurring at $T_1 \sim 90$ K and $T_2 \sim 27$ K, respectively. At T_1 the electrical resistivity increases and magnetic susceptibility decreases in both parallel and perpendicular to b directions consistent with the scenario of spin-density-wave formation. At T_2, resistivity decreases sharply at T_2 with hysteresis while magnetic susceptibility increases along either b direction or *ac* plane. The underlying physics will be discussed by taking into account other physical properties.

5:06PM D23.00012 Superconductivity in SnO: a Nonmagnetic Analogue to Fe-based Superconductors , DANIEL KHOMSKII, M.K. FORTHAUS, K. SENGUPTA, O. HEYER, Koeln University, Germany, N.E. CHRISTENSEN, A. SVANE, Aarus University, Denmark, K. SYASSEN, Max-Plank-Institut fuer Festkoerperforschung, Stuttgart, Germany, T. LORENZ, M.M. ABD-ELMEGUID, Koeln University, Germany — We found that under pressure SnO with α-PbO structure, the same structure as in many Fe-based superconductors, e.g. β-FeSe, undergoes a transition to a superconducting state for $p \geq 6$ GPa with a maximum T_c of 1.4 K at $p = 9.3$ GPa. The pressure dependence of T_c reveals a dome-like shape and superconductivity disappears for $p > 16$ GPa. It is further shown from band structure calculations that SnO under pressure exhibits a Fermi surface topology similar to that reported for some Fe-based superconductors and that the nesting between the hole and electron pockets correlates with the change of T_c as a function of pressure. M.K. Forthaus et al., Phys.Rev.Lett. **105**, 15701 (2010)

5:18PM D23.00013 Development of iron pnictides with very thick perovskite-type blocking layers , HIRAKU OGINO, SHINYA SATO, NAOTO KAWAGUCHI, YASUAKI SHIMIZU, KENJI MACHIDA, AKIYASU YAMAMOTO, KOHJI KISHIO, JUN-ICHI SHIMOYAMA — Recently we have discovered several new layered iron pnictides having extremely thick blocking layers [1]. These compounds have up to 5 sheets of perovskite-type layers between iron pnictide layers. Similar to LiFeAs, these compounds showed bulk superconductivity without intensive carrier doping, and the Tc of the compounds are 40 K-class. On the other hand, the relationship between Tc and the iron-plane interlayer distance suggested that Tc of the iron based superconductor is basically determined by the local structure of Fe2As2 layer. It is thought that there is still considerable room for the development of new layered iron pnictide compounds, due to the structural and chemical flexibility of the blocking layer. However, the results suggest that optimization of the local structure of Fe2As2 layers and the dimensionality of the crystal structure may not lead to further enhancement of Tc. Their structural features as well as physical properties will be presented.

Session D24 DCOMP: Focus Session: Quantum Transport Simulations and Computational Electronics – Nanostructures D167

2:30PM D24.00001 Transient response of a quantum point contact due to the coupling with reservoirs[1]

, BOZIDAR NOVAKOVIC, IRENA KNEZEVIC, University of Wisconsin-Madison — Transient response is important for better understanding of the DC and AC response of open quantum systems connected to large charge reservoirs. In this study we calculate the transient response of a quantum point contact (QPC) due to its coupling with reservoirs. The QPC, an open system, is modeled by a solution to the coupled, two-dimensional Schrödinger and Poisson equations using a discrete subset of the normal modes basis. The normal modes are projected onto the traveling-wave solutions that match the incoming reservoir plane waves. The occupation of the open system states carries the information about the time evolution and is calculated by solving a coarse-grained quantum master equation with suitably defined open system/contact interaction Hamiltonians. The final electronic transient response is obtained by enforcing the current continuity across the open system/contacts boundaries through a time-dependent reservoir drift wavevector. We investigate the transient current response to a voltage step and its dependence on the gate bias and relaxation time in the contacts.

2:42PM D24.00002 Open boundary-conditions using empirical pseudopotentials in quantum transport[1]

, BO FU, MASSIMO FISCHETTI, The University of Texas at Dallas — As device dimensions approach the 10 nm length-scale, the study of electronic transport requires the knowledge of an accurate band structure and of transport equations transcending the semiclassical Boltzmann picture. Having as our ultimate goal the study of dissipative quantum transport using the Pauli Master Equation, in this talk we address the numerical issue of how to formulate and implement numerically the open-boundary-condition Schrödinger equation within an empirical-pseudopotential full- band framework. Results regarding ballistic transport in Si nanowires will be presented.

[1]SRC

2:54PM D24.00003 Quantum Transport in Crossbar Devices

, BRANDON COOK, PETER DIGNARD, KALMAN VARGA, Vanderbilt Univeristy — Electronic devices with crossbar geometries have recently been fabricated with nanoscale features (Zhong. et al, Science Vol. 302). Consisting of a two dimensional grid of wires, devices have been formed with a variety of components including carbon nanotubes and semiconductor nanowires. These devices are assumed to operate classically, but as the dimensions of the device shrink consideration of quantum effects becomes necessary. We consider a single junction between two wires up to a four by four grid of wires. Through a series of calculations with atomistic first-principles, tight-binding and analytic models of multi-terminal devices we demonstrate the presence of unique behavior, such as interference effects, not present in classical models. It is expected that exploitation of these effects will useful in the creation of circuit components.

3:06PM D24.00004 Empirical Pseudopotential Approach to Semiclassical and Quantum Electronic Transport in Nanometer-scale Structures

, MASSIMO FISCHETTI, University of Texas at Dallas — The study of electronic transport in semiconductor structures requires an accurate knowledge of the kinematics ($i.e.$, band structure) and of the dynamics ($i.e.$, transport equations and collision processes). As the VLSI technology looks at various sub-10 nm structures as alternatives to the traditional Si CMOS, neither the conventional bulk band structure of the semiconductor nor the semiclassical (Boltzmann) transport equations can be used with confidence to treat the kinematics and dynamics of electronic transport, the former because of size-dependent (quantum confinement) and interface/surface dependent band structure effects; the latter because of the possibility of quantum interference effects at this length scale. Here we will show that empirical pseudopotentials – obtained from the literature and adjusted to yield correct workfunctions, band-alignment, and strain effects – can be used to obtain a sufficiently accurate (as compared to first-principle results) band structure of several systems of technological interest ($e.g.$, thin Si and Ge layers, III-V hetero-layers, nanowires, graphene nanoribbons and C nanotubes). Using this information, semiclassical transport is studied using a Monte Carlo technique and calculating the scattering rates consistently with the band structure information. In some cases, such as in considering scattering with interface and line-edge roughness, the pseudopotential themselves can be used to obtain accurate scattering potentials. The case of high-field transport in Si inversion layers is discussed, showing how the band-structure near the X symmetry point induces a lower saturated electron velocity. Finally, we discuss the wave equation and open boundary conditions which must be employed to handle ballistic quantum transport accounting for the full band structure. Dissipative transport is discussed in the context of a Master equation approach, illustrating this approach with examples ranging from double-gate FETs to Si nanowires.

3:42PM D24.00005 Self-Consistent Monte Carlo Study of the Coulomb Interaction under Nano-Scale Device Structures[1]

, NOBUYUKI SANO, University of Tsukuba — It has been pointed that the Coulomb interaction between the electrons is expected to be of crucial importance to predict reliable device characteristics. In particular, the device performance is greatly degraded due to the plasmon excitation represented by dynamical potential fluctuations in high-doped source and drain regions by the channel electrons. We employ the self-consistent 3D Monte Carlo (MC) simulations, which could reproduce both the correct mobility under various electron concentrations and the collective plasma waves, to study the physical impact of dynamical potential fluctuations on device performance under the Double-gate MOSFETs. The average force experienced by an electron due to the Coulomb interaction inside the device is evaluated by performing the self-consistent MC simulations and the fixed-potential MC simulations without the Coulomb interaction. Also, the band-tailing associated with the local potential fluctuations in high-doped source region is quantitatively evaluated and it is found that the band-tailing becomes strongly dependent of position in real space even inside the uniform source region.

3:54PM D24.00006 Oxygen vacancy mediated dielectric breakdown in ultrathin high-k gate dielectric stacks

, BLANKA MAGYARI-KOPE, YOSHIO NISHI, Stanford University — The reliability of the high-k gate stack becomes a significant challenge with the continuous scaling of the metal-oxide-semiconductor-field-effect-transistors, due to deposition techniques of ultrathin oxides and defects in the gate stack. One of the key problems associated with ultrathin oxide layers is the degradation of the gate oxides under electrical stress, due to traps generated by oxygen vacancies present in these materials. First principles methods based on density functional theory combined with non-equilibrium Green's function calculations are employed to calculate the tunneling current through ultrathin oxide layers of HfO_2 and SiO_2 in a gate stack structure with TiN metal electrode. Model systems that incorporate the atomistic description of a conductive filament formation due to ordering of oxygen vacancies in the oxide layers and the oxide-oxide interface of the gate stack were investigated. The microscopic effects of defects ordering on the electronic transport through the gate oxides are analyzed and discussed.

4:06PM D24.00007 Electron-phonon coupling in semiconductors and their nanostructures: effect on transport properties , JELENA SJAKSTE, PAOLA GAVA, NATHALIE VAST, Ecole Polytechnique, Laboratoire des Solides Irradiés, CEA-DSM-DRECAM, CNRS, 91128 Palaiseau, France, VALERIY TYUTEREV, Tomsk State Pedagogical University, Tomks, Russia — Parameter-free description of the electron-phonon coupling is crucial for the simulation of the electron and thermal transport in materials, especially nanostructured ones. Recently, we have developed an *ab initio* approach which allows to calculate the electron-phonon constants and scattering times for collisions of carriers in the conduction band with short-wavelength phonons [1,2]. We will present our results on the electron-short-wavelength phonon interaction in silicon, which enables us, on one hand, to shed new light on the transitions between shallow donor levels in doped Si [2], and, on the other hand, to improve the description of its electronic mobility [3]. Finally, we will discuss the effect of the material nanostructuring on the electron-phonon coupling constants, e.g. in semiconducting superlattices.

4:18PM D24.00008 Ballistic Spin Field Effect Transistor Based on Silicon Nanowires[1] , DMITRI OSINTSEV, VIKTOR SVERDLOV, ZLATAN STANOJEVIC, SIEGFRIED SELBERHERR, Institute for Microelectronics, TU Wien — We investigate the properties of ballistic spin field-effect transistors build on silicon nanowires. An accurate description of the conduction band based on the $\mathbf{k}\cdot\mathbf{p}$ model is necessary in thin and narrow silicon nanostructures. The subband effective mass and subband splitting dependence on the nanowire dimensions is analyzed and used in the transport calculations. The spin transistor is formed by sandwiching the nanowire between two ferromagnetic metallic contacts. Delta-function barriers at the interfaces between the contacts and the silicon channel are introduced. The major contribution to the electric field-dependent spin-orbit interaction in confined silicon systems is due to the interface-induced inversion asymmetry which is of the Dresselhaus type [1]. We study the current and conductance through the system for the contacts being in parallel and anti-parallel configurations. Differences between the [100] and [110] orientated structures are investigated in details.

4:30PM D24.00009 Junctionless nanowire field-effect transistor versus inversion mode devices , BART SORÉE, IMEC, Kapeldreef 75, B-3001 Leuven, Belgium. Universiteit Antwerpen, Physics department, Groenenborgerlaan 171, B-2020 Wilrijk, Belgium, ANH-TUAN PHAM, DRIES SELS, AN DE KEERSGIETER, WIM MAGNUS — Several years ago, a novel device concept was proposed : the nanowire (NW) iJFET [1]. Today, this device concept is being explored by several research teams [1-3] and is also known as the pinch-off FET (POFET) or junctionless transistor. The most important advantage of the junctionless transistor is the uniform doping throughout source, channel and drain which greatly simplifies its fabrication. We have performed modeling and simulations to compare the performance of the junctionless pinch-off FET with that of inversion mode devices. In order to make the comparison, we address the regime of thick and long nanowires through analytical modeling of the current- voltage characteristics, while for long and thin nanowires we perform dissipative transport modelling to obtain the low-field mobility. Finally, ballistic transport modelling is performed using the sub band decomposition method for ultra- short nanowires.

4:42PM D24.00010 Gap suppression and delocalization of 1D electron gas driven by a strong AC electric field , KATHLEEN E. HAMILTON, LEONID P. PRYADKO, UCR — We will argue that a strong AC electric field can coherently suppress a band gap in a high-mobility one-dimensional wire. At half-filling, the expected effect is delocalization of the carriers, in contrast to Stark localization at low frequencies, or Dynamical Destruction of Tunneling at frequencies exceeding the bandwidth. Another effect of the gap suppression is the doubling of the Bloch oscillations' period. We support these expectations with numerical simulations of the non-linear current response for several model systems driven by a combined high and low-frequency electric field.

4:54PM D24.00011 Modeling of Phonon-assisted Zener Tunneling in Indirect Semiconductors , WILLIAM VANDENBERGHE, K.U.Leuven / imec, BART SORÉE, imec, MASSIMO FISCHETTI, U.T.Dallas, WIM MAGNUS, Univ. Antwerpen / imec, GUIDO GROESENEKEN, K.U.Leuven / imec — With the scaling in the semiconductor device dimensions, Zener tunneling has become an important source of leakage in conventional MOSFET devices but it could also provide drive current for a novel type of tunnel transistor. A good understanding of the process of Zener tunneling is therefore required and present-day one-dimensional semi-classical models fall short of explaining tunneling in devices with potential profiles with a pronounced two-dimensional shape. We have developed a formalism to calculate the phonon-assisted current under a given three dimensional external potential profile. The current is calculated from the transition probability for an electron to go from the valence to the conduction band. The transition probability is determined from the spectral functions corresponding to the valence and the conduction band. In the presence of a one-dimensional uniform low electric field, the Kane model is recovered. An example of the formalism is given for the case of an abrupt p-n diode and compared with existing semi-classical models. It is seen that the uniform field model is actually better than the WKB model but that none of the semi-classical models give good results at low bias conditions.

5:06PM D24.00012 Zener Tunneling: Correspondence between Quantum and Semi-Classical Formalisms , KARTIK GANAPATHI, SAYEEF SALAHUDDIN, University of California Berkeley — The resurgence of interest in band-to-band tunneling has been due to its usefulness in overcoming the 60 mV/decade limit in turn-on characteristics of a MOSFET thereby providing path for lowering the operating power. The expression due to *Kane*, for calculating transmission coefficient and current due to Zener tunneling in a $p-n$ diode, has been extensively used over the years for explaining experimental tunneling characteristics. While this closed form expression relates tunneling probability with simple quantities like bandgap, effective mass, electric field etc., being a formula based on semi-classical approximation, it is valid strictly in the low-field regime. With finite size effects playing significant role in ultra small device dimensions, this approximation breaks down and one needs to have a full quantum mechanical treatment of the tunneling problem with a realistic band-structure. We report a numerical simulation of this problem within the NEGF formalism with a tight-binding Hamiltonian wherein the extent of validity of Kane's formula is examined. We also discuss how Kane's parameters should be altered and interpreted in high field region. The results are compared with experimental data in two different systems – InAs $p^+ - n^+$ and GaN/AlGaN heterojunction tunnel diodes.

5:18PM D24.00013 Simulation of nanoscale four-probe resistance measurements under finite bias voltages , ASAKO TERASAWA, KEIJI TOBIMATSU, TOMOFUMI TADA, TAKAHIRO YAMAMOTO, SATOSHI WATANABE, Dept. of Materials Engineering, The Univ. of Tokyo — To understand the interesting features in nanoscale four-probe measurements such as the negative value and the oscillation of four-probe resistance [1], we investigate the behavior of nanoscale four-probe resistance theoretically [2-3]. In the present work, we examine the effect of bias voltage on four-probe resistance in nanoscale four-probe systems. For a set bias voltage between current probes, we first estimate the voltage between voltage probes when no current flows between them from the four-probe and two-probe resistances at the zero-bias limit, assuming the linear response. Then we calculate the dependence of currents in the voltage probes on the bias voltage applied to the current probes with applying the voltage thus estimated between the voltage probes. The calculated currents in the voltage probes have nonzero but much smaller values compared with those in current probes, and show the non-linear dependence on the bias voltage. This result indicates assumption of linear response is not valid for the bias voltage of the order of a tenth V, and that currents and voltages should be determined self-consistently to estimate four-probe resistance. Session D25 DCMP: Superconductivity: Vortex Phenomena I D166

2:30PM D25.00001 Anomalous field-symmetric Nernst signal in striped cuprate $La_{2-x}Ba_xCuO_4$[1] , N. PHUAN ONG, LU LI[2], Princeton University, J. M. TRANQUADA, GENDA GU, Brookhaven National Lab — Starting at the structural transition temperature $T_{d2} = 54$ K, the striped cuprate $La_{2-x}Ba_xCuO_4$ ($x = \frac{1}{8}$) displays a remarkable cascade of transitions[1] at the characteristic temperatures $T_{d2} > T_1^{**} > T_{BKT} > T_c$, before settling down to 3D superconductivity with long-range coherence at T_c= 5 K. The Nernst signal e_N and thermopower S have been investigated in detail in these multiple states. As in pure LaSrCuO, the Nernst coefficient $N = lim_{B\to 0} e_N/B$ (initially negative) acquires a positive vortex contribution at 120 K that grows rapidly. However, here, N saturates in the interval T_{d2} (54 K) $\rightarrow T_1^{**}$ (34 K). As the vortex liquid becomes increasingly stabilized below T_1^{**}, N resumes increasing at an even steeper rate. Surprisingly, below 34 K, e_N acquires a B-symmetric component that is very large and oscillatory in B. We have excluded S and quasiparticles as the source of the anomalous term. We will discuss various origins including the possibility of vortex formation mechanisms that break time-reversal invariance.

2:42PM D25.00002 Torque measurements in underdoped $Bi_2Sr_{2-x}La_xCuO_{6+\delta}$ single crystals[1] , T. HU, Kent State University, Kent, Ohio, USA and University of California, Davis, CA, USA, H. XIAO, Kent State University, Kent, Ohio, USA and Institute of Physics, Beijing, China, P. GYAWALI, Kent State University, Kent, Ohio, USA, H.H. WEN, Institute of Physics, Beijing, China, C.C. ALMASAN, Kent State University, Kent, Ohio, USA — We report in-plane and out-of-plane angular-dependent torque measurements on underdoped $Bi_2Sr_{2-x}La_xCuO_{6+\delta}$ single crystals both below and above the zero-field superconducting transition temperature $T_c(0)$ and in applied magnetic fields H up to 14 T. The out-of-plane torque data show that a diamagnetic signal persists into the normal state, which is consistent with previous reports on $Bi_2Sr_2Ca_2CuO_{8+\delta}$. These data also reveal that the vortex matter in the superconducting state has lower dimensionality compared to the one in the normal state. Furthermore, in-plane torque measurements show that the presence of vortices above $T_c(0)$ destroys the phase coherence of the Cooper pairs.

2:54PM D25.00003 Generics of the diamagnetism, Nernst signal, and finite size effects in superconductors above the transition temperature , S. WEYENETH, T. SCHNEIDER, Physics Institute, University of Zurich, CH-8057 Zurich, Switzerland — Various superconductors exhibit peculiar features above the transition temperature T_c. In particular the observation of a large Nernst signal N and a remarkable diamagnetism above T_c in cuprate and conventional superconductors attracted considerable attention. Noting that in these materials the spatial extent of the homogeneous domains is limited, we explore the relevance of a zero dimensional (0D)-model, neglecting thermal fluctuations, to describe the isothermal magnetization curves $m_{\rm d}(H)$ in various superconductors above T_c. It is shown that for cuprates as well as for Pb nanoparticles, both, the full 0D-model as well as its Gaussian approximation, mimic the essential features of the magnetization curves above T_c rather well. Furthermore, the isothermal Nernst signal of a superconducting $Nb_{0.15}Si_{0.85}$ film is fully consistent with this scenario. Accordingly, the observed diamagnetism above T_c in Pb nanoparticles, in the cuprates $La_{1.91}Sr_{0.09}CuO_4$ and $BiSr_2Ca_2CuO_{8-\delta}$, as well as the Nernst signal in $Nb_{0.15}Si_{0.85}$ films, are all in excellent agreement with the scaling properties emerging from the here discussed 0D-model. Therefore, singlet Cooper pairs subjected to orbital pair breaking in a 0D-system are the main source of the observed diamagnetism and Nernst signal in an extended temperature window above T_c.

3:06PM D25.00004 Effects of Vortex Charge Explored by NMR Spectroscopy in $Bi_2Sr_2CaCu_2O_{8+\delta}$, ANDREW MOUNCE, S. OH, Northwestern University, S. MUKHOPADHYAY, W.P. HALPERIN, A.P. REYES, P.L. KUHNS, K. FUJITA, M. ISHIKADO, S. UCHIDA — We measure nuclear magnetic resonance (NMR) spectra for various dopings of $Bi_2Sr_2CaCu_2O_{8+y}$ to determine the variations of local magnetic fields generated by the vortex lattice at low temperatures. With increasing the external magnetic field H_0, the local field variations decrease to values lower than expected by Ginzburg-Landau calculations for an Abrikosov vortex lattice.[1] Taking into account charge accumulation in vortex cores, which has been predicted by theory[2] and suggested by experiment,[3] we are able to identify the amount of charge needed to disturb the vortex lattice and decrease local field variations as in the observed spectra. The amount of charge is found to be $\sim 2\text{x}10^{-3}$e and doping dependent in line with theoretical predictions.[2] This work is supported by DOE/BES: DE-FG02-05ER46248 and the NHMFL by NSF and the State of Florida.

3:18PM D25.00005 Vortex dynamics in ferromagnetic / high T_c superconducting heterostructures , N. HABERKORN, J. KIM, M. MIURA, B. MAIOROV, P. DOWDEN, L. CIVALE, Superconductivity Technology Center, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA — In this work we explore the influence of the ferromagnetic landscape generated by magnetic phase separation in manganites on the vortex pinning of HTS/FM heterostructures. We have grown $Gd_{2/3}Ca_{1/3}MnO_3$(GCMO), $Y_{2/3}Ca_{1/3}MnO_3$(YCMO) and YBCO films, as well as GCMO/YBCO and YCMO/YBCO bilayers by Pulsed Laser Deposition. GCMO is a ferrimagnetic material with Curie temperature of $\sim$ 80 K and a compensation temperature of 15 K, whereas YCMO is ferromagnetic with Curie temperature $\sim$ 80 K. In both materials the saturation magnetization is smaller than the value expected from ferrimagnetic and ferromagnetic order, suggesting phase separation with small ferromagnetic domains. The magnetic domain size as a function of temperature for the magnetic films was investigated using magnetic force microscopy (MFM). We will present a comparison of the vortex pinning and dynamics in the YBCO single layers and the GCMO/YBCO and YCMO/YBCO bilayers that allows us to identify the temperature and field regimes where magnetic pinning is effective.

3:30PM D25.00006 Hysteretic magneto-transport of a High-T_c superconducting/ferromagnetic multilayer with tunable magnetic domain structure , JAVIER E. VILLEGAS, CRISTINA VISANI, PETER J. METAXAS, AURELIE COLLAUDIN, BAPTISTE CALVET, ROZENN BERNARD, JAVIER BRIATICO, CYRILE DERANLOT, KARIM BOUZEHOUANE, Unite Mixte de Physique CNRS/Thales, 1 avenue A. Fresnel, 91767 Palaiseau, and Universite Paris Sud 11, 91405 Orsay, France — The magneto-transport of a hybrid heterostructure combining a $YBaCuO_{7-\delta}$ thin film and a Co/Pt superlattice shows an unusual hysteretic behavior. Depending on the angle between the external applied field and the film plane, and on the magnetic history, either a increase or a decrease of the mixed-state resistance is observed. The combination of magneto-transport, magnetic force microscopy and anomalous Hall effect measurements allows us to correlate these effects to the magnetic domain structures in the Co/Pt superlattice. We unequivocally prove that the hysteretic magneto-transport is induced by the stray magnetic fields from tunable magnetic domain structures, which may induce vortices or produce vortex pinning, leading to the increase/decrease of the mixed-state resistance. Work supported by French ANR "Superhybrids-II" and RTRA "Supraspin" grants.

3:42PM D25.00007 Vortex/Domain Coupling in Superconducting Films on Ferromagnetic Substrates with Different Domain Structures , VITALII VLASKO-VLASOV, ULRICH WELP, DANIEL ROSENMANN, WAI KWOK, Argonne National Laboratory, Argonne, IL, ALEXANDER BUZDIN, University of Bordeaux, France, ALEXANDER MELNIKOV, Institute Ior Physics of Microstructures RAS, Russia, LYUDMILA USPENSKAYA, Institute of Solid State Physics RAS, Russia, VINCENT FRATELLO, Integrated Photonics, Hillsborough, NJ — In this work we address engineering of magnetic pinning in the superconducting/ferromagnetic hybrids. Using direct magneto-optical observations effects of interactions between superconducting vortices in Nb film and magnetization in domains of substituted iron garnet films are studied. Two garnet films with perpendicular anisotropy but different thickness-to-domain width ratios and one showing the reorientation from the in-plane to the normal easy axis are used as substrates. All three samples demonstrate strong domain/vortex coupling and reveal high pinning by domain walls, which persists up to temperatures close to the superconducting Tc. In turn, vortex motion modifies domain structures of garnets at T$<$Tc resulting in the alignment and strong contraction of wide domains but smaller width changes of narrow domains. A model is proposed explaining the results of our observations. This work was supported by DOE-BES under Contract No. DE-AC02-06CH11357.

3:54PM D25.00008 Matching field effects in high-T_c superconductors with self-assembled columnar defects , J.W. SINCLAIR, University of Tennessee, Y.L. ZUEV, Oak Ridge National Laboratory, J.R. THOMPSON, University of Tennessee, Knoxville, D.K. CHRISTEN, C. CANTONI, S.-H. WEE, A. GOYAL, Oak Ridge National Laboratory, C. VARANASI, Univ of Dayton/Air Force Research Lab — Columnar defects (CDs) in a superconductor provide angularly selective vortex pinning, where the density of CDs provides a natural scale for the magnetic field, the "matching field." While dramatic changes in the critical current density J_c might be expected when the vortex density exceeds the CD density, observations of this phenomena has been elusive in systems with chemically produced, self-assembled CDs of $BaSnO_3$, $BaZrO_3$, $SrZrO_3$, etc. Here we describe studies of two $RBa_2Cu_3O_{\sim 7}$ systems containing these self-avoiding CDs, using either contact free magnetic or transport measurements. In magnetic measurements on a material with measured areal CD of $\sim$2.5 T, the J_c decreased abruptly when the applied field H exceeded this level; this feature was observed over a wide temperature range, from 77 to $\sim$ 40 K. All these features disappeared when the field was tilted away from the CD orientation. Research at ORNL sponsored by US DOE.

4:06PM D25.00009 Superconducting vortex dynamics on asymmetric arrays with symmetric pinning centers[1] , JOSE L. VICENT, Universidad Complutense, 28040 Madrid, DAVID PEREZ DE LARA, IMDEA-Nanociencia, 28049 Madrid and Universidad Complutense, 28040 Madrid, ALEJANDRO ALIJA, Universidad Oviedo, 33007 Oviedo, ELVIRA M. GONZALEZ, Universidad Complutense, 28040 Madrid, MARIA VELEZ, JOSE I. MARTIN, Universidad Oviedo, 33007 Oviedo — Arrays of Ni nanodots embedded in Nb superconducting films have been fabricated by sputtering and electron beam lithography techniques. The arrays are periodic triangular lattices of circular Ni dots arranged in a kagomé-like pattern with broken reflection symmetry. DC magnetoresistance shows several fractional matching field minima below the first matching field for vortex motion parallel and perpendicular to the array reflection symmetry. AC magnetoresistance shows reversal ratchet effect when the vortex lattice moves parallel to the array reflection symmetry. These effects could be understood taking into account the vortex lattice density.

[1]Work supported by Spanish MICINN and CAM.

4:18PM D25.00010 Enhanced superconducting vortex pinning in the Corbino geometry[1] , YANIV ROSEN, IVAN K. SCHULLER, Department of Physics and Center for Advanced Nanoscience, University of California San Diego, La Jolla CA 92093 — We probed a dynamic system of superconducting vortices with an artificial pinning landscape in the Corbino geometry. Current was applied from the center of the disc and propagated radially outward to produce a circular force with a strength proportional to 1/r on the vortices. This caused a shearing force on the vortex lattice and was studied with varying current densities and temperature. Matching minima in the magnetoresistance curves were still observed under the Corbino conditions for the square lattice pinning site geometry. Surprisingly the even numbered matching fields show enhanced pinning compared to the odd matching fields. Other interesting temperature and current density dependencies will also be discussed.

[1]This work was supported by the US-NSF.

4:30PM D25.00011 Proximity Effects and Vortex Dynamics in Nanostructured Superconductors , SERENA ELEY, NADYA MASON, Department of Physics and Materials Research Laboratory, University of Illinois Urbana-Champaign — We report transport measurements on triangular arrays of proximity-coupled superconducting islands placed on normal-metal substrates. The superconducting islands are well-understood coherent systems with long-range electron interactions, while the intervening normal metal channels introduce known dissipation into the system. We show how by changing the island spacing, we can tune characteristics such as the critical temperature and field. The arrays undergo a Kosterlitz-Thouless vortex-unbinding phase transition at zero-field, and we observe frustration-induced magnetoresistance oscillations at finite fields. We also observe unusual cusp-like behavior in resistance vs temperature at finite magnetic fields

4:42PM D25.00012 Vortex-induced dissipation in current-biased superconducting nanowires , LEV BULAEVSKII, MATTHIAS GRAF, CRISTIAN BATISTA, Los Alamos National Laboratory, VLADIMIR KOGAN, Ames Lab and Iowa State Univ. — We study the dissipation due to vortex crossings in thin current-biased superconducting films with thickness on the order of the coherence length, and with width much narrower than the magnetic Pearl length in thin films. We find that for technologically relevant thin and narrow films or nanowires with width much larger than the coherence length, the barrier for phase slips by creation of temporary normal regions across the entire film width is too big. Thus phase slips become highly improbable. Instead, we propose the process of a vortex crossing the strip from one edge to the other, perpendicular to the bias current, as the dominant mechanism for generalized phase slips resulting in detectable voltage pulses. We derive phase-current relations and predict the amplitude and duration of voltage pulses induced by vortex motion due to thermal fluctuations and bias current. The consequnces for the current-voltage characteristics and the fundamental limitations for dark counts in superconducting nanowire single-photon detectors are discussed.

4:54PM D25.00013 Synthesis and vortex dynamics of high-Tc superconducting nanoribbons with a periodic array of holes , QIONG LUO, MICHAEL LATIMER, ZHILI XIAO, Northern Illinois University, LEI FANG, WAI-KWONG KWOK, Argonne National Lab — We fabricated nanoribbons of high-temperature superconductors YBCO-123 and BSCCO-2212. Experimental procedures for growing, manipulating and characterizing the nanoribbons will be presented. Furthermore, we introduced regular arrays of nanoscale holes into these nanoribbons through focused-ion-beam (FIB) milling to study the effects of periodic pinning on vortex dynamics. Resistive measurements reveal vortex matching effect and striking feature in the volage-current behavior associated with various driven regimes of the vortex matter related to vortex dynamics phase transitions

5:06PM D25.00014 Strong pinning of vortex lines by nanoparticles[1] , ALEXEI KOSHELEV, Materials Science Division, Argonne National Laboratory, ALEJANDRO KOLTON, Centro Atomico Bariloche and Instituto Balseiro, Argentina — Pinning of vortex lines by array of nanoparticles embedded inside superconductors became the most efficient practical way to achieve high critical currents. In this situation pinning occurs via trapping of the vortex-line segments and the critical current is determined by the typical length of trapped segment. To verify analytical estimates and develop a quantitative description of strong pinning, we use large-scale numerical simulations. We study the dependence of the critical force on the density of pins in the regime of independently pinned lines, statistical properties of trapped lines, and suppression of the apparent critical force by thermal fluctuations.

Session D26 DCOMP DMP: Focus Session: Iron Based Superconductors – Electronic Structure

D162/164

2:30PM D26.00001 Confronting LDA+DMFT results with experiments in the iron pnictide families , GABRIEL KOTLIAR, Rutgers University — The normal state electronic structure of the pnictides is an important challenge to electronic structure theory . Optical conductivity experiments are indicative of electronic electron correlations (with mass renormalizations of the order of three). Neutron scattering experiments have features characteristic of both itinerant and localized electrons. High energy spectroscopies indicate the absence of satellite peaks. In this talk, we will show how LDA+DMFT allows us to reconcile these apparently inconsistent facts, and trace them to the unique chemical ingredients of these compounds: the iron Hunds rule coupling and the hybridization with very broad arsenide bands. Quantitative results for the different iron pnictide families will be presented and the factors that govern the strength of the correlations in this family of compounds will be discussed.

3:06PM D26.00002 Electronic structure of iron-pnictide superconductors: just scratching the surface , ERIK VAN HEUMEN, University of Amsterdam, J. VUORINEN, Tampere University, K. KOEPERNIK, IFW Dresden, F. MASSEE, Y. HUANG, J.B. GOEDKOOP, University of Amsterdam, M. LINDROOS, Tampere University, M. SHI, PSI, K. HAULE, Rutgers University, J. VAN DEN BRINK, IFW Dresden, M.S. GOLDEN, University of Amsterdam — Angle resolved photoemission (ARPES) and scanning tunneling microscopy (STM) are important tools in the study of iron-pnictide high T_c superconductors. These techniques are surface sensitive and one has to ensure that the electronic structure probed in an experiment corresponds to the bulk electronic structure. Using a combination of experimental techniques (STM, ARPES, LEED) and theoretical calculations (LEED simulations, DFT), I will show that the surface structure of $BaFe_{2-x}Co_xAs_2$ is both reconstructed and distorted. LEED data combined with simulations is used to solve the real surface and sub-surface structure. The impact of the surface on the electronic structure is then determined by comparing DFT slab calculations, based on the real surface structure, with ARPES experiments. The presence of surface states gives a natural explanation for the large k-space broadening observed in these materials. Having identified the surface states and bulk bands, I will address the more fundamental questions with regard to the electronic structure and its role in the mechanism of high temperature superconductivity.

3:18PM D26.00003 The superconducting phase and electronic excitations of (Rb,Cs)Fe_2As_2 , J. KANTER, Lab. for Solid State Physics, ETH Zurich, CH-8093 Zurich, Z. SHERMADINI, R. KHASANOV, A. AMATO, Paul Scherrer Institute, CH-5232 Villigen PSI, Switzerland, Z. BUKOWSKI, B. BATLOGG, Lab. for Solid State Physics, ETH Zurich, CH-8093 Zurich — We present specific heat, transport and Muon-Spin Rotation (μSR) results on (Rb,Cs)Fe_2As_2. $RbFe_2As_2$ was only recently found to be superconducting below 2.6 K by Bukowski et al. Compared to the related $BaFe_2As_2$ the electron density is lower and no magnetic order is observed. For the superconducting phase the superfluid density was calculated from μSR data. The temperature dependence of the superfluid density and the magnetic penetration depth is well described by a multi-gap scenario. In addition the electronic contribution the specific heat was studied for different compositions and magnetic fields and reveals a high value for the Sommerfeld coefficient γ.

3:30PM D26.00004 Revealing the degree of magnetic frustration in iron pnictides , CHENG-CHIEN CHEN, Stanford University, RYAN APPLEGATE, University of California at Davis, BRIAN MORITZ, THOMAS DEVEREAUX, SIMES, SLAC National Accelerator Laboratory, RAJIV SINGH, University of California at Davis — Proposed theories for collinear antiferromagnetism in iron pnictides vary greatly in the amount of magnetic frustration and proximity to a quantum critical point. We discuss how imaging the magnetic fields around a non-magnetic impurity can quantify the degree of magnetic frustration and thereby distinguish various theoretical proposals. It is found that in a frustrated J1-J2 model a non-magnetic impurity strongly reduces its neighboring local moments, and overturned dynamical spins appear close to zero energy. In contrast, the spatially anisotropic J1a-J1b-J2 model produces enhanced local moments on sites neighboring the impurity. In both cases, the disturbance in the magnon local density of states exhibits an anisotropic stripe pattern. These predictions can be tested by experiments such NMR or spin-resolved STM measurements. The results can elucidate the role of frustration in antiferromagnets and help narrow the possible models for the iron-pnictide superconductors.

3:42PM D26.00005 Theory for Magnetism and Triplet Superconductivity in LiFeAs[1]

, MARIA DAGHOFER, IFW Dresden, PHILIP BRYDON, CARSTEN TIMM, TU Dresden, JEROEN VAN DEN BRINK, IFW Dresden — Superconducting pnictides are widely found to feature spin-singlet pairing in the vicinity of an antiferromagnetic phase, for which nesting between electron and hole Fermi surfaces is crucial. LiFeAs differs from the other pnictides by (i) poor nesting properties and (ii) unusually shallow hole pockets. Investigating magnetic and pairing instabilities in an electronic model that incorporates these differences, we find antiferromagnetic order to be absent. Instead we observe almost ferromagnetic fluctuations which drive an instability toward spin-triplet p-wave superconductivity.

3:54PM D26.00006 Unified Picture for Magnetic Correlations in Iron-Based Superconductors

, WEI-GUO YIN, CHI-CHENG LEE, WEI KU, Brookhaven National Laboratory — The spin-density-wave mechanism due to Fermi surface nesting is widely used to describe magnetism in the parent compounds of iron-based superconductors; however, the field is puzzled by the different magnetic structure of FeTe, which apparently has similar Fermi-surface topology. Here we propose [1] an orbital-degenerate double-exchange model which includes both itinerant electrons and localized spins. The physical properties of the model are governed by the competition between the antiferromagnetic superexchange and Hund's rule coupling. We show that the strength of the effective Hund's rule coupling term strongly depends on the anion height from the iron plane, leading to the collinear (C-type) magnetic order with the ferro-orbital order in iron pnictides and the bicollinear (E-type) magnetic order without orbital ordering in FeTe. This shows that the magnetism in iron-based superconductors can be described in a unified picture and may have a universal origin for all of the materials. Our results reveal the crucial role of Hund's rule coupling for the strongly correlated nature of the system and suggest exploring the interplay of the spin, orbital, charge, and lattice degrees of freedom in promoting high-temperature superconductivity. Work supported by US DOE.

4:06PM D26.00007 Electronic specific heat of the iron chalcogenide superconductor $Fe(Te_{0.55}Se_{0.45})$

, JIN HU, TIJIANG LIU, BIN QIAN, ZHIQIANG MAO, Department of Physics and Engineering Physics, Tulane University — We report specific heat studies of superconducting $Fe(Te_{0.55}Se_{0.45})$[1]. We have obtained the electronic specific heat by subtracting the phonon contribution evaluated from the normalization of the phonon specific heat of a non-superconducting reference sample $(Fe_{0.9}Cu_{0.1})(Te_{0.55}Se_{0.45})$. Our results show that the superconducting ground state is accompanied by unpaired quasiparticles, as in FeAs superconductors, with γ_0~2.3 mJ/mol K^2. The temperature dependence of the electronic specific heat $C_{es}(T)/T$ can be well fitted using either a single s-wave gap model with $2\Delta = 5.2\ k_BT_c$ or a two-gap model with $2\Delta_1/k_BT_c = 5.8$ and $2\Delta_2/k_BT_c = 4.0$; the two-gap model fitting is slightly better than the single gap fitting. Such large gaps, together with a large specific heat jump $\Delta C(T_c)/T_c$ ~57.3 mJ/mol K^2, suggest a strong-coupling superconducting state. While $C_{es}(T)/T$ exhibits isotropic s-wave gap behavior, the magnetic field-induced change in the electronic specific heat $\Delta\gamma(H)$ exhibits sublinear field dependence, implying the superconducting pairing in iron chalcogenide superconductors also involves a multiple band effect, as seen in pnictide superconductors. [1] M. H. Fang, H. M. Pham, B. Qian, T. J. Liu, E. K. Vehstedt, Y. Liu, L. Spinu, and Z. Q. Mao, Superconductivity close to magnetic instability in $Fe(Se_{1-x}Te_x)_{0.82}$, Phys. Rev. B 78, 224503 (2008).

4:18PM D26.00008 Electronic correlations and superconducting response in the optical properties of $FeTe_{0.55}Se_{0.45}$[1]

, C.C. HOMES, A. AKRAP, J.S. WEN, Z.J. XU, Z.W. LIN, Q. LI, G.D. GU, Condensed Matter Physics and Materials Science Dept., Brookhaven National Laboratory, Upton, New York — The in-plane complex optical properties of the iron-chalcogenide superconductor $FeTe_{0.55}Se_{0.45}$ have been determined above and below $T_c = 14$ K. At room temperature the conductivity is described by a weakly-interacting Fermi liquid with $\omega_{p,D} \simeq 7200$ cm^{-1} and $1/\tau_D \simeq 414$ cm^{-1}. Below 100 K the conductivity is no longer described by the Drude model. Adopting the generalized Drude model reveals that $1/\tau(\omega) \propto \omega$ in the terahertz region just above T_c, signaling the increasingly correlated nature of this material.[2] For $T \ll T_c$ the superconducting plasma frequency $\omega_{p,S} \simeq 3000$ cm^{-1} ($\lambda_{eff} \simeq 5300$ Å); $\omega^2_{p,S}/\omega^2_{p,D} \ll 1$ indicating that this material is not in the clean limit. Allowing $\sigma_{dc} \equiv \sigma_1(\omega \to 0)$, then $\sigma_{dc}(T \simeq T_c) \simeq 3500 \pm 400\ \Omega^{-1}$cm^{-1} and the superfluid density $\rho_{s0} \equiv \omega^2_{p,S} \simeq 9 \pm 1 \times 10^6$ cm^{-2} places material close to the scaling line $\rho_{s0}/8 \simeq 8.1\,\sigma_{dc}T_c$ for a BCS dirty-limit superconductor. Below T_c the optical conductivity reveals two energy scales for the superconductivity at $\Delta_1(0) \simeq 2.5$ meV and $\Delta_2(0) \simeq 5.1$ meV, consistent with the $s^{\pm}$ model.

4:30PM D26.00009 Microwave surface impedance measurements of LiFeAs and LiFe(As,P) single crystals

, Y. IMAI, H. TAKAHASHI, T. OKADA, A. MAEDA, Dept. of Basic science, the University of Tokyo, K. KITAGAWA, K. MATSUBAYASHI, M. TAKIGAWA, Y. UWATOKO, ISSP, the University of Tokyo, N. NAKAI, Y. NAGAI, M. MACHIDA, Japan Atomic Energy Agency — We report results of microwave surface impedance measurements in LiFeAs and LiFe(As,P) single crystals [1]. These crystals were grown by self-flux method. The surface impedances of crystals were measured by a cavity perturbation technique. The in-plane penetration depth calculated from the surface reactance shows an exponential temperature dependence at low temperatures in both of LiFeAs and LiFe(As,P). This indicates that these materials do not have any nodes in the superconducting gap. The temperature dependence of the superfluid density indicates that LiFeAs and LiFe(As,P) are multi-gap superconductors with at least two isotropic gaps. In addition, the real part of complex conductivity exhibits an enhancement below T_c, which is different from the so-called coherence peak. This is due to the rapid increase of the relaxation time of the quasiparticle below T_c. We believe that this enhancement is rather common to all superconductors where an inelastic scattering is dominant above T_c, irrespective of the strength of the electron correlation.

4:42PM D26.00010 Electromagnetic response of Fe(Se,Te) in the superconducting sate

, A. MAEDA, H. TAKAHASHI, D. NAKAMURA, T. AKIIKE, F. NABESHIMA, Y. IMAI, Department of Basic Sciences, University of Tokyo, S. KOMIYA, I. TSUKADA, Central Research Institue of Electric and Power Industry (CRIEPI) — We investigate the electromagnetic response of Fe(Se,Te) from microwave to THz region, with special interests in the superconducting state. Samples were epitaxial thin films or bulk single crystals, depending on the technique of measurements. The results obtained are the followings. (1) Temperature dependence of the penetration depth was almost flat, with a very small contribution of T^2, suggesting nodeless gap plus some disorder induced pair breaking. (2) Temperature dependence of superfluid density is rather different from that of, eg, LiFeAs, suggesting weak interband scattering. (3) Quasiparticle (QP) conductivity, $\sigma(\omega, T)$ shows a broad peak below T_c. Both of temperature dependence and frequency dependence show that this peak is not the coherence peak in conventional s-wave superconductors, but is due to the enhancement of the QP scattering time. These strongly suggest that the symmetry of superconducting wave function is sign-changed s-wave. (4) Sharp peak around T_c was invisible in $\sigma(T)$, suggesting very small superconductivity fluctuation. (5) Conductivity spectra ($\sigma(\omega)$) suggest that the superconducting gap, 2Δ is 1.2 meV, leading to $2\Delta/k_BT_c$ is 1.37. We will discuss possible reasons for the small gap value.

4:54PM D26.00011 Iron isotope effect on the superconducting transition temperature and the crystal structure of $FeSe_{1-x}$, MARKUS BENDELE, Physik-Institut der Universität Zürich, RUSTEM KHASANOV, KAZIMIERZ CONDER, EKATERINA POMJAKUSHINA, VLADIMIR POMJAKUSHIN, Paul Scherrer Institute, ANNETTE BUSSMANN-HOLDER, Max-Planck-Institut für Festkörperforschung, HUGO KELLER, Physik-Institut der Universität Zürich — The Fe isotope effect (Fe-IE) on the transition temperature Tc and the crystal structure was studied in the Fe chalcogenide superconductor $FeSe_{1-x}$ by means of magnetization and neutron powder diffraction (NPD). The substitution of natural Fe (containing $\simeq 92\%$ of ^{56}Fe) by its lighter ^{54}Fe isotope leads to a shift in T_c of 0.22(5) K corresponding to an Fe-IE exponent of $\alpha_{\rm Fe} = 0.81(15)$. Simultaneously, a small structural change with isotope substitution is observed by NPD. This may help to clarify the currently controversal results of the Fe-IE. Upon correcting the isotope effect exponent for these structural effects, an almost unique value of $\alpha \sim 0.35 - 0.4$ is observed for at least three different families of Fe-based HTS.

5:06PM D26.00012 Magnetism of SmFeAsO1-xFx[1] , YOICHI KAMIHARA, Keio Univ., YASUHIRO KOBAYASHI, SHINJI KITAO, Kyoto Univ., YOSHITAKA YODA, JASRI, MAKOTO SETO, Kyoto Univ., HIDEO HOSONO, Tokyo Institute of Technology, JST TRIP COLLABORATION, JST CREST COLLABORATION — Magnetic properties of superconducting $SmFeAsO_{1-x}F_x$ are demonstrated by ^{57}Fe Mossbauer spectroscopy (MS) and ^{149}Sm Nuclear resonant forward scattering (NRFS). Polycrystalline $SmFeAsO_{1-x}F_x$ samples were synthesized using two-step solid state reaction described elsewhere. [New J. Phys. 12, 033005 (2010).] Purity of samples was checked by X-ray diffraction patterns using Cu K-alpha radiation. Resistivity and magnetization measurements, as well as by ^{57}Fe MS and ^{149}Sm NRFS spectroscopy, at various temperatures were performed to define superconducting, magnetic ordering temperatures. [Phys. Rev. B 78, 184512 (2008) & J. Phys. Soc. Japan 77, 103706 (2008).] A magnetic phase diagram we have proposed is closer to that by Hess et al [Europhys. Lett. 87, 17005 (2009).]; that is long-range AF ordering of Fe (a static magnetism) does not persist in the superconducting regime. Such a relation between spin dynamics and SC is a common feature among $LnFeAsO_{1-x}F_x$ (Ln = La, Ce, Pr, Nd, and Sm). Our results indicate that the relation between the static magnetism and T_c of $LnFeAsO_{1-x}F_x$ shows similar topology to that of copper-based high-Tc superconductors. [Phys. Rev. B 42, 7981 (1990).]

5:18PM D26.00013 Surface geometric and electronic structures of $A(Fe, Co)_2As_2$ (A=Ba,Ca) , GUORONG LI, V.B. NASCIMENTO, XIAOBO HE, AMAR B. KARKI, JIANDI ZHANG, RONGYING JIN, Dept. of Physics, Louisiana State University, Baton Rouge, LA 70802, USA, A.S. SEFAT, M.A. MCGUIRE, B.C. SALES, Materials Science & Technology Division, ORNL, Oak Ridge, TN 37831, USA, D. MANDRUS, Dept. of Materials Science & Engineering, The University of Tennessee, Knoxville, TN, 37996, USA, WARD PLUMMER, Depart. of Physics, Louisiana State University, Baton Rouge, LA 70802, USA — We utilize Low Energy Electron Diffraction (LEED) to determine the surface structure combined with real-space scanning tunneling microcopy/spectroscopy (STM/STS), to investigate the local geometric and electronic structures at the (001) surface of the compounds of AFe_2As_2 (A= Ba, Ca). In general two competing surface reconstructions are observed with either a 1x2 or a $(\sqrt{2}\times\sqrt{2})R45^\circ$ (tetragonal notation) structure. The $(\sqrt{2}\times\sqrt{2})R45^\circ$ structure corresponds to the 1x1 orthorhombic phase. While the $(\sqrt{2}\times\sqrt{2})R45^\circ$ phase always present for A=Ba, the 1x2 structure dominates for A=Ca. We will discuss the detailed structural change with Co doping, thermal cycling, contamination, electron beam induced damage, and cleaving temperature. Specifically, 1x2 phase is sensitive to the thermal processing, with indications of a temperature dependence phase transition. *Supported by NSF DMR-1002622

Session D27 GQI: Focus Session: Superconducting Qubits - Gates and Algorithms C155

2:30PM D27.00001 Scaling Superconducting Qubits with the ResQu Architecture , JOHN MARTINIS, University of California at Santa Barbara — This abstract not available.

3:06PM D27.00002 Quantum Logic Gates for Coupled Superconducting Resonators , FREDERICK STRAUCH, Williams College — Superconducting resonators are a promising element for many applications in quantum information processing, such as memory, state transfer, and qubit-qubit coupling. Here I introduce a new application—multi-level quantum logic using superpositions of Fock states. A circuit-QED implementation of single and coupled-resonator gates will be presented and theoretically analyzed. This scheme, using experimentally demonstrated interactions, will be compared with traditional qubit operations.

3:18PM D27.00003 Two-qubit gates and coupling with low-impedance flux qubits , JERRY CHOW, ANTONIO CORCOLES, CHAD RIGETTI, JIM ROZEN, GEORGE KEEFE, MARY-BETH ROTHWELL, JOHN ROHRS, MARK BORSTELMANN, DAVID DIVINCENZO, MARK KETCHEN, MATTHIAS STEFFEN, IBM Research — We experimentally demonstrate the coupling of two low-impedance flux qubits mediated via a transmission line resonator. We explore the viability of experimental coupling protocols which involve selective microwave driving on the qubits independently as well as fast frequency tuning through on-chip flux-bias. Pulse-shaping techniques for single-qubit and two-qubit gates are employed for reducing unwanted leakage and phase errors. A joint readout through the transmission line resonator is used for characterizing single-qubit and two-qubit states.

3:30PM D27.00004 ABSTRACT WITHDRAWN –

3:42PM D27.00005 Entangling ISWAP gate using frequency shifted anharmonic qubits , FELIX MOTZOI, JAY GAMBETTA, SETH MERKEL, AMIRA ELTONY, FRANK WILHELM, University of Waterloo — In this talk, we examine the coupling between frequency separated qubits, typical of superconducting implementations. We show how to correct for errors coming from finite turn-on time (corresponding to bringing the qubits into resonance) as well as leakage error (corresponding to exciting population out of the qubit manifold), namely by bringing the qubits in and out of resonance repeatedly to cancel out the unwanted parts of the Hamiltonian. The gates presented are smooth and robust and represent a whole class of analytic and numeric solutions for the evolution of the composite system.

3:54PM D27.00006 Analytic control methods for high fidelity unitary operations in a weakly nonlinear oscillator , SETH MERKEL, JAYDE GAMBETTA, FELIX MOTZOI, FRANK WILHELM, University of Waterloo — In qubits made from a weakly anharmonic oscillator the leading source of error at short gate times is leakage of population out of the two dimensional Hilbert space that forms the qubit. In this talk we explore a general technique based on an adiabatic expansion to find pulse shapes that correct this type of error. This leads to a family of solutions that can be further refined based on what is feasible for a particular application. This set of pulses contains and improves upon the previously developed DRAG solution [F. Motzoi, et. al., Phys. Rev. Lett. 103, 110501 (2009)] and can be further generalized to more complicated systems with additional leakage channels.

4:06PM D27.00007 CNOT gate for superconducting qubits biased at their symmetry points , SAHEL ASHHAB, FRANCO NORI, Advanced Science Institute, RIKEN, Wako-shi, Japan, PIETER DE GROOT, KEES HARMANS, HANS MOOIJ, Kavli Institute of Nanoscience, Delft University of Technology, The Netherlands, JÜRGEN LISENFELD, Karlsruher Institute of Technology, Germany, ADRIAN LUPASCU, Institute for Quantum Computing, University of Waterloo, Canada — A number of different techniques have been proposed and demonstrated in the past few years for implementing two-qubit gates in a system of two coupled superconducting qubits biased at their symmetry points. Most of these techniques implement the iSWAP gate. I will discuss a new technique that implements the CNOT gate. The two qubits are driven at the frequency of the target qubit, and the amplitudes applied to the two qubits are chosen such that the target qubit undergoes Rabi oscillations for only one of the two possible states of the control qubit. As a result a CNOT gate can be implemented.

4:18PM D27.00008 Controlled-NOT logic gate based on conditional spectroscopy , MICHAEL GELLER, JOYDIP GHOSH, University of Georgia, Athens — A controlled-NOT logic gate based on conditional rotation of a target qubit by applying a microwave pulse of appropriate frequency has been demonstrated experimentally for a pair of superconducting flux qubits [Plantenberg et. al., Nature 447, 836 (2007)] . Here we discuss a related construction appropriate for coupled phase qubits or a phase qubit coupled to a resonator. Our results show that an intrinsic fidelity of more than 99% is achievable in about 45ns.

4:30PM D27.00009 Quantum Logic Gates for the Rezqu Architecture , JOYDIP GHOSH, MICHAEL GELLER, University of Georgia, Athens — A promising quantum computing architecture has been recently proposed by the UCSB superconducting quantum computation group. In this architecture, n phase qubits are capacitively coupled to individual memory resonators as well as a common bus. In this talk we discuss the design of quantum logic gates for this architecture and discuss the intrinsic fidelities.

4:42PM D27.00010 Idling error and SWAP/MOVE operation in RezQu architecture for phase qubits[1] , ANDREI GALIAUTDINOV, ALEXANDER KOROTKOV, University of California - Riverside — We analyze several basic operations in the RezQu architecture for superconducting phase qubits recently proposed by John Martinis, concentrating on the idling error, generation of single-excitation states, and the single-excitation transfer (which we call MOVE) between a phase qubit and its memory. We show that the idling error is negligible, being proportional to the sixth power of the coupling strength. We also show that in the rotating wave approximation the MOVE operation, which is simpler than the usual SWAP, can be realized perfectly using a tune/detune pulse with four adjustable parameters. The pulse consists of the front ramp (with proper shaping), a constant near-resonant overshoot, and an arbitrary rear ramp.

[1]This work was supported by NSA and IARPA under ARO grant No. W911NF-10-1-0334.

4:54PM D27.00011 Experimental demonstration of quantum algorithms on a 4-qubit/5-resonator quantum microprocessor utilizing superconducting qubits in the RezQu architecture , ERIK LUCERO, RAMI BARENDS, RADOSLAW BIALCZAK, YU CHEN, JULIAN KELLY, MIKE LENANDER, MATTEO MARIANTONI, ANTHONY MEGRANT, AARON O'CONNELL, PETER O'MALLEY, DANIEL SANK, AMIT VAINSENCHER, HAUHOA WANG, JAMES WENNER, TED WHITE, YI YIN, JIAN ZHAO, ANDREW CLELAND, JOHN MARTINIS — We present our newly designed and fabricated 4-qubit/5-resonator quantum microprocessor composed of "off-the-shelf" qubit and resonator components in the RezQu ("rez-(,)kyoo") architecture. The RezQu architecture uses resonators with qubits in the zero state to turn off stray coupling. Each qubit is coupled to a $\lambda/4$ memory resonator and coupling between the qubits is mediated by a common $\lambda/2$ resonator bus. Eight microwave lines drive the individual qubits, memory resonators, and coupling resonator. We demonstrate control over the quantum microprocessor via small scale quantum algorithms that require executing high- fidelity single qubit gates, quantum Fourier transform, Toffoli, CNOT, and other entangling gates.

5:06PM D27.00012 Efficient Toffoli Gate in Circuit Quantum Electrodynamics[1] , MATTHEW REED, Department of Applied Physics and Physics, Yale University, New Haven, Connecticut 06520, USA, LEONARDO DICARLO, Kavli Institute of Nanoscience, Delft University of Technology, Delft, The Netherlands, LUYAN SUN, LUIGI FRUNZIO, ROBERT SCHOELKOPF, Department of Applied Physics and Physics, Yale University, New Haven, Connecticut 06520, USA — The fidelity of quantum gates in circuit quantum electrodynamics is typically limited by qubit decoherence.As such, significant improvements can be realized by shortening gate duration [1, 2]. Thethree-qubit Toffoli gate, also called thecontrolled-controlled NOT, is an important operation in basic quantum error correction.We report a scheme for a Toffoli gate that exploits interactions with non-computational excited states of transmon qubits which can be executed faster than an equivalent construction using one- and two-qubit gates. The application of this gate to efficient measurement-free quantum error correction will be discussed.

5:18PM D27.00013 Progress towards a microwave-based high-fidelity Toffoli gate with superconducting qubits , CHAD RIGETTI, JERRY CHOW, ANTONIO CORCOLES, JIM ROZEN, GEORGE KEEFE, MARY BETH ROTHWELL, JACK ROHRS, MARK BORSTELMANN, DAVID DIVINCENZO, MARK KETCHEN, MATTHIAS STEFFEN, IBM Research — We describe recent progress at IBM towards a microwave-based implementation of the Toffoli gate using three capacitively shunted flux qubits dispersively coupled to a resonator. We discuss the device architecture and the microwave protocol, along with expected limits to gate fidelity and scaling.

Monday, March 21, 2011 2:30PM - 5:30PM –

Session D28 DMP: Focus Session: Graphene Growth, Characterization, and Devices: Metal Substrates C156

2:30PM D28.00001 Theory of the Growth of Epitaxial Graphene on Close-Packed Metals , ANDREW ZANGWILL, School of Physics, Georgia Institute of Technology, Atlanta, GA 30332, DIMITRI VVEDENSKY, Blackett Laboratory, Imperial College, London SW7 2BZ, UNITED KINGDOM — We present a simple rate theory of epitaxial graphene growth on close-packed metals. Motivated by recent low-energy electron microscopy experiments [E. Loginova, N.C.Bartelt, P.J. Feibelman, and K.F. McCarty, New Journal of Physics, **10**, 093026 (2008)], our theory supposes that graphene islands grow predominantly by the addition of five-atom clusters, rather than solely by the capture of diffusing carbon atoms. With suitably chosen kinetic parameters, we find quantitative agreement with (i) the measured time-evolution of the adatom density and (ii) the measured temperature-dependence of the adatom density at the onset of nucleation by assuming that the smallest stable precursor to graphene growth is an immobile island composed of six five-atom clusters.

2:42PM D28.00002 Graphene Growth on Cu Surface: A Theoretical Study[1] , ZHENYU LI, PING WU, WENHUA ZHANG, JINLONG YANG, J. G. HOU, University of Science and Technology of China, THE ELECTRONIC STURCTURE TEAM AT USTC TEAM — Graphene is an important material with many unique properties and a great application potential. A promising way to produce wafer-size graphene is chemical vapor deposition (CVD) on metal surfaces. To improve sample quality, it is important to understand the atomic details during graphene CVD growth. In this talk, some relevant elementary processes on Cu surface have been studied from first principles. Although diffusion of atomic carbon on Cu (111) surface is almost barrierless, coalescence of carbon atoms on the surface is found to be hampered by an intermediate bridging-metal structure. The fact which makes things more complicated is that thermodynamic analysis indicates that the main species on the Cu surface during graphene growth is not the simplest atomic carbon. Therefore, CxHy species should be explicitly considered for initial stage growth of graphene on Cu surface.

[1]Partially supported by NSFC (20933006, 20803071, and 50721091), by MOE (FANEDD-2007B23 and NCET-08-0521), and by MOST(2006CB922004)

2:54PM D28.00003 Graphene Made Easy: A Simple Method to Grow Large-Area Single-Layer Graphene on Copper Foils , S. GADIPELLI, UPENN/NIST, I. CALIZO, NIST, J. FORD, UPENN/NIST, G. CHENG, A. H. WALKER, NIST, T. YILDIRIM[1], NIST/UPENN — In order to realize the remarkable properties of graphene in practical devices, an easy, scalable, and inexpensive synthesis method is necessary. Currently the most promising approach is through chemical vapor deposition (CVD). However, this method requires expensive CVD furnaces and flow controllers, as well as a large amount of explosive gases (H_2 and CH_4). Consequently, it is desirable to establish alternative methods to grow large-area, single-layer graphene that are simple and that can be carried out in an ordinary research laboratory. In this talk, we will discuss our systematic study of the parameters that are critical for high-quality, single-layer graphene formation. Our results not only shed light on the graphene growth mechanism, but have also yielded a straightforward synthesis method that requires neither H_2/CH_4 nor any special CVD equipment. We have prepared graphene samples at the inch scale that have been characterized by Raman spectroscopy, optical transmittance, and sheet resistance measurements. Our method is simple, safe, and economical and will be of value to both fundamental researchers and nanodevice engineers.

[1]Contact author: taner@nist.gov, http://www.ncnr.nist.gov/staff/taner

3:06PM D28.00004 Graphene on metals - structure and properties , JOOST WINTTERLIN, University of Munich — The "metal route" to graphene, i.e., the epitaxial growth of graphene on a metal surface by chemical vapor deposition (CVD) of hydrocarbon molecules and the following transfer of the graphene film to an insulating support, has recently made great progress [see, e.g., S. Bae et al., Nature Nanotechnol. 5, 574 (2010)]. However, structurally and from their charge carrier mobilities, metal-grown graphene samples have not yet reached the quality of exfoliated graphene, most likely resulting from uncontrolled processes during the CVD. In order to better understand how graphene interacts with metal surfaces we have performed a series of surface science studies. As experimental techniques we have applied STM, ARPES, LEED, and SXRD, mainly on Ru(0001)/graphene, and we have performed extensive DFT analyses. We find a short metal-graphene separation, a strong deformation of the graphene, a lifting of the Dirac point, and shifts of the electronic bands. The structural and electronic properties evidence surprisingly strong interactions of the graphene with the Ru surface which are probably prototypical for other metals such as Co, Ni, and Pd. A second group of metals, namely Ir, Pt, Cu, Ag, and Au, only show weak interactions. In situ STM experiments at high temperatures (between 380 and 780 C) show that the usual "carpet mode" by which graphene grows across steps of the metal surface [P. W. Sutter et al., Nature Mater. 7, 406 (2008)] can lead to defects. However, the growth mode changes at high temperatures and low pressures of the hydrocarbon precursor, partially a result of the relatively high Ru-graphene interactions. They lead to a faceting of the surface, and one can grow extremely large single-crystalline graphene films on single terraces in this way.

3:42PM D28.00005 Second-layer graphene growth from below on metals[1] , SHU NIE, ELENA STARODUB, NORMAN BARTELT, KEVIN MCCARTY, Sandia National Laboratories — Once a metal substrate is covered by the first graphene layer, CVD processes slow greatly. However, C dissolved in the metal can still segregate to the surface under the first graphene layer. To determine whether these C atoms nucleate a new layer below or above the first layer, we examine growth on Ir(111), where one-layer graphene has several discrete in-plane orientations relative to substrate directions. LEED reveals that the 1st and 2nd graphene layers are not always rotationally aligned in-plane. This misalignment allows determining which sheets are on the top and the bottom by varying the electron energy and thus the escape depth. We first use LEEM to determine the spatial distribution of rotational domains in a single-layer film. We then cool and observe 2nd layer growth. We find that the top sheet of the bilayer has the exact same domain structure as the initially grown single layer. Thus, new layers are added from below. In this mechanism the nucleation and growth of the 2nd layer strongly depends on the difficulty in debonding the 1st layer from the substrate.
