, MOSTAFA GHOREYSHI, Sharif University of Technology — This study considers blood flow in total cavopulmonary connection (TCPC) morphology, which is created in Fontan surgical procedure in patients with single ventricle heart disease. Ordinary process of TCPC operation reduces pulmonary blood flow pulsatility; because of right ventricle being bypassed. This phenomenon causes a lot of side effects for patients. A cardiac surgeon has suggested that keeping main pulmonary artery (MPA) partially open, would increase pulmonary flow pulsations. MPA gets closed in ordinary TCPC operation. The purpose of current study is to verify the effects of keeping MPA partially open on pulmonary flow pulsations, by means of computational fluid dynamics (CFD). 3D geometry is reconstructed from CT Angiography (CTA) scan of a patient who has undergone an ordinary TCPC procedure. The stenosed MPA or pulmonary stenosis (PS) is virtually added to the original geometry. Flow field is studied in six different models in which average antegrade flow (AF) -coming through PS- increases gradually. Results show that adding AF increases flow pulsations in both pulmonary arteries. Moreover, power loss increases with respect to average AF. We conclude that adding AF is an impressive way to increase pulsations of pulmonary flow, but energy losses should be considered too.

S1.00228 Designing self-oscillating cilia using active polymer gels , PRATYUSH DAYAL, AMITABH BHATTACHARYA, OLGA KUKSENOK, ANNA C. BALAZS, University of Pittsburgh — Using theory and simulations, we model the dynamic behavior of synthetic cilia made from soft, active materials. In designing this system, we harness the properties of polymer gels that undergo photosensitive Belousov-Zhabotinsky (BZ) reaction. Driven by the periodic reduction and oxidation of a ruthenium catalyst that is grafted onto the polymer backbone, these BZ gels undergo rhythmic swelling and de-swelling by chemo-mechanical transduction. When these BZ gels are tethered to a substrate, they form cilia that can pulsate autonomously in response to the BZ reaction. To simulate the behavior of the BZ cilia, we developed a nonlinear 3D model that captures the effect of the diffusive exchange of BZ reagents between the gel and the fluid. Using this approach, we determine the factors that govern the bending and beating of individual cilium. We then turn our attention to multiple cilia and show that their collective dynamics strongly depends on the spacing between them. We also establish criteria to regulate the collective behavior of multiple cilia using light as the external stimuli. Our findings provide guidelines for designing ciliated surfaces that can exhibit biomimetic functionality.

S1.00229 APPLICATIONS —

S1.00230 Terahertz microbolometers based on disordered GaAs and GaN heterostructures , KAI WANG, University at Buffalo, SUNY, R. RAMASWAMY, A. MURAVIEV, A. SERGEEV, V. MITIN, R. GASKA, Sensor Electronic Technology, Inc. — We present our results on design, fabrication, and characterization of hot-electron bolometers based on low-mobility two-dimensional electron gas (2DEG) heterostructures for THz heterodyne detection. Microbolometers based on GaAs/AlGaAs and GaN/AlGaN heterostructures have been fabricated and tested. Low contact resistances (0.2 ohm-mm for GaN and 0.7 ohm-mm for GaAs) were achieved. We determined the carrier concentration from the Hall measurements and the electron relaxation time from the mobility measurements. We also investigated kinetic parameters: temperature derivate of the resistivity and the electron cooling time. Optical characterization includes the transitivity measurements. The results show that the coupling to the THz radiation is mainly due to the Drude absorption, which increases in disordered structures. Temperature-dependent resistivity and electron cooling are determined by inelastic electron scattering on optical phonons. Finally, we compare GaAs and GaN microbolometers and analyze their parameters for various applications in THz sensing.

S1.00231 Quantum cascade lasers as LO for THz mixers , RAHUL RAMASWAMY, Uni at Buffalo , ANDREY MURAVIEV, KAI WANG, CHRISTOPH DEUTSCH, JAEKYU CHOI, DAVID EASON, GOTTFRIED STRASSER, MICHAEL SHUR, ANDREI SERGEEV, VLADIMIR MITIN — In this research we fabricate and characterized a number of Fabry-Perot type, multi mode terahertz quantum cascade lasers operating in the range 2 – 3 THz. AlGaAs/GaAs heterostructures for terahertz QCLs have been grown using molecular beam epitaxy (MBE) on a SI-GaAs substrate. The active region design is based on a vertical transition in which a combination of resonant tunneling and LO-phonon scattering is used to selectively depopulate the lower radiative state. Double-sided metal waveguide is employed for QCL mode confinement. Spectral properties of the QCLs have been investigated by means of Fourier transform spectroscopy. All QCLs show the gain spectral band tunability by varying the applied bias voltage. Single mode laser operation is observed in a certain range of applied bias voltages. Our QCLs have an inherently narrow line-width, which is limited in our measurements by the spectrometer resolution of 0.1cm^{-1}.

S1.00232 Voltage Tunable Multicolor GaAs/AlGaAs Coupled Quantum Well Infrared Photodetector , JAE KYU CHOI, DAVID EASON, GOTTFRIED STRASSER, NIZAMI VAGIDOV, VLADIMIR MITIN, University at Buffalo, SUNY — Tunable quantum well infrared photodetectors (QWIP) has attracted attention because of the mature growth technique of GaAs/AlGaAs quantum wells and their diverse applications such as remote temperature sensing, chemical analysis, military applications, and so on. We have designed, grown, and characterized a voltage tunable multicolor QWIP for the long wavelength infrared detection (7.5 – 12.4 μm). The QWIP structure was grown by MBE, and the device is designed to have bound to bound and bound to quasi-continuum transitions in an asymmetrically doped double quantum well. At zero bias we observed several distinctive spectral lines in photoresponse. The device demonstrates strong dependence on a magnitude and a polarity of the bias that is confirmed by the shift of energy levels in the electric field calculated by nextnano^{3}software. In particular, switching bias from +3V to -5V we change the photoresponse of our detector from 8.39 μm to 10.21 μm.

S1.00233 Localized and Synchronous Measurement of Second and Third Order Nonlinearity in Superconductive Transmission Line Resonators[1] , ANNELLE EBEN, Calvin College, STEPHEN REMILLARD, Hope College — A method to locally observe the generation of nonlinearity of multiple orders inside the passband of $Tl_2Ba_2CaCu_2O_8$ and $YBa_2Cu_3O_7$ superconducting resonators has been developed. Nonlinear emission is stimulated locally in the vicinity of the probe by off-resonance, low frequency signals. By mixing of two very low frequency local currents and of one current in the passband, 2^{nd} and 3^{rd} order intermodulation distortion (IMD) occurs around resonance, permitting the determination of the currents associated with each order of nonlinearity. Synchronous measurement of different orders eliminates the ambiguity of emissions occurring on different time scales and at different skin depths. Comparison of synchronous 2^{nd} and 3^{rd} order IMD characterizes the extent of time reversal symmetry breaking (TRSB) in the superconductor. This technique is being used to perform spatially resolved TRSB studies, to examine the effect of doping on nonlinearity in $Tl_2Ba_2CaCu_2O_8$, and to search for a correlation between lithographic edge quality and 2^{nd} and 3^{rd} order nonlinearity.

S1.00234 ABSTRACT WITHDRAWN —

S1.00235 Analysis and Simulation of Generating Terahertz Surface Waves in Laser-Assisted Field Emission , MARK HAGMANN, NewPath Research L.L.C., GAGAN KUMAR, SHASHANK PANDEY, AJAY NAHATA, University of Utah — When the radiation from two lasers is focused on a field emission diode the electric field from the radiation is superimposed on the applied DC field, and the nonlinear dependence of the emitted current on the electric field causes the current to oscillate at the difference frequency for the two lasers. Finite Difference-Time Domain simulations and analytical solutions for a paraboloidal model of the field emission tip show that the current oscillations create a transverse-magnetic (TM) surface wave on the tip. The analytical solution for the TM fields in paraboloidal coordinates consists of products of regular and irregular Coulomb wave functions. The width of the tip is much smaller than the skin depth so interior and exterior solutions are required and a summation of the products is required to satisfy the boundary conditions at the surface of the tip. The simulations are consistent with the analytical solution and show that there is a quasi-stationary region near the apex, a transition region where the surface waves are formed, and the far-field where the waves propagate outward on the tip.

S1.00236 Antireflective Coatings using Layer by Layer Self Assembly of Silica and Titania Nanoparticles

, ANITESH LAL, RAISA VELASCO CASTEDO, DAN MAZILU — Antireflective coatings have a wide range of applications and its usefulness can be found in devices such as cameras, binoculars, microscope lenses, solar panels etc. The major expectation for this research is to add an antireflective coating to a glass substrate which will reduce the reflectance and increase the transmittance of light of the substrate. From theory it is known that uncoated glass substrates transmit approximately 92% of light and reflect approximately 8% of it. However, if an antireflective coating is introduced on the surface of the substrate, there will be some light reflected from the first interface and some from the second interface. If these two reflected rays are made to interfere destructively, reflection can be minimized thus maximizing transmittance. We conducted various experiments with silica particles only in which we tried to change the properties of this antireflective coating such that maximum destructive interference could be achieved. Currently, we are working with a combination of silica and titania nanoparticles with varying thicknesses whereby layers have thickness of a quarter of the desired wave length. So far a number of different factor-level combinations have exhibited transmittance in excess of 96%, well above that of an untreated slide and comparable to commercial coatings.

S1.00237 Light Instability in Pulsed Quantum Cascade Lasers[1]

, YUTING HUANG, Princeton University, YU YAO, Princeton University and MIRTHE, KAIS AL-NAIMEE, National Institute of Applied Optics, University of Florence, Florence, Italy, CLAIRE GMACHL, Princeton University and MIRTHE, MIRTHE TEAM — The instability observed in the light output of high power, pulsed Quantum Cascade (QC) lasers is investigated for potential periodic behavior. We built a set-up to monitor the real-time pulse shape of up to 5,000 sequential light pulses at a fixed pulsed current. In analyzing the data, we use the Fast Fourier Transform to find their frequency components. We found likely quasi-periodic behavior, as well as a broader range of frequencies around the fundamental pulse frequency. To also research a potential spatial component in the laser instability, i.e. beam steering, we modified the set-up to split the beam spatially into two parts, each monitored in real-time over 5,000 pulses. A correlation between the two pulse trains on the two detectors separates the spatial and pure power components of the instability. Subsequently eliminating this instability will help to achieve QC lasers with optimal performance.

S1.00238 Modeling Laser-Tissue Interactions: Implementing the Heat Diffusion Equation and Wave Equation to Simulate Thermal Interactions of Absorber Distributions in Biological Tissues[1]

, FREDERICK BARRERA, ELHARITH AHMED, PATRICK NASH, DHIRAJ SARDAR — The tracking of photons through turbid media (e.g. tissues) has been studied extensively from an experimental vantage point. These turbid media are difficult to characterize- since their components are exceedingly variegated- and thus present many challenges to clinicians who require models which precisely predict the location and time evolution of energy deposition. Furthermore, the interaction of the turbid media sample with the source of radiation typically involves many dynamic mechanisms (e.g. photothermal etc.) Using diffuse light transport, and an electromagnetic wave approach (e.g. Maxwell's equations), an analysis of thermal energy distribution in tissues is performed. Assuming a highly absorbing chromophore model of melanocytes in tissues, a comparison of the variation of thermal energy is determined for different collections of melanocyte spatial distributions.

S1.00239 Tunable TiO2 Nanotubes as Nanotemplate for Solar Cells[1]

, JIA LU, DONGDONG LI, USC, NAMI TEAM — Titanium oxide (TiO2) is an n-type semiconductor with a bandgap energy of 3.0-3.2 eV. It has broad applications, because of the versatile functionalities. Synthesis of anodic titanium oxide (ATO) nanotube templates has gained significant progress in fluoride-ion-contained electrolytes. The one-dimensional (1D) structure provides a large specific surface area as well as a direct pathway for charge transport, thus rendering superior capabilities in lightharvesting, electrochromic switching, environmental sensing, energy storage, etc. In this work, highly ordered ATO nanotubes film has been synthesized by two-step anodization method. After using a reductive doping approach, the metal materials (Cu and Ni) can be electrodeposited into the nanotubes. The versatile process yields reproducible tubular structures in ATO nanotubes due to the conductive nature of crystallized TiO2, indicating great potential for nanotemplate application. A dye-sensitized solar cell is also demonstrated by employing the ATO films. It is observed that bottom treatment greatly enhances short current density and filling factor resulting in improved energy conversion efficiency.

S1.00240 Theoretical Investigation on Cysteine Interactions with Gold Nanoparticles

, JESSICA CARR, HONG WANG, JAMES LEWIS, Physics Department, West Virginia University, Morgantown, WV 26506-6315 — Gold nanoparticles have been intensely investigated due to wide applications in colloidal chemistry, catalysis, medical science, etc. Lately, experiments have shown that ligand-stabilized gold nanoparticles provide a platform for precisely probing the structural and electronic properties of isolated gold nanoparticles, allowing us to further understand the interaction between gold nanoparticles and attaching ligand molecules. Using density functional theory approach, we investigate a series of gold nanoparticles with a size scale of 0.5 to 2 nm that are passivated by a monolayer of cysteine molecules [R-SH, with R=$CH_2CH(COOH)(NH_2)$]. There is a controversy about the attaching pattern of the cysteine monolayer around the gold nanoparticles. We speculate that there is hydrogen bonding between the cysteine molecules, leading to stabilized gold nanoparticles. This research shows potential hydrogen bonding forming with the gold nanoparticle surface, as well as hydrogen bonding between cysteine molecules.

S1.00241 Photocurrent enhancement of an individual gallium nitride nanowire decorated with gold nanoparticles[1]

, JENCY PRICILLA SUNDARARAJAN, MEREDITH SARGENT, DAVID N. MCILROY, Department of Physics, University of Idaho, Moscow, ID 83844 — Variation in electron transport properties of individual n-type gallium nitride (GaN) nanowire and gold decorated gallium nitride (Au-GaN) nanowire were studied with respect to laser exposure of different wavelength and intensity. Single nanowire devices were manufactured by photolithography process in nanotechnology cleanroom, were characterized by scanning electron microscope (SEM) and transmission electron microscope (TEM). A drop in electrical conductivity of Au-GaN nanowire was observed relative to bare GaN nanowire. Under laser illumination, we noticed an enhancement in photocurrent in Au-GaN nanowire, which increased with increase in excitation power at ambient conditions. We present a comparative study of the opto-electrical behavior of bare GaN nanowire vs Au-GaN nanowire and explain the IV characteristics and FET characteristics with respect to the length and diameter of nanowire.

[1]USDA, UI-BANTech

S1.00242 Pulsed Laser Synthesized Magnetic Cobalt Oxide Nanoparticles for Biomedical Applications , HARI BHATTA, Missouri State University, RAM GUPTA, KARTIK GHOSH, PAWAN KAHOL, ROBERT DELONG, ADAM WANEKAWA — Nanomaterials research has become a major attraction in the field of advanced materials research in the area of Physics, Chemistry, and Materials Science. Biocompatible and chemically stable magnetic metal oxide nanoparticles have biomedical applications that includes drug delivery, cell and DNA separation, gene cloning, magnetic resonance imaging (MRI). This research is aimed at the fabrication of magnetic cobalt oxide nanoparticles using a safe, cost effective, and easy to handle technique that is capable of producing nanoparticles free of any contamination. Cobalt oxide nanoparticles have been synthesized at room temperature using cobalt foil by pulsed laser ablation technique. These cobalt oxide nanoparticles were characterized using UV-Visible (UV-Vis) spectroscopy, transmission electron microscopy (TEM), and dynamic laser light scattering (DLLS). The magnetic cobalt oxides nanoparticles were stabilized in glucose solutions of various concentrations in deionized water. The presence of UV-Vis absorption peak at 270 nm validates the nature of cobalt oxide nanoparticles. The DLLS size distributions of nanoparticles are in the range of 110 to 300 nm, which further confirms the presence nanoparticles. This work is partially supported by National Science Foundation (DMR- 0907037).

S1.00243 Diffusion Through Tubular Nanotubes , DIVYA NARAYAN ELUMALAI, Louisiana Tech University, HERVIN MONLOUIS, Grambling State University, PEDRO DEROSA, Louisiana Tech University and Grambling State University — Nanotubes exhibit exceptional properties that make them promising candidates for many applications that require the transport, storage and/or delivery of fluids, through nanotubes. In order to efficiently plan potential applications, transport properties and interactions such as adsorption, diffusion, and solvent interactions must be understood. Our study focuses on the mechanisms that inhibit or encourage diffusion through these nanostructures and the nature of the interactions responsible for movement of any sort in these regimes. As a specific case we study diffusion through tubular nanotubes. This work treats each interaction individually and aims at successfully modeling the diffusion of particles through the nanotubes as a function of the interaction between the diffusing particles and the nanotube walls. To conduct this research we have employed Monte Carlo calculations, implementing a specific forced random walk algorithm. Preliminary results suggest that any delay in diffusion occurs due to a strong molecule-wall interaction. We believe this is due to the columbic attraction between the diffusing particles and the wall.

S1.00244 Role of CNTs in inorganic electroluminescence , JIN-YOUNG KIM, Sungkyunkwan Univ., SEGI YU, Hankuk Univ. Foreign Studies — Inorganic electroluminescence (EL) has been considered to be utilized in flat panel displays in the future. However, the progress of the display device utilizing EL phosphor is rather mild due primary to its low brightness, high voltage operation, and poor expectation lifetime. Carbon nanotubes (CNTs) has been focused in many areas since this material has a number of useful characteristics such as good chemical inertness, high aspect ratio, good thermal conductivity, and etc after the first observation by Dr. Iijima. By adopting (CNTs) in inorganic EL devices of ZnS-based powder phosphor, the performance of devices has improved substantially, i.e., high brightness but with reduced current density. The main reason for this improvement is considered to be caused by the strong local field near the end tips of CNTs. Further efforts have been poured to use the enhanced local field around CNTs but with an intention to maintain the low current density. The details will be posted in this poster and underlying mechanism for this phenomenon will be explained. Email: segiyu@hufs.ac.kr

S1.00245 Graphene Transistor fabricated by Helium Ion Milling , KAIWEN ZHANG, XIANGMING ZHAO, XIANGFAN XU, VISWANATHAN VIGNESH, BAOWEN LI, DANIEL PICKARD, BARBAROS ÖZYILMAZ, National University of Singapore, DEPARTMENT OF PHYSICS, NATIONAL UNIVERSITY OF SINGAPORE TEAM, DEPARTMENT OF ELECTRICAL & COMPUTER ENGINEERING, NATIONAL UNIVERSITY OF SINGAPORE TEAM, ENANOCORE, NATIONAL UNIVERSITY OF SINGAPORE TEAM — We report the direct patterning of graphene for various nano-device applications. The Helium Ion Microscope (HIM), able to resolve nano-scale features on solid samples with an edge resolution of a mere 0.25 nm, has a number of attributes which make it attractive for the imaging of graphene structures. Even more compelling is the ability to directly modify graphene, through surface sputtering, enabling direct pattern transfer for the fabrication of graphene devices. The integration of the HIM with a vector pattern generator (Nano Pattern Generation System, NPGS), provides the capability to directly pattern graphene into nano-ribbons. We have successfully fabricated sub-100nm graphene nano-ribbon devices on Si/SiO2 substrate. Resistance measurement has been made as a function of temperature.

S1.00246 Novel nanostructured high efficiency light-harvesting device structure for a solar cell application , KYUNG-MIN LEE, POOJA SINGH, ARUP NEOGI, SANG-KWON LEE, TAE-YOUL CHOI — In this study, we present a novel photoconductive device structure for a solar cell application. β-Silicon Carbide (β-SiC) nanowire(NW) was placed in between silver (Ag) nanodot(ND) array. With much shorter size than an incoming photon wavelength, Ag ND created plasmonic oscillation, mainly attributed to dipole oscillating term, according to Mie scattering theory. Because of more optical modes in the higher refractive index, the radiation pattern from the dipole oscillation was mostly expanded onto the β-SiC NW rather than free space. We found that Ag ND array played role as collecting and concentrating light to create denser optical paths into the semiconducting β-SiC NW, which in turn provided higher quantum yield for photoconductivity. Since the structure was nanoscaled (i.e. NW and ND), this novel device structure can be a miniaturized building block for high demanding solar cell applications as one of the energy solutions.

S1.00247 Ultrafast Optical Measurements of Thermal Conductivity and Sound Velocity of Amorphous SiC[1] , DONALD HONDONGWA, LAUREN OLASOV, BRIAN DALY, Vassar College, SEAN KING, JEFF BIELEFELD, Intel Corporation — We present ultrafast optical measurements of longitudinal sound velocity and thermal transport in hydrogenated amorphous carbon (a-SiC:H) films. The films were grown on Si wafers by PECVD using combinations of methylsilanes and H_2 and He diluent gases. The films were well characterized and found to have densities (1.0 – 2.5 g cm^{-3}) and dielectric constants (2.8 – 7.2) that spanned a wide range of values. Prior to their measurement, the a-SiC:H films were coated with 40-70 nm of polycrystalline Al. The pump-probe measurements were performed at room temperature using a modelocked Ti:sapphire laser. Transient reflectivity changes that are associated with very high frequency sound waves (picosecond ultrasonics) and the cooling rate of the SiC sample (Time Domain Thermorerflectance (TDTR)) were measured. We extract values for the thermal conductivity and sound velocity of the SiC films, and analyze the results in terms of rigidity percolation effects within the SiC layers.

[1]This work was supported by NSF award DMR-0906753.

S1.00248 Ultrafast optical measurements of ultrasound attenuation in amorphous silicon at 50 and 100 GHz[1] , BRIAN DALY, DONALD HONDONGWA, Vassar College, THEODORE NORRIS, University of Michigan, BAOJIE YAN, JEFF YANG, SUBHENDU GUHA, Uni-Solar Ovonic LLC — We present ultrafast optical measurements of the attenuation of 50 – 100 GHz ultrasound in hydrogenated amorphous silicon (a-Si:H) thin films. The films were grown using a modified very high frequency glow discharge method on steel substrates. The deposition conditions were similar to those used for high efficiency solar cells. The measurements were performed at 300 K using the picosecond ultrasonics technique. Films of varying thickness were measured so that the effect of intrinsic acoustic loss within the a-Si:H could be determined. We find that the ultrasonic attenuation in a-Si:H at 100 GHz is more than an order of magnitude lower than is found in other amorphous materials. Our results may impact theoretical models of thermal transport in amorphous materials, and could provide a new avenue for studying voids in a-Si:H and nanocrystalline Si films.

S1.00249 Charge Carrier Mobility in Conjugated Organic Polymers–A Multi-Step Computational Approach[1]

, YAPING LI, JOLANTA B. LAGOWSKI, Memorial University of Newfoundland — In this work, we investigate charge transport characteristics of conjugated organic polymers (mostly fluorene and carbazole based) used in the construction of the organic solar cells using computational means. In particular we employ a multi-step approach that involves the use of the density functional theory (DFT), semiempirical (ZINDO), and Monte Carlo (MC) theoretical methods to determine their transfer integrals, reorganization energies, transfer rates and mobilities. We find that, in organic conjugated polymers, one dimensional (1D) approach to estimating trends in mobilities gives reasonable results, i.e. is in good agreement with experiment trends, provided their relative intermolecular distances can be obtained with some accuracy. However, greater understanding of the mobilities must take into account the three dimensional (3D) structure and/or the inherent disorder that is present in the organic thin films. We illustrate this requirement with some case studies. Another case study involving orientational disorder will also be presented. The proposed approach illustrates that theoretical computations/simulations based on chemical structure and known morphology of organic semiconductors is an important and reliable approach to studying charge mobility in organic materials used in devices such as solar cells.

S1.00250 High Thermoelectric Performance from Solution-Processed Conducting Polymer/Inorganic Composite Films

, NELSON COATES, SHANNON YEE, University of California, Berkeley, KEVIN SEE, JEFFREY URBAN, Lawrence Berkeley, National Laboratory, RACHEL SEGALMAN, University of California, Berkeley — Conducting polymer/inorganic composite films have great potential for use as thermoelectrics due to the possibility of combining the high electrical conductivity of inorganic materials with the low thermal conductivities of polymer materials. Additionally, the possibility of engineering nanoscale interfaces in these hybrid systems provides a unique means of optimizing thermoelectric figures of merit. We have fabricated films from this new class of materials, and examined their thermoelectric properties. Our solution-processed films, which consist of an inorganic nanostructure matrix linked with conducting polymer ligands, exhibit an electrical conductivity that is greater than either of its components and a thermopower that varies as a function of inorganic nanocrystal-conducting polymer ratio.

S1.00251 Probing the Fluid-Graphene Interface for Electrochemical Storage by *in-situ* Synchrotron X-ray Scattering

, HUA ZHOU, PAUL FENTER, Argonne National Laboratory, JAKE MCDONOUGH, VOLKER PRESSER, YURI GOGOTSI, Drexel University, PASQUALE FULVIO, SHENG DAI, Oak Ridge National Laboratory — The interactions of electrolyte fluids with solids control many complex interfacial processes encountered in electrochemical energy storage systems. In this talk, we will demonstrate how to develop a fundamental atomic-scale understanding of interfacial structures and processes at the electrolyte-graphene interface. We have performed systematic measurements of high resolution X-ray reflectivity from epitaxial graphene films in contact with electrolytes including aqueous solutions and room temperature ionic liquids. The electron density profiles and structural models from the fully analyzed data reveal the intrinsic interfacial structures of these systems. Moreover, we have developed successfully a customized electrochemical sample cell that allows the solvent reorientation and ion adsorption measurements to be done in-situ with control of the surface potential. Specular Bragg rod and resonant anomalous X-ray reflectivity measurements were performed in combination with electrochemical characterizations. The combination of in-situ structural measurements with electrochemical controls will lead to fundamentally new insights and provide unique tests of atomistic fluid-solid interface models for energy storage systems.

S1.00252 *ab initio* Thermodynamic Approach to Identify Good Solid Sorbents for CO_2 Capture Applications

, YUHUA DUAN, National Energy Technology Lab. — By combining thermodynamic database searching with first principles density functional theory and phonon lattice dynamics calculations, a theoretical screening methodology to identify most promising candidates for CO_2 sorbents has been proposed (Duan & Sorescu, PRB(2009), JCP(2010)). For given solids, first we can search their thermodynamic properties from thermodynamic databases and literatures. If their thermodynamic properties are unknown, we perform *ab initio* thermodynamic approach to calculate them out. These properties are used for computing the thermodynamic reaction equilibrium properties of CO_2 absorption/desorption cycle based on the chemical potential and heat of reaction analysis. According to the pre- and post- combustion technologies and conditions in power-plants, based on our calculated thermodynamic properties of reactions for each solid capturing CO_2 varying with temperatures and pressures, only those solid materials, which result lower energy cost in the capture and regeneration process and could work at desired conditions of CO_2 pressure and temperature, will be selected as promised candidates of CO_2 sorbents and further be considered for experimental validations.

S1.00253 ABSTRACT WITHDRAWN –

S1.00254 Development of semi-rigid coaxial cables for application to low temperature experiments

, AKIHIRO KUSHINO, Asahikawa National College of Technology, SOICHI KASAI, COAX CO., LTD. — Fast signal readout with low noise is essential for spectrometric research. Superconducting spectrometers operating below ∼1K are promising with their high spectral resolution, detection efficiency and counting rate. Cables connecting these spectrometers and electronics at high temperature must be coaxial and have low thermal conductance in order to reduce heat into low temperature. We have developed thin semi-rigid coaxial cables using low thermal conductivity alloys, CuNi, SUS and NbTi, for both center and outer conductors. The outer conductor is seamless and separated from the center conductor by a PTFE electrical insulator. We have assembled an adiabatic demagnetization refrigerator (ADR) at the 2nd stage of a GM cryocooler, which enables to cool the coaxial cables below 1K, and have measured low thermal conductance and performance of the cables at high frequencies up to ∼5 GHz.

S1.00255 HIGH PRESSURE PHYSICS –

S1.00256 High-Pressure Structural Studies of AuX_2 (X = Al, Ga, In)[1]

, JASON BAKER, RAVHI KUMAR, ANDREW CORNELIUS, HiPSEC and Dep. Physics, University of Nevada, Las Vegas — High-pressure x-ray diffraction experiments were performed on the group of intermetallic compounds, AuX2 (X = Al, Ga, and In), which at ambient conditions crystallize in the CaF2 [Space group Fm3m] structure. The previously reported retention of the CaF2 phase until 24 GPa in AuIn2 was not observed in these experiments, and instead was observed to undergo a pressure-induced phase transition at 13 GPa. Both AuAl2 and AuGa2 undergo pressure-induced phase transitions at 15 GPa and 9 GPa, respectively. The structural details and the phase transition sequence in these compounds will be presented.

[1]Work at UNLV is supported by DOE [DE-FC52-06NA27684] and NNSA.

S1.00257 High Pressure XRD Structural Study of Intermetallic Hydrogen Storage Material $ZrFe_2$[1] , DANIEL ANTONIO, RAVHI KUMAR, ANDREW CORNELIUS, HiPSEC, Physics Dep. University of Nevada, Las Vegas — Intermetallic compounds show high hydrogen sorption capacities when pressurized with hydrogen. Further, they are also used in hydride compressors [1]. The structure of intermetallic $ZrFe_2$, which can contain about 1.7 wt/GPa, was studied using XRD at high pressures up to 47 GPa using a diamond anvil cell and synchrotron x-rays. The cubic Fd3m Laves phase is found to be stable and the bulk modulus was found to be 163.5 GPa which compares well with other intermetallics. The variation of unit structural parameters and the equation of state are discussed.

[1]Work at UNLV is supported by DOE [DE-FC52- 06NA27684]

S1.00258 Towards a phase diagram for accreting neutron star crusts: total energy calculations of close packed lattices , TYLER ENGSTROM, VINCENT CRESPI, BENJAMIN OWEN, Penn State University — Neutron star crusts are somewhat less exotic than their cores, but may still play an important role in observable astrophysical phenomena, such as pulsar glitches and cooling rates. Recent nucleosynthesis calculations of accreting material being burned and buried on a neutron star crust indicate the possible presence of many species, ranging from around Z=8 to Z=34. In the outer crust regime where these species are completely pressure ionized and have screened-Coulomb interactions due to the relativistic Fermi electron gas, we expect some close-packed lattices may have a lower free energy than the bcc structure that is usually assumed to exist. Our poster shows the results of ground state energy calculations for several candidate binary and ternary close-packed lattices. We compare these ground state energies to those for pure phase separated bcc and fcc structures.

S1.00259 Structure stability of multiferroic compound Bi2NiTiO6 under high pressure and temperature , JINLONG ZHU, Los Alamos National Laboratory, CHANGQING JIN, Institute of Physics, CAS, YANCHUN LI, XIAODONG LI, JING LIU, Institute of High Energy Physics — Structural of multiferroics Bi2NiTiO6 under high pressure was studied in diamond-anvil cell (DAC) combined with synchrotron radiation X-ray diffraction. Crystal structure refinement shows that there are two isostructural phase transitions at $\sim$2 GPa and in the range of 15.5$\sim$18.5 GPa, respectively. The bulk modulus was derived from Birch-Murnaghan equation of state (EOS). Bi iron discontinuous movement is thought to be the source of all the isostructural phase transitions. Temperature dependence of X-ray diffractions were collected from room temperature up to 550 $^{\circ}$C. Structure refinement shows that an isostructural phase transition at temperature higher than 550 $^{\circ}$C can be compare with the isostructural phase transition in the range of 15.5$\sim$18.5 GPa.

S1.00260 GENERAL PHYSICS II —

S1.00261 Proposal to reduce the carcinogenic character of electromagnetic radiation (EMR) , MARJORIE LUNDQUIST, The Bioelectromagnetic Hygiene Institute — Non-ionizing electromagnetic radiation (NIEMR) interacts with matter in 3 ways:[1] it can transfer energy, linear momentum, and angular momentum to matter. At high frequencies (*e.g.*, microwaves), evidence exists of a carcinogenic effect on living creatures irradiated with NIEMR.[2] Which effect is carcinogenic? NIEMR heats matter by transfer of energy; this effect is used to **kill** established cancers. Transfer of linear momentum to matter merely alters the local pressure; cancer has never been associated with pressure changes. So the transfer of non-zero angular momentum to matter is the interaction most likely to be carcinogenic. EMR polarization can be circular, elliptical, or plane. Only plane-polarized EMR possesses **zero** angular momentum and therefore **cannot** transfer any angular momentum to matter. Everything that is true of NIEMR is also true of ionizing EMR, so it seems likely that the carcinogenic potential of **all** EMR (whether ionizing or non-ionizing) will be minimized by filtering it or taking other steps to make it plane-polarized before using it to irradiate a person or animal. Obvious applications are medical/dental X-rays and the full body scanners used on travelers at airports.

S1.00262 Good science, deceptive science, and fraud, plus a brief discussion of peer review , MARJORIE LUNDQUIST, The Bioelectromagnetic Hygiene Institute — What makes scientific publication different from other types of publication? Traditionally, it was that scientists published not only their conclusions, but also their data (which enabled others wanting to re-evaluate the data to do so). Publishing their data helped keep scientists honest. In the mid-20^{th} century the policies of scientific journals changed, partly because very large data sets were being evaluated via computer. Many (but not all) scientific journals paid homage to scientific tradition by establishing archives for data serving as the basis for published scientific papers, while only a description of the study and the conclusions were published in the peer-reviewed scientific journals. This set the stage for scientific deception and scientific fraud, which became widespread in certain fields of study during the latter part of the 20^{th} century. Indeed, some organizations were established that appeared to be legitimate scientific societies, but in fact existed for the purpose of promoting the **incorrect** evaluation of scientific data and publishing deceptive studies masquerading as sound scientific studies. The field of medicine has also become more science than art, with its current emphasis on "evidence-based medicine." The different types of scientific deceit/fraud are identified, and a lifetime of experience with the correction of scientific error, plus encounters with scientific deception and scientific fraud, is summarized.

S1.00263 Both Perelmans Thrown Down Gauntlets Versus Would-Be "Science" But Alas Sadly Mere "SEANCES" Put Jargonial-Obfuscation Sociological-Dysfunctionality(S-D) Ridden/Dominated Would-Be "Sciences" But Alas Sadly Mere SEANCES in "Peril, Man"!!! , J. S1.00265 POST-DEADLINE —

S1.00266 Structural and Dielectric Study of (Dy,Er,Ho)CrO_3 Biferroic Compounds[1] , CESAR MEZA, JESUS SIQUEIROS, ALEJANDRO DURAN, CNYN-UNAM — Technological progress, especially in electronic applications, demands increasingly advanced substances, capable of performing a variety of tasks while simultaneously occupying less space than their predecessors. An answer to this demand lies within the realm of multiferroics. Multiferroic materials are defined as those single phase compounds where more than one ferroic order coexists; they generally belong to the perovskite group. One manifestation of multiferroicity, magnetoelectricity, requires the coexistence of spontaneous electric polarization and magnetic ordering. It is for this reason that rare-earth chromites have been selected as suitable candidates. This work is concerned with synthesis, characterization and dielectric response of the $DyCrO_3$, $ErCrO_3$ and $HoCrO_3$ ceramic compounds. The samples were synthesized by both the traditional solid state ceramic method, and the self-propagating combustion method. The resultant chromites were characterized by TG, DTA and XRD, which confirms the Pbnm space group. Additionally, conductivity analysis was performed and the associated activation energy determined for each system using experimental values and Arrhenius law.

[1]Thanks are due to DGAPA-UNAM for financial support through projects no. IN112909 and IN105711.

S1.00267 Simulation of infrared photodetectors from single-electron models[1] , NELSON STUDART, Dept. de Fisica - UFSCar, MARCOS H. DEGANI, MARCELO Z. MAIALLE, FCA - UNICAMP, PAULO F. FARINAS, Dept. de Fisica - UFSCar — We present results from simulations of potential structures with the method of the split operator. The method is applied to solve for electrons in potential profiles that are typical in the description of quantum dot infrared photodetectors. Various quantities of interest are calculated without the necessity of having the energy spectrum, simulating quantities like the photocurrent directly from a model hamiltonian. By using realistic band offset and mass parameters taken from devices, we are able to explain recent exeperimental results by referring to multiple-photon absorptions. In particular, strong resonance peaks observed in the $\sim 10\mu$m wavelength range in recently fabricated InAs quantum dot infrared photodetectors are obtained from the direct use of intrinsic band and mass parameters. Multiphoton scattering of electrons localized in the quantum dots are not only in accordance with the observed patterns, but are also necessary to explain the photocurrent spectrum obtained in the single-electron calculations.

[1]The authors aknowledge support from CNPq

S1.00268 Extremely nondegenerate two-photon absorption in semiconductors , DAVID HAGAN, CREOL, University of Central Florida, CLAUDIU CIRLOGANU, Georgia Institute of Technology, SCOTT WEBSTER, DMITRY FISHMAN, ERIC VAN STRYLAND, CREOL, University of Central Florida — Degenerate two-photon absorption, 2PA, in direct-gap semiconductors has long been known to scale with the inverse third power of the band gap, resulting in very large 2PA coefficients for narrow-gap semiconductors. We show that for any given pair of photon energies, (sum $=\hbar\omega_1 + \hbar\omega_2$), the 2PA is smallest for the degenerate case, $\omega_1 = \omega_2$, and is enhanced by orders of magnitude in the extremely nondegenerate case ($\omega_1/\omega_2 >> 1$ *or* $\omega_1/\omega_2 << 1$). We experimentally demonstrate that 2PA in direct-gap semiconductors (e.g. GaAs, CdTe, ZnSe, ZnO, GaN) is enhanced over the degenerate value by up to 3 orders of magnitude using extremely nondegenerate pairs of photons (energy ratios $\sim$10/1). These extremely nondegenerate 2PA coefficients are similar in magnitude to coefficients obtained in narrow-gap semiconductors such as InSb and make 2PA feasible for applications such as subfemtosecond gated detection, all-optical switching etc. We demonstrate gated detection in a GaN LED used in a reverse-biased detection mode with fs 5.6μm and 400nm pulses. We see nearly 4 orders of magnitude enhancement over the degenerate case and can also easily detect sub-nW of IR light using modulation methods.

S1.00269 Transport properties of superconducting La and Ce-based ferropnictides , S.J. SINGH, School of Physical Sciences, Jawaharlal Nehru University New Delhi-110067 India, J. PRAKASH, A.K. GANGULI, Department of Chemistry, Indian Institute of Technology New Delhi-110016 India, S. PATNAIK, School of Physical Sciences, Jawaharlal Nehru University New Delhi-110067 India — To understand the role of chemical pressure, we have synthesized a variety of La and Ce-based ferropnicides (La/Ce)OFeAs with substitution of Y, F, Co and Sb in place of La/Ce, O, Fe and As respectively. A broad spectrum of characterizations involving XRD, SEM, magnetoresistance, magnetization, penetration depth, Hall effect and thermoelectric power have been undertaken on these phase pure superconducting compounds. The transition temperature and upper critical field reached maximum of 48.6 K & 146 T in Ce-based sample whereas 35 K and 122 T in La-based superconductor. The magnetization measurements of all samples showed negligible hysteresis reflecting weak link behaviour or an imperfectly connected superconducting state. The thermoelectric power and Hall measurement confirmed the dominant role played by electrons in these multiband superconductors. The rf penetration depth analysis indicated s-wave pairing symmetry with multiple gap values.

S1.00270 Pulsed versus d.c. I-V characteristics of charge-ordered $LuFe_2O_4$, BERTINA FISHER, JAN GENOSSAR, LARISA PATLAGAN, GEORGE MICHAEL REISNER, Physics Department, Technion, Haifa — We report on electronic transport measurements in a polycrystalline sample of $LuFe_2O_4$, over a wide range of electric fields and at temperatures above 230 K , - the range of temperatures was limited by the high resistivity of the sample . This work was motivated by reports about striking non-linear conductivity in polycrystals and single crystals of this multiferroic, in relatively moderate electric fields. Using short ($\sim$msec) single current pulses four probe measurements detected no deviations from linearity in the I-V characteristics, in fields up to E $\approx$ 500 V/cm. However, strong non-linearity and hysteresis were found in d.c. measurements at fields that decreased with increasing temperatures, suggesting self-heating. We include a set of oscillograms showing the time dependence of the voltages between the various probes at fixed current and temperature, which emphasize the importance of time domain studies of non-linear conductivity effects. We gratefully acknowledge Prof. Young Sun from the Institute of Physics, Chinese Academy of Sciences, Beijing, P.R. China, for providing us with the $LuFe_2O_4$ sample.

S1.00271 A Ferroelectric Photovoltaic Capacitor Capable of Direct Solar Energy Conversion and Storage

, CHI-WEI LO, Materials Science Program, University of Wisconsin Madison, CHENSHA LI, HONGRUI JIANG, Department of Elecrical and Computer Engineering, University of Wisconsin Madison — Current solid state photovoltaics and conventional photoelectrochemical cells are not capable of directly storing the converted energy which has to be facilitated by connecting to external storing devices, thus increasing the system complexity. It would thus be highly desirable to create photovoltaic devices that can store solar energy directly. We here report a photo-rechargeable photoelectrochemical capacitor with direct conversion and storage capability by utilizing ferroelectric polyvinylidene fluoride (PVDF) gel with energy storing capability between anode and cathode. With the aid of ferroelectric effect, the device is able to maintain equilibrium between electric field and diffusion force. Results have shown that the device can be charged photovoltaically under 1 sun equivalent of irradiance to an open-circuit voltage of 0.47V, and with capacity of 40.63mC/cm^2. The storage lasts more than 24 hours. Electrochemical impedance analysis and ferroelectric hysteresis are also carried out to show its energy storing capability.

S1.00272 Chiral noncoplanar magnetic ordering driven by itinerant electrons on the pyrochlore lattice[1]

, GIA-WEI CHERN, Department of Physics, University of Wisconsin - Madison — In magnets with strong geometric frustration, the inability of spins to simultaneously satisfy the preferred local correlations leads to an extensive ground-state degeneracy at the classical level. The macroscopic degeneracy is lifted when other perturbations are taken into account. In general, collinear or coplanar magnetic orders are selected by perturbations which preserve the spin-rotational symmetry. Here we show that a complex *noncoplanar* magnetic order with a quadrupled unit cell is stabilized by itinerant electrons on the pyrochlore lattice [1]. Specifically we consider a Kondo-lattice model in which itinerant electrons interact with localized spins via on-site exchange coupling. The electron Fermi 'surface' at quarter filling is topologically equivalent to three intersecting Fermi circles. The noncoplanar magnetic order stems from a weak-coupling instability caused by perfect nesting of the Fermi circles. The magnetic structure characterized by a definite handedness also breaks the chiral symmetry. The chiral order might persist without magnetic order in a chiral spin liquid at finite temperatures.

S1.00273 Including many-body screening into self-consistent calculations–tight-binding model studies with Gutzwiller approximation[1]

, YONGXIN YAO, Iowa State University, J. SCHMALIAN TEAM, C. Z. WANG TEAM, K. M. HO TEAM — We introduce a scheme to include many-body screening process explicitly into self-consistent equations for electronic structure calculations by employing Gutzwiller approximation. The method is illustrated by applying to a tight-binding model of the strongly correlated γ-Ce. The critical Coulomb repulsion U^c_{ff} between the $4f$ electrons for electronic phase transition can be greatly raised over the usual screened value by including the main onsite many-body screening $5d$ channels. The method provides a promising way towards parameter-free *ab initio* Gutzwiller density functional theory.

[1]Work at the Ames laboratory was supported by the U.S. Department of Energy, Office of Basic Energy Science, including a grant of computer time at the National Energy Research Supercomputing Center (NERSC) under Contract No. DE-AC02-07CH11358.

S1.00274 Predicting Sommerfeld coefficients for heavy-fermion materials

, MUNEHISA MATSUMOTO, SERGEY SAVRASOV, UC Davis, JUNYA OTSUKI, Tohoku University, Japan — From electronic-structure calculation standpoint we predict the appearance of heavy-fermion behavior for Cerium and Plutonium-based materials. Local-density approximation (LDA) combined with dynamical-mean field theory (DMFT) formulated for localized f-electrons gives an efficient realistic Kondo-lattice description [1] for the target materials, yielding a quasiparticle renormalization factor z_c for conduction electrons. We invert the data to get the quasiparticle renormalization factor z_f for f-electrons, and restore the effective total density of states to predict the Sommerfeld coefficient γ. Summarizing our data on an analogous "Doniach phase diagram" plotted for z_c, z_f, and γ, γ is found to have a peak around the magnetic quantum critical point and Ce-115's are found to have the largest γ's among target materials.

S1.00275 Atomic Green's function calculations using GPU

, REI SAKUMA, Chiba University — GPU computing or GPGPU has been successfully applied to many scientific computations, such as Monte-Carlo and molecular dynamics. In this presentation we present the application of GPU computing to the calculations of non-relativistic and relativistic atomic Green's functions including the Coulomb interaction.

S1.00276 Production of Short-Lived ^{37}K[1]

, HEATHER STEPHENS, Rose-Hulman Institute of Technology, DAN MELCONIAN[2], PRAVEEN SHIDLING[3], Texas A&M University — The purpose of our work during the summer months of 2010 was to produce a beam of ^{37}K with $\geq$ 99% purity and characterize in detail the remaining contaminants. A projectile beam of ^{38}Ar at 25 and 29 MeV/nucleon from the K500 cyclotron generated the ^{37}K by reacting with an H_2 gas target. The *MARS* spectrometer was then used to separate the reaction products of interest from the primary beam and other unwanted reaction products. From analysis of our production experiment, we were able to successfully produce 807 counts/nC of ^{37}K with 99.19% purity at 25MeV/u and 1756 counts/nC with 98.93% purity at 29MeV/u. The purity of this beam and rate of production is more than adequate for use in determining the half-life of ^{37}K, the next step to be done by the team in August 2010. This measurement will be accomplished by implanting the activity into a Mylar tape, placing it between two high-efficiency gas counters and counting the amount of beta decays as a function of time. It is expected the half-life will be measured using the ^{37}K produced from ^{38}Ar at 29MeV/u.

S1.00277 Self-Assembled Double-Quarter Antireflective Coatings using Silica and Titania Nanoparticles

, ANITESH LAL, RAISA CASTEDO VELASCO, DAN MAZILU, Washington and Lee University — Antireflective coatings have a wide range of applications, from eyeglass and camera lenses, to solar panels and optoelectronic devices, to name just a few. Our study examines several factors that affect the quality of antireflective coatings created by the self-assembly of alternating layers of SiO2 and/or TiO2 nanoparticles and poly(diallyldimethylammonium chloride) polycation on glass substrates. We use a factorial design to investigate the effects of the molarity of the nanoparticle solution, the size of the nanoparticles, the pH of the nanoparticle and polycation solutions, and the number of nanoparticle-polycation bilayers on the optical properties of the films. The first order effects of these factors, as well as their interactions, on the reflectance, transmittance, and uniformity of the coatings are reported.

S1.00278 Magnetic domain configuration of $La_{0.7}Sr_{0.3}MnO_3$ patterned elements , CARLOS A.F. VAZ, JAN RHENSIUS, ANDRE BISIG, MATHIAS KLÄUI, LAURA HEYDERMAN, Paul Scherrer Institut, Switzerland, MIGUEL NIÑO, ANDREA LOCATELLI, Sincrotrone Trieste, Italy, F. GAUCHER, ALICE GALDI, LAURENCE MÉCHIN, Universite de Caen Basse-Normandie, France — The magnetization configuration in small $La_{0.7}Sr_{0.3}MnO_3$ elements is investigated as a function of geometry, film thickness, magnetic field, and temperature using x-ray magnetic circular dichroism photoemission electron microscopy (XMCD-PEEM). The patterned elements were defined by focused ion beam (FIB) lithography, and consist of elements varying in shape (from circular, triangular and quadrangular) and size, from 200 nm up to 10 μm. A strong magnetic contrast is observed for all thicknesses (10-50 nm). The magnetic state in the larger elements tends to be multidomain, with complex configurations that are determined by the presence of local pinning sites. These pinning sites are overcome with increasing temperature, and the magnetic configuration evolves into lower energy states. In contrast, the magnetic configuration of the smaller elements are largely determined by the magnetostatic energy contribution, which gives rise to highly symmetric states as found in 3d ferromagnetic structures. Our results show that the magnetism of small LSMO elements is robust nearly up to the critical temperature, with magnetic configurations that can be controlled by suitable geometrical design.

S1.00279 Visible light photoreactivity from Carbon nitride bandgap states in Nb and Ti oxides , HOSIK LEE, TAKAHISA OHNO, NIMS, ICNSEE TEAM — Lamellar niobic and titanic solid acids (HNb_3O_8, $H_2Ti_4O_9$) are photocatalysts which can be used for environmental cleanup application and hydrogen production through water splitting. To increase their efficiency, bandgap adjustment which can induce visible light reactivity in addition to ultraviolet light has been one of hot issue in this kinds of photo-catalytic materials. Nitrogen-doping was one of the direction and its microscopic structures are disputed in this decade. In this work, we calculate the layered niobic and titanic solid acids structure and bandgap. Bandgap reduction by carbon nitride absorption are observed computationally. It is originated from localized nitrogen state which is consistent with previous experiments.

S1.00280 Statistical Analysis of Biotissues Mueller Matrix Images in Cancer Diagnostics , ROMAN TSYLYAK — This work is directed to the investigation of the scope of the technique of laser polarimetry and polarization spectrometry of oncological changes of the human prostate tissue under the conditions of multiple scattering, which presents real experimental clinical situation. Statistic moments of the first (M), second (σ), third (A) and fourth (E) orders were used as the analytical tool for estimating the ensemble of random values of z, that characterize the image of biological object (intensity I, polarization azimuths α and ellipticities β) and its optical-geometrical structure (orientation directions of the protein fibrils and birefringence index of their substance Δn). It was shown that the difference between the values of average and dispersion of distributions I (0 - 0), I (0 - 90), the intensities of images of various types of prostate tissues are insufficient and are within 10%-25%. The values of the excess of intensity distribution of the images of oncologically changed prostate tissues differ from the similar parameter of a sound tissue by 1-2 times. The third statistic moment proved to be the most sensitive because it's value in the intensity distribution of polarization image I (0 - 90) of oncologically changed tissue is 21 times higher if compared with healthy tissue.

S1.00281 The Itinerant Electron and Local Moment Hybrid Model of Iron-based Superconductors , YIZHUANG YOU, Institute for Advanced Study, Tsinghua University, FANG YANG, Physics Department, Beijing Institute of Technology, SHUPENG KOU, Physics Department, Bejing Normal University, ZHENGYU WENG, Institute for Advanced Study, Tsinghua University — An itinerant electron and local moment hybrid model for iron-based superconductors is studied, with the band structure modeled simply by two pockets. Reasonable phase diagram is obtained on the mean field level. The spin and charge dynamics are further studied by the random phase approximation (RPA). The dynamic spin susceptibility displays a Goldstone mode of the collective itinerant electron and local moment excitations in the SDW phase, and a resonance mode in the superconducting phase which persists all the way to the normal state phase. It is found that the scattering with local moment always tends to reduce the pocket depth of the itinerant electron. The study also suggests that, to correctly account for the features in transport experiments, the multi-band effect that give rise to the nodal SDW should be included.

S1.00282 Synthesizability of Superhard Carbon by Cold Compression of Graphite[1] , SALAH EDDINE BOULFELFEL, ARTEM OGANOV, Stony Brook University SUNYSB, STEFANO LEONI, Technical University Dresden — We present an efficient scheme combining Monte Carlo walk in the space of transition pathways with molecular dynamics simulations for predicting matter modification under high pressure. If crystal structure prediction is a top-interest field for science and technology, the quest is even more exciting for elements such as boron and carbon. While under pressure above 15 GPa and at high temperatures (1600-2500 K) graphite is converted into diamond, room temperature compression gives a new superhard modification of carbon. Its nature remained unresolved until recent theoretical investigations predicted two candidate structures, M-Carbon and BCT4. Both structures have comparable physical properties and refine well the XRD data. To elucidate the nature of the final product of graphite cold compression we performed molecular dynamics transition path sampling simulations and we determined the energy profile of each transition (graphite to M-carbon and graphite to BCT4). The intrinsic mechanism of the reconstruction and the reasons of the favoring of one structure over the other have been determined. A detailed picture of events of nucleation and growth during the transition is finely reproduced. Our procedure do not only determine the nature of a transition final product but predicts its synthesizability under given conditions of pressure and temperature.

[1]We acknowledge DARPA for funding.

S1.00283 Infrared optical absorption spectra of CuO single crystals: Fermion-spinon band and dimensional crossover of the antiferromagnetic order , E.J. CHOI, JOOYEON KIM, University of Seoul, Y. SEIKO, T. KIMURA, Osaka University, Japan, J. LORENZANA, Università di Roma — We have obtained mid-infrared optical absorption spectra of the $S = 1/2$ quasi one-dimensional CuO using polarized transmission measurement and interpreted the spectra in terms of phonon assisted magnetic excitations. When the electric field is parallel to the main antiferromagnetic direction a Δ shaped peak is observed with the maximum at $\omega = 0.23$ eV which is attributed to spinons along Cu-O chains. At low temperatures in the antiferromagnetic phase another peak appears at $\omega = 0.16$ eV which is attributed to two-magnon absorption but the spinon peak remains. This behavior is interpreted as due to a dimensional crossover where the low temperature three- dimensional magnetic phase keeps short range characteristics of a one- dimensional magnet.

S1.00284 ABSTRACT WITHDRAWN —

S1.00285 Development of Graphene for High Frequency Electronics , JOSHUA ROBINSON, The Pennsylvania State University, DAVID SNYDER, MARK FANTON, MATTHEW HOLLANDER, MICHAEL LABELLA, KATHLEEN TRUMBULL, RANDALL CAVALERO, BRIAN WEILAND, THE PENNSYLVANIA STATE UNIVERSITY TEAM — The practicality and success of a graphene technology depends on the ability to regularly and controllably synthesize graphene; integrate it with metals and dielectrics; and to develop device designs that take advantage of graphene's unique properties. We demonstrate graphene synthesis on SiC(0001) and Sapphire with 1.5% variation in sheet resistance across 100mm wafers. Hall mobility measurements indicate that direct growth of graphene on sapphire leads to a 2x increase in mobility (2200 cm^2/Vs) compared to silicon sublimation from SiC(0001). Additionally, we have developed high quality ohmic contacts to graphene, which improves the contact resistance by nearly 6000x (5x10^{-8} Ohm-cm^2) compared to untreated metal/graphene interfaces. Finally, we discuss integration of ultra-thin high-k dielectrics and their impact on graphene transport. Atomic layer deposited oxide heterostructures (seed not equal to overlayer) have deleterious effects on Hall mobility while homostructures lead to an increase in Hall mobility. Importantly, 5nm thick EBPVD HfO_2 gate dielectrics are successfully demonstrated and show improved Hall mobility, on-off ratio, and transconductance relative to Al_2O_3 gates and heterostructure gates.

S1.00286 Synthesis and properties of artificially layered (Ba,K)BiO_3 and Ba(Bi,Pb)O_3 structures[1] , G.W.J. HASSINK, K. MUNATAKA, R.H. HAMMOND, T.H. GEBALLE, M.R. BEASLEY, Geballe Laboratory for Advanced Materials, Stanford University, Stanford, California 94305, USA — The possibility of superconductivity in a negative U material due to the proximity effect with a normal metal (Berg, Phys.Rev.B 78, 094509), and of doping via charge transfer at interfaces (Ohtomo, Nature 427, 423-426) has led us to investigate the properties of artificially-layered films of $BaBiO_3$ (a negative-U insulator) and $BaPbO_3$ (a normal metal) and of their doped variants (Ba,K)BiO_3 and Ba(Bi,Pb)O_3, both of which are isotropic (3D) and are superconducting over a specific range of doping. Samples were either Ruddlessden-Popper phases of (Ba,K)BiO_3 synthesized by pulsed laser deposition or bi-layers of $BaPbO_3$ and $BaBiO_3$ and their variants by e-beam evaporation. We studied the transport properties of these samples to investigate the presence of superconductivity and the influence of anisotropy.

S1.00288 Alignment Behavior of Liquid Crystals on Nanoscopically Heterogeneous Surface , KYUNGHEE LEE, HYO KANG, GUIDUK YU, BONG SEOCK KIM, JONG-CHAN LEE, KYUSOON SHIN — We investigated the alignment behavior of liquid crystal molecules (LCs) on highly ordered polystyrene nanorod arrays. The diameter-controlled and height-controlled substrate was obtained from anodized aluminum oxide template. Upon the introduction of 1D nanostructures to the surface, the LC alignment was strongly influenced by the size of surface pattern. When the diameter of nanorods increased, the LC alignment changed from random planar to vertical orientation. The LC orientation was also altered by the increase of the height of nanorods. This transition happened in a small difference of nanorod diameter/height. The orientation change on the variation of nanorod dimension can be explained by the distortion of elastic-energy. The space between adjacent nanorods is sufficiently narrow to impose entropy penalty on LC molecules, and thus the LCs undergo elastic distortion near nanorod surface.

S1.00289 Metal–nanotube interactions – wetting properties[1] , RUZENG ZHU, LNM, IMech, CAS., Beijing, China, SHUWEN CUI, ChaoYang school of HSRUC — The wetting properties of metal nanoparticles in large-diameter single Carbon nanotubes (LDSWNT) is studied by considering the size effect on surface tension of the metal cluster. For the case of macro-nonwetting, we get finite critical atom number N such that the metal cluster with any atom number smaller than it has contact angle π, and so it shrinks into a ball. For an experiential formula of the surface tension of cluster expressed by the number of atoms, we determine the parameters in it for Pd and Pt respectively by density functional theory (DFT). Taking a graphene sheet as a representative of LDSWNT and using the known data of the surface tensions of solid and liquid, we obtain solid-liquid interface tension through Berthelot rule. Based on these results, we obtain N=5 for Pd and N=6 for Pt. For cluster containing 13 Pd atoms and that containing 13 Pt atoms, we use the above mentioned experiential formula to obtain their contact angles in LDSWNT consistent with those shown by the pictures given by DFT (A Maiti and A Ricca, Chem Phys Letters 395 (2004) 7–11), and thus the validity of our method is proved.

S1.00290 Magnon spectrum in a spiral magnetic order on the pyrochlore lattice: application to $CdCr_2O_4$, EUNSONG CHOI, GIA-WEI CHERN, NATALIA PERKINS, University of Wisconsin, Madison — Recent neutron scattering measurement on a geometrically frustrated antiferromagnet $CdCr_2O_4$ observed an unusual ground state in which a spiral magnetic order characterized by an incommensurate wavevector $\mathbf{Q} = (0, \delta, 1)$ is accompanied by a tetragonal lattice distortion [1]. These results can be consistently explained by a model of Heisenberg interaction with anisotropic exchange constants perturbed by the Dzyaloshinski-Moriya interaction [2]. Based on this spin Hamiltonian, we numerically integrate the Landau-Lifshitz-Gilbert equation to obtain the linear magnon spectrum [3]. Exact diagonalization based on the conventional Holstein-Primakoff transformation is ineffective in our case due to the lack of translational symmetry in the magnon Hamiltonian. We also compare the numerical spectrum with the experimental results and discuss its implications on the model Hamiltonian.

S1.00291 Vortex Confinement in Superconducting/Ferromagnet Hybrid Structures , M. IAVARONE[1], Physics Department, Temple University, Philadelphia, PA 19122, USA, A. SCARFATO, F. BOBBA, M. LONGOBARDI, Physics Department, University of Salerno, Fisciano 84084, Italy, F. GIUBILEO, CNR-SPIN Laboratory, Salerno, Italy, G. KARAPETROV, V. NOVOSAD, V.G. YEFREMENKO, Materials Science Division, Argonne National Laboratory, Argonne, IL 60439, USA, A. CUCOLO, Physics Department, University of Salerno, Fisciano 84084, Italy — Magnetically coupled superconductor-ferromagnet hybrids offer advanced routes for nanoscale control of superconductivity. Scanning tunneling microscopy (STM) and scanning magnetic force microscopy (MFM) coupled to magneto-transport measurements reveal rich vortex phase diagram. The magnetic stripe domain of the ferromagnet induces periodic local magnetic induction in the superconductor, creating a series of pinning and anti-pinning channels for vortices observed with low temperature STM and MFM. Such laterally confined Abrikosov vortices form chains. We also found general equilibrium condition for which vortex-antivortex pairs are spontaneously formed during zero-field cooling. In the non-equilibrium state the strong magnetic pinning of the vortex lattice results in avalanches of antivortices when changing the polarity of the applied magnetic field.

S1.00292 Lipid Bilayer Vesicle extrusion through nanopores: a coarse grained molecular dynamics study[1] , MARTIN BERTRAND, BELA JOOS, University of Ottawa — We conducted Coarse-Grained Molecular Dynamics simulations of the pressure extrusion of vesicles in nanopores that confirm and help explain prior experimental observations (Patty, P. and Frisken, B., Biophys. J., 85, 2003). We demonstrate that, to a first approximation, the final size of extruded vesicles can be obtained by considering an invariable inner vesicle volume enclosed by a finitely extensible lipid bilayer. Using our data, we also describe in details the mechanics of vesicle rupture in a nanopore when pushed by various pressure gradients. This is made possible by tracking local variations of the stress in the lipid membrane via changes in surface area using a triangulation algorithm. The simulations are executed using state of the art GPU accelerated software. Our findings could potentially be useful in the design of liposome based drug delivery systems and in getting a better understanding of how the cell nucleus and the cell as a whole react in similar conditions.

S1.00293 Spin-dependent 8x8 k.p Hamiltonian in silicon[1] , PENGKE LI, HANAN DERY, University of Rochester — Silicon is a promising material choice in spintronics devices due to its long electron spin lifetime and dominant technology. We present a theory that describes the spin properties of conduction electrons in different valleys in silicon. Using the method of invariants, we have developed an 8×8 Hamiltonian with spin-orbit interaction that captures the symmetry of the zone edge states and their spin dependent parameters. We derive analytical results of the energy bands, and more important, of the spin mixing of states. Both are in perfect agreement with the numerical results of an empirical pseudopotential method with spin orbit interaction. The new theory is capable of filling a dominant role in studying spin properties of electrons silicon similar to the way that the Kane model in being used in direct band-gap semiconductors.

S1.00294 Polaron formation and multi-band multi-gap superconductivity in layered materials , ANNETTE BUSSMANN-HOLDER, Max-Planck-Institute for Solid State Research, HUGO KELLER, Physik Institut der Universität Zürich — In cuprates and novel layered superconductors electron-lattice interactions are not strong enough to achieve the high transition temperatures. However, polaron formation may occur locally at intermediate sized regions around the dopants thus leaving the surrounding matrix remains almost unaffected. The coexistence of the dynamical polarons and the host matrix represents a multi-component system, where different physics are combined. The consequences of this scenario are manyfold: The strong *local* electron-lattice coupling induces a *local soft mode* which gives rise to divergences in the relative Cu-O, Fe-As squared displacements. The electronic bands are renormalized and experience an exponential reduction which is the origin of unconventional isotope effects. Superconductivity is characterized by multi-components, which can have system dependent different pairing symmetries. Cuprates and other layered superconductors are discussed and comparison to experimental data is made.

S1.00295 Node-node correlations and transport properties in scale-free networks , BIBIANA OBREGON, Posgrado en Ingenieria, UNAM, Mexico, LEV GUZMAN, UPIITA, Instituto Politecnico Nacional, Mexico — We study some transport properties of complex networks. We focus our attention on transport properties of scale-free and small-world networks and compare two types of transport: Electric and max-flow cases. In particular, we construct scale-free networks, with a given degree sequence, to estimate the distribution of conductances for different values of assortative/dissortative mixing. For the electric case we find that the distributions of conductances are affect ed by the assortative mixing of the network whereas for the max-flow case, the distributions almost do not show changes when node-node correlations are altered. Finally, we compare local and global transport in terms of the average conductance for the small-world (Watts-Strogatz) model

S1.00296 Controlling Rotational Molecular Rotor by Selection of Anchoring Sites , HYO WON KIM, Seoul National University, M. HAN, H.-J. SHIN, S. LIM, Y. OH, K. TAMADA, M. HARA, Y. KIM, M. KAWAI, Y. KUK, SEOUL NATIONAL UNIVERSITY TEAM, TOKYO INSTITUTE OF TECHNOLOGY COLLABORATION, RIKEN ADVANCED SCIENCE INSTITUTE COLLABORATION, TOHOKU UNIVERSITY COLLABORATION, THE UNIVERSITY OF TOKYO COLLABORATION — In future nano-electro-mechanical-systems (NEMS), a molecular motor may become a key component to produce nanoscopic dynamical motions. At the level of a single molecule, rotational motions of various molecules have been observed on clean metal or semiconductor surfaces in scanning tunneling microscope (STM) images. Based on the observations, molecular bearings, nanocars, pinwheels, a rack and pinion device, wheels and gears have been proposed using a hindered molecular rotation. Despite extensive studies, the control of rotational motion in a molecular rotor is quite difficult. In this talk we report a controlled rotational-motion of an azobenzene derivative, EtO-Azo-C10, by inducing a reversible hopping motion between an immobile and a mobile site on a Au(111) surface with tunneling electrons in STM geometry.

S1.00297 Entropic transport - a step beyond Fick-Jacobs , STEFFEN MARTENS, Humboldt-University Berlin, Department of Physics, Newtonstr. 15, 12489 Berlin, Germany, GERHARD SCHMID, University Augsburg, Department of Physics, Universitaetsstr. 1, 86135 Augsburg, Germany, LUTZ SCHIMANKY-GEIER, Humboldt-University Berlin, Department of Physics, Newtonstr. 15, 12489 Berlin, Germany, PETER HÄNGGI, University Augsburg, Department of Physics, Universitaetsstr. 1, 86135 Augsburg, Germany — We investigate the transport of point-size Brownian particles under the influence of a constant and uniform force field through a three-dimensional channel with smoothly varying periodic cross-section. We apply the standard long-wave asymptotic analysis and show that the leading order term is equivalent to the Fick-Jacobs approximation. Using the higher order corrections of the probability density we derive an expression for the spatially dependent diffusion coefficient. In addition, we demonstrate that in the diffusion dominated regime the averaged velocity and the effective diffusion coefficient are determined by the product of the Fick-Jacob result and the expectation value of the spatially dependent diffusion coefficient. Analytic findings are confirmed by numerical simulations of the particle dynamics in a reflection symmetric sinusoidal channel.

S1.00298 Thermally activated fragmentation of a homopolymer chain[1] , SIMON FUGMANN, IGOR M. SOKOLOV, Humboldt University Berlin, Department of Physics, Newtonstr. 15, 12489 Berlin, Germany — We consider the thermally activated fragmentation of a homopolymer chain, which can exhibit strongly non-Markovian behavior on the timescale of interest. In our model the dynamics of the intact chain is a Rouse one until a bond breaks and bond breakdown is considered as a first passage problem over a barrier to an absorbing boundary. Using the framework of the Wilemski-Fixman approximation we calculate activation times of individual bonds for free and grafted polymer chains. We show that these times crucially depend on the length of the chain and the location of the bond yielding a minimum at the free chain ends. Going beyond the Wilemski-Fixman approximation we show that a generalized form of the renewal equation for barrier crossings serves to improve the quantitative agreement between numerical simulations and analytical predictions.

S1.00299 Non-equilibrium ballistic phonon transport in microstructures , OBAFEMI OTELAJA, JARED HERTZBERG, RICHARD ROBINSON[1], Cornell University — A non-thermal spectral distribution of phonon modes may be excited in silicon microstructures by using the decay of quasiparticles injected into an adjacent superconducting film. [1] We demonstrate generation, ballistic transport and detection of phonons of frequency of order 100 GHz in microstructures of dimension 10 to 50 microns. We describe the fabrication process for the superconducting transducers, the measurement procedure, and plans to extend these techniques to build a nanoscale phonon spectrometer. This work is supported by KAUST (KUS-C1-018-02), NSF (DMR 0520404), and DOE (DE-SC0001086).

Session T1 DCMP: Entanglement Spectroscopy Ballroom A1

2:30PM T1.00001 Momentum space entanglement in quantum spin chains , DANIEL AROVAS, University of California, San Diego — I will discuss work performed in collaboration with R. Thomale and A. Bernevig (*Phys. Rev. Lett.* **105**, 116805 (2010)) on entanglement spectra in spin chains. Typically, bipartite entanglement entropy and spectra have been studied in the case of spatial partitions, *i.e.* A denotes the left half of a spin chain, B the right half, $\rho_{\rm A} = {\rm Tr}_{\rm B} |\Psi_0\rangle \langle\Psi_0|$ is the reduced density matrix, and ${\rm spec}(\rho_{\rm A})$ is the entanglement spectrum (ES). We find for the $S = \frac{1}{2}$ Heisenberg model that a remarkable structure in the ES is revealed if the partition is performed in momentum space, *i.e.* A = left-movers and B = right-movers. Further classifying the entanglement eigenstates by total crystal momentum, we observe a universal low-lying portion of the ES with specific multiplicities separated from a higher-lying nonuniversal set of levels by an *entanglement gap*, similar to what was observed by Li and Haldane (*Phys. Rev. Lett.* **101**, 010504 (2008)) for the fractional quantum Hall effect. Indeed, the momentum space ES for the Heisenberg chain is understood in terms of the proximity of the Haldane-Shastry model, which corresponds to a fixed point with no nonuniversal corrections, and whose ground state wavefunction is related to that for the $\nu = \frac{1}{2}$ Laughlin state. We further explore the behavior of the ES as one tunes through the spin-Peierls transition in a model with next-nearest-neighbor exchange. We also discuss entanglement gap scaling and applications to other systems.

3:06PM T1.00002 Identifying Topological Order from the Entanglement Spectrum[1] , F.D.M. HALDANE, Princeton University — The Schmidt decomposition reveals bipartite entanglement of a quantum state. Calculation of the entanglement entropy reduces it to a single number, which can be studied as a function of the size and shape of the entangled regions. However, this reduction discards additional information contained in the full spectrum of the entanglement, which can be presented as a set of (dimensionless) "pseudo-energy" levels spectrum, labeled by quantum numbers such as momentum parallel to the $(d-1)$-dimensional boundary along which the bipartite decomposition of a d-dimensional system is made. The nature of the entanglement is revealed by this spectrum, much as the elementary excitations and collective modes characterizes condensed-matter states. (The von Neumann entropy is equivalent to the the thermodynamic entropy of the system of pseudo-energy levels at a particular fictitious "temperature" $k_B T = 1$.) The previously-unrecognized importance of the spectrum (as opposed to just its entropy) became immediately apparent when the entanglement spectrum of a 2D fractional Quantum Hall state along a 1D cut was first plotted [1]. The gapless spectrum of the conformal field theory related to the topological order of the FQHE can be recognized, and is the only spectrum in model states like the Laughlin or Moore-Read wavefunctions related to cft. For realistic states, corrections due to collective-mode fluctuations give rise to high-pseudo-energy modes that are separated from the gapless (topological) modes by a finite gap. Previously, it had been believed that the extensive O(L) ("area law") part of the entanglement entropy of this spectrum was non-universal, and topological order could only be recognized from the O(1) subleading behavior as the length L of the cut was scaled. However, while the "pseudo-energy" distribution appears to be non-universal, the distribution of the spectrum *as a function of (true) momentum* does not have this drawback, showing that the topological contribution to the O(L) part has a universal character not visible in the numerical value of the entropy itself. In general, (including also systems such as topological or Chern insulators [2]), the signature of topological order is the occurrence of gapless mode in the entanglement spectrum, providing a fingerprint from which this order can be identified.

3:42PM T1.00003 Multiplets in the Entanglement Spectrum , ARI TURNER, UC Berkeley — Often, spin chains do not have any long range order, because of quantum mechanical fluctuations. Surprisingly, there can be phase transitions between two such phases, which suggests the existence of a hidden order. In this talk, I demonstrate that the entanglement spectrum can be used to distinguish between these subtly different phases. The central idea is to reduce a one-dimensional chain to a zero-dimensional imaginary system, called the entanglement Hamiltonian. One can then understand the phases of the original spin chain simply by looking at the spectrum of the entanglement Hamiltonian, just as one deduces the properties of atoms from their spectra. The next question is what the physical meaning of the entanglement Hamiltonian is. Properties of the entanglement Hamiltonian are in fact often reflected in physical properties of the ends of a finite chain, such as the appearance of gapless degrees of freedom or surface charge; I will give some examples in higher dimensional systems such as topological insulators as well as one dimension.

4:18PM T1.00004 Interacting Topological Insulators , LUKASZ FIDKOWSKI, Microsoft Research, Station Q — Topological insulators and superconductors are new phases of matter whose physics is described by non-interacting fermions. They can be understood in terms of the topological "twisting" of the fermion's phase over the Brillouin zone, and using topology one can come up with a full classification of when such phases can occur. Strangely, this classification fails for some one dimensional systems once higher-order interactions are allowed. In this talk I will use the entanglement spectrum to understand the modified interacting classification, in one dimension. I will also discuss general one dimensional gapped models, and how matrix product states allow us to find their phases.

Wednesday, March 23, 2011 2:30PM - 5:30PM –
Session T2 DCMP: Defects and Strain in Graphene Ballroom A2

2:30PM T2.00001 Electron Interactions in Graphene , PHILIP KIM, Department of Physics, Columbia University — Electrons confined in two dimensions (2D) can exhibit strongly correlated states. Recent experimental discovery of integer and fractional quantum Hall effect in graphene amplified interest in correlated 2D electronic systems, owning to presence of the unusual topological phase associated with zero effective mass of charge carriers. In this talk, we will discuss the role of the many-body effects due to the electron-electron interaction in graphene manifested in electron transport phenomena. In particular, we will discuss the nature unusual spontaneous symmetry breaking Landau levels graphene under the extreme quantum condition, the appearance of unique low density insulating states and fractional quantum Hall states. Employing extremely high quality samples obtained by suspending graphene and graphene on atomically flat defect free insulating substrate such as hexa-bron nitride, we now investigate various broken symmetry states under high magnetic field. The nature of these broken symmetry state can be explained generally considering underlying SU(4) symmetry in the single particle level of the Landau levels.

3:06PM T2.00002 Spatially Resolving Spin-split Edge States of Chiral Graphene Nanoribbons[1] , M.F. CROMMIE, U.C. Berkeley Physics Dept. and Lawrence Berkeley National Laboratory — A central question in the field of graphene-related research is how graphene behaves when it is patterned at the nanometer scale with different edge geometries. The most fundamental shape in this regard is the graphene nanoribbon (GNR), a narrow strip of graphene that is characterized by its width and chirality. GNRs have been predicted to exhibit a wide range of behavior that includes tunable energy gaps and unique 1D edge states with unusual magnetic structure. I will discuss a scanning tunneling microscopy and spectroscopy (STS) study of GNRs that allows us to examine how GNR electronic structure depends on the chirality of atomically well-defined GNR edges. Our STS measurements reveal the presence of 1D GNR edge states that closely match theoretical expectations for GNRs of similar width and chirality. We additionally observe width-dependent energy splitting in GNR edge states, providing compelling evidence of their magnetic nature.

[1]This work performed in collaboration with Chenggang Tao, Liying Jiao, Oleg V. Yazyev, Yen-Chia Chen, Juanjuan Feng, Xiaowei Zhang, Rodrigo B. Capaz, James M. Tour, Alex Zettl, Steven G. Louie, and Hongjie Dai.

3:42PM T2.00003 Graphene under a tip[1] , EVA Y. ANDREI, Department of Physics and Astronomy, Rutgers University, Piscataway NJ — The strictly two dimensional structure of graphene results in 2D charge carriers that are readily accessible by surface probes such as scanning tunneling microscopy (STM) and spectroscopy (STS), and in electronic properties that can be controlled through doping, strain and external potentials. At the same time the 2D structure causes graphene to be extremely sensitive to environmental disturbances. I will describe STM, STS and magneto-transport experiments showing that when graphene is decoupled from substrate-induced potential fluctuations the intrinsic properties of the carriers become apparent. This is clearly seen in suspended graphene devices where, in the absence of substrate induced potential fluctuations, electron-electron interactions lead to a fractional quantum Hall effect and to an insulating phase at the Dirac point [1]. We find that even for non-suspended graphene it is possible to find non-invasive substrates on which one can directly observe the sequence of quantized Landau levels [2] and to track their evolution with field and doping down to the Dirac point where interaction effects kick in [3]. When the "substrate" is another graphene layer with relative orientation other than that of the standard Bernal stacking, it can profoundly affect the electronic density of states transforming it from the linear massless Dirac spectrum to one containing prominent Van Hove singularities which are controlled by the degree of twist between the layers [4].

4:18PM T2.00004 High Resolution Tunneling Spectroscopy of Graphene in Strong and Weak Disorder Potentials , JOSEPH STROSCIO, Center for Nanoscale Science and Technology, NIST, Gaithersburg, MD 20899 — Using scanning tunneling spectroscopy (STS), the local density of states can be mapped in real space to give insight into the role the local disorder potential plays in determining the 2-dimensional electron gas (2DEG) properties. In this talk I describe studies using scanning tunneling spectroscopy to examine various graphene systems with varying degrees of disorder. The amount of disorder depends on how the graphene was made. In the growth of graphene on the Si-face termination of SiC in UHV, local defects are found which contribute to strong inter- and intra-valley scattering [1]. Medium disorder is found in exfoliated graphene on SiO_2. Using a back-gated exfoliated graphene device on SiO_2 we observe a Landau level spectrum and charging resonances [2] that are completely different from previous STS measurements on weak disorder graphene systems. Applying a gating potential allows us to obtain "STS gate maps" which show the graphene 2DEG breaking up into a network of interacting quantum dots formed at the potential hills and valleys of the SiO_2-induced disorder potential. Graphene grown on the C-face termination of SiC is shown to have weak disorder with Landau level line widths approaching thermal limits at liquid He temperatures [3]. Using a new STM system operating at 10 mK, we are able to resolve a graphene "quartet" of the N=1 Landau level [4]. The quartet structure shows the complete lifting of the valley and spin degeneracies, which we determine as a function of magnetic field.

4:54PM T2.00005 Influence of edge structure, substrate structure and grain boundaries on the electronic properties of graphene quantum dots and transferred graphene[1] , JOSEPH LYDING, University of Illinois — We have used UHV STM to study the quantum size effect gap and the effects of edge electronic structure on graphene quantum dots (GQDs) and nanoribbons [1]. GQDs on H-Si(100) exhibit the expected size-dependent gap with the exception of those with predominantly zigzag edges, which are metallic. STM spectroscopy elucidates the predicted zigzag metallic edge state, which has a characteristic decay length of 1nm. Monolayer graphene deposited in UHV on cleaved GaAs(110) and InAs(110) substrates exhibits an electronic semitransparency effect in which the substrate electronic structure can be observed 'through' the graphene [2]. This effect is observed when the equilibrium graphene-substrate spacing is reduced by about 0.06nm. We have also studied the grain boundaries in graphene monolayers that have been grown on copper and then transferred to silicon dioxide substrates. On the annealed copper foils, we find many crystallographic facets, grain boundaries, and annealing twins, all of which affect the carbon species nucleation. Graphene does not grow as readily on the foil annealing twins and non-primary crystal facets, leading to varying nucleation and graphene grain boundaries in the transferred film. STM images show graphene misorientation angles of approximately 7°, 23°, and 30° at the grain boundaries. Standing wave patterns with a decay length on the order of 1 nm were observed adjacent to the grain boundaries and depend on the structure of the boundary. Spectroscopy across the boundaries showed enhanced conduction in empty states on the grain boundaries.

Wednesday, March 23, 2011 2:30PM - 5:30PM –

Session T3 DCMP DMP: DCMP/DMP Prize Session: Buckley, McGroddy, Davisson-Germer

Ballroom A3

2:30PM T3.00001 Oliver E. Buckley Condensed Matter Prize Talk I , JUAN CARLOS CAMPUZANO, Argonne National Laboratory — This abstract not available.

3:06PM T3.00002 Oliver E. Buckley Condensed Matter Prize Talk: High-resolution Photoemission Studies of the High Tc Superconductors[1] , PETER JOHNSON, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory — In the last decade, high resolution angle-resolved photoelectron spectroscopy has evolved into one of the most powerful probes of the electronic structure of condensed matter systems. This development reflects new technological advances coupled to the enormous research effort devoted to the study of strongly correlated systems, particularly the high T_c cuprate superconductors. Two decades after their initial discovery the latter still present some of the biggest challenges for materials science. In this talk we review some of the developments in new instrumentation and analysis techniques in photoemission and include discussion of both self-energy effects and Fermi surface studies. In the latter case, the discussion will focus on the pseudogap phase of the underdoped cuprates with particular reference to an observed particle-hole asymmetry and the possibility of hole pockets.

[1]Work at Brookhaven is supported by the U.S. Department of Energy.

3:42PM T3.00003 Oliver E. Buckley Condensed Matter Prize Talk: Energy Gaps and Their Implications on the Phase Diagram of Cuprate Superconductors , ZHI-XUN SHEN, Department of Physics and Applied Physics, Stanford University; Stanford Institute for Materials and Energy Sciences, SLAC, Stanford University — In this talk, I will survey the progress made in understanding the cuprate superconductors using angle-resolved photoemission spectroscopy. I will focus on the discovery and understanding of the anomalous energy gaps, and their implication on the pairing symmetry as well as the phase diagram of cuprate superconductors. This includes the detection of the d-wave superconducting gap structure that contributes to the current consensus of d-wave pairing symmetry, the unexpected discovery of the anisotropic normal state gap in single particle spectra (also known as pseudogap) that has become a defining feature of the cuprate phase diagram, the new progress in demonstrating that the pseudogap state is a distinct phase that breaks the particle-hole (thus translational) symmetry, and the momentum dependent information on the competition between pseudogap and superconducting gap.

4:18PM T3.00004 James C. McGroddy Prize for New Materials Talk: Geometrically Frustrated Materials , ARTHUR RAMIREZ, University of California Santa Cruz — Geometrical frustration occurs when interacting degrees of freedom do not "fit" into the lattice that they occupy and, as a result, are under-constrained at low temperature. While the early ideas behind geometrical frustration originate in Wannier's triangular antiferromagnetic Ising model and Anderson's resonating valence bond model, they are broadened here to define an entire class of magnetic materials whose structures are based on triangular or tetrahedral units. When the degree of misfit is high, conventional long range order is suppressed and thermodynamic spectral weight is pushed to energies much lower than the mean field value. Out of this low energy spectral weight, new states of matter are found to emerge experimentally, such as spin liquid on the kagome lattice and spin ice on the pyrochlore lattice. The concept of geometrical frustration can be broadened beyond magnetism to describe a frustrated soft mode that can lead to persistent negative thermal expansion and giant dielectric constants. A brief review will be given of recent work on excitations in frustrating lattices, including the prediction of, and evidence for, magnetic monopoles in spin ice, and the relevance of frustrated hopping for topological insulators.

4:54PM T3.00005 Davisson-Germer Prize in Atomic or Surface Physics Talk: Soft X-Ray Studies of Surfaces, Interfaces and Thin Films: From Spectroscopy to Ultrafast Nanoscale Movies[1] , JOACHIM STÖHR, SLAC National Accelerator Laboratory — My talk will review the development of soft x-ray spectroscopy and microscopy and its impact on our understanding of chemical bonding, magnetism and dynamics at surfaces and interfaces. I will first outline important soft x-ray spectroscopy and microscopy techniques that have been developed over the last 30 years and their key strengths such as elemental and chemical specificity, sensitivity to small atomic concentrations, separation of charge and spin properties, spatial resolution down to the nanometer scale, and temporal resolution down to the intrinsic femtosecond timescale of atomic and electronic motions. I will then present scientific breakthroughs based on soft x-ray studies in three selected areas: the nature of molecular bonding and reactivity on metal surfaces, the molecular origin of liquid crystal alignment on surfaces, and the microscopic origin of interface-mediated spin alignments in modern magnetic devices. My talk will also cover the use of soft x-rays for revealing the temporal evolution of electronic structure, addressing the key problem of "function," down to the intrinsic femtosecond time scale of charge and spin configuration changes. As examples I will present the formation and breaking of chemical bonds in surface complexes and the motion of the magnetization in magnetic devices.

[1]Work supported by the Office of Basic Energy Science of the US Department of Energy.

Wednesday, March 23, 2011 2:30PM - 5:30PM –

Session T4 GIMS: Keithly Award Session Ballroom A4

2:30PM T4.00001 Joseph F. Keithley Award For Advances in Measurement Science Talk: Beyond the Fringe: measuring ultrafast optical pulses using spectral interferometry , IAN WALMSLEY, University of Oxford — The ability to completely characterize ultrashort electromagnetic pulses has revolutionized the field of ultrafast optics, enabling both new technology and new science. The aim of pulse characterization is to infer the electric field of the pulse from measurements of quantities that rely on standard (relatively slow) photodetectors. Since the field is a fundamental entity in Maxwell's theory, it contains the most information one may obtain about a system probed by an optical pulse, and is, in this sense, much more valuable set of data than a measurement simply of the pulse energy or even the spectral or temporal intensity, Pulse measurement methods may be categorized as spectrographic and tomographic, by which the time-frequency phase space of the pulse is mapped, or interferometric, by which the phase is determined directly. Interferometry provides a sensitivity and robust approach affording a rapid, direct reconstruction algorithm that gives a provably unique solution to the complete space-time field. An important class of self-referencing interferometric are those based on spectral shearing, whereby two frequency shifter replicas of the test pulse are generated encoding the spectral phase derivative in the spectral interferogram resulting from their superposition. The nonlinear implementation of this approach is called spectral phase interferometry for direct electric-field reconstruction (SPIDER). SPIDER has shown itself to be an adaptable and robust method, gaining widespread application in all areas of ultrafast optics, from nonlinear microscopy to attoscience. Some essential concepts and history of the field will be presented, along with recent developments, illustrating applications in ultrafast source diagnosis and certification, dynamical spectroscopy, coherent control, imaging and materials processing.

3:06PM T4.00002 High-Energy Sub-Cycle Waveform Synthesis and Characterization , FRANZ KÄRTNER, Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology — The control of atomic scale electronic motion by ultrafast optical electric field waveforms strong enough to mitigate the atomic Coulomb potential has broken tremendous new ground with the advent of phase controlled high-energy few-cycle pulse sources. Currently, such sources are based on Ti:sapphire amplifiers and hollow-core fiber post-compression or optical parametric chirped pulse amplification, together with optical gating techniques. Significant control of the waveform on sub-cycle time scales, however, requires a fully phase-controlled multiple-octave-spanning spectrum. Here, we present a first fully phase-controlled multi-octave-spanning source that supports gigawatt-peak-power isolated single-cycle waveforms based on pulse synthesis of two carrier-envelope phase (CEP) stable OPCPA systems. It is especially a challenge to fully characterize such ultrawide band waveforms. We apply two-dimensional spectral shearing interferometry (2DSI), which can measure the group delay between all spectral components of the synthesized pulse.

3:42PM T4.00003 Generation, characterization and spectroscopic use of ultrashort pulses fully tunable from the deep UV to the MIR , EBERHARD RIEDLE, LMU München — The impressive work of Ian Walmsley has brought us invaluable new possibilities for the full characterization of ultrashort pulses. Spectroscopy of physical, chemical and biological relevance does, however, need pulses far from the 800 nm Ti:sapphire wavelength used for testing SPIDER and its advanced versions. Fortunately, optical parametric amplification (OPA) allows for easy generation of fully tunable pulses. I will review our efforts, highlighting noncollinear OPA, i.e. NOPA, for visible pulses shorter than 10 fs, mixing into the UV down to below 200 nm at 20 fs duration and novel hybrid schemes to efficiently reach the middle IR. I will show that these schemes can be used equally well from kHz to MHz repetition rates. The tunable ultrafast pulses in turn also demand improvements in characterization. The UV range led us to use difference frequency generation instead of the sum frequency mixing employed in the original SPIDER. The lack of proper beam splitters and auto-referencing led us to the use of two auxiliary pulses and the avoidance of any additional chirp added to the test pulse. We termed this zero-additional-phase SPIDER, i.e. ZAP-SPIDER. Lately, with increased use of UV pulses, we came to the conclusion, that the ubiquitous two-photon-absorption can well serve as nonlinearity, at least in UV autocorrelation measurement. How do we use this for full characterization? Hopefully, Ian will tell us! Since the proof is known to be in the eating, I will demonstrate the success of our technical efforts with examples taken from ultrafast molecular dynamics. Highly pronounced vibronic wavepackets in the product of ultrafast excited state proton transfer and the very primary processes leading to homolytic and heterolytic bond cleavage will serve as easy to comprehend illustrations.

4:18PM T4.00004 Probing Electron Correlation with Sequential Laser–Induced Tunnel ionization , PAUL CORKUM, University of Ottawa — Since 1964 we have known that multiphoton ionization could be approximated by tunnel ionization for long wavelength light. Aside from re-collision, since then multiple ionization has been treated as successive, independent single ionization events. Our results show that this long-held belief is false. Tunnelling is highly directional and highly sensitive to the ionization potential (Ip) of the accessible ionic states (which itself can depend on the direction of ionization). Using rare gas atoms as examples, we show that laser induced tunnelling is suppressed or enhanced depending on how the field is applied. We image the hole left by the first tunnelling electron by measuring in the spatial correlation of the second electron. Laser induced tunnelling gives us experimental access to one of the most difficult to measure properties of matter – electron-electron correlations [1].

4:54PM T4.00005 Pulse Propagation through Dispersive Optical Materials , ROBERT BOYD, University of Ottawa — It is now possible to characterize the complete time-frequency behavior of optical pulses with unprecedented precision [1, 2]. The frequency content of optical pulses determines how they propagate through dispersive optical materials. In this talk, we review recent work on methods for dramatically modifying the velocity with which light pulses propagate through material systems. This modification can be so severe that one speaks of slow light, fast light, and backwards light depending on how the magnitude and sign of the group velocity compares to the vacuum speed of light c. We review the physical processes that can be used to achieve such a strong modification of the velocity of light, and we discuss the conceptual understanding of exotic propagation effects such as backwards propagation. We also review the implications of modified pulse velocities within the context of modern optical technology.

Wednesday, March 23, 2011 2:30PM - 5:30PM –

Session T5 GQI: 20 Years of Quantum Information in Physical Review Letters Ballroom C1

2:30PM T5.00001 Theory of entanglement and entanglement-assisted communication , CHARLES H. BENNETT, IBM Research Division — Protocols such as quantum teleportation and measurement-based quantum computation highlight the importance of entanglement as a resource to be quantified and husbanded. Unlike classical shared randomness, entanglement has a profound effect on the capacity of quantum channels: a channel's entanglement-assisted capacity can be much greater than its unassisted capacity, and in any case is given by much a simpler formula, paralleling Shannon's original formula for the capacity of a classical channel. We review the differences between entanglement and weaker forms of correlation, and the theory of entanglement distillation and entanglement-assisted communication, including the role of strong forms of entanglement such as entanglement-embezzling states.

3:06PM T5.00002 Twenty Years of Quantum Error Correction , DAVID DIVINCENZO, Forschungszentrum Juelich & RWTH Aachen — Starting around 1991 It became clear that the emerging quantum computer would need error correction to be sensible. Almost immediately, Berthiaume, Deutsch, and Jozsa announced the first key ideas (e.g., allowed codewords should live in a well-defined subset of the Hilbert space), and in less than ten years, the problem was "solved." This solution had many components, involving insights from quantum teleportation, the concept of noisy entanglement and its improvement, creative borrowings from classical binary and quaternary codes, pure group theory, and the reliable working of noisy automata. Actually, this "solved" problem continues to produce new difficulties and insights up to the present day, and it is increasingly central for the question of what we do next in the progress towards a functioning quantum computer.

3:42PM T5.00003 Less Reality, More Security , ARTUR EKERT, Oxford University and National University of Singapore — Bell's inequality makes a seemingly insane scenario possible — devices of unknown or dubious provenance, even those that are manufactured by our enemies, can be safely used for secret communication. And this is for real! All that is needed to implement such a bizarre form of cryptography is a loophole-free violation of Bell's inequalities. It is on the edge of being technologically feasible. I will provide a brief overview of quantum and post-quantum cryptography and describe how studies of entanglement and the foundations of quantum theory influenced the way we may soon protect information.

4:18PM T5.00004 Twenty Seven Years of Quantum Cryptography! , RICHARD HUGHES, Los Alamos National Laboratory — One of the fundamental goals of cryptographic research is to minimize the assumptions underlying the protocols that enable secure communications between pairs or groups of users. In 1984, building on earlier research by Stephen Wiesner, Charles Bennett and Gilles Brassard showed how quantum physics could be harnessed to provide information-theoretic security for protocols such as the distribution of cryptographic keys, which enables two parties to secure their conventional communications. Bennett and Brassard and colleagues performed a proof-of-principle quantum key distribution (QKD) experiment with single-photon quantum state transmission over a 32-cm air path in 1991. This seminal experiment led other researchers to explore QKD in optical fibers and over line-of-sight outdoor atmospheric paths ("free-space"), resulting in dramatic increases in range, bit rate and security. These advances have been enabled by improvements in sources and single-photon detectors. Also in 1991 Artur Ekert showed how the security of QKD could be related to quantum entanglement. This insight led to a deeper understanding and proof of QKD security with practical sources and detectors in the presence of transmission loss and channel noise. Today, QKD has been implemented over ranges much greater than 100km in both fiber and free-space, multi-node network testbeds have been demonstrated, and satellite-based QKD is under study in several countries. "Quantum hacking" researchers have shown the importance of extending security considerations to the classical devices that produce and detect the photon quantum states. New quantum cryptographic protocols such as secure identification have been proposed, and others such as quantum secret splitting have been demonstrated. It is now possible to envision quantum cryptography providing a more secure alternative to present-day cryptographic methods for many secure communications functions. My talk will survey these remarkable developments.

4:54PM T5.00005 A Brief Prehistory of Qubits , BENJAMIN SCHUMACHER, Kenyon College — In the early 1990's, alongside the early work on quantum cryptography, there existed a considerable body of research on the classical information capacity of quantum channels. The strongest and most general result known was the theorem of Holevo giving an entropic bound for the accessbile information in a mixture of quantum signals. This motivated the problem of whether the Holevo bound could be closely approached by suitable choice of code and decoding observable. If so, then the quantum (von Neumann) entropy had a straightforward informational interpretation. When this question was found to be very difficult to answer, quantum data compression and the idea of a "qubit" was introduced as an alternate framework for thinking about information in quantum systems and interpreting the quantum entropy. However, the mathematical ideas from the new framework proved essential to solving the original problem of showing that the Holevo bound was asymptotically achievable. This was an early example of the interplay between classical and quantum concepts of information – an interplay that has been, to say the least, extremely fruitful.

Wednesday, March 23, 2011 2:30PM - 5:30PM –

Session T6 FIAP: Theory in Industry Ballroom C2

2:30PM T6.00001 From Atoms to Autos: Adventures of a Theoretical Physicist in Industry , JAN HERBST, GM R&D Center — After earning a PhD in solid state theoretical physics at Cornell and following a post-doc, the author arrived at GM R&D for what has turned out to be his first and only real job. An anecdotal chronicle of his adventures in the auto industry will be presented.

3:06PM T6.00002 Challenging theoretical physics problems in the energy industry , MARTIN-DANIEL LACASSE, Corporate Strategic Research Laboratory, ExxonMobil Research and Engineering Company — Critical reliance on technology is ubiquitous in the energy industry, where considerable resources are dedicated to fundamental research aimed at solving our most challenging problems. For example, technological challenges are found in all aspects of the oil and gas industry ranging from exploration, development, and production of oil fields, to transportation and refining of the raw materials, and all the way to the production of specialty products such as polymers and lubricants. From a scientific perspective, these activities cover a broad range of physical science disciplines. As examples, during the exploration and development of oil and gas fields, sound and electromagnetic waves are used to image the earth's interior, and drilling involves an array of sophisticated tools and detectors at the bore hole, both activities being possible thanks to geophysicists, applied mathematicians, and rock physics specialists. Similarly, the transformation of crude oil to refined products requires a fundamental understanding of physical chemistry, phase transition, and transport processes, while the design of products involves polymer physics, and special disciplines such as tribology. The goal of this talk is to present examples of problems posed by the energy industry in view of encouraging physicists to contribute to finding solution to these problems, either through their academic research, or by pursuing a challenging career as industrial physicists. Many of those problems can benefit from the unique approach provided by a rigorous physics training.

3:42PM T6.00003 Theoretical Physics + Experiments in Superfluid He^4 = Commercial Oilfield Acoustic Service , DAVID JOHNSON, Schlumberger-Doll Research — I will describe a specific project which involved the understanding of the basic physics of acoustics in porous and permeable fluid saturated media. The end product is a commercially available measurement of the fluid-flow resistance of porous rock in a real oil-field borehole using an acoustic technique. One key ingredient of the understanding was obtained by laboratory measurements of the acoustic properties of a porous sample saturated with superfluid He^4. Another key ingredient is the theoretical understanding of the properties of the frequency dependent fluid-flow resistance, and its extension to complex values of the frequency.

4:18PM T6.00004 Industry: Theory Matters , ALEXANDER BRATKOVSKY, Hewlett-Packard Laboratories, Palo Alto, CA 94304 — This talk will try to illustrate on a few examples a significant role that theory and modeling plays in an industrial environment of a diversified company. It is especially clear in case of novel materials and processes that may bring big benefits down the road to those with sufficient time horizon. Relevant global trends will be analyzed in this regards.

4:54PM T6.00005 Technologically relevant, in theory , J. TERSOFF, IBM T. J. Watson Center — This talk will give a personal perspective on the role of theoretical physicists in industry, and in particular at IBM. This role has changed over the decades, and continues to evolve.

Wednesday, March 23, 2011 2:30PM - 5:30PM –

Session T7 GSNP: Structural and Mechanical Properties of Jammed Amorphous Materials Ballroom C3

2:30PM T7.00001 Length scale of dynamic heterogeneity and its relation to time scales in a glass-forming liquid[1] , CHANDAN DASGUPTA, Indian Institute of Science — The role of the length scale of dynamic heterogeneity in the enormous increase in the relaxation times of glass-forming liquids upon supercooling has received much attention recently. Using molecular dynamics simulations and finite-size scaling for a realistic glass-forming liquid, we establish that the growth of dynamic heterogeneity with decreasing temperature is governed by a growing dynamic length scale. We also perform a computational study of a four-point structure factor, defined from spatial correlations of mobility, for the same liquid and show that estimates of the dynamic correlation length and susceptibility obtained from this study are consistent with the results of the finite-size scaling analysis. However, the observed dependence of the simultaneously growing time scale of the long-time α-relaxation on system size does not exhibit the same scaling behavior as the dynamic heterogeneity: this time scale is instead determined, for all studied system sizes and temperatures, by the configurational entropy, in accordance with the Adam-Gibbs relation. We also investigate the dependence of the time scale of the short-time β-relaxation on temperature and system size. A finite-size scaling analysis of this dependence reveals the existence of a length scale that grows as the temperature is reduced. Surprisingly, the temperature dependence of this length scale is found to be identical to that of the length scale that governs the growth of dynamic heterogeneity at the α-relaxation time scale. This result suggests a close connection between short-time dynamics and dynamic heterogeneity at time scales of the order of the α-relaxation time.

[1]This talk is based on work done in collaboration with S. Karmakar, S. Sastry and S. Sengupta.

3:06PM T7.00002 Point-to-Set as a measure of Correlations during Unjamming in Granular Systems , MITCH MAILMAN, Brandeis University — There is evidence indicating that the unjamming of frictionless, soft grain packings occurs at a critrical point, however, no correlation function associated with a diverging, static length scale has been identified. To better understand the nature of this transition, we consider the soft grain packing problem as a constraint satisfaction problem [1]. Jammed configurations are mechanically stable packings with non-zero pressure. Contact forces on each grain therefore satisfy the equations of mechanical equilibrium, which are a set of local constraints, as well as a global constraint from the pressure. In general when jammed, there are more contact forces than constraints, so that an ensemble of force networks exists [2] which satisfy the constraints. These force networks make up a high-dimensional solution space that shrinks to a point at the unjamming transition, suggesting that the unjamming transition can be considered an entropy vanishing transition. We explore a new type of "point-to-set" correlation function which has been used to identify non-obvious length scales in other constraint satisfaction problems [3], and show that it exhibits a diverging length scale. We compare and contrast this length scale with the well established "isostatic length" of Wyart et. al [4].

3:42PM T7.00003 Protocol Dependence in Jammed Particulate Media: Statistics of the Density Landscape[1] , ASHWIN S. SAMPANGIRAJ, Department of Mechanical Engineering & Department of Physics, Yale University, New Haven CT — The density at which hard-sphere fluids jam into amorphous solids depends strongly on the compression protocol. Extremely fast quenching protocols bring each initial point in configuration space to the closest basin-maximum on the density landscape. In contrast, slower quench protocols allow the system to relax and explore configuration space. The protocol-dependence of the density, other structural quantities, and mechanical properties depends strongly on statistical features of the landscape. In this talk, I describe calculations of the the basin volumes associated with jammed hard sphere packings, and the critical quench rate Γ^* above which the probabilities for obtaining jammed packings are determined by their basin volumes. Basin volumes are exponentially distributed; thus, for $\Gamma > \Gamma^*$, so are jammed packing probabilities. We discuss the implications of this result on the statistical mechanics of jammed systems.

4:18PM T7.00004 Vibrational modes identify soft spots in a sheared model glass , M. LISA MANNING, Princeton Center for Theoretical Science, Princeton University — Both solids and fluids can flow under applied stress. In crystalline solids, flow occurs via particle rearrangements controlled by a population of dislocations, while in fluids, particle rearrangements occur everywhere throughout the material. In disordered solids, flow generally occurs via localized rearrangements, but no one has been able to identify a population of flow defects, analogous to dislocations, that are structurally different from the rest of the system and more susceptible to flow. It has therefore remained unclear whether a solid-like or fluid-like description is more appropriate for describing flow in such systems. By analyzing the low-energy vibrational modes in a model glass, we have identified a population of structural "soft spots" and have shown that particle rearrangements are initiated at these spots. Thus, these spots serve as good candidates for flow defects. We analyze statistical and structural features of the spots and find that the density of spots decreases with increasing packing fraction and that the population of spots changes slowly compared to the time between particle rearrangements. These results support a solid-like description of flow controlled by a population of localized flow defects in glassy materials.

4:54PM T7.00005 Jamming Mechanisms and Density Dependence of Dynamic Heterogeneities in a Kinetically-Constrained Model , YAIR SHOKEF, Weizmann Institute of Science — Experiments on granular [1] and colloidal [2] systems show steady growth in dynamic heterogeneities as the relaxation time increases with increasing density. In glass-forming liquids, however, the scale of heterogeneities remains modest even as the relaxation time increases by more than ten orders of magnitude with decreasing temperature [3]. This difference may be attributed to the far greater dynamic range measurable in glass-forming liquids [2]. We introduce a simple lattice model [4] which suggests that this difference signals a fundamental distinction between jamming due to an increase in particle density as opposed to jamming by lowering the temperature, or the strength of external driving forces. The recently proposed spiral model [5] has a kinetic constraint that breaks its ergodicity at a critical density smaller than 1. We add to it relaxation mechanisms that mimic the effect of temperature and non-equilibrium driving. This enables us to explore its jamming phase-diagram and study unjamming by temperature or driving above the critical density, which we relate to the random close packing density in particulate systems. We separate the effects of density, temperature and driving and show that jamming resulting from increasing density gives rise to dynamic heterogeneity that grows unboundedly. Whereas decreasing temperature or driving eventually leads to a saturation of the dynamic correlation length even though the relaxation time diverges.

Wednesday, March 23, 2011 2:30PM - 5:30PM –
Session T8 FIP: Shaping Regional Identities through Research Funding Policies Ballroom C4

2:30PM T8.00001 Europe and research: a multi-speed scenario , LUISA CIFARELLI, University of Bologna & European Physical Society — A review of the European situation concerning physics research facilities, collaborations, networks and funding policies will be sketched, pointing out the diversity among different countries of the enlarged EU. Some special focus will be put on particle physics. The continuing integration of Europe, the higher students' mobility trained in the "Bologna Process" frame, the expansion of the European research infrastructures in physics, the increasing funding from the European Commission, the various research shaping and roadmap attempts, the challenge by Asia in addition to that from the USA, are all issues to be examined.

3:06PM T8.00002 Science, Technology and Innovation in Brazil: Advances and Challenges[1] , CARLOS ARAGAO DE CARVALHO, CNPq and UFRJ — We review the construction of the infra-structure for science and technology in Brazil, its success cases, its major advances, and its challenges, both present and future. We emphasize the budget increases, the new legal framework, new mechanisms of support for S&T, and the plans for the future. Preliminary results of the discussions that took place in the 4^{th} National Conference on Science, Technology and Innovation of May 2010 will also be presented.

[1]CNPq

3:42PM T8.00003 Mega Physics Projects: National and International Initiatives: the Indian Experience , ROHINI GODBOLE, CERN PH/TH Theoretical Physics Department — Indian Physics community is now getting involved in a number of Mega physics projects, both home and abroad, national and International. I will present some information on these efforts.

4:18PM T8.00004 Science and Technology in Africa: The African Union new initiatives and financial support perspectives , JEAN-PIERRE EZIN, Commissioner Human Resources, Science & Technology — Physics, which is widely considered as the most fundamental of the sciences, underpins the progress in all other branches of science and has a wide range of applications in economic development, including in health, energy research, food security, communication technology and climate change. The African Union (AU) Commission articulates the continental vision of its Member States and its programs are designed to directly contribute to its social and economic development and integration efforts. In the area of science and technology the Department has developed *Africa's Science and Technology Consolidated Plan of Action* as a strategic policy document through the AU system of conference of ministers responsible for science to guide the continent on common priority programs. The programs in this plan of action that have been transformed into bankable projects under the Book of "lighthouse projects Phase 1," adequately respond to Africa's challenges and development needs using science. They can be summarized into three main themes: a pan-African university (PAU) initiative (to combine higher education and scientific research as a network of differentiated PAU in each of the five African regions), African research grants (to strengthen the research capacity of the African institutions and upgrading infrastructures, consolidating their accumulated asset of scientific knowledge), popularization of science and technology and promotion of public participation (to build public understanding and raising awareness on science and technology as a driving agent for social and economic progress for Africa and its integration process) and a science and technology institutional capacity building program). This talk will provide a review these programs and their status and impact in Africa.

4:54PM T8.00005 Science for Energy , HARRIET KUNG, Associate Director of Science for Basic Energy Sciences - DOE — This abstract not available.

Wednesday, March 23, 2011 2:30PM - 5:30PM –

Session T9 DFD: Flow Instabilities, Turbulence and CFD D220

2:30PM T9.00001 ABSTRACT WITHDRAWN –

2:42PM T9.00002 Modal decomposition of free and forced circular jets at low and high Reynolds numbers , MURALIDHAR KRISHNAMURTHY, Professor, TRUSHAR GOHIL, doctoral student, ARUN SAHA, Assistant Professor — Free and forced jets are important in applications such as combustion, propulsion, mixing, and aero-acoustics. Jet control for noise reduction and mixing efficiency can be achieved by manipulating the flow structures. The most energetic structures of a flow field can be objectively recovered by proper orthogonal decomposition. POD extracts a basis for modal decomposition as eigenfunctions from an ensemble of signals. In the present work, the snapshot POD method is applied to data recorded from direct numerical simulation as well as large eddy simulation in three dimensions. Free jets are reported at a Reynolds number of 1000 and 10000 and 4300 for forced jets. Results show that all of the kinetic energy of laminar flow is stored in large-scale structures while for the turbulent jet, a broader distribution of kinetic energy is obtained. At Re = 1000, 40 snapshots of the flow field are adequate to resolve the major flow structures. For Re=10000, at least 100 snapshots are required for a good spectral representation. Blooming jets arising from dual mode forcing show the formation of odd-even pairs. The first pair contains the details of branching. In addition, the higher order modes capture the inherent jet instability mechanisms.

2:54PM T9.00003 Generalized Saffman-Taylor formula for multi-layer Hele-Shaw flows , PRABIR DARIPA, Texas A&M University — Stability theory plays a major role from fundamental science to applied sciences. It is useful in the design of many processes and engineering instruments as well as in explaining many phenomena. In this paper we review some of the author's and his collaborator's recent works on the extension of Saffman-Taylor instability which occurs at an interface between two immiscible fluids in porous media and Hele-Shaw cells when displacing fluid is less viscous than the displaced one. The growth rate of interfacial disturbances is given by a formula called Saffman-Taylor formula which plays a very important role in many areas including flows in porous media and oil recovery among many others. In this talk, we will present our results on the generalization of this formula to multi-layer flows involving many interfaces. As an application of the generalized Saffman-Taylor formula, we will derive necessary conditions for suppressing instability of two-layer flows by introducing arbitrary number of constant viscosity fluid layers in between. The important role that these conditions play in stabilization of hydrodynamic instabilities in Hele-Shaw flows will be discussed.

3:06PM T9.00004 The stability of a droplet suspended in a straight micro-channel , HAIDER HEKIRI, TAKUMI HAWA, School of Aerospace and Mechanical Engineering, The University of Oklahoma, Norman, OK 73019 — CFD simulations of the dynamics of a two-dimensional, incompressible, and two coupled spherical-cap water droplets suspended in a straight micro-channel, whose channel height is D, have been conducted to investigate the stability of the droplet. FLUENT with a 2-D pressure based solver is utilized in this simulation. The suspended droplet states are measured by the location of the central of mass of the droplet. We find that there is a critical volume, Vc(D), where asymmetric droplet states appear in addition to the basic symmetric states when V $>$ Vc(D). Using the CFD it is demonstrated that when V $<$ Vc(D) the symmetric droplet states have a stable mode. However, when V $>$ Vc(D) the symmetric states become unstable and asymmetric states have a stable mode. The bifurcation of asymmetric states at Vc(D) has a pitchfork nature. The simulations clarify the relationship between the linear stability results and the experimental results of the droplet behavior.

3:18PM T9.00005 Liquid-air interface instability due to an in-plane electric field , MIKHAIL PEVNYI, JAKE FONTANA, PETER PALFFY-MUHORAY, Liquid Crystal Institute - KSU — We report observations of an instability at the free surface of a liquid due to an in-plane electric field. The horizontal air-liquid interface in a partially filled sample cell between vertical electrodes exhibited first oscillations, then increasingly turbulent fluctuations as the strength of the horizontal electric field was increased. This behavior was observed in toluene and choloroform; the applied AC field was sinusoidal with f= 60Hz. The dynamics of the interface was probed via dynamic light scattering. We present our experimental observations, as well as a simple model and numerical simulations of the interface dynamics under the influence of the applied electric field.

3:30PM T9.00006 Stretch-induced wrinkles in reinforced membranes , ATSUSHI TAKEI, ESPCI, FABIAN BRAU, Universit de Mons , BENOÎT ROMAN, JOSÉ BICO, ESPCI — We study through model experiments the buckling of a rigid stripe (or fiber) embedded in a soft membrane under compression. The compression is induced through Poisson effect when the membrane is stretched perpendicularly to the stripe. The wavelength of the wrinkles is found to depend on the material properties and the stretching strain. A balance between the bending and stretching energies of both the membrane and the stripes dictates this wavelength: $\lambda \sim (Bd\ /E_S H_S \delta\ )^{1/3}$, where B is the bending stiffness, d the width of the rigid band, δ the strain, and E_S andH_S the Young modulus and the thickness of the membrane, respectively. The characteristic extension of the wrinkled zone is set by the wavelength. This result also applies to fibers imbedded in a thin membrane. However, in-plane buckling is observed when the thickness of the membrane is large compared with the radius of the fiber. In this last regime, we find $\lambda \sim R(E_F\ /E_S\ )^{1/4}$, where $E_F$and R are the Young modulus and the radius of the fiber, respectively.

3:42PM T9.00007 Computational Parametric Study of R-M Instability Growth for an Inclined Interface[1] , JACOB MCFARLAND, DEVESH RANJAN, Texas A&M University, JEFF GREENOUGH, Lawrence Livermore National Labratory — An inclined interface perturbation is studied for an RM instability to model upcoming experiments in the Texas A&M inclined shock tube facility. Simulations were created using the ARES code developed at Lawrence Livermore National Lab. A parametric study was performed for inclination angles from 30 to 60 degrees, incident Mach numbers of 1.5 to 2.5, and high Atwood number gas pairs air-SF6 and helium/SF6. Qualitative results are examined to show the relative effects of these parameters. Interface growth rates are calculated and compared to the existing linear growth regime models. A new model is proposed based on the interface geometry and compared to the simulation results.

[1]This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

3:54PM T9.00008 Drop Splashing on a Smooth Surface at Low Velocities , CACEY STEVENS, SIDNEY NAGEL, University of Chicago — When a low viscosity liquid drop impacts on a smooth, dry surface, a thin fluid sheet is emitted which subsequently breaks up into a distribution of secondary droplets. Ambient gas pressure is crucial in creating this splash: splashing is completely suppressed below a threshold pressure [1]. There are several regimes that occur as the velocity and liquid viscosity are varied [2]. Here, we discuss splashing in the low velocity, low viscosity regime. We explore how the threshold pressure scales with drop size, as well as liquid viscosity. We also characterize the dependence of threshold pressure with molecular weight of the surrounding gas.

4:06PM T9.00009 Elastic effects on the shear flow instabilities in viscoelastic fluids , AHMED KAFFEL, Department of Mathematics Virginia Tech, DEPARTMENT OF MATHEMATICS VIRGINIA TECH TEAM, DEPARTMENT OF MATHEMATICS TEAM — A linear stability analysis was applied and the stability equation is derived and solved numerically using the spectral Chebyshev collocation method. The objective is to study the elastic effects on the instability of inviscid parallel shear flows. We focus on the upper convected Maxwell model in the limit of infinite Weissenberg and Reynolds numbers. Specifically, we study the effects of elasticity on the instability of a few classes of simple parallel flows, specifically plane Poiseuille and Couette flows, the hyperbolic-tangent shear layer and the Bickley jet. The algorithm is computationally efficient and accurate in reproducing the discrete eigenvalues. We consider flows bounded by walls as well as flows bounded by free surfaces. In the inviscid, nonelastic case all the flows we study are unstable for free surfaces. In the case of wall bounded flow, there are instabilities in the shear layer and Bickley jet flows. In all cases, the effect of elasticity is to reduce and ultimately suppress the inviscid instability. The numerical solutions are compared with the analysis of the long wave limit and excellent agreement is shown. We found flows which are long wave stable, but nevertheless unstable to wave numbers in a certain finite range. While elasticity is ultimately stabilizing, this effect is not monotone; there are instances where a small amount of elasticity actually destabilizes the flow.

4:18PM T9.00010 Thermal convection in multiphase systems , LUCA BIFERALE, University of Rome "Tor Vergata", PRASAD PERLEKAR, TUE, Eindhoven, MAURO SBRAGAGLIA, ANDREA SCAGLIARINI, University of Rome "Tor Vergata", FEDERICO TOSCHI, TUE, Eindhoven, ICTR COLLABORATION — We present preliminary results of a numerical study of two dimensional and three dimensional multiphase thermal convection close to the phase transition and in presence of phase coexistence. The numerical algorithm is based on a suitable implementation of multiphase Lattice Boltzmann scheme with non-ideal pressure tensor. We discuss the effects of droplets and bubbles formation on the global heat flux from bottom to top boundaries.

4:30PM T9.00011 Vortex Sheet Model for a Turbulent Mixing Layer , UJJAYAN PAUL, RODDAM NARASIMHA, MEHEBOOB ALAM, JNCASR, Jakkur, Bangalore 64 — The primary aim of this work is to study instability induced roll up of a slightly perturbed vortex sheet in an Euler fluid. A point vortex model tends to evolve into a chaotic cloud of point vortices instead of smooth double branched spirals. The present model uses linear splines to interpolate the vortex sheet. Computer simulation of this vortex sheet is numerically prohibitive. However, the evolution of the vortex sheet can be performed conveniently using a closed form equation of motion which derived from the basic equations of vortex dynamics. The vortex sheet rolls up into a smooth double branched spiral. A vortex core is formed by regular windings of the vortex sheet and irrotational fluid in between the layers. Various statistical quantities like the growth rate and mean velocity profiles are computed along with the evolution of the vortex sheet. The problem of spontaneous appearance of singularity in an evolving vortex sheet is treated in detail. The critical time for the present vortex sheet model is calculated analytically and compared to the numerical value.

4:42PM T9.00012 Nonlinear Deformation in Weak Turbulence[1] , NICHOLAS OUELLETTE, DOUGLAS KELLEY, YANG LIAO, Department of Mechanical Engineering & Materials Science, Yale University — Turbulent and chaotic flows are well known to mix efficiently: by repeatedly stretching and folding material volumes, material lines stretch exponentially quickly and gradients of an advected scalar field can become very large. By adapting a technique originally introduced to study plasticity in glassy solids, we explicitly separate stretching (a linear transformation) from folding (a nonlinear transformation) in a quasi-two-dimensional experimental flow and study them independently. We compare results from two forcing schemes: one that is dominated by rotation, and another that is dominated by shear.

[1]This work was supported by NSF Grant No. DMR-0906245.

4:54PM T9.00013 Principal Direction of Scalar Transport in Wall Turbulence[1] , CHIRANTH SRINIVASAN, DIMITRIOS PAPAVASSILIOU, The University of Oklahoma — Lagrangian scalar tracking in conjunction with direct numerical simulation is utilized in an infinitely long channel to study the principal direction of scalar transfer for both forwards and backwards single particle dispersion. Four regions are of interest: the viscous sub-layer, the transition region (between the viscous sub-layer and the logarithmic region), the logarithmic region and the center of channel. Fluctuating velocities of scalar markers released in the flow field are correlated forwards and backwards in time to find the components of the correlation coefficient tensor. Eigenvalues and eigenvectors are obtained for both the forwards and backwards dispersion and for fluids with Prandtl number between 0.1 and 1000. The largest eigenvalues are higher in the case of backwards dispersion compared to the case of forwards dispersion. The eigenvector inclinations relative to the yz plane are different for forwards and backwards dispersion (at times comparable to the Lagrangian timescale).

5:06PM T9.00014 Molecular origins of continuum fluid mechanics: Atomic migrations of single-phase fluid and slip boundary conditions , ALAN GRAHAM, SHIHAI FENG, TONY REDONDO, Los Alamos National Lab — We report the results of molecular dynamics simulations of pressure-driven flows of liquid argon in circular and planar conduits. We find that in inhomogeneous shear flows the molecules migrate to the center of the conduits and establish large radial density gradients under conditions that were previously assumed to be incompressible. These are the first predictions of shear-induced migration in pure fluids subjected to inhomogeneous shear flows. These density gradients increase monotonically with Péclet number. They result in a blunted velocity profile that deviates from the parabolic profile predicted by the Navier-Stokes equations for an incompressible fluid. Comparisons with simulations where the flow exhibits zero or linear shear indicate that this phenomenon is the result of the nonlinear shear flows and the finite size of the molecules.

5:18PM T9.00015 Search for Euler Singularity using Vortex Filaments , SAHAND HORMOZ, MICHAEL BRENNER, Harvard University — A promising mechanism for generating a finite-time singularity in the incompressible Euler equations is stretching of vortex filaments. An exhaustive search of all possible initial conditions involving filaments, however, is not practically feasible. In this talk, I will show that two interacting vortex filaments can not generate a singularity for any initial conditions, by analyzing the asymptotic self-similar limit of their collapse. Essentially, our approach entails a separation of the dynamics of the filament shape, from the shrinking of its core. We solve for the dynamics using a self-similar ansatz and show that the core does not shrink fast enough for a self-consistent collapse. The similarity solution allows for many different collapse geometries, consistent with the tireless effort in the past of investigating new initial conditions. Potential for a singularity at higher number of filaments is also discussed.

Session T10 DMP: Focus Session: Growth, Structure, Dynamics, and Function of Nanostructured Surfaces and Interfaces – Oxides D221

2:30PM T10.00001 Cross-sectional scanning tunneling microscopy and spectroscopy of fractured oxide surfaces and heterostructure interfaces[1] , TEYU CHIEN, Argonne National Laboratory — Recently, interfaces between novel oxide materials have become a playground for manipulation of new functionalities. At interfaces, the broken symmetry and the spatially confined environment have been shown to modify the local interactions and generate wholly new electronic phases (e.g. magnetism, metallicity, superconductivity etc.) distinct from the composite bulk materials. However, to date our understanding of these interface driven phases is still limited. While there exists powerful spatially resolved tools for visualizing the chemical and magnetic structure of an interface, a direct observation of electronic behavior across the interface presents a major experimental challenge. After the success of creating flat fractured surfaces on Nb-doped $SrTiO_3$ (Nb:STO) accessible to scanning tunneling microscopy (STM) [1-3], we have further harnessed the high-sensitivity to electronic local density of states (LDOS) of the scanning tunneling spectroscopy (STS) in cross-sectional geometry to visualize complex oxide interface electronic properties. By extending XSTM/S to the interface between colossal magnetoresistant manganite $La_{2/3}Ca_{1/3}MnO_3$ (LCMO) and semiconducting Nb:STO, we were able to map the LDOS across the boundary to unambiguously visualize the interface by the location of the valence band and elucidate the fundamental issue of band alignment at a complex oxide heterointerface [4].

3:06PM T10.00002 Electrical-stress-induced transport and surface potential characterizations of metal/TiO_2/metal planar junctions , HAERI KIM, DONG-WOOK KIM, Ewha Womans University — Electric-field-induced resistive switching (RS) phenomena in metal oxides have attracted considerable research interest due to their potential use in nonvolatile memory device applications. Intensive investigations have revealed that coupled electron ion dynamics play a key role the RS mechanism. Metal/single crystal junction can be an ideal model system to study how the ionic drift and diffusion can affect the resistance. We investigated transport and local electrical properties of Pt/TiO_2 single crystal/Ti planar junctions with micron- sized gaps between the electrodes. Scanning Kelvin probe microscopy (SKPM) showed that negative (positive) electrical stress to the Pt electrodes significantly reduced (hardly affected) the Pt/TiO_2 contact resistance. The SKPM results also revealed that the electrical stress caused alteration of the local work function of TiO_2. The comparative investigations of the transport and SKPM results suggested that the electrical stress induced redistribution of ions, resulting in the change of the junction resistance.

3:18PM T10.00003 ABSTRACT WITHDRAWN –

3:30PM T10.00004 Theoretical study of Ge/$BaTiO_3$ Interfaces , KURT FREDRICKSON, ALEXANDER DEMKOV — It has been shown (McKee *et al.,* Phys. Rev. Lett. **81,** 3014 (1998), and R. McKee, *et al., Science* **293**,468 (2001)) that perovskite oxides $SrTiO_3$ and $BaTiO_3$ (BTO) can be grown epitaxially on Si and Ge, respectively. It would be interesting to achieve the reverse, i.e. to grow for example, Ge on BTO. It is not clear, however, whether one can achieve wetting of BTO by Ge. Theoretically, the energy of the Ge (001) surface is estimated to be anywhere between 591 and 1700 erg/cm^2 and the surface energy of BTO is in the range of 1083-1496 erg/cm^2 depending on termination and environment. The missing piece of information is the energy of the Ge/BTO interface. We examine five possible Ge/BTO interface structures and calculate their energies using density functional theory to determine which one has the lowest energy, and whether wetting can be achieved.

3:42PM T10.00005 Strain relaxation in single crystal $SrTiO_3$ grown on Si (001) , MIRI CHOI, AGHAM POSADAS, RYTIS DARGIS, The University of Texas at Austin, TX, DINA TRIYOSO, Freescale Semiconductor, Austin, TX, DAVID THEODORE, Freescale Semiconductor, Tempe, AZ, CHIH-KANG SHIH, ALEXANDER A. DEMKOV, The University of Texas at Austin,TX, THE UNIVERSITY OF TEXAS AT AUSTIN, TX TEAM, FREESCALE SEMICONDUCTOR, AUSTIN, TX COLLABORATION, FREESCALE SEMICONDUCTOR, TEMPE, AZ COLLABORATION — A layer of $SrTiO_3$ grown directly on Si may be used as a pseudo-substrate in perovskite deposition. As grown, $SrTiO_3$ is compressively strained, however, by subsequent annealing in oxygen at elevated temperature, a strain relieving SiO_x buffer layer can be grown between the substrate and the perovskite layer. We perform a systematic study of strain relaxation in $SrTiO_3$ films grown on Si by molecular beam epitaxy as a function of the process conditions (annealing time, temperature, and oxygen partial pressure). Using a combination of X-ray diffraction, reflection high energy electron diffraction, and transmission electron microscopy we explore the oxidation and strain relaxation of $SrTiO_3$. We compare the kinetics of the buried oxide growth to that predicted by the conventional Deal-Grove model. An understanding of strain relaxation of $SrTiO_3$ on silicon can potentially be used to control the $SrTiO_3$ lattice constant for lattice matching with functional oxide overlayers.

3:54PM T10.00006 X-ray 3D atomic imaging of Pt nanocrystals supported on $SrTiO_3$(001) , ZHENXING FENG, Department of Materials Science and Engineering, Northwestern University, ALEXANDER KAZIMIROV, CHESS, Cornell University, MICHAEL BEDZYK, Department of Materials Science and Engieneering, Northwestern University — Ultrathin metal or metal-oxide layers deposited onto oxide surfaces have wide applications in catalysis, chemical sensing and electronics. For sub-monolayer Pt deposited on the 2x1 $SrTiO_3$(001) surface, atomic-force microscopy shows the formation of nanoparticles and X-ray standing wave (XSW) atomic imaging shows that these nanoparticles are composed of Pt face-centered-cubic nanocrystals with cube-on-cube epitaxy coherent to the substrate unit cell. The phase sensitivity of the XSW allows for a direct measurement of the interface offset between the two unit cells along the c-axis. Different Pt coverages lead to differences in the observed XSW image of the interfacial structure, which is explained by the Pt-Pt interaction becoming stronger than the Pt-substrate interaction as the coverage is increased from 0.2 to 0.6 ML. Proposed atomic-scale interface models are based on a published double-layer TiO_2 terminated structure for the 2x1 $SrTiO_3$(001) surface and density functional theory.

4:06PM T10.00007 Dynamics of early stage nano-oxidation by *in situ* UHV-TEM[1] , JUDITH YANG, University of Pittsburgh — Environmental stability is one of the most important properties for materials exposed to air. As dimensions of engineered systems approach nanoscale, fundamental understanding of reactions with oxygen at this length scale is critical for environmental stability as well as for processing oxide nanostructures, where surface reactions are commonly utilized. The nanoscale stages of oxidation from the nucleation of the metal oxide to the formation of the thermodynamically stable oxide represent a scientifically challenging and technologically important terra incognito. The kinetics of early stage oxidation of Cu, Cu-Au and Cu-Ni alloys were visualized using in situ ultra-high vacuum transmission electron microscopy (UHV-TEM), where the initial oxidation stages can be observed in real-time under well-controlled surface conditions. We examined the dynamic responses of thin films to variations in thermodynamic variables such as temperature, oxygen pressure, strain, and crystallographic orientation. The kinetics of the nucleation and growth of three-dimensional oxide islands demonstrate that oxygen surface diffusion is the primary mechanism for oxide growth during initial oxidation in dry oxygen, and thus bears a striking resemblance to heteroepitaxy. Compared with the behavior of Cu films, the oxidation of Cu-Au alloys revealed more complexity. For example, the oxidation of (100)-oriented Cu-Au alloys with low Au content at $\sim$ 600C results in the formation of Cu2O oxide islands with a dendritic morphology and a non-uniform lateral distribution of Au around the islands. For Cu-Ni oxidation, the addition of Ni causes the formation Cu2O and/or NiO where the oxide type(s) and the relative orientation with the film depend on the Ni concentration, oxygen partial pressure and temperature. Evolution of the shape and size of the oxide islands can be quantitatively analyzed and provide fundamental insights into the complex kinetics and energetics of oxidation. Models based on surface orientation, strain development, and diffusion will be discussed to explain the formation of some of the novel oxide nano-structures.

4:42PM T10.00008 Controlled surface reorganization of complex oxides by laser MBE , MIKHAIL KAREEV, B. GRAY, JIAN LIU, E.J. MOON, J. CHAKHALIAN, University of Arkansas — We report on the fabrication of ultra-thin layers of complex oxide perovskites, which display a variety of high-order surface reconstructions. In order to obtain the observed complex surface reconstructions (e.g. 6x2, 4x2, 4x4, etc.), nearly stoichiometric complex oxide material are found to be re-arranged into specific combinations of long-ordered periodic structures. We examine details of homo- and heterogeneous growth of SrTiO3 (STO) and LaNiO3 respectively on TiO2 terminated and mixed TiO2/SrO termination STO substrates by the combination of high-pressure RHEED and AFM to investigate mechanisms behind the high order surface reconstruction. J.C. was supported by DOD-ARO under the Contract No. 0402-17291 and NSF Contract No. DMR-0747808.

4:54PM T10.00009 Quantum confinement effects in nanocrystals of SnO_2 in MgO matrix , M.B. SAHANA, Wayne State University, C. SUDAKAR, Indian Institute of Technology Madras, India, A. DIXIT, J.S. THAKUR, R. NAIK, Wayne State University, V.M. NAIK, University of Michigan-Dearborn — We have studied the nanocrystal formations of SnO_2in$x$$SnO_2$-(1-$x$)MgO composite thin films (x =0 to 1 and thickness 0.5 to 1 μm) prepared by metal-organic decomposition method. We find a direct relationship between the size of SnO_2 nanocrystals and the annealing temperature. Similarly, higher concentration of Mg in $x$$SnO_2$-(1-$x$)MgO leads to smaller size nanocrystals of SnO_2. Under the controlled choice of composition and annealing conditions, the bandgap of SnO_2 can be continuously increased from 3.89 eV to 4.5 eV thus providing a generic approach for tuning the bandgap in nanocomposite systems over a wide range of energy. We discuss this behavior in terms of the quantum confinement effect arising from particle size being comparable to the order of Bohr radius of the material.

5:06PM T10.00010 Detection of Dielectric Trap States in Hafnium Oxide By Single Electron Tunneling Force Spectroscopy[1] , DUSTIN WINSLOW, JON JOHNSON, CLAYTON WILLIAMS, Department of Physics, University of Utah — Atomic scale detection and imaging of electronic trap states in dielectric films has recently been demonstrated.[2] Standard methods typically provide characterization over a much larger scale. Single Electron Tunneling Force Spectroscopy has been employed to measure the energy levels of trap states in HfO_2 with sub-nanometer spatial resolution. Analysis of individual spectra obtained at different locations shows variation in the density of defect states. When multiple spectra taken from 40 different locations are averaged, a broad peak 0.3 eV below the conduction band is observed, which agrees with data obtained over large areas by standard measurements.[3] Additional peaks, not seen by the standard methods, are also observed. The method will be described and the data discussed.

5:18PM T10.00011 Charge Injection and Relaxation in HfO_2 Films Measured by Single Electron Tunneling Force Spectroscopy[1] , CLAYTON WILLIAMS, DUSTIN WINSLOW, JON JOHNSON, Department of Physics, University of Utah — Detection and imaging of individual trap states in dielectric materials with atomic scale spatial resolution has been recently demonstrated.[2] Spectroscopic measurements on HfO_2 films by Single Electron Tunneling Force Spectroscopy have now shown evidence of both reversible and irreversible tunneling to and from these electronic trap states. The irreversibility is small near the middle of the band gap, becoming larger at $\sim$ 0.7 eV below the conduction band and 1.3 eV above the valence band. The irreversibilty of tunneling is likely due to charge relaxation. The evidence of charge relaxation in the film and a description of this new nanometer scale spectroscopic capability will be presented. The possible mechanisms by which the relaxation takes place will also be described.

Session T11 FIAP: Spin and Transport in Low Dimensional Semiconductors D222

2:30PM T11.00001 Noble Metals and Transition Metals Adsorbed on Graphene: The Pursuit of Graphene Spintronics , MATHEUS PAES LIMA, Univeristy of Sao Paulo, ADALBERTO FAZZIO, University of Sao Paulo — Via first-principles simulations we study the structural, magnetic and electron transport properties of 2D graphene in the presence of single atoms. We consider Cu, Ag and Au, as well as Mn, Fe, Co and Ni adsorbed on pristine and defective graphene containing vacancies and divacancies. To obtain the transport properties we perform ab-initio calculations based on Density Functional Theory (DFT) coupled to Non-Equilibrium Greens' Function (NEGF) formalism using the Landauer-Büttiker formula within the Meir-Wingreen approach. Our results show that graphene+noble metals systems have a gate controllable spin polarized current, allowing the fabrication of switchable spin filters with a moderated efficiency. In the particular case of Gold adsorbed on pristine graphene, a positive gate leads to a polarized current with excess of up electrons, while a negative gate the converse. Despite the high-spin configuration of Mn, the d levels are very far from the Fermi level. The Ni atom prefers a non-magnetic configuration. Therefore, graphene+transition metals systems present a polarized current only for Fe and Co atoms, allowing the fabrication of spin filters with very high efficiency.

2:42PM T11.00002 ABSTRACT WITHDRAWN –

2:54PM T11.00003 Hole-induced Dynamic Nuclear Polarization in Quantum Dots[1] , WEN YANG, L.J. SHAM, Department of Physics, University of California San Diego — We present a microscopic theory showing that through the non- collinear hole-nuclear dipolar hyperfine interaction, an optically excited heavy hole in a quantum dot can induce a steady-state nuclear polarization. The preferential direction of the nuclear spin flip is set by the energy mismatch of relevant transitions instead of thermal relaxation. The induced nuclear polarization shows a sign dependence on the product of the nuclear Zeeman splitting and the frequency detuning of the pumping laser, leading to bidirectional hysteretic locking of the optical absorption peak onto resonance or bidirectional hysteretic shift of the peak away from zero detuning. This sheds light on a puzzling observation of bidirectional hysteretic locking of the neutral exciton absorption peak in Faraday geometry [C. Latta et al., Nature Phys. 5, 758 (2009)]. By solving the Fokker-Planck equation for the nuclear polarization distribution, we found a 10-fold suppression of the steady- state nuclear fluctuation, in reasonable agreement with the single pump experiment in Voigt geometry [X. Xu et al., Nature 459, 1105 (2009)].

3:06PM T11.00004 Beating of Friedel Oscillations in Spin-Orbit Coupled System[1] , SAMVEL BADALYAN, Department of Physics, University of Regensburg, 93040 Regensburg, Germany, ALEX MATOS-ABIAGUE, University of Regensburg, GIOVANNI VIGNALE, Department of Physics and Astronomy, University of Missouri, Columbia, Missouri 65211, USA, JAROSLAV FABIAN, Department of Physics, University of Regensburg, 93040 Regensburg, Germany — The interplay of different spin-orbit interaction mechanisms induces highly anisotropic modifications of the static dielectric function of a two-dimensional electron system. One of the main changes of the static polarization function is the induced shift of its singularity position, which is in opposite directions for orthogonal momentum orientations. More interestingly, we have found that in certain situations the polarization function exhibits a *doubly-singular* behavior. This new property generates a novel phenomenon–*the beating of Friedel oscillation*s, which can be controlled by an external electric field. This effect is a general feature of systems with Bychkov-Rashba and Dresselhaus spin-orbit fields and should be directly observable through tunneling microscopy imaging of the density distribution around an impurity.

[1]The work is supported from EU Grant No. PIIF-GA-2009-235394 (S.M.B.), SFB Grant No. 689, and NSF Grant No. DMR-0705460 (G.V.).

3:18PM T11.00005 Cyclotron resonance in graphene and Kohn's theorem , KESHAV SHRIVASTAVA, University of Malaya — In 1961 Kohn has shown [1] that the cyclotron frequency is independent of the interaction. In the case of graphene there is some effort to suggest that the electron dispersion is linear in k, instead of $(h/2\pi)^2k^2/2m$ so that the Kohn theorem may not apply [2]. We find that the Kohn theorem does not use the dispersion relation and applies to graphene the same way as in some other material. We find that if e is replaced by $e^*=(1/2)ge$, the Kohn theorem applies with the cyclotron frequency $(h/2\pi)\omega_c = (1/2)geB/mc$. Hence there is no interaction and all of the interaction is contained in $g = (2j+1)/(2l+1)$ which is used only in the unperturbed Hamiltonian. The degeneracy of the levels is found to be related to the flux quantization. We have explained [3] the plateaus observed in the Hall effect resistivity of graphene without the use of interaction. Hence the Kohn's them applies to graphene.

3:30PM T11.00006 Fluctuation-dissipation theorem for chiral systems in nonequilibrium steady states[1] , DIMA FELDMAN, CHENJIE WANG, Brown University — We consider a three-terminal system with a chiral edge channel connecting the source and drain terminals. Charge can tunnel between the chiral edge and a third thermal. The third terminal is maintained at a different temperature and voltage than the source and drain. We prove a general relation for the current noises detected in the drain and third terminal. It has the same structure as an equilibrium fluctuation-dissipation relation with the nonlinear response $\partial I/\partial V$ in place of the linear conductance. The result applies to a general chiral system and may be useful for detecting "upstream" modes on the quantum Hall edges.

[1]This research was supported in part by NSF grant No. DMR-054116.

3:42PM T11.00007 Spontaneous Quantum Hall States in Chirally-Stacked Few-Layer Graphene Systems , FAN ZHANG, JEIL JUNG, GREGORY FIETE, QIAN NIU, ALLAN MACDONALD, PHYSICS DEPARTMENT, UNIVERSITY OF TEXAS, AUSTIN COLLABORATION — Chirally stacked N-layer graphene systems with $N \geq 2$ exhibit a variety of distinct broken symmetry states in which charge density contributions from different spins and valleys are spontaneously transferred between layers. We explain how these states are distinguished by their charge, spin, and valley Hall conductivities, by their orbital magnetizations, and by their edge state properties. We argue that valley Hall states have [N/2] edge channels per spin-valley.

3:54PM T11.00008 Re-entrant Negative Coulomb Drag in a 1D Quantum Circuit , DOMINIQUE LAROCHE, GUILLAUME GERVAIS, McGill University, MIKE P. LILLY, JOHN L. RENO, Sandia National Laboratories — We report Coulomb drag measurements between tunable vertically- coupled quantum wires. The wires are fabricated in a GaAs/AlGaAs double quantum well heterostructure with a 15 nm barrier separating the quantum wells and are non-ballistic. The Coulomb drag signal is mapped out versus the number of subbands occupied in each wire, and regions of both positive and negative drag are observed. Negative Coulomb drag signals are measured in two regimes: one at low electronic density when the drag wire is close to or beyond depletion, and one at higher electronic density when the drag wire has more than a single 1D subband occupied. A discussion of the negative drag signal in terms of electron-hole asymmetry and localization is presented. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04- 94AL85000.

4:06PM T11.00009 Dynamic control over nanoparticle plasmon resonance through variation of refractive index[1] , HARI P. PAUDEL, MICHAEL N. LEUENBERGER, University of Central Florida — In a semiconductor material it is possible to vary the index of refraction by exciting electron-hole pairs through a laser pulse. Generally the change in refractive index changes linearly with the carrier density and also increases with the lattice temperature. We present our results on the variation in index of refraction in the TiO2 shell of an Ag/TiO2 core-shell nanoparticle by exciting electron-hole pairs in TiO2 through a laser pulse. We performed bandstructure calculations using VASP to determine the variation of the optical dielectric tensor as a function of photon frequency. This change in refractive index not only affects the refraction of photons with frequency below bandgap, but also affects strongly the resonance peaks of the surface plasmons due to the Ag core. This effect can be used to dynamically control the plasmon resonance of a hybrid metal-semiconductor nanoparticle, for example for use in cancer therapy or nanoplasmonic circuits.

4:18PM T11.00010 Transport in Coherent Quantum Hall Bilayers[1] , ALLAN MACDONALD, DMYTRO PESIN, The University of Texas at Austin, Austin, TX — We develop an approach to describe transport in bilayer quantum Hall systems in which coherence is established spontaneously between layers. We use Landauer-Buttiker theory with phenomenological parameters which can be fit to experimental data to describe quasiparticle transport in bilayers with strong coherence. We use the above approach to calculate two-probe conductances for various experimental configurations. We also apply the formalism to describe high-current transport in a bilayer with a time-dependent condensate. To describe the transition from strong to weak coherence, we use a pheonomenological single "relaxation length" ansatz for contact-to-contact transmission coefficients. As an application, we consider longitudinal drag, and find a good agreement with experiment in the regime of well- developed Quantum Hall Effect.

Session T12 FIAP: Atomic Structures and Mechanical Properties in Semiconductors D223/224

2:30PM T12.00001 A dual approach to quantum fluctuations in frustrated lattice spin models[1] , ANIRBAN GANGOPADHYAY, VICTOR GALITSKI, University of Maryland, College Park — We develop a dual approach to describe quantum dynamics in lattice spin models, which allows us to describe nonperturbative *quantum* trajectories in the spin path integral. The spin path integral takes the form of a combination of traces of "dynamic density matrices", which belong to either special linear group $SL(2,C)$ for a quantum ferromagnet or $SU(2)$ for an antiferromagnet. We analyze the latter model of a highly frustrated quantum antiferromagnet and find a class of non-perturbative trajectories that contribute to thermodynamics of the model at low temperatures.

2:42PM T12.00002 Potassium-induced semiconducting to metallic transition on the β-SiC(100) c(4x2) surface , BARRY HAYCOCK, Dublin Institute of Technology / West Virginia University — We present new data on the potassium-induced semiconducting to metallic transition of the silicon-terminated β-SiC(100) c(4x2) surface, resulting from density functional theory simulations. In our calculations we have analysed many different K-SiC(100) structures, corresponding to K coverages ranging from 0.08 to 1.25 monolayers (ML), paying special attention to the 2/3 ML and 1 ML cases where the transition has been reported. We find that the K-SiC(100) surface is metallic in all the cases. In spite of that, the K layer shows a semiconducting density of states (DOS) up to K coverages of $\sim$1ML, beyond which the potassium layer undergoes a transition to metallic behaviour, explaining the experimental observation. We propose a new atomic model for the surface reconstruction of the 1ML case which has far lower total energy than the previously suggested model based on linear K chains after simulated annealing studies.

2:54PM T12.00003 The role of structural ordering in the semiconducting behavior of Cr_3Al[1] , ZOE BOEKELHEIDE, UC-Berkeley, D.A. STEWART, Cornell, F.J. WONG, Y. SUZUKI, F. HELLMAN, UC-Berkeley — $Cr_{1-x}Al_x$ displays unexpected semiconducting behavior for x $\sim$ 0.25; an ordered Cr_3Al structure has been proposed to explain it.[1, 2] In this work, density functional theory calculations and nonequilibrium thin film growth were used to study the role of ordering on the transport properties. The atoms in Cr_3Al occupy the sites of a bcc lattice, like Cr. Calculations comparing possible structures show that the proposed chemically ordered, rhombohedrally distorted Cr_3Al structure, with ordering along the <111> direction, is the lowest energy of those considered. In addition, the band structure shows a pseudogap, consistent with experimentally observed transport properties. Thin films of $Cr_{1-x}Al_x$ were grown with various growth and annealing temperatures to vary the properties. Samples with the most rhombohedral ordering are semiconducting. Decreased rhombohedral ordering leads to lower resistivity. Samples with a tetragonal distortion due to the $C11_b$ (Cr_2Al) structure have metallic resistivity. References: [1] D. J. Chakrabarti and P. A. Beck, J. Phys. Chem. Solids 32, 1609 (1971) [2] F. J. A. den Broeder et al, Phys. Status Solidi A, 67, 233 (1981)

3:06PM T12.00004 Raman Investigation of Ru_2Si_3 Single Crystals and Thin Films , A. GLEN BIRDWELL, U.S. Army Research Laboratory, Adelphi, MD 20783 USA, DANIEL LENSSEN, DELO Industrial Adhesives, 86949 Windach, Germany, CONIN B. VINING, ZT Services, Inc., Auburn, AL 36830 USA, FRANK CROWNE, U.S. Army Research Laboratory, Adelphi, MD 20783 USA, ROBERT GLOSSER, Department of Physics, University of Texas at Dallas, Richardson, TX 75080 USA — Raman spectra were obtained from Ru_2Si_3 single crystals and thin films. The spectra were taken with the incident light polarization parallel and perpendicular to each axis of the single crystal. When inspecting all the spectra of multiple geometric configurations, we were able to observe a total of thirteen phonon modes. To the best of our knowledge, there are very few published results with which to compare. However, the encouraging point of this work is that when spectra were obtained on thin film material composed of multiple crystal orientations, we have a very close correspondence to the modes found from the experiments on the single crystal.

3:18PM T12.00005 Long-range-order and Short-range-order Structures in Sn-doped Ge Thin Films[1] , YUN-LIANG SOO, S.L. CHANG, National Tsing Hua University, J.F. LEE, National Synchrotron Radiation Research Center, H.H. CHENG, National Taiwan University — The Sn-doped Ge semiconductor thin films have shown direct bandgap and many other interesting physical properties with great potential for technological applications. To understand the underlying mechanism for the unique properties of these materials, information on the locations of Sn atoms in the matrix and the effects of Sn doping on the crystal structure of Ge host is an important prerequisite. Samples of Sn-doped Ge thin films of thickness around 300Å and Sn concentration 4 at.% to 28 at.% have been prepared by molecular beam epitaxy (MBE) method. Long-range-order and short-range-order structures in these films have been probed by using x-ray diffraction (XRD) and extended x-ray absorption fine structure (EXAFS) techniques, respectively. Our x-ray results demonstrate that Sn impurity atoms are located on the substitutional sites in the Ge films with Sn concentration up to 20 at.%. Variation of lattice constant as a result of Sn doping in the Ge host will also be presented.

[1]The present research has been supported by NSC in Taiwan under project number 97-2112-M-007-023-MY3.

3:30PM T12.00006 Wurtzite-derived polytypes of kesterite and stannite quaternary chalcogenide semiconductors , SHIYOU CHEN, Lab of Polar Materials and Devices, East China Normal University, YE LUO, XIN-GAO GONG, Fudan University, ARON WALSH, University College London, SU-HUAI WEI, National Renewable Energy Lab — The $I_2-II-IV-VI_4$ quaternary chalcogenide semiconductors (*e.g.*, Cu_2ZnSnS_4, $Cu_2ZnGeSe_4$) have been studied for more than 40 years, but the nature of their crystal structures has proved contentious. Literature reports exist for the stannite and kesterite structures, which are zincblende-derived structures, and wurtzite-stannite, which is a wurtzite-derived structure. In this talk we report a new wurtzite-derived structure, wurtzite-kesterite (space group Pc), which is the ground state for some $I_2-II-IV-VI_4$ compounds, but is easily confused with the wurtzite-stannite structure. We show that there is a clear relationship between the properties of the wurtzite-kesterite and zincblende-derived kesterite structures,, as well as between wurtzite-stannite and stannite. The energy stability of different structures are studied according to the strain and Coulomb energy contributions, showing a dependence on the size and ionicity of the component atoms. Electronic structure of the wurtzite-derived structures will also be discussed.

3:42PM T12.00007 Spontaneous symmetry breaking in two coupled nanomechanical electron shuttles[1] , CHULKI KIM, University of Wisconsin-Madison, Physics, JONGHOO PARK, ROBERT BLICK, University of Wisconsin-Madison, Electrical & Computer Engineering — We present spontaneous symmetry breaking in two coupled nanomechanical electron shuttles. The electron shuttles are realized as silicon nanopillars and placed between two capacitor plates in a homogeneous electric field. Instead of being mechanically coupled through a spring they exchange electrons, i.e., they shuttle electrons from the source to the drain capacitor plate. The nonzero dc current through this system by external ac excitation is caused via dynamical symmetry breaking. The oscillation frequencies of the shuttling system are mode locked to the applied voltage frequency.

3:54PM T12.00008 ABSTRACT WITHDRAWN –

4:06PM T12.00009 Vibrational Modes of thin Silicon Membranes , REIMAR WAITZ, University of Konstanz, OLIVIER SCHECKER, now Robert Bosch GmbH, Gerlingen-Schillerhoehe, Germany, ELKE SCHEER, University of Konstanz — Membranes with thicknesses in the range of hundred nanometers and macroscopic lateral size are interesting systems to study the mechanical properties of solids on various length scales. In our experiment a piezo is used to couple in vibrations, which can be observed with a phase-shift interferometer using stroboscopic light. With this technique we image transverse modes of frequencies up to 12 MHz. In general, the observed wave pattern of the membrane deflection will be a superposition of the mode corresponding to the excitation frequency and several higher harmonics. Using a Fourier transformation in time, it is possible to separate these contributions. This way eigenmodes up to the 8th harmonic of the excitation frequency can be imaged. The influence of strain on the dispersion relation is investigated by applying a pressure difference between both sides of the membrane. The results are compared to finite-elements simulations.

4:18PM T12.00010 Phonon-imaging measurements of $CaWO_4$ Elastic Constants[1] , TIMOTHY HEAD, Abilene Christian University, MADELEINE MSALL, Bowdoin College — Recent use of $CaWO_4$ in phonon-mediated detectors for a dark matter interactions by the Cryogenic Rare Event Search using Superconducting Thermometers (CRESST) collaboration have increased interest in precise measurements of $CaWO_4$ elastic constants. Phonon-imaging simulations based on continuum elasticity theory show that position and shape of phonon caustics depend sensitively on the elastic constants. Spatial and Temporal phonon flux distributions arising after point heat-pulse excitation have been measured for [001] and [010] oriented $CaWO_4$ crystals. We report elastic constants derived from time of flight measurements along symmetry directions, and calculated by matching experimental phonon images to simulations based on continuum elasticity theory.

[1]Thanks to the ACU Math/Science Grant for partial support of this work.

4:30PM T12.00011 Kinetic Monte Carlo simulation of GaAs homoepitaxy and droplet epitaxy , KRIS REYES, DENIS NOTHERN, JOANNA MILLUNCHICK, PETER SMEREKA, University of Michigan — We present a new model for atomistic simulation of III-V semiconductors that is based on the solid-on-solid model and allows for multiple species, atom exchanges, and local considerations for atom bonding energies. The model is validated by comparison with experimental observations of GaAs homoeptiaxial growth. In particular the simulated surface concentration and growth modes agree with experiments over a wide range of growth conditions. An important feature of this model is that Ga and As atoms are treated explicitly, resulting in the ability to realistically model Ga droplet formation under low As overpressure and their recrystallization upon exposure to As.

4:42PM T12.00012 First principles determination of vibrational and elastic properties of quaternary compounds Cu_2ZnSnS_4 and $Cu_2ZnSnSe_4$, TANJU GUREL, CEM SEVIK, TAHIR CAGIN, Artie McFerrin Department of Chemical Engineering, Texas A&M University, College Station, TX — Recently, the quaternary compounds, Cu_2ZnSnS_4 and $Cu_2ZnSnSe_4$, have been attracted pretty much attention because of their potential use in the field of energy harvesting applications. Several theoretical calculations have been reported about their first principles electronic, optic and transport properties. However, no lattice dynamic calculations have been published yet despite the discussions about their possible ground state crystal structures and measured low thermal conductivity values. In this systematical study, we examined the vibrational and elastic properties of the two different crystal phases, kesterite (KS) with space group $I\overline{4}$ and stannite (ST) with space group $I\overline{4}2m$, of this quaternary compounds by using density functional perturbation theory. In addition, we predicted the relaxation time dependent lattice thermal conductivity within the solution of phonon Boltzmann transport equation by making use of the acquired vibrational frequency data.

4:54PM T12.00013 Measuring graphene's thermal coefficient of expansion with bimetallic cantilevers , HIRAM CONLEY, Vanderbilt University, NICKOLAY LAVRIK, CNMS Oak Ridge National Lab, DHIRAJ PRASAI, KIRILL I. BOLOTIN, Vanderbilt University — We developed a method for probing the thermal coefficient of expansion of 2D materials by measuring the deflection of a bimetallic cantilever. We fabricate suspended bimetallic cantilevers composed of single-layer or multilayer graphene and either gold or silicon nitride. Because of the mismatch of the thermal expansion coefficients, these cantilevers bend when heated. We employ laser interferometry to measure the bending and to extract the thermal expansion coefficient from -170 C to 250 C. We find that this technique provides a reliable measurement of the thermal expansion coefficient for graphene. Through comparison of the coefficient of expansion obtained from our bimetallic cantilevers and that of suspended graphene we demonstrate how graphene's dimensionality is perturbed by contact with other materials.

5:06PM T12.00014 Temperature Dependence of Cyclotron Decoherance Time in a High Mobility Two-Dimensional Electron Gas , J.A. CURTIS, J.D. MOORE, Department of Physics, University of Alabama, Birmingham, Alabama 35294, T.T. TOKUMOTO, National High Magnetic Field Lab, Florida State University, Tallahassee, Florida 32310, J.G. CHERIAN, Department of Physics, Florida State University, Tallahassee, Florida 32310, X. WANG, Department of Electrical Engineering, Rice University, Houston, Texas 77005, J.L. RENO, Sandia National Laboratories, Albuquerque, New Mexico 87185, A. BELYANIN, Department of Physics, Texas A&M University, College Station, Texas 77843, J. KONO, Department of Electrical Engineering, Rice University, Houston, Texas 77005, S.A. MCGILL, National High Magnetic Field Lab, Florida State University, Tallahassee, Florida 32310, D.J. HILTON, Department of Physics, University of Alabama, Birmingham, Alabama 35294 — Using time-domain THz magneto-spectroscopy, we studied the dynamics of a 2DEG ($\mu = 3.4 \times 10^6 \mathrm{cm}^2\,\mathrm{V}^{-1}\,\mathrm{s}^{-1}$) as a function of temperature (0.4K-100K).The decoherence lifetimes increase monotonically as temperature decreases below 1 K, which we have fit to a power law ($\tau \sim T^{0.29}$). We will discuss the mechanisms that contribute to the lifetimes. The transmitted pulse amplitude increases from 0.4K-1.2K, saturates from 1.5K-25K, and decreases from 50K-100K. J. A. Curtis is supported by a US Dept. Education GAANN Fellowship (P200A090143).

Session T13 GSNP: Focus Session: Transport and Diffusion in Non-equilibrium Systems D225/226

2:30PM T13.00001 Thermodiffusion (Ludwig-Soret Effect) in Geological Systems[1] , CHARLES LESHER, UC Davis — Since its discovery more than a century and a half ago, the Ludwig-Soret effect (development of concentration gradients in response to a temperature gradient) has been documented in a large variety of inorganic and organic solutions, and exploited as an industrial tool for chemical and isotopic refinement. Theoretical treatments are numerous based on kinetic and thermodynamic principles, but none adequately explains the phenomenon operating in complex naturally occurring fluids. In the geological sciences, the Ludwig-Soret effect has received extraordinary attention as an agent for small (and large) scale chemical differentiation and a probe of fundamental fluid properties of the Earth's hydrosphere, and silicate (crust-mantle) and alloy (core) interior. In particular, silicate liquids show significant isotope fractionation by thermodiffusion at temperatures greatly exceeding those where equilibrium fractionation effects are vanishingly small, and this can persist to lower temperatures even with concomitant crystallization. We review these recent findings and present new experimental work on silicate and Fe(FeS) melts, considering the underlying causes towards reconciling observed mass-dependent isotope and mass-independent chemical effects.

3:06PM T13.00002 Galilean thermodynamics of a multicomponent fluid and its induced electromagnetic fields , SYLVAIN BRECHET, JEAN-PHILIPPE ANSERMET, EPFL — The phenomenological theory of irreversible processes in fluid systems has been successfully applied to new research fields, for example spintronics and spincaloritronics (arXiv:1011.2323). We include the electromagnetic interaction into the thermodynamic description of a multicomponent fluid. Our analysis is performed in the Galilean limit of electromagnetism. The tensorial part of the Onsager relations accounts in particular for mutliferroic effects.

3:18PM T13.00003 Thresholds, memory, and self-similarity on river deltas , MEREDITH REITZ, Dept Physics and Astronomy, University of Pennsylvania, DOUGLAS JEROLMACK, Dept Earth and Environmental Science, University of Pennsylvania — The bulk dynamics of river deltas and alluvial fans result from several physical processes acting on a wide range of scales. We study a series of experimental alluvial fans to sort the relevant processes and determine the way in which their interaction drives fan behavior. We find a timescale of channel movement that depends on mass conservation, as sediment fills a wedge of space determined by a separation between conditions of grain entrainment and distrainment, in a manner analogous to the separation between static and dynamic angles of repose in dry granular systems. Channel path selection behavior shows a marked tendency for flow to reoccupy abandoned paths, in a way that can be abstracted with a random walk model in a system with absorbing states, and resulting in a predictable self-similar shoreline growth pattern. Because we isolate the processes that drive the evolution of our experimental fans, we are able to translate our findings to the study of natural fans and deltas in which the same processes operate.

3:30PM T13.00004 Tailoring Polymer Nanocomposite Properties by Nanoparticle Assembly[1] , SANAT KUMAR, Columbia University — Novel materials based on polymer-grafted nanoparticles (NP) are the focus of this talk. Since inorganic NPs and organic polymers typically "dislike" each other, these "hairy" particles behave like block-copolymers or amphiphiles. They can, therefore, self-assemble into a range of superstructures when placed in an organic matrix. Understanding the factors controlling this this assembly state and how it affects the properties of the resulting material are our central interests in this area. As part of this global effort, here we address three questions: (i) Can we direct NP assembly using external fields, e.g., shear, with the ultimate goal of designing membranes with directional transport properties? (ii) Can we assemble grafted NPs at interfaces with the aim of compatibilizing immiscible polymer blends? (iii) Can NP assemblies result in simultaneous improvements in the Young's modulus, the yield stress and strain-to-break of an amorphous polymer in the solid-state? As with all of our work we combine theory and experiments to understand these concepts that underpin our nascent understanding in this area.

4:06PM T13.00005 Thermodynamic Analysis of Nanoporous Membrane Separation Processes[1] , DAVID ROGERS, SUSAN REMPE, Sandia National Laboratories — We give an analysis of desalination energy requirements in order to quantify the potential for future improvements in desalination membrane technology. Our thermodynamic analysis makes it possible to draw conclusions from the vast array of equilibrium molecular dynamics simulations present in the literature as well as create a standardized comparison for measuring and reporting experimental reverse osmosis material efficiency. Commonly employed methods for estimating minimum desalination energy costs have been revised to include operations at positive input stream recovery ratios using a thermodynamic cycle analogous to the Carnot cycle. Several gaps in the statistical mechanical theory of irreversible processes have also been identified which may in the future lead to improved communication between materials engineering models and statistical mechanical simulation. Simulation results for silica surfaces and nanochannels are also presented.

[1]Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

4:18PM T13.00006 Geometric Phase Effect in Heat Transport , JIE REN, National University of Singapore, PETTER HANGGI, University of Augsburg, BAOWEN LI, National University of Singapore — Nonlinear molecular heat-pumping devices, which operate via explicitly modulating at least two parameters, are crucial for energy control in low dimensional nano-scale systems. We have applied slow two-parameter modulations on such a molecular junctions and consequently uncovered an intrinsic heat flux contribution, additional to the known, usual dynamical heat flux (from hot to cold). This additional heat flux derives from a nontrivial geometric origin that relates to a non-vanishing, so termed finite Berry phase. It provides a free lunch for the pumped heat and even can direct heat flux against the temperature bias. In addition we are able to show that this so pumped energy exhibits a novel robust fractional quantization phenomenon. Interestingly, this additional geometric heat pump mechanism is also shown to cause a breakdown of the heat-flux fluctuation theorem, which holds true for the non-driving, stationary heat flux transfer. The validity of this theorem is guaranteed whenever (i) the geometric phase contribution vanishes and (ii) the cyclic protocol preserves the detailed balance symmetry.

4:30PM T13.00007 Contact processes in crowded environments , J.M. SCHWARZ, Syracuse University, BISMAYAN CHAKRABARTI, Indian Institute of Technology, Kanpur — A nonequilibrium absorbing state phase transition with conserved particle number has been realized in a periodically sheared particle suspension. A diffusing (active) particle in the suspension collides with a stationary (inactive) particle and activates it. As the strain amplitude is increased, the fraction of active particles per shear cycle becomes nonzero only above some critical strain amplitude. To further study this system at higher densities, we construct a lattice model with active and inactive particles occupying some fraction of the lattice sites with each site being occupied by at most one particle. The active particles hop to empty neighboring sites and activate k neighboring inactive particles at some rate λ_k. Also, active particles become inactive at some rate γ. We investigate this model for $\lambda_{k=1} = 0$ and $\lambda_{k>1} > 0$ to study the effects of multi-particle collisions which are likely to occur at higher densities, i.e. crowded environments.

4:42PM T13.00008 Mixing of Diffusing Particles , ELI BEN-NAIM, Los Alamos National Laboratory — We study how the order of N independent random walks in one dimension evolves with time. Our focus is statistical properties of the inversion number m, defined as the number of pairs that are out of sort with respect to the initial configuration. In the steady-state, the distribution of the inversion number is Gaussian with the average $\langle m \rangle \simeq N^2/4$ and the standard deviation $\sigma \simeq N^{3/2}/6$. The survival probability, $S_m(t)$, which measures the likelihood that the inversion number remains below m until time t, decays algebraically in the long-time limit, $S_m \sim t^{-\beta_m}$. Interestingly, there is a spectrum of $N(N-1)/2$ distinct exponents $\beta_m(N)$. We also find that the kinetics of first passage in a circular cone provides a good approximation for these exponents. When N is large, the first-passage exponents are a universal function of a single scaling variable, $\beta_m(N) \to \beta(z)$ with $z = (m - \langle m \rangle)/\sigma$. In the cone approximation, the scaling function is a root of a transcendental equation involving the parabolic cylinder equation, $D_{2\beta}(-z) = 0$, and surprisingly, numerical simulations show this prediction to be exact.

4:54PM T13.00009 Crossover behavior in models of depinning , YAN-JIUN CHEN, LASSP, Cornell Univ., LASSE LAURSON, ISI in Torino, Italy and Department of Applied Physics, Aalto University, Helsinki, Finland, STEFANOS PAPANIKOLAOU, LASSP, Cornell Univ., STEFANO ZAPPERI, IENI-CNR, Milano, Italy and ISI in Torino, Italy, JAMES P. SETHNA, LASSP, Cornell Univ. — We explore the behavior of models describing driven interfaces in random media. These models are useful in describing a wide range of real-world systems: disordered magnets, fluids in porous medium, pinning of flux lines in superconductors, and fluid imbibition in paper. Variations of these models have been numerically studied and classified into distinct universality classes at the depinning transition, however the exact structure of the phase space is still not known. We are investigating the crossover behavior in between various linear and nonlinear models with short-range and long-range interactions, and will report on their respective scaling functions of height-height correlation and size distributions of avalanches.

5:06PM T13.00010 An Information-Theoretic Order Parameter for Non-Equilibrium Systems , MARTIN TCHERNOOKOV, ILYA NEMENMAN, Emory University — In non-equilibrium statistical physics, symmetry and free energy are difficult to define, preventing application of classical machinery for analysis of phase transitions. Can one define a "universal" order parameter that would be measurable from experimental data, would allow identification of an onset of a phase transition, and would be meaningful independently of the underlying systems dynamics? We suggest that predictive information, which is the mutual information between the sequence of the observed past states of a system and its future states, introduced by us in 2001,[1] may serve as such order parameter. We study this suggestion in the context of a model non-stationary Langevin process. We show analytically that the predictive information attains its maximum value at the phase transition, diverging logarithmically with the length of the observed past. We demonstrate that the speed of divergence is related to traditional critical exponents. Finally, we show how the onset of a phase transition can be found empirically from data, independently of its parameterization.

5:18PM T13.00011 Classical nucleation theory explains the critical cooling rate of cryoprotectant solutions , MATT WARKENTIN, ROBERT THORNE, Cornell University — We have measured critical cooling rates for a range of concentrations of different solutes in aqueous solutions. Our results show that the glass formability of aqueous solutions is exponential in the concentration for all solutes tested, with a different characteristic concentration for each solute. This characteristic correlates with the Stokes radius of the solute. A simple modification of critical droplet theory relates the characteristic concentration to the critical nucleation radius in pure water, and explains the relationship between the Stokes radius and the exponential characteristic. This simple, general theory of glass formability in aqueous solutions is important at a fundamental level, and will also have broad consequences for the field of cryobiology.

Wednesday, March 23, 2011 2:30PM - 5:30PM –

Session T14 GSNP: Focus Session: Extreme Mechanics: Elasticity and Deformation II D227

2:30PM T14.00001 Elasto-capillarity: The role of stretching , DOMINIC VELLA, OCCAM, University of Oxford — Elasto-capillarity, the interaction between elasticity and surface tension or surface energies, has been much studied in recent years. However, to date the focus has been almost exclusively on situations where the bending stiffness of an object resists deformation by the surface tension of a liquid. In this talk I will consider some situations in which it is instead the stretching stiffness of an elastic object that resists its deformation by surface tension. I will focus on explaining recent experiments that demonstrate the wrinkling of floating elastic membranes [J. Huang *et al.*, *Science* **317**, 650 (2007)] but will also discuss related fundamental problems in wrinkling as well as other situations that involve an interaction between the stretching of an elastic object and capillarity.

3:06PM T14.00002 Building blocks for the shapes of confined elastic sheets[1] , ROBERT SCHROLL, UMass Amherst, ELENI KATIFORI, Rockefeller University, BENNY DAVIDOVITCH, UMass Amherst — Several configurations, such as d-cones, minimal ridges, and developable patches, occur regularly in the configuration of elastic sheets. We dub such features "building blocks." Here, we study elastic sheets confined in a manner that prohibits the sheet from taking on a single-buckle shape. We find not only building blocks where stress focuses, reminiscent of d-cones, but also "diffuse-stress" regions. The former is characterized by a geometrical constraint (inextensibility) while the latter is governed by a mechanical constraint: the dominance of a single component of the stress tensor. We characterize how boundary conditions and applied tension select which building blocks appear and discuss implications for the curtain problem.

[1]We acknowledge support from the NSF-supported MRSEC on Polymers at UMass (DMR-0820506).

3:18PM T14.00003 Droplet Formation and Scaling in Dense Suspensions , MARC MISKIN, HEINRICH JAEGER, University of Chicago — A drop detaching from a nozzle is a prototypical example of scaling behavior. For a pure fluid, this scaling is contingent on the fact that the material parameters remain invariant throughout the detachment. However, for a dense suspension, this assumption is invalid. We use high-speed photography to examine the formation of suspension droplets. We find that the minimum neck radius, R_m, near breakup can be described by a power law $(t_b - t)^{2/3}$, with a material independent exponent. By considering how particles deform the surface and appealing to topological constraints, we develop a modified version of the Laplace-Young equation relating the surface pressure to the macroscopic Gaussian curvature. This model, combined with a scaling argument, allows us to collapse all of our data for R_m near breakup. These results open a new territory for modeling suspensions by asserting that a major stress resides at the boundary, and that it can be calculated using strictly macroscopic parameters.

3:30PM T14.00004 Surface patterns in thermally responsive elastomeric gels , SHAWN CHESTER, LALLIT ANAND, MIT — Many stimulus responsive elastomeric gels operate in non-isothermal, chemically saturated environments in a variety of applications. We have recently developed a three dimensional continuum level theory to describe the coupled fluid permeation and large deformation response of thermally responsive elastomeric materials. In this work, we apply our theory and numerical simulation capability to the specific case of surface wrinkles induced via swelling of a thermally responsive gel bonded on top of a compliant impermeable elastic substrate. We show that we can numerically model the swelling behavior and subsequent surface pattern formation. Also, we examine the effect of substrate thickness by varying the ratio of gel to substrate thickness. Further, we show that it is possible to modulate the amplitude of the surface wrinkles by taking advantage of the thermally responsive nature of this class of materials.

3:42PM T14.00005 Morphologies of Equibiaxially Wrinkled Surfaces , DEREK BREID, University of Massachusetts, SHENGQIANG CAI, ZHIGANG SUO, JOHN HUTCHINSON, Harvard University, ALFRED CROSBY, University of Massachusetts — The morphological characteristics of a wrinkled film are largely determined by the state of stress at the onset of the instability. For surfaces compressed equibiaxially, it is well established that ridge-based structures, including herringbone or labyrinth patterns, provide the lowest energy state for stresses far exceeding critical buckling. For near-critical stresses, the equilibrium morphology is less understood. Using surface-oxidized poly(dimethylsiloxane) as a model wrinkling material, we control the applied stress by swelling the oxide film with a compatible vapor-phase solvent. The extent of swelling is controlled by the vapor pressure of the solvent and the thickness of the oxide layer, and the generated overstress in turn dictates the observed morphology. Analytical and numerical models are used to determine the deformation morphologies that provide the lowest energy state with increasing overstress. Comparison of experimental observations and theoretical predictions provides insight into the importance of substrate curvature in determining final equilibrium morphologies.

3:54PM T14.00006 Revisiting the curvature cancellation in forced thin sheets[1] , JIN WANG, THOMAS WITTEN, University of Chicago — We revisit the numerically observed spontaneous vanishing of mean curvature [1] on a developable cone or "d-cone" [2] made by pushing a thin elastic sheet into a circular container. The deflection of the d-cone is the distance by which the sheet is pushed into the container. We investigate the ratio of the two principal curvatures versus sheet thickness h over a wider dynamic range than was used previously, holding the deflection and radius fixed. Instead of tending towards 1 as suggested by previous work, we find that the ratio scales as $h^{1/3}$. Scaling arguments and geometric variants support this $h^{1/3}$ finding. Thus the mean curvature does not vanish for very thin sheets as previously claimed.

4:06PM T14.00007 Mechanics of Geometrically-Tuned pH-Responsive Polymers , LIFENG WANG, Massachusetts Institute of Technology, LIN HAN, KHEK-KHIANG CHIA, ROBERT COHEN, MICHAEL RUBNER, MARY BOYCE, CHRISTINE ORTIZ — Stimuli-responsive polymer materials have been extensively explored over the past two decades because of their promising applications. We consider the mechanics of mechanomutable polyelectrolyte multilayers (PEMs), which undergo reversible pH-responsive transition from a condensed, ionically crosslinked state (small pH) to a hydrated, ionized state (large pH). Instrumented indentation and micro-structurally-based finite element analysis are conducted on the PEM thin films and PEM tube forests to determine the effective elastic properties and further the mechanomutability as a result of the coupling between inherent responsive material properties and geometry. We demonstrate that geometry can be used to introduce and tailor different deformation mechanisms as a means to tune mechanomutabilibility of stiffness and dissipation in addition to the constitutive material properties. The rate-dependent stimulus-responsive mechanomutability can be finely controlled within a wide range from $\sim$ 2 – 100 times by tailoring the tube geometrical factors at different indentation rates. These studies provide fundamental understanding and mechanics of indentation of PEM thin films and tube forests and show the tremendous potential for dynamically tuning surface and bulk properties of novel complex structured materials.

4:18PM T14.00008 Stretch-induced compressive stresses and wrinkling in hyperelastic thin sheets , RUI HUANG, University of Texas at Austin, VISHAL NAYYAR, K. RAVICHANDAR, CENTER FOR MECHANICS OF SOLIDS, STRUCTURES AND MATERIALS TEAM — Wrinkles are commonly observed in stretched thin sheets. This paper presents a study on stretch-induced wrinkling of hyperelastic thin sheets using the finite element method. The model problem is set up for uniaxial stretching of a rectangular sheet with two clamped ends and two free edges. A two-dimensional stress analysis is performed first under the plane-stress condition to determine stretch-induced stress distributions in the elastic sheets, assuming no wrinkles. As a prerequisite for wrinkling, the development of compressive stresses in the transverse direction is found to depend on the length-to-width aspect ratio of the sheet and the applied stretch. A phase diagram is constructed with a set of different distribution patterns of the compressive stress spanning a wide range of aspect ratios and up to moderately large tensile strain ($\sim$150%). Next, an eigenvalue analysis is performed to find the potential buckling modes of the elastic sheet under the prescribed boundary conditions. Finally, a nonlinear post-buckling analysis is performed to show evolution of the stretch-induced wrinkles. In addition to the aspect ratio and the applied stretch, it is found that the critical condition for wrinkling and the post-buckling behavior both depend sensitively on the sheet thickness.

4:30PM T14.00009 Elastic Instabilities of Nematic Liquid Crystals in Spherical Geometries , VINZENZ KONING, Leiden University, TERESA LOPEZ-LEON, K.B.S. DEVAIAH, ALBERTO FERNÁNDEZ-NIEVES, Georgia Institute of Technology, VINCENZO VITELLI, Leiden University — We investigate elastic instabilities of nematic liquid crystals confined in spherical shells characterized by extreme thickness inhomogeneity. For shells with a uniform thickness there exists an equilibrium defects structure containing two pairs of boojums at the north and south poles. By minimizing the elastic free energy (subject to tangential boundary conditions on both bounding surfaces), we determine the locations of the defects as a function of thickness inhomogeneity. We find that the defects make an abrupt confinement transition to the thinnest hemisphere from the initial antipodal arrangement, when the thickness inhomogeneity exceeds a critical value. Our results agree well with recent experimental studies on nematic double emulsions and suggest design criteria to engineer micron scaled particles with directional binding capabilities.

4:42PM T14.00010 Near critical phenomena in amorphous smart materials , EDUARD OBERAIGNER, University of Leoben, Institute of Mechanics, MICHAEL FISCHLSCHWEIGER, Materials Center Leoben Forschung GmbH — The importance of smart materials e.g. shape memory alloys (SMAs) for technological applications has been growing during the last 20 years. Especially modeling SMAs behavior has become of high interest in materials science for the prediction of macroscopic effects like pseudoelasticity. The key for their behavior is a displacive solid - solid phase transformation, called martensitic phase transformation. However, such a critical phenomenon requires investigations for deep relations between physical quantities nearby the region of phase transformation. The present study is focusing on a statistical mechanics approach for the description of relations between heat capacity, pseudoelasticity, volume fraction compressibility, alternatively fraction expansion coefficient, and a compressibility tensor, leading to the compliance tensor in the case of elasticity. Also a heat expansion tensor along the line of magnetic phase transitions and transformations has been formulated for shape memory alloys. The work discusses martensitic variants (which occur due to a subgroup relation between the austenitic and martensitic phase) and their asymmetry, which influences the above mentioned quantities as well and gives ideas and suggestions for model improvements.

4:54PM T14.00011 The role of membrane viscosity in the relaxation dynamics of fluid membranes , MARINO ARROYO, Universitat Politecnica de Catalunya, Spain, LUCA HELTAI, ANTONIO DESIMONE, SISSA, Italy — Fluid membranes made out of lipid bilayers are the fundamental separation structure in eukaryotic cells. Many physiological processes rely on dramatic shape and topological changes (e.g. fusion, fission) of fluid membrane systems. Fluidity is key to the versatility and constant reorganization of lipid bilayers. Here, we study the role of the membrane intrinsic viscosity, arising from the friction of the lipid molecules as they rearrange to accommodate shape changes, in the dynamics of morphological changes of fluid vesicles driven by curvature elasticity. In particular, we analyze the competition between the membrane viscosity and the viscosity of the bulk fluid surrounding the vesicle as the dominant dissipative mechanism. We consider the relaxation dynamics of fluid vesicles put in an out-of-equilibrium state, but conclusions can be drawn regarding the kinetics or power consumption in regulated shape changes in the cell. On the basis of numerical calculations, we find that the dynamics arising from the membrane viscosity are qualitatively different from the dynamics arising from the bulk viscosity. When these two dissipation mechanisms are put in competition, we find that for small vesicles the membrane dissipation dominates, with a relaxation time that scales as the size of the vesicle to the power 2. For large vesicles, the bulk dissipation dominates, and the exponent in the relaxation time vs. size relation is 3.

5:06PM T14.00012 The star shaped pattern on broken thin sheets , NICOLAS VANDENBERGHE, ROMAIN VERMOREL, EMMANUEL VILLERMAUX — We study transverse impacts of rigid objects on a thin elastic sheet made of acrylic. After impact, a transverse wave propagates on the sheet and orthoradial stresses lead to the formation of radial cracks. The result of this fragmentation process is the star shaped pattern frequently observed on broken windows. We investigate the variation of the pattern and in particular the number of radial cracks with impact speed and material properties. The formation of rayed craters by meteorite impacts will be briefly discussed.

5:18PM T14.00013 How to make sticky tapes stickier , LAURENT PONSON, Institut d Alembert, CNRS - Universite Pierre et Marie Curie Paris VI, SHUMAN XIA, GURUSWAMI RAVICHANDRAN, KAUSHIK BHATTACHARYA, California Institute of Technology, CALIFORNIA INSTITUTE OF TECHNOLOGY TEAM — Thin film adhesives have become increasingly important in various applications such as packaging and coating, and we benefit daily of their adhesion properties by using various kinds of tapes. Despite the apparent simplicity of these systems, a certain number of questions remain open. In particular, important efforts have been deployed recently to understand the effect of the complex tridimensional and highly heterogeneous structure at the interface of some adhesives, such as the one encountered in nature like the geckos toes. Although inspired by these natural adhesives, we studied a much simpler system, and however largely unexplored: a thin film with spatially varying adhesion energy and elastic properties. We will show how these heterogeneities introduced at the microscale can generate quite unexpected macroscopic behaviors, and that one can this way design stronger adhesives with new properties. Beyond their practical interests, these systems involve long range elastic interactions and heterogeneities resulting in a rich and complex physics that will be illustrated through experimental examples and their theoretical interpretation.

Session T15 DMP GMAG FIAP: Focus Session: Spins in Semiconductors - III-V Magnetic Semiconductors D171

2:30PM T15.00001 Valence-band structure of the ferromagnetic semiconductor GaMnAs investigated by resonant tunneling spectroscopy , SHINOBU OHYA, Dept. of Electrical Eng. and Information Systems, The Univ. of Tokyo — The origin of ferromagnetism in the prototype ferromagnetic semiconductor GaMnAs is still controversial due to the insufficient understanding of its band structure and Fermi level position. Here, we investigate the valence-band (VB) structure of GaMnAs by analyzing the resonant tunneling levels of the GaMnAs quantum well (QW) in double-barrier heterostructures. The resonant levels including the heavy-hole first state (HH1) are clearly observed in the metallic GaMnAs QW with the Curie temperature (T_C) of 60 K, which indicates that no holes reside in the VB of GaMnAs in the equilibrium condition. Clear enhancement of tunnel magnetoresistance induced by resonant tunneling is demonstrated. We find that the resonant levels formed in the GaMnAs QW are well explained by using the transfer matrix method with the 6x6 *kp* Hamiltonian and small $p-d$ exchange Hamiltonian. The VB structure of GaMnAs is well reproduced by that of GaAs with a small exchange splitting energy of 3-5 meV and with the Fermi level lying at $\sim$30 meV higher than HH1 in the bandgap. Furthermore, we show our more recent results of resonant tunneling spectroscopy on various surface GaMnAs films (Mn concentration: 6-15%, T_C: 71-154 K) grown on an AlAs layer, where the resonant levels are formed by confinement of the VB holes by the surface Schottky barrier and the AlAs barrier. We systematically investigate the thickness dependence of the resonant levels in GaMnAs by precisely etching the surface of GaMnAs. We find that the p-d exchange interaction is negligibly small (3-5 meV) and that the Fermi level exists in the bandgap. This work was performed in collaboration with I. Muneta, P. N. Hai, K. Takata, and M. Tanaka, and partly supported by Grant-in-Aids for Scientific Research, the Special Coordination Programs for Promoting Science and Technology, and FIRST Program by JSPS.

3:06PM T15.00002 On magnetism and the insulator-to-metal transition in p-doped GaAs , BRIAN CHAPLER, University of California San Diego, R.C. MYERS, Ohio State University, S. MACK, University of California Santa Barbara, A. FRENZEL, B.C. PURSLEY, University of California San Diego, K.S. BURCH, University of Toronto, E.J. SINGLEY, California State University East Bay, A.M. DATTELBAUM, Los Alamos National Laboratory, N. SAMARTH, Pennsylvania State University, D.D. AWSCHALOM, University of California Santa Barbara, D.N. BASOV, University of California San Diego — Although $Ga_{1-x}Mn_xAs$ is often described as the prototypical ferromagnetic semiconductor, many aspects of the electronic structure and nature of mediating carriers remain open. A central question in this regard is whether the insulator-to-metal transition (IMT) in p-doped GaAs is significantly modified when dopants are magnetic. We address this through an infrared spectroscopic study of GaAs doped with either non-magnetic Be or magnetic Mn acceptors. Through our comparison, we are able to isolate effects of magnetic dopants in GaAs from those associated with disorder and proximity to the IMT. Here we show Mn-doped samples exhibit an unusual electronic transport regime, combining elements of both metallic and insulating behavior, at doping concentrations far beyond the onset of the IMT. Be-doped films however, reveal genuine metallicity just above the IMT boundary. These results underscore the pivotal role of magnetism in transport and optical phenomena of $Ga_{1-x}Mn_xAs$.

3:18PM T15.00003 Magnetic properties of narrow gap $In_{1-x}Mn_xSb$ semiconductor films with x>0.10 , CAITLIN FEESER, JOHN PETERS, BRUCE WESSELS, Northwestern University — Narrow gap $In_{1-x}Mn_xSb$ magnetic semiconductors with x $<$ 0.05 have been recently shown to have interesting magnetotransport properties at room temperature.[1] Calculations based on the field dependence of the magnetoresistance indicate that the carriers are highly spin polarized. To increase both the saturation magnetization and potentially the Curie temperature Tc of the alloys, we have investigated MOVPE epitaxial layers with 0.10 $<$ x $<$ 0.22. Films were ferromagnetic at room temperature, showing clear hysteresis in field dependent measurements from 5 to 300 K. Alloys with magnetization values as high as 83 emu/cm^3 for x=0.22 were measured at 5 K. Temperature dependent magnetization indicated that the Curie temperature of the films was above 400 K. These measurements indicated the presence of two magnetic species both with Curie temperatures above 300 K. The high Tc is attributed to carrier mediated ferromagnetism involving Mn and its complexes that form shallow or resonant electronic states with the valence band through correlated substitution.

3:30PM T15.00004 Cyclotron Resonance in InMnAs and InMnSb Ferromagnetic Films[1] , GITI KHODAPARAST, Department of Physics, Virginia Tech, Blacksburg, VA, USA, Y.H. MATSUDA, R. SHEN, S. TAKEYAMA, Institute for Solid State Physics, University of Tokyo, Kashiwa, Japan, X. LIU , J. FURDYNA, Department of Physics, University of Notre Dame, Notre Dame, IN, USA, B.W. WESSELS, Materials Research Center, Northwestern University, Evanston, IL, USA — Ferromagnetic semiconductors are important materials for development of spintronic devices. While effort in this area was made primarily on GaMnAs, other ferromagnetic III-Mn-V alloys have also been developed, including the narrow gap ferromagnetic alloys such as InMnAs and InMnSb. Investigation of the electronic structure of III-Mn-V alloys by techniques such as the cyclotron resonance (CR) can shed important light on the origin of ferromagnetism and the p-d exchange interaction in III-Mn-V systems. In this work we report on CR experiments carried out on the ferromagnetic InMnAs and InMnSb films, on which clear resonance signals have been successfully observed in high magnetic fields generated by a single turn coil technique. The CR in ferromagnetic InMnSb was observed for the first time and we compare our observations with the Landau levels calculations on the basis of an 8-band $k\cdot p$ model.

[1]Supported by: NSF-DMR-0507866, AFOSR YIP 06NE231, NSF-Career Award DMR-0846834, NSF DMR 0804479, NSF DMR-1005851.

3:42PM T15.00005 Visualizing Critical Correlations Near the Metal-Insulator Transition in $Ga_{1-x}Mn_xAs$, ANTHONY RICHARDELLA[1], Department of Physics, Princeton University — Semiconductors have long been an ideal class of materials for studying the metal-insulator transition. Samples of the dilute magnetic semiconductor $Ga_{1-x}Mn_xAs$ with Mn doping levels near to the metal-insulator transition have been studied using low temperature cross-sectional scanning tunneling microscopy (STM). This allows us to visualize the electronic states near the Fermi level which display unique critical properties. Strong modifications to the density of states around the Fermi energy due to electron-electron interactions are observed. In this energy range, the electronic states show a diverging correlation length approaching E_F, where the correction to the density of states due to interactions is strongest. The distance dependence of the correlations at E_F is consistent with a power law decay, expected for multifractal states near criticality in the metal-insulator transition, while away from E_F the correlations fall off exponentially. These results highlight the importance of electron-electron interactions and represent some of the first experimental observations of states near the Mott-Anderson metal-insulator transition, where both disorder and interactions are important for the localization of electronic states.

4:18PM T15.00006 Time resolved spectroscopy of MOVPE grown narrow gap III-Mn-V ferromagnetic semiconductors[1] , T. MERRITT, M. BHOWMICK, G.A. KHODAPARAST, Department of Physics, Virginia Tech, Blacksburg, VA, C. FEESER, B.W. WESSELS, Materials Research Center, Northwestern University, Evanston, IL, S. MCGILL, National High Magnetic Field Laboratory, Tallahassee, FL — The emergence of III-Mn-V magnetic semiconductors, has led to a number of exciting results relevant to the spin and charge based applications. Important advances have now been made in the MOVPE growth of the narrow gap ferromagnetic structures with the Tc above room temperature. As the switching rates in electronic and optoelectronic devices are pushed to higher frequencies, understanding the dynamical behavior of non- equilibrium carriers/spins can provide valuable information about different scattering mechanisms, carrier phonon coupling, and band structures. In this work, we report several time-resolved and magneto-optical measurements on $In_{1-x}Mn_xAs$ and $In_{1-x}Mn_xSb$ ferromagnetic films with the Mn content of 4%. Our measurements on the basis of several time resolved differential transmission techniques in NIR and MIR demonstrate unique and complex dynamics in these material systems where photo-induced absorption and bleaching can co- exist.

4:30PM T15.00007 Structural and Magnetic Characteristics of p-GaAs/MnAs Nanocluster Hybrids , DAVID RENCH, PETER SCHIFFER, NITIN SAMARTH, Department of Physics and Materials Research Institute, The Pennsylvania State University, University Park, Pennsylvania 16802, USA — A possible route towards semiconductor spintronic devices involves the controlled synthesis of hybrid materials that combine ferromagnetic (FM) nanoclusters within a doped semiconductor host lattice. We use molecular beam epitaxy of (Ga,Mn,Be)As followed by in situ annealing to synthesize a systematic set of samples wherein FM nanoclusters are embedded in a p-GaAs matrix. High resolution transmission electron microscopy (HRTEM) and magnetometry demonstrate our ability to reproducibly synthesize two distinct classes of materials: (a) type I samples consisting of uniformly distributed, small clusters ($\sim$6 nm); (b) type II samples consisting of a bimodal distribution of small ($\sim$6 nm) and large ($\sim$25 nm) clusters. HRTEM studies show that while the large clusters are clearly MnAs with NiAs structure, the smaller clusters are possibly zinc blende in structure but with a more complex composition. We analyze the magnetic behavior of these two classes of samples and show measurements of their transport properties. Supported by the ONR-MURI program.

4:42PM T15.00008 Magnetoresistance due to inelastic spin-flip cotunneling within Coulomb blockade regime in III-V semiconductor / MnAs nanoparticle heterostructures , RYOTA AKIYAMA, SHINOBU OHYA, PHAM NAM HAI, MASAAKI TANAKA, Dept. of Electrical Eng. and Information Systems, The Univ. of Tokyo — Inelastic spin-flip cotunneling is a key to understand the spin-dependent single-electron transport in the ferromagnetic nanoparticles systems. We fabricated a heterostructure consisting of Al/ AlAs/ ferromagnetic zinc-blende (ZB) MnAs nanoparticles embedded in GaAs / GaAs:Be on a GaAs(001) substrate, where electrons are expected to go through only one nanoparticle during tunneling. By analyzing the $I-V$ data at various temperatures T, we found that inelastic cotunneling is dominant when T <60 K. The ratio of the inelastic cotunneling energy E to the thermal energy kT, estimated by the $I-V$ data, was remarkably increased with decreasing T. We observed clear magnetoresistance (MR) up to ∼3% (at 1T), and MR was also increased with decreasing T. The shape of the *MR-T* curve was quite similar to that of the *E/kT - T* curve, which strongly suggests that MR is induced by the spin-flip process due to inelastic cotunneling. From the *E/kT - T* curve, the energy needed for the spin-flip process is estimated to be ∼0.04 meV, which corresponds to ∼3.3% of the inelastic cotunneling energy. This work was partly supported by the Grant-in-Aids for Scientific Research, Special Coordination Programs by JST, FIRST Program, and JSPS Fellowship.

4:54PM T15.00009 Magnetism in Cr doped Si nanowires , MICHAEL SHAUGHNESSY, UC Davis/ LLNL, C.Y. FONG, UC Davis, LIN YANG, LLNL — We carry out first principles calculations of magnetic and electronic structures of single and multiple Cr atom dopants in Si nanowires. Both unsupported isolated wires and supported wires on Si 110 surfaces are studied. The relative stability and underlying physical picture of the ferromagnetic and antiferromagnetic configurations of the local moments on the Cr atoms are studied. Results are also presented for fully noncollinear calculations.

5:06PM T15.00010 GaMnAs-based Core-Shell Nanowires Grown by Molecular Beam Epitaxy[1] , R. PIMPINELLA, X. LIU, K. TIVAKORNSASITHORN, J.K. FURDYNA, M. DOBROWOLSKA, Department of Physics, University of Notre Dame, Notre Dame, IN 46556, USA, T. WOJTOWICZ, Institute of Physics, PAS, Al. Lotnikow 32/46, 02-668 Warsaw, Poland — We have successfully fabricated GaMnAs/GaAs core-shell nanowires (NWs) by molecular beam epitaxy (MBE), by first growing Au-assisted GaAs NWs, and subsequently depositing the GaMnAs shells on the Gaas NW side facets under low temperature conditions. Scanning electron microscopy (SEM) and scanning transmission electron microscopy (STEM) show that GaMnAs grows epitaxially on the GaAs NWs, retaining good crystalline quality. SQUID magnetometry shows that the shells obtained so far are ferromagnetic below 20 K. Studies by high resolution transmission electron microscopy (HRTEM) and energy-dispersive X-ray spectroscopy are planned for the future, in order to allow us to relate the observed magnetic properties of these one-dimensional magnetic wires to their chemical and structure profiles, in the hope of designing strategies for increasing the Curie temperature of the GaMnAs shells.

5:18PM T15.00011 Magnetic Nanostructures in the Mn-Si system[1] , PETRA REINKE, KIRIL SIMOV, University of Virginia, CATHERINE JENKINS, Advanced Light Source, LBNL — Magnetic doping of group IV semiconductors is coveted for spintronics building blocks. Theoretical assessment of magnetism in Mn-Si is promising, but many of these structures have not been realized yet. Our STM study combines the study of Mn-nanostructure growth on Si(100)(2x1) with the investigation of the magnetic signature with X-ray magnetic circular dichroism and magnetometry. Mn self-assembles into monoatomic chains on the Si(100) surface. The mechanism of chain-formation and its competition with cluster growth will be presented. The nanostructures are capped with a 10 ML Si-or Ge- layer to form delta-doped layers, and protect the Mn-nanostructure. The Mn-chains are preserved, and the growth process for the cap was studied by STM and is now well understood. The magnetic signature is presented for nanowires and nanocluster structures below about 50 K, and a dense array of Mn-chains shows the highest saturation magnetization with 2-3 $\mu_B$ger Mn. The hysteresis loops indicate a superparamagnetic behavior. We will discuss the relative spin-orbital contributions and the directional dependence of the magnetic signature in relation to the Mn-nanostructure geometry.

Session T16 DMP GMAG: Focus Session: Magnetic Nanostructures, Materials & Effects D173

2:30PM T16.00001 Magnetocaloric effect and refrigerant capacity in $Eu_8Ga_{16}Ge_{30}$ clathrates and $Eu_8Ga_{16}Ge_{30}$-EuO composites , H. SRIKANTH, A. CHATURVEDI, M.H. PHAN, S. STEFANOSKI, G.S. NOLAS, University of South Florida, V. FRANCO, University of Sevilla — $Eu_8Ga_{16}Ge_{30}$ clathrates are widely known for their excellent thermoelectric properties. Recently, we have discovered the giant magnetocaloric effect (MCE) in $Eu_8Ga_{16}Ge_{30}$ type-VIII clathrates. The tunable MCE and refrigerant capacity (RC) have also been achieved in $Eu_8Ga_{16}Ge_{30}$type-I clathrates by partial substitution of Eu with non-magnetic Sr. As an interesting host matrix the type-I clathrates are combined with EuO at different portions (80%/20%, 70%/30%, 65%/35%, 60%/40%, 40%/60%) for making novel composites with enhanced RC over a tunable temperature range (10-100K). We have achieved a very large RC of 794 J/kg at 5T over a 70K in the clathrate type I – EuO (40%/60%) composite, which is the largest value ever achieved among the existing materials for magnetic refrigeration around 70K. This composite is very attractive for magnetic refrigeration for nitrogen liquefaction. A new potential of using the type VIII clathrate – EuO composite (50%-50%) to produce refrigeration in two different temperature ranges has been proposed.

2:42PM T16.00002 Exploration of thermal conductivity, Seebeck coefficient, and Lorenz number deviations in Ni-Fe alloy films[1] , B.L. ZINK, A.D. AVERY, R. SULTAN, D. BASSETT, G. COTTERIL, University of Denver — As electronic and spintronic systems continue to shrink, exploration of the fundamental physics affecting thermal transport in prospective materials becomes increasingly essential. For example, the potential use of spin-torque driven domain wall motion in ferromagnetic nanowires as a memory element requires application of large current densities to these tiny structures. The resulting heating could have both helpful and harmful effects, and is in general not yet well-understood. This is partly due to a gap in the fundamental knowledge of thermal properties of nanoscale systems that is due to the challenging nature of the necessary measurements. We have recently developed a micromachined thermal isolation platform that allows measurement of thermal conductivity, electrical conductivity, and thermopower (or Seebeck effect) in thin film systems. In this talk we present our recent data on thermal conductivity, resistivity, and Seebeck coefficient, for Ni-Fe alloy films with thicknesses varying from 25-100 nm. We compare our results to the predictions of the Wiedemann-Franz law and discuss variations represented by deviations from the Sommerfeld value of the Lorenz number, and conclude with our plans to extend the technique to yet smaller structures.

[1]We thank the NRI-WIN and the NSF CAREER program for support

2:54PM T16.00003 Thermodynamics and Magnetocaloric properties of Fe/Cr Superlattices[1]

T. MUKHERJEE, S. MICHALSKI, R. SKOMSKI, D.J. SELLMYER, CH. BINEK, Department of Physics & Astronomy and the Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, NE, 68588-0111 — We explore MC properties of tailored Fe/Cr superlattices involving simple 3d metals. Our multilayers are fabricated by pulsed laser deposition with emphasis on maximizing magnetic entropy changes near room temperature. We use nanostructuring[2] to tailor magnetic interaction and exploit geometrical confinement in order to fit the FM to paramagnetic transition temperature of the FM constituent films. In concert this leads to an optimized global metamagnetic transition maximizing the isothermal entropy change. Thermodynamic and MC properties of such Fe/Cr superlattices are studied with the help of SQUID magnetometry. Entropy changes are deduced via the Maxwell relation in single phase regions and via the Clausis-Clapeyron relations at first order metamagnetic transitions, X-ray diffraction and X-ray reflectivity are used to correlate structural data with the magnetic properties.

3:06PM T16.00004 Magnetocaloric effect in heterostructures of $Ni_xCu_{(1-x)}$ alloys[1]

C.A. BAUER, P.B. JAYATHILAKA, R.V. RUPANI, D.D. BELYEA, CASEY W. MILLER, University of South Florida — We used 99.9% compound targets to co-sputter $Ni_xCu_{(1-x)}$ thin film multilayers composed of sub-layers with differing alloying compositions on silicon and oxidized silicon substrates. Each system had a Ta underlayer and capping layer. XRD was used to determine structural properties, showing a (111) preferred orientation for all $Ni_xCu_{(1-x)}$ layers. In-Plane XRD was used to check polycrystallinity. Energy-dispersive X-ray scattering is used to determine the relative concentrations of Nickel and Copper, with XRD data corroborating the EDX results from Vegard's law. The magnetic properties of the systems are characterized and the magnetic entropies are calculated near the relevant critical temperature.

[1]Supported by NSF-CAREER.

3:18PM T16.00005 Thermal conductivity behaviour of magnetic fluids[1]

R.A. MEDINA-ESQUIVEL, J. MENDEZ-GAMBOA, J. TAPIA, FIUADY, J.J. ALVARADO-GIL, CINVESTAV-Merida — We study the thermal conductivity of five kinds of Magnetic Fluids (MFs) by varying the magnetic material volume fraction and the direction and intensity of an homogeneous magnetic field: The studied MFs are: Magnetorheological fluids (MRF), carbon coated and uncoated Fe nanofluids (CcFeNF, FeNF), ferrofluis (FF); and two kind of composed fluids; ferrofluids loaded with carbon nanotubes (FFCNTs) and ferrofluids loaded with carbon nanofibers (FFCNFs). MRF and FFCNFs fluids increase its thermal transport along the field direction; the thermal enhancement in MRF was dramatically overtaken by the FFCNFs, but in contrast; the rest of the fluids did not present thermal conductivity enhancement under the field. Theoretical models show that thermal resistance at the nanoscale level presents a very important role in the thermal transport among linked particles, this is the reason why FFCNTs, FF, FeNF, and CcFeNF did not present an increase in its thermal conductivity under the action of the magnetic field, although its chain-like structuring. We believe that these experimental finding may have significant application in the area of thermally tailored materials.

3:30PM T16.00006 Large Seebeck coefficient in frustrated doped Mott insulators

LOUIS-FRANÇOIS ARSENAULT, Université de Sherbrooke, B. SRIRAM SHASTRY, University of California, Santa Cruz, PATRICK SÉMON, ANDRÉ-MARIE TREMBLAY, Université de Sherbrooke — Since calculations based on the standard Kubo formula have proven extremely difficult for electric and thermal transport, Shastry and co-workers [1] suggested two novel approximate ways to obtain the thermopower (S) in interacting systems. One method is based on the high-frequency limit. The other, based on ideas of Kelvin, is purely thermodynamical. With these we study the Hubbard model on a 3d FCC lattice, a frustrated lattice. The high dimensionality of the problem justifies the use of dynamical mean field theory (DMFT). CTQMC in the hybridization expansion and the fast IPT are the impurity solver. The Seebeck coefficient is obtained as a function of doping and temperature for different U. Within DMFT, vertex corrections vanish for transports coefficients, hence the bubble suffices. This enables us to further assess how both approximate methods compare with each other and with the DC Kubo approach. At low T, results can be interpreted in terms of effective Fermi temperatures and carrier number.

3:42PM T16.00007 Spin dynamics simulations for a nanoscale Heisenberg antiferromagnetic film[1]

ZHUOFEI HOU, DAVID LANDAU, Center for Simulational Physics, The University of Georgia, G. MALCOLM STOCKS, Center for Defect Physics, Oak Ridge National Laboratory — Thermoinduced magnetization(TiM) is a novel response predicted to occur in nanoscale antiferromagnetic (AF) materials. Extensive Monte Carlo simulations[2] have shown that TiM is an intrinsic property of the AF classical Heisenberg model. To obtain a fundamental understanding of TiM, spin dynamics (SD) simulations are performed to study the spin wave behavior, which seems to be the cause of TiM. A classical Heisenberg model with an AF nearest-neighbor exchange interaction and uniaxial single-site anisotropy is studied. Simple-cubic lattices with two free-surfaces and periodic boundaries parallel to the surfaces are used. We applied fast SD algorithms with 4th-order Suzuki-Trotter decompositions of the exponential operator. Discrete spin wave modes due to spin wave confinement[3] are found in transverse $S(q,\omega)$ in the perpendicular direction to free surfaces.

3:54PM T16.00008 Thermomagnonic spin transfer in textured magnets[1]

ALEXEY A. KOVALEV, YAROSLAV TSERKOVNYAK — We study interplay between the spin-energy transport and magnetization dynamics in ferromagnetic insulators with magnetic textures. With the help of the Onsager reciprocity principle we construct a phenomenological theory capable of describing various thermomagnonic effects. Motion of domain walls by thermal gradients and generation of heat flows by magnetization dynamics are suggested. By estimating the kinetic coefficients (such as β like viscous coupling) for realistic materials (e.g. Yttrium iron garnet), we analyze the feasibility of mentioned effects for energy related applications.

[1]Supported in part by the Alfred P. Sloan Foundation, DARPA and NSF under Grant No. DMR-0840965.

4:06PM T16.00009 Rotating magnon wavepackets in ferromagnets and thermal Hall effect , RYO MATSUMOTO, Department of Physics, Tokyo Institute of Technology, SHUICHI MURAKAMI, Department of Physics, Tokyo Institute of Technology, PRESTO, Japan Science and Technology Agency — We theoretically construct the semiclassical equation of motion of the magnon wavepacket in an insulating ferromagnets, in analogy with the electron systems. We find that the magnon wave packet has nonzero angular momentum, which consists of two parts: the self-rotational motion and the revolving motion (edge current). We show that these are expressed in terms of the Berry curvature in **k**-space, i.e., these arise from the magnon band structure. Furthermore, we find that the thermal Hall effect of the magnon is totally due to the magnon edge current, and present an intuitive picture of the thermal Hall effect. We also construct the linear response theory for the thermal Hall effect, and compare the results with the previous works with an example of $Lu_2V_2O_7$.

4:18PM T16.00010 Magnetocaloric Properties of Thin Film Heterostructures[1] , H. KIRBY, C. BAUER, University of South Florida, Department of Physics, B.J. KIRBY, J. LAU, NIST, C.W. MILLER, University of South Florida, Department of Physics — In an effort to understand the impact of nanostructuring on the magnetocaloric (MC) effect, we have studied gadolinium in MgO/W(50 Å)/[Gd(400 Å)/W(50 Å)]$_8$ heterostructures [Miller et al., J. Appl. Phys. 107, 09A903 (2010)]. The entropy change peaks at a temperature of 284 K with a value of 3.4 J/kg K for a 0–30 kOe field change. Polarized neutron reflectometry was used to determine the depth profile of the magnetic moment per Gd atom, m_{Gd} in a Gd/W multilayer. Our results suggest that creating materials with Gd-ferromagnet interfaces may increase the m_{Gd}, leading to enhanced MC properties. Therefore SiOx/Fe(50 Å)/Gd(300 Å)/Fe(50 Å) heterostructures have been investigated.

4:30PM T16.00011 Antiferromagnetism in $BaF_2/Fe_xNi_{1-x}F_2$ bilayers , FELIO PEREZ, TRENT JOHNSON, DAVID LEDERMAN, West Virginia University, MULTIFUNCTIONAL MATERIALS LABORATORY TEAM — A series of crystalline BaF_2/epitaxial (110) $Fe_xNi_{1-x}F_2$ samples were deposited on MgF_2 (110) via molecular beam epitaxy. The Fe concentration x was determined from x-ray diffraction measurements of the [110] lattice parameter. The actual thickness of each layer and the roughness of each interface were determined by fitting x-ray reflectivity data. The antiferromagnetic ordering of samples with x = 0.04, 0.27, 0.40, 0.46, 0.50, and 0.85 were studied and compared with BaF_2/NiF_2 (x=0) and BaF_2/FeF_2 (x=1) bilayers, via standard magnetometry measurements. A significant enhancement of the Néel temperature in alloys and evidence of spontaneous magnetization along c-axis were found.

4:42PM T16.00012 $MnCu_4In$: a new high temperature ferromagnet , ALESSIA PROVINO, Department of Chemistry, University of Genova (Italy), DURGA PAUDYAL, Ames Laboratory, Ames (Iowa), SUDESH K. DHAR, CMP & MS Dept, TIFR, Mumbai (India), MARIA LUISA FORNASINI, PIETRO MANFRINETTI, Department of Chemistry, University of Genova (Italy), VITALIJ K. PECHARSKY, KARL A. GSCHNEIDNER JR., Ames Laboratory, Ames (Iowa), THE AMES LABORATORY, US DEPT OF ENERGY, IOWA STATE UNIVERSITY, AMES, IA 50011, USA COLLABORATION, DEPT OF CHEMISTRY, UNIVERSITY OF GENOA, VIA DODECANESO 31, 16146 GENOA, ITALY COLLABORATION, CMP & MS DEPT, TIFR, HOMI BHABHA ROAD, MUMBAI 400 005, INDIA COLLABORATION, CNR-SPIN, CORSO PERRONE 24, 16152 GENOA, ITALY COLLABORATION — The new intermetallic compound $MnCu_4In$ has been synthesized and investigated. The crystal structure, studied by single crystal and powder X-ray diffractions, shows that the compound crystallizes into its own hexagonal prototype ($hP12$-$P6_3mc$) derived from the $MgZn_2$-type. The measured magnetic and physical properties indicate that, in contrast to the antiferromagnetic $MnCu_4Sn$ ($MgCu_4Sn$-type), $MnCu_4In$ is a high temperature ferromagnet with T_C = 540°C. In order to understand the physics involved, the first principles calculations have been performed and compared with the $MnCu_2Al$-type $MnCu_2In$(Sn) phases and the rare earth representatives $GdCu_4In$ and $GdCu_2In$. Work partially supported by the US DOE, Division of Materials Science and Engineering (Office of Basic Energy Sciences).

4:54PM T16.00013 The layer-by-layer growth of ferromagnetic τ phase MnAl thin films by Bias Target Ion Beam[1] , YISHEN CUI, WENJING YIN, JIWEI LU, STUART WOLF, Univ of Virginia — It is well known that the metastable τ phase of MnAl has a L10 structure (chemical ordering along [001] directions) and is the only ferromagnetic phase of this binary intermetallic. In our study, alternating Al/Mn quasi-monolayer deposition was developed using a novel Bias Target Ion Beam deposition technique, that enabled precise control of the microstructural growth. We have obtained epitaxial τ phase MnAl thin films ($\sim$10 nm thick) on single crystal MgO substrates with improved saturation magnetization and anisotropy in comparison with co-sputtered ultra thin films. We will discuss the microstructure and magnetic behaviors of MnAl films in detail.

[1]We acknowledge the support from DARPA.

5:06PM T16.00014 Field induced first order phase transition in the antiferromagnet Yb_3Pt_4[1] , L.S. WU, Stony Brook University, Y. JANSSEN, M.S. KIM, Brookhaven National Lab, C. MARQUES, Stony Brook University & Brookhaven National Lab, K.S. PARK, M. BENNETT, Brookhaven National Lab, M.C. ARONSON, Stony Brook University & Brookhaven National Lab, S.X. CHI, J.W. LYNN, NIST Center for Neutron Research — Yb_3Pt_4 is an antiferromagnet that orders at T_N=2.4K. Magnetic fields B suppress T_N, and the B-T phase line T_N(B) terminates almost vertically at T=0, B_C=2.0 T. Specific heat measurements find a mean-field transition at T_N(B), and the magnetocaloric effect shows that the antiferromagnetic transition is continuous at all fields, with no associated latent heat. However, neutron diffraction measurements performed for B$\sim B_C$ find that a distinct step in the magnetization ΔM occurs near the transition, with a magnitude that increases for T<1 K. The field dependent magnetization M(B) similarly has a metamagnetic-like step at T_N(B) below 1 K, accompanied by a sharp peak in the susceptibility whose magnitude increases but does not diverge as T$\rightarrow$0. We argue that a nonzero magnetization step ΔM is required to give ΔS=0 for T=0, since the vertical phase line at T=0 implies dT_N/dB=-$\Delta M/\Delta S \rightarrow -\infty$. We argue that T_N (B) terminates at B_C in a T=0 first order transition.

Session T17 GMAG DMP: Focus Session: Magnetic Oxide Thin Films - Manganite Thin Films

2:30PM T17.00001 Tunable Percolative Transport in Manganite Thin Films using Strain and Exchange Fields[1]

, T. ZAC WARD, Oak Ridge National Laboratory — Strongly correlated electronic systems are often sensitively dependent on spin-charge-orbital-lattice interactions. We will discuss recent work on manganites that have led to some fascinating new discoveries on the role of these interactions in driving electronic phase separation in strongly correlated systems. We demonstrate that substrate induced anisotropic strain effects and surface exchange coupled magnetic nanodots can be used to preferentially seed electronic domains. These effects have led to a new understanding of how order parameter tuning can lead to highly controllable electronic and magnetic properties. We find that even strain frustrated ultrathin manganite films—where no metal-insulator transition is present—can be selectively tuned with the application of magnetic nanodots at the film surface. Both the magnetoresistance and the metal-insulator transition temperature can be tuned through dot density and dimension. The strain frustrated film's metal-insulator transition and magnetoresistivity can be driven to bulk levels. We expect these results to be applicable in many other systems in which order parameters are tightly correlated.

[1]Supported by the US DOE Office of Basic Energy Sciences.

3:06PM T17.00002 STM study on the electronic phase separation of manganites[1]

, MIN GAO, Oak Ridge National Laboratory, USA; Institute of Physics, Chinese Academy of Sciences, China, ZHENG GAI, PAUL C. SNIJDERS, HANGWEN GUO, THOMAS Z. WARD, Oak Ridge National Laboratory, USA, H.-J. GAO, Institute of Physics, Chinese Academy of Sciences, China, JIAN SHEN, University of Tennessee, USA — Phase separation is a key problem in understanding the exotic properties of complex oxide materials. Combing pulsed laser deposition with in situ scanning tunneling microscopy, we can investigate the electronic phase separation of$La_{5/8-x}Pr_xCa_{3/8}M\ nO_3$. Current imaging tunneling spectroscopy reveals both local domain contrast and global conductivity evolving when the temperature crosses over the metal-insulator transition temperature. The domain size can be several hundred nanometers. This result confirms other experimental results and shows that the surface electronic properties of complex oxide materials can represent their bulk properties.

[1]Research sponsored by the Division of Materials Sciences and Engineering, Office of Basic Energy Sciences, U.S. Department of Energy.

3:18PM T17.00003 Nonlinear optical imaging of antiferromagnetic domains in orbital-ordered $Pr_{0.5}Sr_{0.5}MnO_3$ thin films

, KENJIRO MIYANO, NAOKI OGAWA, Univ of Tokyo, CREST, YASUSHI OGIMOTO, Univ of Tokyo, CREST, Fuji Electric HD — Perovskite manganites develop various ordering patterns of charge, orbital, and spin, whose geometrical correlation brings out a new order, e.g., electronic polarization. As an example in pseudo-cubic systems, the CE-type charge/orbital order (CO/OO) was predicted to be multiferroic. With the use of nonlinear optics, we show that $Pr_{0.5}Sr_{0.5}MnO_3$ thin films exhibit symmetry breaking in the OO phase without CO. Ultrathin films prepared on LSAT(110) substrates reproduce bulk-like properties, showing successive phase transitions from paramagnetic metal, to ferromagnetic metal, and finally to A-type antiferromagnetic (AF) insulator upon cooling. Below T_{OO}=T_N, we detect SHG from these films and visualize the formation of AF domains with the size of several μm, which is much larger than that of phase-separated manganites. With careful examination of the magnetic point group, we can ascribe the broken symmetry to the AF spin order under the monoclinic lattice distortion concomitant with the OO, which also manifests the direction of the AF vector.

3:30PM T17.00004 Novel Resistive Switching Behavior in Phase Separated Manganites[1]

, HANGWEN GUO, The University of Tennessee, Knoxville & Oak Ridge National Laboratory, T. ZAC WARD, DALI SUN, PAUL C. SNIJDERS, Oak Ridge National Laboratory, ZHENG GAI, Oak Ridge National Laboratory & Center for Nanophase Materials Science, JIAN SHEN, The University of Tennessee, Knoxville & Fudan University — Electronic phase separation plays a key role in many novel phenomena in complex materials. Manganites are a prime example of this class of materials and have recently come under increase scrutiny for possible application in resistive random-access memory (RRAM) technology. Here, we will discuss our recent work on spatially confined La5/8-xPrxCa3/8MnO3. We have discovered that it is possible to drive single electronic domain formation/annihilation through electric field pulsing. By measuring the I-V curve, we find such resistive switching is different from normal RRAM mechanisms in manganites and is closely related to the nature of electronic phase separation. These findings open these systems to a new understanding of the nature of electronic phase separation and begin the development of manganites for future applications in RRAM devices.

3:42PM T17.00005 Mesoscopic orientation-ordered percolating network in a strained manganite thin film

, KEJI LAI, Stanford University — Many unusual behaviors in complex oxides are deeply associated with the spontaneous emergence of microscopic phase separation. Recent studies on these strongly correlated materials have shown that multiple states can coexist near certain phase boundaries. In this work, a cryogenic microwave impedance microscope [1] is implemented to investigate the microscopic origin of the colossal magnetoresistance effect in manganite thin films. In a strained $Nd_{0.5}Sr_{0.5}MnO_3$ thin film grown on (110) $SrTiO_3$ surface, the filamentary ferromagnetic metallic domains emergent from the antiferromagnetic charge/orbital-ordered insulating background as increasing magnetic fields align preferentially along certain crystal axes of the substrate [2]. Such an orientation ordering is missing in a relaxed sample with partial loss of the epitaxial coherency. The mesoscopic glassy orders with a period of 100nm indicate that the substrate-induced anisotropic strain rather than the Coulomb interaction plays the dominant role in the phase separation. The microwave images also revealed drastically different domain structures between the zero-field-cool and field-cool processes, consistent with the macroscopic transport measurements in both bulk and thin film materials.

4:18PM T17.00006 Room Temperature Resistive Switching in Manganite Thin Films

, LUIS PEÑA, LUIS GARZON, ZORIÇA KONSTANTINOVIC, LLUIS BALCELLS, CARMEN OCAL, BENJAMIN MARTINEZ, ICMAB - CSIC, INSTITUTO DE CIENCIA DE MATERIALES DE BARCELONA. CSIC TEAM — Resistive switching (RS), i.e. the switching between two distinct resistive states electrically controlled, is currently a subject of major interest because of its very promising properties for the implementation of data storage devices. In this work we report on the reversible transitions from low resistive (LR) to high resistivity (HR) states in high quality manganite thin films (LSMO) prepared by RF sputtering on top of (001) oriented STO substrates. The transitions between the LR and HR states are induced by the application of a bias voltage by means of the conducting tip of a scanning force microscope [1]. The experimental setup is arranged in order to avoid parasitic interfacial phenomena (e.g., metal diffusion) or electrode interconnections (e.g., filamentary formation). These RS experiments have been performed on few microns wide patterned LSMO structures. The magnetotransport properties and thermal stability of these LR and HR states are investigated in order to gain a deeper insight into the nature of the structural/electronic modifications generated by the application of high electric field by means of the AFM tip on the manganite film.

4:42PM T17.00008 Interfacial phase separation in $La_{2/3}(Sr/Ca)_{1/3}MnO_3$ thin films with different complex oxide capping layers , SERGIO VALENCIA, Helmholtz-Zentrum-Berlin, ZORIÇA KONSTANTINOVIC, ICMAB - CSIC, SCHMITZ DETLEF, Helmholtz-Zentrum-Berlin, LLUIS BALCELLS, BENJAMIN MARTINEZ, ICMAB - CSIC, INSITUT FOR COMPLEX MAGNETIC MATERIALS, MI-1 (BESSY) TEAM, INSTITUTO DE CIENCIA DE MATERIALES DE BARCELONA - CSIC TEAM — Interfacial effects in sputtered manganite thin films with different capping layers (MgO, LAO, STO, NGO and Au) have been investigated. The interfaces have been chemically and magnetically characterized by means of local probes such as X-ray absorption spectroscopy (XAS) and X-ray magnetic circular (XMCD) and linear dichroism (XLD). Total electron yield detection at the Mn L-edge guarantees that the spectroscopic information originates from those regions closer to the film/capping interface. A complex phase separated scenario at the interface arises from the spectroscopic data. XAS shows departure of the Mn valence from bulk like values in case of STO and Au capping (Mn2+ presence) and in case of MgO and NGO (Mn4+ increase). XMCD shows concomitant depressed interface magnetization suggesting coexistence of ferromagnetic and non-magnetic phases. Finally XLD proves the presence of an antiferromagnetic (AFM) and orbital ordered (OO) phase.

4:54PM T17.00009 Photoinduced effects in ferromagnetic state of manganites , VERA SMOLYANINOVA, GRACE YONG, RAJESWARI KOLAGANI, Department of Physics, Astronomy and Geosciences, Towson University, Towson, MD 21252, AMLAN BISWAS, Department of Physics, University of Florida, Gainesville, Florida 32611, KILHWAN WANG, Department of Physics, Astronomy and Geosciences, Towson University, Towson, MD 21252 — Rear-earth manganese oxides have a rich phase diagram. Transitions between different magnetic, electronic and structural states can be induced by application of external fields. Light-induced destruction of the charge ordering in some compositions of manganites, which results in significant increase of conductivity, is a well known example of such transition. Significant change in conductivity of these materials makes them attractive for photonic and opto-electronic device applications. We report a study of photoinduced properties of manganites in ferromagnetic metallic state. Since light penetration depth in these materials is small, thin films of manganites were used in this study. Photoinduced resistivity changes in these materials will be reported. Photoinduced effects in compositions with different temperatures of metal-insulator transition will be discussed. This work is supported by the NSF grant DMR-0348939.

5:06PM T17.00010 Bulk-like electronic structure at the surface of epitaxial $La_{1-x}Sr_xMnO_3$ films , ERIC MONKMAN, CAROLINA ADAMO, DANIEL SHAI, DAWEI SHEN, JOHN HARTER, Cornell University, ILYA ELFIMOV, University of British Columbia, DARRELL SCHLOM, KYLE SHEN, Cornell University — We present direct measurements of the electronic structure of $La_{1-x}Sr_xMnO_3$ (LSMO) using a combined molecular beam epitaxy and angle-resolved photoelectron spectroscopy system. Our results allow for the first comparison between theory and experimental results over the entire Fermi surface in the ferromagnetic-metallic phase. We observe both of the predicted Fermi surface sheets, and find that the evolution of the Fermi surface shape with doping is consistent with a rigid-band shifting of the chemical potential. Measurements in the antiferromagnetic phase at x $>$ 0.5 allow us to determine the changes in the low energy electronic structure linked to the magnetic phase transition. The ability of this surface sensitive technique to probe the bulk electronic structure of LSMO limits the possible depth of a surface dead layer. This conclusion is supported by density functional theory calculations for LSMO slabs, which indicate that the polarity of the (001) surface is efficiently screened within ∼1 unit cell.

5:18PM T17.00011 Hall effect on strain-released $La_{0.67}Ca_{0.33}MnO_3$ thin films , LIUQI YU, XIAOHANG ZHANG, S. VON MOLNÁR, P. XIONG, Florida State University, LINGFEI WANG, W.B. WU, University of Science and Technology of China — It has been demonstrated that releasing the in-plane anisotropic strain in thin films of $La_{0.67}Ca_{0.33}MnO_3$ grown on orthorhombic $NdGaO_3$ (001) substrates can induce a charge ordering state below the Curie temperature.[1] Three LCMO films on NGO, (PLD at 735^{o}C and 45 Pa O_2 pressure, 45 nm thick) were annealed at 780^{o}C in flowing O_2 for 1, 10 and 20 hours to increase degrees of strain relaxation. Hall measurements were performed. In all three samples, the Hall resistivity takes on two distinct slopes in the paramagnetic phase: a negative slope at low fields, which varies with temperature, and a temperature-independent positive slope at high fields. Notably, the switching field for the Hall slope decreases linearly with temperature and extrapolates to the paramagnetic Curie temperatures of the samples. The observation is similar to the behavior of the nonlinear Hall effect in EuB_6 and suggests that the switches occur at a *constant critical magnetization*.[2] In strain-released samples, peaks in the Hall resistivity emerge near T_C and become more pronounced with decreasing temperature. The origins and implications of these observations will be discussed. Work supported in part by NSF DMR-0908625. [1]Z. Huang et al., JAP 105, 113919 (2009) [2]X. Zhang et al., PRL **103**, 106602 (2009)

Session T18 GMAG DMP: Focus Session: Low D/Frustrated Magnetism - Molecular Magnets II D172

2:30PM T18.00001 Recent developments in Molecular Magnetism , EUGENIO CORONADO, Instituto de Ciencia Molecular (ICMol). Universidad de Valencia (Spain) — Two hot topics in this area are highlighted namely the design of new multifunctional magnetic materials, and the study of mononuclear single-molecule magnets. In the first topic I will present the attempts to design materials exhibiting coexistence of superconductivity and magnetism using a chemical approach [1]. In the second topic I will show that single-molecule magnets based on lanthanides provides the opportunity to tune quantum tunneling effects and to use these systems as qubits in quantum computing [2]. Finally, I will highlight the relevance of these magnetic systems in molecular spintronics.

3:06PM T18.00002 Random Exchange Antiferromagnetic Heisenberg Chains[1] , CHRISTOPHER LANDEE, FAN XIAO, BRIAN WELLS, BRIAN KOOPMAN, MARK TURNBULL, Department of Physics and Carlson School of Chemistry, Clark University, MATTHIAS THEDE, ANDREY ZHELUDEV, Laboratorium für Festkörperphysik, ETH, Zürich, Switzerland — Copper *bis*pyridine dichloride (CPC) and copper *bis*pyridine dibromide (CPB) are isostructural Heisenberg S = $1/2$ linear chains in which the copper atoms are bridged by two halides with the pyridine molecules in the axial sites. The exchange strengths are 27 K (CPC) and 45 K (CPB). We have prepared mixed halide versions $Cu(py)_2[Cl_{1-x}Br_x]_2$ for values of x from 0 to 1. We will report on the effect of the exchange randomness on the susceptibilities and Néel temperatures of this family of compounds, as determined by dc-magnetometry, muon spin relaxation, and low-temperature calorimetry.

3:18PM T18.00003 Magnetic dilution in the cadmium-doped spin ladder compound $Cd_xCu_{1-x}(quinoxaline)Br_2$, BRIAN KEITH, CHRIS LANDEE, MARK TURNBULL, Clark University — Both $Cu(quinoxaline)(Br_2)$ and $Cu(quinoxaline)(Cl_2)$ are examples of molecule-based magnets where the CuX_4 dimers are linked into ladders by quinoxaline molecules, where X is either Cl or Br. The rung exchange occurs through the bridging halides while the rail exchange occurs through the quinoxaline rings. Introducing random rung interactions into the system $[Cu(quinoxaline)(Br_2)_{1-x}(Cl_2)_x]$ has caused the spin gap to close, in contrast with the gapped pure spin ladder parents. Crystal growth of non-magnetic-doped molecular magnets, $Cd_xCu_{1-x}(2,3-dimethylpyrazine)Br_2$, have been performed for several values of the nominal conentration, x, and have been confirmed. The magnetizations and susceptibilities of the magnetically diluted ladder assemblage are presented along with a comparison of the effects of dilution from the pure case (x=0).

3:30PM T18.00004 Electron and Spin Transport in Mn_{12} Single Molecule Magnets Bridging Gold Electrodes: How to Determine the Easy Axis Orientation Experimentally[1] , FATEMEH ROSTAMZADEH RENANI, GEORGE KIRCZENOW, Simon Fraser University, Burnaby, Canada — We present a tight-binding theory of Mn_{12} single molecule magnets thiol-bonded to gold electrodes. The model includes both the spatial and spin aspects of the electronic states. Spin-orbit coupling is included explicitly in the Hamiltonian and magnetic anisotropy values in agreement with experiment are obtained. We demonstrate that Mn_{12} single molecule magnets strongly coupled to gold electrodes should exhibit strong spin filtering under appropriate conditions. In experiments, the orientation of the molecule's easy axis relative to leads is not controllable and it has not been feasible to measure it. Our calculations reveal the possibility of determining the easy axis orientation experimentally by means of current measurements: In the molecular junction with the easy axis parallel to leads the current is predicted to be at least two orders of magnitude larger than if the easy axis is perpendicular to the leads, for molecules thiol-bonded to the leads with similar gold-sulfur distances in the two cases.

[1]This work was supported by CIFAR and NSERC.

3:42PM T18.00005 Hall magnetometry measurements of the susceptibility of variants of Mn_{12}-ac[1] , PRADEEP SUBEDI, A.D. KENT, NYU, B. WEN, M.P. SARACHIK, CCNY, Y. YESHURUN, Bar-Illan, A.J. MILLIS, Columbia U, S. MUKHERJEE, G. CHRISTOU, UF-Gainsville — The temperature dependence of the inverse magnetic susceptibility of both Mn_{12}-ac and Mn_{12}-ac-MeOH is found to give finite temperature intercepts, indicating a ferromagnetic phase at low temperature [1, 2]. A magnetic field applied transverse to the Ising axis suppresses the Curie temperature, T_{CW}, to a T = 0 quantum critical point. However, the decrease of T_{CW} with transverse field, $H_\perp$, in Mn_{12}-ac does not agree with mean field calculations performed with a spin Hamiltonian that includes dipolar interactions between molecules and $H_\perp$ effects. We attribute the pronounced suppression of T_{CW} of Mn_{12}-ac to the effect of random fields arising from a distribution of molecular easy axis tilts due to ligand disorder [1]. Mn_{12}-ac-MeOH is of interest in this regard because it appears to have no ligand disorder. We discuss these experiments as well as ongoing studies of Mn_{12}-toluate, a faster relaxing variant of Mn_{12}, which has a lower effective anisotropy barrier that permits the study of the susceptibility in larger $H_\perp$ at very low temperature.

3:54PM T18.00006 Local magnetic susceptibility study of long-range order in Mn_{12}-ac[1] , BO WEN, CCNY, P. SUBEDI, NYU, Y. YESHURUN, Bar-Ilan U., Israel, M.P. SARACHIK, CCNY, A.D. KENT, NYU, A.J. MILLIS, Columbia U., S. MUKHERJEE, G. CHRISTOU, U. of Florida — The magnetic susceptibility of single crystals of Mn_{12}-ac obeys a Curie-Weiss law, indicating a transition to a ferromagnetic phase below 1 K [1]. Measurements by Hall magnetometry have yielded different temperature intercepts ranging from 0.4 K to 0.9 K. Moreover, these values differ from those obtained for the same crystals in a SQUID-based MPMS. We have proposed two possible origins: (1) the effect of crystal's aspect ratio, reported in [2]; (2) the possibility that the local ordering temperature differs from the global average value. Here we report an ongoing study of the longitudinal magnetic susceptibility at different locations of a single crystal, performed on a Hall sensor array in both zero and finite transverse magnetic field. Preliminary results yield temperature intercepts that are lower near the end of the crystal than in the middle.

4:06PM T18.00007 Magneto-structural study of M(TCNE)(NCMe)]X molecule-based magnets[1] , KONSTANTIN POKHODNYA, CHRIS OLSON, CHRIS HETH, North Dakota State University, JOHN SCHLUETER, GREGORY HALDER, Argonne National Laboratory — In M^{II}(TCNE)$(NCMe)_2$]X (M=Fe, Mn, Ni; TCNE = tetracyanoethylene; X = monovalent anion) the magnetic properties can be tuned by systematic altering of transition metal from Mn to Ni, as well as adjusting the inter-plane distances via changing the anion volume (e.g., PF_6, AsF_6 and SbF_6). The magnetic properties of the molecule-based magnets are highly responsive to structural perturbations. For the series of M[TCNE]X magnets the synchrotron-based powder diffraction experiments in combination with magnetic susceptibility, all under hydrostatic pressure, were performed revealing the correlations between metal-ligand bonding and magnetic exchange and allowing the structure-magnetic property correlations to be established. The pathways toward important conductivity and band spin polarization improvements substantial for spin-polarized current injection in microelectronic applications are discussed.

[1]This work was supported by NSF and North Dakota EPSCoR grants.

4:18PM T18.00008 Experimental determination of the Weiss temperature of several variants of Mn12-ac[1] , SHIQI LI, CCNY & GC-CUNY, LIN BO, BO WEN, CCNY, P. SUBEDI, NYU, Y. YESHURUN, Bar-Ilan U., Israel, A.D. KENT, NYU, M.P. SARACHIK, CCNY, A.J. MILLIS, Columbia U., C. LAMPROPOULOS, S. MUKHERJEE, G. CHRISTOU, U. of Florida — We report measurements of the susceptibility in the temperature range from 3.5 K to 6.0 K of a series of Mn12-ac and Mn12-ac-MeOH samples in the shape of rectangular prisms. The susceptibility obeys a Curie-Weiss Law, where the temperature intercept varies systematically with sample aspect ratio. Using published demagnetization factors, we obtain the Curie-Weiss intercept for an infinitely long sample corresponding to intrinsic ordering temperatures Tc $\sim$ 0.85 K and $\sim$ 0.74 K for Mn12-ac and Mn12-ac-MeOH, respectively [1]. The difference in Tc for the two materials suggests an additional non-dipolar (exchange) contribution to the Weiss temperature that differs in the two materials because of the difference in ligand molecules. A similar comparison will also be reported for Mn12-toluate.

[1]Supported by NSF-DMR-0506946, ARO W911NF-08-1-0364, NSF-DMR-0705847, NSF-DMR-0451605, CHE-0910472 and German Research Foundation (DFG).

4:30PM T18.00009 Asymmetric Berry-Phase Interference Patterns in a Mn_4 Single-Molecule Magnet , H.M. QUDDUSI, Department of Physics, University of Central Florida, J. LIU, Department of Physics, University of Florida, S. SINGH, Department of Physics, University of Central Florida, K. HEROUX, Department of Chemistry and Biochemistry, University of California at San Diego, E. DEL BARCO, Department of Physics, University of Central Florida, S. HILL, National High Magnetic Field Laboratory and Department of Physics,, D. HENDRICKSON, Department of Chemistry and Biochemistry, University of California at San Diego — We present a low temperature magnetometry study of the quantum interference effect in a Mn_4 single-molecule magnet. Asymmetric modulations of the Berry phase interference patterns upon application of a transverse field are observed for $k > 0$ resonances (i.e. non-zero longitudinal field), contrary to the symmetric patterns obtained at $k = 0$. These asymmetries can be reversed by a full inversion of the total applied field. The observation of a fascinating motion of the Berry-phase minima as a function of both the magnitude and direction of the transverse field can be understood as an outcome of a competition between different intramolecular magnetic interactions. A multi-spin description using non-collinear zero-field splitting tensors and intra molecular dipolar interactions between the manganese ions is employed to explain the results.

4:42PM T18.00010 Observation of double hysteresis in a $MnMn_6(CH_3H_5O_3)_3$ single-molecule magnet , KLAUS GIEB, WOLFGANG KROENER, PAUL MÜLLER, Department of Physics and Interdisciplinary Center for Molecular Materials (ICMM), Universitaet Erlangen-Nuernberg, Germany, CARL-GEORG FREIHERR VON RICHTHOFEN, THORSTEN GLASER, Fakultaet fuer Chemie - Lehrstuhl Anorganische Chemie I, Universitaet Bielefeld, Germany — We report on high field and low temperature magnetization measurements of a novel $MnMn_6(CH_3H_5O_3)_3$ complex. A home-made micro-Hall-probe magnetometer was used to perform the characterization at mK temperatures and fields up to 17 T. Most 3d-ion based single-molecule magnets, known up to now, have a spin ground state well separated from the first excited state, leading to the formation of giant spin at low temperatures. In contrast to this situation, the ground state (S=6) of the present complex can already be exited at moderate magnetic fields. Surprisingly, magnetic hysteresis was observed for both the ground state and the first exited state leading to a double hysteresis in the low temperature magnetization measurements. The blocking temperature was found to be $T_B \approx 1.3$ K. Origin and possible consequences of this unusual behavior will be discussed.

4:54PM T18.00011 A Muon Spin Relaxation Study of NiTCNQ2 , ADAM BERLIE, IAN TERRY, MAREK SZABLEWSKI, Durham University, SEAN GIBLIN, ISIS, RAL — $NiTCNQ_2$ (TCNQ = 7,7,8,8-tetracyanoquinodimethane) is a novel metal-organic material that exhibits a magnetic transition at approximately 20 K. The material was first synthesized by Dunbar *et al* (Chem. Mater. 15, 1840) who identified the low temperature magnetic phase as a glassy ferromagnet. We have investigated this magnetic transition with muon spin relaxation (μSR). We synthesised the deuterated form of the material to minimise hyperfine coupling between the muon and H nuclear moments on TCNQ. Using μSR we probed the transition region to determine whether there was a local or long range coherence of the ferromagnetism. We found that zero field measurements yielded a Lorentzian relaxation along with a nuclear component from the nuclear spins of the nitrogen atoms. A longitudinal field of 0.5 mT decoupled the nuclear component revealing a dynamical Kubo-Toyabe relaxation suggesting that there may be a coexisting static and dynamic field distribution. This may imply a long range static ordering below the transition temperature.

5:06PM T18.00012 Magnetization measurements of a two-leg spin-1/2 ladder with strong leg interactions , K. NINIOS, University of Florida, TAO HONG, Oak Ridge National Laboratory, S.N. HERRINGER, M.M. TURNBULL, C.P. LANDEE, Clark University, Y. TAKANO, University of Florida, H.B. CHAN, The Hong Kong University of Science and Technology — We have measured the magnetization of a single crystal of the spin-1/2 ladder compound bis(2,3-dimethylpyridinium) tetrabromocuprate (DIMPY), using micromechanical force magnetometry down to 30mK. DIMPY undergoes a quantum phase transition from a gapped phase with no long–range magnetic order to a gapless phase, at critical field Hc. Recent specific heat results by Hong et al. show that the gapless phase is a Tomonaga-Luttinger liquid (TLL). Low temperature magnetic susceptibility as a function of field exhibits a maximum near Hc, in consistence with the divergence of the zero temperature susceptibility at Hc expected for an ideal 1-D system. A clear minimum in the magnetization of the gapless phase as a function of temperature is observed, a minimum that marks the limit below which the TLL exists. In addition the field dependence of the TLL parameter K is studied.

5:18PM T18.00013 Field-induced Tomonaga-Luttinger liquid phase of a two-leg spin-1/2 ladder with strong leg interactions[1] , TAO HONG, Oak Ridge National Laboratory, Y.H. KIM, University of Florida, C. HOTTA, Kyoto Sangyo University, Y. TAKANO, University of Florida, G. TREMELLING, M.M. TURNBULL, C.P. LANDEE, Clark University, H.-J. KANG, National Institute of Standards and Technology, N.B. CHRISTENSEN, ETH Zurich and Paul Scherrer Institute, K. LEFMANN, University of Copenhagen, K.P. SCHMIDT, G.S. UHRIG, TU Dortmund, C. BROHOLM, The Johns Hopkins University — We study the magnetic-field-induced quantum phase transition from a gapped quantum phase that has no magnetic long-range order into a gapless phase in the spin-1/2 ladder compound bis(2,3-dimethylpyridinium) tetrabromocuprate (DIMPY) [1]. At temperatures below about 1 K, the specific heat in the gapless phase attains an asymptotic linear temperature dependence, characteristic of a Tomonaga-Luttinger liquid. Inelastic neutron scattering and the specific heat measurements in both phases are in good agreement with theoretical calculations, demonstrating that DIMPY is the first model material for an $S = 1/2$ two-leg spin ladder in the strong-leg regime.

Session T19 GMAG DMP: Focus Session: Spin Transport & Magnetization Dynamics in Metals VII D170

2:30PM T19.00001 Direct observation of strain-induced magnetic domain evolution in Heusler shape memory compounds , C.A. JENKINS, A. SCHOLL, A. DORAN, Lawrence Berkeley National Laboratory, T. OMORI, Graduate School of Engineering, Tohoku University Sendai — The magnetic domain structure in single crystals of a novel Heusler magnetic shape memory (MSM) compound Fe_2MnGa was observed to undergo strain-induced evolution by synchrotron-based photoelectron emission microscopy (PEEM) at Beamline 11.0.1 of the Advanced Light Source. PEEM can produce high resolution, surface-sensitive images reflecting the spatial distribution of magnetism, and a custom flexure rig has been designed for in situ actuation and simultaneous observation of MSM. System energy of an MSM compound is lowered when the volume fraction of the favorably oriented martensitic variant is increased: intermartensitic twin boundary motion is energetically easier than magnetic rotation so magnetic domains evolve not by domain wall motion but by propagation of planar structural defects called twin boundaries. In this ternary MSM intermetallic the direction of tetragonal distortion, which is coupled to the magnetic easy axis, will lie favorably along the axis of compression as defined by the action of the custom rig. The disappearance of unfavorably oriented orthogonal magnetic domains with strain is then observed as expected.

2:42PM T19.00002 Thin film growth and characterization of full Heusler alloys $Rh_{2-x}Co_xFeSn$ and RhCoMnSn , LI GAO, MINGYANG LI[1], MAHESH G. SAMANT, BRIAN P. HUGHES, KEVIN P. ROCHE, CLAUDIA FELSER[2], STUART S.P. PARKIN, IBM Research Division, Almaden Research Center, San Jose, California 95120 — Heusler alloys can be designed and prepared with high spin polarization, high Curie temperature, very low magnetization damping, as well as, tunable magnetic magnetization and anisotropy. Therefore, this family of compounds has great potential for applications such as spin-transfer-torque magnetic random access memory. The growth and characterization of epitaxial thin films of the Rh-based full Heusler compounds, $Rh_{2-x}Co_xFeSn$ and RhCoMnSn, are presented. The magnetization, Curie temperature and crystal structure of these compounds have been investigated and are compared with bulk materials. An important known property of many Heusler alloys is low magnetization damping. Ferromagnetic resonance (FMR) studies using a strip line transmission technique reveals Gilbert damping values of $\sim$0.015 at room temperature in films of RhCoMnSn. These films have Curie temperatures well above room temperature whereas the Curie temperature of Rh_2FeSn is $\sim$350 K.

2:54PM T19.00003 Electronic structure modifications in Cu doped Ni_2MnGa , SUJOY ROY, R. QIAO, P.-A. GLANS, Advanced Light Source, Lawrence Berkeley National Laboratory, USA, A. PATHAK, I.S. DUBENKO, N. ALI, Dept. of Physics, Southern Illinois University Carbondale, USA, E. BLACKBURN, Dept. of Physics and Astronomy, University of Birmingham, UK, W. YANG, Advanced Light Source, Lawrence Berkeley National Laboratory, USA — Ni_2MnGa Heusler alloy is a multifunctional ferromagnetic alloy that exhibits various interesting properties. The compounds typically exhibit a high temperature magnetic and a low temperature martensitic transition. Stoichiometry changes or elemental substitution makes it possible to merge the two transitions to a unique magnetostructural one. We have used resonant inelastic x-ray scattering to study the effects of $d-d$ interactions and charge transfer effects in 25% Cu doped Ni_2MnGa. We find distinct charge transfer effects in the Ni absorption and inelastic x-ray spectrum that are significantly modified by Cu doping. Mn on the other hand shows $d-d$ interaction effects but no charge transfer. Multiplet calculations have been performed and will be compared to the experimental data. These results provide an insight into the origin of multifunctional properties of Ni based Heusler alloys. Work at LBNL is supported by U.S DOE.

3:06PM T19.00004 Approach towards full Heusler alloy based CPP-GMR: from Ag and non-magnetic Heusler to binary intermetallic spacers , OLEG MRYASOV, University of Alabama, Department of Physics, SERGEY FALEEV, S.V. KARTHIK, University of Alabama, MINT — Recently, it has been demonstrated that GMR response can be significantly enhanced by incorporating high spin polarization ferromagnetic (FM) full Heulser alloy into spin valve nano-structures. Experimental results for two types of non-magnetic spacers (i) elemental metal [1] and (ii) non-magnetic Heusler alloy spacers [2] deserve careful comparison. More practical (110) textured combination of Co_2MnGe (CMG) and non-magnetic Heusler alloy Rh_2CuSn (RCS) [2] have been used to build test hard disk drive [3]. In this work, we investigate the mechanism of spin dependent interface scattering for (001) CMG/Ag/CMG (Case1) and (110) CMG/RCS/CMG (Case2) models on the basis of ab-initio electronic structure calculations. We find that in both cases GMR has significant contribution from the spin dependent interface scattering. We propose new binary intermetallic spacer materials Al_2Au and Cu_3Sn as an alternative to Ag and RCS spacers.

3:18PM T19.00005 Spin fluctuations and doping trends in the itinerant magnet Pd_2TiIn_x , JESSICA MISSAGHIAN, ANDREW LAFORGE, DAVID MATTHEWS, GARRETT ROGREN, ZACK SCHLESINGER, ARTHUR RAMIREZ, University of California, Santa Cruz — The intermetallic compound Pd_2TiIn is one of several Heusler-type materials which are remarkable for possessing a significant magnetic moment despite being composed of elements which have no spontaneous local moment. We investigate the nature of the magnetic order and the role of spin fluctuations by studying the magnetic, transport and heat capacity properties of two series of polycrystalline samples derived from Pd_2TiIn_x: one in which the indium content is varied from $x = 0.87$ to 1.22, and another in which 3d and 4d metals are substituted in small quantities for Pd and Ti.

3:30PM T19.00006 Thermal effects on magnetic resonance in single crystal $Co_{1-x}Fe_xS_2$[1] , B. KASTER, M. PECHAN, Department of Physics, Miami University, Oxford, OH 45056, M. MANNO, A. BARUTH, C. LEIGHTON, Department of Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, Minnesota 55455 — Many spintronic applications require spin injection from spin polarized ferromagnetic materials. A promising model system for fundamental studies of such processes is CoS_2, which has -56% spin polarization at the Fermi level and is tunable with Fe doping in $Co_{1-x}Fe_xS_2$ to over 85%. Single crystals of $Co_{1-x}Fe_xS_2$ have been successfully prepared with close to ideal sulfur stoichiometry using chemical vapor transport methods. We have employed variable temperature ferromagnetic resonance (FMR) at 9.2 GHz to investigate the magnetodynamic properties of this system for x=0, 0.05, 0.12 and 0.17. Resonance signals are observed upon cooling to 160 K, well above the Curie temperature, suggesting short-range order enhancements to the susceptibility lead to observable resonances. All concentrations exhibit increasing resonance position, and decreasing damping, with increasing temperature. Both the resonance position and the damping decrease with increasing Fe concentration - the former revealing Fe concentration effects on the moment and anisotropy, while the latter reflects the spin polarization influence on the damping.

3:42PM T19.00007 Spin-dependent intergranular hopping transport in very thin highly spin-polarized CoS_2 thin films[1]

, M. MANNO, A. GUNAWAN, A. BARUTH, R. FRAKIE, A. MKHOYAN, C. LEIGHTON, University of Minnesota, DEPARTMENT OF CHEMICAL ENGINEERING AND MATERIALS SCIENCE COLLABORATION — The $Co_{1-x}Fe_xS_2$ alloy system has been shown to exhibit high, composition tunable, spin polarization (-56 % $< \quad P <$ +85 %) in bulk, demonstrating great promise for fundamental studies in spintronics. Incorporation in heterostructures requires reliable thin film deposition routes, which have recently been developed. We present here a detailed study of the thickness (t) dependence of the structural, magnetic, and electronic properties of polycrystalline CoS_2 thin films (70 – 1600 Å). As t is decreased, we observe a suppression in magnetic properties accompanied by a metal-insulator transition. A distinct 3D to 2D crossover is evident in the conductance-voltage curves and intergranular tunneling magnetoresistance. At t of order 70 Å we observe granular metal conduction, in the presence of a Coulomb charging penalty. We demonstrate quantitative agreement between experiment and proposed models. The very thin film data are understood in terms of enhanced grain boundary resistance, due to S accumulation, which is evidenced via several modes of structural characterization.

3:54PM T19.00008 Synthesis and basic characterization of the itinerant ferromagnet $Cr_{11}Ge_{19}$[1]

, NIRMAL GHIMIRE, University of Tennessee, MICHAEL MCGUIRE, Oak Ridge National Laboratory, DAVID MANDRUS, University of Tennessee and Oak Ridge National Laboratory — $Cr_{11}Ge_{19}$ is a member of the tetragonal, but structurally complex family of materials known as Nowotny chimney-ladder phases. These materials have composition T_nX_m where $2 > m/n > 1.25$ (T=transition element, X=Si, Ge, Sn or Ga). Although $Cr_{11}Ge_{19}$ was reported to be an itinerant ferromagnet, its basic properties have not been well characterized. Here we present resistivity, magnetization, and heat capacity results on polycrystalline $Cr_{11}Ge_{19}$.

[1]Research supported by DOE BES Materials Sciences and Engineering Division.

4:06PM T19.00009 Unusual magnetism of Gd_5Ge_4 with non magnetic rare earths substitutions[1]

, DURGA PAUDYAL, The Ames Laboratory, US Department of Energy, Iowa State University, Ames, IA 50011-3020, USA, Y. MUDRYK, V.K. PECHARSKY, K.A. GSCHNEIDNER, JR., The Ames Laboratory, U. S. Department of Energy, Iowa State University, Ames, IA 50011-3020, USA — We present first principles and experimental studies on the small substitutions of Gd atoms by Lu, La, Y, and Sc atoms in Gd_5Ge_4. While replacing the Gd atoms located inside the slabs with the Lu or Y atoms leads to a substantial loss of ferromagnetism, the identical substitutions of other Gd locations preferred by La atoms have essentially no effect on the magnetostructural transitions. On the other hand, the Sc atoms prefer the same locations as the Lu and Y atoms. This substitution, however, changes the crystal structure of Gd_5Ge_4 from Sm_5Ge_4 type to Pu_5Rh_4type at 25% of Sc which was not observed with the former substitutions. The Pu_5Rh_4-type has structural parameters that are intermediate between the Gd_5Si_4 and Sm_5Ge_4 types. The exchange interactions in this substitution are positive which indicates that the Sc substituted Gd_5Ge_4 has the ferromagnetic ground state.

4:18PM T19.00010 Examining the AF>FM transition in Fe-Rh thin films through specific heat, photoemission, and Mossbauer spectrometry measurements[1]

, DAVID COOKE, University of California at Berkeley, CATHERINE BORDEL, FRANCES HELLMAN — Iron-rhodium alloys near equiatomic composition undergo a metamagnetic antiferromagnetic-to-ferromagnetic (AF>FM) transition at just above room temperature. This material has been proposed as an exchange layer in thermally-assisted magnetic recording, using the ferromagnetic phase to reduce the switching field of a high-anisotropy storage layer, so clearly being able to control this transition is crucial to implementation. However, theoretically there is still much debate as to the precise mechanism of the AF>FM transition, primarily centered on the contributions of electronic and magnetic entropy differences in the two phases. Through thermodynamic measurements on epitaxially- grown ferromagnetic and antiferromagnetic Fe-Rh alloy films, we test two different thermal fluctuation models of the transition. We also discuss complementary photoemission and Mossbauer spectrometry data above and below the transition to examine the magnetic behavior and electronic densities of state in the two phases and compare these to theoretical calculations.

4:30PM T19.00011 Transport Spin Polarization of High-Curie Temperature MnBi Films

, PUSHKAL THAPA, Dept. of Physics, Wayne State University, Detroit, MI, 48202, PARASHU KHAREL, Nebraska Center for Materials and Nanoscience (NCMN), Univ. of Nebraska, Lincoln, NE, 68588, PAVEL LUKASHEV, NCMN, Univ. of Nebraska, Lincoln, NE, 68588, RENAT SABIRIANOV, Dept. of Physics, Univ. of Nebraska, Omaha, NE, 68182, EVGENY TSYMBAL, DAVID SELLMYER, NCMN, Univ. of Nebraska, Lincoln, NE, 68588, BORIS NADGORNY, Dept. of Physics, Wayne State University, Detroit, MI, 48202 — We report on the study of the structural, magnetic and transport properties of highly textured MnBi films with the Curie temperature of 628 K. In addition to detailed measurements of resistivity and magnetization, we measure transport spin polarization of MnBi by Andreev reflection spectroscopy and perform first-principles electronic structure calculations. A transport spin polarization of up to 63% is observed, consistent with the calculations and with a recent observation of a large magnetoresistance in MnBi contacts. The band structure calculations indicate that, in spite of almost identical densities of states at the Fermi energy, the large disparity in the Fermi velocities leads to high transport spin polarization of MnBi. The correlation between the values of magnetization and spin polarization observed in MnBi will be discussed.

4:42PM T19.00012 Anomalous electron transport in ferromagnetic MnBi films

, PARASHU KHAREL, D.J. SELLMYER, Nebraska Center for Materials and Nanoscience and Department of Physics and Astronomy University of Nebraska, Lincoln, NE, 68588 — Materials having high spin polarization, large perpendicular magnetic anisotropy and high Curie temperature hold great potential for a range of spintronic applications.[1] MnBi has the hexagonal NiAs structure and possesses strong permanent magnet and magneto-optical properties. Our recent research shows that MnBi exhibits a high transport spin polarization of 63%, so it is useful to investigate the electron transport properties of this material. We have found that MnBi is a metallic conductor but the resistivity shows an anomalous temperature dependence at low temperature. Analysis of the Hall data for various samples shows that the extraordinary Hall effect is the dominant part in the transverse Hall effect and a Hall angle of 2.8% has been measured. An experimental investigation on the origin of the observed large extraordinary Hall effect in MnBi thin films will be discussed. This research is supported by NSF-MRSEC Grant DMR-0820521, the DOE Grant DE-FG02-04ER46152 and NCMN.

4:54PM T19.00013 $SrMnBi_2$, a new transition metal compound with metallic spacer layer[1] , JIAKUI J. WANG, LIANG L. ZHAO, Department of Physics and Astronomy; Rice University; Houston TX 77005, Q. YIN, G. KOTLIAR, Department of Physics, Rutgers University, Piscataway, NJ 08854, EMILIA MOROSAN, Department of Physics and Astronomy; Rice University; Houston TX 77005 — To explore the correlation between superconductivity and crystal structure in transition metal-pnictides systems, we investigate the band structure and physical properties of $SrMnBi_2$ single crystals. This compound is isostructural with the superconducting Fe-pnictides. In this talk, magnetization, resistivity and specific heat data will be compared with band structure calculations. Both the experimental results and the density functional theory (DFT) calculation are consistent with this material being a bad metal with large residual resistivity, similar to the well-studied Fe-pnictides. The key difference is that the Sr-Bi blocking layer in $SrMnBi_2$ is metallic, which may be more favorable to the occurrence of superconductivity upon doping, likely with a higher transition temperature, commensurate with the high $T_N \approx 280$ K.

5:06PM T19.00014 Doping - induced Quantum Phase Transition in $Sc_{3.1}In$[1] , ETERI SVANIDZE, EMILIA MOROSAN, Department of Physics and Astronomy, Rice University, Houston, TX 77005 — Sc_3In is a known itinerant ferromagnet with a reported $T_c \approx 6$ K. In this talk we will show that Lu doping induces a quantum phase transition in this compound. Temperature and field - dependent magnetization measurements on $(Sc_{1-x}Lu_x)_{3.1}In$ polycrystalline samples were performed, where $0 \leq x \leq 0.08$. The 3.1 : 1 stoichiometry was chosen because it showed the highest $T_c \approx 10$ K for $x = 0$ when Arrott plots were employed to determine the Curie temperature. In this study we use modified Arrott plots M^2 vs. $(H/M)^{1/\alpha}$. For $\alpha = 1.5$, the corresponding isotherms were linear over larger field ranges, and, for the critical composition $x_c \approx 0.02$, the isotherm was linear down to (M,H) = (0,0). The Curie temperature determined using this method was close to 6 K.

5:18PM T19.00015 On the origin of the magnetic susceptibility anomaly in nearly ferromagnetic alloys , ROMEO DE COSS, Cinvestav, Department of Applied Physics, Cordemex 97310, Mérida, Mexico, AARÓN AGUAYO, Universidad Autónoma de Yucatán, Mérida, Yucatán, México, FILIBERTO ORTIZ-CHI, Cinvestav, Department of Applied Physics, Cordemex 97310, Mérida, Mexico — The magnetic susceptibility of the Ni-Rh and Ni-Cu alloys shows an anomaly near the transition from ferromagnetism to paramagnetism. In order to contribute to understand this phenomenon, we have studied the electronic and magnetic properties of the $Ni_{1-x}Cu_x$ alloy by means of first principles calculations. The ground state properties were obtained using the Full-Potential Linear Augmented Plane Waves method. The alloying was modeled using the self-consistent virtual crystal approximation. The spin magnetic susceptibility is calculated from the total energy as a function of the spin moment, obtained using the Fixed Spin Moment methodology. We found that the calculations predict correctly the reduction of the magnetic moment with the Cu concentration and that the critical concentration where the magnetic moment goes to zero is $x_c = 0.5$, in excellent agreement with the experimental data. The calculated magnetic susceptibility is in good agreement with the experimental data in the whole range of concentrations for the $Ni_{1-x}Cu_x$ alloy, in particular the anomaly present at $x \approx 0.4$ is reproduced by the calculations. This research was supported by Conacyt-México under Grant No. 83604.

Session T20 DMP GERA FIAP: Focus Session: Thermoelectric Materials: LAST/TAGS, Heusler, and Silicides D168

2:30PM T20.00001 Charge Neutral Yukawa Lattice Gas on a FCC Lattice , HE HUANG, S.D. MAHANTI, Michigan State University — Structural phase transitions associated with the ordering of Ag and Sb ions in the quaternary systems, $(AgSbTe_2)_x(PbTe)_{2(1-x)}$ (of current thermoelectric interest) has been investigated using an anti-ferromagnetic 3-state Ising model on a FCC lattice with screened Coulomb interaction (Yukawa lattice gas (YLG) model). We have carried out Monte Carlo simulations (MCs) to study phase transitions (PT) in YLG. The nature and the strength of PT depend on the screening parameter κ. The transition is 1^{st} order and the transition temperature T_c is a weak function of the concentration x (excepting when $x \sim 0$ or 1), in agreement with earlier work for $\kappa = 0$. We find $T_c(x,\kappa) = f(x)g(\kappa)$, where $g(\kappa) \rightarrow const$ when $\kappa \rightarrow 0$ and $g(\kappa) \rightarrow 0$ when $\kappa \rightarrow \infty$. For $x = 0.5$, there are two special structures, layered and tubular which have the same ground state energy, independent of κ. This is understood by looking at the connectivity and ordering of ions. Above but near T_c, the generation rates of different micro structures have been analyzed using a simple surface energy density picture. MCs results agree with this analysis and show that the energy barriers decide the generation rates of different micro structures.

2:42PM T20.00002 Effect of doping $Ag_ySb_yGe_{50-2y}Te_{50}$ thermoelectric materials with rare earths , E.M. LEVIN, S.L. BUD'KO, K. SCHMIDT-ROHR, Iowa State University and Ames Laboratory US DOE — The $Ag_ySb_yGe_{50-2y}Te_{50}$ system represents some of the most efficient thermoelectrics, the so-called TAGS materials. In order to understand the effect of doping of $Ag_{6.52}Sb_{6.52}Ge_{36.96}Te_{50}$ ("TAGS-85") with rare earth atoms on the Ge and Te sites, $Ag_{6.52}Sb_{6.52}Ge_{36.96-x}R_xTe_{50}$ and $Ag_{6.52}Sb_{6.52}Ge_{36.96}R_xTe_{50-x}$ materials with R = Gd and Dy (rare earth atoms with large magnetic moments) have been studied by measuring X-ray diffraction (XRD) and ^{125}Te nuclear magnetic resonance (NMR) at 300 K, thermopower and resistivity at 300-760 K, and the magnetization at 1.8-350 K and in magnetic field 0-55 kOe. XRD and ^{125}Te NMR show that some rare earth atoms are incorporated into the lattice and enhance the thermopower by ∼10%. At 700 K, this yields a power factor of up to 36 $\mu W \cdot cm^{-1} \cdot K^{-2}$, which is ∼20% higher than in TAGS-85. All materials studied can be considered as degenerate magnetic semiconductors with non-interacting localized magnetic moments formed by rare earth atoms, with a different effect of rare earths on the Ge and Te sites. Reasons for the thermopower enhancement due to doping with rare earths including magnetic and non-magnetic phenomena are discussed.

2:54PM T20.00003 Nanodopant Induced Band Modulations and Electronic Transport Properties in $AgPb_mSbTe_{2+m}$-type Thermoelectric Nanocomposites[1] , YI ZHANG, CHANGFENG CHEN, Physics Department and HiPSEC, University of Nevada, Las Vegas, XUEZHI KE, Department of Physics, East China Normal University, China, JIHUI YANG, Electrochemical Energy Research Lab, GM R&D Center, PAUL KENT, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory — The remarkable performance of many novel thermoelectric materials is attributed to their nanosized inclusions. By extensive first-principles calculations we show the distinct band structure modulation in $AgPb_mSbTe_{2+m}$ (LAST)-type nanocomposites. A band gap widening and conduction band minimum splitting process resulting from the nanodopants is discovered for a series of nanocomposites. Boltzmann transport calculations demonstrate that this process leads to a pronounced change in the high temperature electronic transport. The effects of different substitutional elements and atomistic orderings are discussed. Our results provide new understanding of nanosized doping in thermoelectric materials and narrow gap semiconductors.

3:06PM T20.00004 Strong off-stoichiometry and large Grüneisen parameter in $AgSbTe_2$: a first principles study[1]

SERGEY V. BARABASH, VIDVUDS OZOLINS, University of California, Los Angeles, MICHELE D. NIELSEN, JOSEPH P. HEREMANS, The Ohio State University — We use first-principles density-functional theory calculations to study the dynamical and compositional instabilities in $AgSbTe_2$, and compare the theoretical predictions to the results of an experimental investigation. For pure $AgSbTe_2$, some native defects, particularly Ag vacancies, have negative formation energies for a wide range of experimental conditions, thus forming in high concentrations even at low T. This leads to large deviations from the formal stoichiometry, in agreement with experimental results. Substantial deviations of the $AgSbTe_2$ phase field away from the isoplethal Ag_2Te-Sb_2Te_3 section may be expected, potentially explaining the contradictions in the low-temperature regions of the previously published phase diagrams. We estimate the defect concentrations and the resulting intrinsic doping levels under various experimental conditions. Finally, we demonstrate that the stoichiometric $AgSbTe_2$ is at the verge of a dynamical instability: the energies of acoustic phonons near the L point depend strongly on volume, changing sign at nearly the experimental volume. This leads to an unusually large value of the Grüneisen parameter, in agreement with experiment.

3:18PM T20.00005 Effect of electron correlation on thermoelectric properties of the full-Heusler compound Fe_2VAl[1]

DAT DO, MAL-SOON LEE, S.D. MAHANTI, Department of Physics and Astronomy, Michigan State University — Heusler-type alloys have been studied extensively since they were first discovered by Heusler in 1903. Among those Fe_2VAl became interesting when Nishino *et. al.*[1] suggested that it might be a heavy fermion system. LDA/GGA calculations have shown that Fe_2VAl is a pseudo-gap system with sharp edges in the density of state near the Fermi level. This feature makes it a promising thermoelectric material. Since then electronic properties of nominally pure and doped Fe_2VAl have been studied extensively. However the exact nature of the ground state of this system is still not well understood. Since it contains d-electrons one expects electron correlation effects to be important. We have carried out band structure calculations using GGA+U method with several values of the on-site Coulomb interaction parameter U. Using the obtained band structure, transport coefficients were calculated within Boltzmann approach. Electronic structure and thermoelectric properties were studied for different values of U and compared to available experiments.

3:30PM T20.00006 Phase-separated-induced changes in the transport properties of Heusler compounds for thermoelectric applications

TANJA GRAF, MICHAEL SCHWALL, PETER KLAER, HANS-JOACHIM ELMERS, BENJAMIN BALKE, CLAUDIA FELSER, Johannes Gutenberg-University Mainz, Germany — The solid solution $Co_2Mn_{1-x}Ti_xSn$ shows a phase separation into two Heusler compounds, Co_2MnSn and Co_2TiSn. Only at the edges of the composition range a slight admixture of Mn and Ti to the respective other phase is observed. This phase separation leads to a distinct microstructure which can be altered by the composition of the material. Due to the formed phase and grain boundaries, pronounced changes in the magnetic and electronic properties take place with varying composition. The observed reduction of the thermal lattice conductivity is of particular interest for an optimization of Heusler compounds for thermoelectric applications. Thus, the concept of phase separated materials is transferred to Half-Heusler compounds with an improved thermoelectric performance.

3:42PM T20.00007 Strategies to Bulk Half-Heusler Nanocomposites with Simultaneously Enhanced Power Factor and Reduced Thermal Conductivity[1]

PIERRE FERDINAND POUDEU, The Advanced Materials Research Institute and Department of Chemistry, University of New Orleans, New Orleans LA, 70148, USA — Among promising thermoelectric materials for power generation, half-Heusler (HH) phases with general compositions TNiSn and TCoSb (T = Ti, Zr, Hf) have attracted tremendous attention not only because they involve abundant and environmentally friendly elements, but also due to their combination of large Seebeck coefficients with moderately low electrical resistivities. However, the ability to synthesize HH based materials with decent figures of merit (ZT>1) has been jeopardized by their very large thermal conductivities. Strategies to reduce the thermal conductivity of HH phases focusing on mass fluctuation phonon scattering via solid solution alloying or phonon scattering at grain boundaries and interfaces in HH phases with embedded pre-synthesized nanoparticles have failed to generate materials with high figures of merit due to simultaneous reductions in the power factor. Here, we introduce innovative approaches to revolutionary increases in the figure of merit of HH based materials through simultaneous large enhancement of the power factor and drastic reduction in the thermal conductivity. Our strategy is focused on atomic-scale structural engineering of the HH matrix through the confinement of full-Heusler (FH) inclusion phases on the lattice constant length-scale. Emphasis will be placed on the n-type $Zr_{0.25}Hf_{0.75}Ni_{1+x}Sn_{1-y}Pn_y$ and $Ti_{0.5}Zr_{0.5}Ni_{1+x}Sn_{1-y}Pn_y$ as well as the p-type $Ti_{0.5}Zr_{0.5}Co_{1+x}Pn_{1-y}Sn_y$, (Pn = Sb, Bi) nanocomposites. We will discuss the underlying mechanism for the formation of half-Heusler/full-Heusler (HH/FH) nanocomposites with coherent matrix/inclusion interfaces. The role of synthetic and processing methods; and size, dispersion and mole fraction of the FH inclusions on the thermoelectric performance of bulk HH/FH nanocomposites will be assessed by combining transmission electron microscopy studies with thermal and electronic charge transport data.

4:18PM T20.00008 Thermoelectric Properties of Boron-doped CoSi

BO YU, HUI WANG, Boston College, HONGLI GAO, Zhejiang University, WEISHU LIU, Boston College, XINBING ZHAO, Zhejiang University, GANG CHEN, MIT, ZHIFENG REN, Boston College — Engineering in density of states $D(E)$ has been found effective in improving the transport properties of thermoelectric materials. As one example, intermetallic CoSi, when doped with boron or other suitable elements, exhibits a good combination of high electrical conductivity (σ) and Seebeck coefficients (S) due to possible sharp structures in $D(E)$near Fermi level. However, despite of its high power factor ($S^2\sigma$), the high thermal conductivity (κ) becomes the obstacle for the performance. Here, we present that mechanical alloying and hot press which had been proved successful in many thermoelectric materials, could also reduce the thermal conductivity of boron doped CoSi while keeping its high power factor.

4:30PM T20.00009 The Electrical Contact for Higher Manganese Silicide Thermoelectric Material[1]

XINGHUA SHI, ZAHRA ZAMANIPOUR, DARYOOSH VASHAEE, Oklahoma State University — The Electrical Contact for Higher Manganese Silicide Thermoelectric Material Xinghua Shi, Zahra Zamanipour, Daryoosh Vashaee Several electrical contact materials for Higher Manganese Silicide (HMS) are introduced. HMS is useful thermoelectric material for medium to high temperature applications. We have investigated several materials including Co, Ni, Cr, Ti, Mo, MnSi, MoSi2, and TiSi2 in search of the best contact material to HMS. The low electrical resistivity and reliability of the contact are two important elements to make a high efficient TE device. Moreover, the contact must maintain its chemical, mechanical, thermal, and electrical properties over a broad range of temperature (20C-700C). The investigated elemental metals failed to make reliable contact in terms of mechanical and chemical stability at high temperature. In contrast, the investigated metal silicides showed superior stability over extended operation at high temperature. The thermal stability and strong mechanical bonding of TiSi2 C54 phase and MnSi were specially observed. Their ohmic contact resistance was also within the range of interest over the whole range of temperature (10^{-5}-$10^{-4}\Omega cm^2$).

4:42PM T20.00010 High Thermoelectric Power Factor in $CoSi_{1-x}B_x$ Alloys[1] , HUI SUN, DONALD MORELLI, Michigan State University — $CoSi_{1-x}B_x$ alloys with x ranging from 0 to 0.1 have been prepared by an arc melting and annealing procedure. X-ray diffraction studies suggest the occurrence of minor CoB phase when $x \geq 0.05$. The thermoelectric (TE) properties were measured from 80 to 300K. The samples with $x \leq 0.02$ showed much lower electrical resistivity than CoSi. The Seebeck coefficient was negative for all samples over the investigated temperature range, indicating dominant transport by electrons in this temperature range. A high TE power factor (70 $\mu W/K^2cm$ at room temperature) was obtained in $CoSi_{0.98}B_{0.02}$, which we ascribe to the appropriate tuning of the Fermi level near the pseudogap in the density of states. In optimized samples the dimensionless figure of merit is in excess of 0.13 due to this enhanced power factor. We will also report on our efforts to further increase the figure of merit by thermal conductivity reduction methods.

4:54PM T20.00011 Thermoelectric properties of FeSi and Related Alloys: Evidence for Strong Electron-Phonon Coupling , BRIAN SALES, OLIVIER DELAIRE, MICHAEL MCGUIRE, ANDREW MAY, Oak Ridge National Laboratory — The effects of various transition metal dopants on the electrical and thermal transport properties of $Fe_{1-x}M_xSi$ alloys (M= Co, Ir, Os) are reported. The thermoelectric figure of merit ZT is improved from 0.007 at 60 K for pure FeSi to ZT = 0.08 at 100 K for 4% Ir doping. A comparison of the thermal conductivity data among Os, Ir and Co doped alloys indicates strong electron-phonon coupling in this compound. The common approximation of dividing the total thermal conductivity into electronic and lattice components ($\kappa_{Total} = \kappa_{electronic} + \kappa_{lattice}$) fails spectacularly for these alloys. The effects of nanostructuring on thermoelectric properties of $Fe_{0.96}Ir_{0.04}Si$ alloys are also reported. The thermal conductivity can be lowered by about 50% with little or no effect on the electrical resistivity or Seebeck coefficient. This results in $ZT_{max} = 0.125$ at 100 K, still about a factor of five too low for solid-state refrigeration applications. Research sponsored by the Materials Science and Engineering Division, Office of Basic Energy Sciences, U.S. DOE.

5:06PM T20.00012 Electron-phonon coupling in FeSi thermoelectrics: inelastic neutron scattering and first-principles simulations[1] , OLIVIER DELAIRE, JIE MA, BRIAN SALES, PAUL KENT, MATTHEW STONE, KAROL MARTY, MATTHEW LUCAS, DOUGLAS ABERNATHY, DAVID MANDRUS, ORNL TEAM — FeSi is a promising thermoelectric material for refrigeration applications, with a Seebeck coefficient over 500μV/K at 40K. FeSi is a narrow band-gap semiconductor at low temperature (B20 structure), and undergoes a semiconductor-to-metal transition around room temperature. Using inelastic neutron scattering, phonons were measured on both single crystals and powders as a function of composition and temperature. We report a strong coupling between the phonons and the semiconductor-to-metal transition, upon increasing temperature and carrier concentration. Using first-principles electronic structure calculations and ab-initio molecular dynamics, we show that the band gap and the sharp features around the band edges are strongly affected by the thermal disordering induced by phonon excitations. We also report on the effect of heavy impurities (Ir, Os) on the phonons.

5:18PM T20.00013 Carrier concentration optimization and electrical and thermal transport properties of the defect manganese silicide $MnSi_\delta (\delta \sim 1.74)$* , V. PONNAMBALAM, GLORIA LEHR, D.T. MORELLI, Dept. of Chemical Engineering and Materials Science, Michigan State University — Defect manganese silicide $MnSi_\delta$ ($\delta \sim 1.74$) is known for unusually low thermal conductivity. In addition, it also exhibits promising thermoelectric properties. We have substituted $MnSi_\delta$ with various elements to optimize the carrier concentration. Electrical and thermal transport properties of the resulting alloys have been studied over a temperature (T) range of 80-300 K. Both resistivity and Seebeck coefficient vary with substitution. Hall measurements suggest that the carrier concentration indeed varies in these alloys. Interestingly, thermal conductivity either remains constant or weakly increases with T in the temperature range 80- 300 K, eventually reaching values $\sim$ 3 W/m K at 300 K. The results will be presented and discussed. *This work was supported as part of the Center for Revolutionary Materials for Solid State Energy Conversion, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number DE-SC0001054.

Wednesday, March 23, 2011 2:30PM - 5:30PM –
Session T21 DCOMP: Classical and Quantum Monte Carlo D161

2:30PM T21.00001 Steps beyond the fixed-phase approximation in diffusion Monte Carlo[1] , FERNANDO REBOREDO, Oak Ridge National Laboratory — The self-healing diffusion Monte Carlo algorithm (SHDMC) [Reboredo, Hood and Kent, Phys. Rev. B **79**, 195117 (2009); Reboredo, *ibid.* **80**, 125110 (2009)] is extended to study the ground and excited states of magnetic and periodic systems. The method converges to exact eigenstates as the statistical data collected increases if the wave function is sufficiently flexible. A recursive optimization algorithm is derived from the time evolution of the mixed probability density, which is given by an ensemble of electronic configurations (walkers) with complex weight. This complex weight allows the amplitude of the fixed-node wave function to move away from the trial wave function phase. This novel approach is both a generalization of SHDMC and the fixed-phase approximation [Ortiz, Ceperley and Martin, Phys Rev. Lett. **71**, 2777 (1993)]. The algorithm is demonstrated to converge to nearly exact solutions of model systems with periodic boundary conditions or applied magnetic fields for the ground state and low energy excitations. The computational cost is proportional to the number of independent degrees of freedom of the phase.

2:42PM T21.00002 Understanding framework flexibility of periodic structures by Monte Carlo simulation , AN GHYSELS, University of California - Berkeley, VERONIQUE VAN SPEYBROECK, MICHEL WAROQUIER, Center for Molecular Modeling, BEREND SMIT, University of California - Berkeley — Metal Organic Frameworks (MOFs) are a new class of porous materials synthesized from metal clusters connected by organic linkers. Most crystalline solids are fairly rigid, and undergo small changes in volume when stress is applied. Although most MOFs are rigid, some have an unexpectedly high flexibility, and swell under pressure, temperature or adsorption changes. A well-known structure showing volume changes of over 50% is MIL-53. A better understanding of the process will allow to design materials with improved properties for carbon capture, i.e. the framework captures CO2 from fuel gasses. In this presentation, we explore framework flexibility effects induced by gas adsorption using Monte Carlo techniques. For instance, when MIL-53 is brought into contact with a gas at increasing pressure, the framework's pores constrict, while at even higher pressures, the pores return to their original geometry. To study this phenomenon, it is essential to incorporate framework flexibility into the Monte Carlo free energy calculation.

2:54PM T21.00003 Quantum Monte Carlo studies of solvated systems , KATHLEEN SCHWARZ, Cornell University, Department of Chemistry, KENDRA LETCHWORTH WEAVER, T.A. ARIAS, Cornell University, Department of Physics, RICHARD G. HENNIG, Cornell University, Department of Materials Science and Engineering — Solvation qualitatively alters the energetics of diverse processes from protein folding to reactions on catalytic surfaces. An explicit description of the solvent in quantum-mechanical calculations requires both a large number of electrons and exploration of a large number of configurations in the phase space of the solvent. These problems can be circumvented by including the effects of solvent through a rigorous classical density-functional description of the liquid environment, thereby yielding free energies and thermodynamic averages directly, while eliminating the need for explicit consideration of the solvent electrons. We have implemented and tested this approach within the CASINO Quantum Monte Carlo code. Our method is suitable for calculations in any basis within CASINO, including b-spline and plane wave trial wavefunctions, and is equally applicable to molecules, surfaces, and crystals. For our preliminary test calculations, we use a simplified description of the solvent in terms of an isodensity continuum dielectric solvation approach, though the method is fully compatible with more reliable descriptions of the solvent we shall employ in the future.

3:06PM T21.00004 Fast evaluation of multideterminant wavefunctions in quantum Monte Carlo[1] , MIGUEL A. MORALES, LLNL, BRYAN K. CLARK, Princeton, JEREMY MCMINIS, JEONGNIM KIM, UIUC, GUSTAVO SCUSERIA, Rice Univ. — Quantum Monte Carlo (QMC) methods such as variational and diffusion Monte Carlo depend heavily on the quality of the trial wave function. Although Slater-Jastrow wave functions are the most commonly used variational ansatz, more sophisticated wave functions are critical to ascertaining new physics. One such wave function is the multislater- Jastrow wave function which consists of a Jastrow function multiplied by the sum of slater determinants. In this talk we describe a method for working with these wave functions in QMC codes that is easy to implement, efficient, and easily parallelized. The algorithm computes the multi determinant ratios of a series of particle hole excitations in time $O(n^2)+O(n_s n)+O(n_e)$ where n, n_s and n_e are the number of particles, single particle excitations, and total number of excitations, respectively. This is accomplished by producing a (relatively) compact table that contains all the information required to read off the excitation ratios. In addition we describe how to compute the gradients and laplacians of these multi determinant terms.

[1]This work was performed under the auspices of: the US DOE by LLNL under Contract DE-AC52-07NA27344, the US DOE under Contract DOE-DE-FG05-08OR23336 and by NSF under No.0904572.

3:18PM T21.00005 ABSTRACT WITHDRAWN –

3:30PM T21.00006 Wave Function Optimization in QMCPACK[1] , JEREMY MCMINIS, University of Illinois and NCSA, MIGUEL MORALES, LLNL, JEONGNIM KIM, DAVID CEPERLEY, University of Illinois and NCSA — Wave function optimization is essential for both the accuracy and efficiency of diffusion, reptation, and variational quantum Monte Carlo (QMC). In this talk we outline the wave function optimization strategy used in the QMC software package QMCPACK developed at the University of Illinois. We use an extension of the linear optimization method originally developed by Umrigar et. al.[1] to optimize parameters in Slater-Jastrow, multi-determinant Slater-Jastrow, and Backflow-Jastrow trial wave functions. The efficiency and accuracy of this method is presented for bulk Silicon, Jellium, and the Nitrogen dimer.

3:42PM T21.00007 Testing of He-core pseudopotentials for 3d elements in quantum Monte Carlo , MINYI ZHU, LUBOS MITAS, North Carolina State University — We construct He-core pseudopotentials for several elements in the 3rd row such as for V, Cr, Mn, Fe and Zn, with the goal of using these in high-accuracy quantum Monte Carlo (QMC) calculations. We study the accuracy of constructed pseudopotentials on MnO molecular states with different spin polarizations. We compare these results also with Density Functional Theory and Hartree-Fock approaches since we previously found noticeable differences between Ne-core pseudopotential and relativistic all-electron calculations in high-spin vs. low-spin state comparisons. The result indicates that these discrepancies stem from method biases related to the presence of core states, as we conjectured earlier. Additionally, we also discuss the computational cost of the He-core pseudopotentials in QMC calculations.

3:54PM T21.00008 Spin-orbit interaction in quantum Monte Carlo , LUBOS MITAS, North Carolina State University, RENE DERIAN, Institute of Physics, Slovak Academy of Sciences, SHI GUO, North Carolina State University — For spinless Hamiltonians (ie, no explicit spin operators), real space quantum Monte Carlo (QMC) methods such as variational and fixed-node diffusion Monte Carlo are well established. In these cases the electron spins and their components commute with the Hamiltonian and therefore are conserved quantities. This implies that spins can be fixed as given by the symmetry of a considered state and one solves only for the spatial part of the corresponding wave function. Indeed, this is a common practice in electronic structure QMC and also in most quantum chemical calculations. However, many systems require treating spins as quantum dynamical variables. We will present progress of our studies in this direction both in variational and diffusion Monte Carlo for heavy atoms with spin-orbit operators. One possibility is to use possibilities offered by various formulations of Hubbard-Stratonovitch transformation as realized in QMC for nuclear systems. We explore also other options both in variational and diffusion Monte Carlo framework. In particular, we define new representation for spinors which enable to formulate the diffusion Monte Carlo along the lines of fixed-phase approximation. We compare the results for the considered approaches also from the point of computational efficiency.

4:06PM T21.00009 A quantum Monte Carlo study of molecular systems with heavy elements , SHI GUO, KEVIN RASCH, LUBOS MITAS, North Carolina State University, ENRIQUE BATISTA, RICHARD MARTIN, Los Alamos National laboratory — We use quantum Monte Carlo method to study the bis-cyclopentadienyl Hafnium dichloride molecule Cp_2HfCl_2. There are two Cl dissociation channels for Cp_2HfCl_2: one is to break into neutral fragments, the other one into charged fragments. We employ the Stuttgart pseudopotential to represent the Hf atom and optimized Slater-Jastrow trial wave function at the variational Monte Carlo level. The calculations of the dissociation energies are carried out by the fixed-node diffusion Monte Carlo. We observe that for the heavy elements the low valence density in the core region can generate large energy fluctuations and we address this by improvements of the correlation factor. Alternatively, we construct Hf pseudopotentials with different core sizes and test for the accuracy of such pseudopotential Hamiltonians. We compare the QMC results also with DFT calculations with hybrid functionals.

4:18PM T21.00010 Fixed-Node Errors in Diffusion Monte Carlo Study of Li Molecular and Solid Systems , KEVIN RASCH, LUBOS MITAS, North Carolina State University — We study the fixed-node bias in the Diffusion Monte Carlo calculations of Li systems such as Li dimer, Li clusters, and Li body-centered cubic crystal at the equilibrium lattice constant. The calculations include both core and valence electrons in order to avoid any possible impact by pseudopotentials. We examine the fixed-node errors for different types of orbitals and wave-function forms. We use estimations of exact total energies from alternative approaches such as correlated basis set methods or from experiment. The results suggest that for Li systems it is possible to construct accurate wave-functions which recover correlation energy at 97-99 % of correlation energy in the full many-body framework.

4:30PM T21.00011 Comparison of the Angular Dependence of Monte Carlo Particle Transport Modeling Software , JEFF CHANCELLOR, National Space Biomedical Research Institute, STEPHEN GUETERSLOH, Texas A&M University — Modeling nuclear interactions is relevant to cancer radiotherapy, space mission dosimetry and the use of heavy ion research beams. In heavy ion radiotherapy, fragmentation of the primary ions has the unwanted effect of reducing dose localization, contributing to a non-negligible dose outside the volume of tissue being treated. Fragmentation in spaceship walls, hardware and human tissue can lead to large uncertainties in estimates of radiation risk inside the crew habitat. Radiation protection mandates very conservative dose estimations, and reduction of uncertainties is critical to avoid limitations on allowed mission duration and maximize shielding design. Though fragment production as a function of scattering angle has not been well characterized, experimental simulation with Monte Carlo particle transport models have shown good agreement with data obtained from on-axis detectors with large acceptance angles. However, agreement worsens with decreasing acceptance angle, attributable in part to incorrect transverse momentum assumptions in the models. We will show there is an unacceptable angular discrepancy in modeling off-axis fragments produced by inelastic nuclear interaction of the primary ion. The results will be compared to published measurements of 400 MeV/nucleon carbon beams interacting in C, CH2, Al, Cu, Sn, and Pb targets.

4:42PM T21.00012 A Quantum Monte Carlo study of Hydrogen Adsorption on Carbon and Transition Metal Systems[1] , TODD D. BEAUDET, University of Illinois at Urbana-Champaign, Presently U. S. Army Research Laboratory, JEONGNIM KIM, RICHARD M. MARTIN, University of Illinois at Urbana-Champaign — We present a quantum Monte Carlo study of many molecular structures of Ti-ethylene with up to 5 H_2 molecules. These structures have been of recent interest due to energetics favorable for reversibly storing hydrogen.[2] Diffusion Monte Carlo is employed with the fixed node approximation and pseudopotentials that have been tested for H_2 adsorbed on benzene and calculations on TiH_2 molecules.[3] Many low energy configurations were studied by calculation of ground and excited states energy surfaces. The formation energies are comparable to other work[4] and indicate that at least 3 hydrogen molecules can be adsorbed with energies in the range considered relevant for practical hydrogen storage.

4:54PM T21.00013 Release-Node quantum Monte Carlo studies for molecules[1] , NORM TUBMAN, Northwestern University, JONATHAN DUBOIS, RANDOLPH HOOD, BERNI ALDER, Lawrence Livermore National Lab — Release-Node quantum Monte Carlo (RN-QMC) is a method that calculates unbiased ground-state energies of fermionic systems. However, while RN-QMC has been successfully applied to the homogeneous electron gas with more than one hundred electrons, obtaining converged results for molecular systems has proven to be problematic for all but the smallest systems. A promising route to extending the method's success to a wider class of physically interesting Hamiltonians lies in the application of projection techniques such as Maximum Entropy (MaxEnt) which, in principle, allows for extrapolation to the converged ground-state energy. Direct application of MaxEnt to higher Z elements is, however, not entirely straightforward. We propose strategies for optimizing MaxEnt analysis of short time RN-QMC data and demonstrate their effectiveness in obtaining ground state energies for the first row dimers. Attention is given to the determination of statistical errors in the resulting extrapolations as well as an attempt to characterize the minimum decay time required for unbiased results.

5:06PM T21.00014 Melting transition of Lennard-Jones particles in two dimensions , KEOLA WIERSCHEM, Nanyang Technological University, EFSTRATIOS MANOUSAKIS, Florida State University and University of Athens — The melting transition of Lennard-Jones particles in two dimensions is investigated along a single isochore using classical Monte Carlo methods. A finite-size scaling analysis is conducted for the second moments of the translational and bond-orientational order parameters, and their critical exponents are determined. The behavior of these exponents is consistent with the predictions of the two-stage Kosterlitz-Thouless-Halperin-Nelson-Young (KTHNY) theory of melting in two dimensions. The translational and bond-orientational correlation lengths are also studied, with evidence of a divergence in the bond-orientational correlation length while the translational correlation length remains finite. This provides further support for the KTHNY melting scenario, although we cannot rule out possible phase co-existence due to a first order phase transition.

5:18PM T21.00015 Micro-canonical Monte Carlo study of spin wave excitations in 2D XY model[1] , SMITA OTA[2], Institute of Mathematics and Applications, Bhubaneswar 751022 — We have carried out micro-canonical Monte Carlo simulation of 2D XY model in a 30x30 lattice using periodic boundary conditions. In this micro-canonical Monte Carlo simulation, the energy is the input quantity and the temperature of the system is obtained from the simulations. Spin waves and bound vortex excitations dominate in the 2D XY model below the topological vortex unbinding transition. We have studied the spin waves from the energy distribution of an individual spin in the 2D XY model. The most probable spin wave energy corresponds to the maximum in the energy distribution. The probability of the spin wave excitation is found to be reduce exponentially, by an order of magnitude as the temperature increases to the topological transition.

[2]Oral presentation

Wednesday, March 23, 2011 2:30PM - 5:30PM –
Session T22 DCMP: Correlated Electrons and Magnetic Phase Transitions D163

2:30PM T22.00001 Quantum spin metal state on a decorated honeycomb lattice , KONSTANTIN TIKHONOV, Texas A&M Univ., MIKHAIL FEIGEL'MAN, Landau ITP — We present a modification of exactly solvable spin-(1/2) Kitaev model on the decorated honeycomb lattice, with a ground state of "spin metal" type. The model is diagonalized in terms of Majorana fermions; the latter form a 2D gapless state with a Fermi-circle those size depends on the ratio of exchange couplings. Low-temperature heat capacity $C(T)$ and dynamic spin susceptibility $\chi(\omega, T)$ are calculated in the case of small Fermi-circle. Whereas $C(T) \sim T$ at low temperatures as it is expected for a Fermi-liquid, spin excitations are gapful and $\chi(\omega, T)$ demonstrate unusual behavior with a power-law peak near the resonance frequency. The corresponding exponent as well as the peak shape are calculated.

2:42PM T22.00002 Quantum Order by Disorder Driven Phase Reconstruction at Itinerant Electron Quantum Critical Points , UNA KARAHASANOVIC, ANDREW GREEN, University of St Andrews, GARETH CONDUIT, Weizmann Institute of Science — Phase reconstruction at itinerant electron quantum critical points is driven by quantum fluctuations lowering the energy of certain deformations of the Fermi surface through second and higher order perturbation theory, i.e. quantum order by disorder. This approach was previously shown to predict a fluctuation-driven spatially modulated phase near to the ferromagnet to paramagnet quantum critical point [1]; a phase that had previously been predicted from diagrammatic evaluation of non-analytic corrections to Moriya-Hertz-Millis theory. We extend our analysis to include several other phases which may be stabilized at the ferromagnetic quantum critical point, including nematic order and superconductivity. The itinerant quantum critical point is unstable to the formation of multiple phases.

2:54PM T22.00003 Fixed Spin Moment Study of Quantum Critical Fe_3Mo_3N , BRIAN NEAL, WARREN E. PICKETT, University of California Davis — Quantum critical behavior and weak magnetism occurs in a handful of intermetallic transition metal compounds, with a recent example being Fe_3Mo_3N with the geometrically frustrated *stella quadrangula* lattice. Neutron scattering reveals antiferromagnetic ordering, but a 14 T magnetic field induces a ferromagnetic state as does substitution of 5% Co on the Fe site [1]. We present the energetics of a transition between these states with density functional based fixed spin moment studies. Our (mean field) ground state occurs with nearly equal Fe1 and Fe2 moments of 1.8 μ_B. As the total moment is reduced, a crossover occurs until at zero total moment the Fe1 moment is -1.1 μ_B (antialigned with the strong Fe2 moment). We use these results to construct scenarios for discussing the observations.

3:06PM T22.00004 Stability of Quantum Critical Points in the Presence of Competing Orders , JIAN-HUANG SHE, JAN ZAANEN, Leiden University, ALAN BISHOP, ALEXANDER BALATSKY, Los Alamos National Laboratory — We investigate the stability of Quantum Critical Points (QCPs) in the presence of two competing phases. These phases near QCPs are assumed to be either classical or quantum and assumed to repulsively interact via square- square interaction. We find that for any dynamical exponents and for any dimensionality strong enough interaction renders QCPs unstable, and drive transitions to become first order. We propose that this instability and the onset of first order transition leads to spatially inhomogeneous states in practical materials near putative QCPs.

3:18PM T22.00005 Field-Induced Orbital Antiferromagnetism in Mott Insulators , K.A. AL-HASSANIEH, C.D. BATISTA, Los Alamos National Laboratory, G. ORTIZ, Indiana University, Bloomington, L.N. BULAEVSKII, Los Alamos National Laboratory — We report on a new electromagnetic phenomenon that emerges in Mott insulators. The phenomenon manifests as antiferromagnetic ordering due to orbital electric currents which are spontaneously generated from the coupling between spin currents and an external homogenous magnetic field. This novel spin-charge-current effect provides the mechanism to measure the so-far elusive spin currents by means of unpolarized neutron scattering, nuclear magnetic resonance or muon spectroscopy. We illustrate this mechanism by solving a half-filled Hubbard model on a frustrated ladder.

3:30PM T22.00006 Global phase diagram of heavy fermions and the Kondo destroyed quantum critical points of Anderson models with a transverse field , JEDEDIAH PIXLEY, Rice University, STEFAN KIRCHNER, Max Planck Institute for the physics of complex systems, QIMIAO SI, Rice University — Recent studies in quantum critical heavy fermion metals have pointed towards a global phase diagram [1]. The zero-temperature phase diagram involves a combination of phases, featuring Kondo screening/breakdown and antiferromagnetic order/disorder as the quantum fluctuations of the local moments are tuned relative to their effective interaction with the spins of the conduction electrons. In the case of Ising-anisotropic Kondo lattice systems, the fluctuations among the local moments can be generated by coupling them to a transverse magnetic field. With these effects in mind, we study the Kondo-destroyed quantum critical behavior of the Anderson impurity model in the presence of a bosonic bath or a transverse field. We extend our recent studies of the low-temperature quantum critical behavior [2,3] based on the continuous time quantum Monte Carlo, and obtain the dynamical scaling functions of the local spin susceptibility and single-electron Green's function.

3:42PM T22.00007 Electron paring instabilities in 8-site Betts lattice: exact result[1] , KUN FANG, GAYANATH FERNANDO, University of Connecticut, ARMEN KOCHARIAN, California State University, Los Angeles — We use numerical methods (exact diagonalization and Lanczos method) to study single-orbital and multi-orbital Hubbard models (off half filling). The whole lattice is divided into identical 8-site square clusters immersed in a thermal bath. The electron pairing instabilities, order parameters and quantum critical points are evaluated by monitoring the charge and spin gaps in a wide range of parameters including the on-site interaction U. Calculations show level crossing behaviors at zero and finite temperature. The corresponding pairing instabilities are remarkably similar to electronic inhomogeneities observed in correlated systems such as the high temperature superconductors and Fe pnictides. The next nearest hopping is also introduced. We find that it can shift quantum crossover point and gap magnitude, but for reasonable hopping amplitudes, it will not eliminate characteristics of electron paring instabilities.

3:54PM T22.00008 Functional RG for the Single Impurity Anderson Model , MICHAEL KINZA, RWTH Aachen University, CARSTEN HONERKAMP, RWTH Aachen Universtity, JUTTA ORTLOFF, Wuerzburg University — We present a functional Renormalization Group (fRG) approach to the Single Impurity Anderson Model at finite temperatures. Starting with the exact spectral function and interaction vertex of a small system ("core") containing a correlated site, we switch on the hybridization with a non-interacting bath in the RG-flow and calculate spectra of the correlated site. Different truncations of the RG-flow-equations and choices of the core are compared and discussed. Furthermore we calculate the linear conductance as function of temperature and interaction strength.

4:06PM T22.00009 Mesoscopic Anderson Box: Connecting Weak to Strong Coupling , DONG E. LIU, Duke University, SEBASTIEN BURDIN, Univ. of Bordeaux I, France, HAROLD U. BARANGER, Duke University, DENIS ULLMO, Univ. Paris Sud, France — Both the weakly coupled and strong coupling Anderson impurity problem are characterized by a Fermi-liquid theory with weakly interacting quasiparticles. In an Anderson box, mesoscopic fluctuations of the effective single particle properties will be large. We study how the statistical fluctuations in these two problems are connected. We use random matrix theory and the slave boson mean field approximation (SBMF, at low temperature) to address this question, obtaining the following results. First, for a resonant level model such as results from the SBMF approximation, we find the joint distribution of energy levels with and without the resonant level present. Second, if only energy levels within the Kondo resonance are considered, the distribution of perturbed levels collapse to one universal form for both GOE and GUE for all values of the coupling V. Finally, a purely Fermi liquid method is developed for calculating the perturbed levels within the Kondo resonance. Comparing the levels that result to those of the SBMF, we find remarkable agreement.

4:18PM T22.00010 Superconducting pairing of interacting electrons: implications from the two-impurity Anderson model[1] , LIJUN ZHU, JIAN-XIN ZHU, Theoretical Division and Center for Nonlinear Studies, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA — We study the non-local superconducting pairing of two interacting Anderson impurities, which has an instability near the quantum critical point from the competition between the Kondo effect and an antiferromagnetic inter-impurity spin exchange interaction. As revealed by the dynamics over the whole energy range, the superconducting pairing fluctuations acquire considerable strength from an energy scale much higher than the characteristic spin fluctuation scale while the low energy behaviors follow those of the staggered spin susceptibility. We argue that the superconducting pairing might not need the spin fluctuations as the glue, but rather originated from the effective Coulomb interaction. On the other hand, critical spin fluctuations in the vicinity of quantum criticality are also crucial to a superconducting pairing instability, by preventing a Fermi liquid fixed point being reached to keep the superconducting pairing fluctuations finite at low energies. A superconducting order, to reduce the accumulated entropy carried by the critical degrees of freedom, may arise favorably from this instability.

[1]This work is supported by the U.S. DOE through the LANL/LDRD program.

4:30PM T22.00011 Pressure Tuning of the Shastry-Sutherland Quantum Phase Transition , S. HARAVIFARD, Argonne National Laboratory, University of Chicago, A. BANERJEE, T.F. ROSENBAUM, University of Chicago, G. SRAJER, J.C. LANG, Y. FENG, Argonne National Laboratory, B.D. GAULIN, H.A. DABKOWSKA, McMaster University — SrCu2(BO3)2 is a quasi-2D quantum spin system known to possess a collective singlet ground state. It serves as an experimental realization of the Shastry-Sutherland model for interacting S=1/2 dimers. The ratio of the intra and inter-dimer exchange in this compound is close to a quantum critical point, where the ground state transforms from a gapped, non-magnetic state to a gapless long-range ordered antiferromagnetic state as a function of the ratio of the strength of the magnetic interactions. We use synchrotron x-ray diffraction in a diamond anvil cell to investigate the pressure-driven quantum phase transition in high-quality single crystals of SrCu2(BO3). We will present the evolution of both the magnetic and structural properties up to pressures of 5 GPa.

4:42PM T22.00012 Quantum phase transitions in generalized J-Q models , ARNAB SEN, ANDERS SANDVIK, Boston University — The "J-Q" model is an extension of the Heisenberg model which contains multi-spin interactions that suppress Néel order and lead to a valence-bond-solid (VBS) ground state. It is free from quantum Monte Carlo (QMC) sign problems. There is now good evidence from QMC studies for a continuous Néel–VBS transition with non-trivial features like a large anomalous exponent η and an emergent U(1) VBS symmetry at the quantum-critical point in this model. We study various generalizations of the J-Q model, with both SU(2) and U(1) symmetric interactions, to further elucidate unusual aspects of the Néel-VBS transition. In the SU(2) case, we construct a model which stabilizes a staggered VBS instead of the columnar pattern obtained in previous studies. This type of VBS does not harbor an emergent U(1) symmetry near the transition. We find that the transition is strongly first-order, unlike in the original J-Q model. This illustrates the importance of the emergent U(1) symmetry for the possibly exotic transition in the standard J-Q model. We also investigate a new U(1)-symmetric generalization of the J-Q model to explore such unconventional transitions in the easy plane case.

4:54PM T22.00013 Criticality of compact and noncompact $(1+1)D$ quantum dissipative Z_4-models , EINAR STIANSEN, IVER SPERSTAD, ASLE SUDBO, Norwegian University of Science and Technology — We study two versions of a $(1+1)D$ Z_4-symmetric model with Ohmic bond dissipation. In one version the phase variable is restricted to the interval $[0, 2\pi\rangle$, while the domain is unrestricted in the other. The compact model features a completely ordered phase with a broken Z_4-symmetry and a disordered phase, separated by a critical line. The non-compact model features three phases. In addition to the two phases exhibited by the compact model, there is also an intermediate phase, characterized by isotropic power-law phase correlations. We calculate the dynamical critical exponent z along the critical lines of both models to see if the compactness of the variable is relevant to the critical scaling between space and imaginary time. We find $z \approx 1$ for the single phase transition in the compact model as well as for both transitions in the non- compact model.

5:06PM T22.00014 Kondo and spin-Peierls phases and Berry phase effects in Heisenberg-Kondo chain[1] , PALLAB GOSWAMI, QIMIAO SI, Rice University — Recent theoretical and experimental results on heavy fermion systems have motivated a global phase diagram, as a function of the Kondo coupling and the strength of quantum fluctuations of the local moments. Correspondingly, there has been growing interest in understanding the phase transition from a small Fermi surface antiferromagnet to large or small Fermi surface paramagnets with or without Kondo screening respectively. Because a perturbative nonlinear sigma model analysis only accesses the small Fermi surface antiferromagnetic phase, the transition into the paramagnetic phases must involve non-perturbative effects. We consider here the effect of the instanton configurations of the nonlinear sigma model and the associated Berry's phase for the Kondo singlet formation, and for concreteness focus on the one dimensional Heisenberg Kondo lattice model. Using semiclassical nonlinear sigma model and bosonization techniques both at and away from half-filling, we demonstrate how the competition between the Kondo singlet and spin Peierls phases are manifested through the effects of such a Berry phase. Based on these results we comment upon similar effects that may be realized in higher dimensional Kondo lattice models.

[1]NSF

5:18PM T22.00015 Complex Critical Exponents in Diluted Systems of Quantum Rotors[1] , RAFAEL FERNANDES, JÖRG SCHMALIAN, Ames Laboratory and Iowa State University — In this work, we investigate the effects of the Berry phase $2\pi\rho$ on the critical properties of XY quantum-rotors that undergo a percolation transition. This model describes a variety of randomly-diluted quantum systems, such as interacting bosons coupled to a particle reservoir, quantum planar antiferromagnets under a perpendicular magnetic field, and Josephson-junction arrays with an external bias-voltage. Focusing on the quantum critical point at the percolation threshold, we find that, for rational ρ, one recovers the power-law behavior with the same critical exponents as in the case with no Berry phase. However, for irrational ρ, the low-energy excitations change completely and are given by emergent spinless fermions with fractal spectrum. As a result, critical properties that cannot be described by the usual Ginzburg-Landau-Wilson theory of phase transitions emerge, such as complex critical exponents, log-periodic oscillations, and dynamically-broken scale invariance.

Session T23 DMP: Focus Session: Search for New Superconductors III: Reduced Dimensionality

D165

2:30PM T23.00001 Understanding anisotropy to develop superconducting design principles , FILIP RONNING, Los Alamos National Laboratory — Superconductivity is often found in families of compounds which share a common building block (e.g. CuO_2 planes in cuprates, FeAs planes in pnictides, and $CeIn_3$ planes in a subset of heavy fermion superconductors). This fact provides a rationale to search for new superconductors, and subsequently a means to try and understand the origin of superconductivity by examining trends in superconducting behavior within a family of superconductors which hopefully transcends any one particular family of compounds. The notion of common building blocks has led us to the recent discovery of superconductivity at 2.1 K in $CePt_2In_7$, coexisting magnetism and superconductivity in $PuCoIn_5$, and a correlated paramagnet in $PuPt_2In_7$. I will discuss our attempts to understand the role of reduced dimensionality and increased bandwidth within the "115" class of heavy fermion superconductors by examining trends in the charge and spin degrees of freedom that are correlated with superconductivity. In this way, we aim to lay the foundation for a modern, microscopic version of Matthias' rules for unconventional superconductivity from which superconducting design principles can be developed. In collaboration with Eric Bauer, Jianxin Zhu, Paul Tobash, Moaz Altarawneh, HB Rhee, Hironori Sakai, Kris Gofryk, Neil Harrison, and Joe Thompson.

3:06PM T23.00002 $PuCoIn_5$: A New Magnetic Superconductor , ERIC D. BAUER, J.N. MITCHELL, P.H. TOBASH, F. RONNING, J.-X. ZHU, B.L. SCOTT, J.D. THOMPSON, Los Alamos National Laboratory — There is renewed interest in actinide research following the discovery of superconductivity at T_c=18.5 K in $PuCoGa_5$ and at T_c=8.7 K in $PuRhGa_5$. These materials appear to be unconventional superconductors with a moderate effective mass enhancement and are similar to the more well characterized $CeMIn_5$ (M=Co, Rh, Ir) superconductors. We have discovered a new member of this "115" family of superconductors, $PuCoIn_5$. This material superconducts at T_c=2.7 K and exhibits another phase transition at T_N=15 K, likely due to antiferromagnetic order. The Sommerfeld coefficient γ = 200 mJ/mol K^2 and the large initial slope of the upper critical field indicate a large enhancement of the effective mass. The physical properties of $PuCoIn_5$ will be discussed.

3:18PM T23.00003 Search for Superconductivity in Carbon Nanotubes Doped by Boron Ion Implantation , NICHOLAS CORNELL, ALEX KUTSENOV, AUSTIN HOWARD, NATHANIEL MAYO, EDUARD GALSTAYAN, WEI KAN CHU, HERBERT FREYHARDT, ANVAR ZAKHIDOV, XUEMEI WANG, UNIVERSITY OF TEXAS AT DALLAS TEAM, UNIVERSITY OF HOUSTON TEAM — The boron doping of single wall carbon nanotubes(CNT) by laser ablation synthesis has been reported to create superconducting B-CNTs with Tc's ranging from 12-19 Kelvin, depending on CNT inter-tube connection strength. We attempt to create boron doped multiwall CNT by ion implantation doping. Ion doping of boron(B) was performed at 60keV and 20keV, and low temperature transport combined with SQUID and ESR/LFMA was used in searching for SC. We have found that R(T) strongly depends on the metallic contact geometry. With thin film contacts on CNT sheets the R(T) shows no SC signatures, while when an Ag or Au paste penetrates the highly porous network of B doped multiwall CNT then R(T) drops and curvature changes are observed resembling SC transitions with Tc depending on B concentration and metallic electrode distances. We discuss these results in terms of possible SC in hybride "metal-CNT" system in which metal was predicted to supress phase fluctuation in one dimensional CNT network [1].

[1] Erez Berg, Dror Orgad, and Steven A. Kivelson, Phys. Rev. B 78, 094509(2008)

3:30PM T23.00004 Low Field Microwave Absorption Studies of Carbon Nanotubes Doped by Chemical and Ion Implantation Techniques , AUSTIN HOWARD, ALEXANDER KUZNETSOV, NICHOLAS CORNELL, MYRON SALAMON, The University of Texas at Dallas, EDUARD GALSTAYAN, WEI KAN CHU, HERBERT FREYHARDT, The University of Houston, RAY BAUGHMAN, The University of Texas at Dallas, JUNJI HARUYAMA, JASON REPPERT, APPARAO RAO, Clemson University, ANVAR ZAKHIDOV, The University of Texas at Dallas — The motivation of this study is to develop a highly sensitive method of microwave absorption in low magnetic fields (LFMA), combined with SQUID magnetometry and resistivity, for searching for superconducting phases in in-situ doped nanomaterials; either chemically (by alkali metals or metalloids) or through Boron ion implantation. These methods have been applied to both MWNTs grown by CVD, as well as SWNTs which have been separated into metallic and semiconducting chiralities. Regardless of the doping technique or element, we have found a much higher rate of doping in the semiconducting SWNTs. Additionally, in the Boron doped SWNTs, we see two transitions at $\sim$8 K and $\sim$30 K, but the nature of the transition is not clear at the moment: it depends on the type of measurement. While SQUID and resistivity indicate a superconducting type transition, LFMA/ESR reveals that there is a clear magnetic transition at 30 K. Resolution of these differing results will be discussed.

3:42PM T23.00005 Electric Field Induced Superconductivity in Layered Materials , J.T. YE, Department of Applied Physics, The University of Tokyo, M.F. CRACIUN, S. RUSSO, Centre for Graphene Science, University of Exeter, M.F. MORPURGO, DPMC and GAP, Université de Genéve, Y. KASAHARA, H.T. YUAN, H. SHIMOTANI, Y. IWASA, Department of Applied Physics, The University of Tokyo — Using electric double layer (EDL) gating, large amount of carriers can be accumulated on a broad range of materials, which provides new opportunities in effectively manipulating their electronic properties in complementary with the chemical doping. In searching for novel transport phenomena, layered materials are advantageous because atomically flat surface can be easily fabricated using the graphene techniques. We used layered material: ZrNCl and graphite to act as the channel of EDL transistors. For both ZrNCl and graphene, we achieved high carrier density up to 10^{14} cm^{-2}, electrostatically. For graphene, we studied the high carrier density transport for graphene of 1-3 layers. Transport properties at the high carrier density exhibit clear layer dependence governed by the intrinsic band structures of graphene and its multi-layers. For ZrNCl EDL transistor, we observed metallic states at gate voltage higher than 3.5 V followed by gate-induced superconductivity after metal-insulator transition when the transistor was cooled down to about 15 K.

3:54PM T23.00006 Electric Double Layer Charging on Graphene[1] , FENG CHEN, BING LV, YUYI XUE, C.W. CHU[2], Dept. of Physics and Texas Center for Superconductivity, University of Houston, Houston, TX 77204-5002, HOWARD WANG, Dept. of Mechanical Engineering, Binghamton University, Binghamton, NY 13902-6000 — Electric Double Layer (EDL) charging as a new charging method has attracted wide interests recently. We have employed this method to graphene and obtained an estimated surface charge density of 4×10^{15} electrons/cm^2. The resistance dropped significantly upon charging and the physical properties under various charging conditions were studied. We will present these along with results of the EDL charging on other superconducting candidates.

4:06PM T23.00007 Search for new superconductors in the La-Si-C system[1] , JOSE DE LA VENTA, ALI C. BASARAN, University of California, San Diego, TED GRANT, ANTONIO JEFFERSON S. MACHADO, ZACHARY FISK, University of California, Irvine, IVAN K. SCHULLER, University of California, San Diego — We have searched for the presence of superconductivity in the La-Si-C system in bulk and thin film samples. This system has some of the common features that are present in high T_C superconducting materials. It is a multi-element compound and also incorporates a light element, Carbon. Furthermore, one of the binary phases, La_5Si_3 exhibits a tetragonal layered structure. This system exhibits the presence of a possible new superconducting compound with T_C's ranging from 6.1 K to 8.5 K. In the binary La-Si system there are five inter-metallic phases. Among these phases, those that exhibit superconductivity are: $LaSi_2$ with T_C of 2.3 K, La_3Si_2 with a T_C of 2.1 K and La_5Si_3 with a T_C of 1.6 K. A careful analysis of several physical properties (SQUID, Modulated Microwave Absorption) and x-ray powder diffraction, (using Rietveld refinement) shows that superconductivity in this system could be ascribed to intermediate binary (La_2C_3) and single (La-β) phases of the system.

[1]This study was supported by an AFOSR MURI "Search For New Superconductors For Energy And Power Applications."

4:18PM T23.00008 Superconducting properties of quasi-one dimensional graphene , GEORGE KARAKONSTANTAKIS, STEVE KIVELSON, Stanford University — We study quasi-one dimensional graphene (polyacene) two leg ladders modeled by repulsive U Hubbard model using DMRG. The strong repulsive interactions along with the high density of states at the Fermi energy enhance the conducting properties of the ladder (which is a conductor) and give rise to enhancement of the pairing energy scales, having to do with the superconducting properties of the ladder. The presence of phonons in this system has been known to give rise to Peierls ans superconducting instabilities as well.

4:30PM T23.00009 Unusual Superconductivity in the Homologous Series $(Cu_{0.75}Mo_{0.25})Sr_2(Ce,Y)_sCu_2O_{5+2s+\delta}$, OMAR CHMAISSEM, Northern Illinois University and Argonne National Laboratory, Illinois, USA, INGA GRIGORAVICIUTE, MAARIT KARPPINEN, HISAO YAMAUCHI, Aalto University School of Science and Technology, Aalto, Finland and Tokyo Institute of Technology, Yokohama, Japan, MASSIMO MAREZIO, CRETA/CNRS, Grenoble, France — The structures and bulk superconductivity (>30% Meissner volume fraction) of the first four members of the high-T_c series $(Cu_{0.75}Mo_{0.25})Sr_2(Ce,Y)_sCu_2O_{5+2s+\delta}$have been successfully determined. Partial Mo substitution for Cu in the square-chains enhances T_c to 87 K (for s= 1) and leads to significant oxygen loading capabilities well beyond the levels achieved in typical $YSr_2Cu_3O_{6+\delta}$, $YBa_2Cu_3O_{6+\delta}$, and other similar cuprates. Higher members of the series have their adjacent superconducting CuO_2 layers separated by increasingly thicker fluorite-like $(Ce,Y)_2O_2$ insulating blocks. Insertion of two or more of these blocks must drastically affect the CuO_2 interlayer coupling and causes T_c to immediately drop and saturate at ∼57 K (s = 2-4). The infinite chains of Cu-centered squares in YBCO change to alternate chains of mixed Cu squares and Cu and Mo octahedra. Neutron diffraction confirms the formation of reservoir blocks with a new structure and stoichiometry and of a surprisingly large Cu oxidation state of ∼2.5+, suggesting the possibility of an unusual superconducting pairing mechanism.

4:42PM T23.00010 Electrical Transport Properties of Boron-Based Nanostructures[1] , JOEL D. CHUDOW, DANIEL F. SANTAVICCA, LUIGI FRUNZIO, DANIEL E. PROBER, Dept. of Applied Physics, Yale University, MICHAEL ROOKS, Yale Institute for Nanoscience and Quantum Engineering, Yale University, ESWARAMOORTHI IYYAMPERUMAL, GAYATRI KESKAR, FANG FANG, LISA PFEFFERLE, Dept. of Chemical Engineering, Yale University — Many metal boride materials exhibit interesting electrical properties. Bulk MgB_2 has a superconducting transition temperature of 39 K. Boron-based nanostructures are predicted to possess special properties superior to those of other one-dimensional nanomaterials. Recent progress in material fabrication has enabled the successful synthesis of boron-based nanomaterials [J. Phys. Chem. C 113, 17661 (2009)]. Magnetization measurements of magnesium-boride nanostructures show evidence of a diamagnetic transition at high temperature, about 80 K. We describe electrical transport measurements of individual single nanowires composed of these and related materials.

4:54PM T23.00011 Structure and electronic properties of the $La_4Ni_3O_8$, KONSTANTIN LOKSHIN, TAKESHI EGAMI, University of Tennessee — The Ni^{1+}/Ni^{2+} states of nickelates have the identical ($3d^9/3d^8$) electronic configuration as Cu^{2+}/Cu^{3+} in the high temperature superconducting cuprates, and are expected to show interesting properties. However, $La_4Ni_3O_8$, has infinite NiO_2 layers with Ni valence 1.33 and demonstrate a magnetic transition at 105 K, which has not been explained unambiguously yet. Here we report X-rays and Neutron diffraction evidences clarifying the nature of the transition. The observed structural changes around 105 K suggest that the magnetic transision in $La_4Ni_3O_8$ originates from Yahn Teller effect that accompanies with high spin – low spin transition. Thus, at low temperature the structural motive, electronic configuration and the spin state of Ni^{1+}/Ni^{2+} nickelates are identical to Cu^{2+}/Cu^{3+} cuprates.

5:06PM T23.00012 Transport and Spectroscopy Studies of Ultrathin Doped Nickelate Films , YARON SEGAL, JOSEPH NGAI, DIVINE KUMAH, ANKIT DISA, JAMES REINER, JARRET MOYER, Yale University Applied Physics, DARIO ARENA, Brookhaven National Lab, FRED WALKER, CHARLES AHN, Yale University Applied Physics — The notion of a rational, first-principles based design of a novel superconducting material has intrigued physicists for decades. Recently it was suggested that by enforcing a two- dimensional confinement and tensile strain on $LaNiO_3$ films, their electronic structure can be made sufficiently similar to that of the Mott-Hubbard system in the cuprates, possibly inducing an antiferromagnetic insulator-superconductor transition [PRL 100, 016404]. We adopt this approach through the synthesis of ultrathin $La_xNd_{1-x}NiO_3$ and hole-doped $La_xBa_{1-x}NiO_3$, $Nd_xBa_{1-x}NiO_3$ films using molecular beam epitaxy. High structural quality is demonstrated by RHEED oscillations and synchrotron x-ray diffraction. Transport measurement show a transition from metallic behavior to localization for films less than 8 uc thick. Tuning of the La/Nd ratio allows the film to be driven into the antiferromagnetic insulating regime. Surprisingly, Ba incorporation increases the localization in the films, which is in contrast to the metallicity-promoting effect of hole doping in bulk nickelates. X-ray absorption measurements allow us to follow the evolution of the Ni and O orbitals and relate it to the observed transport properties.

5:18PM T23.00013 Superconductivity at 7.7 K in new hexagonal bronze Hg_xReO_3 , KENYA OHGUSHI, University of Tokyo, JST-TRIP, AYAKO YAMAMOTO, RIKEN, JST-TRIP, YOKO KIUCHI, CHANDREYEE GANGULI, University of Tokyo, KAZUYUKI MATSUBAYASHI, YOSHIYA UWATOKO, University of Tokyo, JST-TRIP, HIDENORI TAKAGI, RIKEN, University of Tokyo, JST-TRIP — We have successfully synthesized a new rhenium-based hexagonal bronze material, Hg_xReO_3, which exhibits superconductivity with the transition temperature $T_c = 7.7$ K at ambient pressure and 11.1 K at 4 GPa. This compound is a superconductor with the highest T_c among hexagonal bronzes. Moreover, it presents the novel crystallographic feature that $(Hg_2)^{2+}$ polycations, in contrast to monatomic cations in known hexagonal bronzes, are incorporated into open channels. There is evidence that conducting electrons tightly couple with Hg-related phonons. Our results inspire detailed studies on the role of the rattling phonon in the occurrence of superconductivity in the hexagonal bronzes.

Session T24 DCOMP: Focus Session: Quantum Transport Simulations and Computational Electronics – Disorder D167

2:30PM T24.00001 Recent progress in computational electronics: disorder effects in nonequilibrium quantum transport[1]

, HONG GUO, McGill University — Realistic nanoelectronic devices inevitably have some disorder which affect device operation. Unintentional impurities sit at unpredictable locations and any predicted quantum transport property should be averaged over the impurity configurations. Impurity atoms are also intentionally doped into device material where the average is also necessary. One may generate many impurity configurations, calculate all and average the results. Such a brute force approach is not practical for first principles analysis as it is computationally too costly. I shall present the theory of nonequilibrium vertex correction (NVC) [1] where the configurational average is analytically done resulting to a NVC self-energy contributing to the nonequilibrium density matrix. NVC accounts for multiple impurity scattering at nonequilibrium. By integrating NVC with the density functional theory (DFT) and Keldysh nonequilibrium Green's functions (NEGF), nonequilibrium quantum transport in nanoelectronic systems having atomistic disorder can be carried out. By further integrating a recently proposed semi-local exchange potential that accurately determines band gaps [2], semiconductor nanoelectronics can now be analyzed from atomic first principles. Several examples will be presented including disorder scattering in Fe/MgO/Fe magnetic tunnel junction, electronic structure of $In_xGa_{1-x}N$ with varying concentrations x for solar cells, and quantum transport properties of doped Si membrane.

3:06PM T24.00002 Seebeck Coefficients in Nanoscale Junctions: Effects of Electron-Vibration Scattering and Local Heating[1]

, BAILEY C. HSU, Department of Electrophysics, National Chiao Tung University, Taiwan, YU-SHEN LIU, College of Physics and Engineering, Changshu Institute of Technology, China, SHEN HSIEN LIN, Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan. Department of Applied Chemistry, National Chiao Tung University, Taiwan, YU-CHANG CHEN, Department of Electrophysics, National Chiao Tung University, Taiwan — We report first-principles calculations of inelastic Seebeck coefficients in an aluminum monatomic junction. We compare the elastic and inelastic Seebeck coefficients with and without local heating. In the low temperature regime, the signature of normal modes in the profiles of the inelastic Seebeck effects is salient. The inelastic Seebeck effects are enhanced by the normal modes, and further magnified by local heating. In the high temperature regime, the inelastic Seebeck effects are weakly suppressed due to the quasi-ballistic transport.

3:18PM T24.00003 Critical current noise in rough Josephson junctions[1]

, PIERRE-LUC DALLAIRE-DEMERS, FRANK WILHELM, University of Waterloo — While dissipationless, Josephson junctions as elements in superconducting nanocircuits are plagued by intrinsic noise mechanisms that will limit the coherence time of future high-precision quantum devices. Important sources of noise may arise from the non-cristallinity and disorder of the oxide layer sandwiched between the two superconducting leads. This work presents a microscopic calculation of the spectral density of noise of a rough superconducting tunnel junction. As for disordered conductors, a Josephson junction is modeled as a set of pinholes with a universal bimodal distribution of transmission eigenvalues that add their noise power incoherently. Each of these pinholes is treated as a ballistic point contact with an intrinsic thin barrier that modulates the transmission coefficient. The noise spectrum is computed using the quasiclassical Green's function method for superconductivity. This formalism allows us to investigate high and low transmission limits at finite temperature for any relevant frequency. As suggested by experiments, low transmission pinholes are expected to generate shot noise while fast switching between the subgap states of high transmission channels should create a strong non-poissonian low-frequency noise yet to be measured.

3:30PM T24.00004 Computing Transport coefficients from the Microscopic Response Method[1]

, MINGLIANG ZHANG, DAVID A. DRABOLD, Department of Physics and Astronomy, Ohio University, Athens, Ohio 45701 — If an external perturbation to a system may be expressed as additional terms in the Hamiltonian, the microscopic response is determined by the the wave function of the system. To obtain the macroscopic response, an ensemble average can be carried out at the final stage. With the help of a systematic diagrammatic expansion, one is able to consistently compute the corresponding transport coefficient. If the spatial fluctuation of the carrier distribution is small, the microscopic response method reduces to the usual Kubo-Greenwood formula (KGF). We illustrate with the conductivity and Hall mobility of amorphous semiconductors. Because the direction of the Lorentz force is determined by the line connecting the initial and final localized states, the sign of Hall mobility in a-Si:H can be anomalous. The method is being implemented in an *ab initio* code, and it is applicable to any temperature. Thus it significantly improves upon the usual method which averages KGF over a trajectory of classical molecular dynamics.

M.-L. Zhang and D. A. Drabold, Phys. Rev. Lett. **105**, 186602 (2010); Eur. Phys. J. B. **77**, 7-23, (2010); arXiv: 1008.1067.

3:42PM T24.00005 Counting Statistics in Nanoscale Junctions from First Principles

, YU-CHANG CHEN, YU-SHEN LIU, Deparment of Electrophysics, National Chiao Tung University — We present first-principle calculations for moments of the current up to the third-order atomic-scale junctions. The quantum correlations of the current calculated in terms of wave functions obtained self-consistently within the static density functional theory are also demonstrated herein. Relationships between the conductance, the second, and the third moment of the current for carbon atom chains of various lengths bridging two metal electrodes in the linear and nonlinear regimes are investigated. The conductance, the second-, and the third-order Fano factors exhibit odd-even oscillation with the number of carbon atoms. The third-order Fano factor is positively correlates with conductance.

3:54PM T24.00006 The Escape Problem in a Classical Field Theory With Two Coupled Fields and its Application to Monovalent Metallic Nanowires

, LAN GONG, Department of Physics, New York University, DANIEL STEIN, Department of Physics and Courant Institute of Mathematical Science, New York University — We introduced and analyzed a system of two coupled partial differential equations with external noise. The equations are constructed to model transitions of monovalent metallic nanowires with non- axisymmetric intermediate or end states, but also have more general applicability. They provide a rare example of a system for which an exact solution of nonuniform stationary states can be found. We have also explored the escape dynamics numerically, using the String Method, a relaxational technique. We find two kinds of transitions in activation behavior as we tune different parameters in our model, such as the interval length on which the fields are defined, and the bending coefficients of the fields. We discuss how these results apply to real nanowires.

4:06PM T24.00007 Non-linear canonical transformations and Kondo physics

, JOHAN NILSSON, University of Gothenburg — We study the Kondo problem and the Kondo lattice using non-linear canonical transformations starting from the underlying Anderson model, generalizing the work of Ostlund in PRB 76, 153101 (2007). One such transformation, which is suitable to describe Fermi-liquid physics, provides an adiabatic connection between the quasi-particles of the interacting model and the electron- and hole-excitations in the non-interacting system as a function of the interaction parameter. We will also discuss other more unconventional transformations.

4:18PM T24.00008 Spatial correlations in chaotic nanoscale systems with spin-orbit coupling , ANH NGO, Department of Physics, and Nanoscale & Quantum Phenomena Institute, Ohio University, 45701 USA, EUGENE KIM, Department of Physics, University of Windsor, Windsor, Ontario, Canada N9B 3P4, SERGIO ULLOA, Department of Physics, and Nanoscale & Quantum Phenomena Institute, Ohio University, 45701 USA — We investigate the properties of wave functions in chaotic nanostructures with spin-orbit (SO) interactions, focusing, in particular, on the evolution of the wave function statistics as the SO interaction is varied. We compare results obtained via random matrix theory for one- and two-point distribution functions with numerical results obtained from microscopic calculations on a stadium billiard, both with and without magnetic fields. We discuss how SO interactions weaken correlations in the system, as it evolves from the gaussian orthogonal (GOE) to the symplectic ensemble (GSE). In the presence of magnetic fields, a weak SO coupling decorrelates the two spin components, resulting in decoupled gaussian unitary ensembles (dGUE). We discuss experimental consequences of these (weakened) correlations, particularly for spin-dependent phenomena.

4:30PM T24.00009 Test of Lattice Constant with Correction from Zero-Point Energy , PAN HAO, YUAN FAN, JOHN PERDEW — In Born-Oppenheimer system, the total energy doesn't include the kinetic energy of the nucleus. The zero point energy of the crystal can influence the lattice constant found by minimizing the total energy. The zero point anharmonic expansion (ZPAE) can be estimated in the Debye model. We can also use a direct way to get the zero point energy by calculating the phonon frequency using density-functional perturbation theory. Some solids were tested using different functionals to get the total energy and using DFPT to get the zero-point energy. We also expanded the vibration frequency as the compression ratio, which can give us the trends of the zero-point energy. For those different correction ways, the phonon frequency correction should be the most precise method in theory. The Debye model gives a reasonable approximation in most of those solids, but for Diamond structure and the Zinc-Blende structures, the Debye model may overestimate the correction. The expansion frequency way also overestimates the corrections compared to the phonon frequency correction.

2:30PM T25.00001 Microscopic investigation of vortex-vortex interaction in conventional and unconventional superconductors[1] , MASARU KATO, YUHEI NIWA, Department of Mathematical Sciences, Osaka Prefecture University — Recently, we have investigated the vortex structures in nano-sized superconductors. We found the interference of vortex bound states around multiple vortices. And their interaction is affected by such quasi-particle interference. Vortex structures becomes different from which phenomenological theory predicts [1]. Therefore we clarify how such quasi-particle structure changes the vortex-vortex interaction. In order for this, we investigate the quasi-particle structures around a pair of vortices, using the Bogoliubov-de Gennes equation in the elliptical coordinates, where two vortices sit at two foci We expand quasi-particle wave functions by the (modified) Mathieu function. From the numerical results, we discuss the distance dependence of interference of the quasi-particle bound states and free energies. We will extend our method to unconventional superconductors.

2:42PM T25.00002 Type-1.5 superconductivity in multiband systems: the effects of interband couplings[1] , EGOR BABAEV, UMass Amherst and KTH Stockholm, JOHAN CARLSTROM, KTH Stockholm, MARTIN SPEIGHT, University of Leeds — Two-component superconductors can posses a "type-1.5" state which falls outside the usual type-I/type-II dichotomy. In this regime two vortices attract one another at long range but repel at shorter ranges. Multiple vortices thus should form clusters in cases where their interaction could be approximately described by a superposition of such nonmonotonic two-body forces and one can define a negative interface energy inside a cluster and at the same there one can define a positive interface energy associated with the cluster's boundary. We describe the appearance of type-1.5 regimes in the case of two bands with various kinds of substantial interband couplings such as Josephson coupling, mixed gradient coupling and density-density interactions. We show that in these cases the system supports type-1.5 superconductivity with fundamental length scales being associated with the mass of the gauge field and two masses of normal modes represented by mixed combinations of the density fields. Talk based on arXiv:1009.2196 and Phys. Rev. Lett. 105, 067003 (2010)

2:54PM T25.00003 Proposed Aharonov-Casher interferometry of non-Abelian vortices in chiral p-wave superconductors[1] , EYTAN GROSFELD, BABAK SERADJEH, SMITHA VISHVESHWARA, University of Illinois at Urbana-Champaign — We propose a two-path vortex interferometry experiment based on the Aharonov- Casher effect for detecting the non-Abelian nature of vortices in a chiral p-wave superconductor. The effect is based on observing vortex interference patterns upon enclosing a finite charge of externally controllable magnitude within the interference path. We predict that when the interfering vortices enclose an odd number of identical vortices in their path, the interference pattern disappears only for non-Abelian vortices. When pairing involves two distinct spin species, we derive the mutual statistics between half quantum and full quantum vortices and show that, remarkably, our predictions still hold for the situation of a full quantum vortex enclosing a half quantum vortex in its path. We discuss the experimentally relevant conditions under which these effects can be observed.

3:06PM T25.00004 Microscopic theory of vortex interaction in two-band superconductors and type-1.5 superconductivity[1] , MIHAIL SILAEV, Institute for physics of microstructures RAS and Royal Institute of Technology, EGOR BABAEV, Royal Institute of Technology and UMass Amherst — In the framework of self-consistent microscopic theory we study the structure and interaction of vortices in two-gap superconductor taking into account the interband Josephson coupling. The asymptotical behavior of order parameter densities and magnetic field is studied analytically within the microscopic theory at low temperature. At higher temperatures, results consistent with Ginzburg-Landau theory are obtained. It is shown that under quite general conditions and in a wide temperature ranges (in particular outside the validity of the Ginzburg-Landau theory) there can exist an additional characteristic length scale of the order parameter density variation which exceeds the London penetration length of magnetic field due to the multi-component nature of superconducting state. Such behavior of order parameter density variation leads to the attractive long-range and repulsive short-range interaction between vortices.

3:18PM T25.00005 Hairy balls and flux lines in superconductors , MARK LAVER, Paul Scherrer Institut; Risoe DTU; University of Copenhagen, TED FORGAN, School of Physics and Astronomy, University of Birmingham — Many physical phenomena originate from geometrical effects rather than from local physics. For example, the hairy ball theorem — a hairy sphere cannot be combed — is fulfilled by the atmospheric circulation with the existence of stratospheric polar vortices, and the fact that there is always at least one place on Earth where the horizontal wind is still. We examine the consequences of the hairy ball theorem for the flux line lattice (FLL). We find that discontinuities must exist in lattice shape as a function of field direction relative to the crystal. The remarkable ways in which the hairy ball theorem is fulfilled are demonstrated for FLL's in superconducting niobium. We show that extraordinary, unconventional flux line lattice shapes that spontaneously break the underlying crystal symmetry are surprisingly likely across all Type-II superconductors, both conventional and unconventional.

3:30PM T25.00006 Boundary Wess-Zumino-Novikov-Witten model, BCS superconductivity, and Maxwell-Bloch theory[1] , TIGRAN SEDRAKYAN, VICTOR GALITSKI, University of Maryland, College Park — We establish an exact correspondence between the discrete-state pairing Hamiltonian (Richardson model) and the Wess-Zumino-Novikov-Witten (WZNW) model modified by an additional boundary operator. We solve this boundary WZNW model exactly and from this solution re-derive the Richardson equations of the pairing Hamiltonian. As an example of practical applications of the boundary WZNW model we use the obtained results to derive solution to the Maxwell Bloch theory of a two-level laser with damping and pumping. We use the results to calculate various observable characteristics of a laser: (i) the complex electrical field amplitude, (ii) the polarization of the laser medium, (iii) the population inversion. We discuss the relation of our results to recent experimental data.

3:42PM T25.00007 Geometric phases of d-wave vortices in a model of lattice fermions[1] , ZHENYU ZHOU, ALEXANDER SEIDEL, Washington University in St. Louis, OSKAR VAFEK, Florida State University — We study the local and topological features of Berry phases associated with the adiabatic transport of vortices in a d-wave superconductor of lattice fermions. At half filling, where the local Berry curvature must vanish due to symmetries, the phase associated with the exchange of two vortices is found to vanish as well, implying that vortices behave as bosons. Away from half filling, and in the limit where the magnetic length is large compared to the lattice constant, the local Berry curvature gives rise to an intricate flux pattern within the large magnetic unit cell. This renders the Berry phase associated with an exchange of two vortices highly path dependent. However, it is shown that "statistical" fluxes attached to the vortex positions are still absent. Despite the complicated profile of the Berry curvature away from half filling, we show that the average flux density associated with this curvature is tied to the average particle density. This is familiar from dual theories of bosonic systems, even though in the present case, the underlying particles are fermions.

[1]This research was supported by NSF under Grant No. DMR-0907793.

3:54PM T25.00008 Quasiparticle scattering from vortices in d-wave superconductors: Superflow and Berry phase contributions , ADAM C. DURST, SRIRAM GANESHAN, MANAS KULKARNI, Stony Brook University — In the vortex state of a d-wave superconductor, massless Dirac quasiparticles are scattered from magnetic vortices via a combination of two basic mechanisms: effective potential scattering due to the superflow swirling about the vortices and Aharonov-Bohm scattering due to the Berry phase acquired by a quasiparticle upon circling a vortex. First, we consider the superflow contribution by calculating the differential cross section for a quasiparticle scattering from the effective non-central potential of a single vortex. Next, we consider the Berry phase contribution, which results in branch cuts between neighboring vortices across which the quasiparticle wave function changes sign. Here, the simplest problem that captures the physics is that of scattering from a single finite branch cut that stretches between two vortices. Elliptical coordinates are natural for this two-center problem and we proceed by separating the massless Dirac equation in elliptical coordinates. The separated equations take the form of the Whittaker-Hill equations, which we solve to obtain radial and angular eigenfunctions. With these eigenfunctions in hand, we construct the scattering cross section via partial wave analysis. We discuss the scattering effect of each mechanism, superflow and Berry phase, leaving the important issue of interference between the two mechanisms to future work.

4:06PM T25.00009 Ground states of multi-band type-I and type-1.5 superconductors and interlaced type-I/type-II layered superconducting structures in external magnetic field[1] , JULIEN GARAUD, UMass Amherst, JOHAN CARLSTROM, KTH Stockholm, EGOR BABAEV, University of Massachusetts Amherst and KTH Stockholm — We report a numerical study of magnetic field-induced structures in multiband/multi-component superconductors and type-I/type-II multilayers. The magnetic ground state in these different regimes shows very rich structure formation. In particular we report vortex cluster formation in the cases of strong interband Josephson coupling. The results in particular can be applied to layered structures manufactured from interlaced layers of type-I and type-II superconductors yielding effectively the type-1.5 superconducting behavior with tunable intercomponent couplings.

[1]Supported by NSF CAREER Award DMR-0955902, Knut and Alice Wallenberg Foundation through the Royal Swedish Academy of Sciences and Swedish Research Council.

4:18PM T25.00010 Properties of vortex clusters and intercluster interaction in type-II and type-1.5 two-band superconductors and type-I/type-II superconducting bilayers[1] , JOHAN CARLSTROM, KTH Stockholm, JULIEN GARAUD, UMass Amherst, EGOR BABAEV, University of Massachusetts Amherst and KTH Stockholm — We discuss magnetic flux-carrying vortex states in multiband type-II and type-1.5 superconductors and interlaced type-I/type-II superconducting multilayers. Especially we focus on the case where there is a substantial disparity in characteristic variations of superfluid densities in bands or superconducting layers. We discuss the properties of vortex clusters in the type-1.5 regime both in the cases of strong and weak interband Josephson coupling, including interaction between vortex clusters with different numbers of vortices.

[1]Supported by NSF CAREER Award DMR-0955902, Knut and Alice Wallenberg Foundation through the Royal Swedish Academy of Sciences andSwedish Research Council.

4:30PM T25.00011 Novel time-dependent Ginzburg-Landau simulation of extreme type-II superconductors with a focus on the Nernst signal and its fluctuations , SANGWOO CHUNG, University of Cincinnati, PAATA KAKASHVILI, NORDITA, Sweden, CARLOS BOLECH, University of Cincinnati — Recently, different transport coefficients have been measured in High-T_c superconductors to pinpoint the nature of the pseudogap phase. In particular, the thermoelectric coefficients received a considerable attention both theoretically and experimentally. We numerically simulate the Nernst effect in extreme type-II superconductors using the time-dependent Ginzburg-Landau equations. We report the sign reversal of the thermoelectric coefficient, α_{xy}, at temperatures close to the mean-field transition temperature $T_c^{MF}(H)$, which qualitatively agrees with recent experiments on high-T_c materials. We also discuss the noise power spectrum of α_{xy}, which shows $1/f^{\beta}$ behavior. Based on this observation, we propose an experiment to determine different regimes of vortex dynamics by measuring the noise correlations of the Nernst signal.

4:42PM T25.00012 Temperature dependence of the superheating field in type-II superconductors , MARK TRANSTRUM, LASSP, Cornell University, GIANLUIGI CATELANI, JAMES SETHNA — The expulsion of an applied magnetic field is a hallmark characteristic of superconductivity. For a sufficiently large external field, the superconducting state transitions to a normal metal (type-I) or a flux-lattice state (type-II) at a field H_{c1}. The superconducting state is metastable and persists up to a field above H_{c1}, the so-called superheating field. We numerically solve the semi-classical equations of Eilenberger for the anomalous Green's functions, order parameter, and vector potential for a clean superconductor in an external magnetic field. We use a linear stability analysis to explore the local stability of the free energy to two-dimensional fluctuations, mapping the stability onto an eigenvalue problem of a linear operator. We systematically calculate the dependence of the superheating field on both temperature and the Ginzburg-Landau parameter κ. We compare our results with the analogous calculation for Ginzburg-Landau theory, which is valid only near the critical temperature, and to experimental measurements.

4:54PM T25.00013 Molecular dynamic simulation on the rule of the defect size on critical current at low temperature[1] , ABDALLA OBEIDAT, HADEEL ABULAHIM, Jordan University of Science and Technology — Molecular dynamics have been used to study the effect of the pinning center sizes on the critical current density of driven vortex lattices interacting with periodic arrays of pinning sites in two dimensions. In our study, we assumed that the radii of the pinning centers are much larger than the coherence length of the vortices. The critical current density has been studied at different temperatures for several values of pinning strengths. The overdamped equation of vortex motion has been solved taking into account the vortex-vortex repulsion, the thermal force, the attractive vortex-pinning interaction, and the driving Lorentz force. We found that the critical current density is independent of pinning size at low temperatures.

[1]We would like to thank the Jordan University of Science and Technology for the financial support.

Wednesday, March 23, 2011 2:30PM - 5:30PM –

Session T26 DMP DCOMP: Focus Session: Iron Based Superconductors – Magnetic Properties & Phase Diagrams D162/164

2:30PM T26.00001 Magnetic and Structural Phase Diagram of $Ba_{1-x}K_xFe_2As_2$, SEVDA AVCI, DUCK-YOUNG CHUNG, STEPHAN ROSENKRANZ, JOHN-PAUL CASTELLAN, RAY OSBORN, Materials Science Divison, Argonne National Laboratory, Illinois, USA, OMAR CHMAISSEM, Northern Illinois University and Argonne National Laboratory, Illinois, USA, MERCOURI KANATZIDIS, Northwestern University, Illinois, USA, EUGENE GOREMYCHKIN, AZIZ DAOUD-ALADINE, ISIS, Rutherford Appleton Laboratory, UK — It is well known that the partial substitution of Ba by K in $Ba_{1-x}K_xFe_2As_2$ causes a steep suppression of both the antiferromagnetic and tetragonal-orthorhombic transitions, leading to the onset of superconductivity over a large substitution range peaking at 38 K for x = 0.4. We report high resolution neutron powder diffraction results, which show that the magnetic and structural transitions are coincident over the entire phase diagram, in contrast to $Ba(Fe_{1-x},Co_x)_2As_2$. Volume discontinuities show that the combined transitions are first-order. The superconducting phase diagram has been refined with greater precision and a narrow region of phase coexistence have been delineated.

2:42PM T26.00002 Coexistence of Superconductivity and Magnetism in $EuFe_2(As_{0.7}P_{0.3})_2$, A.A. ACZEL, Oak Ridge National Lab, T.J. WILLIAMS, McMaster University, T. GOKO, F.L. NING, Y.J. UEMURA, C. ARGUELLO, Columbia University, W. YU, G.F. CHEN, Renmin University of China, G.M. LUKE, McMaster University — We have performed resistivity, magnetization, and μSR studies on single crystalline $EuFe_2(As_{0.7}P_{0.3})_2$. These measurements provide clear evidence for bulk superconductivity in this system, with the sample resistance dropping to zero around 12 K. This work has also revealed ferromagnetic ordering of the S = 7/2 Eu^{2+} moments along the c-axis ($T_{curie} \sim 19$ K). Finally, our μSR results indicate that the Eu magnetism is very homogeneous and occupies the full-volume fraction, pointing to real-space coexistence of magnetism and superconductivity in this material.

2:54PM T26.00003 Physical and magnetic properties of $Ba(Fe_{1-x}Mn_x)_2As_2$ single crystals[1] , ALEXANDER THALER, SHENG RAN, ALFRED KRACHER, WARREN STRASZHEIM, JIAQIANG YAN, SERGEY BUD'KO, PAUL CANFIELD, Iowa State University/Ames Lab — Single crystals of $Ba(Fe_{1-x}Mn_x)_2As_2$, $0 < x < 1$, have been grown and characterized by structural, magnetic and transport measurements. These measurements show that the structural/magnetic phase transition found in pure $BaFe_2As_2$ at 134 K is suppressed monotonically by Mn doping up to a critical concentration, $x \approx 0.10$. For $x > 0.10$, a similar transition is observed which broadens and trends upward in temperature with increasing doping level. Superconductivity is not observed at any doping level for $T > 1.85K$. Phase diagrams of temperature versus doping level based on electrical transport and magnetization measurements will be presented and compared to those of the $Ba(Fe_{1-x}TM_x)_2As_2$ (TM=Cr, Co, Ni, Cu) series.

[1]Work at the Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

3:06PM T26.00004 The magnetic form factor of SrFe2As2 , WILLIAM RATCLIFF, P.A. KIENZLE, J.W. LYNN, NIST Center for Neutron Research, S. LI, Beijing National Laboratory, Institute of Physics for Condensed Matter Physics, Chinese Academy of Sciences, Beijing China, P. DAI, Department of Physics and Astronomy, University of Tennessee, Knoxville, TN; Neutron Scattering Science Dvision, Oak Ridge National Laboratory, G.F. CHEN, N.L. WANG, Beijing National Laboratory, Institute of Physics for Condensed Matter Physics, Chinese Academy of Sciences, Beijing China — The Fe-pnictide based superconductors have recently been the subject of great interest. In this talk, we discuss recent neutron diffraction measurements of the magnetic form factor of SrFe2As2. These measurements reveal that while the form factor is primarily isotropic, a maximum entropy reconstruction reveals that there is evidence of hybridization between the Fe and As orbitals.

3:18PM T26.00005 Temperature-pressure-composition phase diagram for $Ba(Fe_{1-x}Ru_x)_2As_2$ ($x \leq 0.285$ and $P \leq 84$kbar) , S.K. KIM, Iowa State University and Ames Lab, M.S. TORIKACHVILI, Iowa State University, Ames Lab. and San Diego State University, A. THALER, E.C. COLOMBIER, S.L. BUD'KO, P.C. CANFIELD, Iowa State University and Ames Lab. — $BaFe_2As_2$ shows a structural/magnetic (SM) phase transition near T_{SM}=134K, which is suppressed upon partial substitutions at the Ba (K), Fe (Cr, Mn, Co, Ni, Cu, Ru, Rh, Pd, Ir) or As (P) sites, and also by adding pressure (P), most times leading to the emergence of superconductivity (SC) at low T. Here, we report on the P-dependence of the electrical resistivity in under- to near-optimally doped $Ba(Fe_{1-x}Ru_x)_2As_2$ ($0 \leq x \leq 0.285$) for $P \leq 84$kbar. Pressure suppresses the SM transition at a rate that increases with Ru content, e.g. for x=0.092, 0.161, and 0.210, dT_{SM}/dP ~-0.2, -0.4, and -0.6K/kbar, respectively. Although the x=0.092 and x=0.161 compositions are not SC at P=0, SC is seen when T_{SM} is sufficiently reduced by P. For x=0.161, T_c at first increases to a maximum near 25K at ~20kbar, after which it decreases at a rate of ~-0.4K/kbar. Likewise, the T_c values for the higher dopings peak ~20kbar and decrease at higher P at similar rates. We find that the application of pressure on $Ba(Fe_{1-x}Ru_x)_2As_2$ enhances T_c beyond that which was achieved with only doping, seen before in $Ba(Fe_{1-x}Co_x)_2As_2$. – Supported by U.S. DOE (DE-AC02-07CH11358), AFOSR-MURI (FA9550-09-1-0603), and NSF (DMR-0805335).

3:30PM T26.00006 Phase diagram of superconductivity and antiferromagnetism in single crystals of Sr(Fe1-xCox)2As2 and Sr1-yEuy (Fe0.88Co0.12)2As2[1] , RONGWEI HU, SERGEY BUD'KO, PAUL CANFIELD, Iowa State University — We report magnetic susceptibility, resistivity and heat capacity measurements on single crystals of $Sr(Fe_{1-x}Co_x)_2As_2$ and $Sr_{1-x}Eu_x(Fe_{0.88}Co_{0.12})_2As_2$ series. The optimal Co concentration for superconductivity in $Sr(Fe_{1-x}Co_x)_2As_2$ is determined to be $x = 0.117$. Based on this we grew members of the $Sr_{1-y}Eu_y$ series to examine the effects of well defined local moment scattering on the superconducting state. We show the evolution of superconductivity and development of antiferromagnetism across the whole doping range. The suppression of superconductivity within Abrikosov-Gor'kov's theory and de Gennes scaling as well as the antiferromagnetic transition temperature will be discussed.

3:42PM T26.00007 Lattice distortion and magnetic quantum phase transition in $CeFeAs_{1-x}P_xO$, CLARINA DELA CRUZ, Neutron Scattering Science Division, Oak Ridge National Laboratory — With the advent of Fe-based superconductivity initially discovered in the prototypical electron doped Fe-pnictide LaFeAsOxF1$-x$, came a surge of renewed interest in high temperature superconductivity. The discovery of ubiquitous antiferromagnetic (AFM) order in the parent compounds of iron arsenide superconductors has brought attention to the understanding of the interplay between magnetism and high-transition temperature (high-Tc) superconductivity in these materials. Although superconductivity in iron arsenides arises from charge carrier doping of their semimetal parent compounds, the resulting electronic phase diagrams are dramatically materials dependent, ranging from first-order-like AFM to superconductivity phase transition for LaFeAsO1-xFx, to the gradual suppression of the AFM order before superconductivity for CeFeAsO1-xFx, and finally to the co-existing AFM order with superconductivity in SmFeAsO1-xFx. A feature of the parent compounds is the structural distortion that occurs in the vicinity of the onset of long range magnetic order of the Fe-spins. In the RFeAsO(R=rare earth) family, the magneto-structural transition is suppressed in favor of superconductivity upon doping charge carriers into the system, which alters the system electronically and crystallographically as well. To understand the lattice effect on the suppression of the AFM ground state itself by quantum fluctuations, it is important to isoelectronically tune the crystal lattice structure without the influence of charge carrier doping and superconductivity. Here we use neutron scattering to show that replacing the larger arsenic with smaller phosphorus in CeFeAs1-xPxO simultaneously suppresses the AF order and orthorhombic distortion near x= 0.4, providing evidence for a magnetic quantum critical point. Furthermore, we find that the pnictogen height in iron arsenide is an important controlling parameter for their electronic and magnetic properties, and may play an important role in electron pairing and superconductivity. Preliminary work on systematic phosphorous doping in LaFeAs1-xPxO was also done to possibly identify characteristic changes in the lattice that may be correlated with the phosphorous doping induced superconductivity in the La system and in turn give insights as to the absence of superconductivity in the Ce system.

4:18PM T26.00008 Rare earth substitution in AFe2As2 single crystals[1] , SHANTA SAHA, NICHOLAS BUTCH, TYLER DRYE, JEFF MCGILL, JOHNPIERRE PAGLIONE, Center for Nano Physics and Advanced Materials, Department of Physics, University of Maryland, College Park, MD, PETER ZAVALIJ, Department of Chemistry and Biochemistry, University of Maryland, College Park, MD, JEFFREY LYNN, NIST Center for Neutron Research, Gaithersburg, MD — Synthesis and characterization of aliovalent light rare earth substitutions for alkaline earth atoms are studied in single crystals of FeAs-based compounds with the ThCr2Si2 structure. Electrical resistivity, magnetic susceptibility and structural parameters determined via x-ray and neutron scattering techniques are investigated as a function of chemical pressure and charge doping induced by substitution. Measured physical properties are compared to the effects of external applied pressure on CaFe2As2, known to induce a collapse of the tetragonal unit cell.

[1]This work was supported by AFOSR MURI Grant FA9550-09-1-0603.

4:30PM T26.00009 Magneto-elastic Coupling in Single-crystal CeFeAsO[1] , H.-F. LI, J.-Q. YAN, J.W. KIM, R.W. MCCALLUM, T.A. LOGRASSO, D. VAKNIN, AMES LABORATORY, U.S. DOE, AMES, IOWA 50011, USA TEAM, DEPARTMENT OF PHYSICS AND ASTRONOMY, IOWA STATE UNIVERSITY, AMES, IOWA 50011, USA TEAM, ADVANCED PHOTON SOURCE, ARGONNE NATIONAL LABORATORY, ARGONNE, ILLINOIS 60439, USA TEAM, DEPARTMENT OF MATERIALS SCIENCE AND ENGINEERING, IOWA STATE UNIVERSITY, AMES, IOWA 50011, USA TEAM — Single-crystal synchrotron X-ray diffraction studies of CeFeAsO reveal strong anisotropy in the charge correlation lengths along or perpendicular to the in-plane antiferromagnetic (AFM) wave-vector at low temperatures. The high-resolution setup allows to distinctly monitor each of the twin domains by virtue of a finite misfit angle between them that follows the order parameter. We find that the in-plane correlations, above the orthorhombic (O)-to-tetragonal (T) transition, are shorter than those in each of the domains in the AFM phase, indicating a distribution of the in-plane lattice constants. This strongly suggests that the phase above the structural transition is virtually T with strong O-T fluctuations that are induced by magnetic fluctuations.

4:42PM T26.00010 Competing magnetic ground states in $Ba(Fe_{1-x}Cr_x)_2As_2$[1] , K. MARTY, M.D. LUMSDEN, A.D. CHRISTIANSON, C. WANG, M. MATSUDA, H. CAO, ORNL, L. VANBEBBER, University of Tennessee, J.L. ZARESTKY, ORNL and Ames Laboratory, D.J. SINGH, A.S. SEFAT, ORNL — Understanding the origin of unconventional superconductivity is a great challenge of condensed matter physics. In the so called 122 family, doping in the conductive layer (i.e. on the Fe site) of the $BaFe_2As_2$ iron pnictide parent compound leads to superconductivity for almost any transition metal, except for Cr and Mn. The absence of superconductivity in these cases remains an unresolved issue. We report here neutron diffraction measurements of $Ba(Fe_{1-x}Cr_x)_2As_2$ for concentrations up to x=0.47. The results show that Cr doping stabilizes magnetism across the phase diagram with a competing magnetic order favoured at high Cr-doping, in contrast to the other superconducting $Ba(Fe_{1-x}TM_x)_2As_2$.

[1]The work at ORNL was supported by the Scientific User Facilities Division, Office of Basic Energy Sciences, US DOE.

4:54PM T26.00011 Superconductivity and magnetism in $Eu_{1-x}K_xFe_2(As_{1-y}P_y)_2$, H.S. JEEVAN, J. MAIWALD, PHILIP GEGENWART, Physikalisches Institut, Georg-August-Universitaet Goettingen, D-37077 Goettingen, Germany, DEEPA KASINATHAN, HELGE ROSNER, MPI CPfS - Dresden — We report detail investigation of superconductivity and magnetism in $EuFe_2As_2$ by doping of K in Eu site and P in As site. In this new class of FeAs-based superconductors, it is found that superconductivity appears close to a magnetic instability, suggesting a possible unconventional pairing mechanism. We have synthesized single crystals of both doped and undoped samples and investigated their physical properties by means of heat capacity, resistivity, magnetization and thermal conductivity measurements. The parent compound shows an antiferromagnetic spin-density-wave (T_{SDW}) at $\approx$ 190K related to the Fe_2As_2 layers and magnetic ordering of Eu^{2+} (T_N) moments at $\approx$ 20K. Upon doping Eu with K >30%, T_{SDW} gets suppressed and superconductivity (SC) appears at $\approx$ 32K and also Eu^{2+} ordering suppressed to the low temperature. On the other hand, P doping to the As site suppresses the SDW transition and results in SC, but Eu ordering remains undisturbed. Further increasing the P doping, Eu order transitions from AFM to FM phase which leads to disappearance of SC. We will compare our experimental findings with density functional theory based calculations.

5:06PM T26.00012 Effects of annealing time and temperature on the transition temperature and low temperature state of AFe2As2 materials , SHENG RAN, SERGEY BUD'KO, ALEX THALER, Ames Laboratory U.S. DOE and Department of Physics and Astronomy, Iowa State University, DOMINIC RYAN, Physics Department/McGill University, YUJI FURUKAWA, BEAS ROY, ANDREAS KREYSSIG, ROBERT MCQUEENEY, DANIEL PRATT, ALAN GOLDMAN, PAUL CANFIELD, Ames Laboratory U.S. DOE and Department of Physics and Astronomy, Iowa State University — Over the past couple of years the AFe2As2 (A = Ca, Sr, Ba) family of compounds has become a model system for the study of FeAs-based superconductivity. Superconductivity can be stabilized by hole and electron doping (on A and Fe sites) as well as hydrostatic pressure and isoelectronic substitutions on both the Fe and As sites. In all cases the adequate suppression of the structural / antiferromagnetic phase transition appears to be a necessary condition for the appearance of superconductivity. In this talk we will review the effects of annealing time and temperature on the structural / antiferromagnetic phases of AFe2As2. Transition temperature / time and transition temperature / annealing temperature plots will be presented and discussed.

5:18PM T26.00013 Miscibility gap between $BaMn_2As_2$ and $BaFe_2As_2$[1] , ABHISHEK PANDEY, DAVID C. JOHNSTON, Ames Laboratory and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011 — $BaMn_2As_2$ and $BaFe_2As_2$ both crystallize at room temperature in the same tetragonal $ThCr_2Si_2$-type structure but with divergent unit cell volumes of 234.12 and 204.38 Å^3, respectively, suggesting that the Mn^{+2} is in a high-spin state while Fe^{+2} is in a low-spin state. The physical properties of the two compounds are therefore also highly divergent; *e.g.*, $BaMn_2As_2$ is an insulating local moment antiferromagnet with a high Néel temperature $T_N = 625$ K whereas $BaFe_2As_2$ is a metallic itinerant antiferromagnet with a much lower $T_N = 137$ K.[2] We have discovered a miscibility gap in the pseudobinary phase diagram between these two isostructural compounds, probably arising from their divergent chemistry. Our investigations of the miscibility gap and of the structural, magnetic, electronic transport and thermal properties of various compositions in this system will be discussed.

Session T27 GQI DAMOP: Open Quantum Systems and Decoherence C155

2:30PM T27.00001 Landau-Zener-Stückelberg interference in the presence of quantum noise[1] , YANG YU, LINGJIE DU, MINJIE WANG, National Laboratory of Solid State Microstructures and Department of Physics, Nanjing University, Nanjing 210093, China — We investigated the Landau-Zener-Stückelberg (LZS) interference in strongly driven two-level systems subjected to quantum noise. The transition rate induced by consecutive LZ transitions is obtained, from which LZS interference can be analytically calculated based on rate equation. In the presence of significant frequency dependent noise, the evolving paths of LZS interference is going to be detoured. Therefore, the position of the resonant peaks is shifted and a stationary population inversion in TLS without involving the third qubit state is generated. The LZS interferometry can be used to investigate the noise property hence the decoherence source of the system. In addition, the stationary population inversion may find application in lasing and microwave cooling.

2:42PM T27.00002 Exact master equations for linearly coupled Bosons or Fermions[1] , SHAO-WEN CHEN, REN-BAO LIU, The Chinese University of Hong Kong — Using the coherent-state representation (P-representation), we derived the exact master equation for a quantum system in an environment, which has linear but otherwise arbitrary couplings. This method works for both Boson and Fermion systems, since the coherent states of Bosons and Fermions have the similar algebra structure. The new derivation reproduces the previous works on photon dynamics in coupled cavities or quantum transport through double quantum dots, but it provides a more general theoretical framework for studying quantum dynamics in photonic, mechanical, and photomechanical systems, and quantum transport in nanostructures.

2:54PM T27.00003 Engineering inverse power law decoherence of a qubit , FRANCESCO PETRUCCIONE, FILIPPO GIRALDI, University of KwaZulu-Natal and National Institute for Theoretical Physics, QUANTUM RESEARCH GROUP TEAM — The exact dynamics of a Jaynes-Cummings model for a qubit interacting with a bath of bosons, characterized by a special form of the spectral density, is evaluated analytically. The special reservoirs are sub-ohmic at low frequencies and inverse power law at high frequencies. The exact dynamics of the qubit is described analytically through Fox H-functions. Over estimated long time scales, decoherence results in inverse power laws with powers decreasing continuously to unity, according to the particular choice of the engineered reservoir. If compared to the exponential-like relaxation obtained from the original Jaynes-Cummings model for Lorentzian-type spectral density functions, decoherence is considerably hindered.

3:06PM T27.00004 Decoherence of high-ℓ Rydberg wave packets by collisions and electrical noise , BRENDAN WYKER, S. YE, Rice University, T. MCKINNEY, University of California, Berkeley, F.B. DUNNING, Rice University, S. YOSHIDA, Vienna University of Technology, C.O. REINHOLD, Oak Ridge National Laboratory, J. BURGDÖRFER, Vienna University of Technology — Quantum revivals in very-high-n (n ∼300) high-ℓ Rydberg wave packets generated from parent np states are used to examine decoherence induced by collisions and by the application of "colored" noise from a random pulse generator. In the absence of external perturbations, the high-ℓ wave packets maintain their coherence for periods ~ 1 μs, i.e., for many hundreds of orbits. However, their coherence can be destroyed on sub-microsecond timescales by the presence of even small amounts of electrical noise at a rate that depends markedly on the spectral characteristics of the noise. In contrast, measurements over similar timescales with CO_2 target gas at densities of $\sim 10^{11}$ cm^{-3} provide no evidence of collisional dephasing.

3:18PM T27.00005 Non-Markovian trajectory approach of three-level quantum systems[1] , TING YU, JUN JING, Department of Physics and Engineering Physics, Stevens Institute of Technology, Hoboken, New Jersey 07030, USA — The non-Markovian dynamics of a three-level quantum system coupled to a bosonic environment is a difficult problem due to the lack of an exact dynamic equation such as a master equation. We present for the first time an exact quantum trajectory approach to a dissipative three-level model. We have established a convolutionless stochastic Schrödinger equation called time-local quantum state diffusion (QSD) equation without any approximations, in particular, without Markov approximation. Our exact time-local QSD equation opens a new avenue for exploring quantum dynamics for a higher dimensional quantum system coupled to a non-Markovian environment.

3:30PM T27.00006 Manipulating decoherence of a single solid-state spin by quantum control of its spin bath environment , GIJS DE LANGE, TOENO VAN DER SAR, MACHIEL BLOK, Kavli Institute of Nanoscience Delft, Delft University of Technology, The Netherlands, ZHIHUI WANG, VIATCHESLAV DOBROVITSKI, Ames Laboratory and Iowa State University, Ames, Iowa 50011, USA, RONALD HANSON, Kavli Institute of Nanoscience Delft, Delft University of Technology, The Netherlands — The coherence of solid-state spins is limited by uncontrolled interactions with their spin environment. High-fidelity single-spin control can be used to prolong the coherence by dynamically decoupling the spin from the environment [see De Lange et al., Science 330, 60 (2010)]. Here, we demonstrate a new approach towards decoherence control based on coherent manipulation of the spin bath environment itself. Our system consists of a single NV center spin in diamond, surrounded by a bath of electronic spins belonging to nitrogen impurities. By driving the bath spins resonantly and using the NV spin as a sensor, we are able to detect all transitions of the bath spins and demonstrate independent quantum control of each of them. This newly gained control opens the door to a number of exciting experiments such as measurement of the spin bath dynamics, manipulation of the spin bath correlation time, decoherence editing, and protection of NV spin coherence by suppressing the dynamics in its spin environment. In this talk we will present our latest results towards these goals.

3:42PM T27.00007 Optical cooling of a 122 kHz mechanical resonator , EVAN JEFFREY, PETRO SONIN, University of Leiden, DUSTIN KLECKNER, BRIAN PEPPER, University of California, Santa Barbara, DIRK BOUWMEESTER, University of Leiden — We demonstrate radiation pressure cooling of a 122-kHz, 60-ng mechanical resonator in an optical cavity. We use a dilution refrigerator to achieve a low base temperature ($<$ 100 mK). The resonators consist of high reflectivity mirrors suspended on a stressed silicon nitride cross resonator. Due to their low frequency, high Q ($>$40000) and high finesse ($>$ 10000) these devices are excellent candidates for demonstrating quantum behavior of macroscopic systems, with the possibility of achieving quantum superpositions, entanglement with external degrees of freedom, and studying exotic decoherence mechanisms.

3:54PM T27.00008 Long-lived Fermionic Fock-space coherence in quantum dots , EDUARDO VAZ, JORDAN KYRIAKIDIS, Dalhousie University — The Fock-space coherence between quantum states with different particle numbers naturally arising in an open quantum system, qualitatively differs from the more common Hilbert-space coherence between states with the same particle number. For a quantum dot with multiple channels available for transport, we have found specific energy and coupling regimes where a long-lived resonance in the fermionic Fock-space coherence of the system is realized, even where no resonances are found either in the population probabilities or Hilbert-space coherence of the system. We discuss how this resonance in the Fock-space coherence remains robust even in the presence of both boson-mediated relaxation and transport through the quantum dot, as well as its physical origin.

4:06PM T27.00009 Excitation induced dephasing from indistinguishability , PETER BRYANT, Physics Department, University of Texas at Austin — In a variety of experiments, Rabi oscillations suffer dephasing that often and perhaps generally depends on the Rabi frequency. This unexpected result has been called excitation induced dephasing. Explanations specific to experiments have been suggested, but here we describe a new approach to the treatment of decoherence and open systems, that allows one to address the indistinguishability of quantum systems. When physical systems are indistinguishable, excitation induced dephasing is a general phenomenon, and a preliminary model shows good agreement with a wide range of experimental results.

4:18PM T27.00010 Noise in a Josephson junction qubit due to two-level-systems coupled to a quantum EM field[1] , VICTOR GALITSKI, SO TAKEI, University of Maryland College Park — We theoretically study loss of the dielectric film located within an LC resonator circuit due to two-level defects (TLDs). We present a fully quantum mechanical treatment of the full system in which the TLDs couple to a quantized harmonic oscillator, which models the resonator, and to quantized bosonic fields that describe the feedline used to pump and probe the resonator. We focus on the forward transmission as a function of the microwave pump frequency, and investigate how the fluctuating defects affect the noise spectrum of the transmitted voltage signal. Our quantum mechanical treatment makes connections to experiments conducted down to energies where a single photon is stored in the resonator.

[1]This work was funded by IARPA.

4:30PM T27.00011 Suppression of Decoherence and Disentanglement in Qubits via the Exchange Interaction[1] , AMRIT DE, DONG ZHOU, ROBERT JOYNT, Department of Physics, University of Wisconsin- Madison, WI-53706 — We show that the decoherence and disentanglement for a pair of interacting qubits can be suppressed by the exchange interaction in the presence of one or more uncorrelated random telegraphic noise sources. The suppression of the dissipative dynamics is more apparent for the maximally entangled Bell states, particularly if the noise is non-Markovian. Hence, the entangled singlet-triplet superposition state of two qubits can be protected by the interaction, while for the triplet-triplet state, it is less effective. This makes the former more suitable for encoding quantum information. Our calculations are done using a recently developed quasi Hamiltonian formalism that is suitable for describing non-unitary temporal dynamics in an open quantum system subjected to classical stochastic noise processes. Exact and approximate solutions are obtained for a number of cases.

[1]This work is supported by the DARPA/MTO QuEST program through a grant from AFOSR.

4:42PM T27.00012 Concatenated Stabilizer Dynamical Decoupling , GERARDO PAZ SILVA, DANIEL LIDAR, University of Southern California — We show how to integrate concatenated dynamical decoupling (CDD) techniques with quantum error correction (QEC) codes: the two main strategies to protect quantum information from the decoherence induced by unwanted interaction with the environment. It has been shown that CDD can be used as a lower level protection layer against decoherence and improves the effective error rate of a physical gate, provided one assumes certain locality conditions (local bath assumption) [Ng, Lidar, Preskill, arXiv:0911.3202]. The typical CDD protocol uses pulses from a group of non-commuting operators to decouple to arbitrary order, in the sense of Magnus expansion, the state one wants to protect from the environment. Here, in the same spirit as [Lidar, Phys. Rev. Lett. 100, 160506 (2008)], we show how to decouple a state encoded in some stabilizer QEC code to arbitrary order by applying pulses from the stabilizer group of the QEC code. We demonstrate the technique for concatenated and non-concatenated QEC codes and show that, in contrast to the CDD case, (i) one can omit the local bath assumption, and (ii) has the freedom of simultaneously introducing evolution for the protected state.

4:54PM T27.00013 Decoherence and entanglement of a pair of coupled qubits , MOHAMMAD SAHRAPOUR, NANCY MAKRI, University of Illinois at Urbana-Champaign — We analyze the quantum dynamics of a pair of qubits coupled via Ising-type coupling under the influence of a common dissipative bath. We present results of simulations for a range of system biases and spin-spin couplings at two values of bath temperature ($\beta = 1, 5$). We also discuss the dynamics of entanglement when starting with fully entangled states and find that for some values of the system parameters, steady-state entanglement is observed. These simulations are carried out via the iterative path integral methodology developed earlier in our group which delivers efficient, numerically exact long time quantum dynamics.

5:06PM T27.00014 Entanglement and Coherence: Differences and Similarities , ROBERT O'CONNELL, Louisiana State University, Physics Dept. — Entanglement and coherence both decay due to environmental (heat bath) effects. Apart from the well-known fact that decoherence occurs exponentially and disentanglement occurs with a sudden death, there are many other differences. Here, we concentrate on the effects of temperature T along in the absence of dissipation. Thus, whereas the effect of T on decoherence increases exponentially with time [1], the effect of T on disentanglement is constant for all times [2], reflecting a fundamental difference between the two phenomena. Also, the possibility of disentanglement at a particular T increases with decreasing initial entanglement. Supported in part by NSF under Grant No. ECCS-0757204.

5:18PM T27.00015 Quantum signatures of chaos in quantum tomography[1] , CARLOS RIOFRIO, VAIBHAV MADHOK, IVAN DEUTSCH, Center for Quantum Information and Control, University of New Mexico — We study the connection between quantum chaos and information gain in the time series of a measurement record used for quantum tomography. The record that is obtained as a sequence of expectation values of a Hermitian operator evolving under repeated application of the Floquet operator of the quantum kicked top on a large ensemble of identical systems. We find that, in the limit of vanishing noise, the fidelities of reconstruction are independent of the underlying chaos of the Floquet map. In the presence of noise, however, the fidelities on an average increase with the chaoticity of the map. Moreover, the number of time steps required to achieve a given fidelity decreases with the increase in the chaoticity, suggesting a connection between the rate of information gain and classical Lyapunov exponents.

Wednesday, March 23, 2011 2:30PM - 5:30PM –
Session T28 DCMP: Graphene: Optical and Transport Properties C156

2:30PM T28.00001 Selection rule for Raman spectroscopy at graphene edge , KEN-ICHI SASAKI, KATSUNORI WAKABAYASHI, National Institute for Materials Science, TOSHIAKI ENOKI, Department of Chemistry, Tokyo Institute of Technology — The optical matrix element may depend on position in graphene since an electronic wave function is position dependent. In particular, the matrix element near the edges of graphene can differ greatly from that in the bulk. We are pursuing our studies on this point in relation to Raman spectroscopy. We found a selection rule for the G band near the edges of graphene: the intensity is enhanced when the polarization of incident laser is parallel (perpendicular) to the armchair (zigzag) edge [1]. This asymmetry between the armchair and zigzag edges is useful in identifying the orientation of the edge of graphene. Some application of the selection rule is mentioned. We have extended our study to the polarization dependences of the D and 2D (G') bands [2]. The D and 2D bands have different selection rules at bulk and edge. At bulk, the 2D band intensity is maximum when the polarization of the scattered light is parallel to that of incident light, whereas the D band intensity does not have a polarization dependence. At edge, the 2D and D bands exhibit a selection rule similar to that of the G band.

[2] Sasaki et al., Phys. Rev. B 82, 205407 (2010).

2:42PM T28.00002 Photoconductive response study on a dual-gated bilayer graphene , M.-H. KIM, J. YAN, G.S. JENKINS, A.B. SUSHKOV, D.C. SCHMADEL, M.S. FUHRER, J. MELNGAILIS, H.D. DREW, Department of Physics, University of Maryland, College Park — A continuously tunable bandgap as high as 100 meV is produced in a gated bilayer graphene (BLG) by applying an electric field perpendicular to the layers (J. Yan, Nano Lett. 2010). The bandgap and the Fermi energy of BLG are tuned by top and bottom gate potentials. We measure the infrared photoconductive response from the dual-gated BLG from far infrared 30 cm^{-1} to mid-infrared 5000 cm^{-1} by broadband spectroscopy and with a CO_2 laser near 10.6 μm. We report the photoresponse and the measured band gap as a function of an applied electric field perpendicular to the BLG layers. This work is supported by IARPA grant #W911NF1010443.

2:54PM T28.00003 Ultrafast carrier dynamics in pristine and $FeCl_3$-intercalated bilayer graphene , XINGQUAN ZOU, Nanyang Technological University, Singapore, DA ZHAN, XIAOFENG FAN, DONGWOOK LEE, SARITHA K. NAIR, LI SUN, ZHENHUA NI, ZHIQIANG LUO, LEI LIU, TING YU, ZEXIANG SHEN, ELBERT E.M. CHIA — Ultrafast carrier dynamics of pristine bilayer graphene (BLG) and bilayer graphene intercalated with $FeCl_3$ ($FeCl_3$-G), were studied using time-resolved transient differential reflection ($\Delta R/R$). Compared to BLG, the $FeCl_3$-G data showed an opposite sign of $\Delta R/R$, a slower rise time, and a single (instead of double) exponential relaxation. We attribute these differences in dynamics to the down-shifting of the Fermi level in $FeCl_3$-G, as well as the formation of numerous horizontal bands arising from the d-orbitals of Fe. Our work shows that intercalation can dramatically change the electronic structure of graphene, and its associated carrier dynamics. Appl. Phys. Lett. **97, 141910** (2010)

3:06PM T28.00004 Microwave microscopy of graphene and graphite , VLADIMIR TALANOV, Neoceral LLC Beltsville, MD 20705, CHRISTOPHER DEL BARGA, LEE WICKEY, IRAKLI KALICHAVA, Materials Engineering Department, New Mexico Tech, Socorro NM 87801, EDWARD GONZALES, ERIC SHANER, AARON GIN, Center for Integrated Nanotechnologies and Sandia National Laboratories, Albuquerque, NM 87185, NIKOLAI KALUGIN, Materials Engineering Department, New Mexico Tech, Socorro NM 87801 — Graphene has emerged as a promising material for high speed nano-electronics applications due to the relatively high carrier mobility that can be achieved. To further investigate electronic transport in graphene and reveal its potential for microwave applications [1,2], a near-field scanning microwave microscope with the probe formed by an electrically open end of a 4 GHz half-lambda parallel-strip transmission line resonator has been employed [3]. We find that the microwave response of mono- and few-layer graphene flakes is determined by the local sheet impedance, which is found to be predominantly active. From fitting a quantitative electrodynamic model (relating the probe resonant frequency shift to 2D conductivity of single- and few-layer graphene) to the experimental data we evaluate graphene sheet resistance as a function of thickness. Near-field scanning microwave microscopy can simultaneously image location, geometry, thickness, and distribution of electrical properties of graphene without a need for device fabrication.

3:18PM T28.00005 Laser Scanning Microscopy of Few-Layer Graphene: Optical Reflectivity Contrast[1] , BEHNOOD GHAMSARI, Center for Nanophysics and Advanced Materials, University of Maryland, College Park, ALEXANDER ZHURAVEL, B. Verkin Institute for Low Temperature Physics & Engineering, NAS of Ukraine, DANIEL LENSKI, Intel Corporation, 5200 NE Elam Young Parkway, Hillsboro, OR 97124, MICHAEL FUHRER, STEVEN ANLAGE, Center for Nanophysics and Advanced Materials, University of Maryland, College Park — We report laser scanning microscopy (LSM) of few-layer graphene, where a laser beam is raster scanned over the samples and the local reflectivity of the structure is directly measured through a silicon photodiode. The samples are grown by ambient-pressure chemical vapor deposition on copper foils, and transferred to SiO2/Si substrates, and consist of regions of single- and multi-layer graphene (D. R. Lenski, and M. S. Fuhrer, e-print arXiv: 1011.1683). While the local reflectivity of the structure depends on the thickness of the graphene layer, the LSM data is used to construct a two-dimensional reflectivity image of the sample which, in turn, enables identifying the local distribution of different graphene multilayers and local microscopic properties of the graphene sample.

3:30PM T28.00006 Terahertz Imaging and Spectroscopy of Large-Area Single-Layer Graphene[1] , ETHAN MINOT, JOE TOMAINO, ANDREW JAMESON, JOSHUA KEVEK, MICHAEL PAUL, Oregon State University, AREND VAN DER ZANDE, ROBERT BARTON, PAUL MCEUEN, Cornell University, YUN-SHIK LEE, Oregon State University — The high electron mobility of graphene points to potential for high-speed electronic and opto-electronic devices operating at terahertz (THz) switching rates. Therefore, there is great interest in probing the electronic properties of large-area graphene at ultrafast time scales. We have demonstrated THz imaging and spectroscopy of a 15x15-mm^2 single-layer graphene film using broadband THz pulses. The THz images clearly map out the THz carrier dynamics of the graphene-on-Si sample, allowing us to measure sheet conductivity with sub-mm resolution without fabricating electrodes. The THz carrier dynamics are dominated by intraband transitions and the THz-induced electron motion is characterized by a flat spectral response. A theoretical analysis based on the Fresnel coefficients for a metallic thin film shows that the local sheet conductivity varies across the sample from 1.7 – 2.4 x 10^{-3} Ohm^{-1} (sheet resistance 420 - 590 Ohm/sq).

[1]This work was partially supported by Oregon Nanoscience and Microtechnologies Institute

3:42PM T28.00007 Aromatic molecule-like fluorescence from Graphene Oxide , CHARUDATTA GALANDE, Rice University, ADITYA MOHITE, Los Alamos National Laboratory, ANTON NAUMOV, WEI GAO, LIJIE CI, ANAKHA AJAYAN, HUI GAO, Rice University, ANCHAL SRIVASTAVA, Banaras Hindu University, R. BRUCE WEISMAN, PULICKEL M. AJAYAN, Rice University — Graphene Oxide (GO) is a functionalized derivative of graphene, obtained by chemical exfoliation and chemical oxidation of graphite. Recent NMR studies on GO have revealed presence of hydroxyl, epoxy, carbonyl, carboxyl and lactols. Although there have been several studies on electronic and optical properties of GO, the role of functional groups in determining the electronic density of states is still unclear. Here we report pH dependent fluorescence and excitation spectra of GO, with spectroscopic signatures indicating the presence of molecule-like fluorophores in GO. In acidic medium, a single, broad emission peak is observed at ca. 660nm. In contrast, relatively sharp emission at lower wavelengths (480nm-515nm) appears in a short pH range between 7.6 and 8.0, while the broad peak is completely quenched in basic conditions. The fluorescence and excitation spectra have pH-dependence strikingly similar to several aromatic carboxylic acids. The observed spectral features are proposed to arise from quasi-molecular fluorophores, similar to polycyclic aromatic compounds that are formed by the electronic coupling of carboxylic acid groups with nearby carbon atoms of the graphene.

3:54PM T28.00008 Broadband spatial self-phase modulation of few-layer graphene sheet in solution , RUI WU, YINGLI ZHANG, FEI BIAN, SHICHAO YAN, RUI WANG, WENLONG WANG, XUEDONG BAI, XINGHUA LU, JIMIN ZHAO, Institute of Physics, Chinese Academy of Sciences — Spatial self-phase modulation (SPM) was found for a suspension of few-layer graphene flakes. Multiple concentric conical diffraction rings was observed as a 532nm cw laser beam passes through the nearly transparent suspension, of which self-focusing occurred. The dependence of ring numbers and ring diameters on the laser intensity was recorded, from which we obtained the third order optical nonlinearity $n_2$of the sample. In our case n_2=10^{-9} m^2/W, which is the one of the largest among the reported carbon materials including carbon nanotubes and C_{60} samples. We also found that the intensity threshold for observing the diffraction rings is as low as about $0.6W/cm^2$, which is the smallest compared with most of the reported sample having spatial SPM, including nematic liquid crystals. Furthermore we found that both 267nm and 800nm ultrashort laser pulses can also easily generate spatial SPM. This large and broadband optical nonlinearity is a manifestation of the few-layer graphene's conical-shaped band structure, which is true for a relatively large energy scale.

4:06PM T28.00009 Optical transitions between Landau levels: AA-stacked bilayer graphene[1] , YEN-HUNG HO, Physics, National Sun Yat-Sen University, Taiwan, RONG-BIN CHEN, Center of General Education, National Kaohsiung Marine University, Taiwan, JHAO-YING WU, YU-HUANG CHIU, MING-FA LIN, Physics, National Cheng Kung University, Taiwan — The magneto-absorption spectra are calculated for the AA- stacked bilayer graphene. Two groups of Landau levels with different symmetry in wave function are found to coexist in the low energy region. The optical transitions between the two groups give rise to two kinds of absorption peaks. The wave- function distribution can clearly characterize individual Landau levels, and further determine the optical selection rules and absorption rates. The AA bilayer has quite different spectral features compared to the AB bilayer and monolayer, as a result from the interlayer interactions and stacking symmetry. Only a single absorption survives below certain critical frequency, while other peaks are paired together and sequentially emerged above this critical energy. With a continuous change in field strength, the excitation channels are switched, associated with the abrupt changes in their frequency.

4:18PM T28.00010 High temperature Graphene-based Quantum Hall Effect Infrared photodetector[1]

, NIKOLAI G. KALUGIN, New Mexico Tech, LEI JING, WENZHONG BAO, UC-Riverside, LEE WICKEY, CHRISTOPHER DEL BARGA, MEKAN OVEZMYRADOV, New Mexico Tech, ERIC A. SHANER, SNL, CHUN NING LAU, NEW MEXICO TECH TEAM, UC-RIVERSIDE TEAM, SNL COLLABORATION — We demonstrate successful operation of quantum Hall effect (QHE) graphene-based detectors at 70K, a temperature achievable using simple pumped liquid Nitrogen cryostats, and in magnetic field of 7.35T. Because of graphene's unique band structure, the first few Landau levels are well-separated energetically, thus allowing observation and manipulation of QHE at unprecedentedly high temperatures [1]. Our results overcome the obstacle of low operating temperature of traditional semiconductor systems-based QHE photodetectors [2], and open the door for wide arrays of applications.

4:30PM T28.00011 Phonon scattering in intrinsic graphene using tight-binding Bloch waves[1]

, NISHANT SULE, IRENA KNEZEVIC, University of Wisconsin - Madison — The overall interest in graphene as a material for devices has led to tremendous advances in the understanding of transport in graphene. However, there are still questions about the intrinsic limit to electron mobility. Recent experiments have demonstrated mobility greater than 10^7 cm^2/Vs at temperatures close to 50 K, exceeding previous theoretical predictions of the limit for intrinsic mobility. Here, we present a simple model for phonon scattering rates in intrinsic graphene using tight-binding Bloch wave functions for electrons. The tight binding approximation produces an accurate band structure near the Dirac points, as opposed to the nearly free electron model; thus, it is reasonable to assume that the electron wave functions are localized near the atomic centers. These tight-binding Bloch wave functions are calculated by linear combination of the carbon p_z orbitals. We show that the scattering matrix is anisotropic and the small overlap of the Bloch functions results in scattering rates that are lower in comparison to those calculated by assuming plane-wave wave functions. Electron mobility calculated in the relaxation time approximation is compared for scattering rates with Bloch functions and as well as plane waves.

4:42PM T28.00012 Chirality-dependent phonon-limited resistivity in graphenes[1]

, HONGKI MIN, EUYHEON HWANG, SANKAR DAS SARMA, Condensed Matter Theory Center, Department of Physics, University of Maryland — We develop a theory for the temperature and density dependence of phonon-limited resistivity $\rho(T)$ in bilayer and multilayer graphene, and compare with the corresponding monolayer result. For the unscreened case, we find $\rho \approx CT$ with $C \propto v_{\rm F}^{-2}$ in the high-temperature limit, and $\rho \approx AT^4$ with $A \propto v_{\rm F}^{-2} k_{\rm F}^{-3}$ in the low-temperature Bloch-Grüneisen limit, where $v_{\rm F}$ and $k_{\rm F}$ are Fermi velocity and Fermi wavevector, respectively. If screening effects are taken into account, $\rho \approx CT$ in the high-temperature limit with a renormalized C which is a function of the screening length, and $\rho \approx AT^6$ in the low-temperature limit with $A \propto k_{\rm F}^{-5}$ but independent of $v_{\rm F}$. These relations hold in general with $v_{\rm F}$ and a chiral factor in C determined by the specific chiral band structure for a given density.

4:54PM T28.00013 Boundary properties between monolayer and bilayer graphene and valley filter

, TAKESHI NAKANISHI, AIST, MIKITO KOSHINO, Tohoku Univ., TSUNEYA ANDO, Tokyo Inst. Tech. — Graphene consists of a two-dimensional hexagonal crystal of carbon atoms, in which electron dynamics is governed by the Dirac equation. The purpose of this paper is to study the boundary between monolayer and bilayer graphenes and show a valley polarization in transmission probability through the boundary [1]. We consider the boundary of monolayer and bilayer graphene, in which lower layer in bilayer graphene is continuously connected to the monolayer graphene and upper layer is terminated along a straight edge having zigzag or armchair structures. Boundary conditions between monolayer and bilayer graphene are derived in an effective-mass scheme. The transmission probability vanishes at the Dirac point and increases roughly in proportional to the electron density. The transmission probability varies strongly as a function of the incident angle and its maximum appears at an angle deviating from the vertical direction. This asymmetry is opposite between the K and K' points, showing that strong valley polarization can be induced across the interface of monolayer and bilayer graphenes.

5:06PM T28.00014 Anomalous tunneling of dressed Dirac electrons through potential barrier[1]

, ANDRII IUROV, Graduate Center, CUNY; Hunter College, CUNY, OLEKSIY ROSLYAK, GODFREY GUMBS, Hunter College, CUNY — It has been shown that when a potential barrier is placed on a layer of graphene, electrons incident on the barrier head-on can be transmitted without any reflection, regardless of how high the barrier is made to become. This anomalous scattering has also been investigated in the case of bilayer graphene. The energy gap between the valence and conduction bands for bilayer graphene leads to perfect reflection for head-on collisions for all barrier heights. We report on results for reflection and transmission coefficients for dressed Dirac electrons when circularly polarized light is applied to graphene and an energy gap in the energy bands is opened up. Since this gap depends on the frequency and intensity, we investigate how the electron and hole scattering off a fixed barrier is modified by varying the energy gap produced by light. We also present results for the transmission for the perpendicular incidentce. Both numerical and analytical results are obtained.

5:18PM T28.00015 In-gap transport in random-gap grapheme: metallic and insulating phases

, VAGHARSH MKHITARYAN, MIKHAIL RAIKH, Department of Physics and Astronomy, University of Utah, Salt Lake City, UT 84112, USA — 1D- like counter-propagating states at a gap center of graphene with random gap constitute two chiral networks. In the absence of intervalley scattering, transport over each network is either metallic or insulating, depending on the gap randomness. We demonstrate that properties of both phases as well as transitions between them are accurately captured within a simple real-space renormalization group approach. The most striking feature of this network transport is that it can be metallic even when the neighboring plaquettes are weakly coupled. We show that randomness in local gap signs reflected in randomness in signs of local transmission coefficients, gives rise to resonant transmission of the RG superblock. Delocalization occurs by proliferation of these resonances to larger scales. As the disorder exceeds a critical value, the RG flow towards insulator switches to a flow towards metallic fixed point. Evolution of the conductance distribution to metallic fixed point is synchronized with evolution of transmission coefficient signs, so that delocalization is accompanied with sign percolation.

Session T29 GQI: Focus Session: Superconducting Qubits - Coherence and Materials I

2:30PM T29.00001 Feedback suppression of the low-frequency noise in qubits by the low-frequency quantum measurements , QIANG DENG, DMITRI AVERIN, Department of Physics and Astronomy, SUNY, Stony Brook — The problem of the low-frequency noise has dominated the development of the solid-state qubits. Up to now, the main approach to solve this was to employ the qubit structures with the basis states having the same values of the main qubit coordinate (e.g., electric charge or magnetic flux) that are, as a result, not decohered by the noise. The goal of this work is to suggest an alternative approach based on direct suppression of the low-frequency noise in a qubit through the measurement/feedback loop. Continuous quantum measurement required for this loop should also be "low-frequency" so that it does not affect the quantum dynamics of the qubit. We calculate the minimal noise induced in the qubit by such a feedback loop when the measurement is the quantum-limited.

2:42PM T29.00002 Tunable quantum beam splitters for quantum manipulation of a hybrid tripartite qubit system[1] , G.Z. SUN, J. CHEN, P.H. WU, Research Institute of Superconductor Electronics, School of Electronic Science and Engineering, Nanjing University, X.D. WEN, Y. YU, Department of Physics, Nanjing University, Nanjing 210093, China, B. MAO, S.Y. HAN, Department of Physics and Astronomy, University of Kansas, Lawrence, KS 66045, USA — We demonstrated coherent control of quantum states in a tripartite system consisting of a superconducting qubit and two microscopic two-level states (TLS). An initially prepared qubit state was swept through qubit-TLS avoided crossings in the energy-level spectrum. The avoided crossings act as tunable quantum beam splitters of wave function. In an analogy to optics, the transmission coefficient of the beam splitters can be varied from zero to unity or any value in between by adjusting the rate of energy sweep. When performed within the decoherence time, consecutive crossings through the beam splitters lead to coherent quantum oscillations between the quantum states of the tripartite qubit-TLS system. This Landau-Zener-Stueckelberg interference controlled by the sweeping rate provides an alternative means to manipulate multiple qubits and demonstrates macroscopic quantum coherence.

[1]Supported by NCET, NSFC, the MOST of China (2011CB922104), NSF (DMR-0325551), and DMEA (H94003-04-D-0004-0149).

2:54PM T29.00003 Surface and Interface Defects in Linear and Nonlinear Superconducting Resonators , STEVEN WEBER, KATER MURCH, UC Berkeley, ALLISON DOVE, University of Illinois Urbana-Champaign, GUSTAF OLSON, gustafolson@gmail.com, ZACK YOSCOVITS, University of Illinois Urbana-Champaign, R. VIJAY, ELI LEVENSON-FALK, UC Berkeley, JAMES ECKSTEIN, University of Illinois Urbana-Champaign, IRFAN SIDDIQI, UC Berkeley — We report on progress to identify and mitigate noise mechanisms in both linear superconducting resonators and devices embedded with Josephson junctions. Defects, either microscopic fluctuators or remnant residue layers associated with nanofabrication, can exist on metal surfaces, at the metal-dielectric interface, within the dielectric, or within the Josephson junctions themselves. We have investigated the quality factor and phase noise of lumped element and distributed element resonators at low temperature and photon number- the operating regime of superconducting qubits. In particular, we compare the performance of poly-crystalline and epitaxial films, silicon and sapphire substrates, and weak link and tunnel type Josephson junctions.

3:06PM T29.00004 Quantum model for superconducting resonator loss via a two-level system , MISHKATUL BHATTACHARYA, K. OSBORN, A. MIZEL, Laboratory for Physical Sciences, University of Maryland, College Park, MD 20740 — Clarifying the mechanisms of dissipation in superconducting resonators is crucial for advancing superconducting quantum computation. The models currently employed to study dielectric loss due to two level charge fluctuators have been based largely on a classical treatment of the problem. In contrast, we carry out a quantum mechanical investigation using a dissipative Jaynes-Cummings model in which the resonator is coupled to a two-level system that is in turn coupled to a bath. We present an analysis of the dynamics of energy decay in the system, comparing its predictions to those of well-known classical models, which agree with our results in the limit of high oscillator excitation.

3:18PM T29.00005 Possible interactions between two-level system defects in SiNx films , SERGIY GLADCHENKO, MOE KHALIL, Laboratory for Physical Sciences, MD, C.J. LOBB, F.C. WELLSTOOD, University of Maryland, Department of Physics, KEVIN D. OSBORN, Laboratory for Physical Sciences, MD — Low-temperature properties of PECVD SiNx dielectric films are measured within the capacitor of superconducting LC resonators. Experiments are made at temperatures from 30 to 300 mK, and at storage energies from 1 to 10^6 photons in a resonant cavity. While the power and temperature dependence of the loss agrees with two-level system (TLS) theory above 60 mK, below this temperature we observe significant deviations. In this regime we observe a reduction in loss upon lowering dielectric temperature, in direct contrast with the independent TLS model of defects within our film. This new phenomena may indicate interactions between two-level systems. We can also spectroscopically resolve the loss from dominant defects in our capacitors, which have a volume of $\sim$2000 μm^3.

3:30PM T29.00006 A study of glassy behavior in amorphous dielectrics using GHz frequency superconducting resonators , MOE KHALIL, M.J.A. STOUTIMORE, University of Maryland and Laboratory for Physical Sciences, AARON HOLDER, CHARLES MUSGRAVE, University of Colorado, C.J. LOBB, F.C. WELLSTOOD, University of Maryland, K.D. OSBORN, Laboratory for Physical Sciences — It has been shown that the dielectric constant of certain glassy materials can be changed with a dc electric field bias. Here we extend those studies to higher frequencies where both the real and imaginary part of the dielectric constant can be studied. We have designed a dc electric-field tunable LC resonator built from superconducting thin-film aluminum to test this effect in SiN_x at GHz frequencies. We will report progress on measuring these devices down to single photon storage energies at temperatures of approximately 30 mK, where the dynamics are dominated by the tunneling of two-level defects.

3:42PM T29.00007 Microwave loss of novel epitaxial superconductor-insulator-superconductor (SIS) trilayers , U. PATEL, Department of Physics, University of Wisconsin, Madison, Wisconsin 53706, USA, K.H. CHO, Department of Materials Science and Engineering, University of Wisconsin, Madison, Wisconsin 53706, USA, L. MAURER, S. SENDELBACH, D. HOVER, Department of Physics, University of Wisconsin, Madison, Wisconsin 53706, USA, C.B. EOM, Department of Materials Science and Engineering, University of Wisconsin, Madison, Wisconsin 53706, USA, R. MCDERMOTT, Department of Physics, University of Wisconsin, Madison, Wisconsin 53706, USA — The performance of superconducting phase qubits is currently limited by spurious coupling of the qubit to two-level state (TLS) defects in the amorphous dielectric materials of the circuits. Thus, it is highly desirable to develop defect free epitaxial dielectric materials for improved junction barriers and capacitor dielectrics. We have characterized the dielectric loss of several candidate SIS trilayers including Re/MgO/Al and Re/$LaAlO_3$/Al grown on c-sapphire substrates. We describe our multiplexed microstrip resonator device layout and present data on the intrinsic quality factors of the MBE-grown dielectrics.

3:54PM T29.00008 Growth of epitaxial superconductor/dielectric heterostructures using a sputtering PLD hybrid system with in-situ RHEED , KWANG HWAN CHO, JACOB PODKAMINER, CHAD FOLKMAN, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison — One of limiting factors in superconducting qubits is decoherence caused by microscopic defects in dielectric layer such as nanocrystalline regions and grain boundaries in a shunted capacitor. We have grown epitaxial Re thin films on a c-plane sapphire substrate using RF magnetron sputtering, then transferred *ex-situ* to a pulsed laser deposition (PLD) system where dielectrics thin film layer is deposited. One drawback of this fabrication approach is the necessity to expose the sample to air when the sample is transferred to different deposition chambers. In order to avoid these drawbacks, we have employed a hybrid PLD-sputtering deposition that will allow us to grow the oxide dielectric/Re heterostructures in an *in-situ* environment without breaking vacuum. The system is also equipped with a reflection high energy electron diffraction (RHEED) which will allow us to perform *in-situ* characterization of the structure and growth dynamics. We will discuss our strategy of epitaxial growth of various single crystal dielectrics on superconducting thin films in this system and their structural and electrical properties of the heterostructures

4:06PM T29.00009 Barrier defect analysis using Josephson junction resonators[1] , M.J.A. STOUTIMORE, BAHMAN SARABI, MOE KHALIL, University of Maryland and Laboratory for Physical Sciences, C.J. LOBB, University of Maryland, K.D. OSBORN, Laboratory for Physical Sciences — We have designed Josephson junction (JJ) resonators by adding an Al/AlO_x/Al Josephson junction in parallel with a coplanar sapphire capacitor and an inductor so that the total loss will be dominated by the junction barrier. JJ resonators couple to individual defects in the junction barrier, causing splittings in the spectroscopy of the resonator when it is excited near single-photon energies, similar to phase and other qubits. Measurements are performed in a dilution refrigerator at 30mK with a drive frequency of approximately 7GHz. By applying a dc flux bias, we can tune the resonance frequency by as much as 1GHz. Analysis of the frequency of splittings as a function of junction area and barrier growth process provides a method for determining the source of the defects. We will use these devices to study amorphous aluminum oxide barriers and will report our progress towards studying novel barrier dielectrics.

[1]This research was supported by the Intelligence Advanced Research Projects Activity through the U.S. Army Research Office award No. W911NF-09-1-0351.

4:18PM T29.00010 Losses in Josephson junction resonators , MARTIN WEIDES, National Institute for Standards and Technology, Boulder, JIANSONG GAO, JEFFREY KLINE, MICHAEL VISSERS, DAVID WISBEY, DAVID PAPPAS — Josephson junctions for superconducting circuits such as SQUIDs and qubits are conventionally based on Al-AlO_x-Al multilayer technology, which was shown to have a low quality factor and two-level-fluctuators in the dielectric AlO_x as limiting decoherence source. By replacing the amorphous Al-rich tunnel oxide with nearly stoichiometric Al_2O_3 we aim to increase the qubit coherence times by reducing the number of dangling bonds in the Josephson tunnel junction. In this talk a test platform for loss determination in high-Q tunnel oxides based on junction resonators will be presented. We will show alternative tunnel junctions based on high temperature grown tunnel oxides.

4:30PM T29.00011 Growth and Properties of Epitaxial Dielectrics/Superconducting Thin Film Heterostructures , CHANG-BEOM EOM, University of Wisconsin-Madison, KWANG-HWAN CHO, JACOB PODKAMINER, CHAD FOLKMAN — Our objective is the growth of epitaxial dielectrics on crystalline superconducting underlayers to improve the performance of superconducting Qbits. A major challenge is heteroepitaxial growth of single crystal dielectric layers with high crystalline quality and atomically sharp interfaces between the dielectric and superconducting electrodes. First, we have grown high quality epitaxial rhenium (Re) thin films on c-plane sapphire substrates by DC magnetron sputtering. The full width at half maximum (FWHM) of Re 0002 rocking curve is less than 0.5 degrees. The RMS surface roughness determined by AFM is less than 1 nm. We have also grown epitaxially various dielectric thin films on top of the single crystal Re bottom electrode by pulsed laser deposition with in situ high pressure reflection high energy electron diffraction (RHEED). In this talk, we will discuss our strategy of epitaxial growth of various single crystal dielectrics on superconducting thin films and their structural and electrical properties of the heterostructures.

4:42PM T29.00012 Microwave Response of Superconducting Resonant Circuits based on 3D Aluminum Nanobridge Josephson Junctions , ELI LEVENSON-FALK, R. VIJAY, KATER MURCH, IRFAN SIDDIQI, QNL, UC Berkeley — Metallic weak links are attractive candidates for low loss superconducting circuits as they offer a route to realize Josephson junctions without the need for an amorphous tunnel barrier-a potential source of both low and high frequency noise. We discuss microwave measurements of high quality factor resonators incorporating both single nanobridges and nanobridge-based SQUIDs. Our results indicate low loss and strong nonlinearity, suggesting the future utility of these devices in qubit and amplifier circuits. Our data are in quantitative agreement with numerically computed nanobridge current-phase relations and dc transport measurements. We show preliminary results on nanobridge-based qubits and parametric amplifiers.

4:54PM T29.00013 Josephson junctions formed from superconducting nanowires[1] , B. XIAO, H.Y. CHEN, I. NSANZINEZA, C. SONG, B.L.T. PLOURDE, Syracuse University — We are investigating the possibility of forming Josephson junctions from thin-film superconducting nanowires. The Josephson coupling through such a constriction can provide the necessary nonlinearity, for example, for forming a qubit, while avoiding the influence of defects in the amorphous tunnel barriers used in conventional Josephson junctions that can contribute to qubit decoherence. We have developed a fabrication process based on high-resolution electron-beam lithography with a negative-tone resist combined with ion-beam etching to pattern nanowires from 10 nm-thick, sputter-deposited, amorphous MoGe thin films. We have studied nanowires with widths between 20 - 100 nm and lengths between 50 - 200 nm. A Nb wiring layer provides electrical connections to the nanowires. Low-temperature transport measurements allow us to study the nanowire critical current and the influence of microwave irradiation on the current-voltage characteristics.

[1]Work supported by IARPA

5:06PM T29.00014 Via fabrication process for epitaxial superconducting qubits , JEFFREY KLINE, FABIO DA SILVA, MICHAEL VISSERS, DAVID WISBEY, MARTIN WEIDES, DAVID PAPPAS, NIST — Reducing the density of spurious two level systems (TLS) in the dielectric layers of superconducting qubits has been shown to improve performance. We aim to reduce TLS density in the Josephson junction tunnel barrier through the use of epitaxial materials. The investigation of some new material systems using a trilayer process wherein the base electrode, tunnel barrier, and top electrode are grown and subsequently patterned is problematic due to sidewall damage during the mesa etch. We apply the via fabrication process wherein the base electrode and wiring insulator layers are grown and patterned prior to tunnel barrier growth. The via process is compatible with a different set of electrode materials than the trilayer process and allows us to investigate the suitability of these materials for qubit applications. We present room temperature and low temperature data for Re/Al_2O_3/Re Josephson junctions fabricated using the via process.

5:18PM T29.00015 Introduction of a DC Bias into a High-Q Superconducting Microwave Cavity , FEI CHEN, JULIANG LI, M.P. BLENCOWE, A.J. RIMBERG, Dartmouth College, ADAM SIROIS, University of Colorado, Boulder, RAYMOND SIMMONDS, National Institute of Standards and Technology, Boulder — The circuit quantum electrodynamics (QED) architecture has been demonstrated to allow study of cavity QED physics in a high-Q on-chip microwave cavity[1]. Here we develop a technique to apply a DC current or voltage bias to nanostructures embedded in the microwave cavity without significantly degrading the Q at high frequencies. Experimental results show good agreement with theoretical predictions. New highly non-linear fully quantum mechanical devices can be developed by embedding Josephson junction devices such as single electron transistors (SETs) in the high-Q microwave cavity. The interplay between the SET and the microwave cavity offers an interesting system for studying nonlinear quantum dynamics and the quantum-to-classical transition. Recent experimental results will be discussed.

2:42PM T30.00002 UHV-Compatible Aerosol-Molecule Beam Deposition Source for Organic Electronic Films[1] , LEVAN TSKIPURI, QIAN SHAO, JANICE REUTT-ROBEY, University of Maryland — The rapidly advancing technologies of flexible electronics and organic photovoltaics have triggered strong interest in new methods for electronic materials deposition from the solution phase. Materials deposition based upon direct aerosol flow offers advantages both for fundamental studies of film growth and analysis and for industrial preparation of high-performance materials. We describe an aerosol deposition source based upon a spray-jet molecular beam technique. The source produces a supersonic molecular beam of solutes (such as C_{60}PCBM ([6,6]-phenyl-C_{61}-butyric acid methyl ester) or graphene flakes) in $\sim$10 μ solvent droplets entrained in a nitrogen carrier gas. The twice-differentially pumped source is then mated to a UHV-STM system, for fundamental studies. The source has been used to generate films of C_{60}PCBM, CNT's, and graphene/PPV composites on SiO_2 and mica substrates. The spray-jet deposition provides much greater control of the growth kinetics, relative to conventional spin-coating, permitting films to be grown with submonolayer control, as we demonstrate in the growth of C_{60}PCBM films.

2:54PM T30.00003 Preparation and Characterization of α-Fe_2O_3 Nanoparticles by a Solution-Phase Auto-Combustion Method , MARC DOYLE, Drexel University, MICHAEL LATTANZI, BRIAN KELLY, KARL UNRUH, University of Delaware — The effects of the reaction conditions on the structural and magnetic properties of α-Fe_2O_3 nanoparticles prepared from the combustion products of Fe(III)-nitrate/citric acid/NaOH solutions have been systematically studied in order to gain insights that might be useful in the preparation of more complex oxides from other solution-phase auto-combustion precursors. This work has focused on the effects of the initial solution pH and fuel/oxidant ratio. In particular, precursor powders have been prepared from solutions with pH values between 1 and 12 and with fuel/oxidant ratios between 0.5 and 1.5. Increasing the solution pH and/or the fuel/oxidant ratio lead to significantly less dense and more porous precursor powders due to the greater amount of gaseous reaction products produced under these conditions. X-ray diffraction measurements indicated that under these reaction conditions a higher annealing temperature was required to obtain a phase pure α-Fe_2O_3 product.

3:06PM T30.00004 Synthesis, Microstructure and Bulk Properties of Complex Nasicon-Type Ceramics[1] , KRISTINA LIPINSKA, OLIVER HEMMERS, JULIEN ROMANN, Harry Reid Center for Environmental Studies, University of Nevada Las Vegas, NV, USA, STANISLAV SINOGEIKIN, Geophysical Lab, Carnegie Institution of Washington, Washington, DC, USA, PATRICIA KALITA, HiPSEC & Dept.of Physics, University of Nevada Las Vegas, Las Vegas, NV, USA, SHEKAR BALAGOPAL, ANTHONY NICKENS, CERAMATEC Inc. Salt Lake City, UT, USA — Fast ion-conductors from the NASICON family ($Na_{1+x}Zr_2Si_xP_{3-x}O_{12}$) have been the subject of extensive research due to their use in electrochemical devices such as batteries, fuel cells, thermoelectric generators and chemical sensors A fabrication challenge for these materials is to maintain long term chemical and physical stability in harsh environments We apply a multi-technique approach to show how partial substitutions with tetravalent and pentavalent cations produce NASICONs with specific morphology and modify the primary to secondary crystalline phase ratios. We use in situ synchrotron x-ray diffraction to investigate pressure-induced structural modifications and compressibility.

3:18PM T30.00005 Crystal structure and multiferroic properties of the $0.7(BaTiO_3) - 0.3(Bi_{0.45}Dy_{0.55}FeO_3)$ ceramic composite , RICARDO MARTINEZ, NORA ORTEGA, ASHOK KUMAR, RATNAKAR PALAI, RAM S. KATIYAR, University of Puerto Rico — Magnetoelectric multiferroics are a novel class of next generation multifunctional materials. Intensive research is being pursued towards the development of new room temperature multiferroics with strong magnetoelectric (ME) coupling. $BaTiO_3$(BT) is well known ferroelectric and $Bi_{0.45}Dy_{0.55}FeO_3$(BDFO) is multiferroic in nature with weak ferroelectric properties. We have synthesized lead free ceramic composite consisting of 0.7BT–0.3BDFO (BT-BDFO) by conventional solid state. X-ray diffraction and Raman analysis revealed two sets of peaks which belong to BT and BDFO suggesting that the individual phases are retained in the composite ceramic, no additional peaks were observed. The presence of ferromagnetic and ferroelectric hysteresis loops at room temperature (M_s=14.3 emu/cm^3, M_r=1.7 emu/cm^3, P_r=3.6 μC/cm^2 and E_c=1.7 kV/cm) showed multiferroic nature of the BT-BDFO ceramic. Although the polarization and magnetization values obtained were lower compared with pure $BaTiO_3$and BDFO respectively, magneto-dielectric measurements reveled a shifting of the dielectric constant peak from 2 MHz to 4 MHz with increase of magnetic field from 0 T to 2 T.

3:30PM T30.00006 Cation Ordering within the Perovskite Block of a Six-layer Ruddlesden-Popper Oxide from Layer-by-layer Growth , LEI YAN, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, H.J. NIU, M.J. ROSSEINSKY, Department of Chemistry, University of Liverpool, Liverpool, L697ZD, UK — The $(AO)(ABO_3)_n$ Ruddlesden-Popper structure is an archetypal complex oxide consisting of two distinct structural units, an (AO) rock salt layer separating an n-octahedra thick perovskite block. Conventional high-temperature oxide synthesis methods cannot access members with $n > 3$, but low temperature layer-by-layer thin film methods allow the preparation of materials with thicker perovskite blocks, exploiting high surface mobility and lattice matching with the substrate. This presentation describes the growth of an $n = 6$ member $CaO/(ABO_3)_n$ (ABO_3: $CaMnO_3$, $La_{0.67}Ca_{0.33}MnO_3$ or $Ca_{0.85}Sm_{0.15}MnO_3$) epitaxial single crystal films on the (001) $SrTiO_3$ substrates by pulsed laser deposition with the assistance of a reflection high energy electron diffraction (RHEED).

3:42PM T30.00007 Morphological Transformation of Copper Catalysts within Helically Coiled Carbon Nanofibers[1]

, LIFENG DONG, Missouri State University, LIYAN YU, QIAN ZHANG, Qingdao University of Science and Technology — With tailoring synthesis parameters, different carbon nanostructures including carbon nanotubes, carbon nanofibers, and graphene, can be synthesized using copper (Cu) as catalysts and acetylene as carbon source. Some remarkable progress has been made in synthesis techniques; however, pioneering breakthroughs have not been made yet in terms of growth mechanism, especially interactions between catalyst particles and acetylene molecules. In this study, the growth mechanism of helically coiled carbon nanofibers and morphological changes of Cu catalysts were investigated using a number of electron microscopy and microanalysis techniques, such as scanning electron microscopy (SEM), transmission electron microscopy (TEM), scanning transmission electron microscopy (STEM), and electron energy loss spectroscopy (EELS). Following the synthesis, single-crystal Cu particles deformed to small nanoparticles of cuprous oxide (Cu2O) due to internal strain, and Cu2O nanoparticles migrated within carbon nanofibers.

4:06PM T30.00009 Templated Electrodeposition of Highly Porous Nanostructured Materials[1]

, HAN-CHANG YANG, STEPHANIE LIM, JIABIN LIU, QIAN WU, X.M. CHENG, Bryn Mawr College — The fabrication of nanoporous materials has been of great interest for applications such as biosensors, photonic materials and energy storage. Compared to many other methods, the templated electrodeposition method is low cost, fast, and compatible with large-scale production. In this work, we developed a templated electrochemical deposition technique for fabricating highly ordered and highly porous nanostructured materials. The fabrication involves the following steps: self-assembly of monodispersed polystyrene spheres, electrochemical deposition of the desired materials, and sphere removal by a dissolution process. Deposition of Au and Ni layered metallic nanoporous structures were studied using different electrolytes at appropriate potentials. The pore size of the materials was tuned by using different sizes of template polystyrene spheres ranging from 50nm to 1000nm. Scanning electron microscopy images confirmed the highly ordered 3-dimensional hexagonal closed pack (hcp) structures in the samples. The templated electrochemical deposition technique provides a promising alternative approach to preparing highly porous anode materials for battery applications.

4:18PM T30.00010 Entropic inflation of ideal zeolitic frameworks

, VITALIY KAPKO, COLBY DAWSON, MICHAEL TREACY, Arizona State University — Ideal zeolites can be viewed as flexible networks of rigid, corner-sharing tetrahedra. Recent studies have shown that such systems can exist at a range of densities (termed the "flexibility window") without breaking topology or deforming the comprising tetrahedra. They also have shown that densities of real zeolites almost always correspond to the lowest densities within this range. This anomalous behavior is usually attributed to coulombic repulsion between oxygen atoms in framework cavities and channels. In this paper we show that the inflation of ideal zeolites can be driven by entropy. This effect is closely related to displacive phase transitions often observed in zeolites and related materials like quartz, which cannot be explained by potential energy minimization alone. We show that periodicity and high symmetry in ideal zeolites is a result of entropy maximization. An estimation of entropy using a harmonic oscillator model with a realistic force field is given.

4:30PM T30.00011 Topological defects in model nanoporous carbon: population, structural characterizations and adsorption properties

, XI MI, JEREMY PALMER, JORGE PIKUNIC, KEITH GUBBINS, YUNFENG SHI — Nanoporous carbon materials have drawn substantial research interests because of their unique capabilities to mediate the mass-transport, uptake through adsorptions and catalyze chemical reactions of the guest species. All aforementioned properties depend sensitively on the structural characteristics of the nanoporous carbon, including hybridization state of carbon, presence of functional groups, topology of carbon rings and curvature/connectivity of graphene sheets. Among all these defects, carbon pentagons are of particular interests since they possess 108° C-C-C bond angles which are dramatically different from the 120° angles typical for carbon hexagons and larger carbon rings. However, the pentagon concentration in the bulk has not been determined. Here we use a realistic nanoporous carbon model proposed recently to systematically synthesize a large number of samples with different concentrations of carbon pentagons using molecular simulation methods. We evaluate the different porous structures in terms of their deviations in s(q) from experiments so as to estimate pentagon concentrations. Moreover, the porous structures are related to the adsorption properties through simulated argon adsorption tests.

4:42PM T30.00012 The stability of capillary climbing flows in porous media opposed by gravity force

, B. MARKICEVIC, H.K. NAVAZ, Kettering University — The experimental and numerical data reveal that the capillary climb opposed by gravity force starts as a stable flow for low climbing height, which is followed by unstable flow and multiphase pattern for higher climbing heights. For the stable flow, a sharp interface between the liquid and gas phase exists, which transforms later into a flow front of increasing thickness as climbing progresses. The flow front thickness is calculated from the difference between instantaneous climbing height and maximum stable climbing height. We carry out the analysis of capillary climb flow stability using the capillary and the Bond number, as well as using the generalized Bond number. The critical generalized Bond number defines the condition for which the interface transforms to the flow front. For three distinct porous media consisting of glass beads, and having a thin layer of low permeable material at the bottom of the glass beads columns, the values of critical generalized Bond number and the exponents in the power law of flow front thickness as a function of the generalized Bond number are compared. Furthermore, the flow stability analysis is extended to two additional cases in which a low-permeable layer is removed from the column bottom, and the case of pure capillary flow (without gravity). The corresponding critical generalized Bond numbers and the power law exponents are compared.

4:54PM T30.00013 Soaring to New Heights in Natural Materials[1]

, SARA BODDE, JAMES KIANG, JOANNA MCKITTRICK, University of California, San Diego — Feathers are the most distinguishable feature of all modern Aves. Flight feathers exemplify several materials science phenomena. The most obvious attribute is the branching or hierarchical structure at macroscale to mesoscale. The primary shaft, or rachis from which secondary features project, of the flight feather is a sandwich structured composite. The thin brittle cortex of the rachis and barbules encloses a relatively thick, low-density medullary core or cellular solid. The cortex of the rachis is constructed as a fiber-reinforcement composite, and structural variations along the length of the feather invoke the comparison to functionally graded materials. We have studied microstructure and mechanical properties of the feather rachis in a piecewise fashion, and we will present results of investigations of the mechanical behavior and failure of the composite and parts thereof in tension, compression, and flexure.

5:06PM T30.00014 Three-dimensional video imaging of drainage and imbibition processes in model porous medium , PRERNA SHARMA, P ASWATHI, ANIT SANE, SHANKAR GHOSH, SABYASACHI BHATTACHARYA, TIFR, Mumbai, India — We report experimental results where we have performed three dimensional video imaging of the displacement of an oil phase by an aqueous phase and vice versa in a model porous medium. The stability of the oil water interface was studied as a function of their viscosity ratios, the wettability of the porous medium and the variation in the pore size distribution. Our experiments captures the pore scale information of the displacement process and its role in determining the long time structure of the interface.

Wednesday, March 23, 2011 2:30PM - 5:30PM –
Session T31 DCMP: Novel Structural Chemistry & Materials C145

2:30PM T31.00001 Theoretical studies of the caged hydrocarbon, octahedrane ($C_{12}H_{12}$, D_{3d})[1] , STEVEN RICHARDSON, Howard University, DANIEL FINKENSTADT, U. S. Naval Academy, MICHAEL MEHL, MARK PEDERSON, Naval Research Laboratory — Polyhedral hydrocarbon cages provide an interesting class of molecules for experimental and theoretical study because of their unique shapes. One such molecule is octahedrane ($C_{12}H_{12}$, D_{3d}) which was first synthesized by Lee *et al.* in 1993.[2] Octahedrane contains two fused three-membered rings and six five-membered rings. Theoretical work by de Meijere *et al.*[3] using density-functional theory (DFT) has shown that octahedrane is more strained than the structurally related molecules decahedrane ($C_{16}H_{16}$, D_{4d}), which has two fused four-membered rings and eight five-membered rings, and dodecahedrane ($C_{20}H_{20}$, I_h), which has two fused-membered rings and ten five- membered rings. In this work we report the first DFT calculations of the infrared and Raman vibrational spectra for octahedrane which will be of importance for future efforts in characterizing this unique caged hydrocarbon.

[1]We are grateful to the ONR for financial support of this work.

2:42PM T31.00002 Golcondane (C20H24): Theoretical studies of a novel strained, caged hydrocarbon molecule[1] , DANIEL FINKENSTADT, U.S. Naval Academy, MICHAEL MEHL, MARK PEDERSON, U.S. Naval Research Laboratory, STEVEN RICHARDSON, Howard University — In 1993 Mehta and Reddy reported the synthesis of a new C_{20} polyhedrane, which they named golcondane ($C_{20}H_{24}$, D_{2d}) in honor of the 400^{th} anniversary of the founding of the Indian city of Hyderabad, whose original name was Golconda. Golcondane is a caged, nonacyclic hydrocarbon that has two fused four-membered rings, four fused five-membered rings, and two fused seven-membered rings. Its chemical structure was determined by ^{13}C NMR spectroscopy and unpublished X-ray crystal diffraction studies. Motivated by our previous success in using density-functional theory (DFT) to compute the structural, electronic, and vibrational properties of other hydrocarbons such as cubane, octanitrocubane, the medium-sized diamondoid molecule cyclohexamantane, as well as the novel class of materials known as *sila*-diamondoids, we have used DFT and tight- binding molecular dynamics (TBMD) to compute from first- principles similar properties for golcondane. Our work is especially significant with the lack of other theoretical or experimental studies on this interesting molecule in the published literature.

[1]We are grateful to the ONR for financial support of this work.

2:54PM T31.00003 Spectroscopic identification of bond strain and pi interactions in a series of saturated carbon-cage molecules: adamantane, twistane, octahedrane, and cubane , TREVOR M. WILLEY, J.R.I. LEE, T. VAN BUUREN, LLNL, L. LANDT, TU Berlin, P.R. SCHREINER, A.A. FOKIN, B.A. TKACHENKO, N.A. FOKINA, JLU Giessen, D. BREHMER, SLAC — Novel nanocarbons such as fullerenes, nanotubes, graphene, and nanodiamond reside at the cutting edge of nanoscience and technology. Along with chemical functionalization, geometrical constraints such as extreme curvature or defects in crystallites can modify the electronic properties. This paper presents a fundamental study of how bond strain affects electronic structure in a benchmark series of novel saturated carbon cage compounds. Adamantane, the smallest diamondoid, has carbon atoms commensurate with the diamond lattice. Twistane has the same stoichiometry ($C_{10}H_{16}$), but introduces some bond strain into the cage. Octahedrane ($C_{12}H_{12}$) and cubane (C_8H_8) have increasing strain, culminating in cubane where C-C bonds lie either parallel, or orthogonal to one another. Using gas-phase NEXAFS spectroscopy, we observe the broad C-C σ* splits into two more narrow and intense resonances with increasing strain. Also, LUMO states associated with tertiary C-H σ* broaden and shift to lower energy, and are 3X more intense in cubane than octadedrane. The differences are entirely due to the shape rather than stoichiometry, and indicate, we believe, some π interaction between parallel C-C bonds in the cubane.

3:06PM T31.00004 Spectroscopy and Structure of Diamondoid-Fullerene Hybrid Molecules at the Single-Molecule Level[1] , JASON C. RANDEL, GEORGES NDABASHIMIYE, HARI C. MANOHARAN, Stanford University — Diamondoids—a nanometer-scale form of carbon sharing the sp^3 bonding structure of bulk diamond—are promising new electronic and mechanical device elements and have recently become accessible to experiments. While new fields of research have also sprouted from carbon's sp^2 forms (such as graphene, fullerenes, and carbon nanotubes), materials representing the intersection of sp^2 and sp^3 bonding structures are an exciting new arena for nanoscale science and technology. In this study, we investigate hybrid molecules fusing sp^2 and sp^3 allotropes of carbon (in the form of C_{60} fullerenes and molecular diamondoids, respectively) into one well-defined system. We use low-temperature scanning tunneling microscopy to characterize monolayers and single molecules with sub-molecular resolution. We show the degree to which the electronic properties of the hybrid molecules differ from their single-allotrope components, and highlight the intriguing electronic features that emerge which have no analog in either of the separate molecular constituents.

[1]We thank S. Melinte for aiding measurements, and J. E. P. Dahl, R. M. Carlson, and P. R. Schreiner for materials and synthesis. We acknowledge support from DOE and the Chevron Corporation.

3:18PM T31.00005 The Study of Hypothetical Carbon Allotropes Using Hartree Fock and Density Functional Computational Methods , P.A. ECTON, C.J. MORRIS, J.M. PEREZ, Department of Physics, University of North Texas, S.G. SRIVILLIPUTHUR, Department of Materials Science and Engineering, University of North Texas, G.F. VERBECK, Department of Chemistry, University of North Texas — We have investigated the possibility of hypothetical alternative carbon allotropes using computational methodologies using Gaussian and VASP molecular simulation programs. We investigate the possible existence of carbon based balls, nanotubes and sheets composed of hexagonal rings, cyclobutane rings or pentagonal rings. The possibility of the existence of a hypothetical allotrope is determined by the convergence of the given allotrope under geometric optimization. The theories used to compute such convergence are Hartree-Fock theory and density functional theory. The theoretical Raman spectra of each allotrope can also be computed using Gaussian. The results concerning the reality of the substances under investigation are inconclusive except for a C_{24} ball, which has been shown to converge to graphene and is therefore an unstable molecule.

3:30PM T31.00006 Electron Beam Stimulated Molecular Motions of C_{60}s inside Single-Walled Carbon Nanotubes , KE RAN — Electron beam irradiation stimulated motions of carbon nanostructures from single C_{60} to C_{60}s chain inside single-walled carbon nanotubes (CNTs) were investigated by low voltage and high resolution TEM. Single C_{60}'s jump in a defective zigzag C_{60}s molecular chain inside host CNT was observed. A cluster of C_{60}s inside an isolated partially filled CNT can translate back and forth within the hollow space for several times. Intermediate states of these translations were recorded as well, together with pickup of additional C_{60}s when the moving cluster reached either end of the hollow space. Continuous rotation of a zigzag C_{60} molecular chain inside an overloaded CNT resulted in alternate expansion and contraction of the projected width of the host CNT in the TEM images. The maximum expansion was up to 29%. Potential calculation for the molecular motion was performed based on the van der Waals interaction among C_{60}s and CNT. Activation energies ranging from 0.3 eV to 0.7 eV were estimated. The molecular motion was attributed to momentum transfer during elastic scattering of electrons by the molecules, instead of thermal energy or thermal gradient. Our study demonstrates the potential of driving molecular motion by electron irradiation.

3:42PM T31.00007 First-Principles Calculations of Graphene Nanomesh , WILLIAM OSWALD, ZHIGANG WU, Colorado School of Mines — Graphene has recently attracted intensive attentions owing to its remarkable structural and electronic properties and its significant potential for applications in electronic and optoelectronic devices for size miniaturization and fast electron transportation. However, bulk graphene is a semi-metal with zero bandgap E_g, and opening a sizable E_g is critical for building operational graphene-based transistors. Recently, a new scheme of opening bandgap through punching nanoscale holes in graphene sheet, the graphene nanomesh, was proposed and verified experimentally [1]. However, the mechanism leading to the bandgap opening remains unknown. We have carried out first-principles calculations based on density functional theory (DFT) to study the bandgap opening mechanism and E_g as functions of structural parameters, including the hole size, the hole shape, and the hole-hole distances. Our results suggest that the bandgap opening is a result of quantum confinement at nanomesh necks, while the value of E_g depends not only on the width of nanomesh necks, but also on the chirality of the hole edge. This work was supported by the start-up research funds from Colorado School of Mines.

3:54PM T31.00008 ABSTRACT WITHDRAWN –

4:06PM T31.00009 Effects of shape and edge-passivation on magnetic moments in graphene nanomesh by first-principles investigation , HONGXIN YANG, MAIRBEK CHSHIEV, SPINTEC, UMR-8191, CEA-INAC/CNRS/UJF-Grenoble 1/Grenoble-INP, Grenoble, France, SPINTEC TEAM — First-principles calculations of electronic and magnetic properties of pure and H-terminated graphene nanomesh (GNM) are presented. We found stable antiferromagnetic and non-magnetic ground state for GNM with balanced zigzag and armchair-type edge structures, respectively. At the same time, a band gap opening in the balanced zigzag edge GNMs which can reach up to 0.40 eV is also found. Interestingly, GNM with unbalanced edge structure shows stable ferrimagnetic state giving rise to a net moment up to 4 Bohr magnetons per unit cell, and the exchange energy between ferrimagnetic state and paramagnetic state is larger than 1 eV per unit cell providing potential for high Curie temperature in this material. Furthermore, we found that the ground states for H-terminated GNM strongly depend on the hole symmetry: large spin polarization ground state is found for GNMs with triangle and pentagon hole shapes, while for GNMs with parallelogram and hexagon shaped holes the ground states are paramagnetic. Finally, we found that the magnetization of the GNM structure is strongly affected by the hole size: the larger hole size attains large moments, while small one may even kill all the moments.

4:18PM T31.00010 Sensing gas molecules using graphitic nanoribbon films and networks , YANBIN AN, JASON L. JOHNSON, ASHKAN BEHNAM, S.J. PEARTON, ANT URAL, University of Florida — We fabricate and study the gas sensing properties of graphitic nanoribbon (GNR) films and networks consisting of multi-layer graphene nanoribbons with an average width of 7 nm. We experimentally demonstrate the high sensitivity of these films and networks for sensing gas molecules at the parts-per-million (ppm) level, in particular hydrogen and ammonia. The sensing response exhibits excellent repeatability and full recovery in air. Furthermore, our results show that functionalization by metal nanoparticles could significantly improve the sensitivity. We characterize the sensing response at various temperatures, gas concentrations, recovery ambients, and film thicknesses. We find that the relative resistance response of the GNR films shows a power-law dependence on the gas concentration, which can be explained by the Freundlich isotherm. The activation energy obtained from the sensing experiments is consistent with the theoretical calculations of the adsorption energies of gas molecules on graphene sheets and nanoribbons. Their simple and low-cost fabrication process and good sensing response open up the possibility of using graphitic nanoribbon films and networks for large-scale sensing applications.

4:30PM T31.00011 Opening of slit-shaped pores from bending of graphene walls[1] , MATTHEW CONNOLLY, University of Missouri-Columbia, CARLOS WEXLER, University of Missouri - Columbia — Graphene has gained particular interest in many areas of research including adsorption. Recent studies have shown deformations in graphene resulting from the pressure of intercalants or edge bonds. In this talk, the opening of slit shaped pores from uniaxial bending of the graphene walls of the pore is examined. The energy functional associated with the deformation from equilibrium shape is minimized to obtain an optimal shape. The minimization is done analytically for a simple model and numerically for various graphene-graphene interaction potentials. The strain induced from bending has been shown to effect the hybridization of carbon bonds within the graphene sheet. The effect of any increase in the number of binding sites due to bending as well as hybridization effects on excess adsorption are studied by Molecular Dynamics simulations.

[1]This material is based upon work supported in part by the Department of Energy under Award Nos. DE-FG02-07ER46411, DE-FG36-08GO18142 and DE-AC02-06CH11357.

4:42PM T31.00012 Magneto-reflectance studies of graphite in intense magnetic field , LI-CHUN TUNG, National High Magnetic Field Laboratory, PAUL CADDEN-ZIMANSKY, Columbia University, JINBO QI, Los Alamos National Laboratory, ZHIGANG JIANG, Georgia Innstitute of Technology, DMITRY SMIRNOV, National High Magnetic Field Laboratory — Magnetic subbands of Kish graphite have been investigated by the magneto-infrared reflectance spectroscopy at 4K up to 31T. Both of the Schrödinger- (K-point) and Dirac-like (H-point) Landau level transitions have been observed. The intense magnetic field resolves the transitions caused by the symmetry breaking of the doubly degenerate E3 band near the charge-neutrality point and the splitting of interband transitions due to electron-hole asymmetry. These transitions were not evident in the recent magneto-transmittance studies at high magnetic fields and are important in understanding electron-hole asymmetry and the opening of the energy gap between electron and hole bands. From the SWMC model, we derived a new formula to describe the magnetic field dispersion of the K-point transitions and a good agreement is achieved with a set of band parameters consistent with the ones reported in the literature.

4:54PM T31.00013 Size-dependence of electronic and optical properties of armchair graphene nanoislands[1] , JONATHAN MOUSSA, JAMES CHELIKOWSKY, UT Austin — Atomicly precise armchair graphene nanoislands (benzenoid polycyclic aromatic hydrocarbons) have been produced by organic synthesis and to-date have attained sizes up to 222 carbon atoms. The electronic and optical properties of these nanoislands are studied using a combination of semi-empirical methods, time-dependent density functional theory, and the GW/Bethe-Salpeter formalism. Comparisons are made with experimental measurements where available. For this class of materials, theory is able to predict the necessary nanoisland sizes required for potential photovoltaic and light-emitting applications. The study of large nanoislands is focused on parallelogram-shaped islands, which should be particularly amenable to synthesis over a wide range of sizes.

5:06PM T31.00014 Modifying Electronic and Magnetic Properties of BCN sheets by Boron Nitride Domain Size and Tensile Strain[1] , CHUN TANG, CHANGFENG CHEN, Department of Physics and Astronomy and High Pressure Science and Engineering Center, University of Nevada, Las Vegas, NV 89154 — Recent experiments have successfully synthesized atomic thin BCN hybrid composites with controllable BN domain concentration. Using first principles calculations, we report the scaling law of electronic and magnetic properties of this novel structures with respect to BN domain size and geometry. We find due to the BN domain induced internal electric field, the magnetic moment can be effectively modified. External tensile strain engineering can also be applied as an efficient tool to modify the electronic and magnetic properties. Our results may have important applications in semiconducting devices.

[1]Work supported by DOE Grant:DE-FC52-06NA26274.

5:18PM T31.00015 Functionalized 2D atomic sheets with new properties , QIANG SUN, JIAN ZHOU, Peking University, QIAN WANG, PURU JENA, Virginia Commonwealth University — Due to the unique atomic structure and novel physical and chemical properties, graphene has sparked tremendous theoretical and experimental efforts to explore other 2D atomic sheets like B-N, Al-N, and Zn-O, where the two components offer much more complexities and flexibilities in surface modifications. Using First principles calculations based on density functional theory, we have systematically studied the semi- and fully-decorated 2D sheets with H and F and Cl. We have found that the electronic structures and magnetic properties can be effectively tuned, and the system can be a direct or an indirect semiconductor or even a half-metal, and the system can be made ferromagnetic, antiferromagnetic, or magnetically degenerate depending upon how the surface is functionalized. Discussions are made for the possible device applications.

Session T32 FIAP: Semiconducting Devices & Applications C144

2:30PM T32.00001 Tunable nonadiabatic excitation in a single-electron quantum dot , J.D. FLETCHER, MASAYA KATAOKA, P. SEE, S.P. GIBLIN, T.J.B.M. JANSSEN, National Physical Laboratory, Hampton Road, Teddington, Middlesex TW11 0LW, United Kingdom , J.P. GRIFFITHS, G.A.C. JONES, I. FARRER, D.A. RITCHIE, Cavendish Laboratory, University of Cambridge, J J Thomson Avenue, Cambridge CB3 0HE, UK — We report observation of nonadiabatic excitation of single electrons in a quantum dot. We have developed a way of measuring the excitation spectrum of the quantum dot formed in a tunable-barrier single-electron pump. When the confinement potential is deformed at sub-nanosecond timescales, electrons are excited to states with higher back-tunneling rates leading to a measureable reduction in the pumped current. In the presence of a perpendicular magnetic field we have observed that these states follow a Fock-Darwin spectrum. Our experiments demonstrate a simple model system to study nonadiabatic processes of quantum particles.

2:42PM T32.00002 The dynamic quantum dot as an accurate electron pump[1] , STEPHEN GIBLIN, National Physical Laboratory, SAMUEL WRIGHT, University of Cambridge, JONATHAN D. FLETCHER, MASAYA KATAOKA, National Physical Laboratory, MICHAEL PEPPER, University College London, J.T. JANSSEN, National Physical Laboratory, DAVID RITCHIE, CHRISTINE NICOLL, DAVE ANDERSON, GEB JONES, University of Cambridge — We have developed an accurate single electron pump based on a dynamic quantum dot realised in a GaAs two-dimensional electron system. We report an accurate comparison between the pump current and a reference current derived from quantum standards of voltage and resistance: the Josephson effect and quantum Hall effect. We find that, at a clock frequency of several hundred Megahertz, the pump can transfer one electron per clock cycle with an accuracy approaching 10 parts per million. We discuss the significance of this result in relation to the proposed re- definition of the SI base unit Ampere. Theoretical estimations of the pump error rate indicate that an accuracy of one part in a hundred million is attainable, making our type of pump a candidate for a metrological current standard.

[1]We acknowledge support from the European Metrology Research Programme, grant no. 217257.

2:54PM T32.00003 Measurement of Tunneling Conductance of Two-Dimensional Electrons in a Si MOSFET Nanostructure , HONG PAN, MATTHEW HOUSE, MING XIAO, HONGWEN JIANG — The properties of strongly correlated two-dimensional electrons in semiconductor heterostructure continue to be of a fundamental interest of condensed matter physics [1]. A collection of transport studies have revealed a wealthy of interesting effects in the low-electron density limit, particularly in Si MOSFET structures [2]. In this talk, we present an alternative, tunneling conductance measurement of the 2D electrons in a Si MOSFET nanostructure. In our device, a global gate is used to control the 2D electron density. In addition, a set of small gates, as small as 50nm, forms a lateral tunneling barrier for the measurements. We find that there is a strong correlation between the still puzzling metal-insulator transition observed in transport [2] and our tunneling characteristics. The tunneling conductance is studied under different carrier density and in-plane Magnetic field. The project is supported by the NSF under Grant No. DMR-0804794.

3:06PM T32.00004 The magnetized quantum wire: a potential candidate to act as an *active* laser medium , MANVIR KUSHWAHA, Rice University — The fundamental issues associated with the magnetoplasmon excitations are investigated in a quantum wire characterized by a confining harmonic potential and subjected to a perpendicular magnetic field. We embark on the charge-density excitations in a two-subband model within the framework of Bohm-Pines' random-phase approximation. Essentially, the focus of our study is the intersubband (magnetoroton) collective excitation which changes the sign of its group velocity twice before merging with the respective single-particle continuum. The computation of the gain coefficient suggests an interesting and important application: the electronic device based on such magnetoroton modes can act as an *active* laser medium. The situation is analogous to the (quasi-two dimensional) superlattices where the crystal can exhibit a negative resistance: it can refrain from consuming energy like a resistor and instead feed energy into an oscillating circuit.

3:18PM T32.00005 Gain-Induced Refractive Index Changes in Resonantly Pumped Optical Pumping Injection Cavity Lasers , LINDA OLAFSEN, LAUREN BAIN, LAUREN ICE, BEN BALL, Baylor University — An optical pumping injection cavity (OPIC) laser contains a type-II W active region enclosed between two GaSb/AlAsSb distributed Bragg reflector mirrors, where the thickness of the etalon cavity surrounded by the mirrors is tuned to the desired pump wavelength. Multiple reflections of the pump photons result in more efficient absorption of the pump beam and consequently higher efficiencies and lower lasing thresholds. An optical parametric oscillator is used to pump the OPIC lasers at resonance, where the threshold pump intensities are minimized and output efficiencies are maximized. The resonant pump wavelength is found to vary quadratically with temperature, not linearly as would be expected from temperature-dependence of the lattice constant and refractive indices. Possible sources of this nonlinearity are lattice heating and gain-induced changes in the refractive indices resulting from the increase of optical pumping intensity with temperature. Through spectral measurements using step-scan Fourier Transform Infrared spectroscopy and multilayer reflectivity modeling, the relative contributions of these possible sources of parabolic temperature dependence of resonant wavelength are investigated.

3:30PM T32.00006 ABSTRACT WITHDRAWN –

3:42PM T32.00007 Mapping of Strain and Induced Polarization in GaMnAs/GaAs nanowires , EDWIN FOHTUNG, Physics Department, University of California San Diego, A. MINKEVICH, A.A. MATYSHEV, M. RIOTTE, D. GRIGORIEV, T. SLOBODSKYY, V. HOLY, O.G. SHPYRKO, T. BAUMBACH — The effects of surface energy and non-localized interactions are the two major physical mechanisms that guarantees size dependent of elastic properties at the nanoscale. With the limit for linear elasticity defined in the vicinity of the lattice parameter for most materials, non-localized interaction can only arise due to the discrete nature of matter and fluctuations in interatomic forces averaged out within the elastic tensors. Using an extended elasticity theory that introduces higher order perturbations to the classical energy density state of a crystalline material, we demonstrate the possibility of mapping the strain and polarization in device nanostructures with the aid of synchrotron radiation coherent diffraction imaging. We provide experimentally confirmed 2D mapping of the strain field and polarization in etched GaMnAs on GaAs periodic wires.

3:54PM T32.00008 Reflectance Spectra of Plasmon Waveguide Interband Cascade Lasers , ROBERT HINKEY, ZHAOBING TIAN, RUI YANG, TETSUYA MISHIMA, MICHAEL SANTOS, University of Oklahoma — Non-invasive reflectivity measurements have been explored as a method for measuring the carrier concentrations of the Si-doped cladding layers of Plasmon-Waveguide Interband Cascade (IC) Lasers. We present measurements and modeling done both on the IC laser structures, as well as highly doped InAs films grown on GaAs substrates that were used to calibrate the Molecular Beam Epitaxy growth. We have found that there is a sharp drop in the signal of the reflectance spectrum for p- polarized light oscillating near the plasma frequency, which falls in the mid-infrared for the cladding layers of the laser structure. This feature in the spectrum is caused by the interaction of the incident light with collective plasmon modes, and is distinct from the plasma edge feature seen in the reflectance spectrum of semi-infinite samples. A similar "plasma absorption" effect has been observed in thin metal films in the ultraviolet. The doping concentration and layer thicknesses of the structure were obtained by fitting a modeled curve to the measured spectrum. We were able to obtain measurements of the cladding layer doping concentrations (in a range from 10^{18} to 10^{19} cm^{-3}) with values that were in good agreement with those found using Hall effect measurements. We will discuss how these results can aid in improving the design of mid-infrared plasmon waveguide lasers.

4:06PM T32.00009 ABSTRACT WITHDRAWN –

4:18PM T32.00010 Electrical and Optical Characterization of α-Silicon Thin Films[1] , KIRAN SHRESTHA, TANWEER MIRZA BEIG, PRADEEP GALI, PRATHYUSHA NUKALA, CHRIS LITTLER, VINCENT LOPES, USHA PHILIPOSE, Dept. of Physics, University of North Texas, NIGEL SHEPHERD, Materials Science and Eng., University of North Texas, A. J. SYLLAIOS, L-3 Communications EOS — We report on progress in the characterization of amorphous silicon thin-films utilized in infrared detectors. Specifically, we have observed changes in the Raman spectra, resistivity, and activation energy in protocrystalline Si films grown by PECVD as substrate temperature, dopant type and concentration, and hydrogen dilution of the reactants are varied. Both n- and p-type films exhibit four Raman spectral peaks [1]. The TO Raman peak becomes better defined and shifts towards the crystalline TO energy for increasing substrate temperature or H dilution, or for decreasing dopant concentration. Hall and resistivity measurements as a function of both magnetic field and temperature on the same material have been conducted to better understand the relationships between specific growth parameters and key electrical properties.

4:30PM T32.00011 Single-Crystalline Germanium Nanowire Heterostructure for High-Performance Transistors and Spintronics[1] , JIANSHI TANG, KANG L. WANG, Device Research Laboratory, Department of Electrical Engineering, University of California, Los Angeles, California, 90095, USA, CHIU-YEN WANG, LIH-JUANN CHEN, Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan, 30013, Republic of China — The formation of single-crystalline $Ni_2Ge/Ge/Ni_2Ge$ nanowire heterostructure and its field effect characteristics by controlled reaction between a Ge nanowire and Ni contacts were studied. Transmission electron microscopy (TEM) studies reveal a wide temperature range to convert the Ge nanowire to single-crystalline Ni_2Ge by a thermal diffusion process. The *in-situ* reaction examined by TEM shows atomically sharp interfaces for the $Ni_2Ge/Ge/Ni_2Ge$ heterostructure with good epitaxial matches of Ge[-110]//Ni_2Ge[0-11] and Ge(111)//Ni_2Ge(100). Field effect transistors (FETs) built on this nanowire heterostructure show a high-performance p-type FET behavior with an on/off ratio over 10^5 and a field-effect hole mobility of 210 cm^2/Vs. This nanowire heterostructure with atomically sharp interfaces opens an opportunity to achieve high-performance nanowire transistors and explore promising application in spintronics.

4:42PM T32.00012 Schottky Barrier Heights in low-k dielectric/Cu Interconnects as Determined by X-ray Photoelectron Spectroscopy , MARC FRENCH, MILT JAEHNIG, MARKUS KUHN, BENJAMIN FRENCH, SEAN KING, Intel Corporation — In order to understand the various possible leakage mechanisms in low-k/Cu interconnects, a knowledge of the basic band alignment between Cu and low-k dielectric materials is needed but has gone largely unreported. In this regard, we have utilized X-ray Photoelectron Spectroscopy (XPS) to measure the Schottky Barrier at interfaces of importance to Cu/low-k interconnects. Specifically, we have utilized XPS to determine the Schottky Barrier at the interface between Cu and low-k SiCN capping layers deposited on Cu via Plasma Enhanced Chemical Vapor Deposition (PECVD). We have also utilized XPS to determine the Schottky Barrier at interfaces between Ta barrier layer materials and low-k SiOC:H ILD materials and the valence band alignment at low-k SiCN:H/SiOC:H interfaces. Lastly, the impact of various plasma surface treatments on the band alignment at these interfaces was also investigated. The cumulative results indicate that electron transport along the SiCN:H/SiOC:H may represent the lowest energy barrier path for line-line Schottky emission based leakage.

4:54PM T32.00013 Plasma Process to Simultaneously Clean ILD and CMP Cu Surfaces[1] , XIN LIU, SANDEEP GILL, FU TANG, Arizona State University, SEAN KING, Intel Corp., R.J. NEMANICH, Arizona State University — Low-k inter-layer dielectrics (ILD) with copper interconnects display advantages for reducing energy consumption in silicon technology. However, the processing induced degradation of the ILD low-k properties has become a challenge. In this work, we have employed remote N_2/H_2 plasma processes to simultaneously clean both low-k ILD (k=2.5) and chemical-mechanical polished (CMP) Cu surfaces. FTIR and C-V results indicate that N_2 plasma cleaning processes show low carbon abstraction as well as a relatively small increase in the dielectric constant (k=2.6). A carboxamide layer is formed which apparently inhibits further etching. In contrast, the k value increases to 3.5 after an H_2 plasma treatment. For the CMP-Cu surfaces, an N_2/H_2 plasma process at 380C effectively removes the oxide and carbon contamination. In addition, the affects of plasma-induced UV light has been studied, and the results indicate enhanced carbon depletion in the ILD. Degradation of the low-k properties is attributed to carbon abstraction which is enhanced by the plasma induced UV and hydrophilic character. The results establish a range of N_2/H_2 plasma processes for simultaneous cleaning of CMP Cu and low-k ILD surfaces.

5:06PM T32.00014 Elastic properties of high porosity low-k thin films measured by Brillouin light scattering , S. BAILEY, R. SOORYAKUMAR, The Ohio State University, S. KING, G. XU, E. MAYS, C. EGE, J. BIELEFELD, Intel Corporation — The continued scale down of material components present increasing challenges to technology development in the semiconductor industry. In particular, with the introduction of more porous materials and air gaps to further reduce permittivity, one significant issue is that low-k dielectrics in interconnects have sufficient mechanical strength. Since nano-indentation methods are questionable at these ultra-small thicknesses there is a need for non-invasive methods to characterize the mechanical properties of such highly compact porous structures. In this talk results of Brillouin scattering to measure elastic constants of thin ($<$ 200 nm) low-k SiOC:H films with porosities up to 35% will be presented. Discrete longitudinal and transverse acoustic standing modes and their transformation to propagating excitations are investigated. The resulting mode dispersions provide for the Poisson's ratio (ν) and Young's modulus (E) and confirm that, for highest porosity, the reduction in dielectric constant does not result in severe degradation in ν and E.

5:18PM T32.00015 Effective Materials Properties of Interconnections in Industrial Microprocessor Designs , MARY LANZEROTTI, Pacific Lutheran University, GIOVANNI FIORENZA, RICK RAND, IBM T J Watson Research Center — This talk presents a methodology to evaluate tradeoffs between technology and design to obtain the highest performance in industrial VLSI designs [1]. It is well known that the most significant circuitry constraint is that signals must arrive on time. Since the design cycle is time-consuming and complex, there is a need to migrate designs to future technology nodes to amortize design cost. However, models do not exist [1] to guide designers in their evaluation of whether migrated designs will operate successfully in a future technology or whether migrated designs will cause chip failure. There is therefore a need to evaluate the impact of design changes on performance. This talk evaluates this impact and describes it as an effective change in material properties of the design interconnections. Model estimates are compared with industrial microprocessor design data [1]. References [1] M. Y. Lanzerotti, G. Fiorenza, R. Wednesday, March 23, 2011 2:30PM - 5:30PM –

Session T33 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides: Pb-based and novel materials C143/149

2:30PM T33.00001 Origin of diffuse scattering in relaxor ferroelectrics , P. GANESH, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, TN — High-pressure and variable temperature single crystal synchrotron X-ray measurements combined with first-principles based molecular dynamics simulations study diffuse scattering in the relaxor ferroelectric system PSN (PbSc1/2Nb1/2O3). Constant temperature experiments show pressure induced transition to the relaxor phase at different temperatures characterized by butterfly and rod shaped diffuse scattering around the {h00} and {hh0} Bragg spots, respectively. The simulations [1] reproduce the observed diffuse scattering features as well as their pressure-temperature behavior, and show that they arise from polarization correlations between chemically-ordered regions, which in previous simulations were shown to behave as polar nanoregions. Simulations also exhibit radial diffuse scattering (elongated towards and away from Q=(000)), that persists even in the paraelectric phase, consistent with previous neutron experiments on (PbMg1/3Nb2/3O3) (PMN). DFPT calculations to elucidate origin of Raman peaks in the relaxor phase will also be presented.

[1] P. Ganesh, E. Cockayne, M. Ahart, R. E. Cohen, B. Burton, Russell J. Hemley, Yang Ren, Wange Yang and Z.-G. Ye, Phys. Rev. B **81**, 144102 (2010)

3:06PM T33.00002 Linear dichroism dependence on ferroelectric polarization , SRINIVAS POLISETTY, JINLING ZHOU, MIKEL HOLCOMB, West Virginia University, ANDREAS SCHOLL, Lawrence Berkeley National Laboratory, LANE W. MARTIN, University of Illinois at Urbana-Champaign — X-ray absorption spectroscopy (XAS) and photoemission electron microscopy (PEEM) have been used to determine the magnetic properties of magnetoelectrics, possessing both ferroelectric and magnetic order; however, the additional sensitivity to the ferroelectricity in these films complicates the analysis. Nevertheless, an exclusive knowledge of ferroelectric order is important due to its vital role in manipulating magnetic properties of the magnetoelectrics. To shed light on ferroelectric order and polarization near surface region, we employed mainly PEEM and XAS on ferroelectric $PbZr_{0.2}Ti_{0.8}O_3$ (PZT) film deposited on $LaAlO_3$ substrate. Both out-of-plane and in-plane ferroelectric contributions at Ti $L_{3,2}$ and O-absorption edges have been measured over multiple poled regions on the sample to test various potential mechanisms causing this ferroelectric dichroism, such as surface charge. The ferroelectric order in PZT determined to be systematically evolving as a function of incident x-ray polarization for different rotated angles of the sample revealing a similar angular dependence to that of magnetic samples, allowing a formula for linear dichroism in complex ferroelectrics. This development allows this dynamic approach to be used to study the effect of ferroelectricity on interface coupling in a various materials.

3:18PM T33.00003 Second harmonic generation and high pressure ferroelectricity in $PbTiO_3$(II)[1] , MUHTAR AHART, ALEXANDER F. GONCHAROV, MADDURY SOMAYAZULU, RUSSELL J. HEMLEY, Geophysical Laboratory, Carnegie Institution of Washington — We employed the Raman scattering, x-ray diffraction, and second harmonic generation (SHG) experiments to investigate the behavior of $PbTiO_3$ under pressure up to 100 GPa at 300 K. The experimental results reveal that lead titanate undergoes a second order phase transition from a tetragonal to a cubic at 12 GPa and continuously to a non-cubic structure at 30 GPa. The integral intensity of SHG in the material decreases monotonically with pressure below 12 GPa, and does not depend on pressure above 12 GPa. The results provide no-evidence for high pressure ferroelectricity in $PbTiO_3$ at high pressure and room temperature.

[1]This work is supported by the Carnegie/Department of Energy Alliance Center (CDAC) (DF-FC03N00144).

3:30PM T33.00004 First-principles study to identify heterostructures of (Pb, Sr)TiO_3 with enhanced ferroelectric polarisation , ZHE LIU, Department of Mechanical Engineering, Monash University, Australia — A first-principle cluster expansion method is employed to study the ferroelectric (FE) polarisation properties of $Pb_xSr_{1-x}TiO_3$ perovskite oxide grown on $SrTiO_3$ (001)-substrate. Our results indicate that some heterostructures can significantly enhance polarisation in comparison with the (001) superlattice and the random alloy structures. At $x = 0.5$, an (110) A/B mono-layer superlattice is identified as the structure with the most enhanced polarisation, and at $x = 0.25$, the optimal structure is determined to be a body-centred superstructure. Detailed structural analysis reveals the atomic configurational patterns in the (001) plane that benefit the off-centering of Pb and Sr cations. Explanation is provided in terms of dipole interactions. Our results should apply to other multicomponent FE perovskites as well and they could have a significant impact in the design of FE materials.

3:42PM T33.00005 Interatomic force constants and effective Hamiltonians for structural phase transitions , ANIL KUMAR, KARIN M. RABE, Rutgers University — Expansion of the total energy of a crystal around a high-symmetry reference structure provides information about material properties including the phonon dispersion, responses to applied fields, magnetostructural coupling, and structural transitions. For complex oxides, parameterization of the structural energetics by real-space interatomic force constants (IFCs) provides a computationally convenient and physically transparent way of analyzing these properties. By projection into a subspace containing the relevant degrees of freedom, one can construct an effective Hamiltonian to study properties that are not readily accessible with DFT based calculations, including properties at finite temperature or long length scales. It is well known that first-principles density-functional-theory (DFT) based-calculations can be systematically used to determine real-space IFCs of materials; this is part of several first-principles packages including ABINIT and Quantum Espresso. Here, we discuss a simple and efficient approach for construction of first-principles effective Hamiltonians which uses this computational capability to generate and compute the quadratic inter-cell parameters in a single step. We illustrate the method through the application to systems for which effective Hamiltonians have previously been constructed, and show how this approach facilitates the construction of effective Hamiltonians for new classes of crystal structures.

3:54PM T33.00006 All-atom effective models for first-principles simulations of the temperature-dependent behavior of complex ferroelectric oxides[1] , JORGE INIGUEZ, JACEK C. WOJDEL, ICMAB-CSIC, PATRICK HERMET, PHILIPPE GHOSEZ, University of Liege, ZEILA ZANOLLI, ICMAB-CSIC and University of Liege — Since its introduction in the 90's, the first-principles effective-Hamiltonian method has been successfully used to simulate temperature-driven phenomena in increasingly complex ferroelectrics, from classic compound $BaTiO_3$ to multiferroic $BiFeO_3$. Currently, the emergence of nano-structured materials – e.g., in the form of ultra-thin films or short-period superlattices – poses new challenges to the simulations, and the development of predictive models seems to require a reconsideration of the traditional approach. Of particular interest are cases in which novel interfacial effects determine the behavior, as in the $PbTiO_3$-$SrTiO_3$ superlattices of Bousquet *et al.* [Nature **452**, 7188 (2008)]. In such situations a large number of structural distortions may become active, and it may be difficult to decide which ones need to be included in the model. In order to tackle these difficulties, we are extending the first-principles effective-Hamiltonian method so as to retain a full atomistic description of the material, thus removing the so-called *local mode* approximation. I will describe our new approach and show preliminary results for $PbTiO_3$.

4:06PM T33.00007 Prediction of a Low Band Gap Oxide Ferroelectric[1] , DAVID SINGH, ORNL, BO XU, National University of Singapore, VALENTINO R. COOPER, ORNL, YUAN PING FENG, National University of Singapore — We report a first principles study of $Bi_6Ti_4O_{17}$ which is an alternate stacking of ferroelectric $Bi_4Ti_3O_{12}$ (BiT). We the standard PBE GGA functional for the structure and polarization and a recently developed functional that yields accurate band gaps for the electronic structure. We find that this compound is ferroelectric although with a reduced polarization relative to BiT. Importantly, calculations of the electronic structure yield a band gap of approximately 1.4 eV. Therefore, we predict that this stacking is a low band gap oxide ferroelectric.

[1]This work was supported by A*STAR (BX,YPF), the DOE, BES, Materials Sciences and Engineering (DJS,VRC, Ferroelectricity), and the ORNL LDRD Program (DJS, Electronic Structure).

4:18PM T33.00008 Band Gap Engineering via Local Environment in Complex Oxides[1] , TINGTING QI, ILYA GRINBERG, ANDREW RAPPE, University of Pennsylvania — We describe how the electronic structure energy level of the recently-developed highly polar tetragonal perovskite oxides, most prominently $Bi(Zn,Ti)O_3$, can be dramatically changed by a simple rearrangement of the B-cation. Using LDA+Hubbard U, we determine the impact of B-site cation ordering, lattice strain, cation identity, and oxygen octahedral cage tilts on the valence and conduction bands. We find that a combination of ultra-high tetragonality and a careful choice of B-cations can lead to changes of 1-2 eV in the band gap for the same composition, through a change in the B-cation ordering alone. We also find that a layered B-cation ordering exhibits high-mobility 2D hole gas (2DHG) behavior. The lower band gaps of the layered B-cation ordering makes these materials suitable for photovoltaic and photocatalytic applications, due to their good match with the solar spectrum. Our analysis of the crystal structure and the valence and conduction bands shows that these unusual effects can be explained in the framework of crystal field theory and underscores the crucial role that ultra-high tetragonality plays in making the band gap sensitive to the B-cation ordering.

4:30PM T33.00009 Modeling the Frequency Dependence of the Complex In-plane Permittivity of Strained Ruddlesden-Popper Series Sr(n+1)Ti(n)O(3n+1) (n = 2, 3, 4, 5, 6) Phases on DyScO3 and GdScO3 , N.D. ORLOFF, National Institute of Standards and Technology, C.-H. LEE, Cornell University, M.D. BIEGALSKI, Oak Ridge National Laboratory, ICHIRO TAKEUCHI, University of Maryland, D.G. SCHLOM, Cornell University, J.C. BOOTH[1] — We explore the in-plane complex relative permittivity as a function of frequency of epitaxial thin-films of the Ruddlesden-Popper series Srn+1TinO3n+1 (n = 2, 3, 4, 5, 6) grown on the rare-earth scandate substrates DyScO3 and GdScO3, which correspond to biaxial tensile strain of approximately 1.1% and 1.7%, respectively. The thin films are 50 nm on DyScO3 and 25 nm thick on GdScO3, to ensure uniform strain throughout the film. We characterize the thin films with a set of optimally designed coplanar waveguides from 45 MHz to 40 GHz and with a set of interdigitated electrodes of varying active lengths from 10 Hz to 100 MHz. We then extract the in-plane complex permittivity from 10 Hz to 40 GHz for these thin films. We report the dependence of the Curie temperature, tunability, and loss tangent on series number and strain at 1 MHz. We also present a frequency-dependent model and the corresponding fit parameters for these thin films as a function of temperature. The model assumes a distribution of domains below the Curie temperature and high frequency relaxation that we attribute to the lowest-order phonon

4:42PM T33.00010 Study of Temperature-Graded Ferroelectrics Using First-Principle-Based Approaches[1] , QINGTENG ZHANG, INNA PONOMAREVA, University of South Florida — Temperature-graded ferroelectrics have attracted a lot of attention in the recent years owing to their many remarkable properties. Here we develop a microscopic approach based on first-principles effective Hamiltonian to simulate temperature-graded ferroelectrics. Accuracy of such approach is confirmed by comparing our computational results for $(Ba_{0.75}Sr_{0.25})TiO_3$ alloy with available experimental data. Our computations further reveal: 1) strong anisotropy in polarization response: the polarization offset along the temperature gradient is an order of magnitude smaller than in the perpendicular direction; 2) coexistence of different phases (including low-symmetry phases) in chemically homogeneous regions; 3) rotation of polarization in response to temperature gradient in the unclamped samples. These findings could potentially lead to many novel applications such as energy converters, thermally tunable devices and efficient photovoltaics [1].

4:54PM T33.00011 Ferroelectric polarizations of $Pb(Zr_{0.5}Ti_{0.5})O_3$ nanotube array , R. ADHIKARI, HUAXIANG FU, Department of Physics, University of Arkansas, Fayetteville, AR 72701 — Ferroelectric polarization and structural properties are determined for the $Pb(Zr_{0.5}Ti_{0.5})O_3$ (PZT) nanotube array embedded in matrix materials of different polarizability, by means of first-principles derived effective Hamiltonian and finite-temperature Monte Carlo simulations. The polarizability of the matrix is controlled by the on-site κ_2 quantity. We found three drastically different structural phases in PZT nanotubes, depending on the polarizability of the matrix. Microscopic insight for these structural phases will be revealed.

5:06PM T33.00012 Raman scattering studies of the pressure- and temperature-dependent phases of the orbital ordering material $KCuF_3$[1] , SHI YUAN, S. LANCE COOPER, Department of Physics and Frederick Seitz Materials research laboratory, University of Illinois at Urbana-Champaign, Urbana, IL 61801 — We present a study of the temperature- and pressure-dependence of the prototypical orbital ordering system $KCuF_3$ using Raman scattering. Temperature-dependent measurements offer evidence for structural instabilities in $KCuF_3$ at temperatures well below the putative 800K orbital ordering temperature; this evidence includes the observation of anomalous softening of several phonon modes between 50K and 300K and an E_g phonon mode splitting below 50K. The latter indicates a tetragonal-to-orthorhombic structural transition near 50K just preceding the 3D magnetic ordering temperature at $T_N \approx 40$K. Low-temperature, pressure-dependent Raman studies of $KCuF_3$ are also reported to clarify the pressure dependence of the low temperature structural phases in this material.

[1]Work supported by the U.S. Department of Energy under Award No. DE-FG02-07ER46453.

5:18PM T33.00013 Unusually strong Stark effect in electronic ferroelectric $Er_{1-x}Yb_xFe_2O_4$, JIMIN ZHAO, Institute of Physics, Chinese Academy of Sciences, RUI WANG, HUANXIN YANG, JIANQI LI — Strong Stark splitting, which is nearly independent of the R-ions replacement, has been observed through the photoluminescence investigation of electronic ferroelectric $Er_{1-x}Yb_xFe_2O_4$(x=0, 0.8, 0.9, and 0.95). Initially multiple radiative decay channels have been investigated, especially the visible transition $^4F_{9/2} \rightarrow ^4I_{15/2}$, of which a quenching effect has been observed. A series of small non-Raman peaks have been observed superimposed on a broadband photoluminescence spectrum, of which we tentatively assign Stark splitting to be the cause. The splitting of the $^4F_{9/2}$ and $^4I_{15/2}$ levels is found to be 54 meV and 66 meV, respectively. This unusually large Stark splitting at visible range indicates the existence of strong local field originated from the W-layer in the charge-frustrated $ErFe_2O_4$.

Session T34 DCMP: Optical and Electronic Properties of Nanocrystals and Wires C141

2:30PM T34.00001 Colloidal Quantum Dot Red-Shifting on Textured Metal Surfaces[1] , CHRISTOPHER FERRI, University of California, Merced, School of Natural Sciences, ANTHONY GRIMES, University of California, Merced, School of Engineering, SAYANTANI GHOSH, University of California, Merced, School of Natural Sciences — We have studied the influence of textured metal surfaces on the emission of an ensemble of colloidal CdSe/ZnS core-shell quantum dots (QDs). The texture was generated by sputter coating a thin film of Gold Paladium (AuPd) on a thermoplastic Polydimethylsiloxane (PDMS) sheet. We used two separate protocols to generate two types of surfaces. We constrained some substrates such that they shrunk along only one planar dimension (uniaxial) while some were allowed to shrink along both planar directions (biaxial). The uniaxial substrates forced the metal to buckle along one dimension and the biaxial substrates buckled into a pseudorandom texture. We found that the QDs deposited on the biaxial substrates had a general red shift in the emission wavelength compared to their emission in solution, which also corresponded to a change in the temporal dynamics of the emission. The QDs on the uniaxial substrates showed a change in their temporal dynamics corresponding to plasmonic coupling, but no spectral shift. We hypothesize that the effects observed on the biaxial substrates are caused by the Franz-Keldysh effect.

2:42PM T34.00002 Single-molecule spectroscopy study of interfacial charge separation and energy transfer between quantum dots and conjugated polymers , ZHIHUA XU, MIRCEA COTLET, Center for Functional Nanomaterials, Brookhaven National Laboratory — Blends of semiconducting quantum dots (Qdots) and conjugated polymers (CPs) are promising materials for light-emitting diodes or photovoltaic devices. Effective design of optoelectronic devices relies on further understanding of the photophysics in these hybrid materials, including charge separation (CS) and energy transfer (ET). We have studied the photophysics of the blends of two water-soluble conjugated polymers and CdSe/ZnS quantum dots with varying shell thickness, which enable us to control the competitive CS and ET processes by tuning energy-band alignment and interfacial distance. Combining single –molecule spectroscopy with ensemble-based measurements provides deeper understanding of the dynamic interactions at inhomogeneous interfaces.

2:54PM T34.00003 Broadband ultrafast transient absorption of multiple exciton dynamics in lead sulfide nanocrystals , FELICE GESUELE, CHEE WEI WONG, Columbia University, MATTHEW SFEIR, JAMES MISEWICH, Brookhaven National Laboratory, WEONKYU KOH, CHRISTOPHER MURRAY, University of Pennsylvania — Multiple exciton generation (MEG) is under intense investigation as potential third-generation solar photovoltaics with efficiencies beyond the Shockley-Queisser limit. We examine PbS nanocrystals, dispersed and vigorously stirred in TCE solution, by means of supercontinuum femtosecond transient absorption (TA). TA spectra show the presence of first and second order bleaches for the 1Sh-Se and 1Ph-Pe excitonic transition while photoinduced absorption for the 1Sh,e-Ph,e transitions. We found evidence of carrier multiplication (MEG for single absorbed photon) from the analysis of the first and second order bleaches, in the limit of low number of absorbed photons (Nabs$\sim$0.01), for energy three times and four times the Energy gap. The MEG efficiency, derived from the ratio between early-time to long-time TA signal, presents a strongly dispersive behavior with maximum red shifted respect the first absorption peak. Analysis of population dynamics shows that in presence of biexciton, the 1Sh-Se bleach peak is red-shifted indicating a positive binding energy. MEG efficiency estimation will be discussed with regards to spectral integration, correlated higher-order and first excitonic transitions, as well as the nanocrystal morphologies.

3:06PM T34.00004 The effects of controlled charging on photoluminescence of individual "giant" core/shell nanocrystals , CHRISTOPHE GALLAND, YAGNA GHOSH, BHOLA PAL, JENNIFER HOLLINGSWORTH, MILAN SYKORA, VICTOR KLIMOV, HAN HTOON, Los Alamos National Laboratory — We report the first single-nanocrystal photoluminescence (PL) study under controlled charge injection. We investigate so-called "giant" nanocrystal quantum dots (g-NQDs) that comprise a CdSe core and a thick CdS shell. We use solid-state gated devices as well as electrochemical cells for charged injection. When the gate bias or electrochemical potential is tuned, we observe dramatic changes in the PL dynamics that are accompanied by spectral shifts and intensity modulations. Our initial results suggest that negatively charged excitons are at least as bright as neutral excitons in these g-NQDs for which Auger recombination has been shown to be strongly suppressed. Surprisingly, hole injection leads primarily to quenching of the NQD emission, which might explain the appearance of "gray" or "dark" periods in the single-dot PL trajectories.

3:18PM T34.00005 Near-Unity Biexciton Quantum Yields in Individual Giant Nanocrystal Quantum Dots , YOUNG-SHIN PARK, Los Alamos National Lab, ANTON MALKO, University of Texas at Dallas, JAVIER VELA, YONGFEN CHEN, YAGNASENI GHOSH, FLORENCIO GARCIA-SANTAMARIA, JENNIFER HOLLINGSWORTH, VICTOR KLIMOV, HAN HTOON, Los Alamos National Lab — We report quantitative studies of photoluminescence (PL) quantum yields of biexcitons (Q_{BX}) in individual CdSe/CdS core/shell nanocrystal quantum dots (NQDs) as a function of shell thickness. Q_{BX}s measured by two independent techniques show a gradual increase with increasing shell thickness, reaching a near-unity value of $\sim$0.9 for the NQDs with a 19 monolayer-thick shell. These results imply a strong suppression of Auger decay. However, Q_{BX}s show a wide variation among nominally identical NQDs implying a strong dependence of Q_{BX} on subtle structural differences of the core/shell interfaces. Surprisingly, despite a wide variation in Q_{BX}, all thick-shell NQDs exhibit a complete suppression of PL blinking, implying that this non-blinking behavior does not result from the suppression of Auger decay and instead may simply arise from a reduced likelihood of photocharging.

3:30PM T34.00006 Axially localized optical properties of individual nanowires[1] , JUNPING ZHUANG, YAO LIANG, S.K. HARK, The Chinese University of Hong Kong — Nanowires are not always uniform in their properties. Studying the localized optical properties of the nanowires is thus important for their characterization and potential applications. Micro-photoluminescence spectra and fluorescence lifetime along individual ZnSe nanowires were measured and studied using laser scanning confocal microscopy. The nanowires were selected from an array that was synthesized via self catalyzed VLS mode on GaAs substrates. Through fluorescent imaging, the distribution of the deep-level emissions along the nanowires, in which a bright-tip and a dim-tail were observed, is found to be very different from the relatively uniform distribution of the near-band-edge emissions. Using fluorescence lifetime imaging, we found that the fluorescence decay behaviors are very different between the two emission bands and have position dependence. We believe that the unintended Ga diffusion during the growth of the nanowires should be responsible for the observed distributions.

[1]Supported by a grant from the RGC of the HKSAR, China (Project 417507).

3:42PM T34.00007 Polarization dependence of ultrafast dynamics in single Si nanowires , M.A. SEO, S.A. DAYEH, P.C. UPADHYA, S.T. PICRAUX, Los Alamos National Laboratory, USA, J. MARTINEZ, B.S. SWARTZENTRUBER, Sandia National Laboratory, USA, A.J. TAYLOR, R.P. PRASANKUMAR, Los Alamos National Laboratory, USA — Understanding how light interacts with individual nanowires (NWs), particularly depending on its polarization with respect to the NW alignment, is essential for a wide range of applications. We present the first ultrafast time-resolved, polarization-dependent experiments on both single- and ensemble-silicon nanowires using non-degenerate pump-probe spectroscopy to excite and probe carriers above the indirect band gap. Polarization sensitive pump-probe excitation and detection reveal a clear anisotropy in the ultrafast dynamics measured parallel and perpendicular to the long axis of a single nanowire. In addition, the magnitude of the photoinduced change in ensembles of NWs varies for four different sets of pump and probe polarization, without an anisotropy in relaxation time. The comparison of ultrafast dynamics between single and ensemble nanowires provides great insight into the influence of incident light polarization on different absorption and interaction mechanisms. The observed anisotropy in single NWs could enable advanced applications, such as optical switching and polarization sensitive photo detection, on the nanoscale, where directional control and high spatial resolution are much desired

3:54PM T34.00008 Space-and-Time-Resolved Spectroscopy of Single GaN Nanowires , PRASHANTH UPADHYA, Los Alamos National Laboratory, JULIO MARTINEZ, QIMING LI, GEORGE WANG, BRIAN SWARTZENTRUBER, Sandia National Laboratories, ANTOINETTE TAYLOR, ROHIT PRASANKUMAR, Los Alamos National Laboratory — Understanding the carrier relaxation pathways in individual semiconductor nanowires (NWs) is crucial, since the geometry of these nanostructures can significantly influence carrier recombination and trapping. In particular, GaN NWs are promising wide bandgap semiconductors for applications in nanophotonics, but the efficiency and lifetime of GaN-based devices are largely affected by the presence of structural and point defects. In this study we employ wavelength-tunable femtosecond optical pump-probe spectroscopy to study carrier relaxation through the defect states responsible for yellow luminescence in both a single GaN NW and NW ensembles. These are the first ultrafast optical experiments on single group III-V NWs, revealing spatially resolved carrier dynamics along the length of an individual wire.

4:06PM T34.00009 Electronic Structure of PbSe Nanorods , ADAM BARTNIK, Cornell University, ALEXANDER L. EFROS, Naval Research Laboratory, WEON-KYU KOH, University of Pennsylvania, JUN YANG, Cornell University, CHRISTOPHER MURRAY, University of Pennsylvania, FRANK WISE, Cornell University — In spherical lead-salt (PbS and PbSe) nanocrystals, their large dielectric constant and mirror-like band structure significantly weaken the Coulomb interaction, while their large exciton Bohr radii place them at the limit of strong confinement. But in a 1-dimensional structure, the Coulomb interaction can act primarily through the medium, greatly reducing screening. Thus, by controlling their length, the lead-salts can uniquely switch from strong confinement to strong Coulomb binding. To investigate this, we develop a 4-band k-p model of the electronic structure of lead-salt nanorods (NRs), which includes the Coulomb interaction through an effective 1D potential along the NR axis. Perpendicular to the cylindrical axis, confinement dominates and is the major determinant of the location of peaks in the optical spectra. Along the rod axis, the effective Coulomb potential dominates, highly correlating the electron and hole in this direction and enhancing multiparticle interactions, with the observable effect of producing isolated peaks in optical spectra. Predictions of the locations of these enhanced transitions are shown to have good agreement with measured optical spectra of recently synthesized colloidal PbSe NRs.

4:18PM T34.00010 Atomistic calculations of the exciton-biexciton mixing and biexciton lifetime in CdSe nanocrystals[1] , MAREK KORKUSINSKI, OLEKSANDR VOZNYY, PAWEL HAWRYLAK, Institute for Microstructural Sciences, NRC Ottawa, Canada K1A 0R6 — We present an atomistic tight-binding theory of multi-exciton complexes in spherical CdSe nanocrystals. As shown previously [1] the properties of exciton (X) and biexciton (XX) are determined by the shell of four quasi-degenerate states at the top of the valence band, resulting in a band of correlated XX states. This XX fine structure affects the Coulomb mixing of the low-lying XX with excited X states. Here we compare different approaches to computation of the XX ground state lifetime. The Fermi's golden rule accounting only for directly coupled XX and X configurations is compared to configuration-interaction approach where XX and X with energy close to 2Eg are taken into account. We show that the expansion of the basis of single particle configurations used to describe XX leads to a significant increase of the amount of X configurations to which XX can couple. The effect of inclusion of the X configurations coupled to XX indirectly via the intermediate X states is also discussed.

4:30PM T34.00011 Can nanocrystals be charge-doped using surface adsorbates? , ALEX KUTANA, STEVE ERWIN, Center for Computational Materials Science, Naval Research Laboratory — We study theoretically the possibility that lead selenide nanocrystals can be doped with electrons or holes by charge transfer from molecules (hydrazine, N2H4) adsorbed on their surface. Despite experiments showing that hydrazine adsorption greatly increases the conductivity of PbSe nanocrystal films, our density-functional theory results show no evidence that carriers are directly created by adsorption. Instead, we find that PbSe always remains intrinsic for a variety of hydrazine coverages and PbSe surface orientations. Moreover, analysis of the charge density shows negligible electron transfer from hydrazine to the surface. We tentatively attribute the discrepancy between experiment and theory to extrinsic factors such as surface defects, doping by surface ligands, or dopant activation by hydrazine. For example, we predict that adsorption of acetic acid will create mobile holes in PbSe, and that surface adsorption of lead atoms will result in mobile electrons.

4:42PM T34.00012 Surface states in CdSe nanocrystals with carboxylic acid ligands: an ab initio study[1] , OLEKSANDR VOZNYY, Quantum Theory Group, Institute for Microstructural Sciences, NRC Ottawa, Canada K1A 0R6 — The electronic properties of the realistic Cd-rich CdSe quantum dots with covalently bound (X-type) carboxylic ligands are investigated using density functional theory for the nanocrystal (NC) sizes sufficient to distinguish core and surface states. We find that Cd and Se atoms with only one dangling bond do not create surface traps. The amount of ligands and the crystal shape is dictated by the overall electronic balance of the NC rather than by the surface free energies of particular ligated facets. To achieve this balance more ligands are required than there are "ideal" adsorption sites for them, creating ligand-induced trap states near the valence band maximum. These extra ligands are mobile on surface, resulting in spectral diffusion of the trap levels, providing first atomistic example of diffusion and activated recombination centers models for blinking.

4:54PM T34.00013 First-Principles Calculations of Lattice-Strained Core-Shell Nanocrystals[1] , K.H. KHOO, Institute of High Performance Computing, A*STAR, J.T. ARANTES, Universidade Federal do ABC, JAMES R. CHELIKOWSKY, University of Texas at Austin, G.M. DALPIAN, Universidade Federal do ABC — We have studied the properties of CdS-ZnS and ZnS-CdS core-shell nanocrystals over a range of shell thicknesses using real-space pseudopotential density functional theory. The effect of structural relaxation was shown to be important as it leads to significant changes in the HOMO-LUMO gap and frontier orbital localizations. Also, strains due to lattice mismatch are predicted to be highly localized around the core-shell interface, giving rise to a thin shell regime where both confinement and strain effects are important and a thick shell regime where confinement effects dominate. This has interesting implications for the evolution of the HOMO-LUMO gap with shell thickness.

5:06PM T34.00014 First Principles Study of Core-Shell Semiconductor Nanocrystals[1] , IGOR VASILIEV, New Mexico State University — Core-shell nanocrystals composed of two different semiconductors have recently attracted considerable attention. These structures provide enhanced functionality and possess more degrees of freedom than single-component semiconductor nanocrystals and quantum dots. I present the results of *ab initio* density functional calculations for the structures, electronic densities of states, and optical absorption gaps of core-shell nanocrystals composed of group II-VI semiconductors, such as CdSe, CdTe, ZnSe, and ZnTe. The outer surfaces of the nanocrystals are passivated using partially charged hydrogen atoms. The calculations are performed for "traditional" core-shell nanocrystals, in which a core a narrow gap semiconductor is covered with a shell of a wide gap material, and "inverted" core-shell nanocrystals, in which a wide-gap core is enclosed in a narrow-gap shell.

5:18PM T34.00015 Jahn-Teller distortion in semiconductor nanocrystals[1] , GUSTAVO M. DALPIAN, ALINE L. SCHOENHALZ, JEVERSON T. ARANTES, Universidade Federal do ABC — Semiconductor nanocrystals or quantum dots can present properties that are very different from their bulk counterparts. Quantum confinement and surface effects play important roles in determining these unusual properties. Here we report a Jahn-Teller distortion in pristine nanocrystals upon the addition of charges. Results will be presented for Si, InAs and CdSe nanocrystals. In order to observe this effect, we have performed calculations using the Density Functional Theory and hybrid functionals. We will discuss the implications of this distortion on the electronic and optical properties of these materials.

5:30PM T34.00016 Memory, Photoconductivity, and Traps in Semiconducting Nanocrystal Arrays , JESSAMYN FAIRFIELD, LAUREN WILLIS, TALI DADOSH, MARIJA DRNDIC, University of Pennsylvania — Nanoscale devices are extensively studied for their tunable electronic and optical properties, but the influence of impurities and defects is amplified at these length scales and can lead to poorly understood variations in material characteristics. By performing a large ensemble of photoconductivity measurements in nanogaps bridged by core-shell CdSe/ZnS semiconductor nanocrystals, we discover optoelectronic methods for affecting solid-state charge trap populations. We show that the magnitude and temperature dependence of the photocurrent depends on the illumination and electric field history on a few-hour timescale. Subband gap illumination of nanocrystals prior to measurements modifies the photocurrent more than band gap illumination. We introduce a model that unifies previous work and transforms the problem of irreproducibility in nanocrystal electronic properties into a robust photocurrent response due to trap state manipulation. Because traps dominate many physical processes, these findings may lead to improved performance and device tunability for nanoscale applications through the control and optimization of impurities and defects.

Wednesday, March 23, 2011 2:30PM - 5:30PM –
Session T35 DCMP: Metals: Defects and Surfaces C140

2:30PM T35.00001 Orientation effect on dislocation nucleation and related interaction during void growth simulations in Aluminum , AMITAVA MOITRA, MEHUL BHATIA, KIRAN N. SOLANKI, Mississippi State University — Molecular dynamics simulations are performed to understand the void growth for fcc Aluminum. Dislocation nucleation at the void surface and growth of those dislocations in matrix, are studied for seven different crystallographic orientations: [100], [110], [111], [210], [211], [221], and [321]. A significant effect of the loading orientation on dislocation loop nucleation and configuration, and consequently the shape change of voids are found. Calculations related to the interaction of burgers vectors of the nearby leading and trailing dislocations are performed to find the reason why dislocation extremities are attached to the void surface. It has been also shown for a particular orientation that the extremities leave the void surface in order to reduce the interaction energy. Cross slip and triplanar loops are also found during the study of void growth simulations.

2:42PM T35.00002 MD Study of the Nucleation and Growth of Deformation Twins in Polycrystalline Tantalum[1] , LUIS SANDOVAL, DAVID RICHARDS, Condensed Matter and Materials, Lawrence Livermore National Laboratory, Livermore, California 94550, USA — Recovered samples from high strain rate experiments clearly show that twin formation serves as an important plasticity mechanism in Tantalum. Despite years of study however, the nucleation and growth mechanisms of twining are still poorly understood, especially in bcc metals. Twins are typically thought to nucleate at grain boundaries via a cooperative emission of partials after a critical value of shear stress. We have used molecular dynamics (MD) simulation to observe the nucleation and growth of twin domains from grain boundaries and grain boundary junctions in polycrystalline cells, which have been prepared as arrangements of hexagon-columnar grains. Using a Finnis-Sinclair potential, we have examined the role of strain rate, temperature and hydrostatic pressure on the kinetic phenomena, in particular the twinning threshold and twin growth rates. We discuss how kinetic parameters extracted from MD simulations help inform a multiscale strength model for Tantalum that includes both twinning and slip as deformation mechanisms in the regime of high strain rates.

[1]This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344 (LLNL-ABS-461533).

2:54PM T35.00003 Large Scale Dislocation Dyniamics Simulation of Precipitation Hardening in Ni-based Superalloys , RENGE LI, ZHIQIANG WANG — The precipitation hardening in Ni-based superalloys, which contain up to 73% volume fraction of γ', has been investigated by large scale 3D dislocation dynamics simulations. Dislocations glide under external stress across a {111} plane of γ/ γ' phase, intersected by cubic γ'precipitates. The critical resolved shear stress (CRSS) has been investigated for different microstructureal parameters: γ'volume fraction, anti-phase boundary (APB) energy and channel width. It is shown that the CRSS depends on the square root of the volume fraction of γ'. The CRSS is linearly proportional to the APB energy. Stuctures with a non-uniform distribution of γ'have CRSS that is 20%-30% smaller than a stucture with unique γ' size corresponding to the average size of the non-uniform disribution of γ'. The fact is that the channel width is not uniform and some channel width is larger than the average channel width of a stucture with a non-uniform distribution of γ', which makes the dislocation line easier to bend. This reveals that the channel width plays more important role than the γ' size. When channel width decreases to about 20nm, CRSS weakly depends on the γ'size and increases dramatically.

3:06PM T35.00004 Thermodynamics of point defects in deformable lattices , ROMAN GROGER, LIBOR SMEJKAL, Institute of Physics of Materials, Academy of Sciences of the Czech Republic, TURAB LOOKMAN, Theoretical Division, Los Alamos National Laboratory, USA — We develop a mean-field model that can be used to study the evolution of microstructure and the density of point defects in irradiated materials. Within this model, the lattice is viewed as an elastic template that is distorted by point defects. The stresses that each defect exerts on its immediate neighborhood in the lattice are represented by its elastic dipole tensor. The lattice responds to these stresses by developing long-range strains that mediate interactions between spatially separated defects. Nonlocal (gradient) elasticity is used to describe the elastic strain energy of the distorted lattice. This gives rise to the gradients of strain in the free energy and ensures an accurate representation of the phonon dispersion curves. In order to demonstrate this model, we consider a cubic lattice with a given density of randomly distributed vacancies and $\langle 100 \rangle$ split interstitials (dumbbells). The occupation of each cell is described by a "spin" with the states {ideal lattice, vacancy, and the three orientations of the $\langle 100 \rangle$ dumbbell}. The evolution of this spin field is obtained by the Monte Carlo (Metropolis) method, with the free energy calculated for each state of the system as described above. Double spin-flip mechanism is adopted to conserve the total mass of the system.

3:18PM T35.00005 Continuum dislocation dynamics: comparison between models , WOOSONG CHOI, YONG CHEN, STEFANOS PAPANIKOLAOU, JAMES SETHNA, Cornell University — Many continuum theories of dislocation dynamics have been proposed to bridge the gap in between discrete microscopic simulations and macroscale phenomenology. As of yet, however, these theories had limited success in explaining or predicting the physics of microstructure formation and evolution. Recently, we have shown that a simple isotropic continuum model dynamically form walls[1] and exhibit complicated microstructure formation and evolution[2] similar to experiments. Most other continuum theories have not seen such structures emerging, and to what extent this theory explains the physics remains to be answered. We explore several variants of the current theories which have different microscopic physics as to how slip systems, cross-slip, statistically stored dislocations, explicit or effective short range interactions, etc. are treated. Comparisons among simulation results of these models will be presented, and we will discuss the relevant mechanisms and their consequences in the dynamics of microstructures.

3:30PM T35.00006 Quantum Monte Carlo calculations of defects in aluminum[1] , RANDOLPH Q. HOOD, Lawrence Livermore National Laboratory, PAUL R.C. KENT, FERNANDO A. REBOREDO, Oak Ridge National Laboratory — We use first-principles fixed-node diffusion quantum Monte Carlo to calculate the energetics of point defects in bulk FCC aluminum demonstrating a very high accuracy when compared to experiment. Aluminum has been well studied experimentally as a "simple" metal prototype for investigating the effects of radiation damage such as void formation and helium embrittlement. Often accuracies at the level of milli-electronvolts are required, which is not achieved even for the simple case of pairs of vacancies in aluminum, using common density functionals. Perhaps surprisingly, even single vacancy energies are not reliable in many simple structural materials. Also presented are results for the bulk properties of aluminum - the equilibrium lattice constant, the cohesive energy, and the bulk modulus. These calculations bring a new level of rigor to the study of defects in metals.

[1]This work was supported by the U.S. Department of Energy, Office of Basic Energy Sciences as part of an Energy Frontier Research Center and was performed under the auspices of the U.S. Department of Energy by LLNL under Contract DE-AC52-07NA27344.

3:42PM T35.00007 Molecular dynamics simulation of ablation and spallation in nickel films irradiated by ultra-short laser pulses , BRIAN DEMASKE, VASILY ZHAKHOVSKY, University of South Florida, NAIL INOGAMOV, Landau Institute for Theoretical Physics, CARTER WHITE, Naval Research Laboratory, IVAN OLEYNIK, University of South Florida — Ablation and spallation of micron-sized Ni films irradiated by ultra-short laser pulses were investigated via large-scale molecular dynamics simulations. The interatomic interactions are described by a new embedded atom method potential that was specifically developed to accurately simulate response of Ni to strong compression and tensile waves as well as to high temperatures. It was shown that ablation results from cavitation within strongly stretched molten layer beneath the surface of the Ni film. Owing to a superposition of tensile waves, ablation threshold fluence is an increasing function of film thickness, which asymptotically approaches the experimental value for micron-sized films. Processes of wave-breaking and formation of ultra-short shock waves were also investigated in detail. Fluence threshold for onset of spallation at the rear of the film and spall strength of solid Ni subjected to ultrahigh strain rates were predicted.

3:54PM T35.00008 The thresholds of twinning in *bcc* tantalum[1] , KYLE CASPERSEN, ROBERT RUDD, MIKE SURH, LUIS SANDOVAL, DAVID RICHARDS, Lawrence Livermore National Laboratory — The dominate stress relaxation mechanism for most crystalline materials under most conditions is dislocation motion, or slip. However, materials subjected to extreme conditions (for example, conditions that arise in laser based dynamic compression experiments) can exhibit more complex stress relaxation mechanisms. Specifically, for large stress and large strain rates there is a competition between slip and phase transformations and twinning. The conditions at which phase transformations and twinning become important are not known. Therefore, here we present a molecular dynamics study of thresholds of twinning in *bcc* tantalum under various temperatures, pressures, and strain rates.

[1]Prepared by LLNL under Contract DE-AC52-07NA27344.

4:06PM T35.00009 Development of Phase-Field Crystal model free energy functionals based on molecular dynamics , D.M. NICHOLSON, Oak Ridge National Lab, J.A. DANTZIG, Univ. of Illinois, SARMA GORTI, Oak Ridge Natioanl Lab, BALA RANHAKRISHNAN, Oak Ridge National Lab, D.D. JOHNSON, Ames Lab — The Phase-Field Crystal (PFC) model represents the density as a continuous function, whose spatial distribution evolves in time at diffusional, rather than vibrational time scales. PFC provides a tool to study defect interactions at the atomistic level but over longer time scales than those achievable with MD. We examine the behavior of the PFC model with the goal of relating the PFC parameters to physical parameters for Fe and Mo, derived from molecular dynamics (MD) simulations (using either classical force fields or on density-functioanl-theory-based Hellmann-Feynman forces). MD and PFC results for diffusion rates, energy and volumes of fusion, and melting points as a function ofvacancy concentration are used to validate free energy functionals used in the PFC model. Acknowledgments: This work was supported by the Center for Defect Physics, an Energy Frontier Research Center funded by the US Department of Energy, Office of Science, Office of Basic Energy Sciences.

4:18PM T35.00010 Terminating Surface Electromigration at the Source[1] , KIRK BEVAN, McGill University / Oak Ridge National Laboratory, WENGUANG ZHU, University of Tennessee / Oak Ridge National Laboratory, HONG GUO, McGill University, ZHENYU ZHANG, Oak Ridge National Laboratory / University of Tennessee / University of Science and Technology of China — Through an extensive search across the periodic table utilizing first-principles density functional theory, we have established a general elemental trend for determining electromigration inhibiting impurities on the technologically important Cu(111) surface – the dominant diffusion pathway in modern nanoelectronics interconnects. Unrecognized thus far, such inhibitors are characterized by energetically favoring (and binding strongly at) the kink sites of step edges. These properties are determined to generally reside in elements that form strong covalent bonds with substrate metal atoms. This finding sheds new light on the possibility of halting surface electromigration via kink blocking impurities.

[1]Funding support from the US Department of Energy and NSERC of Canada is gratefully acknowledged.

4:30PM T35.00011 Coverage Dependent Collective Diffusivity of Dense Pb Wetting Layer on Si(111) , LI HUANG, CAI-ZHUANG WANG, Ames Laboratory, MAOZHI LI, Department of Physics, Renmin University of China, Beijing & Ames Laboratory, KAI-MING HO, Ames Laboratory — The anomalous mass transport in the Pb wetting layer on Si(111) surface observed in recent experiments is studied using dynamical calculations of a generalized Frankel-Kontorova model. Instead of typical random-type diffusion, a novel collective liquid-like motion of the Pb atoms within the dense wetting layers is revealed to give rise to the ultrafast kinetics of the wetting layers even at low temperatures. With this collective spreading mechanism of the dense wetting layer, a simple kinetic Monte-Carlo simulation quantitatively reproduces the experimental observations.

4:42PM T35.00012 Atomic layer deposition of metallic cobalt , JINHEE KWON, the University of Texas at Dallas, MARK SALY, RAVI KANJOLIA, SAFC, YVES CHABAL, the University of Texas at Dallas, THE UNIVERSITY OF TEXAS AT DALLAS COLLABORATION, SAFC COLLABORATION — Metallic cobalt has rich catalytic, electronic and magnetic properties, which makes it critical to have a better control of Co thin film deposition for various applications. This work focuses on the atomic layer deposition (ALD) of cobalt using (tertiarybutylallyl)cobalttricarbonyl (^{t}BuAllyl)Co(CO)$_3$ and dimethylhydrazine (DMHy) on H-terminated Si to uncover the growth mechanisms. The first pulse of (^{t}BuAllyl)Co(CO)$_3$ reacts with surface H–Si bonds completely, forming one monolayer of metallic silicide. In situ infrared absorption spectra show that further deposition of Co is made possible only after linear carbonyl groups which remain after the first (^{t}BuAllyl)Co(CO)$_3$ pulse as the surface ligand are removed by subsequent ALD cycles. Further ALD cycles give rise to metallic Co growth through ligand exchange after a nucleation period of 8–10 cycles. The derived growth rate of cobalt is 0.6 $\pm$ 0.1 Å/cycle. The resultant Co film shows low concentration of carbon and nitrogen impurities in the bulk according to X-ray photoemission spectroscopy.

4:54PM T35.00013 Periodic Stacking Faults in Ag Films Grown on Si(111) Decorated by Atomic Chains , AARON GRAY, University of Illinois Urbana Champaign, MANAMI OGAWA, University of Tokyo, HAWOONG HONG, Argonne National Lab, IWAO MATSUDA, University of Tokyo, TAI CHAING, University of Illinois Urbana Champaign — Thin films grown on a substrate decorated by a periodic array of atomic wires can exhibit unusual properties such as stacking faults and electronic topological phase transitions due to the interfacial modulation. We report a study of Ag films grown on an array of atomic In chains on Si(111). Prior STM studies have suggested an array of stacking faults in the Ag films that allow the film lattice structure to match the interfacial modulations. STM however can only probe the surface. Our work uses x-ray diffraction to elucidate the internal 3-dimensional structure of this system. The measurements are found to be best explained by a model in which the unit cell contains a single stacking fault.

5:06PM T35.00014 Measurement of the Spectral Distribution of Low Energy Electrons emitted as a result of NVV Auger Transitions in Ag (100)[1] , S. KALASKAR, Univ Of Texas at Arlington, S.L. HULBERT, Q. DONG, Brookhaven National Lab, NY, B.R. BARTYNSKI, Rutgers University, NJ, A.H. WEISS, Univ of Texas at Arlington — Auger Photoelectron Coincidence Spectroscopy (APECS) was used to investigate the physics of the Low Energy Tail (LET) of the Auger spectrum of Ag (100) at the National Synchrotron Light Source, Brookhaven National Lab, NY. The incident photon energy was set at 180eV. The APECS spectrum contains the contributions from electrons excited by the NVV Auger transition plus a background due to true coincidences between photoemitted valence band electrons that undergo inelastic scattering and transfer part of their energy with other valence electrons which exit the sample. A series of coincidence measurements were made with the fixed analyzer set at energies 150,160,171.5 and 175eV. These measurements were used to obtain an estimate of the background due to the inelastically scattered valance band electrons. The estimated background was then subtracted from the NVV APECS data to obtain the spectrum of electrons emitted solely as a result of the NVV Auger transitions, which contains implications for quantitative interpretation of the Auger spectrum.

[1]Welch Y1100 NSF DMR 0907679

5:18PM T35.00015 First measurements of the Low Energy Tail (LET) down to 0 eV using Auger Photoelectron Coincidence Spectroscopy (APECS) in Ag (100) and Cu (100)[1] , K. SHASTRY, S. KALASKAR, Univ of Texas at Arlington, S.L. HULBERT, Brookhaven National Labs, B.R. BARTYNSKI, Rutgers university, A.H. WEISS, Univ of Texas at Arlington — We present the Auger Photoelectron Coincidence Spectroscopy (APECS) measurements of Ag (100) and Cu (100) over a full range of emitted energies from 0 eV to 81eV. The measurements were successful in separating the low energy Auger lines from a large background, due to loss processes unrelated to the Auger transition. The measurements reveal a well formed Auger peak at 60 eV for Cu and an Auger peak at 40 eV for Ag accompanied by a low energy tail (LET). The LET extends to 0 eV with a broad maximum at 6eV and 10 eV in the case of Cu and Ag respectively. The integrated intensity of the LET in Cu (100) and Ag (100) were 6 and 2 times larger than that of the Auger peak itself. The origin of this LET is discussed in terms of extrinsic mechanisms in which electrons from the peak lose energy as they propagate to the sample surface, as well as intrinsic mechanisms in which multi-electron Auger processes distribute the energy gained by the filling of the core-hole to multiple valence electrons.

Session T36 DMP: Focus Session: Graphene Growth, Characterization, and Devices: Structure, Interfaces and Transfer C142

2:30PM T36.00001 Rotated graphene bilayers : from independent layers to electronic localization , LAURENCE MAGAUD, Institut Neel, CNRS, FRANCE — Graphene outstanding electronic properties rely on its pristine honeycomb lattice. Interaction with the environment - substrate, other C layers- and how it affects graphene properties will form the guiding line of the talk. While some interactions might degrade graphene properties, others can open new and interesting possibilities. We focus first on graphene on SiC. The atomic and electronic structures of the interface and of the first C-layers will be discussed on the basis of ab initio calculations (VASP) and STM experiments. At variance with the Si face, the interaction with the substrate is weak on the C face so that the first C-layer already presents graphene properties. We propose a model for the interface which explains the observed rotational disorder. We then discuss the effect of a rotation between two graphene layers to show how it can lead to an effective decoupling of these layers and a linear graphene like dispersion. To tackle very small rotation angles, we developed a tight binding scheme based on ab initio calculations. Three regimes can be defined as a function of the rotation angle. In the first one (teta$>$15°) the two layers are decoupled and behave like independent graphene layers. In the second one (1$<$teta$<$15°) the Dirac velocity of the bilayer is renormalised with respect to the velocity of a monolayer while in the last one (teta$\sim$1° or smaller) the velocity drops to zero which results in localisation. Theses three regimes will be discussed in the light of analytical developments. Experimental evidence or discrepancies with these three regimes will be given.

3:06PM T36.00002 Atomic Scale Transport in Graphene on Stepped SiC(0001) Surfaces , SHUAIHUA JI, JAMES B. HANNON, RUUD M. TROMP, ARTHUR W. ELLIS, MARK C. REUTER, FRANCES M. ROSS, IBM T. J. Watson Research Center, Yorktown Heights, NY — Thermal decomposition of SiC is a promising route to wafer-scale epitaxial graphene. However, the initial SiC surface contains steps, and graphene formation induces additional steps. Here we consider how these steps affect current transport in graphene. 1-2ML graphene was grown by annealing SiC above 1300°C in disilane. Low energy electron microscopy was used to determine graphene thickness, and transport through 1ML thick regions was measured by scanning tunneling potentiometry. In this technique a bias is applied between two fixed probes while a third, scanning probe measures the local electrochemical potential as well as topography. This allows us to determine the resistivity of the graphene sheet on terraces and across substrate steps. Single steps with 0.5nm height show very weak scattering. However, multiple steps of height 1.0 and 1.5nm scatter strongly, exhibiting a potential drop equivalent to $\sim$80nm and 120nm respectively of terrace graphene. Thus, step bunching is important, and steps separated by less than a few hundred nm can dominate transport through a graphene sheet.

3:18PM T36.00003 Twisting and Interlayer Coupling of Few Layer Graphene[1] , MINGHU PAN, XIAOTING JIA, VINCENT MEUNIER, MILDRED S. DRESSELHAUS, JING KONG — Few layer graphene (FLG) can be synthesized by chemical vapor deposition methods. Considering a graphene bilayer with a small angle rotation between the layers—a stacking defect was observed by high resolution scanning tunneling microscopy. Low-energy Van Hove singularities in twisted graphene layers are identified as two sharp peaks in the density of states by low temperature scanning tunneling spectroscopy. Electronic instabilities at the crossing of the Fermi energy with a Van Hove singularity in the density of states often lead to new phases of matter such as charge/spin density waves. We here observe the coexistence of a charge density wave (CDW) phase and a normal phase on the top graphene layer. By analyzing the Moiré pattern in a normal region, a twisting between the two layers by a relative large angle about 3.9° is identified. This implies that the interlayer coupling for twisted layers is playing a role in the formation of different electronic phases in FLG.

[1]This research was conducted at the Center for Nanophase Materials Sciences, which is sponsored at Oak Ridge National Laboratory by the Division of Scientific User Facilities, U.S. Department of Energy.

3:30PM T36.00004 Electronic structure of twisted bilayer graphene with doping and under electric fields , LEDE XIAN, SALVADOR BARRAZA-LOPEZ, MEI-YIN CHOU, Georgia Tech — Rotational stacking faults of graphene layers in epitaxial graphene are believed to electronically decouple adjacent layers, thus single-layer graphene-like behavior can be observed. In addition, the layers close to the SiC substrate are known to be electron doped. Using density functional theory and a pi-electron, highly tuned tight-binding model, we study the modifications of the band structure in rotational stack-faulted bilayer graphene induced by doping and by external electric fields. In particular, the interlayer coupling, the magnitude of the Fermi velocity, and the possible impact on charge transport will be discussed.

3:42PM T36.00005 Imaging the first few layers of Multilayer Epitaxial Graphene grown on SiC $(000\bar{1})$, JEREMY HICKS, M. SPRINKLE, B. ZHANG, Georgia Institute of Technology, A. TEJEDA, A. TALEB-IBRAHIMI, P. LE FÉVRE, F. BERTRAN, Synchrotron SOLEIL, W.A. DE HEER, E.H. CONRAD, Georgia Institute of Technology — Multilayer Epitaxial Graphene (MEG) grown on the C-terminated $(000\bar{1})$ face of SiC has been shown to behave as a series of nearly independent graphene sheets, distinguishing it from few-layer graphite. We present photoemission data from MEG films of 10 Å or less, finding that the first few graphene layers on top of SiC are easily visible and are n-doped in a similar fashion to graphene grown on the Si-terminated face. Combined with the characteristic diversity of rotations in MEG films, we have obtained numerous different combinations of cone doping and rotation angles, allowing us to explore a variety of phenomena associated with the graphene-SiC interface interaction. We find that, unlike similarly-doped graphene grown on the Si-terminated face, there exists no large mismatch between the conduction and valence bands. Other potential effects of the substrate are discussed, as well as efforts in modifying the graphene-SiC interface.

3:54PM T36.00006 ABSTRACT WITHDRAWN –

4:06PM T36.00007 Epitaxial graphene on SiC(0001): More than just honeycombs , L. LI, University of Wisconsin, Milwaukee, WI 53211, Y. QI, R.H. RHIM, G.F. SUN, M. WEINERT — Combing scanning tunneling microscopy using transition-metal (Fe, Cr)-coated W tips and first-principles calculations, we show that the interface of epitaxial graphene/SiC(0001) is a warped graphene layer with periodic inclusions of hexagon-pentagon-heptagon ($H_{5,6,7}$) defects [1]. These defects break the six-fold honeycomb symmetry, thereby inducing a gap and two states below E_F near the Dirac point. Furthermore, we show that the next graphene layer assumes the perfect honeycomb lattice, but its interaction with the warped interfacial layer modifies the linear dispersion about the Dirac point, leading to parabolic dispersion and an apparent gap of $\sim$0.25 eV. These results explain recent angle-resolved photoemission and carbon core-level shift data, and resolve the long-standing issue of the interfacial structure of epitaxial graphene on SiC(0001).

4:18PM T36.00008 Interfacial Structures of Graphene on 4H- SiC Substrates: SCED-LCAO Molecular Dynamics[1] , MING YU, University of Louisville, SEAN FANCHER, Purdue University, JOSEPH H. BUTERA, C.S. JAYANTHI, S.Y. WU, University of Louisville — The purpose of this work is to obtain a microscopic understanding of the interface between the graphene and Si-terminated as well as C-terminated 4H-SiC substrates by studying several cases of nearly commensurate overplayed structures. Relative energies of these different structures are calculated using the SCED-LCAO method [PRB **74**, 15540; PHYSE **42**,1] to gain insight into the role played by the lattice mismatch in releasing the strain and thus lowering the energy of the system. Further insight into the interfacial properties is obtained by analyzing the local strain in terms local atomic and bonding arrangements [PRB **59**, 7745] which will be correlated to the lattice mismatch. Our results will be compared with current experimental [PRL **100**, 176802; PRB **77**, 155303; J. Phys: Condens Matter **21**, 134016; PRB **78**, 205424; J. Phys: Condens Matter **20**, 323202] and theoretical [PRL **99**, 076802; PRL **99**, 126805; PRB **77**, 235412; PRL **100**, 176802] results.

[1]This work is supported by the Research Corporation (RC19902).

4:30PM T36.00009 Epitaxial graphene on SiC(0001): It takes a Si jump , G.F. SUN, Y. LIU, S.H. RHIM, University of Wisconsin, Milwaukee, WI 53211, J.F. JIA, Q.K. XUE, Tsinghua University, Beijing 100084, P. R. China, M. WEINERT, L. LI, University of Wisconsin, Milwaukee, WI 53211 — Using scanning tunneling microscopy with transition metal (Fe, Cr)-coated W tips and first-principles calculations, we have recently shown that interface of epitaxial graphene/SiC(0001) is a warped graphene layer with periodic inclusions of hexagon-pentagon-heptagon ($H_{5,6,7}$) defects that break the six-fold honeycomb symmetry [1]. Here we show that this unique structure facilitate a novel pathway for the disposal of Si during growth: the diffusion of Si vertically through the warped interfacial layer via a series of configurations that involve the dissociation and formation of C-C and Si-C bonds within the pentagon and heptagon of the $H_{5,6,7}$ complex. The calculated energy barrier for this diffusion path is 4.7 eV. These results and their implications on the self-limiting growth of epitaxial graphene on SiC(0001) will be presented at the meeting.

[1] Qi et al., Phys. Rev. Lett. **105**, 085502 (2010).

4:42PM T36.00010 Inhomogeneous strain fields in epitaxial graphene[1] , DIEDRICH A. SCHMIDT, Ruhr-University Bochum Dept. Physical Chemistry II, TAISUKE OHTA, LAURA B. BIEDERMANN, THOMAS E. BEECHEM, STEPHEN W. HOWELL, GARY L. KELLOGG, Sandia National Laboratories — We report a large, inhomogeneous in-plane compressive strain (up to 0.5%) and its local variation at micrometer length scales in single layer graphene films on silicon carbide (SiC) (0001). The strain, due to the difference in lattice constants and thermal expansion coefficients of graphene and SiC substrate, is probed using Raman scattering and low energy electron diffraction. We show that both the growth mechanism and the relaxation along the mismatched symmetry of the graphene and underlying substrate can affect the exact amount of local strain. The large compressive strain implies that monolayer graphene is tightly grafted to the underlying interface layer and SiC substrate; otherwise it would delaminate to relieve the strain. The magnitudes of the structural strain and its local variation are significant and need to be taken into account for electronics applications of the graphene-SiC(0001) system.

[1]This work was supported by BMBF grants 05KS7PC2 and 05K10PCA, the LDRD program at SNL, and the US DOE Office of Basic Energy Sciences' Division of Materials Science and Engineering (Contract No. DE-AC04-94AL85000).

4:54PM T36.00011 Direct Printing of Graphene onto Plastic Substrates. , DANIEL HINES, Laboratory for Physical Sciences, EVGENIYA LOCK, SCOTT WALTON, MIRA BARAKET, MATTHEW LASKOSKI, SHAWN MULVANEY, PAUL SHEEHAN, WOO LEE, JEREMY ROBINSON, Naval Research Laboratory — Graphene films have been synthesized on metal foils using CVD growth and have the potential to be compatible with roll-to-roll printing. To be usable in electronic devices, these films need to be removed from the metallic substrate. Currently this is accomplished by spin coating a polymer film over the graphene and chemically etching away the metal substrate. We have developed a direct printing method that allows graphene films to be printed off the metal substrate onto a polymer substrate. This printing process does not generate chemical waste, is compatible with roll-to-toll processing and renders the metal foil reusable. Adhesion of the graphene film to the polymer substrate is established by attaching perfluorophenylazides (PFPA) azide linker molecules to a plasma activated polymer surface. The transfer printing was performed by placing the PFPA treated polymer surface in contact with a graphene covered Cu foil and heating under pressure. Graphene films successfully printed onto a polystyrene substrate have been characterized by Raman spectroscopy and electrical measurements revealed the presence of Gr on the polymer surface. Details of the printing process along with characteristics of the graphene film after printing will be presented.

5:06PM T36.00012 Improved methods of transfer of graphene from growth substrate to other surfaces and devices , YUJIE REN, HUIFENG LI, Univ. of Texas at Austin, WEIWEI CAI, Xiamen University, SHANSHAN CHEN, RICHARD PINER, RODNEY RUOFF, Univ. of Texas at Austin — Transfer of graphene films from the growth substrate to other surfaces has turned out to be one of the important challenges to creating graphene based devices. In this talk we will review new techniques which we are developing to meet these challenges. In addition to describing the best technique we have to date, we will show data demonstrating the effectiveness of these techniques. Our analysis includes scanning micro-Raman spectroscopy, electronic measurements with FET devices created with our techniques and other microscopic techniques. FET measurements indicate a strong influence of transfer technique on the doping of the device.

Wednesday, March 23, 2011 2:30PM - 5:30PM –

Session T37 DMP: Focus Session: Graphene Structure, Dopants, and Defects: Nanoribbons

C146

2:30PM T37.00001 Atomically Precise Bottom-up Fabrication of Graphene Nanoribbons , JINMING CAI, Empa, Swiss Federal Laboratories for Materials Science and Technology — Graphene nanoribbons (GNRs) – narrow stripes of graphene – are predicted to exhibit remarkable properties making them suitable for future electronic applications. Contrary to their two-dimensional (2D) parent material graphene, which exhibits semimetallic behavior, GNRs with widths smaller than 10 nm are predicted to be semiconductors due to quantum confinement and edge effects. Despite significant advances in GNR fabrication using chemical, sonochemical and lithographic methods as well as recent reports on the successful unzipping of carbon nanotubes into GNRs, the production of sub-10 nm GNRs with chemical precision remains a major challenge. In this talk, we will present a simple GNR fabrication method that allows for the production of atomically precise GNRs of different topologies and widths [1]. Our bottom-up approach consists in the surface-assisted coupling of suitably designed molecular precursors into linear polyphenylenes and their subsequent cyclodehydrogenation, and results in GNRs whose topology, width and edge periphery are defined by the precursor monomers. By means of STM and Raman characterization, we demonstrate that this fabrication process allows for the atomically precise fabrication of complex GNR topologies. Furthermore, we have developed a reliable procedure to transfer GNRs fabricated on metal surfaces onto other substrates. It will for example be shown that millimeter sized sheets of crosslinked GNRs can be transferred onto silicon wafers, making them available for further processing, e.g. by lithography, prototype device fabrication and characterization.

3:06PM T37.00002 Templated graphene nanoribbon growth on SiC , MING RUAN, MIKE SPRINKLE, YIKE HU, JOHN HANKINSON, MIGUEL RUBIO-ROY, BAIQIAN ZHANG, RUI DONG, ZELEI GUO, Georgia Institute of Technology, CLAIRE BERGER, Georgia Institute of Technology & CNRS- Institut Néel, WALT DE HEER, Georgia Institute of Technology — We demonstrate a photo-lithography fabrication method of graphene nanoribbon. Epitaxial graphene is grown selectively on SiC (1-10n) facets. For this, SiC is patterned to define 3-dimensional structures. Epitaxial graphene nanoribbons grow preferentially on the exposed sidewalls recrystallized facets that avoids post-processing lithography damage of graphene ribbons. Graphene ribbons narrower than 30nm were produced with this method and all-graphene interconnected structures are fabricated. Metal contacts are evaporated on large graphene areas seamlessly connected to nanoribbons. Transport measurement shows gap opening and high mobility. SiC crystal faceting was also explored. Low index crystal facets where found to be energetically favored.

3:18PM T37.00003 Influence of size effects and substrate morphology on the conductance of epitaxial graphene nanoribbons , SARAH BRYAN, YINXIAO YANG, RAGHU MURALI, Georgia Institute of Technology — To utilize graphene's superior electrical properties and achieve transistor operation comparable to that of silicon, the properties of graphene nanoribbons need to be better understood and optimized. Lithographically patterned nanoribbons suffer from line edge roughness which can result in a detrimental effect on the graphene conductivity. In addition to edge-induced scattering, the morphology of the silicon carbide substrate appears to have a strong effect on the line width scaling behavior. In this talk, we present experimental data that clearly shows the interplay between substrate morphology and line edge roughness in epitaxial graphene nanoribbons. Resistivity is shown to strongly increase as nanoribbon line width is reduced, although the line width at which this behavior sets in varies depending upon the substrate morphology. We also propose a model which can be used to predict the dependence of graphene nanoribbon resistivity on line width.

3:30PM T37.00004 Large-scale production of Graphene Nanoribbons with controlled width: Electrical Properties of Graphene Nanoribbon Films[1] , VIKAS BERRY, NIHAR MOHANTY, ASHVIN NAGARAJA, Kansas State University, DAVID MOORE, University of Kansas — In this talk, we will demonstrate a novel large scale production (10^7 ribbons/ sec) scheme for several microns long, smooth-edged graphene nanoribbons (GNRs) with controlled widths (from 5 – 50 nm). We will then present detailed structural, optical and electrical properties of GNR-films $\sim$ 100 nm thick produced from 5, 15, and 45 nm wide GNRs; including their band-gap evolution and electrical transport mechanism. The high throughput method to synthesize GNR of high-quality will be a quantum leap in the graphene research. The work indents to bridge the gaps in the understanding of monodisperse-GNR film properties.

[1]NSF CMMI 0939523

3:42PM T37.00005 Correlated crystallographic etching of graphene and nanoribbon formation , STEPHEN JOHNSON, D. PATRICK HUNLEY, University of Kentucky, JOSEPH STIEHA, ABHISHEK SUNDARARAJAN, ARUNITA KAR, University of Kentucky, A.T. CHARLIE JOHNSON, University of Pennsylvania , DOUGLAS STRACHAN, University of Kentucky — Catalytic etching is a promising method for constructing crystallographically defined graphene structures such as nanoribbons. Catalytic etching experiments are performed and shown to contain significant correlation yielding crystallographic graphene nanoribbons. This correlation is investigated as a function of etching conditions and compared to simulations with possible sources discussed. Supported in part by NSF Award No. DMR-0805136, the Kentucky NSF EPSCoR program, the University of Kentucky Center for Advanced Materials, and the University of Kentucky Center for Nanoscale Science and Engineering.

3:54PM T37.00006 Aligned, ultra-long graphene nanoribbon network fabrication by nanowire etch masks , JOSHUA WOOD, SEAN SIVAPALAN, VINCENT DORGAN, CATHERINE MURPHY, ERIC POP, JOSEPH LYDING, University of Illinois at Urbana-Champaign — Patterning semi-metallic graphene into quasi one-dimensional structures known as nanoribbons (GNRs) can open a ∼0.5 eV bandgap by quantum confinement [1]. To circumvent GNR lithographic difficulties, Si nanowires (NWs) were used previously as an etch mask for exfoliated graphene [2], but with no scalability or alignment control. Conversely, we transfer ∼1 in^2 graphene sheets off copper to silicon dioxide, giving us a template for array fabrication. We meniscus align both Au NWs (<w>=20 nm, <l>=400 nm) and Ag NWs (<w>=200 nm, <l>=10 μm), respectively, on the graphene surface. By reactive ion etch (RIE), we remove the unmasked graphene, and we etch the NWs. Based on the starting NWs, the resulting GNR arrays have lengths ranging from 200 nm to tens of microns, and widths from 10 nm to 250 nm. We create single GNRs that can span micron-separated contacts and GNR networks, similar to a graphene nanomesh. Using atomic force microscopy and Raman spectroscopy, we determine that we have monolayer GNRs with a high disorder intensity I_D/I_G ∼1, indicating rough edges and graphene grain boundaries, which are deleterious to transport. 4:06PM T37.00007 Polymer electrolyte enhanced performance in graphene nanoribbon field-effect transistors[1] , CHENG LING, MING-WEI LIN, YIYANG ZHANG, XUEBIN TAN, MARK MING-CHENG CHENG, ZHIXIAN ZHOU, Wayne State University — Graphene nanoribbon Field-effect transistors were fabricated from unzipped multiwall carbon nanotubes on Si/SiO2 substrate by standard electron beam lithography and metal deposition. A small drop of polymer electrolyte consisting of poly(ethylene oxide) and lithium perchlorate was applied to the graphene nanoribbon devices. Electrical transport properties of the polymer electrolyte covered devices were measured using both the Si-back-gate and polymer-electrolyte-gate configurations. We observed dramatic increase of carrier mobility, significant reduction of the peak-width of the resistance as a function of the back-gate voltage, and the shift of the charge neutrality point toward zero gate-voltage in polymer electrolyte covered graphene nanoribbon devices. These experimental results will be presented and discussed in the context of ionic and dielectric screening of charged impurities on or near the graphene nanoribbons.

4:18PM T37.00008 Enhanced Conductance Fluctuation by Quantum Confinement Effect in Graphene Nanoribbons[1] , GUANGYU XU, Dept. Electrical Engineering, UCLA, CARLOS TORRES JR., JIANSHI TANG, UCLA EE, JINGWEI BAI, Dept. Material Science and Engineering, UCLA, EMIL SONG, UCLA EE, YU HUANG, UCLA MSE, XIANGFENG DUAN, Dept. Chemistry and Biochemistry, UCLA, YUEGANG ZHANG, Molecular Foundry, LBNL, WANG KANG, UCLA EE, UCLA EE TEAM, UCLA MSE TEAM, UCLA CHEM TEAM, LBNL TEAM — Conductance fluctuations are usually unavoidable in graphene nanoribbons (GNR) due to the presence of disorder along its edges. By measuring the low-frequency noise in GNR devices, we find that the conductance fluctuations are strongly correlated with the density-of-states of GNR [1]. In single-layer GNR, the gate-dependence of noise shows peaks whose positions quantitatively match the subband positions in the band structures of GNR. This correlation provides a robust mechanism to electrically probe the band structure of GNR, especially when the subband structures are smeared out in conductance measurement.

4:30PM T37.00009 Doping Level Dependence of Transfer Characteristic of n-type Graphene Nanoribbon Field Effect Transistors , LU WANG, RUI QIN, JING ZHOU, HONG LI, JIAXIN ZHENG, JING LU, State Key Laboratory for Mesoscopic Physics and Department of Physics, Peking University, Beijing 100871, P. R. China, WAI-NING MEI, Department of Physics, University of Nebraska at Omaha, Omaha, Nebraska 68182-0266, SHIGERU NAGASE, Department of Theoretical and Computational Molecular Science, Institute for Molecular Science, Okazaki 444-8585, Japan — By performing first principles calculations and electron transport simulations, we demonstrate that the transfer curves of graphene nanoribbon field effect transistors can be controlled by changing the concentration of potassium atoms and cobaltocene molecules doping, or nanoribbon edge carbon atoms substitution by nitrogen. We reveal that Dirac point shift downward from 0 to -12 V when the impurity concentration increase from 0 to 1.37%, while the transfer curves maintain bipolar characteristics with reasonably high on/off ratios. Moreover, we observed strong charge transfer from the adsorbed atoms and molecules that facilitates n-type characteristics in graphene nanoribbons. Thus, we suggest that an effective way to achieve tunable n-type graphene nanoribbons field effects transistors is to dope them with electron donors.

4:42PM T37.00010 The search for stable sp2 zigzag edge graphene nanoribbon termination , CHENGING CHIA, VINCENT CRESPI, Department of Physics, Penn State University — The zig-zag edge of a graphene ribbon has attracted much attention, since it is predicted to support a spin-polarized edge state. However, it is difficult to produce thermodynamic conditions that favor a pure sp^2 termination of a graphene sheet, since the edge carbons generally prefer to bond to two hydrogen atoms, in sp^3 hybridization, rather than one hydrogen, as sp^2. We examine several candidate alternative termination groups which can modify the thermodynamics of various edge configurations to favor the sp^2 edge termination. Ab-initio calculations demonstrate these alternative terminations can support robust edge states across a broad range of synthetic conditions.

4:54PM T37.00011 High resolution thermal properties study of Joule self-heated graphene nanoribbon[1] , YOUNG-JUN YU, MELINDA Y. HAN, STÉPHANE BERCIAUD, TONY F. HEINZ, LOUIS E. BRUS, Columbia University, KWANG S. KIM, Pohang University of Science and Technology, PHILIP KIM, Columbia University — We present high resolution thermal properties of Joule self-heated graphene nanoribbons (GNRs) by scanning thermal microscope (SThM) which enables local temperature survey within 100 nm spatial resolution. In order to calibrate the SThM probes, we employ the micro-Raman spectroscopy to measure the temperature distribution across a standard graphene device as a function of applied electrical power. This calibrated SThM measurement allows us to scrutinize the temperature distributions in GNRs attributed to Joule heating variation in the channel due to the locally enhanced scattering which forms hot spot formation. We also estimate the junction thermal resistance between GNR and SiO_2 substrate from the temperature distribution of the GNR devices. In addition, we will discuss simultaneous SThM and scanning Kelvin probe microscopy study of high quality exfoliated graphene on hexagonal boron nitride substrate.

5:06PM T37.00012 Thermal transport in graphene nanoribbons: R-Matrix theory approach[1] , K.G.S.H. GUNAWARDANA, Homer L .Dodge Department of Physics and Astronomy, Center for Semiconductor Physics in Nanostructures, The University of Oklahoma, KIERAN MULLEN, Homer L. Dodge Department of Physics and Astronomy, Center for Semiconductor Physics in Nanostructures, The University of Oklahoma — We have developed a new theoretical tool based on R-Matrix theory to calculate phonon scattering on the atomic scale. As device sizes shrink, boundary and interface scattering have become bottlenecks to thermal transport. Therefore, calculating thermal transport considering the atomistic constitution of a device is very important. In this R-Matrix approach, we consider a finite region, which is the main scattering center of the system, connected to semi-infinite leads. We develop interior region solutions (normal modes of the finite system) and lead solutions(periodic waves with dispersion) independently that can be matched at predefined boundaries to extract the transmission probabilities of each phonon modes in the lead. In this work we demonstrate the implementation of the theory for graphene nanoribbons.

5:18PM T37.00013 Strong suppression of thermal conductivity in edgedisordered graphene nanoribbons: Order-N methodology and thermoelectric properties , HALDUN SEVINCLI, Institute for Materials Science and Max Bergmann Center of Biomaterials, Dresden University of Technology, 01062 Dresden, Germany, WU LI, STEPHAN ROCHE, GIANAURELIO CUNIBERTI, Institute for Materials Science and Max Bergmann Center of Biomaterials, TU-Dresden, 01062 Dresden, Germany — We investigate electron and phonon transport through edge disordered graphene nanoribbons. Electronic transport is calculated using Green's functions[1] while for phonons we develop an efficient linear scaling method [2-3] which is based on the Chebyshev polynomial expansion of the time evolution operator and the Lanczos tridiagonalization scheme. We show that edge disorder dramatically reduces phonon thermal transport in both armchair and zigzag ribbons, while in zigzag graphene nanoribbons edge disorder is only weakly detrimental to electronic conduction. The behavior of the electronic and phononic elastic mean free paths points to the possibility of realizing an electron-crystal coexisting with a phonon-glass. The calculated thermoelectric figure of merit (ZT) values qualify zigzag graphene nanoribbons as a promising material for thermoelectric applications.

Session T38 DCP DBP: Focus Session: Quantum Coherence in Biology IV A130/131

2:30PM T38.00001 Biophysics of Magnetic Orientation: Radical Pairs, Biogenic Magnetite, or both? , JOE KIRSCHVINK, California Institute of Technology — Two major biophysical mechanisms for magnetoreception in terrestrial animals, one based on biogenic magnetite and another on radical-pair biochemical reactions, have been the subject of experiment and debate for the past 30 years. The magnetite hypothesis has stood the test of time: biogenic magnetite is synthesized biochemically in Bacteria, Protists, and numerous Animal phyla, as well as in some plants. Chains of single-domain crystals have been detected by clean-lab based SQUID magnetometry in animal tissues in all major phyla, followed by high-resolution TEM in selected model organisms, as well as by electrophysiological studies demonstrating the role of the ophthalmic branch of the trigeminal nerve in the magnetoreceptive process. Pulse-remagnetization - configured to uniquely flip the polarity of single-domain ferromagnets - has dramatic effects on the behavior of many birds, honeybees, mole rats, turtles, and bats, to cite a growing list. Magnetite-containing cells in the vicinity of these neurons in fish are now the subject of intense study by our consortium. The existence of a specialized class of magnetite-containing magnetoreceptor cells in animal tissues is no longer controversial. In contrast, less success has been achieved in gaining experimental support across a range of taxa for the radical-pair hypothesis. Although this mechanism was proposed to explain an early observation that birds would not respond to complete inversion of the magnetic vector, many organisms (even some birds) do indeed respond to the field polarity. We also note that few, if any, of these critical experiments have been done using fully double-blind methods. This is joint work with: M. M. Walker (University of Auckland, New Zealand) and M. Winklhofer (LMU Munich, Germany).

3:06PM T38.00002 Magnetic compasses in biological systems: Does quantum physics play a role? , THORSTEN RITZ, Dept of Physics and Astronomy, University of California, Irvine — One hypothesis of the process underlying the magnetic compass of animals surmises that the magnetic field is perceived by its effect on the coherent spin evolution within a non-equilibrium photochemical radical pair reaction. If this hypothesis were proven, it would be a dramatic demonstration of a quantum process with clear biological significance. We will review the physics of the radical pair mechanism and the current state of evidence supporting it. Experimentally, we will focus on the use radio-frequency magnetic fields to affect a radical-pair based mechanism in birds and discuss the approach and its limitations. Theoretically, we will focus on the question of how one should design a radical pair to be optimally sensitive to the direction of a weak magnetic field. Regardless of whether or not a radical pair mechanism is indeed used by birds or other animals, optimal design features could be used to manufacture biologically inspired, but man-made magnetic compass systems.

3:42PM T38.00003 Quantum Control and Entanglement in a Chemical Compass , GIAN GIACOMO GUERRESCHI, JIANMING CAI, HANS J. BRIEGEL, University of Innsbruck, Institute for Quantum Optics and Quantum Information (IQOQI) of the Austrian Academy of Science — The radical-pair mechanism is one of the two main hypotheses to explain the navigability of animals in weak magnetic fields, enabling, e.g., birds to see Earth's magnetic field. It also plays an essential role in spin chemistry. Here, we show how quantum control can be used to either enhance or reduce the performance of such a chemical compass, providing a new route to further study the radical-pair mechanism and its applications. We study the role of radical-pair entanglement in this mechanism, and demonstrate its intriguing connections with the magnetic-field sensitivity of the compass. Beyond their immediate application to the radical-pair mechanism, these results also demonstrate how state-of-the-art quantum technologies could potentially be used to probe and control biological functions.

3:54PM T38.00004 A Biochemical Double Slit , IANNIS KOMINIS, University of Crete - Physics Department — Radical-ion-pair reactions, fundamental in photosynthesis and at the basis of the avian magnetic compass mechanism, have been recently shown to offer a rich playground for applying methods and concepts from quantum measurement/quantum information science. We will demonstrate that radical-ion-pair reactions are almost the exact analog of the optical double slit experiment, i.e. Nature has already engineered biochemical reactions performing the act of quantum interference. We will further elaborate on the non-trivial quantum effects pertaining in these reactions and the recent debate on their fundamental theoretical description that these effects have sparked.

Wednesday, March 23, 2011 2:30PM - 5:18PM –

Session T39 DBP: Computational Molecular Biophysics A124/127

2:30PM T39.00001 Simulation of pH-dependent Behavior of Liposome , REJWAN ALI, Fordham University & Queensborough Community College of CUNY — Optimized liposome for biomedical delivery applications has been a field of vigorous research for past few decades. While experimental techniques of fluorescence spectroscopy, differential scanning calorimetry and dynamic light scattering report physical suitabilities in several applications of liposomes, molecular dynamics simulation can provide more detailed feature at atomistic level for such biophysical systems. In recent times, experimental results of liposome's physical properties in different pH environment have widely been reported. The system draws interest for potential applications in several biomedical areas. We will present our molecular simulation results for such system highlighting the effect of pH on hydrogen bonding as well as correlation of dynamics to observed phase behavior.

2:42PM T39.00002 *In silico* investigation of molecular effects caused by missense mutations in creatine transporter protein[1] , ZHE ZHANG, Clemson University, CHARLES SCHWATZ, Greenwood Genetic Center, EMIL ALEXOV, Clemson University — Creatine transporter (CT) protein, which is encoded by SLC6A8 gene, is essential for taking up the creatine in the cell, which in turn plays a key role in the spatial and temporal maintenance of energy in skeletal and cardiac muscle cells. It was shown that some missense mutations in CT cause mental retardation, while others are harmless non-synonymous single nucleoside polymorphism (nsSNP). Currently fifteen missense mutations in CT are known, among which twelve are disease-causing. Sequence analysis reveals that there is no clear trend distinguishing disease-causing from harmless missense mutations. Because of that, we built 3D model of the CT using highly homologous template and use the model to investigate the effects of mutations of CT stability and hydrogen bond network. It is demonstrated that disease-causing mutations affect the folding free energy and ionization states of titratable group in much greater extend as compared with harmless mutations.

2:54PM T39.00003 Investigating the mechanism of DNA bulk hybridization with Forward Flux Sampling , DANIEL HINCKLEY, Department of Chemical and Biological Engineering, University of Wisconsin-Madison — DNA has become increasingly common as a building block for constructing nanomaterials. However, the mechanism by which DNA hybridization occurs is largely unknown, even in the bulk. Previous work using Transition Path Sampling and a coarse grain DNA model has shown that DNA bulk hybridization occurs via a "slithering" mechanism for repetitive sequences and a distinct nucleation event for random sequences. This mechanistic description remains somewhat incomplete as only configurations within the general vicinity of the transition state ensemble have been examined. In this work, we use Forward Flux Sampling and Langevin Dynamics to examine configurations along the entire transition pathway. We find that, for random sequences, barriers to hybridization arise at certain points in the hybridization pathway requiring reorientation of the two strands. Such barriers are not as pronounced for repetitive sequences where rearrangement occurs without the large scale disruption of hydrogen bonding. The formalism which we use has allowed us to calculate reaction constants for hybridization that are consistent with experiments. It has also allowed us to explain the precipitous decay of reaction rates that is observed when molecular weight is increased.

3:06PM T39.00004 A backbone based protein model with explicit solvent , SUMIT SHARMA, Princeton University, SERGEY BULDYREV, Yeshiva University, PETER J. ROSSKY, University of Texas Austin, H. EUGENE STANLEY, Boston University, PABLO G. DEBENEDETTI, Princeton University, C. AUSTEN ANGELL, Arizona State University, SANAT K. KUMAR, Columbia University — The computational expense of folding atomistically detailed protein models is prohibitive. Hence minimalist models of proteins are a popular choice. The minimalist models developed so far have excluded water, and treated the hydrophobic effect as an effective attraction between hydrophobic monomers. This simplified treatment does not capture the temperature-dependent variations in entropy and enthalpy of water molecules. Proteins have a predominantly water-screened hydrophobic core and water-exposed polar groups. This structural feature should alter the dynamics of proteins and surrounding water from that of a hydrophobic homopolymer in water. To include these features in a minimalist model, we designed heteropolymers of polar and hydrophobic monomers in explicit water-like medium. The polar monomers and water molecules were modeled with the Jagla potential, which has been shown to reproduce many water-like thermodynamic properties, and the hydrophobic monomers as hard spheres. We discuss a methodology for optimizing the sequence of these heteropolymers and how the hydrophobic collapse of these heteropolymers differs from that of a random heteropolymer.

3:18PM T39.00005 Connecting ion channel simulations to experiment , PETER HUGO NELSON, Benedictine University — A simple theoretical framework is used to connect MD simulation with ion channel permeation experiments. MD simulations of potassium channels typically exhibit at least two stable selectivity filter states, one with double occupancy and another with triple occupancy. In the association/dissociation (A/D) model, transitions between these two states occur via concerted motion of all three ions in a shunt-on shunt-off mechanism that is consistent with a large group of published MD simulations. This is the simplest model that explains the universal saturating behavior observed experimentally for many ion channels. Published permeation experiments through the MaxiK channel over a wide range of concentrations and positive voltages are shown to be remarkably consistent with the predictions of this model. Published MD simulations of the Kv1.2 potassium channel exhibit an extended shunt-on shunt-off mechanism at one end of the selectivity filter and a pop-off pop-on mechanism at the other end. This two-step mechanism is incorporated into an asymmetric variant of the A/D model that successfully explains published permeation data through the Shaker potassium channel at physiological concentrations, and successfully predicts qualitative changes in the negative current-voltage data (including a transition to super-Ohmic behavior) based solely on a fit to positive voltage data (that appear linear). Support from NSF 0836833 is gratefully acknowledged.

3:30PM T39.00006 On the Minimum Energy Path to Membrane Pore Formation , CHRISTINA TING, ZHEN-GANG WANG, California Institute of Technology — Several experimental methods have been developed to study the mechanical response of vesicles under an applied tension. Of particular note are the micropipette aspiration techniques and the use of a viscous solution to extend the lifetime of pores. MD simulations have also been used to study the energetic and structural properties of these transient pores on a molecular level. However, they often require extremely high tensions beyond the regime where pore formation is a thermally-activated event. We approach the nucleation problem by combining the string method with dynamic self-consistent field (DSCF) theory to obtain the full minimum energy path (MEP) to pore formation for a range of surface tensions γ. We compare our results with classical nucleation theory (CNT). Near the coexistence ($\gamma \to 0$) the rim of the pore is well-defined and the line tension is well approximated by the macroscopic definition given by CNT. However, when the free energy barrier is within $\sim 10\ \mathrm{kT}$, the transition state is somewhere between a stalk-like structure and a thinned membrane leading to a hole that is partially exposed to solvents. These molecular rearrangements involved in the formation of a pore are not captured by CNT.

3:42PM T39.00007 Capturing electrostatic interactions explicitly with the 3SPN model for DNA , GORDON S. FREEMAN, DANIEL M. HINCKLEY, JUAN J. DE PABLO, Department of Chemical and Biological Engineering, University of Wisconsin-Madison — The "Three Sites Per Nucleotide" (3SPN) model for nucleic acid simulation provides a powerful tool for computational studies of biological phenomena. Previously, this model has relied on an implicit representation of the surrounding ionic environment at the level of Debye-Hückel theory. In this work, we eliminate this limitation and implement an explicit representation of ions, both monovalent and divalent. The coarse-grain ion-ion and ion-phosphate$_{DNA}$ potential is adapted after the model of Lenart *et al.* and parameterized to reproduce the key features in the local structure and organization of ions in the bulk and in the presence of DNA. The parameters of the previous generation of 3SPN (3SPN.1) have been modified to reproduce melting temperatures observed experimentally employing a biased parallel tempering scheme. The resulting model is capable of reproducing the local structure observed in fully detailed atomistic simulations as well as the melting temperature of DNA reported experimentally for a range of DNA oligonucleotide lengths, CG-content, Na^+ concentration and Mg^{2+} concentration. The usefulness of the model is demonstrated in the context of confinement of dsDNA within a viral capsid and the exploration of pathways between dehybridized and hybridized DNA.

3:54PM T39.00008 Intrinsic noise in stochastic models of gene expression with molecular memory and bursting , TAO JIA, RAHUL V. KULKARNI, Department of Physics, Virginia Polytechnic Institute and State University — Regulation of intrinsic noise in gene expression is essential for many cellular functions. Correspondingly, there is considerable interest in understanding how different molecular mechanisms of gene expression impact variations in protein levels across a population of cells. In this work, we analyze a stochastic model of bursty gene expression which considers general waiting-time distributions governing arrival and decay of proteins. By mapping the system to models analyzed in queueing theory, we derive analytical expressions for the noise in steady-state protein distributions. The derived results extend previous work by including the effects of arbitrary probability distributions representing the effects of molecular memory and bursting. The analytical expressions obtained provide insight into the role of transcriptional, post-transcriptional and post-translational mechanisms in controlling the noise in gene expression.

4:06PM T39.00009 First-Principles Study of Muon Trapping in Singlet and Triplet States of Oxyhemoglobin , S.R. BADU, Department of Physics and Astronomy, University of Utah, ACHANA DUBEY, Department of Physics, UCF, LEE CHOW, Physics Department, UCF, R.H. PINK, Physics Department, SUNY Albany, R.H. SCHEICHER, Department of Physics and Astronomy, Uppsala University, K. NAGAMINE, Physics Department, UCR, N. SAHOO, UTMD Anderson, T.P. DAS[1], Department of Physics, SUNY Albany — Observation of muon spin-lattice relaxation effects in Oxyhemoglobin by the muon-spin rotation (μSR) technique [1] has sparked current interest in the possibility of magnetic character in Oxyhemoglobin (OxyHb). First-Principles variational Hartree-Fock Many Body Perturbation Theory (VHFMBPT) technique investigations on the singlet and triplet states of pure (OxyHb) have shown [2] that the triplet state is considerably higher than the singlet state ruling out magnetic character. However the charge distribution obtained by the VHFMBPT procedure in both states show a number of sites that have negative charges where the trapping of muon is being investigated to examine if the energy gap in the ordering of singlet and triplet states can be reduced or reversed leading to magnetic effects. Other possible sources of magnetism in Oxyhemoglobin will also be discussed. [1] K. Nagamine et al. Proc. Japan. Acad. B-Physics 83, 120 (2007); [2] S.R. Badu et al. Reported at Third Joint HFI-NQI International Conference, CERN, Geneva, September 2010.

4:18PM T39.00010 Binding-rebinding dynamics of proteins interacting non-specifically with a long DNA molecule , AZITA PARSAEIAN, Department of Materials Science and Engineering, Northwestern University, JOHN F. MARKO, D, MONICA OLVERA DE LA CRUZ, Department of Materials Science and Engineering, Northwestern University — Protein interactions with DNA chains and/or fibers regulate a large number of cell functions, and are also important in the understanding of experiments that reveal biochemical and physical cell processes. In order to determine the time range and length range of interactions between proteins and DNA, we analyze the adsorption and de-sorption of units (proteins) that bind reversibly to linear chains (DNA fibers) via non specific interactions through Monte Carlo simulations. We assume the particles are random walkers and that bind reversibly to stretched DNA fiber. In particular we determine the number of re-bindings events. We find that the number of protein re-bindings have a logarithmic dependence on DNA fiber length.

4:30PM T39.00011 Regulation of gene expression by small RNAs via coupled stoichiometric degradation: a variational approach , THIERRY PLATINI, Virginia Bioinformatics Institute, TAO JIA, RAHUL V. KULKARNI, Department of Physics, Virginia Tech — Regulatory genes called small RNAs (sRNAs) are known to play critical roles in cellular responses to changing environments. For several bacterial sRNAs, regulation is effected by coupled stoichiometric degradation with messenger RNAs (mRNAs). The nonlinearity inherent in this regulatory scheme implies that exact analytical solutions for the corresponding stochastic models are intractable. Based on the mapping of the master equation to a quantum evolution equation, we use the variational method (introduced by Eyink) to analyze a well-studied stochastic model for regulation by sRNAs. Results from the variational ansatz are in excellent agreement with stochastic simulations for a wide range of parameters, including regions of parameter space where mean-field approaches break down. The results derived provide new insights into sRNA-based regulation and will serve as useful inputs for future studies focusing on the interplay of stochastic gene expression and regulation by sRNAs.

4:42PM T39.00012 Spatial gradients of Ran-GTP-importin-β complex around chromosomes in a cell of spheroidal shape[1] , GUILLERMO RAMIREZ-SANTIAGO, GERARDO SOSA, Instituto de Fisica, UNAM, Mexico — The concept of signaling gradients of a diffusible and slowly degraded chemical plays an important role in the description of cell signal transduction. It has been suggested that the generation of spatial gradients around chromosomes of the complex, Ran-GTP-importin-β, promotes microtubule nucleation and growth of the mitotic-spindle in Xenopus egg extracts. Here we solved the appropriate reaction-diffusion equation in spheroidal coordinates, and use measured values of the diffusion coefficients and activities to find out how the magnitude of the gradients depend upon the shape and geometry of the chromatin and cytoplasm. We found that the greater the eccentricity the smaller the magnitude of the stationary gradient. When the chromatin becomes spherical the magnitude of the gradient of the complex appears to be optimized.

4:54PM T39.00013 Kinetic simulations of tension-induced DNA strand-unpeeling transition , YUANYUAN QU, Department of Physics, National University of Singapore, HONGXIA FU, Mechanobiology Institute, Singapre, National University of Singapore, JIE YAN, Mechanobiology Institute, Singapore, Department of Physcis, National University of Singapore — Sequence- and salt- dependent kinetic simulation assuming strand-unpeeling from B-DNA using the Gellispie's stochastic kinetics simulation algorism was performed for DNA fragments of a few hundred base pairs. Similar to DNA unzipping experiments, sequence-dependent energy barriers resulted stepwise extension changes were observed during the transition. The simulations were compared with recent single-molecule studies of overstretching transition of the same DNAs occurring at around 65 pN. The results quantitatively reproduced the dynamics of overstretching transition of the same DNAs under conditions when overstretching led to strand separation, and were distinct from that when the transition led to a double-stranded overstretched DNA called "S-DNA" through the B-S transition pathway. We conclude that the strand separation transition pathway was a strand-unpeeling transition from the two free ends of DNA. Further, our results suggest that the B-S transition pathway does not involve base-pair separation.

5:06PM T39.00014 Determination of NMR chemical shifts for cholesterol crystals from first-principles , EMINE KUCUKBENLI, STEFANO DE GIRONCOLI, International School for Advanced Studies (SISSA) and CNR-IOM DEMOCRITOS Simulation Center, via Bonomea 265, 34136 Trieste, Italy — Solid State Nuclear Magnetic Resonance (NMR) is a powerful tool in crystallography when combined with theoretical predictions. So far, empirical calculations of spectra have been employed for an unambiguous identification. However, many complex systems are outside the scope of these methods. Our implementation of ultrasoft and projector augmented wave pseudopotentials within *ab initio* gauge including projector augmented plane wave (GIPAW) method in Quantum Espresso simulation package allows affordable calculations of NMR spectra for systems of thousands of electrons. We report here the first *ab initio* determination of NMR spectra for several crystal structures of cholesterol. Cholesterol crystals, the main component of human gallstones, are of interest to medical research as their structural properties can shed light on the pathologies of gallbladder. With our application we show that *ab initio* calculations can be employed to aid NMR crystallography.

Wednesday, March 23, 2011 2:30PM - 5:06PM –

Session T40 DBP: Physics of Proteins V: Protein-Protein Interaction, and Protein Aggregation

A122/123

2:30PM T40.00001 Early aggregation studies of diabetic amyloid in solution , SADANAND SINGH, JUAN DE PABLO, University of Wisconsin-Madison — Islet amyloid polypeptide (IAPP, also known as amylin) is responsible for pancreatic amyloid deposits in type II diabetes. The deposits, as well as intermediates in their assembly, are cytotoxic to pancreatic β-cells and contribute to the loss of β-cell mass associated with type II diabetes. To better understand the mechanism and cause of such aggregation, molecular simulations with explicit solvent models were used to compare monomer structure and early aggregation mechanism. Using free-energy maps generated through a variety of novel, enhanced sampling free-energy calculation techniques, we have found that, in water, the peptide adopts three major structures. One has a small α-helix at the N-terminus and a small β-hairpin at the other end. The second and the most stable one, is a complete β-hairpin, and the third is a random coil structure. Transition Path Sampling simulations along with reaction coordinate analysis reveal that the peptide follows a "zipping mechanism" in folding from α-helical to β-hairpin state. From studies of the dimerization of monomers in water, we have found that the early aggregation proceeds by conversion of all α-helical configurations to β-hairpins, and by two β-hairpins coming together to form a parallel β-sheet. Several aspects of the proposed mechanism have been verified by concerted 2D IR experimental measurements, thereby adding credence to the validity of our predictions.

2:42PM T40.00002 Applied Electric Fields and the Aggregation of Highly Charged Proteins , LOUIS NEMZER, BRET FLANDERS, CHRISTOPHER SORENSEN, Kansas State University — The abnormal aggregation of misfolded proteins is associated with the onset of Alzheimer's disease, along with other neurodegenerative disorders, and there is increasing evidence that prefibrillar clusters, rather than fully-formed amyloid plaques, are primarily responsible. Therefore, weakly invasive methods, such as dynamic light scattering, which can probe the size distribution and structure factor of early nuclei and proto-aggregate clusters, can serve an important role in understanding this process, and may lead to insights regarding future therapeutic interventions. Here we study a highly charged model protein, lysozyme, under the influence of applied AC and DC fields in an effort to evaluate general models of protein aggregation, including the coarse-grained "patchy protein" method of visualizing charge heterogeneity. This anisotropy in the interprotein interaction can lead to frustrated crystalline order, resulting in low density phases. Dynamic measurements of the size distribution and structure factor can reveal local ordering, hierarchical clustering, and fractal properties of the aggregates. Early results show that applied fields affect early cluster growth by modulating local protein and counterion concentrations, in addition to their influence on protein alignment.

2:54PM T40.00003 Ion Specificity in Protein Aggregation Predicted from Diffusivity Measurements in Stable Protein Solutions , JONATHAN RUBIN, ADRIANA SAN MIGUEL, ANDREAS BOMMARIUS, SVEN BEHRENS, Georgia Tech — The aggregation of therapeutic proteins in solution represents a major challenge in pharmaceutical development, as the mid- and long-term stability of these proteins is crucial for their efficacy and for compliance with FDA requirements. Monitoring slow aggregation experimentally is notoriously time-consuming, yet often unavoidable, since no theory with predictive power is currently available. In the present work, diffusion and aggregation kinetics of the globular model proteins lysozyme and BSA were studied in sodium-salt solutions of different composition and ionic strength using dynamic light scattering. We find a strong correlation between the concentration dependent protein diffusivity in stable solutions and the kinetics of protein aggregation in unstable solutions of similar composition but higher salt content. Our findings suggest a fast and convenient new way to assess a protein's specific tendency to aggregate in different types of electrolytes and buffer solutions.

3:06PM T40.00004 ABSTRACT WITHDRAWN –

3:18PM T40.00005 Controlling Protein Oligomerization with Surface Curvature on the Nanoscale , MARTY KURYLOWICZ, JOHN DUTCHER, University of Guelph — We investigate the effect of surface curvature on the conformation of beta-lactoglobulin (βLG) using Single Molecule Force Spectroscopy. βLG is a model interfacial protein which stabilizes oil droplets in milk and is known to undergo structural rearrangement when adsorbed onto a surface. We reliably control nanoscale surface curvature by creating close-packed monolayers of monodisperse polystyrene (PS) nanoparticles with diameters of 20, 40, 60, 80 and 140 nm, which are stable in aqueous buffer. By adsorbing βLG onto these hydrophobic surfaces and collecting force-extension curves in the fluid phase we can compare the conformation of βLG on 5 different surface curvatures with that on a flat PS film. We demonstrate a transition from oligomeric to monomeric βLG as the surface curvature is increased. Histograms of contour length from fits to peaks in the force-extension curves show a single maximum near 30 nm for βLG adsorbed onto nanoparticles with diameters less than 80 nm. For the larger nanoparticles, the histogram approaches that observed for βLG adsorbed onto a flat PS film, with maxima indicative of βLG dimers and trimers.

3:30PM T40.00006 Computational Analysis of β-Peptide Self-Assembly[1] , MICHAEL MCGOVERN, University of Wisconsin-Madison — $\beta-$peptides are a class of synthetic oligomers that are capable of folding in precise patterns. The wide variety of side chains that are available for insertion into β-peptide sequences along with the stability of these folded secondary structures allow precise control over the nanoscale presentation of various chemical functional groups in three dimensional space. Some β-peptides have been shown to spontaneously fold into complex supramolecular structures, and others have been shown to be effective antimicrobial agents that are believed to act by aggregating in certain types of cell membranes. However, more work is needed to understand what drives this assembly in order to design β-peptides that assemble in particular ways. Using molecular simulations, the process of β-peptide aggregation is examined in a variety of environments that allow for direct comparison to experiment. Using new simulation techniques, the structure of the aggregates formed by several β-peptides are predicted in both bulk solutions, and at interfaces. Free energy surfaces are generated using multiple geometric parameters to directly compare the favorability of different modes of aggregation. By analyzing these results, we gain an understanding of the factors that drive self-assembly and aggregation.

3:42PM T40.00007 Electrospun Synthetic Polypeptide Nanofibrous Biomaterials , DHAN KHADKA, DONALD HAYNIE, University of South Florida — Water-insoluble nanofiber mats of synthetic polypeptides of defined composition have been prepared from fibers electrospun from aqueous solution in the absence of organic co-solvents. 20-50 kDa poly(L-glutamate, L-tyrosine) 4:1 (PLGY) but not 15-50 kDa or 50-100 kDa poly(L-glutamate) was spinnable at 20-55% (w/v) polymer in water. Applied voltage and needle-collector distance were crucial for spinnability. Attractive fibers were obtained at 50% polymer. Fiber diameter and mat morphology have been characterized by electron microscopy. Exposure of spun fiber mats to 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide hydrochloride (EDC), which reacts with carboxylate, decreased fiber solubility. Fluorescein-conjugated poly(L-lysine) (FITC-PLL) but not the fluorophore alone was able bind PLGY fiber mats electrostatically, judging by fluorescence microscopy. Key advances of this work are the avoidance of an animal source of peptides and of an inorganic co-solvent to achieve polypeptide spinnability. Polypeptide fiber mats are a promising type of nano-structured biomaterial for applications in biomedicine and biotechnology.

3:54PM T40.00008 Exploring the dewetting transition in the hydrophobic collapse of melittin , PATRICK VARILLY, University of California, Berkeley, AMISH J. PATEL, Rensselaer Polytechnic Institute, DAVID CHANDLER, University of California, Berkeley — We present our recent results on understanding the hydrophobic collapse of melittin dimers. Melittin dimers have large, complementary hydrophobic patches, and the dimer collapse mechanism involves a dewetting transition [Liu, Huang, Zhou and Berne, *Nature* **437**, 159–162 (2005)]. As a result, melittin has become a model system for studying dewetting transitions in proteins. We apply our recently- developed tools for probing density fluctuations in water [Patel, Varilly and Chandler, *JPCB* **114**, 1632–1637 (2010)] to understand this dewetting transition in terms of free energy surfaces, their bistability and their barrier heights. We show how the hydrophobic character of melittin's tetramerization surface results in an enhanced probability of density depletion next to that surface. When two dimers come together, the density depletion is further enhanced, so that even at large separations, there is a metastable dry phase in the region between the dimers. As the dimers come together, the dry phase is stabilized and eventually the wet phase is destabilized, leading to the collapse of the dimers. We explore how mutations that have been observed to suppress the dewetting transition affect the corresponding free energy surfaces and discuss our ongoing efforts to fully map out the reaction coordinate of melittin collapse.

4:06PM T40.00009 Effect of the ordered interfacial water layer in protein complex formation: a non-local electrostatic approach , ALEXANDER RUBINSTEIN, RENAT SABIRIANOV, University of Nembraska at Omaha — Using a non-local electrostatic approach that incorporates the short-range structure of the contacting media, we evaluated the electrostatic contribution to the energy of the complex formation of two model proteins. In this study, we have demonstrated that the existence of an low-dielectric interfacial water layer at the protein-solvent interface [1] reduces the charging energy of the proteins in the aqueous solvent, and consequently increases the electrostatic contribution to the protein binding (change in free energy upon the complex formation of two proteins). This is in contrast with the finding of the continuum electrostatic model, which suggests that electrostatic interactions are not strong enough to compensate for the unfavorable desolvation effects [2].

4:18PM T40.00010 Modeling virus capsids and their protein binding – the search for weak regions within the HIV capsid , OTTO F. SANKEY, DARYN E. BENSON, C. MICHAEL GILBERT, Arizona State University — Viruses remain a threat to the health of humans worldwide with 33 million infected with HIV. Viruses are ubiquitous, infecting animals, plants, and bacteria. Each virus infects in its own unique manner making the problem seem intractable. However, some general physical steps apply to many viruses and the application of basic physical modeling can potentially have great impact. The aim of this theoretical study is to investigate the stability of the HIV viral capsid (protein shell). The structural shell can be compromised by physical probes such as pulsed laser light [1,2]. But, what are the weakest regions of the capsid so that we can begin to understand vulnerabilities of these deadly materials? The atomic structure of HIV capsids is not precisely known and we begin by describing our work to model the capsid structure. We have constructed three representative viral capsids of different CA protein number – HIV-900, HIV-1260 and HIV-1740. The complexity of the assembly requires a course grained model to investigate protein interactions within the capsid which we will describe.

4:30PM T40.00011 Low-Frequency Raman Spectroscopy of Trialanine.[1] , RACHEL M. STEPHENSON, ANGELA R. HIGHT WALKER, NIST — The effect of sample conditions on the structural conformation of trialanine has been investigated with visible Raman spectroscopy. Trialanine is used here as a simple protein-mimetic system in order to more easily isolate the backbone amide vibrational modes, low-frequency tortional modes and modes from hydrogen bonding. Crystalline trialanine is known to exist with both parallel (p-Ala$_3$) and antiparallel (ap-Ala$_3$) β-sheet crystal structures, depending on the solvent composition during crystallization. The *ap*-sheet form of trialanine co-crystallizes with water, which is easily removed under vacuum, offering a further opportunity to examine the effect of solvation on the vibrational spectra, especially when also compared with trialanine in solution. By collecting Raman spectra in different sample phases, and at different concentrations, pH and temperatures, the vibrational modes most sensitive to the secondary structure can be identified. The collected data will be compared to the literature, including other vibrational spectroscopic data and high-level simulations.

4:42PM T40.00012 Fast X-ray Photon Correlation Spectroscopy measurements from the diffusion of concentrated Alpha Crystallin suspensions[1] , VIDANAGE NUWAN KARUNARATNE, JANAE DEBARTOLO, JUSTIN BERRY, LAURENCE LURIO, Northern Illinois University, GEORGE THURSTON, Rochester Institute of Technology, SURESH NARAYANAN, ALEC SANDY, JOHN WEIZEORICK, Advanced Photon Source — Alpha Crystallin constitute up to half of the total protein found in the mammalian eye lens. It has chaperone like behavior and may play a key role in maintaining lens transparency by preventing condensation of other lens proteins. We report here Fast X-ray Photon Correlation Spectroscopy (XPCS) measurements of protein diffusion within concentrated suspensions of Alpha Crystallin. Bovine calf eye lens cortices were homogenized, centrifuged and ultra-filtered to obtain concentrated Alpha Crystallin suspensions. Diffusion of proteins within these suspensions was measured as a function of temperature. The overall observed diffusion rates imply that the proteins exist in a glassy or gel phase, even at concentrations where equivalent hard sphere system would still be liquid. We interpret these results within the context of strongly interacting proteins, with protein-protein interactions possibly mediated by subunit exchange among Alpha Crystallin oligormers.

4:54PM T40.00013 Ultrasound and Hypersound Speeds in Lysozyme Solutions , ALFONS SCHULTE, Department of Physics and College of Optics, University of Central Florida, Orlando, CHRISTIAN PRUNER, EMMERICH WILHELM, AUGUSTINUS ASENBAUM, Department of Materials Science and Physics, University of Salzburg, A-5020 Salzburg — Ultrasound velocimetry and Brillouin spectroscopy provide information on the compressibility of proteins and the surrounding hydration layer. Employing both techniques we investigate the sound speeds at GHz (hypersound) and MHz (ultrasound) frequencies in lysozyme solutions (250 mg / ml, pH 7) and pure water over the temperature range from 275 K to 335 K. Compared to water the Brillouin peaks in the lysozyme solutions are shifted by about 400 MHz towards higher frequencies. This shift reflects the change in sound speed and is attributed to the influence of the compressibility of the protein and bound water in the hydration shell. In addition, we measure a dispersion of the sound velocity in the lysozyme solution. The higher sound speed at GHz frequencies, as measured by Brillouin scattering, may indicate additional relaxation processes as compared to pure bulk water, where no sound dispersion between ultrasound speed and hypersound speed is observed.

Session T41 DCP: Focus Session: The Role of Water in Energy Production and Utilization I

2:30PM T41.00001 Deciphering the morphology of ice films on metal surfaces[1] , KONRAD THÜRMER, Sandia National Laboratories, CA — Although extensive research has been aimed at the structure of ice films [1], questions regarding basic processes that govern film evolution remain. Recently we discovered how ice films as many as 30 molecular layers thick can be imaged with STM [2]. The observed morphology yields new insights about water-solid interactions and how they affect the structure of ice films. This talk gives an overview of this progress for crystalline ice films on Pt(111) [2-5]. STM reveals a first molecular water layer very different from bulk ice: besides the usual hexagons it also contains pentagons and heptagons [3]. Slightly thicker films ($\sim$1nm, at T>120K) are comprised of $\sim$3nm-high crystallites, surrounded by the one-molecule-thick wetting layer. These crystals dewet by nucleating layers on their top facets [4]. Measurements of the nucleation rate as a function of crystal height provide estimates of the energy of the ice-Pt interface. For T>115K surface diffusion is fast enough that surface smoothing and 2D-island ripening is observable [5]. By quantifying the T-dependent ripening of island arrays we determined the activation energy for surface self-diffusion. The shape of these 2D islands varies strongly with film thickness. We attribute this to a transition from polarized ice at the substrate towards proton disorder at larger film thicknesses. Despite fast surface diffusion ice multilayers are often far from equilibrium. For example, ice grows between $\sim$120 and $\sim$160 K in its cubic variant rather than in its equilibrium hexagonal form. We found this to be a consequence of the mismatch in the atomic Pt-step height and the ice-bilayer separation and propose a mechanism of cubic-ice formation via growth spirals around screw dislocations [2].

3:06PM T41.00002 *A Priori* Method for First Principles Study of Aqueous Electrochemistry: Application to Biofuels and Catalysis , KENDRA LETCHWORTH WEAVER, RAVISHANKAR SUNDARARAMAN, TOMAS ARIAS, Cornell University — We present a novel description of water which will allow the first *a priori* studies of catalysis of biofuels in aqueous electrochemical environments. Our method offers a computationally efficient alternative to the thermal sampling required by molecular dynamics yet provides a more realistic description of bulk water than including explicit frozen water or traditional continuum solvation models. Into Joint Density Functional Theory (JDFT), which joins an electron density-functional for the solute with classical density-functional theories for liquid water[1] into a single variational principle for the free energy of the combined system, we introduce the innovation of an *a priori* form of the coupling functional between the quantum-mechanical system and liquid water based on a local density approximation to the Hohenberg-Kohn density-only functional. Without any fits to solvation data whatsoever, this new method predicts solvation energies of small organic molecules well compared to state-of-the art empirical quantum-chemical cavity approaches. The site interaction potentials produced closely resemble the widely used TIP3P site potentials for water without requiring any empirical parameters.

[1]R. Sundararaman et al, unpublished, to be presented at the APS March Meeting (2011)

3:18PM T41.00003 *A priori* classical density functionals of water: toward first principles exploration of aqueous based energy systems , RAVISHANKAR SUNDARARAMAN, KENDRA LETCHWORTH WEAVER, TOMAS ARIAS, Cornell University — The microscopic structure of inhomogeneous water plays a critical role in the properties of a wide variety of important energy systems including fuel cells and photoelectrochemical cells. Joint density functional theory has proven to be an efficient tool for the quantum-mechanical modeling of systems such as Pt electrodes in the presence of water, but requires theories for water which go beyond semi-empirical continuum solvation models, and accurate models for the coupling between water and electronic systems [1]. Toward this end, we present a new density-functional description of liquid water capable of predicting interatomic correlation functions, the linear and nonlinear dielectric response, and solvation energies without empirical fit parameters. The functional itself is built upon the site-potential representation of the ideal gas, a hard sphere reference fluid for the repulsive correlations, and an equation of state that reproduces the bulk properties of water over the entire extent of its liquid phase. Hydrogen bonding, the local tetrahedral structure and orientational correlations are captured *a priori* by a density-functional reformulation of the Kirkwood model for the dielectric constant.

[1]K. L. Weaver et al, to be presented at APS March Meeting 2011

3:30PM T41.00004 Quasicrystal and ice phases tiled with pentagons in confined water , VALERIA MOLINERO, Department of Chemistry, University of Utah — Bulk water is known to form a wealth of ice polymorphs and two distinct amorphous phases. Less is known of the structures that confined and interfacial water can adopt, and whether there is a correspondence between the structures and phase diagrams of water in bulk and in confinement. In this talk I will present a molecular simulations study of the phase behavior of a water bilayer confined between two non-hydrogen bonding walls and demonstrate that a water bilayer also presents rich polymorphism, including an ice crystal fully tiled by pentagons and a quasicrystal, the first ever reported for water. The water quasicrystal and the ice polymorph tiled with pentagons are not templated by the confining surfaces. This indicates that these novel phases are intrinsically favored in bilayer water and suggests that they may be formed, without confinement, on surfaces.

4:06PM T41.00005 The role of interfacial water in "nano" , ALENKA LUZAR, Virginia Commonwealth University, JIHANG WANG, CHRIS DAUB, DUSAN BRATKO, CHEMISTY DEPARTMENT, VCU TEAM — To understand the role of interfacial water on nanostructred surfaces is important for materials science and biology. The talk will describe some of our recent progress in predicting and understanding the effects of nanopatterning on topologically or chemically heterogeneous surfaces on wetting via *in silico* experiments.

4:18PM T41.00006 Ordering of confined water between metallic surfaces[1] , ADRIEN POISSIER, MARIA V. FERNANDEZ-SERRA, Stony Brook University — It has been pointed out (PCCP 2010, Poissier et al.) that the hydrogen bonding type interaction occuring at water/metal interface makes the two type of interfacial water orderings (hydrophobic or hydrophilic overlayers) very close in energy. The most stable, hydrophobic, overlayer has very small net dipole moment perpendicular to the surface, while the least stable (in vacuum) hydrophilic interface has a large ($\approx 1.8D$) net dipole moment. First principles molecular dynamics simulations of liquid water confined between two Pd surfaces have been performed and structural and electronic water properties have been studied in detail. We show that water confinement in this situation results in a spontaneous symmetry breaking of the system, inducing an electric field across the liquid water slab. We discuss the origin of this spontaneous polarization and show its dependence with the confinement distance along the direction perpendicular to the planes of the surfaces.

4:30PM T41.00007 Exploring hydration at the nanoscale[1] , PETER ROSSKY, University of Texas at Austin — It is widely appreciated that water molecules contribute a critical element to the forces governing chemical processes in an aqueous environment, and the purported differences in water structure induced by the presence of confining surfaces are correspondingly likely to play a role in interfacial chemistry. The development of a detailed understanding of the organization of fluid water at the interface with real materials is therefore of great interest. In this presentation, results obtained from fully atomistic computer simulations of water in the presence of confining interfaces will be discussed, with the goal of elucidating the molecular level influence of surface character on water structure and energetics. Further, we emphasize the extension of studies to temperatures and pressures well outside the conventional realm of the ambient solvent thermodynamic state. The interface examples to be considered in this presentation emphasize systematic studies designed to elucidate guiding principles. These include extended and nanoscale hydrophobic and hydrophilic crystalline surfaces and interfaces with systematically patterned hydrophobicity.

5:06PM T41.00008 ABSTRACT WITHDRAWN –

5:18PM T41.00009 Energy transport during sessile-water-droplet evaporation[1] , HADI GHASEMI, Unversity of Toronto, CHARLES WARD, University of Toronto — Energy transport mechanisms for a steadily evaporating water droplet maintained on Cu or Au(111) surfaces are compared. In the absence of buoyancy-driven convection, thermal conduction and thermocapillary convection are the active modes of energy transport. The dominant mode varies along the liquid-vapor interface. Although thermal conduction is the dominant mode in regions far from the contact line, thermocapillary convection is by far the larger mode of energy transport near the three-phase contact line. The latter region is where most of the droplet evaporation occurs. Evaporation experiments on both Cu and Au(111) suggest that the thermocapillary convection provides more than 92% of the total energy required for the evaporation.

Session T42 DCP DBP: Focus Session: The Physics of Evolution I A302/303

2:30PM T42.00001 Insights into protein evolution landscapes from folding models , EUGENE KOONIN, National Center for Biotechnology Information, National Library of Medicine, National Institutes of Health — Off-lattice models of protein folding were employed to investigate the origins of the evolutionary rate distributions and fitness landscapes. For each robust folder, the network of sequences that share its native structure is identified. The fitness of a sequence is a simple function of the number of misfolded molecules produced to reach a characteristic protein abundance. Fixation probabilities of mutants are computed under a simple population dynamics model, and the fold-averaged evolution rate is computed a using a Markov chain on the fold network. The distribution of the logarithm of the evolution rates exhibits a peak with a long tail on the low rate side and resembles the universal empirical distribution of the evolutionary rates more closely than either distribution resembles the log-normal distribution. We next addressed the question of the extent of determinism in protein evolution. Limited empirical studies suggest that the fitness landscapes of protein evolution are significantly smoother, or more additive, than random landscapes. However, widespread sign epistasis seems to restrict evolution to a small fraction of available trajectories, thus making the evolutionary process substantially deterministic. Access to complete fitness landscapes within the model framework enables exhaustive analysis of evolutionary trajectories. The model landscapes were compared to a continuum of artificial landscapes of varying smoothness. In maximally smooth, fully additive landscapes, evolution cannot be predicted because all paths are accessible. However, a small amount of noise can make most paths inaccessible while preserving the overall structure of the landscape. Although the model landscapes are almost additive, most paths are non-monotonic with respect to fitness, so evolutionary trajectories can be approximately predicted. Thus, protein folding physics seems to dictate the universal distribution of the evolutionary rates of protein-coding genes and the quasi-deterministic character of evolution.

3:06PM T42.00002 A mechanism for the evolution of allosteric control in proteins , KIMBERLY REYNOLDS, RAMA RANGANATHAN, Green Center for Systems Biology, and Department of Pharmacology, University of Texas Southwestern Medical Center — Co-evolution analysis indicates a general architecture for natural proteins in which sparse networks of physically contiguous amino acids underlie basic aspects of structure and function. These networks, termed sectors, are spatially organized such that active sites are linked to many surface sites distributed throughout the protein structure. Here, we propose that sectors represent an evolutionarily conserved "wiring" mechanism that effectively functionalizes a large but non-random fraction of the protein surface - that is, perturbation at sector-connected surface positions should preferentially yield coupling to the active site. To test this premise, we conducted a comprehensive "domain insertion scan," and show that sector-connected surface sites are statistically significant locations for the emergence of allosteric control in vivo. This finding suggests practical guidelines for the engineering of new allosteric systems, and permits description of a plausible model for the evolution of intermolecular communication and regulation.

3:18PM T42.00003 Biophysical Aspects of Spindle Evolution , REZA FARHADIFAR, Harvard University, CHARLIE BAER, University of Florida, DANIEL NEEDLEMAN, Harvard University — The continual propagation of genetic material from one generation to the next is one of the most basic characteristics of all organisms. In eukaryotes, DNA is segregated into the two daughter cells by a highly dynamic, self-organizing structure called the mitotic spindle. Mitotic spindles can show remarkable variability between tissues and organisms, but there is currently little understanding of the biophysical and evolutionary basis of this diversity. We are studying how spontaneous mutations modify cell division during nematode development. By comparing the mutational variation - the raw material of evolution - with the variation present in nature, we are investigating how the mitotic spindle is shaped over the course of evolution. This combination of quantitative genetics and cellular biophysics gives insight into how the structure and dynamics of the spindle is formed through selection, drift, and biophysical constraints.

3:30PM T42.00004 The relationship between relative solvent accessibility and evolutionary rate in protein evolution , CLAUS WILKE, The University of Texas at Austin — Recent work with the yeast Saccharomyces cerevisiae shows a linear relationship between the evolutionary rate of sites and the relative solvent accessibility (RSA) of the corresponding residues in the folded protein. Here, we aim to develop a mathematical model that can reproduce this linear relationship. We first demonstrate that two models that both seem reasonable choices (a simple model in which selection strength correlates with RSA and a more complex model based on RSA-dependent amino-acid distributions) fail to reproduce the observed relationship. We then develop a model based on observed site-specific amino-acid distributions and show that this model behaves appropriately. We conclude that evolutionary rates are directly linked to the distribution of amino acids at individual sites. Because of this link, any future insight into the biophysical mechanisms that determine amino-acid distributions will improve our understanding of evolutionary rates.

4:06PM T42.00005 Quantum Darwinian Evolution Implies Tumor Origination , W. GRANT COOPER, International Physics — Quantum uncertainty limits operating on metastable amino DNA protons drive the arrangement, keto-amino ? enol-imine, which contributes to time-dependent stochastic mutations. Product enol-imine protons participate in coupled quantum oscillations at frequencies of about 1013 s-1 until "measured by" an evolutionarily selected quantum reader, the transcriptase. This introduces entanglement states between coherent protons and transcriptase components, which ultimately yield an ensemble of decohered, non-reequilibrated enol and imine isomers that participate in "molecular clock" base substitutions at G'-C' and *G-*C sites. This introduces a quantum Darwinian evolution model which (a) simulates incidence of cancer data and (b) implies insight into quantum origins of evolutionary extinction. Data identify an inherited "genetic space," s, which is initially mutation-free and satisfies the inequality, 1 = s = 0.97. When accumulated stochastic mutations cause s-values to approach their evolutionarily allowed threshold limit, s 0.97 + e, age-related degenerative disease is manifested. This implies a gain in evolutionary advantage which protects the gene pool against acquiring unsafe levels of mutation. Data requiring coherent states imply that classical duplex DNA contains an embedded microphysical subset of electron lone-pairs and hydrogen bonded protons that govern time-dependent genetic specificity in terms of quantum probability laws.

Session T43 DBP: Physics of Bacteria A306/307

2:30PM T43.00001 Guided Motion of Individual and Collective Swimmers in Funnel Arrays , CYNTHIA OLSON REICHHARDT, Los Alamos National Laboratory, THUC MAI, Syracuse University, CHARLES REICHHARDT, Los Alamos National Laboratory — We generalize a model of swimming bacteria in asymmetric arrays of obstacles [1] to include different rules of motion, including various rules for collective behvaiors. For individual noninteracting swimmers, we observe guided motion and rectification by the asymmetric barriers when the particles align with the walls they contact, but we find no rectification if the particles are reflected by the walls or bounce off the walls. For collectively interacting swimmers, it is possible for the particles to form large swimming clumps that can move against the normal rectification direction of the asymmetric barrier array. In general, the rectification by the barriers is lost when the length scale of the swarms of collectively moving particles is significantly larger than the length scale of the funnel shaped barriers. A particle swarm can become trapped inside a funnel; however, individual strings of particles that follow each other can escape from the trap and move against the funnel direction.

[1] M.B. Wan, C.J. Olson Reichhardt, Z. Nussinov, and C. Reichhardt, Phys. Rev. Lett. 101, 018102 (2008).

2:42PM T43.00002 Surface motility of Myxococcus Xanthus , MAXSIM GIBIANSKY, University of California, Los Angeles, Bioengineering Department, WILLIAM HU, University of California, Los Angeles, School of Dentistry, FAN JIN, University of California, Los Angeles, Bioengineering Department, KUN ZHAO, WENYUAN SHI, University of California, Los Angeles, School of Dentistry, GERARD WONG, University of California, Los Angeles, Bioengineering Department — We examine the surface motility of Myxococcus Xanthus, a bacterium species found in soil that exhibits a broad range of self-organizing behavior, including predatory "swarms" and survival-enhancing "fruiting bodies." To quantify the effects of exopolysaccharides (EPS) on surface adhesion and motility, we use modified versions of particle tracking algorithms from colloid physics to analyze bacterial trajectories, and compare the wild type (WT) strain to EPS knockout and EPS overproducer strains. We find that EPS deficiency leads to an increase in the number of "standing" bacteria oriented normal to the surface, attached by one end with minimal motility. EPS overproduction, by contrast, suppresses this phenotype. A detailed investigation of the influence of EPS on Myxococcus social motility will be presented.

2:54PM T43.00003 Dynamics of microorganisms with autochemotactic interactions , JOHANNES TAKTIKOS, Technical University Berlin, Germany, VASILY ZABURDAEV, Harvard University, HOLGER STARK, Technical University Berlin, Germany — Our work aims at the description of the early stage of bacterial biofilm formation. In light of this, we model bacteria as self-propelled particles that move on a surface with constant speed and whose directions of motion diffuse on the unit circle. Individual cells communicate by autochemotaxis, so they follow the gradient of a chemical which is produced by the microorganisms themselves. We investigate how the autochemotactic coupling influences the mean squared displacement of a single particle and show that the long-time dynamics is diffusive. We present theoretical predictions for the diffusion coefficient and compare them to numerical results. To incorporate the size of bacteria, we model them as disks that experience a harmonic repulsion force when they start to overlap. Our repulsion mechanism for particles in contact assumes a linear relationship between force and velocity. For such a soft model microorganism, we present numerical results on two-particle collisions and study the cluster formation in a multi-particle system.

3:06PM T43.00004 Shear flow influences the twitching motility of *Pseudomonas Aeruginosa*[1] , YI SHEN, Princeton University, SIGOLENE LECUYER, Harvard University, ALBERT SIRYAPORN, ZEMER GITAI, HOWARD STONE, Princeton University — Twitching motility is one of the mechanisms by which bacteria can spread on surfaces and is important in the process of biofilm formation. Flow is often involved in biofilm formation, for instance when bacteria contaminate medical devices or water systems. We have studied the twitching mobility of *Pseudomonas aeruginosa* in straight microfluidic channels under laminar shear flow at low Reynolds number. We tracked all the bacteria adhering and moving on the immersed glass surface. We observed that upon applying a flow, a significant fraction of bacteria started to twitch, and that many twitched upstream, opposite to the flow direction. By measuring the displacement and residence time of the bacteria staying on the surface, we found that the flow not only tuned the direction of twitching by orienting bacteria, but also that the shear rate significantly influenced the fraction of bacteria moving upstream, with an optimal shear rate about $500s^{-1}$.

[1]Princeton University MAE Complex fluids group

3:18PM T43.00005 Biofilm growth: a lattice Monte Carlo model , YUGUO TAO, GARY SLATER, University of Ottawa — Biofilms are complex colonies of bacteria that grow in contact with a wall, often in the presence of a flow. In the current work, biofilm growth is investigated using a new two-dimensional lattice Monte Carlo algorithm based on the Bond-Fluctuation Algorithm (BFA). One of the distinguishing characteristics of biofilms, the synthesis and physical properties of the extracellular polymeric substance (EPS) in which the cells are embedded, is explicitly taken into account. Cells are modelled as autonomous closed loops with well-defined mechanical and thermodynamic properties, while the EPS is modelled as flexible polymeric chains. This BFA model allows us to add biologically relevant features such as: the uptake of nutrients; cell growth, division and death; the production of EPS; cell maintenance and hibernation; the generation of waste and the impact of toxic molecules; cell mutation and evolution; cell motility. By tuning the structural, interactional and morphologic parameters of the model, the cell shapes as well as the growth and maturation of various types of biofilm colonies can be controlled.

3:30PM T43.00006 Transitions in biofilm formation , VERNITA GORDON, TRAVIS THATCHER, BENJAMIN COOLEY, Center for Nonlinear Dynamics and Department of Physics, University of Texas at Austin — Biofilms are multicellular, dynamic communities formed by interacting unicellular organisms bound to a surface. Forming a biofilm is a developmental process, characterized by sequential changes in gene expression and behavior as bacteria and yeast progress from discrete, free-swimming cells though stages that arrive at a mature biofilm. We are developing automated metrics to identify key transitions in early biofilm formation as cells attach to a surface, populate that surface, and adhere to each other to form early microcolonies. Our metrics use high-throughput tracking and analysis of microscopy movies to localize these transitions in space and time. Each of these transitions is associated with a loss of entropy in the bacterial system and, therefore, with biological activity that drives this loss of entropy. Better understanding of these transitions will allow automated determination of the strength and turn-on of attractive cell-surface and cell-cell interactions as biofilm development progresses.

3:42PM T43.00007 Changes in the Mechanical Properties of Pseudomonas aeruginosa Bacterial Cells Induced by Antimicrobial Peptides , SHUN LU, JOHN DUTCHER, University of Guelph — In our research group, we have developed an atomic force microscopy nano-creep technique [1] to study the mechanical properties of individual Pseudomonas aeruginosa bacterial cells in a liquid environment. In the present study, we have used this technique to measure changes to the mechanical properties of the cells produced by exposing the cells to well-studied antimicrobial peptides: polymyxin B (PMB) and its derivative polymyxin B nonapeptide (PMBN). We find that the creep response of cells under a fixed applied load is very different after exposure of the cells to PMB and PMBN, which is possibly due to the disruption of its outer membrane. To describe the viscoelastic properties of the cells exposed to PMB and PMBN, we found that it was necessary to use a four element spring and dashpot model, instead of the three element standard linear solid model that describes the viscoelastic properties of cells in Millipore water [1]. We also found that PMB and PMBN have qualitatively different effects on the stiffness of the cell membrane. These measurements provide a first step towards understanding the different mechanisms of action of PMB and PMBN on bacterial cells.

3:54PM T43.00008 Nanofabrication and Detection of Molecular Shuttles powered by Kinesin Motor Proteins , DANIEL OLIVEIRA, WPI - Advanced Institute for Materials Research, Tohoku University, Sendai, Japan, KIM DOMYOUNG, Dept. of Biomolecular Engineering, Tohoku University, Sendai, Japan, MITSUO UMETSU, WPI - Advanced Institute for Materials Research and Dept. of Biomolecular Engineering, Tohoku University, Sendai, Japan, TADAFUMI ADSCHIRI, WPI - Advanced Institute for Materials Research, Tohoku University, Sendai, Japan, WINFRIED TEIZER, WPI - Advanced Institute for Materials Research, Tohoku University, Sendai, Japan and Dept of Physics, Texas A&M University, College Station, TX, USA — The intracellular cargo delivery performed by kinesin motor proteins can be biomimetically employed to engineer tailor-made artificial nanotransport systems. Kinesin (expressed on an *Escherichia coli* system) and microtubules (obtained from the polymerization of tubulin proteins) were prepared and characterized. We report recent results and explore the aim of the construction of Nanoelectromechanical Systems and their potential applications, e.g. as drug delivery systems. This work was supported by the WPI Program.

4:06PM T43.00009 Electrodynamics of Nanosystems , SAMINA MASOOD, Univ. of Houston Clear Lake — We use Electrodynamics to study the nanosystems. Quantum nature of electrodynamics has been used to describe the physics of nanosystems including carbon nanotubes as well as the cellular growth. We use bacterial cell as an example and test a part of our theory on the bacterial growth experimentally. Preliminary results of these experiments are also mentioned here.

4:18PM T43.00010 Long range electronic transport in microbial nanowires bridging an electrode and scanned probe[1] , JOSHUA VEAZEY, SANELA LAMPA-PASTIRK, KATHY WALSH, JIEBING SUN, PENGPENG ZHANG, GEMMA REGUERA, STUART TESSMER, Michigan State University — The filament-like appendages known as pili, expressed by the bacterium *Geobacter sulfurreducens*, are believed to act as electrically conductive nanowires [1]. Previously, we used scanning tunneling microscopy to study the local density of states at different positions along the wire. However, the long range electron transfer believed to occur in this protein has not been directly observed. Here we discuss a system for verifying long range transport using a scanning probe technique. Transport at distances of more than a few nanometers would require a novel biological electron transfer process.

4:30PM T43.00011 Heterogeneous diversity of spacers within CRISPR , MICHAEL DEEM, JIANKUI HE, Rice University — Clustered regularly interspaced short palindromic repeats (CRISPR) in bacterial and archaeal DNA have recently been shown to be a new type of anti-viral immune system in these organisms. We here study the diversity of spacers in CRISPR under selective pressure. We propose a population dynamics model that explains the biological observation that the leader-proximal end of CRISPR is more diversified and the leader-distal end of CRISPR is more conserved. This result is shown to be in agreement with recent experiments. Our results show that the CRISPR spacer structure is influenced by and provides a record of the viral challenges that bacteria face. 1) J. He and M. W. Deem, Phys. Rev. Lett. 105 (2010) 128102

4:42PM T43.00012 Filament depolymerization can pull a chromosome during bacterial mitosis , EDWARD BANIGAN, University of Pennsylvania, MICHAEL GELBART, Harvard University, ZEMER GITAI, Princeton University, ANDREA LIU, NED WINGREEN, Princeton University — Chromosome segregation is fundamental to all cells, but the force-generating mechanisms underlying chromosome translocation in bacteria remain mysterious. *Caulobacter crescentus* utilizes a depolymerization-driven process in which a ParA protein structure elongates from the new cell pole and binds to a ParB-decorated chromosome, and then retracts via disassembly, thus pulling the chromosome across the cell. This poses the question of how a depolymerizing structure can robustly pull the chromosome that is disassembling it. We perform Brownian dynamics simulations with a simple and physically consistent model of the ParABS system. The simulations suggest that the mechanism of translocation is "self-diffusiophoretic": by disassembling ParA, ParB generates a ParA concentration gradient so that the concentration of ParA is higher in front of the chromosome than behind it. Since the chromosome is attracted to ParA via ParB, it moves up the ParA gradient and across the cell. We find that translocation is controlled by the product of an effective relaxation time for the chromosome and the rate of ParA disassembly. Our results provide a physical explanation of the mechanism of depolymerization-driven translocation and suggest physical explanations for recent experimental observations.

4:54PM T43.00013 Polymerization and oscillation stuttering in a filamentous model of the subcellular Min oscillation , ANDREW RUTENBERG, Dalhousie University, SUPRATIM SENGUPTA, Jawaharlal Nehru University, ANIRBAN SAIN, Indian Institute of Technology - Bombay, JULIEN DERR, Harvard University — We present a computational model of the *E. coli* Min oscillation that involves polymerization of MinD filaments followed by depolymerization stimulated by filament-end zones of MinE. Our stochastic model is fully three-dimensional, and tracks the diffusion and interactions of every MinD and MinE molecule. We recover self-organized Min oscillations. We investigate the experimental phenomenon of oscillation stuttering, which we relate to the disruption of MinE tip-binding at the filament scale.

5:06PM T43.00014 Effect of Antimicrobial Agents on MinD Protein Oscillations in E. coli Bacterial Cells , COREY KELLY, MEGAN MURPHY, MAXIMILIANO GIULIANI, JOHN DUTCHER, University of Guelph — The pole-to-pole oscillation of the MinD proteins in E. coli determines the location of the division septum, and is integral to healthy cell division. It has been shown previously that the MinD oscillation period is approximately 40 s for healthy cells [1] but is strongly dependant on environmental factors such as temperature, which may place stress on the cell [2,3]. We use a strain of E. coli in which the MinD proteins are tagged with green fluorescent protein (GFP), allowing fluorescence visualization of the MinD oscillation. We use high resolution total internal reflection fluorescence (TIRF) microscopy to observe the effect of exposure to antimicrobial agents on the MinD oscillation period and, more generally, to analyze the time variation of the spatial distribution of the MinD proteins within the cells. These measurements provide insight into the mechanism of antimicrobial action.

5:18PM T43.00015 Pattern Transitions in Bacterial Oscillating System under Nanofluidic Confinement[1] , JIE-PAN SHEN, CHIA-FU CHOU, Academia Sinica — Successful binary fission in E. coli relies on remarkable oscillatory behavior of the MinCDE protein system to determine the exact division site. The most favorable models to explain this fascinating spatiotemporal regulation on dynamic MinDE pattern formation in cells are based on reaction-diffusion scenario. Although not fully understood, geometric factors caused by bacterial morphology play a crucial role in MinDE dynamics. In the present study, bacteria were cultured, confined and reshaped in various micro/nanofluidic devices, to mimic either curvature changes of cell peripherals. Fluorescence imaging was utilized to detail the mode transitions in multiple MinDE patterns. The understanding of the physics in multiple pattern formations is further complemented via in silico modeling. The study synergizes the join merits of in vivo, in vitro and in silico approaches, to grasp the insight of stochastic dynamics inherited from the noisy mesoscopic biophysics.

2:30PM T44.00001 Spatial Disorder in Cyclic Three-Species Predator-Prey Models[1] , QIAN HE, Department of Physics, Virginia Tech, MAURO MOBILIA, Department of Applied Mathematics, University of Leeds, U.K., UWE C. TÄUBER, Department of Physics, Virginia Tech — By numerically studying the oscillatory dynamics of several variants of cyclic three-species predator-prey models with conserved total particle density, we investigate the effects of spatial variability of the reaction rates and site occupancy restrictions on the system's co-evolutionary dynamics. It is shown that both quenched disorder in the reaction rates and lattice site occupancy restrictions have only minor effects on the dynamics of cyclic competing systems. This result is starkly different from the finding in two-species predator-prey model where spatial disorder can greatly enhance species fitness. We also numerically compute the dependence of the mean extinction time, for small systems, on system size.

2:42PM T44.00002 A Two-Species Social Dominance Model , SWAPNIL JAWKAR, Department of Physics, Virginia Tech, GEOFFREY ADAMS, Department of Neurobiology, Duke University, UWE C. TÄUBER, Department of Physics, Virginia Tech — We study the general properties of a stochastic two-species social-domination model defined on a d-dimensional lattice. The introduction of spatial degrees of freedom and allowance of stochastic fluctuations surprisingly does not invalidate the deterministic mean-field picture. In the active state, where the dominant and submissive species coexist, no patch formation is observed, with correlation lengths restricted to a few lattice sites. Oscillations seen in the submissive population density are strongly damped and restricted to a small section of the parameter space. Observations are explained to be a result of the two-particle reactions being restricted to the same social group.

2:54PM T44.00003 Cooperation and cheating in microbes , JEFF GORE, Massachusetts Institute of Technology — Understanding the cooperative and competitive dynamics within and between species is a central challenge in evolutionary biology. Microbial model systems represent a unique opportunity to experimentally test fundamental theories regarding the evolution of cooperative behaviors. In this talk I will describe our experiments probing cooperation in microbes. In particular, I will compare the cooperative growth of yeast in sucrose and the cooperative inactivation of antibiotics by bacteria. In both cases we find that cheater strains—which don't contribute to the public welfare—are able to take advantage of the cooperator strains. However, this ability of cheaters to out-compete cooperators occurs only when cheaters are present at low frequency, thus leading to steady-state coexistence. These microbial experiments provide fresh insight into the evolutionary origin of cooperation.

3:06PM T44.00004 Cooperative Bacterial Growth Dynamics Predict the Evolution of Antibiotic Resistance , TATIANA ARTEMOVA, YLAINE GERARDIN, SOPHIA HSIN-JUNG LI, JEFF GORE — Since the discovery of penicillin, antibiotics have been our primary weapon against bacterial infections. Unfortunately, bacteria can gain resistance to penicillin by acquiring the gene that encodes beta-lactamase, which inactivates the antibiotic. However, mutations in this gene are necessary to degrade the modern antibiotic cefotaxime. Understanding the conditions that favor the spread of these mutations is a challenge. Here we show that bacterial growth in beta-lactam antibiotics is cooperative and that the nature of this growth determines the conditions in which resistance evolves. Quantitative analysis of the growth dynamics predicts a peak in selection at very low antibiotic concentrations; competition between strains confirms this prediction. We also find significant selection at higher antibiotic concentrations, close to the minimum inhibitory concentrations of the strains. Our results argue that an understanding of the evolutionary forces that lead to antibiotic resistance requires a quantitative understanding of the evolution of cooperation in bacteria.

3:18PM T44.00005 Slowly switching between environments facilitates reverse evolution in small populations , LONGZHI TAN, JEFF GORE, Department of Physics, Massachusetts Institute of Technology — The rate at which a physical process occurs usually changes the behavior of a system. In thermodynamics, the reversibility of a process generally increases when it occurs at an infinitely slow rate. In biological evolution, adaptations to a new environment may be reversed by evolution in the ancestral environment. Such fluctuating environments are ubiquitous in nature, although how the rate of switching affects reverse evolution is unknown. Here we use a computational approach to quantify evolutionary reversibility as a function of the rate of switching between two environments. For small population sizes, which travel on landscapes as random walkers, we find that both genotypic and phenotypic reverse evolution increase at slow switching rates. However, slow switching of environments decreases evolutionary reversibility for a greedy walker, corresponding to large populations (extensive clonal interference). We conclude that the impact of the switching rate for biological evolution is more complicated than other common physical processes, and that a quantitative approach may yield significant insight into reverse evolution.

3:30PM T44.00006 Bacterial cheating limits the evolution of antibiotic resistance , HUI XIAO CHAO, MANOSHI DATTA, EUGENE YURTSEV, JEFF GORE, Department of Physics, Massachusetts Institute of Technology — The widespread use of antibiotics has led to the evolution of resistance in bacteria. Bacteria can gain resistance to the antibiotic ampicillin by acquiring a plasmid carrying the gene beta-lactamase, which inactivates the antibiotic. This inactivation may represent a cooperative behavior, as the entire bacterial population benefits from removing the antibiotic. The cooperative nature of this growth suggests that a cheater strain–which does not contribute to breaking down the antibiotic–may be able to take advantage of cells cooperatively inactivating the antibiotic. Here we experimentally find that a "sensitive" bacterial strain lacking the plasmid conferring resistance can invade a population of resistant bacteria, even in antibiotic concentrations that should kill the sensitive strain. We observe stable coexistence between the two strains and find that a simple model successfully explains the behavior as a function of antibiotic concentration and cell density. We anticipate that our results will provide insight into the evolutionary origin of phenotypic diversity and cooperative behaviors found in nature.

3:42PM T44.00007 A slowly evolving host moves first in symbiotic interactions , JAMES DAMORE, JEFF GORE, MIT — Symbiotic relationships, both parasitic and mutualistic, are ubiquitous in nature. Understanding how these symbioses evolve, from bacteria and their phages to humans and our gut microflora, is crucial in understanding how life operates. Often, symbioses consist of a slowly evolving host species with each host only interacting with its own sub-population of symbionts. The Red Queen hypothesis describes coevolutionary relationships as constant arms races with each species rushing to evolve an advantage over the other, suggesting that faster evolution is favored. Here, we use a simple game theoretic model of host- symbiont coevolution that includes population structure to show that if the symbionts evolve much faster than the host, the equilibrium distribution is the same as it would be if it were a sequential game where the host moves first against its symbionts. For the slowly evolving host, this will prove to be advantageous in mutualisms and a handicap in antagonisms. The model allows for symbiont adaptation to its host, a result that is robust to changes in the parameters and generalizes to continuous and multiplayer games. Our findings provide insight into a wide range of symbiotic phenomena and help to unify the field of coevolutionary theory.

3:54PM T44.00008 How do the effects of mutations add up? , ANDREA VELENICH, MIT, MINGJIE DAI, Harvard University, JEFF GORE, MIT — Genetic mutations affect the fitness of any organism and provide the variability necessary for natural selection to occur. Given the fitness of a wild type organism and the fitness of mutants A and B which differ from the wild type by a single mutation, predicting the fitness of the double mutant AB is a fundamental problem with broad implications in many fields, from evolutionary theory to medicine. Analysis of millions of double gene knockouts in yeast reveals that, on average, the fitness of AB is the product of the fitness of A and the fitness of B. However, most pairs of mutations deviate from this mean behavior in a way that challenges existing theoretical models. We propose a natural generalization of the geometric Fisher's model which accommodates the experimentally observed features and allows us to characterize the fitness landscape of yeast.

4:06PM T44.00009 Theory of cooperation in a micro-organismal snow-drift game[1] , ZHENYU WANG, NIGEL GOLDENFELD, Department of Physics, Center for the Physics of Living Cells and Institute for Genomic Biology, University of Illinois at Urbana-Champaign — We present a mean field model for the phase diagram of a community of micro-organisms, interacting through their metabolism so that they are, in effect, engaging in a cooperative social game. We show that as a function of the concentration of the nutrients glucose and histidine, the community undergoes a phase transition separating a state in which one strain is dominant to a state which is characterized by coexisting populations. Our results are in good agreement with recent experimental results, correctly predicting quantitative trends and the phase diagram.

[1]We thank Jeff Gore for sharing with us his experimental data. This work was supported in part by the National Science Foundation through grant number NSF-EF-0526747.

4:18PM T44.00010 Spatial population genetics in a petri dish , KIRILL KOROLEV, MIT, JOAO XAVIER, MELANIE MULLER, NILAY KARAHAN, OSKAR HALLATSCHEK, KEVIN FOSTER, ANDREW MURRAY, DAVID NELSON — The evolution of natural populations involves more than mutations followed by natural selection: Stochasticity and spatial migrations are also important. The effects of fluctuations and spatial structure become especially pronounced when organisms expand to new territories. The fluctuations are enhanced because the number of organisms at the front of the expansion is typically small, and the spatial structure is more pronounced due to dimensional reduction from two to one spatial dimension (because colonization occurs along the quasi-one-dimensional periphery of the population). The interplay of fluctuations and space leads to spatial segregation of different genotypes, which significantly alters the evolutionary dynamics of the population. We investigate this process by combining theory, simulations, and experiments on microbial expansions on the surface of a Petri dish. In particular, I will discuss how one can use simple microbiology experiments to measure important parameters of microbial populations such as the strength of fluctuations, migration rate, and relative fitness.

4:30PM T44.00011 The Goldilocks Principle and Rapid Evolution of Antibiotic Resistance in Bacteria[1] , QIUCEN ZHANG, ROBERT AUSTIN, Department of Physics, Princeton University — Goldilocks sampled the three bear's wares for the "just right" combination of taste, fit and comfort. Like Goldilocks's need for the just right parameters, evolution proceeds most rapidly when there is the just right combination of a large number of mutants and rapid fixation of the mutants. We show here using a two-dimensional micro-ecology that it is possible to fix resistance to the powerful antibiotic ciprofloxacin (Cipro) in wild-type E. coli in 10 hours through a combination of extremely high population gradients, which generate rapid fixation, convolved with the just right level of antibiotic which generates a large number of mutants and the motility of the organism. Although evolution occurs in well-stirred chemostats without such Goldilocks conditions, natural environments are rarely well stirred in nature.For complex environments such as the Galapagos Islands, spatial population gradients and movement of mutants along these population gradients can be as important as genomic heterogeneity in setting the speed of evolution. The design of our micro-ecology is unique in that it provides two overlapping gradients, one an emergent and self generated bacterial population gradient due to food restriction and the other a mutagenic antibiotic gradient. Further, it exploits the motility of the bacteria moving across these gradients to drive the rate of resistance to Cipro to extraordinarily high rates.

4:42PM T44.00012 Evolution on a Lattice under Strong Mutation[1] , JAKUB OTWINOWSKI, STEFAN BOETTCHER, Emory University — The most common approach to study biological evolution in a population considers mutations to arise one at a time, and spread to the whole population. However, recent experimental work has shown that under conditions of strong mutation and strong selection, multiple mutations may arise simultaneously. Such overlapping mutations compete with each other and make the results difficult to analyse. Theorists are working on understanding the relationships between different parameters such as population size, mutation rate, and selection coefficients, in the way they affect observables such as the speed of evolution, and the probability of fixation. We have shown with simulations that under additional spatial constraints the dynamics are very different compared to well-mixed populations. A surface in fitness space evolves, akin to surface growth phenomena, with non-trivial power-law exponents. The result is that the speed of evolution is restricted and the probability of fixation is reduced.

4:54PM T44.00013 Modeling Political Populations with Bacteria , CHRIS CLEVELAND, Princeton University, DAVID LIAO, U. California San Francisco — Results from lattice-based simulations of micro-environments with heterogeneous nutrient resources reveal that competition between wild-type and GASP rpoS819 strains of E. Coli offers mutual benefit, particularly in nutrient deprived regions. Our computational model spatially maps bacteria populations and energy sources onto a set of 3D lattices that collectively resemble the topology of North America. By implementing Wright-Fishcer re- production into a probabilistic leap-frog scheme, we observe populations of wild-type and GASP rpoS819 cells compete for resources and, yet, aid each other's long term survival. The connection to how spatial political ideologies map in a similar way is discussed.

5:06PM T44.00014 Mutualistic Interactions and Community Structure in Biological Metacommunities[1] , PER ARNE RIKVOLD, Florida State Univ., ELISE FILOTAS, Univ. du Quebec a Montreal, MARTIN GRANT, McGill Univ., LAEL PARROTT, Univ. de Montreal — The role of space in determining species coexistence and community structure is well established. However, previous studies mainly focus on simple competition and predation systems, and the role of mutualistic interspecies interactions is not well understood. Here we use a spatially explicit metacommunity model, in which new species enter by a mutation process, to study the effect of fitness-dependent dispersal on the structure of communities with interactions comprising mutualism, competition, and exploitation [1]. We find that the diversity and interaction network undergo a nonequilibrium phase transition with increasing dispersal rate. Low dispersion rate favors spontaneous emergence of many dissimilar, strongly mutualistic and species-poor local communities. Due to the local dissimilarities, the *global* diversity is high. High dispersion rate promotes local biodiversity and supports similar, species-rich local communities with a wide range of interactions. The strong similarity between neighboring local communities leads to reduced global diversity.

5:18PM T44.00015 Universal Description of Interactive Growth[1] , CARLOS CONDAT, LUCAS BARBERIS, FaMAF - Universidad Nacional de Cordoba and IFEG - CONICET — Although the existence of organism-organism interactions during ontogenesis is well documented, ontogenetic growth models usually focus exclusively on the organism-environment interaction. We develop a new formalism to describe the interactive growth of two or more organisms in a given environment. Using a vector formulation of the Phenomenological Universalities concept, we are able to characterize the joint growth of two or more interacting organisms and assess the direct mutual influences between them, as well as the indirect influences that operate through environment modifications. The resulting equations describe synergetic, antagonistic, and cooperative growth, and can be applied to biological and ecological problems. As an example, we examine the growth dynamics in a mixed-species plantation.

5:30PM T44.00016 Large fluctuations and fixation in evolutionary games , MICHAEL ASSAF, MAURO MOBILIA — One of the most striking effects of fluctuations in evolutionary game theory is the possibility for mutants to fixate (take over) an entire population. In this work we use a semi-classical theory to study fixation in evolutionary games under non-vanishing selection, and investigate the relation between selection intensity and demographic (random) fluctuations. This approach allows the accurate treatment of rare large fluctuations and yields the probability and mean time of fixation beyond the weak-selection limit, often considered in previous works. The power of the theory is demonstrated on prototypical models of cooperation dilemmas with multiple absorbing states, and we find excellent agreement between the theoretical predictions and numerical simulations. Furthermore, we show that our treatment is superior to the Fokker-Planck approximation for finite selection intensity. M. Assaf and M. Mobilia, J. Stat. Mech. P09009 (2010). M. Mobilia and M. Assaf, Euro. Phys. Lett. 91, 10002 (2010).

Session T45 GMAG DAMOP: Focus Session: Magnetic and Spin Ordering in Atomic and Optical Systems A310

2:30PM T45.00001 Macroscopic quantum phenomenon in a spin-orbit coupled Bose-Einstein condensate , SHIZHONG ZHANG, TIN-LUN HO, Department of Physics, the Ohio-State University — It is well-known in electron physics in semiconductors that the spin-orbit coupling gives rise to many exciting new physics, for example, the topological insulator that is now being actively studied. With the advent of artificial gauge field that can be generated using Raman lasers for neutral bosonic atoms, we can now study the corresponding effects in the boson system. In this talk, I shall discuss the structure of the spinor condensate with spin-orbit coupling. In particular, we show that the system develops stripe structure in each spin component, as a result of the fact that the ground state consists of two dressed states carrying different momentum. We also work out the phase diagram of the system, which compares well with the recent experiment.

2:42PM T45.00002 Spin-orbit coupled spinor Bose-Einstein condensate , HUI ZHAI, CHUNJI WANG, CHAO GAO, CHAO-MING JIAN, Institute for Advanced Study, Tsinghua University — An effective spin-orbit coupling can be generated in cold atom system by engineering atom-light interactions. We study spin-1/2 and spin-1 Bose-Einstein condensates with Rashba spin-orbit coupling, and find that the condensate wave function will develop non-trivial structures. From numerical simulation we have identified two different phases. In one phase the ground state is a single plane wave, and often we find the system splits into domains and an array of vortices plays the role as domain wall. In this phase, time-reversal symmetry is broken. In the other phase the condensate wave function is a standing wave and it forms spin stripe. The transition between them is driven by interactions between bosons. We also provide an analytical understanding of these results and determines the transition point between the two phases.

2:54PM T45.00003 Phase transitions of spin-orbit coupled Bose-Einstein Condensate in an external trap potential , XIANGFA ZHOU, The Department of Physics, University of Science and Technology of China, IAN MONDRAGON-SHEM, The Department of Physics, Cornell University, CONGJUN WU, The Department of Physics, Univeristy of California, San Diego — Recently, the experimental realization of artificial magnetic fields using laser beams in a Rb87 Bose-Einstein condensate provides a valuable opportunity to investigate the rich physics of atomic gases in the presence of external Abelian and Non-Abelian gauge fields. We investigate the ground state properties of two-component BECs with Rashba spin-orbit coupling in the presence of external trapping potential. In the presence of density-density interaction between particles, the competitions among interaction, spin-orbit coupling and trap potential results in phase transitions of the ground states from a spiral spin-density wave state to a skyrmion type spin texture with rotational symmetry. We numerically solve the Gross-Pitaevskii equation and plot the phase diagram. The corresponding physics with asymmetrical Rashba coupling is also discussed.

3:06PM T45.00004 Artificial Staggered Magnetic Field for Ultracold Atoms in Optical Lattices[1] , CRISTIANE MORAIS SMITH, ITP, Utrecht University — Uniform magnetic fields are ubiquitous in nature, but this is not the case for staggered magnetic fields. In this talk, I will discuss an experimental set-up for cold atoms recently proposed by us [1], which allows for the realization of a "staggered gauge field" in a 2D square optical lattice. If the lattice is loaded with bosons, it may be described by an effective Bose-Hubbard Hamiltonian, with complex and anisotropic hopping coefficients. A very rich phase diagram emerges: besides the usual Mott-insulator and zero-momentum condensate, a new phase with a finite momentum condensate becomes the ground-state at strong gauge fields [2]. By using the technique of Feshbach resonance, the dynamics of a coherent superposition of a vortex-carrying atomic condensate and a conventional zero-momentum molecular condensate can also be studied within the same scheme [3]. On the other hand, if the lattice is loaded with fermions, a highly tunable, graphene-like band structure can be realized, without requiring the honeycomb lattice symmetry [2]. When the system is loaded with a mixture of bosons and two-species fermions, several features of the high-Tc phase diagram can be reproduced. A dome-shaped unconventional superconducting region arises, surrounded by a non-Fermi liquid and a Fermi liquid at low and high doping, respectively [4].

3:42PM T45.00005 Itinerant ferromagnetism in a Fermi gas with contact interaction: Magnetic properties in a dilute Hubbard model[1] , CHIA-CHEN CHANG, SHIWEI ZHANG, Department of Physics, College of William and Mary, DAVID M. CEPERLEY, Department of Physics, University of Illinois Urbana-Champaign — Motivated by recent experiments addressing the issue of itinerant ferromagnetism in a dilute ultra-cold Fermi gas with contact interaction, we examine ground state properties of the repulsive Hubbard model on a cubic lattice [1] by means of a very accurate auxiliary-field quantum Monte Carlo method [2]. We focus on low-density systems with varying on-site interaction U/t, in the range relevant to the experiments. Twist-averaged boundary conditions are used to eliminate open-shell effects and large lattice sizes are studied to reduce finite-size effects. The sign problem is controlled by a generalized constrained path approximation [2]. We find no ferromagnetic phase transition in this model. The ground-state correlations are consistent with those of a paramagnetic Fermi liquid.

3:54PM T45.00006 Magnetic instabilities in spin imbalanced ultracold Fermi gases[1] , INTI SODEMANN VILLADIEGO, DMYTRO PESIN, ALLAN MACDONALD, University of Texas at Austin — We study the possibility of preparing magnetic states of spin imbalanced ultracold Fermi gases near a broad Feshbach resonance by analyzing the unstable collective magnetization modes developed when the system is placed on the BEC side. Within the approximation of momentum independent interatomic scattering, transverse magnetization instabilities appear at lower critical interaction strengths than those corresponding to the longitudinal instabilities, suggesting that the former ones are primarily responsible for driving the system into a textured state with inhomogeneous magnetization direction. The critical interaction for the onset of transverse instabilities increases with polarization. However the system already has ferromagnetic character below these interaction strengths because of a change in sign of the spin stiffness which occurs close to the Stoner transition of the corresponding unpolarized gas. We also discuss the behavior expected beyond the momentum independent scattering approximation across the resonance for, both, the superfluid and ferromagnetic instabilities present in the system and the implication of these results for experiments.

4:06PM T45.00007 Energy decay constant in sodium spinor condensates , JIE JIANG, YINGMEI LIU, Department of Physics, Oklahoma State University, Stillwater, OK 74078, EDUARDO GOMEZ, D.A. QUINONES , Instituto de Fisica, Universidad Autonoma de San Luis Potosi, San Luis Potosi 78290, P.D. LETT, Joint Quantum Institute, University of Maryland and National Institute of Standards and Technology, Gaithersburg, MD 20899 — Spinor condensates of F=1 sodium atoms display rich spin dynamics due to the antiferromagnetic nature of the interactions in this system. Damped spin oscillations are observed in sodium spinor condensates, which eventually lead to the mean-field ground state. In recent experiments we have been able to track and observe the time evolution of atom number fluctuations, which enables the first quantitative measure of energy dissipation in the spinor condensate. We also develop a method to extract the energy in spinor dynamics from experimental data, and characterize the energy dissipation with a decay constant. This decay constant appears to follow a power-law dependence with the energy of spinor condensates. This power-law dependence has been experimentally checked for a wide range of the spinor energy, by varying the applied magnetic field strength, the magnetization and the density of the spinor condensate.

4:18PM T45.00008 Tunneling properties of collective spin wave excitations in the supercurrent state of a spin-1 spinor BEC , SHOHEI WATABE, Keio University, and CREST(JST), YUSUKE KATO, The University of Tokyo, YOJI OHASHI, Keio University, and CREST(JST) — We theoretically investigate tunneling properties of spin wave excitations through a barrier in the supercurrent state of a spin-1 BEC. In the ferromagnetic phase, we show that the transverse spin wave always exhibits perfect transmission, when the spin- wave momentum p coincides with the momentum of supercurrent q. This is quite different from the case of the Bogoliubov mode, where the so-called anomalous tunneling phenomenon always occurs when $p = 0$, unless the system is in the critical current state ($q = q_c$). In the polar phase, spin wave modes always exhibit perfect transmission when $p = 0$, as in the case of the Bogoliubov mode. However, this anomalous tunneling behaviors of spin wave modes are shown to still hold even in the critical current state, in contrast to the breakdown of the perfect transmission of the Bogoliubov mode at q_c. Only when the Gross-Pitaevskii equation for the spin-1 BEC is integrable, perfect transmission of the spin wave is absent at q_c. Using a simple $delta$-functional barrier, we also discuss similarity between the condensate wave function in the supercurrent state and the wave functions of spin wave excitations when perfect transmission occurs.

4:30PM T45.00009 Quantum rotor theory of spinor condensates in tight traps , RYAN BARNETT, HOI-YIN HUI, CHIEN-HUNG LIN, JAY D. SAU, S. DAS SARMA, Joint Quantum Institute and Condensed Matter Theory Center — In this talk, we theoretically construct exact mappings of many-particle bosonic systems onto quantum rotor models. In particular, we analyze the rotor representation of spinor Bose-Einstein condensates. There is an exact mapping of a spin-one condensate of fixed particle number with quadratic Zeeman interaction onto a quantum rotor model. We use the rotor mapping to describe the different dynamical regimes recently observed in ^{23}Na condensates. We also suggest a way to experimentally observe quantum mechanical effects (collapse and revival) in spinor condensates. We classify three distinct physical limits of the rotor model: the Rabi, Josephson, and Fock regimes. The last regime corresponds to a fragmented condensate and is thus not captured by the Bogoliubov theory. The semiclassical limit of the rotor problem is discussed and connections with the quantum wave functions are made through use of the Husimi distribution function. Finally, we describe how to extend the analysis to higher-spin systems and derive a rotor model for the spin-two condensate. This work was supported by the NSF JQI Physics Frontier Center.

4:42PM T45.00010 Spin susceptibility of spin-1/2 fermions with dipole interactions[1] , BENJAMIN M. FREGOSO, University of Chicago, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — The general form of the spin susceptibility is found for spin- 1/2 fermions with dipole interactions. In the paramagnetic phase and partially magnetized phase (ferro-nematic) the spin susceptibility is explicitly computed in the Random Phase Approximation. Important modifications to the static susceptibility are discussed which are relevant for future experiments. Unconventional collective modes in the paramagnetic and ferro-nematic phases are also discussed.

[1]NSF DMR 0758462

4:54PM T45.00011 Quasi-two-dimensional fermionic dipolar gases in the Hartree-Fock approximation: band renormalization, inter-subband excitons and the liquid-solid phase diagram , MEHRTASH BABADI, EUGENE DEMLER, Department of Physics, Harvard University, Cambridge, Massachusetts 02138, USA — We study quasi-two-dimensional systems of fermionic dipolar gases in the Hartree-Fock approximation for various trap frequencies and dipolar interactions at finite temperatures and evaluate the energy dispersions of the renormalized subbands. We also study the inter-subband excitation spectrum of the system in the Time-Dependent Hartree-Fock approximation and predict the energy absorption rates in lattice modulation spectroscopy experiments. It is shown that the spectrum consists of inter-subband particle-hole excitation continuums as well as excitonic modes, and that their observation is highly likely in current experiments. Finally, we calculate the liquid-solid phase diagram of the system and find novel features such as multiple crystalline orders and re-entrant crystallization.

5:06PM T45.00012 Probing non-Abelian statistics of Majorana fermions in ultracold atomic superfluid , SHI-LIANG ZHU, School of Physics, South China Normal University, L.B. SHAO, Z.D. WANG, Department of Physics, The University of Hong Kong, LU-MING DUAN, Department of Physics, Michigan University — We propose an experiment to directly probe the non-Abelian statistics of Majorana fermions by braiding them in an s-wave superfluid of ultracold atoms. We show different orders of braiding operations give orthogonal output states that can be distinguished through Raman spectroscopy. Realization of Majorana bound states in an s-wave superfluid requires strong spin-orbital coupling and a controllable Zeeman field in the perpendicular direction. We present a simple laser configuration to generate the artificial spin-orbital coupling and the required Zeeman field in the dark state subspace.

5:18PM T45.00013 Magnetism and Cooper pairing in one-dimensional large spin fermions with repulsive interactions , HSIANG-HSUAN HUNG, The department of Physics, Univeristy of California, San Diego, YUPENG WANG, Institute of Physics, Chinese Academy of Sciences, Beijing, China, CONGJUN WU, The department of Physics, Univeristy of California, San Diego — The recent experimental realization of ultracold large-spin fermionic systems provides a new opportunity to investigate exotic magnetism and Cooper pairing physics. By means of exact diagonalizaton and the density matrix renormalization group, we systematically study the magnetic properties of the Mott-insulating state of the simplest large-spin systems with hyperfine spin $F = 3/2$ in one-dimension and at quarter filling. Such a system is characterized by an exact $SO(5)$ symmetry. The ground state shows various profiles at various $\theta = \tan^{-1} J_0/J_2$, where J_0/J_2 is the ratio of exchange strengths of the singlet ($S_T = 0$) and quintet ($S_T = 2$) channels. As $\theta > 45^\circ$ the ground state is a gapped state with dimerization patterns whereas as $\theta \leq 45^\circ$ it is a gapless Luttinger liquid state. Furthermore, we found that in the Luttinger liquid phase the static correlation functions show power-law decays with a four-site periodicity, which is similar to an SU(4) chain. We also study the spin-$3/2$ model with doping. In the regime of $\theta > 45^\circ$ and at moderate doping, the singlet pairing correlations indicate power-law decays whereas the quintet pairing correlations have exponential decays. On the other hand, in the regime of $\theta \leq 45^\circ$ the quintet pairing correlations are more robust than the singlet pairing correlations.

Session U1 APS: Nobel Prize Session: Graphene: Materials in the Flatland Ballroom C1

5:45PM U1.00001 Graphene: Materials in the Flatland , KONSTANTIN NOVOSELOV, University of Manchester, Manchester —

6:15PM U1.00002 Discussion –

Wednesday, March 23, 2011 7:30PM - 9:00PM –

Session U55 APS: "Trends" in the APS Publication Physics Hyatt Regency Dallas Reunion A-D

7:30PM U55.00001 Topological order, topological insulators, and the search for the Majorana fermion , JOEL E. MOORE, University of California — In condensed matter physics complex order often emerges from simple interactions. Recent experiments show that topological order, previously seen only in 2D electron systems in high magnetic field, can exist in zero field and even in bulk 3D materials called topological insulators, in which spin-orbit coupling induces the topological order. Topologically ordered phases can support new kinds of emergent particles, such as the Majorana fermion. Current experiments in condensed matter, in both fractional quantum Hall systems and strong spin-orbit materials, are probing the physics of Majorana fermions, which may eventually enable a topological approach to quantum computing.

8:00PM U55.00002 Quantum information in solid-state systems , DANIEL LOSS, University of Basel — I review the theoretical concepts for spin qubits and scalable quantum computers in nanostructures and highlight the experimental progress in this fast moving field [1]. I describe the standard model of quantum computing and the basic criteria for its potential realization in solid state systems such as GaAs heterostructures, carbon nanotubes, InAs or SiGe nanowires, etc. Other alternative formulations such as measurement-based and adiabatic quantum computing are mentioned briefly. I then focus on qubits formed by individual electron spins in single and double GaAs quantum dots. Introducing the problem of decoherence arising from spin orbit and hyperfine interactions I discuss ways to overcome it, such as state narrowing and nuclear magnetism induced by strong correlations [2].

8:30PM U55.00003 Graphene: Deep physics from the all-surface material , MICHAEL S. FUHRER, University of Maryland, College Park — The 2010 Nobel Prize in Physics was awarded to Andre Geim and Kostya Novoselov for their experiments on graphene, a single-atom plane of graphite. I will discuss why graphene has generated such excitement in condensed matter physics. Graphene is different: graphene's electrons mimic massless Dirac Fermions. But graphene is also amazingly tunable: Bandgaps can be generated by nanostructuring. Interactions can be tuned by the surrounding dielectric. Strain generates effective "pseudomagnetic" fields up to 300 Tesla. The work function can be tuned over a large range. Such tunability promises that graphene will remain interesting as a laboratory for condensed matter physics.

Thursday, March 24, 2011 8:00AM - 11:00AM –

Session V1 DCMP: Iron Pnictides versus Iron Chalcogenides: Magnetism and Pairing Fluctuation Ballroom A1

8:00AM V1.00001 Symmetry and structure of the pairing gap in Fe-based superconductors[1] , ANDREY CHUBUKOV, University of Wisconsin — I review recent works on the symmetry and structure of superconducting gap in Fe-pnictides and related compounds. I show that the gap very likely has s-wave symmetry, and is either nodal or has nodes along the two electron Fermi surfaces, depending on the parameters. I argue that the nodal gap is most likely outcome in systems with less pronounced tendency towards antiferromagnetism. I compare 4-and 5-pocket models for Fe-pnictides and argue that the parameter range where the gap is nodal is much wider in 4-pocket models. I review recent experiments aimed to understand whether the gap has nodes, e.g., experiments on the variation in the field-induced component of the specific heat C(H) with the direction of the applied field in $FeSe_{0.4}Te_{0.6}$. I show that, for extended s-wave gap, C(H) has $\cos 4\phi$ component, where ϕ is the angle between H and the direction between hole and electron Fermi surfaces, but only if the gap has no nodes. When the gap has accidental nodes, the $\cos 4\phi$ variation does not hold. I also plan to discuss the interplay between direct Coulomb interaction at large momentum transfer and spin-fluctuation contribution to the pairing, and the interplay between antiferromagnetism and superconductivity. In particular, I show that in 4-pocket (but not in 5-pocket) model superconductivity becomes the leading instability in some range of parameters even at perfect nesting, i.e, antiferromagnetism is not a pre-condition for superconductivity. This agrees with functional RG studies.

[1]In collaboration with Ilya Eremin and Saurabh Maiti

8:36AM V1.00002 Anisotropic Superconducting Gap Revealed by Angle Resolved Specific Heat, Point Contact Tunneling and Scanning Tunneling Microscope in Iron Pnictide Superconductors[1] , HAI-HU WEN, Institute of Physics, CAS — Angle resolved specific heat was measured in $FeSe_{0.55}Te_{0.45}$ single crystals. A four-fold oscillation of C/T, with the minimum locating at the Fe-Fe bond direction, was observed when the sample was rotated at 9 T, which can be understood as due to the gap modulation on the electron pocket within the scheme of S$\pm$ pairing. Accordingly, by measuring the point contact Andreev reflection spectrum on the $BaFe_{2-x}Ni_xAs_2$ single crystals in wide doping regimes, we found a crossover from nodeless to nodal feature of the superconducting gap. In K-doped $BaFe_2As_2$ single crystals, we performed the low temperature STM measurements and observed a well ordered vortex lattice in local region. In addition, the statistics on over 3000 dI/dV spectra illustrate clear evidence of two gaps with magnitude of 7.6 meV and 3.3 meV, respectively. Detailed fitting to the tunneling spectrum shows an isotropic superconducting gap. Work collaborated with B. Zeng, C. Ren, L. Shan, Y. L. Wang, B. Shen, G. Mu, H. Q. Luo, T. Xiang, H. Yang, I. I. Mazin and P. C. Dai. References:

9:12AM V1.00003 From magnetism to superconductivity in $FeTe_{1-x}Se_x$[1] , DIMITRI ARGYRIOU[2], European Spallation Source ESS AB P.O Box 117, SE-221 00 Lund, Sweden — The iron chalcogenide $FeTe_{1-x}Se_x$ is structurally the simplest of the Fe-based superconductors and exhibits a Fermi surface similar to iron pnictides. Despite this similarity, the parent compound $Fe_{1+y}Te$ orders antiferromagnetically with an in-plane magnetic wave vector (π,0) with an ordered moment of $\sim 2\mu_B$/Fe, suggestive of a localized rather than itinerant character of the magnetic order. This contrasts the pnictide parent compounds where the magnetic order has an in-plane magnetic wave vector (π,π) that likely arises from Fermi Surface nesting. Regardless both the pnictide and chalcogenide Fe superconductors exhibit a superconducting spin resonance around (π,π) as probed by neutron scattering. A central question in this burgeoning field is therefore how (π,π) superconductivity emerges from a (π,0) magnetic instability ? Using neutron scattering we show that incommensurate magnetic excitations around (π,π) are found even in the undoped parent compound $Fe_{1+y}Te$. With increasing x, the (π,0)-type magnetic long-range order becomes unstable and correlates with a weak charge carrier localization, while the mode at (π,π) becomes dominant for x>0.29. Our results suggest a common magnetic origin for superconductivity in iron chalcogenide and pnictide superconductors. This work was carried out in close collaboration with the groups of W.Bao (Renmin), Arno Hies (ILL), Zhiqiang Mao (Tulane), C. Brohom (John Hopkins) and I. Eremin (MPI-Dresden/Bochum).

9:48AM V1.00004 The nature of electronic nematic states in iron-pnictides , JIANGPING HU, Purdue University — We show that the electronic nematic states in iron-pnictides is driven by frustrated spin fluctuations. A three dimensional effective spin model is constructed to explain the nematicity. This model explains the relation between the structural and magnetic transitions, and the spin excitations measured in recent neutron scattering experiments. Moreover, the model naturally predicts the separation between the two transitions are controlled by the c-axis magnetic exchange coupling , and the existence of an non-collinear magnetic state before spin-glass state upon replacing irons by nonmagnetic impurities. The experimental evidence supporting the predictions and the relation to orbital ordering and superconductivity will also be addressed.

10:24AM V1.00005 Differences in the degree of correlations between Pnictides and Chalcogenides: LaFeAsO vs. FeSe[1] , MARKUS AICHORN, TU Graz, Institute of theoretical and computational physics — The discovery of high-temperature superconductivity in iron-based compounds triggered an enormous amount of research in condensed matter physics. A very intriguing property of these new compounds is the rather high flexibility concerning elemental substitutions, leading to several families of superconductors, termed "1111," "122," "11," and so on, depending on their chemical composition. In this talk we will analyse the single-particle properties of prominent iron-based superconductors using a combination of density-functional theory with the Dynamical Mean-Field Theory, where also the interaction parameters are calculated ab-initio. This approach enables us to understand also these more complex materials at a first-principle level. We will show that there are significant differences in the electronic properties, when going from more weakly correlated members as LaFeAsO, to more correlated ones like FeSe. For reasonable Coulomb parameters, the properties range from Fermi-liquid like to incoherent bad-metal like.

Session V2 DCMP: Fermi Surface Reconstruction and Competing Orders in High Tc Cuprates

Ballroom A2

8:00AM V2.00001 Broken rotational and translational symmetries in the pseudogap phase of cuprates[1] , LOUIS TAILLEFER, University of Sherbrooke and Canadian Institute for Advanced Research — A large in-plane anisotropy of the Nernst coefficient in YBCO is found to set in precisely at the pseudogap temperature $T^\star$ throughout the doping phase diagram [1]. This implies that the pseudogap phase is an electronic state that breaks the four-fold rotational symmetry of the copper-oxide planes. At a somewhat lower temperature, of order $T^\star/2$, the positive Hall and Seebeck coefficients of YBCO start dropping, and they reach large negative values at $T = 0$, in the normal state accessed by applying high magnetic fields [2,3]. We interpret this in terms of an electron pocket forming in the Fermi surface of YBCO as a result of a Fermi-surface reconstruction caused by some order which breaks the translational symmetry of the lattice. Because very similar transport anomalies are observed in Eu-LSCO [4], where they coincide with the onset of stripe order, we infer that some form of stripe order is also at play in YBCO, and argue that the pseudogap phase is a precursor region of stripe (or spin-density-wave) fluctuations [5].

8:36AM V2.00002 Quantum oscillation measurements and their reconciliation with ARPES results in underdoped cuprates[1] , SUCHITRA SEBASTIAN, University of Cambridge — A current conundrum relating to the normal state electronic structure of the underdoped cuprates is the apparent dichotomy between photoemission and quantum oscillations measurements. New quantum oscillation measurements performed over an extended regime on underdoped YBCO are presented that bring results of these two techniques into closer agreement. Further, from the latest quantum oscillation results, we are able to distinguish between various scenarios involving single or multiple carrier types – we show that the experimental findings are only consistent with one of these possibilities. *Work performed in collaboration with N. Harrison, M. Altarawneh, P. A. Goddard, R. Liang, W. N. Hardy, D. A. Bonn, and G. G. Lonzarich

9:12AM V2.00003 Magnetic phase diagram and magnetic dynamics of $YBa_2Cu_3O_{6+x}$: Implications for the mechanism of high-T_c superconductivity , BERNHARD KEIMER, Max Planck Institute for Solid State Research, Stuttgart, Germany — We will present a comprehensive study of the magnetic phase diagram of the high-temperature superconductor $YBa_2Cu_3O_{6+x}$. Using elastic neutron scattering, we show that the phase diagram includes incommensurate spin density wave and electronic liquid-crystal states, in addition to the well-known antiferromagnetic, d-wave superconducting, and paramagnetic phases [1]. Using a combination of inelastic neutron scattering and resonant inelastic x-ray scattering, we have also arrived at a comprehensive picture of the magnetic excitation spectrum in all of these phases [2]. The dispersion relations and spectral weights of all compounds, including the slightly overdoped superconductor $YBa_2Cu_3O_7$, are closely similar to those of magnons in undoped, antiferromagnetically ordered $YBa_2Cu_3O_6$. The results are in excellent agreement with the spin excitations obtained by exact diagonalization of the t-J Hamiltonian on finite-sized clusters. A numerical solution of the Eliashberg equations based on the experimental spin excitation spectrum of $YBa_2Cu_3O_7$ reproduces its superconducting transition temperature T_c within a factor of two, strongly supporting magnetic Cooper pairing models for the cuprates. Neutron scattering data of the buckling phonon in $YBa_2Cu_3O_7$ suggest that coupling to this phonon does not substantially enhance d-wave pairing [3].

9:48AM V2.00004 The spin density wave quantum phase transition in two dimensional metals , SUBIR SACHDEV, Harvard University — The mean-field theory for the onset of spin density wave order in a metal describes a quantum phase transition which reconstructs the "large" Fermi surface to small Fermi pockets. Fluctuations near this transition are described by a quantum field theory of fermions near the reconstruction points, and the bosonic order parameter. This field theory is shown to be strongly-coupled in two spatial dimensions. We find an instability near the quantum critical point to d-wave pairing: this is a "log-squared" instability, stronger than the familiar logarithmic BCS instability. A similar instability is also found towards a modulated bond order. We also discuss an alternative route for the onset of spin density wave order, via intermediate non-Fermi liquid phases which have small Fermi pockets but without long-range spin density wave order.

Session V3 DCMP: Controlling Quantum Interactions of Single Spins and Photons in Diamond

Ballroom A3

8:00AM V3.00001 Spin quantum measurements on diamond defects , JOERG WRACHTRUP, University of Stuttgart — Diamond defects allow for precise measurement of single electron and nuclear spin quantum states. The excellent controllability of these spins as well as efficient decoupling from environment make them an ideal playground for engineering complex quantum states and development of elaborate control schemes. The talk will describe how nuclear spin states can be efficiently read-out and used as Qbits in spin clusters. Routs towards the controlled engineering of extended spin arrays as well as coupling to control structures will be discussed.

8:36AM V3.00002 Observation of spin-light coherence for single spin measurement and control in diamond[1] , BOB BUCKLEY[2], Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106 — The long spin coherence and optical addressability of nitrogen-vacancy (NV) centers in diamond makes them excellent candidates for studies of quantum information science with potential technological applications. We demonstrate the coherent coupling of light to the electronic spin of a single NV center for both non-destructive, single-spin readout via the Faraday effect and unitary, single-spin control via the optical Stark effect[3]. By monitoring the Faraday effect of laser light focused on a single NV center and detuned from optical resonances, we are able to read out an NV center's spin state without destroying it, in contrast to traditional spin readout techniques which polarize the spin during measurement. In a complimentary way, the spin coherently rotates in response to the light through the optical Stark effect, which we demonstrate as a method of all-optical spin control. These measurements have important consequences for future single-spin quantum non-demolition measurements and spin-photon entanglement schemes in diamond that may be exploited for the development of quantum repeater technologies and photonic coupling of spins over large distances.

[3]B. B. Buckley, G. D. Fuchs, L. C. Bassett, D. D. Awschalom, *Science Express* (DOI: 10.1126/science.1196436)

9:12AM V3.00003 Quantum entanglement between an optical photon and a solid-state spin qubit , EMRE TOGAN, Harvard University — Quantum entanglement is among the most fascinating aspects of quantum theory. In this work quantum entanglement between the polarization of a single optical photon and a solid-state spin qubit is realized. The experimental entanglement verification demonstrates that a high degree of control over interactions between a solid-state qubit associated with the single electronic spin of a nitrogen vacancy centre in diamond and the quantum light field can be achieved. The reported entanglement source can be used in studies of fundamental quantum phenomena and provides a key building block for the solid-state realization of quantum optical networks.[1]

[1]Quantum entanglement between an optical photon and a solid-state spin qubit, Nature 466, 730-734, (2010)

9:48AM V3.00004 Coupling single electron spins in diamond to integrated optical structures , RAY BEAUSOLEIL, HP Laboratories — Diamond is an attractive material for some electronic and photonic applications because of its excellent chemical stability and high thermal conductivity and carrier mobility. Diamond appears to be an excellent material for quantum information processing and magnetic sensing applications as well, with many optically active paramagnetic centers. Of these, the most carefully studied to date has been the nitrogen-vacancy (NV) color center, since it is optically addressable and can exhibit electron spin coherence lifetimes exceeding 1 ms at room temperature. This long-lived coherence is usually attributed to the nuclear spin-zero environment of the diamond lattice, which can be further improved with isotopic purification. These capabilities have recently allowed for some remarkable demonstrations in this system such as controlled coupling between single electronic and nuclear spins. For quantum information technologies, NV centers that are mutually optically coupled could enable long-distance quantum communication through repeaters. However, given the low branching ratio of natural emission from NV centers in bulk diamond into the zero phonon line, coupling these centers to cavities with at least moderately large Purcell factors is a critically important step. In this talk I will describe our recent progress in realizing microcavities with low loss and small mode volume in two hybrid systems: silica microdisks coupled to diamond nanoparticles, and gallium phosphide microdisks coupled to single-crystal diamond. In both cases, we have demonstrated coupling between NV centers and whispering-gallery-type cavity modes. Finally, I will present our most recent progress toward fabricating waveguides and microcavities directly in diamond.

10:24AM V3.00005 Quantum control and decoherence of a single spin in diamond[1] , VIATCHESLAV DOBROVITSKI, Ames Laboratory US DOE and Iowa State University — Nitrogen-vacancy (NV) impurity centers in diamond have recently emerged as a unique platform for investigating quantum dynamics and quantum control of single spins in solid-state environments. NV centers demonstrate an unusual combination of spin-dependent optical properties, individual addressability, and long spin coherence times. The NV spin state can be manipulated both optically and magnetically, and very fast quantum control operations can be performed with high fidelity [1,2]. Due to these uniquely favorable properties, quantum dynamics of a single NV spin can be investigated in great detail. I will present the results of our work on decoherence of NV spins by spin baths of atomic nitrogen impurities (P1 centers) and the spins of ^{13}C nuclei, and discuss different regimes of the decoherence dynamics. We will consider modern dynamical decoupling techniques which aim at preserving coherence of quantum spins, and the experimental implementation of the decoupling protocols, as well as more advanced quantum control of NV spins. Using a variety of analytical and numerical tools, we can characterize and optimize the factors which limit our control over these quantum spin systems [2]. We will also examine how the quantum control approaches can be used to elucidate the quantum dynamics of NV centers and the properties of the spin bath [3].

Session V4 DPOLY: Dynamics of Polymers: Phenomena Due to Confinement Ballroom A4

8:00AM V4.00001 Direct measurement of molecular motion in freestanding polystyrene thin films , MARK EDIGER, University of Wisconsin-Madison — An optical photobleaching technique has been used to measure the reorientation of dilute probes in freestanding polystyrene films as thin as 14 nm. Temperature-ramping and isothermal anisotropy measurements reveal the existence of two subsets of probe molecules with differing dynamics. While the slow subset shows bulk-like dynamics, the more mobile subset reorients within a few hundred seconds even at Tg-25 K (Tg is the glass transition temperature of bulk polystyrene). At Tg -5 K, the mobility of these two subsets differs by 4 orders of magnitude. These data are consistent with the presence of a high mobility layer at the film surface whose thickness is independent of polymer molecular weight and total film thickness. The thickness of the mobile surface layer increases with temperature and equals 7 nm at Tg.

8:36AM V4.00002 Molecular dynamics at nanometric length-scales , FRIEDRICH KREMER, Universität Leipzig — Broadband Dielectric Spectroscopy, Spectroscopic vis-Ellipsometry, X-Ray Reflectometry, Alternating and Differential Scanning Calorimetry are combined to study glassy dynamics and the glass transition in nanometric thin ($\geq$5 nm) layers of polystyrene (PS) having widely varying molecular weights and Polymethylmethacrylate (PMMA) deposited on different substrates. For the dielectric measurements two sample geometries are employed, the common technique using evaporated electrodes and a recently developed approach taking advantage of nanostructures as spacers. *All* applied methods deliver the concurring result that deviations from glassy dynamics and from the glass transition of the bulk never exceed margins of $\pm$3 K *independent* of the layer thickness, the molecular weight of the polymer under study and the underlying substrate. Our findings are discussed in the context of the highly controversial literature and prove that an appropriate sample preparation is of paramount importance in order to avoid artefacts.

9:12AM V4.00003 Gas Permeation in Thin Glassy Polymer Films , DONALD PAUL, University of Texas at Austin — The development of asymmetric and composite membranes with very thin dense "skins" needed to achieve high gas fluxes enabled the commercial use of membranes for molecular level separations. It has been generally assumed that these thin skins, with thicknesses of the order of 100 nm, have the same permeation characteristics as films with thicknesses of 25 microns or more. Thick films are easily made in the laboratory and have been used extensively for measuring permeation characteristics to evaluate the potential of new polymers for membrane applications. There is now evidence that this assumption can be in very significant error, and use of thick film data to select membrane materials or predict performance should be done with caution. This presentation will summarize our work on preparing films of glassy polymers as thin as 20 nm and characterizing their behavior by gas permeation, ellipsometry and positron annihilation lifetime spectroscopy. Some of the most important polymers used commercially as gas separation membranes, i.e., Matrimid® polyimide, polysulfone (PSF) and poly(2,6-dimethyl-1,4-phenylene oxide) (PPO), have been made into well-defined thin films in our laboratories by spin casting techniques and their properties studied using the techniques we have developed. These thin films densify (or physically age) much faster than thicker films, and, as result, the permeability decreases, sometimes by several-fold over weeks or months for thin films. This means that the properties of these thin films can be very different from bulk films. The techniques, interpretations and implications of these observations will be discussed. In a broader sense, gas permeation measurements can be a powerful way of developing a better understanding of the effects of polymer chain confinement and/or surface mobility on the behavior of thin films.

9:48AM V4.00004 Surface Dynamics in Glass forming Materials[1] , JAMES FORREST, University of Waterloo — There is mounting evidence that the surface of glassy polymers exhibits enhanced dynamics compared to the bulk material at the same temperature. Using nanoparticle embedding and relaxation of nanodeformations on the surface, we have developed a detailed characterization of the dynamics of glassy polymers (polystyrene (PS), isotactic-poly(methyl methacrylate)). This includes the effects of temperature, molecular weight and film thickness on the surface dynamics. We have extended the studies to the molecular glass former TNB, which display striking similarities to PS. The results of these studies allow us to begin to develop an understanding of the surface properties of glassy material, and how these properties may lead to observed changes in thin film polymer properties.

Work done in collaboration with Chad Daley and Dongping Qi, University of Waterloo; Zahra Fakhraaim, University of Pennsylvania; and Mark Ilton, University of Waterloo.

[1]Funded by NSERC (Canada)

10:24AM V4.00005 Confinement effects on polymer structure and glassy dynamics[1] , ALEXEY LYULIN, Eindhoven University of Technology — We have performed molecular-dynamics simulations to explore the influence of confinement on the glass-transition temperature T_g for supported atactic-polystyrene thin films of different thickness (1 nm $\div$ 10 nm) and different strengths of attraction to the substrate (0.1 kcal/mol $\div$ 3.0 kcal/mol). The films have been equilibrated in a melt at 540 K and further cooled down with a constant cooling velocity of 0.01 K/ps below T_g to room temperature, 300 K. Based on the density measurements we have defined three different (substrate, middle and surface) layers for each film. We found that the monomers close to the surface and in the substrate layer are partially oriented, which leads to more effective monomer packing. For the whole film the average T_g value remains almost constant for films down to 2 nm thickness, where middle layer vanishes. For the middle layer itself T_g does not depend on the total film thickness, while an increase up to 70 K is measured for the substrate layer depending on the strength of attraction to the actual substrate. The surface layer remains liquid-like in the whole temperature range (300 K $\div$ 540 K). We claim that the redistribution of mass in the three film layers may explain the change with film thickness of the average T_g, if the latter is determined from linear fits of the average glass and melt densities. First results on the shear cycling and the rejuvenation phenomena will be discussed as well.

[1]This study is a part of the research program of the Dutch Polymer Institute. This work was also sponsored by the Stichting Nationale Computerfaciliteiten (National Computing Facilities Foundation, NCF) for the use of supercomputer facilities.

Session V5 DMP DCMP: Physics for Everyone Ballroom C1

8:00AM V5.00001 Biomagnetism and Magnetotaxis in Bacteria: What Bacteria Know About Magnetic Materials and Permanent Magnet Design , RICHARD FRANKEL, California Polytechnic State University, San Luis Obispo, CA — Magnetotactic bacteria (mtb) migrate along geomagnetic field lines, i.e., they behave like self-propelled magnetic compass needles. Mtb make single-magnetic-domain crystals of magnetite (Fe_3O_4) and greigite (Fe_3S_4) in intracellular structures called magnetosomes. The magnetosomes are arranged in linear chains that comprise permanent magnetic dipoles with remanent moments approaching the saturation moment, causing the mtb to be oriented in the geomagnetic field as they swim. This allows them to keep their heading and efficiently migrate to, and remain in, a preferred, microaerobic, aquatic habitat. The mtb have solved the difficult problem of designing a permanent magnet that is sufficiently robust to cause the cell to be oriented in the geomagnetic field at ambient temperature, yet fit inside a micron-sized object, and be assembled *in situ* from potentially toxic materials scavenged from the environment. I will describe some recent advances in mtb genetics that illuminate the process by which they make and arrange their magnetosomes.

8:36AM V5.00002 Voodoo Science , ROBERT PARK, American Physical Society — A remarkable scientific result that appears to violate natural law may portend a revolutionary advance in human knowledge. It is, however, more likely an experimental screw up. Error is normal; it can be reduced by repeating measurements and better design of controls, but the success and credibility of science is anchored in a culture of openness. Ideas and observations are freely exposed to independent testing and evaluation by others. What emerges is the book of nature. On its pages we find, if not a simple world, at least an orderly world, in which everything from the birth of stars to falling in love is governed by the same natural laws. These laws cannot be circumvented by any amount of piety or cleverness, they can be understood - with the possible exception of String Theory. For those who elect to work outside the scientific community, errors may go unrecognized. We will examine examples of this, including claims of perpetual motion and cancer caused by cell-phone radiation.

9:12AM V5.00003 MMs Packing and Research with Undergrads , PAUL CHAIKIN, New York University — This abstract not available.

9:48AM V5.00004 Science and Cooking: Motivating the Study of Freshman Physics[1] , DAVID WEITZ, Harvard University — This talk will describe a course offered to Harvard undergraduates as a general education science course, meant to intrduce freshman-level science for non-science majors. The course was a collaboration between world-class chefs and science professors. The chefs introduced concepts of cooking and the professors used these to motivate scientific concepts. The lectures were designed to provide a coherent introduction to freshman physics, primarily through soft matter science. The lectures were supplemented by a lab experiments, designed by a team of very talented graduate students and post docs, that supplemented the science taught in lecture. The course was very successful in motivating non-science students to learn, and even enjoy, basic science concepts.

[1]This course depended on contributions from Michael Brenner, Otger Campas, Amy Rowat and a team of talented graduate student teaching fellows.

10:24AM V5.00005 Making a frothy shampoo or beer[1] , DOUGLAS DURIAN, University of Pennsylvania, Department of Physics and Astronomy — The terms "foam" and "froth" refer to a dispersion of gas bubbles in a liquid. Why do certain liquids show a tendency to foam while others do not? For example, bubbles can be produced in pure water by vigorous agitation, but then they rapidly coalesce and disappear. While foams cannot be produced with pure water, foams associated with beer or shampoo can persist for several minutes or even hours. What ingredient(s) in shampoo and beer make their foams stable, and what physical concepts control their stability? In this talk I'll review three basic mechanisms underlying foam stability, and I'll make connection with current research on coarsening by the diffusion of gas from smaller to larger bubbles.

Session V6 DCOMP: Hybrid Functionals Applied to Solids Ballroom C2

8:00AM V6.00001 The shortcomings and advantages of hybrid functionals in the description of solids[1] , GEORG KRESSE, University of Vienna — For extended systems, density functional theory currently possesses the optimal balance between computational efficiency and accuracy. Hence its wide spread acceptance and application in quantum chemistry, materials science and computational catalysis is in no way astonishing. However, it is also well known that standard density functionals underestimate the band gap in particular for small gap systems, and resultantly structural properties related to the band gap are difficult to predict. In quantum chemistry this has long be realized, and hybrid functionals mixing Hartree-Fock and local density functionals are generally preferred over purely local functionals. Such functionals usually predict a much larger band gap than purely local density functionals. With the exception of the Crystal code, hybrid functionals were not available in popular periodic codes, and only recently successful implementations and applications using plane wave based codes, such as VASP, were reported. In this talk, I will survey the expertise we have acquired for hybrid functionals for extended systems. For simple prototypical materials, such as metals, semiconductors, and insulators many ground state properties are indeed found to be in much better agreement with experiment than using purely local functionals. This concerns lattice constants and bulk moduli, but phonon dispersion relations are also often significantly improved, in particular, for those semiconductors where DFT predicts no band gap. Some specific applications will be discussed in detail. This includes the description of (small) polarons in semiconductors, the properties of ferroelectric materials (specifically $BaTiO_3$ and $SrTiO_3$), phonon dispersion relations in the group IV elements, and magnetic impurities in semiconductors.

[1]Support by the Austrian FWF is acknowledged

8:36AM V6.00002 The effects of long-range exact exchange in hybrid-functional methods , THOMAS HENDERSON, Departments of Chemistry and of Physics and Astronomy, Rice University — Over the past several years, hybrid density functional theory, which mixes a fraction of exact exchange into conventional semilocal exchange-correlation functionals, has become the dominant method used in molecular electronic structure calculations. While hybrid functionals are responsible for many successes of modern Kohn-Sham theory, they suffer from several drawbacks as well. The rapid decay of semilocal exchange causes errors in describing many phenomena, including charge transfer and Rydberg excitations, polarizabilities of long chains, and several others. Further, different properties seem to require different amounts of exact exchange; calculations near equilibrium, for example, appear to require less exact exchange than do calculations far from equilibrium. Including long-range exact exchange in finite systems improves accuracy in quantities sensitive to the long-range potential and makes it possible to treat systems both near and away from equilibrium on a fairly even footing. This talk discusses the motivations for including long-range exact exchange, as well as some remarkable successes and notable failures caused by doing so. Alternatives which attempt to retain most of the successes while eliminating most of the failures are also discussed.

9:12AM V6.00003 Structure of oxygen vacancies and electron localization on $CeO_2(111)$[1] , MARIA VERONICA GANDUGLIA-PIROVANO, Humboldt-Universität zu Berlin, Berlin, Germany and Institute of Catalysis and Petrochemistry-CSIC, Madrid, Spain — In the many applications of ceria-based materials in heterogeneous catalysis, the reducibility of ceria is essential to the catalytic function. Thus, having a theoretical approach that is able to describe the changes in the oxidation state of the multivalent cerium atoms appears desirable. The use of density functional theory with hybrid functionals is shown to be adequate [1]. It has been generally accepted that the electrons left behind upon oxygen removal from CeO_2 surfaces, driving the $Ce^{4+} \rightarrow Ce^{3+}$ reduction, localize on cationic sites in next-neighbor distance to the defect. We apply density-functional theory (DFT) with the HSE06 hybrid functional as well as the DFT+U approach and predict that vacancies on $CeO_2(111)$ are likely to be bound to Ce^{4+} ions rather than to Ce^{3+} as priorly suggested. This prediction has been recently confirmed by means of STM imaging and spectroscopy [3]. We further find that subsurface vacancies are energetically preferred when compared to surface vacancies by up to 0.5 eV, and thus provide support for the most recent experimental result [4]. Defect-induced lattice relaxations are crucial to the electron localization on more distant cation sites to the defect and to the subsurface preference.

9:48AM V6.00004 Orbital-dependent functionals in FLAPW: hybrid functionals and optimized effective potentials[1] , STEFAN BLÜGEL, Institut fuer Festkoerperforschung and Institute for Advanced Simulation, Forschungszentrum Juelich and JARA, 52425 Juelich, Germany — Orbital-dependent functionals are a new class of exchange-correlation (xc) functionals for density-functional theory. Hybrid functionals combine a local or semi-local xc functional with a nonlocal orbital-dependent exchange functional and improve the band gaps of semiconductors and insulators as well as the description of localized states. As an alternative to nonlocal hybrid potentials, one can also construct local optimized effective potentials (OEP) from the exact exchange (EXX) functional. So far, most implementations for periodic systems use a pseudopotential plane-wave approach. We present an efficient all-electron, full-potential implementation of the PBE0 [1] and HSE [2] hybrid functionals as well as the OEP-EXX functional [3] within the FLAPW method (`Fleur` code: www.flapw.de). Results for prototype semiconductors and insulators are in very good agreement with other implementations. We will demonstrate the improvement over conventional local or semilocal functionals for oxide materials and focus in particular on systems where standard functionals yield qualitatively wrong results. In particular, we will discuss the geometric and magnetic structures of EuO and GdN. Additionally, we will address the possibility of using the hybrid-functional ground state as starting point for a GW quasiparticle correction [4] and show results for complex perovskite systems.

10:24AM V6.00005 Hybrid functional studies of InGaN alloys and oxides for photochemical watersplitting[1] , POUL GEORG MOSES, Stanford University — Photochemical watersplitting can potentially be a future sustainable energy source, converting sunlight and water into hydrogen. However, in order to have highly efficient devices materials are needed that absorb a large proportion of the solar spectrum while at the same time having valence and conduction bands that straddle the hydrogen and oxygen evolution redox potentials. It is well known that DFT consistently underestimates the band gap (the so-called "band-gap problem"). As a consequence, the positions of the valence and conduction bands (and hence the band offsets) also suffer from uncertainties. To address these deficiencies of the local density approximation (LDA) and generalized gradient approximation (GGA) we use the HSE exchange correlation functional in order to accurately calculate the electronic band structure [1]. We will discuss bowing effects in InGaN alloys based on accurate calculation of band gaps of InGaN alloys and on an analysis of experimental results using our calculated deformation potentials to disentangle the effect of strain and alloying on the band gap. We will also discuss calculations of the absolute position of the valence band maximum and the conduction band minimum. Including a discussion and comparison with generalized gradient and local density approximations results. Finally we show that HSE may be used to understand the nature of surface defects.

Thursday, March 24, 2011 8:00AM - 11:00AM –
Session V7 GIMS: High Resolution Tunneling Spectroscopy of Dirac Fermions Ballroom C3

8:00AM V7.00001 Strain-Induced Pseudo–Magnetic Fields in Graphene: MegaGauss in Nanobubbles , NIV LEVY[1], Department of Physics, University of California & Materials Science Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA. — Recent theoretical proposals suggest that strain can be used to modify graphene electronic states through the creation of a pseudo–magnetic field. This effect is unique to graphene because of its massless Dirac fermion-like band structure and particular lattice symmetry (C3v). Scanning tunneling microscopy shows that graphene grown on a platinum (111) surface forms nanobubbles, which are highly strained due to thermal expansion mismatch between the film and the substrate. We find that scanning tunneling spectroscopy measurements of these nanobubbles exhibit Landau levels that form in the presence of strain-induced pseudo–magnetic fields greater than 300 Tesla. This demonstration of enormous pseudo–magnetic fields opens the door to both the study of charge carriers in previously inaccessible high magnetic field regimes and deliberate mechanical control over electronic structure in graphene or so-called "strain engineering".

In collaboration with S. A. Burke[§,2], K. L. Meaker[2], M. Panlasigui[2], A. Zettl[2,3], F. Guinea[4], A. H. Castro Neto[5] and M. F. Crommie[2,3]. §. 8:36AM V7.00002 Scanning tunneling microscopy studies of topological insulators grown by molecular beam epitaxy , XI CHEN, Tsinghua University — I will summarize our recent activities of using scanning tunneling microscope (STM) to study topological insulators grown by molecular beam epitaxy (MBE). The Landau quantization in three-dimensional topological insulators was directly observed in the tunneling spectra. In particular, we discovered the zeroth Landau level, which is predicted to give rise to the half-quantized Hall effect for the topological surface states. The existence of the discrete Landau levels and the suppression of Landau levels by surface impurities strongly support the 2D nature of the topological states. In addition, we studied the quantum interference pattern formed by the topological surface states near the step edges and magnetic impurities in Bi_2Se_3 and Bi_2Te_3. The decay behavior of the standing waves is in good agreement with the Dirac cone structure of the topological surface states. We show that the combination of MBE and high energy resolution scanning tunneling spectroscopy provides a powerful way to probing the novel physics in the topological insulators.

9:12AM V7.00003 Spatially Resolved Spectroscopy of Magnetic States in Epitaxial Graphene , DAVID MILLER, Georgia Institute of Technology — Graphene grown epitaxially on silicon carbide provides a potential avenue toward industrial-scale graphene electronics. A predominant aspect of the multilayer graphene produced on the carbon-terminated $(000\bar{1})$ face of SiC is the rotational stacking faults between graphene layers and their associated moire-pattern superlattice. We use scanning tunneling microscopy (STM) and spectroscopy (STS) in high magnetic fields to obtain detailed information about the massless Dirac fermions that carry charge in graphene. In agreement with prior investigations, we find that for small magnetic fields, the rotational stacking effectively decouples the electronic properties of the top graphene layer from those below. However, in maps of the wavefunction density at magnetic fields above 5 Tesla, we discover atomic-scale features that were not previously known or predicted. A phenomenological theory shows that this high-field symmetry-breaking is a consequence of small cyclotron-orbit wavefunctions, which are sensitive to the local layer stacking internal to the moire superlattice cell.

9:48AM V7.00004 Landau-level spectroscopies of a topological insulator , TETSUO HANAGURI, RIKEN — Topological insulators such as Bi_2Se_3 are characterized by massless Dirac surface state which would give rise to unique quantum phenomena in a magnetic field. Although it was experimentally verified by many ARPES experiments that the surface electrons are indeed massless, there has been a lack of studies exploring their quantum properties due to the inevitable contribution from the bulk electrons in a real material. Using surface-sensitive STM/STS technique, we selectively probed the surface massless electrons in Bi_2Se_3. Under magnetic field perpendicular to the cleaved surface, a series of Landau levels (LLs) has been observed in the tunneling spectra. Remarkably, there is a field-independent LL at the Dirac point, which is a hallmark of Dirac fermions. We developed a scaling analysis scheme of LLs based on the Bohr-Sommerfeld quantization condition which allowed us to determine the energy-momentum dispersion of the surface state [1]. Width of the LL peaks in the spectra becomes smaller near the Fermi energy, which may suggest that electron-electron correlation plays a role. In addition to the narrowing of LLs, the spectra near the Fermi energy exhibit complicated fine structures, which may be responsible for the anomalous magneto-fingerprint effect [2]. This work has been done in collaboration with K. Igarashi, M. Kawamura, H. Takagi and T. Sasagawa.

10:24AM V7.00005 Scanning Tunneling Spectroscopy of a Gated Single- and Bilayer Graphene Devices in the Quantum Hall Regime , SUYONG JUNG, CNST, NIST — We have performed scanning tunneling spectroscopy (STS) measurements on a gated single- and bilayer graphene devices. The combination of STM/STS capability and an electrostatic back gate enables us to investigate the interactions of Dirac particles with local impurities at the atomic scale in zero magnetic field and in the quantum Hall regime while varying the Fermi-energy with respect to a Dirac (charge neutrality) point. In an applied magnetic field, well-resolved Landau levels (LLs) following the Dirac particle scaling are observed in both single- and bilayer graphene. Additionally, in single layer graphene, spatial dispersion of LLs caused by disorder potential lead to formation of graphene quantum dots (QDs). The tunneling spectra measured as a function of gate and sample biases are governed by Coulomb blockade physics. In contrast, no QDs are seen in bilayer devices. Instead, the main feature of the spectra is an energy gap formed around the charge neutrality point. The possible origin of energy gap will be discussed in a context of broken layer symmetry caused by gate electric field and disorder potential variation. Other noticeable features in the tunneling spectra of single- and bilayer graphene such as the formation of electron- and hole-puddles and the Fermi-level pinning effect will be discussed.

Thursday, March 24, 2011 8:00AM - 11:00AM –
Session V8 FEd FGSA: Enhancing Graduate Education in Physics: Focus on Skills Ballroom C4

8:00AM V8.00001 Teaching graduate students The Art of Being a Scientist[1] , ROEL SNIEDER — Graduate education in the classroom traditionally focuses on disciplinary topics, with non-disciplinary skills only marginally discussed, if at all, between graduate student and adviser. Given the wide range of advisers with different types and quality of communication skill (or lack thereof), the professional coaching delivered to students often is restricted to just the technical aspects of research. Yet graduate students have a great need to receive professional training aimed at, among other things, helping their graduate career be more efficient, less frustrating and less needlessly time-consuming. We have addressed this gap in graduate education by developing the one-credit course "The Art of Being a Scientist." This course covers a diverse range of topics of importance to being an effective and creative researcher. Topics covered include the following: What is science? Choosing a research topic, department, and adviser. The adviser and thesis committee. Making a work plan. Setting goals. Ethics of research. Using the scientific literature. Perfecting oral and written communication. Publishing papers and writing proposals. Managing time effectively. Planning a scientific career. Applying for jobs in academia or industry. In evaluations of the course, students invariably comment that they could have avoided significant problems in their graduate study and saved valuable time if they would have taken the course earlier on. This is an indication that the course not only useful for students, but also that it is best taken early in a their graduate career. The material covered in the course is captured in the book "The Art of Being a Scientist: A Guide for Graduate Students and Their Mentors," published by Cambridge University Press; more information can be found at: `www.mines.edu/~rsnieder/Art_of_Science.html` From this website one can download a description of the curriculum used in the class, including homework exercises. Currently we are expanding of professional education by offering more lectures and workshops in order to better prepare graduate students for a career in science.

[1]Roel Snieder, Tom Boyd, and Ken Larner, Center for Wave Phenomena and Office of the Graduate School, Colorado School of Mines

8:36AM V8.00002 Got Skills? On-the-Job Activities of Physicists , RACHEL IVIE, American Institute of Physics — It goes almost without saying that physics doctorates do a lot more than just physics research or teaching at their jobs. But what exactly do they do? First, I will share basic data showing where physics doctorates are employed. Then I will present data from two of AIP's surveys about the employment of physicists. The first set of data comes from our survey of physics PhDs one year after doctorate. We will consider how often physics doctorates do a variety of activities on the job, including management, technical writing, teamwork, design and development, programming, and advanced mathematics. The second set of data comes from AIP's new survey of PhDs in physics 10 to 13 years after graduation. Data for many of the same activities will be shown for physics doctorates who have been in the workplace about a decade. Depending on the type of job, most industrially employed physics doctorates do some type of physics at work, but they are also very likely to report managing projects, writing for technical audiences, working on a team, and collaborating with non-physicists, among many other activities. This examination of the types of activities physics doctorates perform in the workplace will provide insight on the non-scientific training that would benefit graduate students the most.

9:12AM V8.00003 Communication and Critical Thinking Skills , ELIZABETH H. SIMMONS, Michigan State University — This talk will discuss how faculty can help graduate students (and even postdocs) improve non-technical professional skills required for success in scientific careers. Examples to be covered will include a) planning and delivering high-quality presentations b) listening critically to others' presentations c) writing grant proposals, cover letters, and CV's d) reviewing manuscripts and responding to referee reports. The faculty member(s) involved must be prepared to project a welcoming attitude, to convey the importance of these skills, and to make a consistent investment of time.

9:48AM V8.00004 Tuning Higher Education , BRADLEY CARROLL, Weber State University — In April 2009, the Lumina Foundation launched its Tuning USA project. Faculty teams in selected disciplines from Indiana, Minnesota, and Utah started pilot Tuning programs at their home institutions. Using Europe's Bologna Process as a guide, Utah physicists worked to reach a consensus about the knowledge and skills that should characterize the 2-year, batchelor's, and master's degree levels. I will share my experience as a member of Utah's physics Tuning team, and describe our progress, frustrations, and evolving understanding of the Tuning project's history, methods, and goals.

10:24AM V8.00005 Shedding light on molecular dynamics: The role of physicists in the age of biomedical science , FU-JEN KAO, Institute of Biophotonics, National Yang-Ming University, Taipei, Taiwan — Fundamental discoveries of the physics of imaging in the areas of microscopy, MRI, and CCD image sensing have produced innovations throughout the 20th century and continuing into the 21st. Not only have these fundamental discoveries received recognition from the Nobel Foundation in 1953, 1986, 1986, 2003, and 2009, but they have also revolutionized basic interdisciplinary research in areas such as biophysics and biomedical physics to the point at which applied physicists, engineers, and medical clinicians are working together to design experiments and develop tools for use in a broad range of areas including clinical diagnosis and pharmaceutical clinical trials. In this presentation, I will describe several innovative approaches in physics combined with engineering that have revolutionized the frontier in the biomedical sciences. Specifically, I will present examples of basic research as well as design, development, and commercialization of photonics research in the biomedical area within the context of biophotonics and molecular imaging. These examples will include the use of optical, photonics, and imaging techniques to (1) understand and elucidate the fundamental physics and chemistry of biological functions; and (2) understand and describe the critical role of these techniques for disease diagnosis, prognosis, prevention, and treatment with novel noninvasive (or minimally invasive) procedures.

Thursday, March 24, 2011 8:00AM - 11:00AM –

Session V9 DFD: Self Assembly I D220

8:00AM V9.00001 Effects of cluster diffusion on the island density and size-distribution in submonolayer island growth , YEVGEN KRYUKOV, JACQUES AMAR, University of Toledo — The effects of cluster diffusion on the submonolayer island density and island-size distribution (ISD) $N_s(\theta)$ (where $N_s(\theta)$ is the number of islands of size s at coverage θ) are studied for the case of irreversible submonolayer growth of compact islands on a 2D substrate. In our model, monomers are deposited with deposition rate F while the mobility D_s of an island of size s satisfies $D_s \sim s^{-\mu}$. Results are presented for $\mu = 1/2$ (corresponding to Brownian motion) as well as for higher values of μ. In general, we find that the exponents describing the flux-dependence of the island and monomer densities vary continuously as a function of μ. For $\mu < 1$ we also find that the ISD exhibits power-law behavior up to a cross-over size S_c. However, the values of the corresponding exponents are significantly larger than previous theoretical predictions. A generalized scaling form for the ISD for $\mu < 1$ is also proposed which leads to excellent scaling of the entire distribution. In contrast, for $\mu \geq 1$ we find that, due to a competition between size-scales, neither our generalized scaling form nor the standard scaling form $N_s(\theta) = \theta/S^2\ f(s/S)$ (where S is the average island-size) lead to scaling of the entire ISD. Instead, the scaled ISD becomes more sharply peaked with increasing D_1/F and coverage. This is in contrast to models with limited cluster mobility for which good scaling occurs over a wide range of coverages and D_1/F.

8:12AM V9.00002 Rate-equation approach to irreversible island growth with cluster diffusion , BRADLEY HUBARTT, YEVGEN KRYUKOV, JACQUES AMAR, University of Toledo — A self-consistent rate-equation (RE) approach to irreversible island growth and nucleation is presented which takes into account the effects of cluster mobility. As a first application we consider the irreversible growth of compact islands on a 2D surface in the presence of monomer deposition (with rate F) and monomer diffusion (with rate D_1) while the mobility of an island of size s is assumed to satisfy $D_s = D_1 s^{-\mu}$ where $\mu \geq 0$. For coverages up to the peak island-density, we find excellent agreement between our RE and simulation results for the dependence of the island-density $N(\theta)$ on coverage θ for all values of μ considered, ranging from $\mu = 1/2$ (Brownian motion) to $\mu = \infty$ (immobile clusters). For $\mu \leq 2$, excellent agreement is also found between our simulation and RE results for the island-size distribution (ISD), while for higher values of μ the effects of correlations become important. We also demonstrate that the discrepancies between recent theoretical predictions for the exponents $\tau(\mu)$ and $\zeta(\mu)$ describing the size-dependence of the ISD for $\mu < 1$ and simulations can be explained by the geometry of compact islands. Our self-consistent RE approach may also be generalized to higher dimensions as well as to an arbitrary dependence of the cluster mobility on island-size.

8:24AM V9.00003 Kinetics and Thermodynamics of the Association of DNA Coated Colloids , KUN-TA WU, FENG LANG, Center for Soft Matter Research, New York University, RUOJIE SHA, Chemistry Department, New York University, REMI DREYFUS, Complex Assemblies of Soft Matter, CNRS-Rhodia-UPenn UMI 3254, NADRIAN SEEMAN, Chemistry Department, New York University, PAUL CHAIKIN, Center for Soft Matter Research, New York University — We have investigated the aggregation kinetics and thermodynamics of complementary DNA coated particles as a function of DNA coverage. The streptavidin on our particles can accommodate 69800 biotinalated DNA which has 50 base pair double strands and 11 base sticky ends. For full 100% coverage, the melting temperature, T_m, is 50.3 C. The transition width, ΔT, is 0.8 C, and the characteristic aggregation time, τ, is 4 minutes. For 2.5% (40 times less) coverage $T_m = 22$ C, $\Delta T = 5$ C, and $\tau = 11$ hours. A simple model which takes into account the number of DNA bonds and the multiplicity of their arrangements accounts for the full time and temperature dependence of the particle aggregation.

8:36AM V9.00004 DNA driven 2D Assembly of Nanoparticles on Lipid Surfaces , SUNITA SRIVASTAVA, DMYTRO NYKYPANCHUK, OLEG GANG, Brookhaven National Laboratory, Upton, NY, 11973 — Use of biomolecular linkers such as DNA due to its sequence-specific hybridization properties provides a versatile platform for assembly of nanoscale components. Here we investigated the DNA-based self-assembly of gold nanoparticles in 2D using lipid layer as fluid substrate. We examined the effect of lipid composition by vary the fraction of cationic and zwitterion lipids on formation of a particle monolayer. Using in-situ X -ray reflectivity we observed adsorption of DNA functionalized nanoparticles on charged lipid surfaces. The surface density of the particle monolayer can be tuned by changing the electrostatic interaction between the particles and the lipid surface. The in-situ measured particle desorption from the lipid surface due to a change of a salt concentration provides quantitative information on particle-surface interactions. The ex-situ studies on samples using XPS under similar conditions support our observations. Our studies explore the possibility to form regulated 2D systems, as well as provide basic understanding of interactions of charge nano-objects with lipids, which is important for the biomedical applications.

8:48AM V9.00005 Computational Analysis of DNA-Mediated Crystallization of Binary Colloidal Superlattices , TALID SINNO, RAYNALDO SCARLETT, MARIE UNG, JOHN CROCKER, University of Pennsylvania — Colloidal self-assembly provides a potential avenue for the design of novel devices with unique optical and structural properties. Colloidal systems also provide useful insights into fundamental mechanisms of phase transitions such as crystal nucleation, growth and melting that are otherwise difficult to probe in atomic systems. A promising approach for realizing highly tunable colloidal assembly is to graft single-stranded DNA oligomer brushes onto the surfaces of particles in order to create attractive interactions between them. Using this approach, micro- and nanoscale particles have now been successfully assembled into several crystalline phases, including ordered, binary superlattice structures. Here, we apply Monte Carlo simulations and free energy calculations to generate a detailed picture for the assembly binary superlattice crystals. The interparticle potential used to perform the calculations was generated specifically for DNA-mediated interactions and verified by measurements. We develop a pseudo-phase diagram for the binary superlattice system which includes both thermodynamic and kinetic influences. The predictions of the pseudo-phase diagram are validated using direct simulations of crystal nucleation. Finally, we discuss recent findings related to diffusionless transformations in growing superlattice crystals that may be important in experiments aimed at growing these structures.

9:00AM V9.00006 DNA Linker Mediated Assembly of Gold Nanoparticles Superlattice[1] , HUIMING XIONG, CFN, BNL & Shanghai Jiao Tong University, MATTEW Y. SFEIR, CFN, BNL, DANIEL VAN DER LELIE, Biology Department, BNL, OLEG GANG, CFN, BNL — A BCC (body-centered-cubic) crystalline phase forms when flexible ssDNA linkers are added to the mixture of two types of dispersed, ssDNAs capped gold nanocolloids which are mutually non-complementary but complementary to the respective ends of the linker DNA. The state diagram of DNA linker mediated nanoparticle assemblies has been experimentally investigated and constructed by using in-situ small angle x-ray scattering. The optically active three-dimensional superlattice containing plasmonic particles and DNA-encoded chromophors were further fabricated using this approach. We investigated structural tunability and corresponding optical response of the multicomponent superlattices.

[1]Support from the U. S. DOE Office of Science and Office of Basic Energy Sciences under contract No. DE-AC-02-98CH10886 and Shanghai Pujiang Program (10PJ1405400) is appreciated.

9:12AM V9.00007 Directed Self-Assembly of Colloidal Particles , ZORANA ZERAVCIC, School of Engineering and Applied Sciences, Harvard University, JESSE COLLINS, Department of Physics, Harvard University, VINOTHAN MANOHARAN, School of Engineering and Applied Sciences, Harvard University and Department of Physics, Harvard University, MICHAEL BRENNER, School of Engineering and Applied Sciences, Harvard University — In nature, simple constituents like atoms, molecules and polymer chains, spontaneously organize into larger, higher order structures. Interactions involved in this self-assembly act on a local level. These facts inspire experimental and theoretical engineering of components able to organize into pre-designed complex systems. We perform numerical simulations of collections of DNA coated colloidal particles. We test different design rules for self-assembly with short-range interactions and explore the stability of equilibrium structures.

9:24AM V9.00008 Replication of nanoscale DNA patterns[1] , CORINNA MAASS, TONG WANG, RUOJIE SHA, MIRJAM LEUNISSEN, REMI DREYFUS, NADRIAN SEEMAN, PAUL CHAIKIN — We present an artificial supramolecular system mimicking self- replication and information transmission strategies in nature, but without the aid of enzymes or equivalent biological mechanisms. Using DNA nanotechnology techniques, we can make DNA tiles with selective interactions based on complementary single-strand connections. A linear tile pattern distinguished by their connector sequences is transmitted to a subsequent generation of copies by connector hybridisation. Longitudinal pattern formation and transverse copy attachment are well separated by different melting temperatures. We have achieved a faithful transmission of the pattern information to the second replication generation. We use AFM imaging to test for pattern fidelity and gel electrophoresis for quantitative yield analysis.

9:36AM V9.00009 Designing colloids for alignment , REMI DREYFUS, CNRS, Compass Lab, TYCHO SLEATOR, NYU, KENNY MAYORAL, THOMAS G. MASON, UCLA, PAUL M. CHAIKIN, NYU — Inducing the spontaneous association of microscopic building blocks into macroscopic structures has been a promising way to create new materials for a variety of useful applications. Such fabrication processes typically require interactions between microscopic building blocks. The interactions that govern the assembly of these microscopic building clocks: electrostatic, magnetic, Van der Waals, depletion, and DNA interactions, are all currently being investigated. For all these cases, the attractive energy between the particles is proportional to the overlapping surface between the colloids. Controlling the positions and orientations of the microscopic building blocks is a critical issue in such processes. To date there has been no efficient or reliable process that enables such spontaneous assembly of building blocks. For the successful alignment of any particles that we desire to self-assemble, a shape with unique physical and mathematical properties must be identified. Under the assumption that energy is reduced in proportion to area overlap, we present a geometrical shape which, when encountering a similar shape from any initial configuration, is forced into a single relative orientation maximizing the overlap. The unique minimum of energy in the energy landscape drives the particles to self-assemble in a controlled orientation.

9:48AM V9.00010 Self-assembly of Nanoparticles into Planar Modulated Superstructures , MICHAEL ENGEL, University of Michigan — The advance in the synthesis of nanoparticles and colloids opens up the possibility to use them as building blocks for self-assembling novel materials. Ordered structures are especially interesting because they have unique photonic and electronic properties. Among the most complex ordered phases are commensurately and incommensurately modulated crystals. Although frequently found on the atomic scale in the bulk and as ordered structures of noble gases in adsorbed layers, modulated phases have so far not been known to self-assemble with nanoparticles. Here, we use computer simulations to study a two-dimensional system characterized by a simple isotropic interaction that could be realized in future with building blocks on the nanoscale. We find that the particles arrange themselves into planar hexagonal superstructures whose superlattice vector can be tuned reversibly by changing the temperature. Thermodynamic stability is confirmed by calculating the free energy with a combination of thermodynamic integration and the Frenkel-Ladd method. Different contributions to the free energy difference are discussed.

10:00AM V9.00011 Programmable, directed assembly of micron-scale components , CASPAR FLORYAN, ROBERT WESTERVELT[1], Harvard University — Self assembly is a nascent paradigm for assembling components in the micron to millimeter size range. Such assemblies are often performed by modifying the surface chemistries of the individual components or by creating flow fields directing them into position. We propose a method of directed assembly using dielectric contrast between the components and a surrounding fluid. A hybrid integrated-circuit / microfluidic device[2] will be used to trap and manipulate pieces into pre-defined patterns. The device contains an array of electrically-chargeable pixels on its surface, with a resolution of 10 μm.

10:12AM V9.00012 Synthesis and Evaporative Self-Assembly of Polystyrene Nanotubes under Confinement , LU ZHANG, JODIE LUTKENHAUS, Texas A&M University, TEXAS A&M UNIVERSITY TEAM — Synthesis and manipulation of anisotropic building blocks into ordered structures has attracted increasing attention in recent years as nanowires and nanotubes (NWs/NTs) show great potential in many emerging technologies such as novel electric devices, optical units and biosensors. Here we use evaporation to align polystryrene NWs/NTs into distinct and interesting patterns. We synthesized polystyrene (PS) NWs/NTs of varied aspect ratio using anodic aluminum oxide (AAO) templates (200 nm pore size) using a melt-wetting technique. The template was removed, and NWs/NTs of controllable length ranging from several hundred nanometers to a few micrometers were released from the bulk PS film under ultrasonication. We further investigate the evaporative self-assembly of the synthesized polystyrene NTs under confined and "open" geometries and observe the alignment and assembled structures of the polystyrene NTs using scanning electron microscopy. Confocal laser scanning microscopy was also used to monitor the kinetics of the alignment process during evaporation. Results indicate that many factors (solvent, aspect ratio) contribute to the degree of NW/NT alignment relative to the evaporation front.

10:24AM V9.00013 Dynamic self-assembly of chemically-propelled nanoscale building blocks , YANPING CHEN, YUNFENG SHI, Rensselaer Polytechnic Institute — Self-assembly technique offers spontaneous, massively-parallel structure formation from bottom-up. So far, most research efforts have been focused on static self-assembly that is thermally driven towards a thermodynamic equilibrium. Less attention has been paid to dynamic self-assembly that evolves to a non-equilibrium steady state under a dissipative driving force. This project aims to investigate the non-equilibrium self-assembly behaviors of chemically-propelled nanoscale building blocks via molecular dynamics simulations. We utilize a catalytic building block, that has been shown, when isolated, to exhibit self-motile behavior when immersed in a fuel environment. Upon increasing the number density of the building blocks, interesting collective behaviors emerge due to direct interactions between the building blocks or indirect interactions via the fuel environment. The simulation system is also subjected to an artificial operation of converting products back to fuel molecules. The heat generated by the exothermic chemical reaction will also be removed. In this way, a steady-state, as well as the resulting dynamic self-assembly pattern, can be obtained.

10:36AM V9.00014 Dynamic Self-Assembly and Self-Propulsion in Nonequilibrium Magnetic Colloidal Ensembles at a Liquid/Liquid Interface[1] , ALEXEY SNEZHKO, IGOR ARANSON, Argonne National Lab — Ensembles of interacting particles subject to external periodic energy fluxes often develop nontrivial dynamics. Magnetic colloidal particles suspended over an interface of two immiscible liquids and energized by vertical alternating magnetic fields give rise to novel dynamic self-assembled structures ("asters") which are not accessible at the liquid/air interfaces. Ferromagnetically ordered nickel spherical particles have been used in our experiments. Novel structures are attributed to the interplay between surface waves, generated at the liquid/liquid interface by the collective response of magnetic microparticles to the alternating magnetic field, and hydrodynamic fields induced in the boundary layers of *both* liquids forming the interface. Two types of magnetic order is reported. We show that self-assembled aster structures become distorted in the presence of a small in-plane dc magnetic field and develop self-propulsion. The speed of locomotion can be effectively tuned by the amplitude of the dc field.

10:48AM V9.00015 A Tunable Terahertz Detector Based On Self Assembled Plasmonic Structure on a GaAs 2DEG , CHE JIN BAE, DEEPU GEORGE, ROHIT SINGH, ANDREA MARKELZ, SUNY at Buffalo — Recently compact frequency sensitive THz detection has been achieved using gated gratings on 2DEG structure. The method is based on the resonant absorption of the 2D plasmon dependence on system dimension and the tunability of that dimension by depletion gating. Here we attempt to improve detector sensitivity, tunability and remove polarization dependence through the development of a gated grid design. The requirement for imaging applications of device dimensions on the order of < 1 micron over a detector area of 4 mm2, suggest that standard lithographic approaches will be too costly for large scale detector production. Here we realize the gated grid plasmonic structure on 2DEG material by using nanosphere self assembly lithography. This fabrication method has not been widely developed for III-V processing but allows us to achieve large area sensitive detectors with tunability in the 1-4 THz range. In this paper we will discuss the fabrication method and characterization of the devices as a function of gate bias and temperature using FTIR and THz time domain measurements.

Session V10 DMP: Focus Session: Growth, Structure, Dynamics, and Function of Nanostructured Surfaces and Interfaces – Semiconductors D221

8:00AM V10.00001 In situ x-ray scattering investigation of Ag/Si(111)7x7 , YIYAO CHEN, M.W. GRAMLICH, S.T. HAYDEN, University of Missouri, Columbia, MO, M.C. TRINGIDIES, Ames Lab-USDOE, Iowa State University, Ames, Iowa, P.F. MICELI, University of Missouri, Columbia, MO — We have used in situ synchrotron x-ray scattering to investigate the growth of quantum-size-effect (QSE) Ag nanocrystals on Si(111)-7x7. The experiments explore the buried interface and the wetting layer as well as the interlayer spacings and the height distribution of the islands at different coverage and temperatures. The areal density of the wetting layer is found to be 30% of Ag(111) and it is located above the adatom layer at a sharp interface. As the coverage is varied, all Ag layer heights are observed in the height distribution except for 2 atomic layers (measured from the Si surface), which were negligible. The structure of the islands and wetting layer will be discussed in relation to recent work that questions whether Ag/Si(111) is a QSE system. Research funding is supported by NSF DMR-0706278. The experiments were performed at the Advanced Photon Source Sector 6 beam-line at Argonne National Laboratory, which is supported by the US-DOE through Ames Lab under Contract No. W-7405-Eng-82.

8:12AM V10.00002 Grazing incidence surface scattering in the Pb/Si(111) system using an Area Detector , M.W. GRAMLICH, S.T. HAYDEN, YIYAO CHEN, P.F. MICELI, U. of Missouri — Geometrical effects are considered when using an area detector for in situ x-ray grazing incidence scattering studies of the Pb/Si(111) system. Rod-like scattering and 3D-crystallite diffraction can both occur during in situ studies and these require different geometrical considerations. The Pb/Si(111) system conveniently exhibits different surface phases that provide useful examples, including randomly oriented 3D-crystallites on the surface that form powder diffraction rings. The shape of a diffraction ring depends on the position of the detector in real space. For rod scattering, the length of the image on the detector depends on resolution as well as domain size. We will discuss methods for obtaining reciprocal space information from area detector images in surface diffraction. Research funding is supported by NSF DMR-0706278. The experiments were performed at the Advanced Photon Source Sector 6 beam-line at Argonne National Laboratory, which is supported by the US-DOE through Ames Lab under Contract No. W-7405-Eng-82.

8:24AM V10.00003 Increased structural ordering of the low temperature wetting layer in the Pb/Si(111)-7x7 system , P.F. MICELI, M.W. GRAMLICH, S.T. HAYDEN, YIYAO CHEN, U. of Missouri-Columbia, C. KIM, Kyung Hee U., Korea, E.H. CONRAD, Georgia Inst. Tech., M.C. TRINGIDES, Iowa State U. — The Pb/Si(111)-7x7 system exhibits interesting quantum size effects (QSE) for Pb nano-islands, including anomalously fast island coarsening that is facilitated by the wetting layer between the islands. While it is known that the wetting layer has a disordered 8x8 structure, the exact structure of the layer is still an open question. Our in situ x-ray scattering studies show that the wetting layer structure evolves temporally over a remarkably broad range of temperatures due to *two* physically independent mechanisms. The as grown low temperature wetting layer is found to slowly anneal into a *better-ordered 8x8 structure*, which suggests that it is highly dynamic as it attempts to accommodate the large corrugation of the Si(111)7x7 substrate. This increased order has important implications for the fast atom transport between the QSE-islands. Research funding is supported by NSF DMR-0706278 and the Ministry of Knowledge Economy of Korea 2009-F014-01 (CK). The experiments were performed at the Advanced Photon Source Sector 6 beam-line at Argonne National Laboratory, which is supported by the US-DOE through Ames Lab under Contract No. W-7405-Eng-82.

8:36AM V10.00004 Quantum Growth of a Metal/Insulator System , HAWOONG HONG, Argonne Natinoal Laboratory, AARON GRAY, University of Illinois at Urbana-Champaign, RUQING XU, Argonne National Laboratory, LONGXIANG ZHANG, TAI-C. CHIANG, University of Illinois at Urbana-Champaign — Quantum confinement of electrons in thin metal films can lead to novel effects on the growth, structure, stability, and various other physical and chemical properties, as demonstrated by recent work on metal films grown on semiconductor substrates. We report herein the observation of quantum growth behavior in a metal-on-insulator system; the results show substantial differences. Insulating substrates, with their large band gaps, offer minimal electronic coupling at the interface. This decoupling should maximize quantum confinement effects. Indeed, in a study of Pb film growth and thermal processing on sapphire, we have observed robust preferred island height selection over a wide thickness range – a hallmark of quantum confinement effects – for processing temperatures up to 250 degrees C. By contrast, room temperature is the limit for Pb films prepared on the semiconducting substrate Si(111). These results provide the first evidence connecting the quantum growth behavior of overlayers with the substrate band gap.

8:48AM V10.00005 Electron coherence in Pb/Ag heterostructures epitaxially grown on Si(111)[1] , JISUN KIM, Department of Physics, The University of Texas, Austin, TX 78712, CHENDONG ZHANG, Department of Physics, The University of Texas, Austin; Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, CAS, HONGJUN GAO, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, CAS, CHIH-KANG SHIH, Department of Physics, The University of Texas, Austin, TX 78712 — Along with other metals, Pb and Ag can form globally flat ultra- thin films on the Si(111) surface. Due to electron confinement along the growth direction, such films exhibit distinctive quantum well states (QWS's). Confinement occurs between the vacuum-solid and solid-solid interfaces. It was reported earlier, using angle-resolved photoemission, that quantum confined states existing in Ag thin films can coherently propagate through a Pb overlayer with thickness much thicker than the typical electron mean free path. Here we use scanning tunneling microscopy and spectroscopy to investigate the quantum well states formed in double quantum wells (Pb quantum well and Ag quantum well) formed in Pb/Ag/Si(111) double- heterostructures. Both the growth mechanism and the coherent coupling between the Pb and Ag quantum wells will be reported.

9:00AM V10.00006 Surface plasmon excitation in ultrathin Mg films on Si(111) , AO TENG, The University of Tennessee, Knoxville, TN, GEUNSEOP LEE, Inha University, Incheon, Korea, SABAN HUS, The University of Tennessee, Knoxville, TN, HANNO WEITERING, The University of Tennessee, Knoxville, TN & Oak Ridge National Laboratory, Oak Ridge,TN — We investigated the dispersion of the surface plasmon in ultrathin Mg(0001) films, grown on a Si(111)-7×7 surface, as a function of film thickness and parallel momentum ($q_{||}$), using angle-resolved high-resolution electron-energy-loss spectroscopy (HREELS). In Mg films thicker than ~ 3 ML, surface plasmon excitations exhibit negative dispersions for small $q_{||}$(long wavelength limit). In contrast, the surface plasmons of ultrathin Al(111) films are known to exhibit positive dispersions near $q_{||} \sim 0$. The surface plasmon energies of the Mg films increase as the film thickness decreases. The plasmon line widths reveal similar trends, namely, for a given film thickness the line width decreases initially with increasing $q_{||}$ while it increases with film thickness. Possible explanations for the observed thickness dependence of the surface plasmon dispersion and damping will be discussed.

9:12AM V10.00007 Plasmon response of a quantum-confined electron gas probed by core-level photoemission[1] , MUSTAFA M. OZER, Oak Ridge National Laboratory, EUN JU MOON, ADOLFO G. EGUILUZ, HANNO H. WEITERING, University of Tennessee — The emergence of the "bulk" plasmon in *atomically-smooth* ultrathin Mg(0001) films on Si(111) has been determined using x-ray photoelectron spectroscopy (XPS). Plasmons in this quasi two-dimensional (2D) regime turn out to be excited primarily via the sudden creation of the core hole, as the extrinsic loss channel (which is dominant in bulk XPS spectra) is suppressed by electron confinement. The collective plasmon response of the films is remarkably similar to that of a thin slice of *bulk matter*, subject to quantum-size boundary conditions, in spite of the fact that the one-electron degrees of freedom are quantized. The energy-loss spectra of the thinnest films are characterized by a gradual transfer of spectral-weight from the bulk-like collective modes to the low-energy one-electron excitations, and the plasmon ultimately collapses below six monolayers. Our results represent striking manifestations of the role of electronic confinement on plasmon resonances in precisely-controlled nanostructures.

9:24AM V10.00008 Controlled Surface functionalization via self-selective metal adsorption and pattern transformation on vicinal Si(111) surface[1] , F.K. MEN, A.L. CHIN, Department of Physics, National Chung Cheng University, Chia-Yi 621, Taiwan, ROC, FENG LIU, Department of MSE, University of Utah, Salt Lake City, UT 84112, USA — We demonstrate a self-selective metal adsorption and pattern transformation process on vicinal Si(111) surfaces. When Au atoms are deposited onto the self-organized periodic Si(111) surface patterns, the Au atoms self-select to adsorb predominantly onto one of the two distinct domains, the Si(111) terrace or the step-bunched facet, at different Au coverage. This leads to a systematic transformation of the surface pattern, whose domain population changes while its periodicity remains intact with the increasing Au coverage. A stress-domain model is used to explain the observed phenomenon. Our findings suggest a unique method for controlled functionalization of surfaces at the nanoscale, as illustrated further by domain- selective self-assembly of uniform $CoSi_2$ nanoclusters on the Au-functionalized vicinal Si(111) surface.

[1]Work supported by NSC of Taiwan, ROC (Men) and NSF and DOE-BES of US (Liu).

9:36AM V10.00009 Epitaxial silicene formed on single-crystalline ZrB_2 thin films: structure and electronic properties[1] , ANTOINE FLEURENCE, RAINER FRIEDLEIN, YING WANG, YUKIKO YAMADA-TAKAMURA, School of Materials Science and Research Center for Integrated Science, Japan Advanced Institute of Science and Technology (JAIST) — The experimental realization of extended, two-dimensional sheets of silicene, the silicon counterpart of graphene, has been elusive so far. Here, we demonstrate that such a two-dimensional, epitaxial honeycomb Si layer forms through surface segregation on a metallic zirconium diboride (ZrB_2) film grown itself epitaxially on Si(111). The honeycomb Si layer uniformly covers the ZrB_2(0001) surface forming a (2×2) reconstruction. Surface-sensitive core-level photoelectron spectroscopy performed using a photon energy of 130 eV identifies Si atoms in different chemical states that are either in contact with Zr atoms or not, confirming details of the slightly-buckled honeycomb structure obtained through scanning tunneling microscopy. Angle-resolved ultraviolet photoelectron spectra reflect surface electronic states related to the predicted band structure of slightly-buckled, free standing silicene together with those of the uppermost Zr layer.

9:48AM V10.00010 Endotaxial Si nanolines in Si(001):H[1] , JAMES OWEN, FRANÇOIS BIANCO, SIGRUN A. KÖSTER, DANIEL MAZUR, CHRISTOPH RENNER, University of Geneva, DAVID BOWLER, University College London and London Centre for Nanotechnology — The study of one dimensional wires is of great interest in the area of low-dimensional physics, and these structures also have potential applications in future nanodevices. A perfectly straight nanoline embedded in a H-terminated silicon surface has been fabricated by a process of hydrogenation of a Bi nanoline surface using an atomic H beam source, and comprises a triangular core of Si embedded in the top five layers of the Si substrate. The defect density of this nanoline is extremely low, and being H- terminated, it is stable in air for limited periods of time. Scanning Tunnelling Microscopy experimental data and Density Functional Theory calculations have been used to determine the atomic structure of this nanoline, so-called the Haiku Stripe, and have revealed that there exists a 1D state localised to the nanoline core, lying just above the conduction band minimum.

[1]This work is supported by the Swiss National Science Fundation.

10:00AM V10.00011 Atomic Layer Epitaxy of Si and Ge on Si(100)-(2x1) , JEAN-FRANCOIS VEYAN, HEESUNG CHOI, M.S.E Department, University of Texas at Dallas, Richardson, Texas 75080, USA, JOSHUA BALLARD, Zyvex Labs, Richardson, Texas 75081, USA, STEPHEN MCDONNELL, WILEY P. KIRK, ROBERT M. WALLACE, M.S.E Department, University of Texas at Dallas, Richardson, Texas 75080, USA, JOHN RANDALL, Zyvex Labs, Richardson, Texas 75081, USA, KYEONGJAE CHO, YVES J. CHABAL, M.S.E Department, University of Texas at Dallas, Richardson, Texas 75080, USA — Atomic Layer Epitaxy of Si and Ge on Si(100) surface using disilane (Si_2H_6) and digermane (Ge_2H_6) as precursors is a critical step for constructing 3-D nano-structures, and is indispensable for Atomically Precise Manufacturing of new devices such as quantum dots. Using IRAS and STM together with DFT calculations, we show that Si_2H_6 chemisorbs on clean Si(100)-(2x1) via beta-hydride elimination pathway, involving the intermediate states Si-H and Si-SiH_2-SiH_3. Thermal decomposition of the chemisorbed Si_2H_5 leads to the formation of Si_2H_2 as an added dimer rotated 90 degrees with respect to the initial dimer row. A similar chemisorption pathway is observed for Ge_2H_6 on Si(100)x(2x1). The thermal decomposition of Ge_2H_5 involves the migration of H from Ge to Si, and Ge ad-dimer formation. Evidence for Ge epitaxial growth on Si(100)x(2x1) using Ge_2H_6 will be presented.

10:12AM V10.00012 Kinetics-Limited Composition Profile of Semiconductor Alloy Quantum Dots[1] , XIAOBIN NIU, GERALD STRINGFELLOW, FENG LIU, Department of Materials Science and Engineering, University of Utah — Semiconductor alloy quantum dots (QDs) with controlled composition profile are promising nanoscale building blocks for modern nanophotonic and nanoelectronic devices. The overall composition profile of such low-dimensional nanostructures is usually far from equilibrium, because bulk diffusion is negligible at typical growth conditions. However, local equilibrium may be established in the surface regions via surface diffusion. Consequently, the kinetic growth mode, which dictates the way of surface mass transport and alloy mixing in the growth fronts, becomes a key factor in determining the kinetics-limited composition profile. In this talk, we report our recent discovery of a striking correlation between the composition profiles of the strained semiconductor alloy QDs and their growth modes, based on atomistic-strain-model Monte Carlo simulations of InGaN (GeSi) QDs. The layer-by-layer growth forms core-shell structures with the core-rich unstrained component; while the faceted growth forms the core-rich strained component. Our findings suggest a promising method for the control of composition profile of semiconductor alloy QDs by selecting the growth mode.

10:24AM V10.00013 Coarsening and Saturation of Quantum Dot Evolution during Strained Film Heteroepitaxy , CHAMPIKA GIGIRIWALA GAMAGE, ZHI-FENG HUANG, Department of Physics and Astronomy, Wayne State University, Detroit, MI — Morphological properties of an epitaxially grown film and the self-organization process of coherent strained islands are analyzed via the development of a continuum elasticity model based on the 2nd order perturbation method. Effects of wetting stress due to film-substrate interactions have been incorporated in the resulting nonlinear dynamic equation governing the film morphological profile. We study the formation and evolution of surface strained islands or quantum dots for different film/substrate misfit strains, via analyzing the time-dependent behavior of the structure factor for surface heights, its various moments, and the surface roughness. Three regimes of island array evolution have been identified, including a film instability regime at early stage, a slow power-law-type coarsening at intermediate time, and the crossover to a saturated state, with detailed behavior dependent on misfit strains but not qualitatively on finite system sizes. The results are compared to previous experimental and theoretical efforts on quantum dots coarsening and saturation.

10:36AM V10.00014 Directed Self Assembly and Self-Limiting Growth (SLG) of Mound Formation on Patterned GaAs(001) Surface During MBE Homoepitaxy[1] , CHUAN-FU LIN, University of Maryland, HUNG-CHIH KAN, National Chung-Cheng University, Taiwan, SUBRAMANIAM KANAKARAJU, CHRIS RICHARDSON, Laboratory for Physical Sciences, RAY PHANEUF, University of Maryland — We present the results of molecular beam epitaxial growth experiments on nanopit-patterned GaAs(001) surfaces at temperatures near 500°C. We find that in the initial stage of growth, the pattern directs the spontaneous formation of multilayer islands at 2-fold bridge sites between neighboring nanopits along [110], seemingly due to the presence of an Ehrlich-Schwoebel barrier [1]. However, as growth continues, the height of mounds at 2-fold bridge "self-limits": the mounds cease to grow. Beyond this point an initially less favored 4-fold bridge site for mounds dominates and a different pattern of self assembled mounds begins. We propose that a minimum, "critical terrace size" at the top of each mound is responsible for the observed self-limiting growth.

10:48AM V10.00015 Spontaneous Microfaceting and Pyramid Formation during Si(100) Etching , MELISSA HINES, MARC FAGGIN, ANKUSH GUPTA, Cornell University — The spontaneous, etching-induced transformation of an initially flat Si(100) surface to a completely nanofaceted morphology consisting of overlapping pyramidal hillocks has been observed using a combination of morphological and spectroscopic probes and modeled using a kinetic Monte Carlo (KMC) simulation of Si(100) etching. The morphological transformation is driven by highly anisotropic chemical reactions that generate self-propagating pyramidal features with near-perfect microfacets. The atomic-scale mechanism of this etching-induced transformation will be discussed. In contrast to the more commonly studied Si(111) surface, the reactivity of the (100) face is dominated by interadsorbate strain.

Thursday, March 24, 2011 8:00AM - 11:00AM –
Session V11 FIAP: Electronic Structure: Theory and Spectra II D222

8:00AM V11.00001 First principles study of strained Si/Ge core-shell nanowires along [110] direction , XIHONG PENG, PAUL LOGAN, Arizona State University — First principles density-functional calculations were performed to study the electronic properties of Si/Ge core-shell nanowires along the [110] direction with the diameter of the wires up to 5 nm. It was found the band gap of the core-shell wires is smaller than that of both pure Si and Ge wires, given the same diameter. This reduced band gap is ascribed to the intrinsic strain between Ge and Si layers, which partially counters the quantum confinement effect. External uniaxial strain is further applied to the Si/Ge core-shell nanowires for tuning the band structure. At the Γ point, the energy levels of both conduction and valence bands are significantly altered by applied strain, which results in an evident change of the band gap. In contrast, for the K vectors far away from Γ, the variation of the conduction/valence band with strain is much reduced. In addition, with a sufficient tensile strain ($\sim$1%), the valence band edge shifts away from Γ, which indicates that the band gap of the Si/Ge core-shell nanowires experiences a transition from direct to indirect.

8:12AM V11.00002 Electronic structure of partially hydrogenated graphene superlattices , JOO-HYOUNG LEE, JEFFREY GROSSMAN, Massachusetts Institute of Technology — First-principles calculations based on density functional theory are performed to investigate the electronic structure of graphene-graphane superlattices (GSLs) by varying the widths of both the graphene and graphane regions. For the armchair-type interface between the graphene and graphane strips (AGSLs), the superlattices become semiconducting with a band gap exhibiting a similar dependence on the width of the graphene region as in armchair graphene nanoribbons. In contrast with the nanoribbons, however, the band gap of AGSLs shows both direct and indirect characteristics, depending on the graphane width. On the other hand, GSLs with a zigzag interface (ZGSLs) possess magnetic ground states except for those with a very narrow graphene strip. While an anti-ferromagnetic (AFM) phase is found to be energetically more stable than the ferromagnetic (FM) one, the energy difference between the two phases is so small (< 10 meV) that these two phases become nearly degenerate. These findings point toward an alternative route for graphene-based applications without requiring physical cutting as in graphene nanoribbons.

8:24AM V11.00003 First-Principle Calculations of The Conductivity of Br-Doped Graphite[1] , RASHID HAMDAN, CHAO CAO, ALEXANDER KEMPER, HAI-PING CHENG — First-principles calculations are used to study the enhanced in- plane conductivity that was observed experimentally in Br-doped graphite systems.[2] The band structure near the Fermi surface of the doped systems with different bromine concentrations compared to that of pure graphite, and the charge transfer between carbon and bromine atoms are analyzed to understand the conductivity change in the different directions. In addition, we address the effect of the compression of graphite layers on the stability of the bromine molecule Br_2 between these layers and thus on the conductivity of the system. Our calculations show that for large separation between doped graphite layers bromine is more stable in the molecular form (Br_2) and has a negligible effect on in- plane conductivity. However, with increased compression (decreased layer-layer separations) Br_2 molecule tend to dissociate and exchange charge with the nearby graphite layers causing an increase in hole conductivity.

8:36AM V11.00004 Study of Bulk Modulus in Zincblende Nitrogen-doped Gallium Phosphide Alloys Using Density Functional Theory , BRANDON M. BUTLER, University of Texas at Arlington, JOHN A. TURNER, National Renewable Energy Laboratory, MUHAMMAD N. HUDA, University of Texas at Arlington — The prospect of solar energy as a renewable resource is ever-increasing. Density functional theory (DFT) calculations can elicit reliable behavior predictions in energy conversion materials to achieve higher efficiencies. Chemical stability of the photo-catalysts in aqueous solution is of particular interest for its long term performances. The bulk modulus is a mechanical property that is a good indicator of material stability. GaP has a low band gap and is a good candidate for use as a photocatalyst for hydrogen evolution by splitting water. Unfortunately, it is not stable and highly susceptible to corrosion over a very short time period, making it unfeasible for long-term use. GaN has too high of a band gap but a good stability factor. While these materials both possess desirable qualities, they cannot be used solitarily. We will report electronic properties and bulk moduli from the total energy calculations of the zincblende and wurtzite species using DFT-GGA and DFT+U as a function of doping concentration x. We will also present the density of states and charge density distribution of the alloy materials to study the localization/delocalization effects of N defects levels and their impact on the alloys' stability.

8:48AM V11.00005 Topological Insulators in Ternary Compounds with a Honeycomb Lattice[1] , HAI-JUN ZHANG, Stanford University, STANISLAV CHADOV, LUKAS MUCHLER, Institut fur Anorganische Chemie und Analytische Chemie, Johannes Gutenberg - Universtitat, Germany, BINGHAI YAN, XIAO-LIANG QI, Stanford University, JÜRGEN KÜBLER, Institut für Festkörperphysik, Technische Universit"at Darmstadt, Germany, SHOU-CHENG ZHANG, Stanford University, CLAUDIA FELSER, Institut fur Anorganische Chemie und Analytische Chemie, Johannes Gutenberg - Universtitat, Germany — One of the most exciting subjects in solid state physics is a single layer of graphite which exhibits a variety of unconventional novel properties. The key feature of its electronic structure are linear dispersive bands which cross in a single point at the Fermi energy. This is so-called Dirac cone. The ternary compounds, such as LiAuSe and KHgSb with a honeycomb structure of their Au-Se and Hg-Sb layers feature band inversion very similar to HgTe which is a strong precondition for existence of the topological surface states. These materials exhibit the surface states formed by only a single Dirac cone at the G point together with the small direct band gap opened by a strong spin-orbit coupling (SOC) in the bulk. These materials are centro-symmetric, therefore, it is possible to determine the parity of their wave functions, and hence, their topological character.

9:00AM V11.00006 The electronic structures of Cu delafossites nanocrystals for PEC hydrogen production: A density functional theory study[1] , MUHAMMAD N. HUDA, Physics Department, University of Texas at Arlington, YANFA YAN, MOWAFAK M. AL-JASSIM, National Renewable Energy Laboragory — Efficient photo-electrochemical (PEC) splitting of water to hydrogen by sun light usually requires that the semiconductor which will be used as a photoelectrodes will satisfy several electronic criteria. As naturally available semiconductors do not meet all these criteria, a thorough understanding of "band-engineering" for mixed alloys both at bulk and nano phases is necessary to successfully design these photoelectrodes. Recently Cu delafossites, CuMO_2, have received much attentions as photo-catalysts for hydrogen production due to their unique properties such as stability in most aqueous solutions and excellent hole mobility. However, due to their large optical band gap they can absorb sun light only in the ultra-violet region. Hence, it is necessary to tailor their electronic properties to enhance their catalytic activities in the visible light regions. In this presentation density functional study of the Cu-delafossite nanocrystals will be presented. The stability of the nanocrystals will be discussed along with the reactivity of the different crystal faces. It will be shown that O-terminated$M$-O octahedrons play a major role in the stability of these nanocrystals, which also makes these surfaces less reactive. We will discuss the charge (electron-hole) separation problems in these nanocrystals.

9:12AM V11.00007 Lateral Quantum Well States on Pb Films Grown on Cu Step Surface , PINGHENG ZHOU, Louisiana State University, Baton Rouge LA 70806, USA, YANG LIU, TOM MILLER, TAI-CHANG CHIANG, Department of Physics, University of Illinois at Urbana-Champaign,1110 West Green Street, Urbana, Illinois 61801-3080, USA, PAOLO MORAS, CARLO CARBONE, Istituto di Struttura Materia, Consiglio Nazionale delle Ricerche, Trieste, Italy, LOUISIANA STATE UNIVERSITY, BATON ROUGE LA 70806, USA TEAM, DEPARTMENT OF PHYSICS, UNIVERSITY OF ILLINOIS AT URBANA-CHAMPAIGN, ILLINOIS 61801-3080, USA TEAM, ISTITUTO DI STRUTTURA MATERIA, CONSIGLIO NAZIONALE DELLE RICERCHE, TRIESTE, ITALY TEAM — The highly ordered Pb films were found to grow on Cu step surface as a "magic" heteroepitaxial grown model. The lateral quantum well states in these Pb have been investigated by angle-resolved photoemission. Across the step direction, the quantum well state display a dispersive character, with periodicity in reciprocal space defined by the step superlattice geometry. These observations are compared and analyzed with *ab initio* calculations based on the full-potential linearized augmented plane wave method.

9:24AM V11.00008 Influence of local environment on the characterization of the p-type TCO in silver vanadates[1] , JINO IM, GIANCARLO TRIMARCHI, HAOWEI PENG, KENNETH POEPPELMEIER, ARTHUR FREEMAN, Northwestern University, Evanston, IL 60208, USA — Cu and Ag oxides are often considered as possible candidates for p-type transparent conducting oxides (TCO's) because the d^{10} valence structure usually gives rise to dispersive d-bands at the valence band maximum. Among them, multi-cation oxides of silver and vanadium show various atomic structures such as the $\alpha-$ and the $\beta-$phase of Ag_3VO_4 and $KAg_{11}(VO_4)_4$. Hence, these compounds, especially $KAg_{11}(VO_4)_4$, offer several local environments at Ag sites and it is interesting to assess how they influence the electronic structure. Based on first-principles density functional theory, we point out a relation between the local environment and d-s orbital mixing at the Ag site. In turn, this mixing determines the orbital composition of the band extrema and band gaps. The influence on band gaps of the substitution of Nb and Ta for V in Ag_3VO_4 and of the substitution of alkali metals for K in $KAg_{11}(VO_4)_4$ will also be discussed.

9:36AM V11.00009 Electronic structures of Tl-based materials for γ-ray detectors; First-principles study[1] , JUNG-HWAN SONG, HOSUB JIN, ARTHUR J. FREEMAN, SIMON JOHNSEN, JOHN ANDROULAKIS, PETER SEBASTIAN, ZHIFU LIU, JOHN A. PETER, NAM-KI CHO, BRUCE WESSELS, MERCOURI G. KANATZIDIS, Northwestern University — For Tl-based semiconductors, investigated to find good candidate materials for γ-ray detectors, we performed ab-initio calculations using the full-potential linearized augmented plane wave (FLAPW) method[2] to find their electronic structures and to estimate their physical properties such as band gaps, effective masses, absorption coefficients, dielectric constants, and work functions. Within the LDA scheme, the underestimation of the band gap is well-known and causes serious problems in obtaining optical properties. Therefore, we adopted the screened-exchange LDA (sX-LDA) scheme and acquired correct gap values close to experimental ones. With the sX-LDA, we found that Tl_6I_4S and Tl_6I_4Se have direct band gaps of 2.36 and 1.88 eV, respectively, and they exhibit dispersive bands near the band edges. Based on the calculated and experimental results, we discuss the relationship between atom species/crystal structure and electronic characteristics, and suggest several materials for γ-ray detectors.

9:48AM V11.00010 Non-equilibrium Fermi-edge Singularity in Mesoscopic Devices , JIN ZHANG, NICHOLAS D'AMBRUMENIL, BORIS MUZYKANTSKII, University of Warwick, DAVID COBDEN, University of Washington — The non-equilibrium Fermi-edge singularity (NFES) was observed as a non-linearity in the random telegraph signal [1] in mesoscopic devices at low temperatures. Based on a modified NFES theory, we found that when a low-frequency ac signal is applied, the Fumi shift and the electron dephasing contribute in an opposite way to the violation of the detailed balance, which is measured in the logarithmic ratio of tunneling rates. In the case of large electron phase shift and weak dephasing, the usually-ignored Fumi shift plays an important role, and manifests itself as an "S"- shape curve in the logarithmic ratio of rates. For stronger dephasing, near the transition threshold, the tunneling spectra are dominated by the increased effective temperature because of the bias voltage, while for energies larger than that of the probing signal, the thermal excitation restores the system to pseudo-equilibrium. The overall shape of the logarithmic ratio of rates shows a "Z"-shape.

10:00AM V11.00011 Dirac Point Degenerate with Massive Bands at a Topological Quantum Critical Point , SWAPNONIL BANERJEE, UC Davis, WARREN PICKETT, JUSTIN SMITH, VICTOR PARDO, RAJIV SINGH TEAM — In the band structure of the Skutterudite, as the Sb sublattice in the unit cell is moved slightly retaining the crystal symmetry, the small gap at the Fermi energy closes due to a band crossing at Gamma. At this critical point a pair of linear ("Dirac") bands are degenerate with two conventional bands. Because of the crystal symmetry three out of the four bands are degenerate even when one is away from the critical point. Insulators in 3D, as well as in 2D, can be characterized by topological invariants. When inversion symmetry is present (as in the space group 204 of Skutterudite), the Z2 invariant can be obtained from the parities of the occupied states at the invariant momenta, which in the bcc structure consist of Gamma, three H points, and the four P points. Here only the Gamma point requires consideration, since reoccupation occurs only there. The singlet has odd parity at Gamma while for the triplet it is even. As the critical point is crossed, the product of the parities of the occupied bands at Gamma, and hence the Z2 invariant, changes sign due to the reversal of the singlet- triplet position; the signal of a trivial to topological transition.

10:12AM V11.00012 Sixteen-band atomic bond-orbital model for zinc-blende structures , HSIU-FEN KAO, JIH-CHEN CHIANG, W.T. WANG, IKAI LO, Y.C. HSU, C.L. WU, D.J. JANG, Department of Physics, National Sun Yat-sen University, Kaohsiung 80424, Taiwan, MENG-EN LEE, C.Y. REN, YEN-CHIH TSENG, Department of Physics, National Kaohsiung Normal University, Yanchao, Kaohsiung County 82444, Taiwan, CHUN-NAN CHEN, Department of Physics, Tamkang University, Tamsui, Taipei County 25137, Taiwan — We develop a sixteen-band atomic bond-orbital model (16ABOM) which is able to compute the spin splitting induced by bulk inversion asymmetry. This model is derived from the linear combination of atomic orbital (LCAO) scheme such that the characteristics of real atomic orbitals can be preserved for spin-splitting calculations. We derive the Hamiltonian of 16ABOM by performing a similarity transform on the nearest-neighbor LCAO Hamiltonian, followed by taking a second-order Taylor series expansion over k-vector at the Γ point. The spin-splitting energies in bulk zinc-blendes are calculated using this model, and the results are in good agreement with LCAO and first-principles calculations. In addition, it is found the spin-orbit coupling between anti-bonding and bonding p-like states, which can be evaluated directly by this 16ABOM, dominates the magnitude of the spin splitting of the lowest conduction bands in middle-bandgap and wide-bandgap materials.

10:24AM V11.00013 Real-space Green's Function Calculations including Hubbard Contributions[1] , TOWFIQ AHMED, J. J. KAS, J. J. REHR, U. Washington — Hubbard model contributions are introduced into the real space Green's function formalism in terms of an effective self-energy, based on the LDA+U method of Anisimov et al.[2] The effective self-energy is then applied to localized d-states in a material, e.g. at the metal sites of transition metal oxides. The approach is implemented in an extension of the FEFF9 spectroscopy code and leads to an efficient procedure for including strong correlation effects in the electronic structure and x-ray spectra of d-electron materials, such as transition metal oxides and high T_c cuprates. Calculations are presented for the angular momentum projected density of states of MnO, NiO and $La_{(2-x)}Sr_xCuO_4$ and for the K-edge x-ray absorption and emission spectra of the O atoms in these materials, and the results are found to be in reasonable agreement with experiment.

10:36AM V11.00014 A Plane-Wave Implementation of Quasiparticle Self-Consistent GW (QSGW)[1] , DEREK VIGIL CURREY, JACK DESLIPPE, STEVEN G. LOUIE, University of California-Berkeley and Lawrence Berkeley National Lab — The use of GW techniques in calculating the quasiparticle properties of certain classes of materials, e.g. complex oxides, is sometimes hindered by the poor mean-field starting point that density functional theory (DFT) within standard Kohn-Sham implementations provides. There has been considerable effort in the community to improve upon the mean-field starting point for a broad range of materials. A recently proposed method, the quasiparticle self-consistent GW (QSGW) method, employs a process in which a mean-field exchange-correlation potential is approximated from and updated self-consistently using the self-energy operator from previous iteration GW calculations. We present an implementation of this method in a plane-wave basis, and discuss its accuracy, computational cost, and physical implications for a variety of semiconducting materials.

[1]This work was supported by NSF Grant No. DMR10-1006184 and U.S. DOE Contract No. DE-AC02-05CH11231. Computational resources were provided by NERSC. Derek Vigil Currey acknowledges funding from UC-Berkeley through the Chancellor's Fellowship.

10:48AM V11.00015 Assessment of dispersion-corrected density functional approaches for extended systems , WISSAM AL-SAIDI, University of Pittsburgh, Chemical and Petroleum Engineering, VAMSEE VOORA, KEN JORDAN, University of Pittsburgh, Department of Chemistry — Standard density functional (DFT) methods are known to fail in describing the long range van der Waals interactions, and currently, there is a great interest in incorporating dispersion corrections in density functionals. Recently, Tkatchenko and Scheffler introduced a new scheme where dispersion corrections are included by a summation of damped interatomic C_6/R^6 terms. However, contrary to the DFT-D2 approach of Grimme, the C_6 coefficients depend on the electron density through a Hirshfeld atom-in-a-molecule decomposition scheme. We have implemented the vdW-TS approach in VASP and applied it to the study of a series of prototype dispersion-dominated systems including layered materials, noble-gas solids and molecular crystals. Full optimization of all degrees of freedom is possible in our implementation because dispersion corrections are computed for the forces acting on the atoms, and also the stresses on the unitcell. Our results show that the vdW-TS method yield good structure, bulk moduli, and cohesive energies of weakly bonded systems in much better agreement with experiment than those obtained with standard DFT approaches.

Thursday, March 24, 2011 8:00AM - 11:00AM –
Session V12 FIAP: Transport in 2-D Systems D223/224

8:00AM V12.00001 In-Plane Field Magneto-transport in a Six-fold Degenerate Si-(111) 2DEG , TOMASZ M. KOTT, BINHUI HU, ROBERT N. MCFARLAND, STEPHEN H. BROWN, BRUCE E. KANE, University of Maryland, College Park — In-plane magneto-transport is an effective tool for measuring sub-band occupancy and differentiating between effects such as the so-called "reentrant Metal-Insulator Transition" or a ferromagnetic to paramagnetic phase transition. Using a two-dimensional electron gas (2DEG) on high mobility (up to $100,000$ cm^2/Vs) hydrogen terminated Si-(111) surfaces [1], we have studied the magneto-resistance due to in-plane magnetic fields of this six-fold degenerate system. While high perpendicular field (up to 12 T) measurements indicate field-dependent valley splitting, parallel field data helps differentiate this dependence from spin dynamics. The application of an in-plane field polarizes the 2DEG into distinct sub-bands. I will present measurements of both spin and valley sub-band polarization in parallel magnetic fields from samples of various mobility ($10,000 - 100,000$ cm^2/Vs) and discuss these results in the context of the broader question of field-dependent valley splitting. In a simple picture of valley splitting on Si-(111) surfaces, one would expect two valley polarization fields in addition to the spin polarization. I will discuss how this interaction-free model fits with the perpendicular field measurements, and what we can learn about the six-fold degenerate system.

8:12AM V12.00002 Zero Differential Resistance State in double GaAs quantum wells at high filling factors[1] , ALEXEY BYKOV, E.G. MOSULEV, Institute of Semiconductor Physics, 630090 Novosibirsk, Russia, S.A. VITKALOV, The City College of New York, New York, NY 10031, USA — Differential resistance r_{xx} of 2D electrons was investigated in double GaAs quantum wells placed in magnetic fields $B < 0.5$ (T) at temperatures $T = 1.6 - 4.2$ (K). Electron state with Zero Differential Resistance (ZDR) is found in finite current range at maximums of inter-subband quantum oscillations. The experiment shows that the ZDR state exists at $2R_cE_H/\hbar\omega_c < 1/2$, where R_c is electron cyclotron radius at Fermi level, E_H is Hall electric field, induced by the dc bias, and ω_c is cyclotron frequency.

8:24AM V12.00003 Degenerate versus semi-degenerate transport in a correlated 2D hole system[1] , RICHARD L.J. QIU, XUAN P.A. GAO, Dept. of Physics, Case Western Reserve University, LOREN N. PFEIFFER, KEN W. WEST, Dept. of Electrical Engineering, Princeton University — It has been puzzling that the resistivity of high mobility two-dimensional (2D) carrier systems in semiconductors with low carrier density often exhibits a large increase followed by a decrease when the temperature (T) is raised above a characteristic temperature comparable with the Fermi temperature (T_F). We find that the metallic 2D hole system (2DHS) in GaAs quantum well (QW) has a linear density (p) dependent conductivity, $\sigma \approx e\mu^*(p - p_0)$, in both the degenerate ($T << T_F$) and semi-degenerate ($T \sim T_F$) regimes. The T-dependence of $\sigma(p)$ suggests that the metallic conduction (dσ/dT <0) at low T is associated with the increase in μ^*, the effective mobility of itinerant carriers. However, the resistivity decrease in the semi-degenerate regime ($T > T_F$) is originated from the reduced p_0, the density of immobile carriers in a two-phase picture. Quantum oscillations in the magneto-resistivity are also found to persist into the semi-degenerate regime in our strongly correlated 2DHS.

[1]Supported by NSF grant (DMR-0906415)

8:36AM V12.00004 Nonlinear transport in very high Landau levels of a high mobility quantum Hall systems[1] , M.A. ZUDOV, H.-S. CHIANG, A.T. HATKE, University of Minnesota, M. KHODAS, University of Iowa, L.N. PFEIFFER, K.W. WEST, Princeton University — When a dc current is passed through a high-mobility two-dimensional electron system its differential resistivity exhibits oscillations with the applied magnetic field. The minima of these oscillations can extend all the way to zero leading to states with zero-differential resistance. This talk will discuss our recent experiments studying the evolution of the differential resistivity with temperature and with perpendicular and in-plane magnetic fields.

[1]This work is supported by NSF DMR-0548014.

8:48AM V12.00005 Charge carrier velocity distribution in amorphous oxide field-effect transistors , CHEN-GUAN LEE, BRIAN COBB, ANANTH DODABALAPUR, University of Texas at Austin — Charge transport in field-effect transistors (FETs) and the underlying physical mechanisms have been the subjects of numerous studies. Many types of transistors have been studied utilizing organic/polymer, amorphous silicon, and thin-film inorganic active layers. Most of these studies involve the evaluation of charge carrier mobility from steady-state characteristics as a function of temperature, electric field, channel dimensions, etc. In this study, we describe a technique to measure the velocity distribution of charge carriers in a thin-film transistor. We use this technique to evaluate velocity distributions in zinc-tin oxide (ZTO) thin-film transistors at various temperatures. In ZTO FETs, we observe multiple distinct transport pathways, each with a distinct activation energy. In contrast, steady state measurements yield a single activation energy. This shows that new insights into charge transport mechanisms and phenomena can be obtained with such time-resolved transport measurements which are not possible with steady-state approaches.

9:00AM V12.00006 Electronic Transport Properties of Epitaxial ZnO Films by Electron Dephasing and Mobility Spectrum Analysis , KUI ZHANG, WEI GUO, MICHAEL KATZ, Department of Materials Science and Engineering, University of Michigan, Ann Arbor, MI 48109, TASSILO HEEG, DARRELL SCHLOM, Department of Materials Science and Engineering, Cornell University, Ithaca, NY 14853, MINGRUI HAO, WENZHONG SHEN, Department of Physics, Shanghai Jiao Tong University, Shanghai 200240, China, XIAOQING PAN, Department of Materials Science and Engineering, University of Michigan, Ann Arbor, MI 48109 — Epitaxial ZnO films were grown by pulsed laser deposition on (111) Si substrates with bixbyite oxide buffers. Carrier transport properties were investigated using Hall measurements (4–300 K) under magnetic fields of 0–10 T, indicating mobility up to 113 cm^2/Vs. A diffusive Fermi surface (DFS) model incorporating electron dephasing theories was used to fit the abnormally positive magneto-conductivity observed below 150 K. Quantitative mobility spectrum analysis revealed the presence of a hole group at lower mobility accompanying the major electron group. Geometric distribution of the conducting groups was examined by capacitance-frequency experiments, while both temperature-dependent photoluminescence and mobility fitting confirmed a donor binding energy of ∼60 meV.

9:12AM V12.00007 Response of the Cyclotron Harmonic Spike to an In-Plane Magnetic Field[1] , YANHUA DAI, R.R. DU, Rice University, L.N. PFEIFFER, K.W. WEST, Princeton University — Microwave-induced resistance oscillations (MIRO) have been commonly observed in high- mobility GaAs/AlGaAs two-dimensional electrons systems (2DES) under microwave irradiations. In ultraclean GaAs/AlGaAs quantum wells (mobility $\sim 3.0 \times 10^7 cm^2/Vs$) we have recently observed an extraordinary resistance spike at the second harmonic of cyclotron resonance. In order to elucidate its origin, we have studied the response of microwave photoresistances in a two-axis magnetic field configuration, where the perpendicular (B_{perp}) and the in-plane ($B_{//}$) components can be independently applied to the sample. The experiments reveal a distinctive response of the spike to the $B_{//}$ as compared with that of the MIRO. While the major MIRO peaks show an increasing phase-shift towards 0.25 in increasing $B_{//}$, the spike position shows an essentially zero shift. This finding lends additional support for the notion that the spike is a new effect in the microwave-driven 2DES.

[1]The work at Rice was supported by NSF DMR-0706634.

9:24AM V12.00008 Conductivity kinks in the transport of ultra-dilute GaAs two-dimensional hole systems in zero field , JIAN HUANG, Wayne State University, L.N. PFEIFFER, K.N. WEST, Princeton University — Though Wigner crystal was first observed for electrons on helium in 1979, a Fermi Liquid-to-Wigner crystal transition has never been demonstrated. Important questions on how interaction drives such a transition and the nature of the transition remain unanswered. Apart from the complexity associated with the disorder which competes with or even dominates interaction by rendering the system into an Anderson insulator, an important question is whether there exists intermediate phases that hinder a direct first order transition. We report findings obtained via measuring ultra-high-purity GaAs two-dimensional hole systems with dilute charge concentrations down to 8x10^8 cm^{-2}. For fixed charge densities below 4x10^{9}cm^{-2}, a conductivity (σ) kink is observed while sweeping the temperature across some characteristic value where the derivative dσ/dT exhibits a discontinuous step. For charge densities above 4x10^{9}cm^{-2}, the kink evolves into a dip which diminishes for charge densities beyond 7x10^{9}cm^{-2}. A possible first order phase transition will be discussed.

9:36AM V12.00009 The Zero-Resistance States in InN Films , XIAOWEI HE, IVAN KNEZ, YANHUA DAI, RUIRUI DU, Rice University, XINQIANG WANG, BO SHEN, Peking University, RICE UNIVERSITY COLLABORATION, PEKING UNIVERSITY COLLABORATION — InN is a narrow gap semiconductor which possesses interesting transport properties. Besides the 2D electron accumulation layer on the surface, low temperature zero-resistance states have been observed in InN thin films and attributed to superconductivity. In order to elucidate the origin of superconductivity, we have studied systematically the temperature and magnetic field dependences of resistance in InN films of various thicknesses. High quality InN film samples of thickness between 50 nm and 5 μm were grown by molecular beam epitaxy on Al_2O_3 substrate with a GaN buffer layer. Typically these films have an electron density of 3x10^{17}- 6 x10^{18} cm^{-3}, and the mobility between 1000-2400 cm^2/Vs at 300 mK. Zero-resistance states were observed in films of thickness above 1 μm with the transition temperature of $\sim$ 1K, along with marked nonlinear I-V characteristics suggesting the presence of supercurrent. We observed anisotropic dependences of resistance on in-plane magnetic fields with respect to the direction of applied current. This work in Rice was supported by NSF DMR-0706634 and Welch Foundation C-1682, in Peking University was supported by the NSFC of China (Nos. 60990313, 10774001), and RFDP (No. 20090001120008).

9:48AM V12.00010 Electron interaction effects on Aharonov-Bohm resonances in an antidot-based quantum Hall interferometer , WOO-RAM LEE, Korea Institute for Advanced Study, HEUNG-SUN SIM, Korea Advanced Institue of Science and Technology — We theoretically study the electron interaction effects on Aharonov-Bohm resonances in an antidot-based quantum Hall interferometer in the integer quantum Hall regime. We introduce a general capacitive interaction model for an antidot with multiple bound modes of edge states, and find that the pattern of Aharonov-Bohm resonances is governed by the spectator behavior: The resonances of some modes disappear and instead are replaced by those of the other modes, due to charge relaxation between bound modes in the cotunneling regime. This behavior gives a reasonable understanding on the nontrivial features of previous experimental data, e.g., spectator behavior in an antidot molecule and resonance peaks in a single antidot with two, three, or four modes.

10:00AM V12.00011 Effective interlayer charge transfer in an electron bilayer system , VICTOR SOLOVYEV, Russian Academy of Sciences, Chernogolovka, STEFAN SCHMULT, WERNER DIETSCHE, Max-Planck-Institute for Solid State Research, Stuttgart, IGOR KUKUSHKIN, Russian Academy of Sciences, Chernogolovka — An electron bilayer system is realized in a wide GaAs quantum well. The chemical potentials of both layers can be tuned by intrinsic back and top gates. The Landau level spectrum for various charge distributions is probed by photoluminescence (PL), able to discriminate between both layers independently. The PL spectra show unambiguously how the system spontaneously deforms itself in strong magnetic fields as a consequence of energy minimization under Landau quantization and huge SAS energy gaps, reaching up to the cyclotron energy, become visible in the PL spectra [1].

10:24AM V12.00013 Spin-full quantum Hall states: squeezing techniques , EDDY ARDONNE, Nordita, Stockholm, MARIA HERMANNS, B. ANDREI BERNEVIG, Department of Physics, Princeton University, NICOLAS REGNAULT, Laboratoire Pierre Aigrain, ENS and CNRS, Paris — Despite the high magnetic field does the spin of the electron play an important role in the quantum Hall effect. Various spin (singlet) quantum Hall states have been proposed to explain various observed quantum Hall plateaux. In this talk, we present a method to generate spin-full quantum Hall states, by employing a squeezing procedure, as is used in the polarized state. This squeezing procedure also sheds additional light on the underlying (topological) structure of such states. By using connections between polarized and un-polarized states, one gains insight in the polarized state, as is the case for the Haffnian and Haldane-Rezayi states.

10:36AM V12.00014 Spin polarization measurement of the $\nu = 5/2$ fractional quantum Hall state via NMR , LARS TIEMANN, NTT and ERATO-JST, GERARDO GAMEZ, NORIO KUMADA, NTT, KOJI MURAKI, NTT and ERATO-JST — The $\nu = 5/2$ fractional quantum Hall state has attracted much interest due to its possible non-Abelian statistics, which are expected for the *Pfaffian* state. While the *Pfaffian* model assumes full spin polarization, recent optical experiments suggest a spin-unpolarized ground state at $\nu = 5/2$ instead [1, 2], and have thus posed a new challenge for understanding the true nature of the 5/2 state. Here, we report a spin polarization measurement of the $\nu = 5/2$ state using resistively-detected NMR and demonstrate its full polarization. The measurements were performed at $T = 10$ mK on a gated 30-nm quantum well at 4.4 T. For the resistive read-out of the nuclear resonance frequencies, we used the $\nu = 2/3$ spin transition by comparing its R_{xx} prior to and after the application of an *rf* pulse at $\nu = 5/2$. The NMR spectrum at $\nu = 5/2$ is shifted to lower frequencies from the one at $\nu = 2$, where the system is unpolarized, indicating a nonzero polarization at $\nu = 5/2$. Our analysis, which considers the changes of the sub-band wave function under a gate bias, indicates that the polarization at $\nu = 5/2$ is very close to its maximal value. This, in turn, gives support for the Pfaffian state.

10:48AM V12.00015 Observation of a Well-Developed $\nu = 5/2$ Fractional Quantum Hall State in Low-Mobility Electron Systems , GERARDO GAMEZ, KOJI MURAKI, NTT Basic Research Labs — The fractional quantum Hall (FQH) state at filling factor 5/2 is currently one of the hottest issues in FQH physics. This is mainly due to the predicted non-Abelian statistics of its quasiparticles and their possible implementation in quantum computation. However, experimental efforts to explore the 5/2 FQH state are severely hampered by the extremely high sample quality required for its emergence. Indeed, well-developed 5/2 FQH states have been reported only in samples with an ultra high mobility in excess of 1x10^7 cm^2/Vs. Here, we report the observation of a fully developed 5/2 FQH state in a GaAs/Al_xGa_{1-x}As quantum well with a mobility of 4.8x10^6 cm^2/Vs, which was established after illumination at low temperatures by a red LED. To clarify the mechanism underlying the emergence of the 5/2 state, we carried out a systematic study on a series of samples with different parameters. Our study unveils that the screening of the remote impurity (RI) potential by the nearby neutral donors in the modulation doping layer plays the essential role. We also find that while the emergence of the 5/2 state is governed by the RI potential, once this state has emerged, the energy gap at 5/2 is still limited by the background impurity potential. Based on the analysis of the transport and quantum lifetimes, the relation between the 5/2 gap and these parameters will be discussed.

8:00AM V13.00001 Phonon Spectra in Disordered Clusters of Colloidal Particles with Attractive Interactions[1] , ARJUN G. YODH, PETER J. YUNKER, KE CHEN, University of Pennsylvania, ZEXIN ZHANG, Soochow University — The influence of size and morphology on the vibrational properties of disordered clusters of colloidal particles with attractive interactions is studied experimentally. Water- lutidine mixtures induce fluid mediated attraction between micron-sized polystyrene particles, leading to the formation of attractive glasses with high local packing fractions. By measuring displacement correlations between particles, we extract the vibrational properties of these disordered clusters. Surprisingly, the spectra and character of vibrational modes did not depend on the number of particles involved. Rather, it depended strongly on the average number of nearest neighbors. An increase in the number of nearest neighbors shifted the phonon spectrum to higher frequencies, independent of the total number of particles in in the cluster. Simulations of structureless random networks of springs support these results, and further suggest that the dependence of phonon spectrum on number of nearest neighbors is a generic property of disordered networks.

8:12AM V13.00002 Dynamics of Small-Molecule Glass Formers Confined in Nanopores[1] , TIMOTHY PRISK, Indiana University Department of Physics, MADHUSUDAN TYAGI, NIST Center for Neutron Research, PAUL SOKOL, Indiana University Department of Physics — We report a comparative neutron scattering study of the molecular mobility and non-exponential relaxation of three structurally similar glass-forming liquids (isopropanol, propylene glycol, and glycerol) in bulk and confined in porous Vycor glass. Confinement reduces molecular mobility in all three liquids, and suppresses crystallization in isopropanol. High-resolution quasi-elastic neutron scattering spectra were fit to Fourier transformed Kohlrausch functions $\exp[-(t/\tau)^{\beta}]$, describing α-relaxation. The stretching parameter β is roughly constant with wavevector Q and temperature. Average relaxation times $\langle\tau(Q)\rangle$ are longer at lower temperatures and in confinement. They obey a power law $\langle\tau(Q)\rangle \propto Q^{-\gamma}$, where the exponent γ is modified by both temperature and confinement. Comparison of the bulk and confined liquids lends support to the idea that structural and/or dynamical heterogeneity underlies the non-exponential relaxation of glass- formers, as widely hypothesized in the literature.

8:24AM V13.00003 ABSTRACT WITHDRAWN –

8:36AM V13.00004 Emergence of rigidity at the dynamic glass transition: a replica approach calculation[1] , GRZEGORZ SZAMEL, ELIJAH FLENNER, Department of Chemistry, Colorado State University — According to the mean-field replica theory of the glass transition, at the so-called dynamic transition the relaxation stops and the liquid freezes into one of many metastable states. We identify Goldstone modes of the resulting amorphous solid and derive a formal expression for its shear modulus. This expression is complementary to the formula used by Yoshino and Mezard [Phys. Rev. Lett. **105**, 015504 (2010)]. We combine our formal expression with the recently proposed version of the replica approach [G. Szamel, Europhys. Lett. **91**, 56004 (2010)] to calculate the shear modulus.

[1]We gratefully acknowledge the support of NSF Grant CHE 0909676.

8:48AM V13.00005 Experimental study of dynamic rearrangements in repulsive and attractive glasses , ZEXIN ZHANG, Soochow University, PETER YUNKER, University of Pennsylvania, PIOTR HABDAS, Saint Joseph's University, ARJUN YODH, University of Pennsylvania — The influence of interparticle attraction versus repulsion on heterogeneous glass dynamics is explored with colloidal particles suspended in water-lutidine mixtures. The mixtures permit interparticle potentials to be tuned in situ from short-range repulsive to short-range attractive. Thus, a direct comparison of colloidal glass dynamics in samples composed of the same particles at the same volume fraction is possible. In both types of glasses, dynamics are found to be heterogeneous, and particles rearrange in a cooperative manner. By comparison to repulsive glasses, attractive glasses exhibit dynamics that are heterogeneous over a wider range of time and length scales, and involve more particles. Clusters of rearranging particles form string-like structures in repulsive glasses, and more compact clusters in attractive glasses. The experiments demonstrate explicitly that interparticle interactions affect glass dynamics.

9:00AM V13.00006 A family of systematically softened glass-formers , ZANE SHI, PABLO DEBENEDETTI, FRANK STILLINGER, Princeton University — We present a computational study of a family of binary glass-forming mixtures that interact via the generic $U = 4\epsilon[\lambda(\sigma/r)^n - \alpha(\sigma/r)^6]$, where $n = 7, 8, 9, 10, 11, 12$. λ and α are chosen such that the location and depth of the potential minimum are constant across all members of the family. We investigate the effects of softening on thermodynamic quantities such as energy and entropy, as well as dynamic properties such as diffusion and scattering. We also investigate the effects of softening on the energy landscape. In spite of the imposed constraint on well depth and location, we find profound effects of softening on all aspects of liquid and glassy behavior. The stability of the glasses is greatly enhanced by softening (soft liquids make hard glasses), and the relaxation rates in the corresponding liquids increase markedly upon softening. We present a comprehensive analysis of kinetic and thermodynamic fragilities in this family of glass-formers.

9:12AM V13.00007 Low-Frequency Vibrational Modes and Rearrangements in a Colloidal Glass Subject to Point Expansion[1] , KEVIN APTOWICZ, MATTHEW COLAGRECO, RYAN MARGOLIS, West Chester University, PETER YUNKER, KE CHEN, ARJUN YODH, University of Pennsylvania — We conduct experiments on two-dimensional packings of colloidal thermosensitive hydrogel particles. The packing fraction of the colloidal suspension is tunable from liquid to deeply jammed by varying the global temperature of the sample. In addition, by tightly focusing an infrared laser on the sample, point expansion of the colloidal glass is induced via thermophoretic forces. We utilize displacement correlation matrix techniques employed in recent papers, and we employ video microscopy to derive the vibrational modes. The response of the sample to induced point expansion is analyzed over a range of packing fractions, with particular focus on the correlation between quasi-localized low-frequency vibrational modes and regions of rearrangements.

9:24AM V13.00008 Crystallization of the Lewis-Wahnström ortho-terphenyl model , ULF PEDERSEN, UC Berkeley, TOBY HUDSON, PETER HARROWELL, School of Chemistry, University of Sydney — Crystallization is observed during long molecular dynamics simulations of bent trimer molecules - one of the standard models in computational studies of viscous supercooled liquids. The crystal was not anticipated, but is surprisingly simple: the three spheres that make up the rigid molecule sit near the sites of a body centered cubic lattice (the trimer bond angle being almost optimal for this structure). Interestingly, the crystal exhibits orientational disorder with molecules aligned randomly along the three Cartesian axis (an example of cubatic orientational order). While crystallization does not disqualify this model for viscous dynamics studies (it may even be valuable that the crystal is known), it illustrates the stubborn ingenuity of molecules to pack in periodic structures and questions our intuition to predict such structures. Finally, this is a rare example of crystallization of a molecular model from melt.

9:36AM V13.00009 Vitrification of a monatomic simple liquid in two dimensions[1] , TAKASHI ODAGAKI, Tokyo Denki University, TOMOKO MIZUGUCHI, Kyushu University — We investigate vitrification and crystallization process of a monatomic system by molecular dynamics simulation, where atoms interact via Lennard-Jones-Gauss potential. We first determine the time-temperature-transformation diagram by observing the crystallization time of the rapidly quenched state from the melt. The crystallization time becomes shortest at a certain temperature T*. The glassy state at low temperatures is shown to be fairly long-lived. In order to examine atomic mechanism of the crystallization, we introduce a modified incoherent intermediate scattering function which measures the structural correlation to a target structure. We show that the crystallization above and below T* take different paths. We also determine the free energy landscape (FEL) and show that the atomic dynamics is consistent with the FEL picture of the glass transition.

9:48AM V13.00010 Time reparametrization symmetry in a structural glass model , GCINA MAVIMBELA, HORACIO E. CASTILLO, Ohio University, CLAUDIO CHAMON, Boston University, LETICIA CUGLIANDOLO, Université Pierre et Marie Curie - Paris VI — We explore the existence of time reparametrization symmetry in a particle system with quenched disorder. The system's density fluctuations are described by a stochastic equation (D. S. Dean, J. Phys. A:Math. Gen **29**, L613 (1996)). Using the Renormalization Group (RG) on the Martin-Siggia-Rose generating functional, we analytically probe the long time dynamics by systematically integrating over short time scale fluctuations. We find that the RG flow converges to a fixed point that is invariant under reparametrizations of the time variable.

10:00AM V13.00011 Viscosity, Shear Waves and Atomic Level Stress Correlations[1] , VALENTIN LEVASHOV, JAMES MORRIS, TAKESHI EGAMI, University of Tennessee and Oak Ridge National Laboratory — The Green-Kubo equation relates the macroscopic stress-stress correlation function to a liquid's viscosity. The concept of the atomic level stresses allows the macroscopic stress-stress correlation function in the equation to be expressed in terms of the space/time correlations between the atomic level stress-stress correlation functions. Molecular dynamics studies show surprisingly long spatial extension of stress-stress correlations and also longitudinal and transverse waves propagating in liquids over ranges exceeding the system size. The results reveal that the range of propagation of shear waves corresponds to the range of distances relevant for viscosity. Thus our results show that viscosity is a fundamentally non-local quantity. We also show that periodic boundary conditions play very non-trivial, previously undiscussed, role in molecular dynamics simulations effectively masking the long range nature of viscosity.

10:12AM V13.00012 Study of the de Almeida-Thouless line using power-law diluted one-dimensional Heisenberg spin glasses[1] , AUDITYA SHARMA, PETER YOUNG, University of California at Santa Cruz — In a recent study, we showed that in mean-field theory, there is a de Almeida-Thouless (AT) line, that separates the low-temperature, low-field spin-glass phase from a high-temperature, high-field paramagnetic phase, for arbitrary m-component vector spin glasses, provided one applies a magnetic field that is *random in direction*. Building on this piece of work, here, we investigate whether or not there is an AT line beyond mean-field theory for Heisenberg spin glasses by performing Monte Carlo simulations on a power-law diluted one-dimensional Heisenberg spin glass for very large system sizes.

10:24AM V13.00013 Renormalization group analysis of the random first order transition , CHIARA CAMMAROTA, GIULIO BIROLI, IPhT, CEA/DSM-CNRS/URA 2306, CEA, Saclay France, MARCO TARZIA, GILLES TARJUS, LPTMC, CNRS-UMR 7600, Universite Pierre et Marie Curie, Paris — We consider the approach describing glass formation in liquids as a progressive trapping in an exponentially large number of metastable states. To go beyond the mean-field setting, we provide a real-space renormalization group (RG) analysis of the associated replica free-energy functional. The present approximation yields in finite dimensions an ideal glass transition similar to that found in mean field. However, we find that along the RG flow the properties associated with metastable glassy states, such as the configurational entropy, are only defined up to a characteristic length scale that diverges as one approaches the ideal glass transition. The critical exponents characterizing the vicinity of the transition are the usual ones associated with a first-order discontinuity fixed point.

10:36AM V13.00014 Influence of pressure on fast relaxation in glass-forming materials , VLADIMIR NOVIKOV, University of Tennessee, Chemical Department, 1420 Circle Dr., TN, 37996, LIANG HONG, ALEXANDER KISLIUK, Oak Ridge National Laboratory, Oak Ridge, TN 37831, ALEXEI SOKOLOV, University of Tennessee, Chemical Department, 1420 Circle Dr., Knoxville, TN, 37996 — The spectra of GHz-THz dynamics in glass forming materials have two main contributions: the boson peak and the fast relaxation that overlaps with the low-frequency flank of the boson peak. The nature of both contributions remains a subject of active discussions. Applying pressure helps to separate the temperature and volume effects on the fast dynamics. Although the boson peak under pressure was investigated recently by several groups, less attention was devoted to the fast relaxation. In this work we present the study of the fast relaxation measured in some molecular and polymeric glass formers under pressure by light (Raman and Brillouin) scattering. Different experimental conditions were applied: isothermal, isobaric, isokinetic, and isochoric. The results are analyzed within the frames of various theoretical models. In particular, we check in detail the predictions of the soft-potential model of glassy dynamics.

Session V14 GSNP: Focus Session: Statistical Mechanics of Complex Networks I D227

8:00AM V14.00001 Sensitive Dependence on Network Structure , ADILSON MOTTER, Northwestern University — Much of the recent research in complex networks has been focused on establishing relations between network structure and dynamics and on exploiting these relations to optimize network processes. Using diffusion, consensus, and synchronization dynamics as model processes of broad significance, I will show that optimization can often lead to sensitive dependence of the dynamics on the structure of the network. This sensitivity, which is characterized by cuspy or discontinuous dependence of the fitness function on network structural parameters, is shown to be determined by transitions in the complement graph that are reminiscent of explosive percolation. I will also discuss the prevalence of sensitive dependence. I will argue that this phenomenon is not limited to optimized systems, and may in fact be observed under rather general conditions in systems as diverse as power-grid and laser networks. This phenomenon sets experimental limits but also leads to improved controllability, in which the dynamics can be enhanced by exploiting antagonistic interactions between different fitness-inhibiting network structures.

8:36AM V14.00002 Critical percolation phase, geometric phase transitions with continuously varying exponents, and thermal Berezinskii-Kosterlitz-Thouless transition in a scale-free network with short-range and long-range random bonds , A. NIHAT BERKER, Sabanci University, MICHAEL HINCZEWSKI, University of Maryland, ROLAND R. NETZ, Technical University of Munich — Percolation in a scale-free hierarchical network is solved exactly by renormalization-group theory in terms of the different probabilities of short-range and long-range bonds [1]. A phase of critical percolation, with algebraic [Berezinskii-Kosterlitz-Thouless (BKT)] geometric order, occurs in the phase diagram in addition to the ordinary (compact) percolating phase and the nonpercolating phase. The algebraically ordered phase is underpinned by a renormalization-group fixed line along which the flows reverse stability, thus also leading to geometric phase transitions with continuously varying exponents. It is found that no connection exists between, on the one hand, the onset of the geometric BKT behavior and, on the other hand, the onsets of the highly clustered small-world character of the network and of the thermal BKT transition of the Ising model on this network. Nevertheless, both geometric and thermal BKT behaviors have inverted characters, occurring where disorder is expected, namely, at low bond probability and high temperature, respectively. This may be a general property of long-range networks. [1] A.N. Berker, M. Hinczewski, and R.R. Netz, Phys. Rev. E 80, 041118 (2009).

8:48AM V14.00003 Renormalization Group Classification of Critical Phenomena in Complex Networks[1]

, STEFAN BOETTCHER, TRENT BRUNSON, Physics Dept, Emory University — We discuss critical phenomena for a variety equilibrium statistical models on hierarchical networks with long-range bonds. An exact renormalization group (RG) study reveals that the observed critical behavior, albeit non-universal, can be classified into three generic categories. The non-universality is a direct result of the existence of long-range bonds, while the categories derive from their relative coupling strength. One of these categories is characterized by an infinite-order transition similar in appearance to the Kosterlitz-Thouless type, which has been observed recently in a number of network problems. Our result, if applicable to a wider set of networks, may explain the prevalence of such transitions, and may provide the basis for a generalized RG classification of criticality in complex networks.

[1]We thank the NSF-DMR for its support under grant #0812204.

9:00AM V14.00004 Contact process on static and adaptive preferred degree networks[1]

, SHIVAKUMAR JOLAD, WENJIA LIU, BEATE SCHMITTMANN, R.K.P. ZIA, Virginia Polytechnic Institute and State University — We consider epidemic spreading on an adaptive network where individuals have a fluctuating number of connections around some preferred degree κ. Using very simple rules for forming such a network, we find some unusual statistical properties which provide an excellent platform to study adaptive contact processes. For example, by letting κ depend on the fraction of infected individuals, we can model behavioral changes in response to how the extent of the epidemic is perceived. Specifically, we explore how various simple feedback mechanisms affect transitions between active and inactive states. In addition, we investigate the effects of two interacting networks, e.g., with a variety of κ's and cross links.

9:12AM V14.00005 Synchronization with Time Delays in a Noisy Environment[1]

, D. HUNT, G. KORNISS, B.K. SZYMANSKI, Rensselaer Polytechnic Institute — We study the effects of nonzero time delays in stochastic synchronization problems with linear couplings in an arbitrary network. We provide the synchronizability threshold using the known exact threshold value from the theory of differential equations with uniform delays and establish the limit of synchronization efficiency by constructing the scaling theory of the underlying fluctuations [2]. Nonzero delays lead to a scaling function for each fluctuation mode that does not vary monotonically as communication is improved (i.e., increasing strength or frequency). The strength and/or frequency of communication can then be tuned in order to subdue the stresses caused by growing the network to larger sizes, the presence of hubs, or lengthening delays. The implications can be counterintuitive: Improving communication is not always beneficial. In fact, making communication worse may salvage an otherwise unsynchronizable network. Insights into these trade-offs allow one to maintain and optimize the synchronization of the networks.

[2]Hunt, Korniss, Szymanski, Phys. Rev. Lett. **105**, 068701 (2010)

9:24AM V14.00006 A simple model for studying interacting networks[1]

, WENJIA LIU, SHIVAKUMAR JOLAD, BEATE SCHMITTMANN, R.K.P. ZIA, Virginia Tech — Many specific physical networks (e.g., internet, power grid, interstates), have been characterized in considerable detail, but in isolation from each other. Yet, each of these networks supports the functions of the others, and so far, little is known about how their interactions affect their structure and functionality. To address this issue, we consider two coupled model networks. Each network is relatively simple, with a fixed set of nodes, but dynamically generated set of links which has a preferred degree, κ. In the stationary state, the degree distribution has exponential tails (far from κ), an attribute which we can explain. Next, we consider two such networks with different κ's, reminiscent of two social groups, e.g., extroverts and introverts. Finally, we let these networks interact by establishing a controllable fraction of cross links. The resulting distribution of links, both within and across the two model networks, is investigated and discussed, along with some potential consequences for real networks.

[1]Supported in part by NSF-DMR-0705152 and 1005417.

9:36AM V14.00007 Controllability of Complex Networks

, YANG LIU, Northeastern University, JEAN-JACQUES SLOTINE, Massachusetts Institute of Technology, ALBERT-LASZLO BARABASI, Northeastern University — The ultimate proof of our understanding of natural or technological systems is reflected in our ability to control them. While control theory offers mathematical tools to steer engineered systems towards a desired state, we lack a general framework to control complex self-organized systems, like the regulatory network of a cell or the Internet. Here we develop analytical tools to study the controllability of an arbitrary complex directed network, identifying the set of driver nodes whose time-dependent control can guide the system's dynamics. We apply these tools to real and model networks, finding that sparse inhomogeneous networks, which emerge in many real complex systems, are the most difficult to control. In contrast, dense and homogeneous networks can be controlled via a few driver nodes. Counterintuitively, we find that in both model and real systems the driver nodes tend to avoid the hubs. We show that the robustness of control to link failure is determined by a core percolation problem, helping us understand why many complex systems are relatively insensitive to link deletion. The developed approach offers a framework to address the controllability of an arbitrary network, representing a key step towards the eventual control of complex systems.

9:48AM V14.00008 Optimization of flow and cascading effects in weighted complex networks[1]

, ANDREA ASZTALOS, SAMEET SREENIVASAN, Dept. of Physics and Dept. of Computer Science, Rensselaer Polytechnic Institute, Troy NY, BOLESLAW SZYMANSKI, Dep. of Computer Science, Rensselaer Polytechnic Institute, Troy NY, GYORGY KORNISS, Dept. of Physics, Rensselaer Polytechnic Institute, Troy NY — We investigate the effect of edge weighting scheme $\sim(k_i.k_j)^\beta$ on the optimality of flow efficiency and robustness in complex networks. We achieve this by analyzing a simple distributed flow model: current flow in resistor networks. In this scenario the centrality measure of a node (edge) is given by the current-flow betweenness, that is the amount of current flowing through the node (edge), averaged over all source-target pairs, when unit current enters simultaneously at each node and flows towards a randomly chosen target. The largest loads formed on either the nodes or the edges set the maximum amount of input current for which the network is still congestion free. These two optimal values do not occur for the same value of β. As congestion may appear on nodes as well as on edges, we also study the cascading behavior of networks, triggered by the removal of one or more entities.

[1]Supported in part by DTRA

10:00AM V14.00009 Winning consensus on social networks[1] , SAMEET SREENIVASAN, Dept. of Physics and Dept. of Computer Science, Rensselaer Polytechnic Institute, NY, J. XIE, Dept. of Computer Science, Rensselaer Polytechnic Institute, NY, G. KORNISS, Dept. of Physics, Rensselaer Polytechnic Institute, NY, BOLESLAW SZYMANSKI, Dept. of Computer Science, Rensselaer Polytechnic Institute, NY — The adoption of a specific behavior (opinion) by a population of individuals is influenced dramatically by the social network through which the individuals interact. Here, we show the conditions under which a randomly distributed sub-population of committed agents – nodes on the network that consistently profess a unique opinion and are not influenceable to change – can win over an entire population of individuals initially opposed to that opinion. We model the opinion dynamics by a variant of the Naming Game (Baronchelli et al. (2006)), which effectively captures the persistence of dominant opinions. Given this model, we demonstrate that in the asymptotic network size limit, there exists a critical value p_c of the fraction of committed agents, above which the network-state attains consensus, and below which the network-state converges to a non-consensus fixed point. We also discuss finite size corrections to p_c and the scaling of consensus times for finite networks.

10:12AM V14.00010 Eigenvalue Spectra of Random Geometric Graphs[1] , AMY NYBERG, KEVIN E. BASSLER, University of Houston — The spectra of the adjacency matrix and the graph Laplacian of networks are important for characterizing both their structural and dynamical properties. We investigate both spectra of random geometric graphs, which describe networks whose nodes have a random physical location and are connected to other nodes that are within a threshold distance. Random geometric graphs model transportation grids, wireless networks, as well as biological processes. Using numerical and analytical methods we investigate the dependence of the spectra on the connectivity threshold. As a function of the number of nodes we consider cases where the average degree is held constant and where the connectivity threshold is kept at a fixed multiple of the critical radius for which the graph is almost surely connected. We find that there exists an eigenvalue separation phenomenon causing the distribution to change form as the graph moves from well connected to sparsely connected. For example, the Laplacian spectra of well connected graphs exhibit a Gaussian envelope of integer values centered about the mean connectivity and superimposed on a real valued distribution. As connectivity decreases, the distribution shifts and includes an accumulation of eigenvalues near zero.

10:24AM V14.00011 Renormalization group fixed point analysis on small-world Hanoi networks[1] , TRENT BRUNSON, STEFAN BOETTCHER, Emory University — The Hanoi networks (HN) are a class of small-world hierarchical networks with varying degree distributions. Because of their unique self-similar structure, the renormalization group (RG) can be solved exactly on these networks.[2] The real-space RG framework is used to study the Ising model phase diagrams on HNs and to interpolate between different types of networks using a tunable parameter in the recursion equations. This interpolation between different HNs reveals tunable transitions and critical behavior including the inverted Berezinskii-Kosterlitz-Thouless transition. The fixed point analysis of the RG in HNs explains the behavior of the divergence of the correlation length at critical temperatures as well as other critical phenomena observables.[3,4]

10:36AM V14.00012 Quantum Transport through Hanoi Networks , M.A. NOVOTNY, CHRIS VARGHESE, Mississippi State U., STEFAN BOETTCHER, Emory U. — We present a renormalization group (RG) method to calculate the transmission of quantum particles through networks. The RG method is based on finite-dimensional matrix algebra for a tight-binding Hamiltonian [1], not a Green's function method [2]. The RG method is particularly well suited to application to hierarchical lattices. We apply the RG to obtain the quantum transmission T for Hanoi networks [3] HN3 (three bonds per site) and HN5 (on average 5 bonds per site). We give the transmission T as a function of the energy E of the incoming particle and the tight-binding parameters (on-site energy ϵ and hopping parameters t) for both linear and ring geometries. We have obtained T for up to 2^{200} sites, and have analyzed the RG equations to obtain asymptotic expressions. We find that the HN3 lattice exhibits band gaps, while no such band gaps exist in linear networks or in HN5.

Session V15 GMAG DMP FIAP: Focus Session: Spins in Semiconductors - Spin Currents III

D171

8:00AM V15.00001 Temperature Dependent Spin Transport in Silicon Controlled by an Electrostatic Gate[1] , JING LI, IAN APPELBAUM, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park, MD 20742 — Long-distance ($\sim$500μm) lateral spin polarized electron transport in undoped silicon under the control of an electrostatic gate is studied from 40K to 120K. The temperature dependence of average spin polarization, transport time, and spin dephasing during coherent precession can be largely attributed to reduction of finite spin lifetime at higher temperatures. Measurements on devices with different transport lengths are shown to modify the effect of electrostatic gating.

[1]Support from ONR is acknowledged

8:12AM V15.00002 Electrical detection of spin accumulation at 500K at FM/SiO2/Si(001) contacts via the Hanle effect[1]

, CONNIE H. LI, OLAF M. J. VAN 'T ERVE, EUGENE A. IMHOFF, BERRY T. JONKER, Naval Research Lab — We demonstrate the electrical detection of spin accumulation in Si (doped n-type 3E18 and 3E19/cm3) via injection from a ferromagnetic contact through a SiO2 tunnel barrier formed by plasma oxidation. The injection of spin-polarized carriers produces a net spin accumulation described by the splitting of the spin-dependent electrochemical potential, and is detected as a voltage. The decrease of this voltage with increasing out-of-plane magnetic field due to spin dephasing, i.e., Hanle precession of the electron spin, is observed at temperatures up to 500K. Lorentzian fits to the Hanle curves yield a spin lifetime of 100 and 320ps for the high and lower doped Si. The direct correlation between spin lifetime and carrier concentration in the Si, and that the magnitude of the Hanle signal agrees well with that expected from theory [1], provide clear evidence that the spin accumulation indeed occurs in the Si and not interface states. These results demonstrate that spin accumulation in Si can be a viable basis for spin-based devices. Supported by ONR.

8:24AM V15.00003 Quantifying Electron Spin Polarization from Polarized EL in Si spin-LEDs

, G. KIOSEOGLOU, University of Crete, P. LI, H. DERY, University of Rochester, A.T. HANBICKI, C.H. LI, O.M.J. VAN 'T ERVE, P.E. THOMPSON, B.T. JONKER, NRL — We analyze the circular polarization (P_{circ}) of the electroluminescence (EL) from Si-based spin-LEDs using a recent theory [1] which provides a quantitative relation between the polarization of phonon-assisted optical transitions measured in the EL, and the electron spin polarization electrically injected from Fe/Al2O3 and Fe/SiO2 tunnel barrier contacts [2,3]. EL spectra include features due to transverse acoustic (TA) and transverse optical (TO) phonon-mediated recombination occurring in the p-doped (p$\sim 10^{19}$cm-3) substrate. P_{circ} of 3.5% is typical for the TA at 5K, and is systematically higher than that of the TO by a factor $\sim$1.7, consistent with theory. The maximum polarization predicted for the TA is 13% for recombination of 100% polarized electrons in p-type Si (10^{19}cm-3). Thus the measured P_{circ} 3.5% corresponds to an electron spin polarization (P_{spin}) of 27% produced by electrical injection from our tunnel barrier contacts. A similar analysis applied to the TO phonon at 80K yields P_{spin} of 25%. Thus the theory enables quantitative interpretation of optical polarization in indirect gap semiconductors, facilitating future studies of spin injection. [1] P. Li and H. Dery, Phys. Rev. Lett. 105, 037204 (2010). [2] B.T. Jonker, et al., Nature Physics 3, 542 (2007). [3] C.H. Li, et al, Appl. Phys. Lett. 95, 172102 (2009).

8:36AM V15.00004 Electrical spin injection to Germanium using a single crystalline Fe/MgO/Ge tunneling junction

, YI ZHOU, LI-TE CHANG, University of California, Los Angeles, WEI HAN, University of California, Riverside, FAXIAN XIU, MINSHENG WANG, University of California, Los Angeles, MICHAEL OEHME, JOERG SCHULZE, Universitaet Stuttgart, ALEXANDROS SHAILOS, California Nano System Institute, ROLAND KAWAKAMI, University of California, Riverside, KANG WANG, University of California, Los Angeles — Germanium has long been predicted a superior candidate for spintronics with enhanced spin lifetime and transport length due to low spin–orbit interaction and lattice inversion symmetry. One of the critical challenges, however, is to electrically create spin accumulation in otherwise non-magnetic Ge. In this work, we report electrical spin injection to bulk n-type Ge using a single crystalline Fe/MgO/Ge tunneling junction. The spin lifetime and diffusion length are extracted from both 3-terminal Hanle measurement and non-local spin valve measurement. The spin relaxation mechanism in n-type Ge has also been explicitly analyzed from the bias and temperature dependence of the spin relaxation rate.

8:48AM V15.00005 Spin accumulation in Fe/MgO/Si heterostructures[1]

, A.T. HANBICKI, O.M.J. VAN 'T ERVE, S.-F. CHENG, R. GOSWAMI, C.H. LI, G. KIOSEOGLOU, P.E. THOMPSON, B.T. JONKER, Naval Research Laboratory — We report on spin injection experiments at Fe/MgO/Si interfaces using all electrical injection and detection. MgO is a promising magnetic tunnel junction material, and its incorporation with Si-based spintronics has only recently been reported in degenerately doped Si (n $\sim 10^{20} cm^{-3}$) [1]. We focus here on spin accumulation under the injecting contact for much lower n-doping levels by measuring the Hanle effect in a standard 3-terminal scheme where injection and detection are done using the same contact. The Fe/MgO spin injector was sputter deposited onto various n-doped Si bulk substrates using a variety of different substrate temperatures. The best tunnel barriers were obtained when the MgO was deposited at 70°C and annealed $in-situ$ before Fe deposition. Fits to Hanle curves using the drift-diffusion model for Si samples with n=$4x10^{18} cm^{-3}$ yield spin lifetimes τ_s = 0.28 ns up to 30 K and a spin diffusion length $L_s=\sqrt{D\tau_s}$ of 0.65 μm (the diffusion constant D is obtained from the mobility assuming degenerate statistics). We determine the dependence on n, and comment on the potential differences between SOI and bulk Si wafer transport channels. [1] T. Sasaki, et al., Appl. Phys. Exp. 2 (2009).

9:00AM V15.00006 Electrical spin injection and detection in Si[1]

, YONG PU, Center for Emergent Materials/Department of Physics, Ohio State University, ADRIAN SWARTZ, Department of Physics and Astronomy, University of California-Riverside, JONAS BEARDSLEY, VYDIA BHALLAMUDI, CHRIS HAMMEL, ROLAND KAWAKAMI, EZEKIEL JOHNSTON-HALPERIN, JON PELZ, Center for Emergent Materials/Department of Physics, Ohio State University — We report electrical spin injection from Fe into Si in a Fe/MgO/Si tunnel diode grown by molecular beam epitaxy. Incorporating the spin-degree of freedom into Si adds significant new functionality in a system with established utility. In addition, the use of spin as an intrinsically quantum mechanical degree of freedom may enable more speculative computing paradigms such as spin-based quantum computation. In this work, we investigate spin injection and spin detection and spin-related transport properties in Si. This work also lays the foundation for ongoing studies correlating structural, electronic and magnetic device properties with spin injection efficiency, spin transport mechanism and real-space imaging of spin transport.

[1]Funding for this research was provided by the Center for Emergent Materials at the Ohio State University, an NSF MRSEC (Award Number DMR-0820414).

9:12AM V15.00007 Spin injection into Silicon using Al_2O_3, SiO_2 and MgO tunnel barriers

, OLAF VAN T ERVE, CONNIE LI, AUBREY HANBICKI, GEORGE KIOSEOGLOU, BEREND JONKER, Naval Research Laboratory — We recently demonstrated injection of spin-polarized electrons from an Fe film into Si.[1] The tunnel barrier is the key component in achieving a large spin accumulation in the semiconductor. Here we will compare three different tunnel barriers, Al_2O_3, SiO_2 and MgO, on highly doped Si using three terminal Hanle measurements. Hanle measurements give insight in the spin-accumulation directly underneath the spin injecting contact. We will compare temperature dependence and bias dependence as well as the tunnel barrier properties such as density of interface states based on I-V and C-V measurements. We will compare spin-injection properties, such as spin lifetimes and spin injection efficiency with the oxide/Silicon interface. A spin lifetime of 120ps was obtained for 3e19 n-doped Silicon for both the Al_2O_3 and SiO_2 tunnel barrier, indicating that the spin accumulation occurs in the Si rather than in surface states. Support by ONR.

[1]B. T. Jonker et al., Nature Phys. 3, 542 (2007), O.M.J. van 't Erve et al., App. Phys. Lett. 91, 212109, (2007)

9:24AM V15.00008 Spin injection studies on thin film Fe/MgO/Si tunneling devices , JONAS BEARDSLEY, YONG PU, Ohio State University, ADRIAN SWARTZ, University of California Riverside, VIDYA BHALLAMUDI, Ohio State University, ROLAND KAWAKAMI, University of California Riverside, EZEKIEL JOHNSTON-HALPERIN, CHRIS HAMMEL, JON PELZ, Ohio State University — We report progress on the injection of spin polarized electrons into 35 nm thick Si films, using Fe/MgO injector/tunnel barrier structures grown by molecular beam epitaxy on SIMOX silicon-on-insulator substrates. The device requires heavy top-surface n-type doping of the Si film to produce a suitable tunnel barrier, accomplished by diffusion from a spin-on phosphorous-doped glass. Measurements indicate a roughly exponential doping profile with 7E20 per cubic cm at the top surface and a 2 nm decay length. Three terminal measurements showed evidence of spin injection similar to reports of Jansen et al. [1], while injection with a thinner MgO barrier shows more complicated behavior. On-going measurements and modeling will be discussed.

[1] R. Jansen et al.; Nature 462; 491 (2009) Funding for this research was provided by the Center for Emergent Materials at the Ohio State University, an NSF MRSEC (Award Number DMR-0820414).

9:36AM V15.00009 Room-temperature magnetocurrent in antiferromagnetically coupled Fe/Si/Fe[1] , RASHID GAREEV, MAXIMILIAN SCHMID, JOHANN VANCEA, CHRISTIAN BACK, University of Regensburg, REINERT SCHREIBER, DANIEL BUERGLER, CLAUS SCHNEIDER, Forschungszentrum Juelich, FRANK STROMBERG, HEIKO WENDE, University of Duisburg-Essen — Epitaxial Si-based ferromagnet/semiconductor structures demonstrate strong antiferromagnetic coupling (AFC) as well as resonant-type tunneling magnetoresistance, which vanishes at temperatures above T∼50K [1]. Magnetoresistance effects in Fe/Si/Fe close to room temperature (RT) were not established yet. By using the ballistic electron magnetomicroscopy (BEMM) techniques, with its nanometer-scaled locality [2] we observed for the first time a spin-dependent ballistic magnetotransport in AFC structures. We found that the hot-electron collector current with energies above the Fe/GaAsP Schottky barrier reflects magnetization alignment and changes from I_{cAP} ∼50fA for antiparallel alignment to I_{cP} ∼150fA for the parallel one. Thus, the magnetocurrent [(I_{cP}-I_{cAP})/ I_{cAP}]*100% is near 200 % at RT. The measured BEMM hysteresis loops match nicely with the magnetic MOKE data.

9:48AM V15.00010 Theory of spin-dependent phonon-assisted optical transitions in Si and quantifying spin polarization in Si[1] , HANAN DERY, University of Rochester — The spin polarization of conduction electrons in a direct-gap semiconductor is readily quantified by measuring the circular polarization of the recombination light luminescence. However, in silicon, owing to its indirect band-gap, such a direct connection between spin polarization and luminescence has been conspicuously absent. This missing link is established with a theory that provides concise relations between the degrees of spin polarization and measured circular polarization for each of the dominant phonon-assisted optical transitions [1]. This theory has two important applications. First, it allows one to determine in a parameter-free manner the spin polarization of electrons from the measured circular polarization of the luminescence. Second, it provides a means to extract the spin relaxation time or the spin injection efficiency across ferromagnet/silicon interfaces. In the first part of the talk, by invoking symmetry arguments, I will derive concise optical selection rules for each of the phonon-assisted optical transitions in unstrained bulk silicon. It will be shown that phonon symmetries play a key role in determining the circular polarization degrees of the various phonon-assisted luminescence peaks. In the second part, the optical selection rules will be used to analyze the polarized luminescence spectrum that is calculated by a comprehensive rigid-ion model for doped silicon. The analysis is used to elucidate results of recent spin injection experiments in silicon [2]. The effect of the (weak) spin-orbit coupling in silicon on the luminescence turns out to be unique due to the proximity of the split-off band to the heavy and light hole bands in unstrained bulk silicon (44 meV). This proximity gives rise to a fast reduction in the circular polarization degree of the luminescence in p- type silicon.

10:24AM V15.00011 Tunability of spin lifetimes in strained silicon and germanium , JIAN-MING TANG, BRIAN T. COLLINS, University of New Hampshire, MICHAEL E. FLATTE, University of Iowa — The spin lifetimes due to electron-phonon interactions in silicon and germanium are calculated using a sp^3 tight-binding model. Despite of the strong spin-orbit interaction in germanium, the spin lifetime in germanium is only about one order of magnitude shorter than what is in silicon. Near room temperature, the spin-flip scattering is dominated by the inter-valley f processes in silicon and by the inter-valley X processes in germanium. The inter-valley scattering processes can be suppressed by shifting the valley minima with strain. We show that the spin lifetimes can be enhanced by about an order of magnitude in both materials.

10:36AM V15.00012 Theory of optical spin orientation in silicon , JINLUO CHENG, J. RIOUX, Department of Physics and Institute for Optical Sciences, University of Toronto, 60 St. George Street, Toronto, Ontario, Canada M5S 1A7, J. FABIAN, Institute for Theoretical Physics, University of Regensburg, 93040 Regensburg, Germany, J.E. SIPE, Department of Physics and Institute for Optical Sciences, University of Toronto, 60 St. George Street, Toronto, Ontario, Canada M5S 1A7 — Despite weak spin-orbit coupling and an indirect band gap, significant optical spin orientation is possible in silicon. We show this by performing full band-structure calculations of the phonon-assisted absorption of circularly polarized light in bulk silicon. At 4 K a maximum spin polarization of 25% is found at the band edge; at room temperature the polarization is still 15%. We present the selection rules and give the contributions from the individual phonon branches, valence bands, and conduction band valleys. Dominant are the TO/LO phonon-assisted transitions from the heavy-hole to the conduction band.

10:48AM V15.00013 Spin-Dependent Phonon-Assisted Optical Transitions in Germanium , DHARA TRIVEDI, Department of Physics, University Of Rochester, PENGKE LI, Department of Electrical and Computer Engineering, University of Rochester, HANAN DERY, Department of Physics & Department of Electrical and Computer Engineering, University Of Rochester — We study the circular polarization of the photoluminescence due to phonon-assisted indirect optical transitions in Germanium. The band structure is calculated by empirical pseudopotential method with the spin-orbit interaction. Phonon modes are obtained by the adiabatic bond charge model and the L - Γ electron-phonon matrix elements are calculated within the rigid-ion approximation. We have used group theory extensively to account for all possible transitions. We quantify the circular polarization of various phonon-assisted optical transitions.

Thursday, March 24, 2011 8:00AM - 11:00AM –

Session V16 DMP GMAG: Focus Session: Magnetic Nanostructures, Exchange Coupled System

8:00AM V16.00001 Mu metal exchage bias[1] , PRIYANGA JAYATHILAKA, SCOTT CAMPBELL, CASEY MILLER — The exchange bias of the soft ferromagnet mu-metal, Ni77Fe14Cu5Mo4, with the metallic antiferromagnet Fe50Mn50 has been studied. Two series of multilayer heterostructures were grown with (111) texture induced by different buffer layer materials: Cu(300 A)/Ni77Fe14Cu5Mo4(200 or 400 A)/Fe50Mn50 (100 A)/Cu(300 A) and Ta(50 A)/Ni77Fe14Cu5Mo4(60–400 A)/Fe50Mn50(150 A); control samples were grown without Fe50Mn50. The samples have a clear unidirectional anisotropy induced by depositing in a magnetic field, the exchange bias magnitude is inversely proportional to the mu-metal thickness, and the interfacial coupling energy of 0.045 erg/cm2 agrees with previous results for FeMn antiferromagnets. While the Cu-buffered samples reveal a significant increase in coercivity and saturation field when exchange biased, the Ta-buffered samples retain the soft magnetic properties of the mu-metal simultaneously with the exchange bias. The ability to preserve soft ferromagnetic behavior in an exchange biased heterostructure may be useful for device and sensing applications.

[1]Supported by NSF ECCS

8:12AM V16.00002 Intrinsic Exchange Bias and Origin of Uncompensated Magnetization in FeF_2[1] , IGOR V. ROSHCHIN, KARIE E. BADGLEY, Texas A&M University, K.D. BELASHCHENKO, University of Nebraska-Lincoln, M. ZHERNENKOV, M.R. FITZSIMMONS, LANL, IVAN K. SCHULLER, University of California - San Diego — After more than 50 years since the discovery of Exchange Bias, its microscopic mechanism remains unknown. Several experimental findings demonstrate and many models agree that uncompensated magnetization (UM) in the antiferromagnet (AF) plays an important role in exchange bias. However, the origin of the UM is unknown. Magnetometry and polarized neutron reflectometry (PNR) measurements indicate that the UM is present even in the AF-only, (110)-FeF_2 grown on MgF_2, samples, and the PNR reveals the spatial distribution of the UM. Exchange bias in the AF-only sample is reported. Coupling of the UM to the bulk antiferromagnetic order parameter is supported by several experimental results, including high value of exchange bias field, its temperature dependence and the absence of training effect. We will discuss the origin of the UM based on general symmetry arguments.

[1]Work is supported by Texas A&M University, TAMU-CONACYT Collaborative Research Program, AFOSR, DOE.

8:24AM V16.00003 Tuning the Magnetic Properties in Exchange Coupled FeO/Fe_3O_4Core-Shell Nanoparticles , NATALIE FREY HULS, NIST, XIAOLIAN SUN, SHOUHENG SUN, Brown University, NIST COLLABORATION, BROWN UNIVERSITY COLLABORATION — Chemically synthesized FeO with a native oxide shell has recently received attention due to the large exchange bias effects observed in this system. The magnetic properties reported thus far have been highly dependent upon the aging affects of the system given the vulnerability of FeO to further oxidation resulting in degradation of the exchange bias effects. We report on the magnetic properties of FeO nanoparticles chemically synthesized to form several base diameters (10 nm, 20 nm, and 30 nm) which have each been annealed at various temperatures to obtain a variety of core/shell FeO/Fe_3O_4 size ratios. This controlled oxidation method has also given excellent chemical stability to the particles. XRD analysis confirms the existence of polycrystalline phases of FeO and Fe_3O_4, and magnetometry experiments reveal the existence of large exchange bias (up to 230 mT) as well as coercivity enhancements (up of 250 mT) which persist up the Néel temperature (which scales with core size). Other exchange coupling effects such as a large vertical shift in the field cooled hysteresis loops and asymmetric magnetization reversal are observed. Our results further advance the understanding of this exchange coupled system and imply that the properties can be chosen utilizing as-synthesized particle size and annealing temperatures.

8:36AM V16.00004 Tuning exchange bias in Ni/FeF_2 heterostructures using antidot arrays , XAVIER BATLLE, M. KOVYLINA, A. LABARTA, Dept. Física Fonamental, Universitat de Barcelona, 08028 Barcelona, Catalonia, Spain, R. MORALES, Basque Foundation for Science, IKERBASQUE, 48011 Bilbao, Spain, J.E. VILLEGAS, CNRS/Thales, Université Paris Sud, 91405 Orsay, France, M. EREKHINSKY, IVAN K. SCHULLER, Physics Department, University of California San Diego, La Jolla 92093 CA, USA — The transition from positive to negative exchange bias can be systematically tuned with antidot arrays artificially introduced into Ni/FeF_2 ferromagnetic (FM)/antiferromagnetic (AF) heterostructures. This is a consequence of the energy balance between the Zeeman coupling of the AF spins to the cooling field, and the AF exchange coupling at the FM/AF interface. The nanostructure plays a key role in the formation of pinned uncompensated spins in the AF: the antidot carving produces regions of locally pinned uncompensated spins throughout the antidot faces of the FeF_2 and these *non* interfacial magnetic moments favor the onset of positive exchange bias at lower cooling fields, by increasing the Zeeman energy of AF domains and favoring the alignment with the latter. Those *non* interfacial AF spins, and the pinned uncompensated interfacial AF spins responsible for the exchange bias (loop shift), align simultaneously with the cooling field since they belong to the same AF domain and become pinned below the Néel temperature.

8:48AM V16.00005 Depth Profiles of Exchange Stiffness and Anisotropy in a Spring Magnet with Intermixed Interfaces[1] , YAOHUA LIU, S.G.E. TE VELTHUIS, J.S. JIANG, Y. CHOI, S.D. BADER, Argonne National Laboratory, A.A. PARIZZI, H. AMBAYE, V. LAUTER, Oak Ridge National Laboratory — With complementary studies of Polarized Neutron Reflectometry (PNR) and micromagnetic simulations, we determined the depth profiles of the intrinsic magnetic properties in an Fe/Sm-Co spring magnet with intermixed interfaces, including saturated magnetiztion, exchange Stiffness and magnetic anisotropy. We found that intermixed region at the Fe/Sm-Co interface is about 8 nm wide, where the magnetic properties change gradually. We compared the results to a model based on a simple mixture of the Fe phase and the Sm-Co phase, as determined from the chemical depth profile using x-ray and neutron reflectivities. In the intermixed region, the saturation magnetization is slightly lower than the value estimated from the model but the exchange stiffness is higher. The magnetic anisotropy is also lower than the expected value from the model. Therefore the intermixed interface yields superior exchange coupling between the Fe and the Sm-Co layers but at the cost of total magnetization.

9:00AM V16.00006 Geometric Structure of Magnetic Domains in CoPd/IrMn Multilayer Films[1] , RUN SU, Physics Department, University of Oregon, SUJOY ROY, Advanced Light Source, Lawrence Berkeley National Laboratory, KEOKI SEU, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, DANIEL PARKS, Physics Department, University of Oregon, JIMMY KAN, ERIC FULLERTON, Department of Electrical and Computer Engineering, University of California, San Diego, STEPHEN KEVAN, Physics Department, University of Oregon — Using coherent x-ray resonant scattering in a transmission geometry, we collected magnetic scattering signal from CoPd/IrMn exchange biased multilayer films. The incident photon energy was tuned to the Co L3 edge allowing the magnetic domain configuration in Q space to be probed. Rotational autocorrelation functions of the resulting speckle diffraction patterns manifest the local geometric character of domain structure in Q-dependent fashion. These results are compared to microscopic magnetic domain memory probed by cross correlating different patterns. The memory under two different cooling conditions, with saturating field or with zero field was investigated, as well as the dependence of memory on external parameters, such as applied magnetic field and temperature.

[1]This research used the Lawrencium computational cluster resource provided by the IT Division at the Lawrence Berkeley National Laboratory.

9:12AM V16.00007 Correlation between bias fields and magnetoresistance in CoPt biased NiFe/Ta/NiFe heterosystems , YI WANG, XI HE, TATHAGATA MUKHERJEE, Department of Physics and Astronomy, University of Nebraska-Lincoln, SARBESWAR SAHOO, Seagate Technology, MICHAEL FITZSIMMONS, Los Alamos National Laboratory, CHRISTIAN BINEK, Department of Physics and Astronomy, University of Nebraska-Lincoln — Exchange coupled magnetic hard layer/soft layer (SL) thin films show SL biasing in close analogy to exchange bias systems with antiferromagnetic pinning. Here we study CoPt(35nm)/NiFe(450nm)/Ta(d)/NiFe(450nm) heterostructures with 0.7 <d<5nm. We use alternating gradient force magnetometry to measure the overall magnetization reversal and minor loop behavior. Magnetoresistance (MR) is measured by four-point methodology and modeled using magnetization data thus confirming the assumptions of uniform rotation of the top layer and exchange spring behavior of the pinned NiFe layer. In addition, Polarized Neutron Reflectometry (PNR) provides an independent data set for magnetization depth profiles. We compare and contrast results from our magnetometry and MR technique with PNR results. The objective of this comparison is to show that single-component magnetometry in concert with MR and modeling reveals the full vector and depth profile information of the distinct magnetization reversal mechanisms. Financial support by NSF through Career, MRSEC, DOE-OBES

9:24AM V16.00008 Growth and magnetism of highly (001)-oriented $[Fe/Pt]_n/Pt$ films[1] , T.A. GEORGE, X.Z. LI, L. YUE, DAVID J. SELLMYER, University of Nebraska — Highly (001) textured non-epitaxial $L1_0$ FePt films have been fabricated on SiO_2 substrates by post-deposition annealing 11 nm magnetron sputtered multilayers of Fe and Pt with an additional overlayer of 1 nm Pt. An identical series of films was made without the thick Pt terminating layer for comparison. All films were post-deposition annealed at 600 $^\circ$C for 300 s in a rapid thermal processor and show a high degree of chemical order. The ordered films without a Pt overlayer include a mixture of (001) and randomly oriented grains. In the samples with a Pt overlayer only the $(00l)$ peaks are visible, demonstrating an enormous enhancement in the degree of (001) texture. Structural analysis reveals a decrease in surface roughness from over 2 nm to less than 1 nm, elimination of voided regions, and an increase in average grain size from 50 to 150 nm with the inclusion of a Pt overlayer. Magnetic hysteresis loops show a high squareness ratio for Pt-overlayer samples with coercivities much smaller than their no-overlayer counterparts. The effects of Fe:Pt stoichiometry and bilayer thickness are investigated along with the involved grain-growth process.

[1]This research is supported by NSF-MRSEC, DOE, and NCMN.

9:36AM V16.00009 Exchange bias and magnetic anisotropy in ultrathin iron films grown on (001) GaAs[1] , KRITSANU TIVAKORNSASITHORN, XINYU LIU, MALGORZATA DOBROWOLSKA, JACEK FURDYNA, Department of Physics, University of Notre Dame, Notre Dame, IN 46556 — Ultrathin iron films grown by MBE on GaAs substrates were studied by SQUID and by ferromagnetic resonance (FMR). Exchange bias (EB) was observed in this system at temperatures below 20 K, but disappeared at higher temperatures. The angular dependence of asymmetric hysteresis loops of the sample were understood as resulting from the coexistence of the cubic and uniaxial magnetic anisotropy fields of the Fe film and the EB field arising from a yet unidentified inter-layer between Fe and GaAs (possibly Fe2As). Magnetic anisotropy of the Fe films was investigated by FMR in a manner similar to that described by Aktas et al. [1]. By fitting the angular dependence of the FMR field we have obtained magnetic parameters of the sample, which are similar to those reported in Ref. [1]. However, the g- factor obtained from the fitting shows an unexpected anomalous increase in the low temperature range. Since this behavior occurs exactly in the range where EB appears, it is tempting to speculate that these two effects are causally related.

9:48AM V16.00010 Measuring Exchange Bias in Patterned Films using Ferromagnetic Resonance , ROHAN ADUR, INHEE LEE, YURI OBUKHOV[1], The Ohio State University, CHRISTINE HAMANN, JEFFREY MCCORD[2], IFW Dresden, DENIS V. PELEKHOV, P. CHRIS HAMMEL, The Ohio State University — Exchange bias exploits the exchange interaction at the interface between a ferromagnet and an adjacent antiferromagnet to create a preferred orientation for the ferromagnet. He-ion bombardment has been used to create stripe-patterned films displaying anti-parallel exchange bias in adjacent stripes. As the width of these stripes approaches micron-size, magnetization reversal within individual stripes can be hindered by dipolar fields from magnetic charges at boundaries, making magnetometry measurements difficult to interpret. Here we report Ferromagnetic Resonance measurements of the magnitudes of the two opposing exchange bias fields perpendicular to the stripe axis, the dipolar fields experienced by neighboring stripes, and we quantify the effect of ion irradiation on the saturation magnetization of the $Ni_{81}Fe_{19}$ films.

10:00AM V16.00011 Scanning Probe Ferromagnetic Resonance Imaging of Stripe Patterned Exchange Bias IrMn-NiFe Film Using Nanoscale Confined Modes , INHEE LEE, ROHAN ADUR, The Ohio State University, CHRISTINE HAMANN, IFW Dresden, YURI OBUKHOV, The Ohio State University, JEFFREY MCCORD, Forschungszentrum Dresden-Rossendorf, DENIS PELEKHOV, The Ohio State University, BERND BUCHNER, IFW Dresden, CHRIS HAMMEL, The Ohio State University — We report scanned probe Ferromagnetic Resonance (FMR) imaging of the spatially modulated internal exchange-bias field in the exchange coupled ferromagnet (FM)/antiferromagnet (AF) $Ni_{81}Fe_{19}$ /$Ir_{23}Mn_{77}$ bilayer material using Magnetic Resonance Force Microscopy (MRFM). The exchange bias is spatially modulated by ion beam irradiation into a periodic stripe pattern having 2 or 20 micron periods. Adjacent stripes have oppositely aligned exchange bias fields. Our new method of FMR imaging employs the locally confined FMR modes created by a strong, non-uniform probe tip field on the out-of-plane saturated $Ni_{81}Fe_{19}$ film. We image the spatial variation of the inhomogeneous internal field with spectroscopic precision clearly resolving two exchange bias regions. Analysis of the local magnetic properties and their transition at the boundary of two exchange bias regions will be presented. This work was supported by the U.S. Department of Energy through Grant No. DE-FG02-03ER46054.

10:12AM V16.00012 Large exchange bias after zero-field cooling from an unmagnetized state[1] , LAN WANG, Nanyang Technological University, BAOMIN WANG, Nanyang Technological Univeristy, YONG LIU, Nanyang Techological University, PENG REN, Nanyang Technological University, BIN XIA, Nanang Technological University, KAIBIN RUAN, Nanyang Technological University, JIABAO YI, National Univeristy of Singapore, JUN DING, National University of Singaore, XIAOGUANG LI, University of Science and Technology of China — Exchange bias (EB) is usually observed in systems with interface between different magnetic phases after *field cooling*. Here, we report an unexpected finding that a *large* EB can be realized in Ni-Mn-In bulk alloys after *zero-field cooling from an unmagnetized state*. We propose that the size of superparamagnetic domains in the alloys can grow up under external magnetic fields, which induces a transition from a superspin glass to a superferromagnetic (SFM) state. The SFM unidirectional anisotropy, which is the origin of EB effect, can be created at the *newly* formed SFM-antiferromgantic interface during the initial magnetizing process.

10:24AM V16.00013 High energy product of Sm_2Co_7/FeCo nanocomposites prepared by severe plastic deformation , NARAYAN POUDYAL, CHUANBING RONG, J. PING LIU, Department of Physics, University of Texas at Arlington, Arlington, TX 76019, USA, YING ZHANG, M.J. KRAMER, Division of Materials Science and Engineering, Ames Laboratory, Iowa State University, Ames, IA 50011, USA — Nanocomposite magnets, consisting of exchange coupled hard magnetic and soft magnetic phases exhibit enhanced remanent magnetization and therefore high energy product *(BH)*$_{max}$. In addition to the high performance, nanocomposites magnets are of commercial interest because the alloys require less expensive rare-earth elements. Here, we report Sm_2Co_7+ x wt % FeCo (x = 0 to 50) nanocomposites prepared by high energy ball-milling and subsequent heat treatments. The evolution of structure and magnetic properties with soft phase fraction was systematically studied. Effect of the soft phase composition Fe_{100-X} Co_X (x = 20, 35 and 50) was also investigated. Microstructural studies by energy filter transmission electron microscopy revealed a homogeneous distribution of -Fe phase in the matrix of hard magnetic Sm-Co phase with grain size less than 20 nm after severe plastic deformation. Enhanced remanence and *(BH)* $_{max}$ (up to 17 MGOe) in the nanocomposites with 40 % of the soft phase are obtained.

10:36AM V16.00014 Microstructure refinement in $Nd_2Fe_{14}B$/(Fe,Co) nanocomposite ribbons produced by melt-spinning in a magnetic field , VUONG VAN NGUYEN, CHUANBING RONG, J. PING LIU, Department of Physics, University of Texas at Arlington, Arlington, TX 76019, USA — $Nd_2Fe_{14}B$/(Fe,Co) ribbons were prepared by melt-spinning in a magnetic field perpendicular or parallel to the wheel surface. The starting alloy $Nd_{15}Fe_{77}B_8$ was mixed with soft magnetic Fe, or Co, or $Fe_{65}Co_{35}$. The amount of the soft phases was varied from10 to 40 wt.% of the hard phase. The wheel was reconstructed to provide the surface magnetic fields in the range of 1 to 4 KG perpendicular or parallel to the wheel surface. The obtained results show that grain size in the ribbons was significantly reduced while the texture was enhanced. The mechanism remains to be fully understood, though it may be related to a change of the C-shaped diagram. The observed results suggest that a magnetic field can be used to control and optimize microstructures of nanocomposite ribbons. The effect of field strength and configuration is also discussed in details.

10:48AM V16.00015 Structure and magnetism of epitaxial NiMn single layers and Co/NiMn bilayers on $Cu_3Au(100)$[1] , WALDEMAR MACEDO, (1), WOLFGANG KUCH, (2), PEDRO GASTELOIS, (1), JORGE MIGUEL[2], (2), MAXIMILIANO MARTINS, (1), YAQOOB KHAN, (2), 1- NANOTECNOLOGIA, CENTRO DESENV. TECNOL. NUCLEAR, BELO HORIZONTE, MG, BRAZIL TEAM, 2- EXPERIMENTALPHYSIK, FREIE UNIV. BERLIN, GERMANY TEAM — The structure of single-crystalline NixMn100-x (NiMn) ultrathin films on Cu3Au(100) and also the magnetic properties of Co films on the NiMn/Cu3Au(100) films have been investigated by multiple techniques. For $10 \leq x \leq 77$, our results revealed good epitaxial, layer-by-layer growth at a substrate temperature of 300 K for all NiMn films with near equiatomic composition. The results indicate a face-centered tetragonal (fct) structure for NiMn, as expected for the L1o phase, and with the c-axis along the film normal. For the Co/NiMn bilayers, MOKE hysteresis loops show a thickness independent coercivity, suggesting no magnetic coupling at the Co/NiMn interface. Although the structural results indicate the formation of ftc NiMn in the equiatomic concentration range, we have no indication of antiferromagnetism for NiMn on Cu3Au(100) at room temperature. This is contrary to the observations for Co/NiMn on Cu(100).

Session V17 DMP GMAG: Focus Session: Bulk Properties of Complex Oxides - 5d Oxides D174

8:00AM V17.00001 Spin-Orbit Interaction Rediscovered in Transition Metal Oxides[1] , GANG CAO, University of Kentucky — The 5d-transition metal oxides are a class of novel materials that exhibit nearly every collective state known for solids. It is commonly expected that iridium oxides should be more metallic and less magnetic than their 3$d$and 4f counterparts due to the extended nature of the 5$d$orbitals. In marked contrast, many iridates are magnetic insulators that exhibit a large array of phenomena seldom or never seen in other materials. We review the anomalous physical properties of several iridates and address potential underlying mechanisms, which include strong orbital magnetism, the $J_{eff} = 1/2$ insulating state, and spin-orbit coupling; the latter strongly competes with other interactions to create an unusual balance between relevant degrees of freedom in this class of materials.

8:36AM V17.00002 Resonant inelastic x-ray scattering study of charge ordering in CuIr2S4 , HLYNUR GRETARSSON, University of Toronto, Canada, JUNG-HO KIM, DIEGO CASA, THOMAS GOG, Argonne National Laboratory, USA, SANG-WOOK CHEONG, Rutgers University, USA, YOUNG-JUNE KIM, University of Toronto, Canada — We present Ir L_3-edge resonant inelastic x-ray scattering (RIXS) spectra and resonant x-ray emission spectra (RXES) on the thiospinel, $CuIr_2S_4$, which has been attracting much interest due to intriguing metal-insulator transitions. At room temperature $CuIr_2S_4$ is metallic, but goes through a metal insulator transition at $T_{MI} \sim 226$ K due to the formation of charge order (CO) of Ir^{3+} and Ir^{4+} together with spin dimerization between Ir^{4+} ions. By exposing the sample to x-ray below T = 50 K, the crystal symmetry goes from triclinic to tetragonal, accompanied by reduced resistivity. The RIXS signal was dominated by a broad and strong feature around 3 eV, arising from t_{2g} to e_g transition, but we were able to observe a clear signature of opening of the insulating gap across the metal-insulator transition. In addition, we also found that this gap is partially filled in the irradiation-induced phase. The emission spectra reveals the existence of an excited Ir-5d t_{2g} state, which is hidden in the Ir L_3-edge XAS of $CuIr_2S_4$. The result indicates that the electronic reconstruction that takes place in the irradiation-induced phase comes from the Ir^{3+} while the Ir^{4+} dimers are unchanged.

8:48AM V17.00003 Electron-doped $Sr_2IrO_{4-\delta}$ $(0 \leq \delta \leq 0.04)$: Evolution of a disordered $J_{eff} = 1/2$ Mott insulator into an exotic metallic state[1] , O.B. KORNETA, T.F. QI, S. CHIKARA, L.E. DE LONG, G. CAO, Department of Physics and Astronomy, University of Kentucky, S. PARKIN, Department of Chemistry, University of Kentucky, P. SCHLOTTMANN, Department of Physics, Florida State University — Stoichiometric Sr_2IrO_4 is a ferromagnetic $J_{eff} = 1/2$ Mott insulator driven by strong spin-orbit coupling. Introduction of very dilute oxygen vacancies into single-crystal $Sr_2IrO_{4-\delta}$ ($\delta < 0.04$) leads to significant changes in lattice parameters and drives a number of intriguing phenomena such as insulator-to-metal transition at $T_{MI} \approx 105K$, anomalous non-Ohmic behavior and an abrupt current-induced transition in the resistivity. Highly-anisotropic resistivity of the samples continues to decrease by several orders of magnitude below T_{MI} without saturation to a residual limit at the lowest temperature studied $T = 1.8K$. The low-temperature metallic state exhibits two distinct regimes (separated at $T \approx 52K$) of switching in the non-linear $I - V$ characteristics. The novel behavior illustrates an exotic ground state and constitutes a new paradigm for device structures.

[1]This work was supported by NSF through grants DMR-0552267, DMR-0856234 (GC) and EPS-0814194 (GC, LED), and by DoE through grants DE-FG02-97ER45653 (LED) and DE-FG02-98ER45707 (PS).

9:00AM V17.00004 Magnetic ordering in Sr_2IrO_4 from first principles , SABINA RUIZ-CHAVARRIA, GREGORIO RUIZ-CHAVARRIA, PABLO DE LA MORA, Facultad de Ciencias, UNAM, CARLOS COSIO-CASTANEDA, GUSTAVO TAVIZON, Facultad de Quimica, UNAM — Sr_2IrO_4 is a layered compound with IrO_2 planes, separated by two SrO planes. Experimentally Sr_2IrO_4 shows weak ferromagnetism. This behavior can be assigned either as band magnetism or canted antiferromagnetic ordering. The latter has been confirmed by Arpes. With DFT calculations (using the WIEN2k package and Quantum Expresso) we show that the antiferromagnetic ordering is more stable than the ferromagnetic one, and due to the Dzyaloshinskii-Moriya rules there is a possibility of canted magnetic ordering.

9:12AM V17.00005 Effect of spin-orbit coupling on the band structure, magnetic ground states and low energy excitations of double perovskites[1] , ONUR ERTEN, ANAMITRA MUKHERJEE, MOHIT RANDERIA, NANDINI TRIVEDI, PATRICK WOODWARD, The Ohio State University — We investigate a model for double perovskites $A_2BB'O_6$ that describes the coupling of local moments on the B site to itinerant electrons contributed by the B′ sites. To model materials like Sr_2CrOsO_6 we examine the role of spin-orbit coupling on the the B′ site, which cannot be ignored because of the large Z of Os. First, we present $T = 0$ results for the net moment in the ferrimagnetic state. We show that direct B′-B′ hopping plays just as important role as the spin orbit coupling in determining the ordered moment. We use our model Hamiltonian approach to discuss the question of metallic versus insulating ground states, by including the effects of Coulomb U on the spin-orbit split electronic structure. Finally, we investigate the low energy excitations of this model to understand the origin of the experimentally observed nonmonotonic behavior of magnetization as a function of temperature.

[1]Supported by the NSF-MRSEC grant DMR-0820414.

9:24AM V17.00006 Magnetic and structural properties of Sr2CrReO6 epitaxial films fabricated by ultra-high vacuum sputtering[1] , A.J. HAUSER, B. PETERS, J. SOLIZ, R.E. WILLIAMS, M. DIXIT, H.L. FRASER, P.M. WOODWARD, F.Y. YANG, The Ohio State University — Sr2CrReO6, a double-perovskite half-metallic ferromagnet, has attracted much attention due to its high Tc of 620 K. However, balancing the stoichiometry and ordering of a quaternary oxide is no trivial matter. We have deposited pure-phase Sr2CrReO6 epitaxial films on SrTiO3 substrates by ultrahigh vacuum off-axis magnetron sputtering with precise control of the oxygen partial pressure and in-situ monitoring by high-pressure residual gas analyzer. The films exhibit saturation magnetization at T = 5K approaching 0.9 Bohr magnetons per formula unit and Tc close to 600 K. X-ray diffractometry spectra demonstrate epitaxy and phase purity with a rocking curve FWHM of 0.012 degrees. Laue oscillations give evidence of exceptionally smooth surface and interface as well as precise film thickness determination. Finally, direct observation of the films by HAADF STEM show nearly defect free films with double-perovskite ordering. We will discuss the effects of stoichiometry, growth pressure and oxygen content on sample properties.

[1]Funding for this research was provided by the Center for Emergent Materials at The Ohio State University, an NSF MRSEC (Award Number DMR-0820414).

9:36AM V17.00007 Electron doped CrO_2: An unsual example of a charge ordered ferromagnet , PRIYA MAHADEVAN, ABHINAV KUMAR, S.N.Bose National Centre for Basic Sciences, DEBRAJ CHOUDHURY, D.D. SARMA, Solid State and Structural Chemistry Unit, Indian Institute of Science — Usually metallicity accompanies ferromagnetism. $K_2Cr_8O_{16}$ is one of the less common examples of magnetic materials, exhibiting ferromagnetism in the insulating state [1]. Analyzing the electronic and magnetic properties within first principle electronic structure calculations, we find [2] that K acts like a donor. The doped electrons associated with the introduction of K in the lattice, induces a charge ordered and insulating ground state and interestingly also introduces a ferromagnetic coupling between the Cr ions. The primary considerations driving the charge ordering are found to be electrostatic ones with the charge being localized on two Cr atoms that minimize the electrostatic energy. The structural distortion that accompanies the ordering, generates a pathway for the electron localized on one site to hop on to the neighboring sites, a process more favorable in the ferromagnetic case, thus, giving rise to a rare example of a charge-order driven ferromagnetic insulator.

9:48AM V17.00008 Ab initio study of the anti-ferromagnetic, non-collinear CuB_2O_4 Crystal[1] , YIING-REI CHEN, Department of Physics, National Taiwan Normal University, Taipei, Taiwan 116, P.-R. LEE, J.-Y. LIN, Institute of Physics, National Chiao Tung University, Hsinchu, Taiwan 300, J.-M. CHEN, National Synchrotron Radiation Research Center, Hsinchu, Taiwan 300, A.N. VASILIEV, Department of Low Temperature Physics, Moscow State University, Moscow 119992, Russia — The spiky features in the crystal absorption spectrum, and the distinct differences in the directional oxygen K-edge absorption spectroscopy of the non-collinear anti-ferromagnetic, incommensurate CuB_2O_4, had led us to this LDA+U study of the crystal, although in the commensurate phase, due to the instrumental limitation. The calculated band structure matches the spiky features in the absorption spectrum, while the orbital analyzed DOS data explain the differences in the directional oxygen K-edge absorption spectroscopy. The two groups of dispersion-less bands, immediately above the gap, come from different groups of plaquettes, of Cu(A) and Cu(B), and are responsible for the spiky features observed experimentally.

10:00AM V17.00009 Doping Rules in A_2BO_4 Spinel Oxides , ALEX ZUNGER, T. PAUDEL, V. STEVANOVIC, S. LANY, Natl. Renewable Energy Lab., CO — Many of the physical phenomena surrounding Complex Oxide involve the creation and annihilation of charge carriers by cross –substitution of atoms or by the formation of vacancies and interstitials. We have used the machinery of First-Principles defect calculation, developed and tested over the years on semiconductors (where experimental data needed to test DFT corrections is rather clear), applying it to a large number of oxides, initially from the Spinel family. We calculate defect formation energies as a function of temperature and oxygen partial pressure, as well as the concentration of donors and acceptors and the ensuing free carriers. A number of regularities emerge. (i) Oxygen vacancies are not a viable source of electrons and cation vacancies are (usually) not a viable source of holes. (ii) Instead, cation-anti-sites (A-on-B donor and B-on-A acceptors) tend to form in significant numbers and release carriers. (iii) For the group of A3+ and B2+ spinels we find four "doping classes" (a) both donor and acceptor are in the gap (Al_2MgO_4) (b) Only acceptor is in the gap (Co_2ZnO_4) (c) only donor in the gap and (d) none in the gap. Simple regularities can be used as first-order rules to guess electrical behavior from composition. This work was supported through the Center for Inverse Design, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences.

10:12AM V17.00010 Magnetoelectricity and magnetostriction due to the rare-earth moment in $TmAl_3(BO_3)_4$, RAJIT CHAUDHURY, Department of Physics and TcSUH, University of Houston, Houston,TX 77204-5002, B. LORENZ, Y.Y. SUN, C.W. CHU, Department of Physics and TcSUH, University of Houston, Houston,TX 77204-5002, L. N. BEZMATERNYKH, V.L. TEMEROV, Institute of Physics, Siberian Division, Russian Academy of Sciences, Krasnoyarsk 660036, Russia — We investigated the magnetic, magnetostriction and magnetoelectric properties of d-electron free rare-earth aluminum borate $TmAl_3(BO_3)_4$ between room temperature and 2 K. The magnetoelectric polarization along the 'a' and 'c' directions reaches up to 300 μ C/m^2 at 70 kOe with the field is applied along the 'a' axis. 'c' axis magnetic field does not show any significant effect, which correlates with the fact that χ_a changed very rapidly compared to χ_c. We find that the polarization is proportional to the magnetostriction. The result of this investigation prove the existence of a significant coupling between the rare-earth magnetic moment and the lattice in $RAl_3(BO_3)_4$ compounds (R=rare earth). This compound shows that the rare-earth moment is sufficient enough to generate a large magnetoelectric effect. This is comparatively a simpler system to study and understand the origin of magnetoelectric effect.

10:24AM V17.00011 On the Pairing Instability in Rutile MO_2 , L. ANDREA SALGUERO, CRAIG J. FENNIE, School of Applied and Engineering Physics, Cornell University — The metal-dioxide family of compounds such as TiO_2, SnO_2, VO_2, NbO_2, and WO_2 have been of much recent interest for reasons as diverse as understanding novel correlated electron physics to designing new photo/electro-catalysis. All can be thought of as forming in a prototypical tetragonal "rutile" structure, yet members with unpaired d^1 and d^2 electrons undergo a structural phase transition to a monoclinic, "distorted rutile," structure. In some cases this metal pairing transition accompanies a metal to insulator transition, the precise role, however, is still not clear. Here we present a comparative first-principles study of the lattice instabilities in d^1 and d^2 MO_2 rutile, paying particular attention to the d^2 system WO_2, which remains metallic even in the distorted phase. We calculate the phonon dispersion in the tetragonal prototypical structure. Using unstable high symmetry modes as a guide, we calculate the energy surface around the high-symmetry structure and perform full structural relaxations in the distorted ground states. We elucidate the interplay between the electronic structure and the pairing transition and discuss the possibility of controlling it with strain.

10:36AM V17.00012 Relativistic effect determines the oxidation states: a study of Rh and Ir oxides by first principles methods , MAOSHENG MIAO, Materials Research Lab, University of California Santa Barbara, RAM SESHADRI, Materials Department & Department of Chemistry and Biochemistry, University of California Santa Barbara — The relativistic effect becomes significant on determining the structure and properties of $4d$ and $5d$ transition-metal compounds. It is found in some iridates that the relativistic effect, mainly contributed as spin-orbit interactions, can enhance the otherwise weak correlation of $5d$ electrons and cause an unusual Mott transition. Utilizing such effects in creating new phase such as topological insulator has grown into a hot spot in the frontier of functional oxide research. However, the relativistic effects on orbital energies, although important on determining the structure, has not been systematically studied. The general trend of the oxidation states of transition metals in the same group is to decrease with increasing atomic number. However, in contrast to this trend, Ir tends to form IrO_2 (4+) whereas Rh forms both Rh_2O_3 (3+) and RhO_2. Using relativistic and non-relativistic first principles calculations, we demonstrate that the unusually high oxidation state of Ir and the high stability of IrO_2 is caused by relativistic effect. Because relativity contracts the s and p orbitals, it repels Ir $5d$ electrons outwards and increases their energies. As a consequence, Ir tends to be oxidized to 4+ state and forms IrO_2.

Thursday, March 24, 2011 8:00AM - 11:00AM –

Session V18 GMAG DMP: Focus Session: Low D/Frustrated Magnetism - Spin Ice, et al. D172

8:00AM V18.00001 ABSTRACT WITHDRAWN –

8:12AM V18.00002 Magneto-optical Kerr Effect Studies of Artificial Frustrated Magnets , K.K. KOHLI, A.L. BALK, J. LI, S. ZHANG, P. LAMMERT, V.H. CRESPI, P. SCHIFFER, N. SAMARTH, Pennsylvania State University — We use the magneto-optical Kerr effect (MOKE) to study the collective magnetic behavior of geometrically frustrated arrays of single-domain ferromagnetic islands. By varying the island spacing, lattice geometry and the orientation relative to the magnetic field, we probe the properties of the arrays via MOKE measurements of the net moment of the arrays. We study the influence of local geometry and frustration on the collective magnetization reversal process, using the switching field as a measure. Further, angle-resolved MOKE measurements probe the influence of individual island shape anisotropy on the collective anisotropy of interacting arrays. Finally, we present preliminary measurements in an oscillating magnetic field. The results are compared to the results of micromagnetic simulation. We thank M. Ericson and C. Leighton for sample preparation. This research was supported by the US Dept. of Energy.

8:24AM V18.00003 Measuring Disorder in Artificial Kagome Ice , STEPHEN DAUNHEIMER, JOHN CUMINGS, Dept. of Materials Science & Engineering, University of Maryland — Artificial spin ice is proving to be a valuable tool in understanding magnetic interactions on the nanoscale. It can directly show the interactions responsible for geometric frustration, and different geometries have been used to model real pyrochlore spin ice compounds and other lattices. The strength in the approach lies in the ability of a synthetic material, fabricated from macroscopic artificial "atoms," to mimic real materials, where atoms are essentially identical with low disorder from lattice site to lattice site. However, in artificial spin ice materials there can be substantial variation among the artificial atoms in relevant quantities such as coercive field, with some systems showing standard deviations as high as 20%. By carefully studying the reversal process of artificial kagome ice along specific crystallographic directions, we can directly measure the distribution of coercivities of the individual nanoscale magnets. By using a lattice of connected magnets fabricated from Ni80Fe20, we find that the coercivity distribution can have a deviation of less than 5%. These narrow deviations should allow the observation of behavior that mimics more closely what would be expected in real spin ice materials.

8:36AM V18.00004 Dynamics of magnetization in artificial spin ice on kagome[1] , OLGA PETROVA, YICHEN SHEN, Johns Hopkins University, PAULA MELLADO, Harvard University, OLEG TCHERNYSHYOV, Johns Hopkins University — We model magnetization dynamics in artificial spin ice on kagome under an applied magnetic field. Magnetization reversal is mediated by domain walls carrying two units of magnetic charge emitted from and absorbed by lattice junctions and propagating along the wires. The Coulomb interaction between magnetic charges induces avalanches in magnetization reversal. Distributions of avalanche lengths for various angles between the initial magnetization and the applied magnetic field were considered. We used a Gaussian distribution in the magnitude of the links' critical fields to mimic disorder in a real system [1]. An asymmetric distribution of topological defects at a wire junction gives rise to an offset angle α in the reversal field $H(\theta) = H_c/\cos(\theta + \alpha)$ where θ is the angle between the link and the applied magnetic field [2]. The model reproduces the salient features of magnetization reversal curves observed experimentally.

8:48AM V18.00005 Disorder and field-induced dynamics in artificial spin ice , ZOE BUDRIKIS, The University of Western Australia, Perth, Australia, PAOLO POLITI, Instituto dei Sistemi Complessi CNR, Sesto Fiorentino, Italy, ROBERT STAMPS, The University of Western Australia, Perth, Australia — Artificial spin ices are athermal systems for which dynamics are induced by a time varying applied field. The field induced dynamics have received a lot of attention, both experimental and theoretical (see, e.g., [1,2]), but these studies have not dealt explicitly with the effects of disorder. We show, through numerical simulations and studies of the phase space of the system, that disorder in fact has a strong and fundamental effect on the field-induced dynamics. This highlights the fact that an understanding of the dynamics of artificial spin ice must take into account both the sequence of applied fields and the spin ice lattice.

9:00AM V18.00006 Control of Ground State Order in Artificial Square Ice , JASON MORGAN, University of Leeds, AARON STEIN, CFN, BNL, SEAN LANGRIDGE, ISIS, RAL, CHRIS MARROWS, University of Leeds — Anisotropy in nanomagnet arrays can be tailored to enforce geometrical frustration, so that analogs of spin-ice materials can be fabricated [1-2]. We have studied artificial square ice, which consists of interlinked vertices of four Ising moments. Previously, energy minimisation via ac demagnetization has received significant attention, however, the long-range ordered ground state (GS) is inaccessible via this method. Furthermore, equilibriation is disallowed in the athermal limit so far explored. We show it is possible to realise GS order in as-prepared arrays, fabricated via electron beam lithography and evaporation, due to early-growth thermalization [3]. Monopole and string-like excitations from the GS are seen to be Boltzmann factor-weighted. Monopole propagation and interactions can be inferred within an energy band structure. Lattice spacing and buffer material allow control of ordering.

9:12AM V18.00007 Monopole Dynamics in Spin Ice , CLAUDIO CASTELNOVO, Royal Holloway University of London — The last couple of years have witnessed intense interest in spin ice materials due to the unique nature of its low energy excitations, which take the form of emergent magnetic monopoles. Through combined theoretical and experimental work, it has become increasingly apparent that an effective description of these excitations in terms of free, Coulomb interacting point-like quasiparticles is essential to develop an understanding of the thermodynamic properties of these materials beyond numerical simulations. On the other hand, we are only just beginning to unravel the repercussions of such exotic excitations on the dynamics of spin ice, in relation for instance to how the system relaxes when driven out of equilibrium, or in relation to thermal transport experiments. In this talk we review some of the latest theoretical and experimental results on the out of equilibrium properties of spin ice materials, ranging from thermal and field quenches [Castelnovo, Moessner, & Sondhi, PRL 104, 107201 (2010) and ongoing work] to thermal runaways in response to a varying magnetic field [Slobinsky *et al.*, arXiv:1010.4143v1]. In particular, we discuss how these phenomena can be understood as consequences of the specific nature of the low energy excitations.

9:48AM V18.00008 Magnetic Monopoles in Matter: An Analytic Theory , BERNARD KAAS, University of Twente — Transport theory is presented which, starting from the microscopic field equations, incorporates the magnetic monopole physics occurring in materials such as spin ice. Hall effect, Landau levels, and thermopower are calculated for magnetic charges. Magnetic charge currents in elementary lattices are shown to exist even in the absence of geometrical frustration.

10:00AM V18.00009 Theoretical and computational models of emergent magnetic monopoles and Dirac strings in kagome spin-ice , REMO V. HUGLI, HANS-BENJAMIN BRAUN, GERARD DUFF, University College Dublin, CONDENSED MATTER THEORY, UCD TEAM, MAGNETIC NANOSTRUCTURES, PAUL SCHERRER INSTIUTE, SWITZERLAND TEAM — Magnetic monopoles and their associated Dirac strings have recently been experimentally observed as emergent quasiparticles in frustrated magnetic spin-ice systems. Detection of reciprocal signatures of monopoles were reported for 3D pyrochlore systems, and subsequently, direct real-space observations of monopoles and their associated Dirac strings were made in 2D artificial kagome lattices. In contrast to conventional domain growth, the magnetization process in these spin ice systems proceeds through nucleation and avalanche-type propagation of overturned dipoles - physical versions of a Dirac string. The 1D nature of these avalanches in a 2D system provides an example of dimensional reduction through frustration. We establish a theoretical model and perform Monte Carlo simulations which faithfully reproduce the observed hysteresis, string-avalanche statistics and monopole densities.

10:12AM V18.00010 Hunting a [111] magnetization plateau to test the quantum spin ice model in Tb2Ti2O7 , PETER BAKER, ISIS Facility, STFC Rutherford Appleton Laboratory, Didcot OX11 0QX, United Kingdom, MARIA MATTHEWS, Department of Physics and Materials Research Institute, Pennsylvania State University, University Park, Pennsylvania 16802, USA, SEAN GIBLIN, ISIS Facility, STFC Rutherford Appleton Laboratory, Didcot OX11 0QX, United Kingdom, PETER SCHIFFER, Department of Physics and Materials Research Institute, Pennsylvania State University, University Park, Pennsylvania 16802, USA, CHRISTOPHER BAINES, Laboratory for Muon-Spin Spectroscopy, Paul Scherrer Institute, Villigen CH-5232, Switzerland, DHARMALINGHAM PRABHAKARAN, Oxford University Department of Physics, Clarendon Laboratory, Parks Road, Oxford OX1 3PU, United Kingdom — The pyrochlore magnet Tb2Ti2O7 may be described by a quantum spin ice model. This model predicts a magnetization plateau will occur for weak fields applied along the [111] axis at low-temperature. We have carried out muon-spin relaxation measurements to test this hypothesis. Features are observed at 15 and 65mT, agreeing with the predicted boundaries of the magnetization plateau. In the intermediate region the field dependence of the muon relaxation rate suggests a constant distribution of local magnetic fields of 10mT, and a constant fluctuation time of 20ns. ac susceptibility measurements are being carried out to investigate the bulk response on a longer timescale.

10:24AM V18.00011 Creation and Measurement of Magnetic Charge Currents in Spin Ice , SEAN GIBLIN, Rutherford Appleton Lab, UK, STEVEN BRAMWELL, Uuniveristy College London, UK, PETER HOLDSWORTH, University of Lyon, France, PRABHAKARAN DHARMALINGAM, University of Oxford, UK, IAN TERRY, University of Durham, UK — The recent discovery of magnetic charge in spin ice raises the question of whether long-lived currents of magnetic "monopoles" can be created and manipulated by applying magnetic fields. Here we show that they can; by applying a magnetic field pulse to a $Dy_2Ti_2O_7$ spin ice crystal at 0.36 Kelvin, we create a relaxing magnetic current that lasts for several minutes. We measure the current by means of the electromotive force it induces in a solenoid coupled to a susceptometer and quantitatively describe it using a chemical kinetic model of point-like charges obeying the Onsager-Wien mechanism of carrier dissociation and recombination.

10:36AM V18.00012 d-wave Metal phase of itinerant electrons with ring exchange on a 2-leg ladder , M.S. BLOCK, Dept. of Physics, UCSB, H.-C. JIANG, Microsoft Research, Station Q, UCSB, R.V. MISHMASH, Dept. of Physics, UCSB, D.N. SHENG, Dept. of Physics and Astronomy, CSU, Northridge, O.I. MOTRUNICH, Dept. of Physics, Caltech, M.P.A. FISHER, Dept. of Physics, UCSB — I will present recent results in the search for theoretical insights into non-Fermi liquid phases in two dimensions. In particular, we propose a novel conducting phase for itinerant electrons on the square lattice with strong d-wave correlations (i.e. a "d-wave metal"; see [1] for the bosonic analog of this phase) and a candidate Hamiltonian (hopping plus four-site electron ring exchange), which we examined in search of this phase (at $T = 0$) over some portion of the phase diagram. For numerical tractability, we specialize to the 2-leg ladder and study this model using variational Monte Carlo (VMC) and the density matrix renormalization group (DMRG). For the VMC, we construct trial wavefunctions corresponding to a particular slave particle decomposition of the electrons and consistent with the properties of the proposed d-wave metal as well as for the "normal" Fermi liquid phase to map out a VMC phase diagram for the candidate Hamiltonian. Meanwhile, DMRG is employed as a quasi-exact probe of this Hamiltonian and the successes and failures of the trial wavefunctions, relative to the unbiased DMRG results, will be presented. [1] O. I. Motrunich and M. P. A. Fisher, Phys. Rev. B, **75**, 235116 (2007).

10:48AM V18.00013 Entanglement Hamiltonians for quantum spin chains[1] , RONNY THOMALE, Princeton University, STEPHAN RACHEL, Yale University, DANIEL AROVAS, UC San Diego, B. ANDREI BERNEVIG, Princeton University — We report on our analysis of entanglement phenomena in gapped and gapless quantum spin chains. In particular we discuss criteria of correspondence between entanglement spectra and Hamiltonian spectra with respect to symmetries, spectral gaps, and eigenstate properties. We find that the structure of the entanglement Hamiltonian associated with the ground state is helpful to discover various spectral properties of the full system.

8:00AM V19.00001 ABSTRACT WITHDRAWN –

8:36AM V19.00002 Ferromagnetic resonance studies of CoFeB-MgO[1] , ERIK SHIPTON, UC San Diego, KEN LEE, Qualcomm Corporation, JONATHON SAPAN, JIMMY KAN, KEITH CHAN, UC San Diego, ERIC FULLERTON — There has been much interest in ferromagnetic magnetic tunnel junctions (MTJs) as a potential candidate for spin transfer torque memories. Many parameters are important in order to optimize the spin transfer torque effect to minimize the critical switching current density (J_c) without compromising an energy barrier (E_B) between stable states. CoFeB/MgO systems have many desirable properties including high spin polarization and, thereby high tunnel magnetoresistance. Recently, Ikeda et al. reported that Fe-rich CoFeB/MgO MTJs can induce perpendicular anisotropy that is strong enough to overcome the in-plane shape anisotropy, demonstrating CoFeB-based perpendicular MTJs [1]. In this work, we have performed FMR studies as a function of alloy composition, layer thickness, pre and post annealing of CoFeB/MgO systems. Coplanar waveguide method VNA FMR experiments were performed [2]. From the FMR resonance frequency and linewidth we were able to extract the Gilbert damping as well as the effective magnetization. Experimental details as well as results will be presented.

8:48AM V19.00003 Energy distributions of defects causing barrier-resistance noise in CoFeB/MgO/CoFeB tunnel junctions[1] , RYAN STEARRETT, XIAOMING KOU, JOHN XIAO, ED NOWAK, University of Delaware — Magnetic tunnel junction devices, such as field sensors, are well known to exhibit low frequency resistance noise having a $1/f$ spectrum. This noise has its origins in a combination of electrical and magnetic mechanisms. Previously, we have shown that the resistance noise can be reduced significantly through thermal annealing. Here, we report on the energy distribution of the defects causing tunnel-barrier-resistance noise. The distributions are determined from a Dutta-Horn model for thermally activated charge trapping and detrapping kinetics. We also discuss how the distribution changes as a function of annealing time and its relation to the current-voltage characteristics and the voltage bias dependence of the $1/f$noise.

9:00AM V19.00004 Ultrafast Switching in Magnetic Tunnel Junction based Orthogonal Spin Transfer Devices , HUANLONG LIU, DANIEL BEDAU, DIRK BACKES, JORDAN KATINE, JÜRGEN LANGER, ANDREW KENT, NEW YORK UNIVERSITY, NEW YORK, NY 10003 USA TEAM, HITACHI-GST, SAN JOSE, CALIFORNIA 95135 USA TEAM, SINGULUS, 63796 KAHL AM MAIN, GERMANY TEAM — Orthogonal spin-transfer magnetic random access memory (OST-MRAM) uses a spin-polarizing layer magnetized perpendicularly to the free layer to achieve large spin-transfer torques and ultrafast energy efficient switching. We have fabricated and studied OST-MRAM devices that incorporate a perpendicularly magnetized polarizer and a magnetic tunnel junction, which consists of an in-plane magnetized free layer and synthetic antiferromagnetic reference layer. A switching probability of 100% is observed for 500 ps pulses, requiring an energy of 250 fJ. The fast switching process indicates there is no incubation delay of several nanoseconds as observed in conventional collinear magnetized devices. Due to the perpendicular polarizer switching is possible for both pulse polarities. There is also evidence for precessional switching in the non-monotonic dependence of the switching probability versus pulse amplitude. This work was supported by Spin Transfer Technologies.

9:12AM V19.00005 The effect of annealing on the spin-transfer torques of MgO MTJ nanopillars , YUN LI, HSIN-WEI TSENG, PINSHANE HUANG, JOHN READ, DAN RALPH, ROBERT BUHRMAN, Cornell University, Ithaca NY 14853 — Thermal annealing is essential for enhancing the tunneling magnetoresistane (TMR) of magnetic tunnel junctions, and many studies have focused on the effect of annealing on MTJ chemical, structural, and electrical transport properties. Here, we report the magnetic, electronic properties and the in-plane and field-like spin-transfer torques (STT) in both as-grown and post-annealed FeCoB/MgO/FeCoB MTJs nanopillars. We find that the 350 $^\circ$C vacuum annealing breaks the symmetry of the bias dependence of the TMR, conductivity, and switching phase diagram (SPD). Moreover STT-FMR measurements indicate that annealing substantially increases the in-plane torque asymmetry with bias voltage direction, as well as affecting the field-like torque magnitude, with the latter indicating a very significant enhancement of interlayer exchange coupling across the barrier. This STT change is consistent with the change in chemical composition and structural coherency of the MTJ interfaces and electrodes, indicated by XRD and analytical STEM analyzes.

9:24AM V19.00006 Bias voltage dependence of the total magnetic field in CoFeB magnetic tunnel junctions[1] , M.D. RIEMER, NYU/IBM Research, J.Z. SUN, IBM Research, A.D. KENT, NYU — We report experimental thermal-noise spectrum-based ferromagnetic resonance (T-FMR) measurements on CoFeB magnetic tunnel junctions in magnetic fields perpendicular to the film plane. The junctions tested have lateral sizes of 45×80 nm^2. In a simple model a dc junction bias voltage should affect both the slope and the intercept of the T-FMR frequency's dependence on applied magnetic field. The intercept would vary linearly with changes in bias voltage due to an electric field-induced change in uniaxial anisotropy [1]. The slope would have a quadratic dependence on changes in bias voltage based on the existence of a perpendicular spin-torque as discussed by Sankey *et al.* [2]. In this experiment we attempt to de-construct the contribution from these two mechanisms. This is done by a careful analysis of the magnetic field dependence of the T-FMR spectra [3].

9:36AM V19.00007 Confirm existence of 90°-type coupling in Fe/MgO/Fe junction by investigating magnetic components perpendicular to the plane of incidence[1] , XIAOJING TAN[2], Department of Physics & Astronomy, University of California, Riverside — We study 90°-type interlayer exchange coupling (IEC) in a Fe/MgO/Fe junction by linear magneto-optical Kerr effect (MOKE) in $p_{in} - p_{out}$ configuration, in which only in-plane magnetization perpendicular to the external field $H$is detected. By investigating the switching processes of the ferromagnetic vectors from parallel with- to perpendicular to H, we find there is a switching correlation between them: the ferromagnetic vector in the bottom layer always follows the switching direction of that in the top layer. Further analysis shows this kind of switching sequence is the direct consequence of 90°-type coupling between the two magnetic vectors, i.e., 90°-type coupling is indeed exists in Fe/MgO/Fe junction.

9:48AM V19.00008 Influence of Interface on Conductance in AlO_x Based Magnetic Tunnel Junctions[1] , FENG GUO, E. DAN DAHLBERG, School of Physics and Astronomy, University of Minnesota — A surprising minimum in the differential conductance at nonzero bias is observed in some magnetic tunnel junctions consisting of CoFe/AlO_x/CoFe; this pronounced conductance feature occurred for electrons tunneling from the bottom to top electrode. The presence of this conductance feature depends upon the oxidation time for creating the barrier from a thin Al layer; for short and moderate oxidation times the feature was present while for long oxidation times the conductance was found to be both symmetric about zero bias and monotonic with increasing bias voltage. To determine the origin of this feature samples were prepared where the oxidation states of the CoFe on each side of the barrier were studied by X-ray photoelectron spectroscopy: the conductance feature is observed only when the top CoFe layer is partially oxidized and it disappears when the CoFe on both sides of the junction has some oxidation present. More interestingly, the bias voltage of the conductance feature decreases with oxidation time. We attribute the differential conductance feature to the electronic structure and the chemical bonding at the bottom CoFe/AlO_x interface.

10:00AM V19.00009 Spin transfer torque in magnetic tunnel junctions with a perpendicularly magnetized polarizer , TAKAHIRO MORIYAMA, THEODORE GUDMUNDSEN, LUQIAO LIU, R.A. BUHRMAN, D.C. RALPH, Cornell University — Spin-torque devices containing magnetic layers with perpendicular magnetic anisotropy are of interest for strategies to reduce the switching currents in memory applications. We report spin-torque-driven ferromagnetic resonance (ST-FMR) measurements of the bias-dependent torque in magnetic tunnel junctions containing $[Co/Ni]_x$ multilayers possessing perpendicular anisotropy, acting as the polarizer layer providing spin-polarized current. We observe unusual dependence of the bias-dependent torque as a function of the magnetic orientation of the $[Co/Ni]_x$ multilayer. We speculate that this sensitivity to the magnetic orientation may originate from changes in the occupation of spin-polarized states at the Co/Ni interfaces associated with the perpendicular magnetic anisotropy.

10:12AM V19.00010 Spin transfer induced domain wall motion by perpendicular current injection in MgO-based magnetic tunnel junctions[1] , A. CHANTHBOUALA, R. MATSUMOTO, J. GROLLIER, V. CROS, A. ANANE, A. FERT, A. V. KHVALKOVSKIY, Unite Mixte de Physique CNRS/Thales, France, K.A. ZVEZDIN, Istituto P.M., Italy, A. FUKUSHIMA, S. YUASA, National Institute of Advanced Industrial Science and Technology, Japan — The spin transfer effect allows to manipulate magnetic domain walls in ferromagnetic wires by current injection. Most experiments use the lateral configuration in which the current is injected directly through the wire where the domain wall (DW) propagates. In this geometry the critical current densities are of the order of 10^8 A.cm^{-2}. Here we show that by using the current-perpendicular to plane geometry, the current densities can be decreased by two orders of magnitude. Depending of the current sign, the DW propagates in the free layer of a magnetic tunnel junction in both directions, inducing large resistance variations. By investigating the physical origin of DW motion, we find that the field-like torque has a large contribution to the effect, as recently predicted by Khvalkovskiy *et al.* (Phys. Rev. Lett. 2009). This result paves the way towards a new type of domain wall based magnetic memories.

10:24AM V19.00011 High Voltage Pulse Measurements of Microwave Emission and Spin-Torque Effects in Magnetic Tunnel Junction , H.W. TSENG, Y. LI, Cornell Univ., J.A. KATINE, HGST, San Jose, CA, P.G. GOWTHAM, D.C. RALPH, R.A. BUHRMAN, Cornell Univ. — The character and strength of the in-plane and field-like spin transfer torque (STT) components in magnetic tunnel junctions at high bias voltages are crucial to the successful utilization of MTJs in STT MRAM. If the field-like torque (FLT), which is generally found to be symmetric with respect to bias direction for moderate voltages, $<$ $\pm$ 0.5 V, is too large it could result in unreliable switching (back-hopping) for negative bias voltage pulses (anti-parallel to parallel switching). Here we discuss pulse measurements of MgO MTJs at high bias that yield important information about the FLT component in the $\pm$ 0.5 to 1.0 V regime through analysis of both the thermally-excited FMR behavior and spin torque driven oscillations. In the structures studied we find a strong and highly asymmetric voltage-dependent FLT at high bias that under some field and voltage conditions can result in large amplitude, incoherent microwave dynamics that could have a strong effect in enhancing back-hopping. We will analyze possible mechanisms, including junction asymmetries and inelastic tunneling.

10:36AM V19.00012 Microwave phase detection with a magnetic tunnel junction[1] , XIN FAN, Department of Physics and Astronomy, University of Delaware, SANGCHEOL KIM, Department of Electrical Engineering and Computer Science, University of Delaware, XIAOMING KOU, Department of Physics and Astronomy, University of Delaware, JAMES KOLODZEY, Department of Electrical Engineering and Computer Science, University of Delaware, HUAIWU ZHANG, State Key Laboratory of Electronic Films and Integrated Devices, University of Electronic Science and Technology of China, JOHN XIAO, Department of Physics and Astronomy, University of Delaware — A magnetic tunnel junction (MTJ) can detect microwave magnetic field due to the interplay between the ferromagnetic resonance and tunneling magneto resistance. Based on the fact that the tunneling resistance change is quadratically proportional to the rf magnetic field, we have designed a mixing circuit in which two microwaves interfere, giving rising to a dc voltage containing the phase difference between the two microwaves. With ability to detect microwave intensity and phase, the MTJ-based device may be used for on-chip microwave network analyzer and spectrum analyzer.

10:48AM V19.00013 Time-resolved detection of spin-transfer-driven ferromagnetic resonance and spin torque measurement in magnetic tunnel junctions[1] , CHEN WANG, Y.-T. CUI, R.A. BUHRMAN, D.C. RALPH, Cornell University — Several experimental techniques have been introduced in recent years in attempts to measure spin transfer torque in magnetic tunnel junctions (MTJs). The dependence of spin torque on bias is important for understanding fundamental spin physics in magnetic devices and for applications. However, previous techniques have provided only indirect measures of the torque and their results to date for the bias dependence are qualitatively and quantitatively inconsistent. Here we demonstrate that spin torque in MTJs can be measured directly by using time-domain techniques to detect resonant magnetic precession in response to an oscillating spin torque. The technique is accurate in the high-bias regime relevant for applications, and because it detects directly small-angle linear-response magnetic dynamics caused by spin torque it is relatively immune to artifacts affecting competing techniques. At high bias we find that the spin torque vector differs markedly from the simple lowest-order Taylor series approximations commonly assumed.

[1]We acknowledge J.A. Katine and D. Mauri for fabrication of the devices used in our experiment.

Session V20 FIAP/DMP GERA/DCOMP: Focus Session: Physics of Energy Storage Materials V – Thermal Storage and Conventional Hydrides D168

8:00AM V20.00001 Origin of the Diverse Melting Behaviors of Aluminum Nanoclusters with Around 55 Atoms[1] , JOONGOO KANG, SU-HUAI WEI, National Renewable Energy Laboratory, YONG-HYUN KIM, Korea Advanced Institute of Science and Technology — Microscopic understanding of thermal behaviors of metal nanoparticles is important for nanoscale catalysis and thermal energy storage applications. Using first-principles molecular dynamics simulations, we reveal the microscopic origin of the diverse melting behaviors of Al_N clusters with N around 55 [1,2]. The conceptual link between the degree of symmetry (e.g., T_d, D_{2d} and C_s) and solidity of atomic clusters is quantitatively demonstrated through the analysis of the configuration entropy. The size-dependent, diverse melting behaviors of Al clusters originate from the reduced symmetry ($T_d \rightarrow D_{2d} \rightarrow Cs$) with increasing the cluster size. In particular, the sudden drop of the melting temperature and appearance of the dip at N = 56 are due to the T_d-to-D_{2d} symmetry change, triggered by the surface saturation of the tetrahedral Al_{55} with the T_d symmetry.

8:12AM V20.00002 Azonbenzene-functionalized carbon nantubes as a high energy density solar thermal fuel , ALEXIE KOLPAK, ENGIN DURGAN, JEFF GROSSMAN, Massachusetts Institute of Technology — Solar thermal fuels, which store energy from the sun in the chemical bonds of molecules, are a fascinating energy storage prospect: in principle they are 100% renewable, produce no emissions or by-products, are easily transportable in the form of liquids or powders, and can be recharged by the sun without any special equipment. However, adaptation of solar fuels as a viable, low-cost, large-scale means of energy storage will require the discovery of new materials other than the one known case based on Ruthenieum that can perform the process over many cycles with no degradation. Here we discuss a novel approach to the design of solar fuels based on photoswitchable molecules covalently bonded to carbon nanotubes (CNTs). Using density functional theory, we examine the potential for maximizing the energy density via a combination of steric and intermolecular interactions between metastable azobenzene photoisomers and a CNT substrate. In addition, we investigate how a tuning parameter unique to the nanoparticle/molecule geometry — the packing density of the molecules on the nanotube — can be varied to produce significant, controlled changes in the transition pathway and barriers via ordered molecule-molecule interactions, potentially leading to new classes of nanoparticle-based solar fuels.

8:24AM V20.00003 A high volume, high throughput volumetric sorption analyzer[1] , Y.C. SOO, M. BECKNER, J. ROMANOS, C. WEXLER, P. PFEIFER, U of Missouri, P. BUCKLEY, J. CLEMENT, MRI — In this talk we will present an overview of our new Hydrogen Test Fixture (HTF) constructed by the Midwest Research Institute[2] for The Alliance for Collaborative Research in Alternative Fuel Technology[3] to test activated carbon monoliths for hydrogen gas storage. The HTF is an automated, computer-controlled volumetric instrument for rapid screening and manipulation of monoliths under an inert atmosphere (to exclude degradation of carbon from exposure to oxygen). The HTF allows us to measure large quantity (up to 500 g) of sample in a 0.5 l test tank, making our results less sensitive to sample inhomogeneity. The HTF can measure isotherms at pressures ranging from 1 to 300 bar at room temperature. For comparison, other volumetric instruments such as Hiden Isochema's HTP-1 Volumetric Analyser can only measure carbon samples up to 150 mg at pressures up to 200 bar.

8:36AM V20.00004 Synthesis of Li_2MgIr and $LiMgIrH_6$: Guidance from DFT , JAN HERBST, JAMES SALVADOR, MARTIN MEYER, GM R&D Center — Formation of Li_2MgIr was suggested by theoretical modeling of Li_2MgX systems and their hydrides with density functional theory (DFT). Verifying our DFT results, we have synthesized Li_2MgIr and determined its crystal structure and hydrogen sorption behavior. The phase crystallizes in the cubic $P\bar{4}3m$ space group and is isostructural to the known ternary Li_2MgSi. Its reaction with hydrogen proceeds according to $Li_2MgIr + \frac{7}{2}H_2 \rightarrow LiMgIrH_6 + LiH$. The hydride $LiMgIrH_6$ also features $P\bar{4}3m$ symmetry; its detailed crystal structure is established via a combination of x-ray diffraction and DFT analyses. A metal $\rightarrow$ insulator transition accompanies formation of the hydride.

8:48AM V20.00005 Thermodynamics of MgH_2 hydrogen storage materials: nanoparticle size and topological structure effects[1] , JASON REICH, Chemisry, University of Illinois, Urbana-Champaign, IL 61801, LINLIN WANG, DUANE JOHNSON, Ames Laboratory/US DoE, Iowa State University, Ames, IA 50011-3020 — Via plane-wave-based Density Functional Theory calculations, we investigate H-desorption from (110) rutile MgH_2, a surface step, and surfaces of nanoscale $Mg_{30}XH_{62}$ clusters having catalytic dopants (X=Mg, Ti, or Fe). All calculated desorption enthalpies are endothermic, in contrast to results in the literature,[2] and no particle size effect is found for desorption of H singly, doubly, or triply-bonded to metal atoms, indicating only local bond energy is relevant. In contrast to recent results, we show that exothermic results are not obtained when initial cluster structures are carefully relaxed globally via simulated annealing, in which amorphous structures are found to be favored. A topological feature is identified that offers potential utility for using nanostructured MgH_2 as a hydrogen-storage solution.

9:00AM V20.00006 Hydrogen desorption from $MgH_2(110)$ surface with transition-metal catalyst: a DFT study of energetics and barriers[1] , LIN-LIN WANG, DUANE D. JOHNSON, Division of Materials Science and Engineering, Ames Laboratory/US DoE, Iowa State University, Ames, IA 50011-3020 — Transition-metal (TM) catalysts are widely used in hydrogen-storage materials to increase hydrogen absorption and desorption kinetics. Using density functional theory calculations, we elucidate the catalytic effect of Ti on H-desorption from $MgH_2(110)$ surface. Kinetic energy barriers of different reaction pathways of hydrogen desorption are calculated via nudged-elastic-band method. We find that Ti dopant is effective in reducing kinetic barriers, in agreement with experimental observations. We also find that magnetic degrees of freedom must be carefully included to describe the change of magnetic states during catalytic-enhanced desorption. As vacancy migration barriers are lower than desorption barrier, bulk diffusion of H inherently feeds into the favorable surface desorption mechanism.

[1]Supported by the DOE/BES under DE-FG02-03ER15476 (Catalysis), DEFC36-05GO15064 (Sandia Metal-Hydride Center of Excellence), DE-FG02-03ER46026 (Materials), and DE-AC02-07CH11358 at the Ames Laboratory operated by Iowa State University

9:12AM V20.00007 Tuning the Hydrogen Storage in Magnesium Alloys , SULEYMAN ER, University of Twente, GILLES A. DE WIJS, GEERT BROCKS — We investigate the hydrogen storage properties of promising magnesium alloys. MgH_2 (7.6 wt % H) would be a very useful storage material if the (de)hydrogenation kinetics can be improved and the desorption temperature is markedly lowered. Using first principles calculations, we show that hydrides of Mg-transition metal (TM) alloys adopt a structure that promotes faster (de)hydrogenation kinetics, as is also observed in experiment [1]. Within the lightweight TMs, the most promising alloying element is titanium. Alloying Mg with Ti alone, however, is not sufficient to decrease the stability of the hydride phases, which is necessary to reduce the hydrogen desorption temperature [2]. We find that adding aluminium or silicon markedly destabilizes Mg-Ti hydrides and stabilizes Mg-Ti alloys. Finally, we show that controlling the structure of Mg-Ti-Al(Si) system by growing it as multilayers, has a beneficial influence on the thermodynamic properties and makes it a stronger candidate for hydrogen storage [3].

9:24AM V20.00008 Neutron, Thermodynamic, and Modeling Studies of Hydrogen Interaction with MgO(100) , JOHN LARESE, University of Tennessee, L.L. DAEMEN, Los Alamos National Lab, J. OLLIVIER, T. SEYDEL, Institut Laue-Langevin, E. CRUZ SILVIA, B. SUMPTER, Oak Ridge National Lab — We report our investigations of thermodynamic, neutron diffraction, inelastic and quasielastic neutron scattering (INS and QENS) studies of hydrogen adsorbed onto MgO(100). Guided by our volumetric adsorption measurements, we used INS and QENS to probe the dynamics of the adsorbed H2 molecules. Our structural studies indicate that near monolayer completion the intermolecular distance of the H2 molecules on MgO are $\sim$20% more compressed than the closest packed bulk solid plane. The melting of this compressed solid takes place at temperatures above the bulk triple point, whereas most other 2D films melt at about 70% of the triple point. Using INS, the motion of the adsorbed hydrogen is examined as a function of film thickness. For rotational motions, we use the ortho-to-para transition as a guide and find that the rotational barrier for H2 adsorbed on MgO is shifted to lower energy at low surface coverage. These results are compared with modeling for additional insight into the microscopic processes that underpin the observed behavior. This work partially supported by the U.S. DOE, BES under contract DE-AC05-00OR22725 with ORNL managed and operated by UT-Battelle, LLC, the NSF under grant DMR-0412231 and a grant from the University of TN, JINS.

9:36AM V20.00009 Enhanced Hydrogen Storage Properties of Magnesium Nanotrees by Glancing Angle Deposition , MEHMET CANSIZOGLU, TANSEL KARABACAK, Department of Applied Science, University of Arkansas at Little Rock, Little Rock, AR, 72204 — Magnesium has a high hydrogen storage capacity of 7.6 wt %. In addition it is one of the most abundant low cost materials in nature. However, absorption/desorption of hydrogen in Mg mainly suffer from slow kinetics. In this study, we investigate the hydrogen storage properties of Mg "nanotrees with nanoleaves" fabricated by glancing angle deposition (GLAD) method and compare to those of conventional thin films of Mg. A recently developed quartz crystal microbalance (QCM) gas absorption/desorption technique was used for hydrogen storage measurements on our thin film and nanostructured coatings. Storage experiments were performed at temperatures between 100-300 $^{\circ}$C, and at 30 bars of H_2 pressure. Our results reveal that Mg nanotrees have significantly faster kinetics and lower absorption temperatures for hydrogen storage compared to Mg thin films. The enhancement in absorption properties is believed to be due to decreased diffusion lengths, favorable crystal orientations for diffusion of hydrogen, and resistance to surface oxidation of Mg nanotrees.

9:48AM V20.00010 Neutron spectroscopy of gamma-MgH2 , ALEXANDER KOLESNIKOV, Oak Ridge National Laboratory, VLADIMIR ANTONOV, VADIM EFIMCHENKO, Inst. Solid State Phys. RAS, Chernogolovka, Russia, GARRETT GRANROTH, Oak Ridge National Laboratory, S.N. KLYAMKIN, Moscow State Un., Russia, A.V. LEVCHENKO, MICHAEL SAKHAROV, Inst. Solid State Phys. RAS, Chernogolovka, Russia, YANG REN, Argonne National Laboratory, TIMMY RAMIREZ-CUESTA, ISIS, Rutherford Appleton Laboratory, UK — Under ambient conditions, magnesium dihydride exists in two forms, alpha-MgH2 (the most stable modification) and gamma-MgH2 (a less stable modification). The alpha-phase partly transforms to gamma-MgH2 in the course of ball-milling and under high pressure and temperature. Due to the high hydrogen content of 7.6 wt.%, MgH2 has been intensively studied as a prospective material for hydrogen storage. By exposing of alpha-MgH2 to a pressure of 5 GPa and temperature 840 K, we prepared a sample, in which about 60% of the alpha-MgH2 was transformed to gamma-MgH2. We have measured inelastic neutron scattering (INS) spectra of both the high pressure treated MgH2 and starting alpha-MgH2, and extracted the spectrum for gamma-MgH2. The differences between the INS spectra and their agreement with the first-principles calculations for these compounds will be discussed.

10:00AM V20.00011 The chemical potential of hydrogen in Mg-films and metal-doped carbon nanostructures[1] , MINA YOON, Oak Ridge National Laboratory and Fritz-Haber-Institut der Max-Planck-Gesellschaft, HANNO WEITERING, ZHENYU ZHANG, Oak Ridge National Laboratory — We use first-principles density functional theory to study the binding mechanism of hydrogen to nanoscale systems. We investigate the performance of the exchange-correlation functional in describing the interaction between hydrogen and metal systems and the importance of the vibrational contribution in the formation enthalpy. In ultrathin Mg films the stability of hydrides is much lower than in the corresponding bulk systems and it can be modified by metal alloying. We calculate the chemical potential of hydrogen in Mg films for different dopant species and film thicknesses while including all vibrational degrees of freedom. By comparing the chemical potential with that of free hydrogen gas at finite temperature and pressure, we construct a hydrogenation phase diagram and identify the conditions for hydrogen absorption/desorption. The vibrational contribution to the chemical potential of hydrogen becomes more prominent for dihydrogen adsorption to metals, where its significance dramatically changes depending on the binding characteristics. This feature is illustrated by the example of metal-doped nanocarbon systems.

10:12AM V20.00012 Computational search for hydrogen storage materials: accuracy and alloys[1] , LUCAS WAGNER, Massachusetts Institute of Technology, ERIC MAJZOUB, University of Missouri-Saint Louis, MARK ALLENDORF, Sandia National Labs, JEFFREY GROSSMAN, Massachusetts Institute of Technology — Metal hydride materials are among the strongest contenders for hydrogen storage, offering good weight and volume density. The main reason that these materials are not used now is that it is very challenging to find a material that is both light enough and has the proper binding to allow for easy absorption/desorption near room temperature. We will evaluate two routes to controlling the binding energy: particle size and alloy composition using the highly accurate quantum Monte Carlo method. We find that traditional methods of calculating the binding energy such as the Wulff construction and density functional theory should be applied with caution, as they can lead to misleading results. We will also report on the prospects for finding a sweet spot of size and alloy composition that has the correct binding energy for hydrogen storage applications.

[1]Supported by the Department of Energy.

10:24AM V20.00013 Ultra-low diffusion barriers for the AlH_3-related vacancies in γ-$NaAlH_4$, FENG ZHANG, YAN WANG, MEI-YIN CHOU, School of Physics, Georgia Institute of Technology — It has been suggested that the diffusion of AlH_3-related vacancies plays an essential role in the decomposition of $NaAlH_4$, a prototypical material for hydrogen storage[1,2]. We find from first-principles calculations that the diffusion barrier for both the neutral AlH_3 vacancy and the charged AlH_4^- vacancy in the newly proposed γ-phase of $NaAlH_4$ [3] is only about 0.1 eV, much lower than the barrier for the diffusion of corresponding vacancies in the conventional α-phase 0.5 eV, calculated with the same method. Possible schemes to facilitate the $\alpha \rightarrow \gamma$ phase transformation in order to improve the kinetics of the decomposition reaction of $NaAlH_4$ will also be discussed.

10:36AM V20.00014 Defect-mediated Alane formation on Ti-doped Al(111) surfaces: a DFT study , ADITI HERWADKAR, LIN-LIN WANG, DUANE D. JOHNSON, Ames Laboratory/US Department of Energy, Iowa State University — Understanding of Alane (AlH_3) formation on Al surface remains elusive, including interpreting STM results under various conditions. Using density functional theory calculations, we study Alane formation on close-packed (111) and stepped surfaces with {111} and {100} microfacets of Al, with and without Ti as a catalyst. We find that Ti dopants act as catalyst in the formation of Alane on Al(111) via a vacancy-mediated mechanism. Additionally, we find the Alane formation energy at steps is 40% less than that from the flat surface. We assess the energetics of various surface-defect configurations to understand the concerted roles that Ti dopants, surface vacancies, and step defects play in Alane formation. Work was supported in part by Department of Energy, Office of Basic Energy Science under contract DEFC36-05GO15064 (Sandia Metal-Hydride Center of Excellence), DE-FG02-03ER15476, DE-FG02-03ER46026, and DE-AC02-07CH11358 at the Ames Laboratory operated by Iowa State University.

10:48AM V20.00015 Molecular hydrogen interaction with Ti doped Al(111) surfaces , IRINDER CHOPRA, University of Texas at Dallas, SANTANU CHAUDHURI, Washington state University, JEAN-FRANCOIS VEYAN, YVES CHABAL, University of Texas at Dallas — Alanates are promising hydrogen storage materials, but have poor re-hydrogenation kinetics. Decomposition[1] of $NaAlH_4$ can be made reversible at reasonable temperatures and pressures by adding titanium. There is however little understanding of the role of Ti as a catalyst,[2] and no experimental evidence for H_2 dissociation on Ti-doped Al surfaces. Using CO as a probe molecule in conjunction with in-situ infrared absorption spectroscopy, we present unambiguous evidence for molecular hydrogen dissociation, chemisorptions and spill over on with Ti doped Al(111) surfaces. The optimum catalytic activity of the Ti-doped Al surface occurs for a Ti coverage of 0.1 monolayer. At high hydrogen coverage, no CO physisorption is observed, indicating that the dissociated hydrogen spill over from the catalytic active Ti site. CO molecules can be chemisorbed at the catalytic sites but do not spill over. These findings provide important information on the nature of the catalyst during the hydrogenation reactions.

Session V21 DCOMP FEd: Focus Session: Teaching Computational Physics to Classroom and Research Students D161

8:00AM V21.00001 Computational (Physics Education) vs. (Computational Physics) Education: Many Body for Anybody , ROBERT PANOFF, Shodor Education Foundation — The substantial role of computational approaches to physics research is not currently reflected proportionately in how we prepare future physicists. We can do better in using computation to teach the concepts of physics –Computational (Physics Education) – and to prepare students to be computational physicists – (Computational Physics) Education. We have the opportunity to demonstrate that effective use of computing in physics really matters. A computational approach in physics education is essential because quantitative reasoning, computational thinking, and multiscale modeling are the intellectual "heart and soul" of 21st Century physics and therefore are the essential skills of the 21st Century physicist. Computing matters because we can apply the power of interactive computing to reach a deeper understanding of physics and the mathematics underlying the theory and their role in understanding the world. We will explore a transformation in physics education, supported by interactive computing resources, promoting a dynamic encounter with the world through guided discovery. We will explore a variety of free and low-cost sources for modeling tools from Shodor and its Computational Science Education Reference Desk, a pathway project of the National Science Digital Library.

8:36AM V21.00002 ABSTRACT WITHDRAWN –

8:48AM V21.00003 Computing Band Structures in Undergraduate Solid State , JAVIER HASBUN, University of West Georgia — Understanding band structures is quite challenging for undergraduate solid state physics students. Calculating the band structures is even more difficult. However, using the techniques developed earlier [1], and which were applied to the simple cubic structures, it is possible to extend them to semiconducting systems in a simple way. The idea is to employ the 8-band model concept of Harrison's Hamiltonian approach [2] to model and parametrize the bands. The method also uses the system's band structure's Green's function and employs the k-space Brillouin-zone ray approach [3] combined with a complex integration method [4] to obtain the density of states. The number of occupied electron states up to a certain energy is obtained using Romberg's method and example results will be shown. 9:00AM V21.00004 Introducing Computational Physics in Introductory Physics using Intentionally Incorrect Simulations[1] , ANNE COX, Eckerd College — Students in physics courses routinely use and trust computer simulations. Finding errors in intentionally incorrect simulations can help students learn physics, be more skeptical of simulations, and provide an initial introduction to computational physics. This talk will provide examples of electrostatics simulations that students can correct using Easy Java Simulations and are housed in the Open Source Physics Collection on ComPADRE (http://www.compadre.org/osp).

[1]Partial support through the Open Source Physics Project, NSF DUE-0442581.

9:12AM V21.00005 Computational ... Physics Education: Letting physics learning drive the computational learning[1] , NORMAN CHONACKY, Yale University — For several years I have been part of a team researching and rethinking why physicists are more willing to admit the value of computational modeling than to include it in what they teach. We have concluded that undergraduate faculty face characteristic barriers that discourage them from starting to integrate computation into their courses. Computational tools and resources are already developed and freely available for them to use. But there loom ill-defined "costs" to their course learning objectives and to them personally as instructors in undertaking this. In an attempt to understand these issues more deeply, I placed myself in the mindset of a relative novice to computational applications. My approach: focus on a physics problem first and then on the computation needed to address it. I asked: could I deepen my understanding of physics while simultaneously mastering new computational skills? My results may aid appreciation of the plight of both a novice professor contemplating the introduction of computation into a course and the students taking it. These may also provide insight into practical ways that computational physics might be integrated into an entire undergraduate curriculum.

9:48AM V21.00006 Teaching computational physics: An embarrassment of riches for teaching computational physics , AMY BUG, Swarthmore College, LARRY ENGELHARDT, Francis Marion University — The first decade of the 21st century has provided a wealth of exceptional resources for teaching computational physics, including numerous textbooks, libraries of computer codes (visual as well as numerical), and high-level interfaces for accessing these libraries. We are now faced with the very real challenge of choosing which of these resources to incorporate into the finite number of courses available in a given curriculum. This choice depends on several factors: How much time can be allocated to teaching computational methods and at what stage in the curriculum? What are the goals? (Learning physics better? Being prepared to work in research labs studying large-scale problems?) Are commercial packages an appropriate option for your student population? In recent years one of us (L.E.) has taught three undergraduate computational physics courses per year. The other (A.B.) has taught at various points in the undergraduate spectrum (a seminar for seniors, a computational methods lab for sophomores, a summer research experience for freshmen from underrepresented groups). Thus, while there are no right or wrong answers to these questions, we will present some of the decisions we have made, and will discuss the consequences.

10:00AM V21.00007 A course in Computational Physics , GEORGE RAWITSCHER, University of Connecticut — This course, taught at UConn, has several objectives: 1) To make the students comfortable in using MATLAB; 2) To reveal the existence of unavoidable inaccuracies due to numerical roundoff errors and algorithm inaccuracies; 3) to introduce modern spectral expansion methods [1], and compare them with conventional finite difference methods. Some of the projects assigned in the course will be described, such as the motion of a falling parachute, and the vibrations of an inhomogeneous vibrating string [2].

10:12AM V21.00008 Using Python as a first programming environment for computational physics in developing countries , GODFREY AKPOJOTOR, Physics Department, Delta State University, Abraka, Nigeria, LOUIS EHWERHEMUEPHA, Physics Department, University of Lagos, Lagos, Nigeria, MYRON ECHENIM, Physics Department, Delta State University, Abraka, Nigeria, FAMOUS AKPOJOTOR, Physics Department, University of Benin, Benin City, Nigeria — Python unique features such its interpretative, multiplatform and object oriented nature as well as being a free and open source software creates the possibility that any user connected to the internet can download the entire package into any platform, install it and immediately begin to use it. Thus Python is gaining reputation as a preferred environment for introducing students and new beginners to programming. Therefore in Africa, the Python African Tour project has been launched and we are coordinating its use in computational science. We examine here the challenges and prospects of using Python for computational physics (CP) education in developing countries (DC). Then we present our project on using Python to simulate and aid the learning of laboratory experiments illustrated here by modeling of the simple pendulum and also to visualize phenomena in physics illustrated here by demonstrating the wave motion of a particle in a varying potential. This project which is to train both the teachers and our students on CP using Python can easily be adopted in other DC.

10:24AM V21.00009 Undergraduate research in numerical relativity: How to put a black hole on a graphics card , JASON D. GRIGSBY, Friedrich-Schiller-University of Jena — Andreas Weyhausen, a diploma student at the Friedrich-Schiller University, ported a standard code for the full 3D stable simulation of black holes to run on a graphics processing unit (GPU), a first in the field. A presentation will be made describing the task he accomplished with key results, including a speed-up comparison to the serial code. This will be placed in context of the course work that prepared him for the project and advising provided by the FSU gravity group prior, during and after the execution leading to his thesis on Numerical Algorithms of General Relativity for Heterogeneous Computing Environments.

Thursday, March 24, 2011 8:00AM - 11:00AM –

Session V22 DCMP: Magnetic Phase Transitions I D163

8:00AM V22.00001 Pressure-induced antiferromagnetism in pure CeFe2 , JIYANG WANG, THOMAS ROSENBAUM, U. of Chicago, YEJUN FENG, Argonne National laboratory, RAFAEL JARAMILLO, Harvard University, SARA HARAVIFARD, Argonne National laboratory — CeFe2 is a ferromagnet that exhibits antiferromagnetic fluctuations in its ground state at low temperature. We use x-ray diffraction to measure directly the emergence of antiferromagnetic order in pure CeFe2 at high pressure. We present an analysis of both the magnetic and lattice symmetries in the newly discovered high pressure phase, and compare our results to those from doped CeFe2 systems. This comparison provides insights into the roles of pressure and chemical doping in driving the magnetic quantum phase transition.

8:12AM V22.00002 Transition-metal dihalide MX_2 as magnetoelectric multiferroics , SHINICHIRO SEKI, TAKASHI KURUMAJI, SHINTARO ISHIWATA, HIROYUKI MATSUI, YOSHINORI TOKURA, University of Tokyo, HIROSHI MURAKAWA, YUSUKE TOKUNAGA, YOSHIO KANEKO, ERATO-JST, TATSUO HASEGAWA, AIST — Magnetoelectric properties were investigated for transition-metal dihalide MX_2, which turns out to be the first example of non-chalcogen based spiral-spin induced multiferroics. We discovered the emergence of ferroelectric polarization (P) in helimagnetic state for several compounds such as $CuCl_2$ with edge-shared $S = 1/2$ chain and MnI_2 with stacked triangular lattice. In the latter material, in-plane magnetic field (H) was found to induce the rearrangement of six possible multiferroic domains. With every $60°$-rotation of H around the c-axis, discontinuous $120°$-flop of P-vector is observed as a result of the flop of magnetic modulation vector (q). In-plane H also alters the stable direction of q-vector from original $q \parallel \langle 1\bar{1}0 \rangle$ to $q \parallel \langle 110 \rangle$ above 3 T, which leads to significant change of P-flop patterns under rotating H. At the critical field region ($\sim$ 3T), due to the enhanced q-flexibility, P-vector smoothly rotates clockwisely twice while H rotates counter-clockwisely only once.

8:24AM V22.00003 Infrared spectroscopy of phonons and electromagnons in multiferroic $TbMnO_3$, R.P.S.M. LOBO, R. SCHLECK, LPEM, ESPCI-ParisTech, CNRS, Paris, France, R.L. MOREIRA, Depto. Fisica, UFMG, Brazil, H. SAKATA, Dept. Physics, Tokyo Univ. Science, Japan — We measured the temperature dependent infrared reflectivity spectra of $TbMnO_3$ with the electric field of light polarized along each of the three crystallographic axes. We analyzed the effect, on the phonon spectra, of the different phase transitions occurring in this material. We show that the antiferromagnetic transition at T_N renormalizes the phonon parameters along the three directions. Our data indicate that the electromagnon, observed along the a direction, has an important contribution in building the dielectric constant. We show that this electromagnon spectral weight comes only from a few phonons which can be clearly identified. We also determined that only one phonon, observed along the c-axis, has anomalies at the ferroelectric transition. This phonon is built mostly from Mn vibrations, suggesting that Mn displacements are closely related to the formation of the ferroelectric order.

8:36AM V22.00004 Ultrafast pump-probe spectroscopy of multiferroic $TbMnO_3$, JINGBO QI, LI YAN, STUART TRUGMAN, JIANXIN ZHU, ALEXANDER BALATSKY, QUANXI JIA, ANTOINETTE TAYLOR, ROHIT PRASANKUMAR, Los Alamos National Laboratory, CENTER FOR INTEGRATED NANOTECHNOLOGIES TEAM — $TbMnO_3$, exhibiting simultaneously both magnetic and ferroelectric phases, is an excellent multiferroic candidate for demonstrating the strong coupling between different degrees of freedom, i.e. spin, orbital and charge order. Previously, ultrafast optical pump-probe spectroscopy has proven to be an ideal technique for unraveling the interplay between different orders in the time domain. In this work, we used this technique to study ultrafast dynamics in multiferroic $TbMnO_3$. At low temperatures, we initially observed an extraordinarily slow rising process, with a timescale of tens of picoseconds, followed by another decay process with a relaxation time of hundreds of picoseconds. An analysis of these two processes as a function of temperature reveals the influence of the magnetic and ferroelectric phase transitions on carrier dynamics in $TbMnO_3$, which agrees well with other experimental results.

8:48AM V22.00005 Photoinduced Femtosecond Formation of Ferromagnetism in a Strongly Correlated Antiferromagentic Manganite , TIANQI LI, AARON PATZ, Dept. of Physics and Astronomy, Iowa State University; Ames Lab - USDOE, JIAQIANG YAN, THOMAS LOGRASSO, Ames Lab - USDOE, JIGANG WANG, Dept. of Physics and Astronomy, Iowa State University; Ames Lab - USDOE — There has been strong current interest to manipulate collective spins and even induce magnetic phase transitions in their highly *non-equilibrium, non-thermal* states at *femtosecond* time scales. Such processes offer opportunities to exceed the upper limit of the magnetic switching speed (0.1-10 GHz) in modern magneto-optical recording industry and magnetic storage/logic devices. One prominent system to explore such femtosecond magnetism is strongly correlated manganites, which are truly "responsive" near the phase boundary, exhibiting extreme sensitivity to external stimuli, such as light, electric and magnetic fields. Using ultrafast two-color magnetic circular dichroism spectroscopy, we have observed a substantial photoinduced magnetization enhancement in $Pr_{0.7}Ca_{0.3}MnO_3$ within 180 fs above a threshold pump fluence and at low temperature. Such a photoinduced critical behavior vanishes at elevated temperature. These results clearly show a photoinduced ultrafast antiferromagnetic to ferromagnetic phase transition, demonstrating particularly, that one can reveal a hidden, thermally inaccessible ground state at fs time scales.

9:00AM V22.00006 Polaron Glass in $La_{0.35}Pr_{0.275}Ca_{0.375}MnO_3$[1] , MARK BURKHARDT, Stanford University and SLAC National Accelerator Laboratory, M.A. HOSSAIN, S. SARKAR, J. STÖHR, SLAC National Accelerator Laboratory, Y.-D. CHUANG, A.G. CRUZ GONZALEZ, A. DORAN, A. SCHOLL, A.T. YOUNG, Advanced Light Source, Lawrence Berkeley National Laboratory, Y.J. CHOI, S.-W. CHEONG, Rutgers Center for Emergent Materials and Department of Physics & Astronomy — Manganite compounds in the $La_{1-x-y}Pr_yCa_xMnO_3$ series are known for exhibiting phase separation over a large temperature range. We combined the x-ray photoemission electron microscopy (PEEM) and resonant elastic soft x-ray scattering (REXS) techniques to study the interplay between the ferromagnetic and charge-ordered/antiferromagnetic phases, respectively, in $La_{0.35}Pr_{0.275}Ca_{0.375}MnO_3$. We found a polaronic glassy state at intermediate temperatures, when the material is dominated by charge- and orbital-order domains. When the sample is cooled below T_C, the magnetization increases, accompanied by a relaxation of the lattice deformations that accompany the polaron glass.

[1]This Work and the Advanced Light Source are funded by the DOE Office of Basic Energy Science.

9:12AM V22.00007 The role of oxygen in the colossal magnetoresistance in manganites[1] , M.A. HOSSAIN, M.H. BURKHARDT, SIMES, Stanford, S. SARKAR, H. OHLDAG, S. DE JONG, SLAC, A. SCHOLL, A.T. YOUNG, A. DORAN, Y.-D. CHUANG, Berkeley Lab, D. DESSAU, U. Colorado, J. MITCHELL, Argonne Lab, H.A. DÜRR, J. STÖHR, SLAC — We have used Low temperature Photo-Emission Electron Microscopy (PEEM) measurements on the bi-layered manganite compound $La_{1.8}Sr_{1.2}Mn_2O_7$ to explore the origin of the colossal magnetoresistance (CMR) effect. It is generally agreed that CMR cannot be explained by double exchange only, and that other interactions mediated by oxygen atoms such as polarons must be important. We have imaged the magnetic domain structure by x-ray magnetic circular dichroism PEEM spectro-microscopy at both the O and Mn sites. By probing the ferromagnetic domain formation below T_c, we find that the insulator-to-metal transition is mediated by magnetic interactions involving a strong magnetic moment on oxygen. The spatially resolved oxygen K-edge XMCD signal reveals the role of the in-plane and out-of- plane e_g orbitals in the magnetic transitions and thereby sheds light on the very origin of CMR.

[1]DOE, NSERC

9:24AM V22.00008 Momentum-Space Dichotomy in the Metal-Insulator Transition in doped EuO , DANIEL SHAI, ALEXANDER MELVILLE, JOHN HARTER, ERIC MONKMAN, DAWEI SHEN, DARRELL SCHLOM, KYLE SHEN, Cornell University — EuO possesses a wide variety of remarkable properties, most which can be accessed only upon carrier doping. In addition to its large ferromagnetic moment (S = 7/2), doped EuO exhibits a metal-insulator transition with a change in resistivity of over 10^{13} and highly spin polarized carriers. Furthermore, the ferromagnetic Curie temperature can be enhanced from 69 K in undoped EuO to over 200 K in carrier doped EuO. We present angle-resolved photoemission studies of $Eu_{1-x}Gd_xO$ thin films which elucidate the electronic structure and mechanism of the metal-insulator transition. Our ARPES studies verify that the exchange coupling between the Eu 4f moments and the delocalized Eu 5d states pushes the bottom of the majority-spin conduction band through E_F below T_C. We also reveal a surprising dichotomy between the delocalized carriers at the Brillouin zone boundary below T_C, and localized carriers around the zone center above T_C which are responsible for the respective low-temperature ferromagnetic metallic and high-temperature paramagnetic semiconducting behaviors observed in transport measurements.

9:36AM V22.00009 Anharmonic Lattice Effect in the Giant Negative Thermal Expansion Antiperovskite $Cu_{1-x}Sn_xNMn_3$, PENG TONG, DESPINA LOUCA, Department of Physics, University of Virginia, GRAHAM KING, ANNA LLOBET, Los Alamos National Laboratory, BOSEN WANG, YUPING SUN, Institute of Solid State Physics, Chinese Academy of Sciences — The antiperovskite $ANMn_3$ (A: transitional metals and semiconducting elements) often shows a large, discontinuous volume contraction at the magnetic transition associated with a large negative thermal expansion (NTE). The NTE property was initially observed in $Cu_{1-x}Ge_xNMn_3$ where Ge-doping broadens the discontinuous volume contraction. It was recently reported that although the average symmetry is cubic in the solid solutions, locally, the symmetry is tetragonal with the I4/mcm symmetry of the end member $GeNMn_3$. We investigated the local structure of a "Ge"-free NTE system, the $Cu_{1-x}Sn_xNMn_3$ with x= 0.1 and 0.5. On average, both compounds are cubic at all temperatures. At base temperature, the local structure is cubic as well. As the temperature rises however, local lattice distortions evidenced by the splitting of the Mn-Cu and Mn-Sn bonds are observed. This local distortion can be described by the I4/mcm symmetry but this symmetry is different from the P4/mmm symmetry of $SnNMn_3$. The splitting of the Mn-Cu and Mn-Sn bond gives rise to a local lattice anharmonicity that may in turn be significant in the NTE behavior in this class of compounds.

9:48AM V22.00010 Magneto-elastic coupling in molecule-based materials: $[Ru_2(O_2CMe)_4]_3[Cr(CN)_6]$ and $Mn[N(CN)_2]_2$[1] , T.V. BRINZARI, Q.-C. SUN, J.L. MUSFELDT, University of Tennessee, L.-C. TUNG, Y.J. WANG, National High Magnetic Field Laboratory, J. LIU, M.-H. WHANGBO, North Carolina State University, J.S. MILLER, University of Utah, J.L. MANSON, Eastern Washington University, J.A. SCHLUETER, Argonne National Laboratory — We measured the infrared vibrational response of two prototypical molecule-based magnets, $[Ru_2(O_2CMe)_4]_3[Cr(CN)_6]$ and $Mn[N(CN)_2]_2$. We find that both temperature and magnetic field driven transitions impact spin-lattice interactions in these materials. For instance, through the Néel transition, Cr–CN stretching and bending modes as well as Ru-O stretching mode in $[Ru_2(O_2CMe)_4]_3[Cr(CN)_6]$ display sudden frequency shifts and a strong hysteresis that reveal local structure changes around Cr and Ru centers in response to magnetic ordering. On the other hand, the dicyanamide ligands in $Mn[N(CN)_2]_2$ display pronounced sensitivity to the 30 T magnetic quantum critical transition, in line with our calculations that point toward the importance of N–C–N and C–N–C angles for the mediation of Mn$\cdots$Mn spin exchange interactions.

10:00AM V22.00011 Neutron diffraction study of the magnetic order in magnetic coordination polymer $CuF_2(H_2O)_2(pyz)$ (pyz=pyrazine) , CUIHUAN WANG, MARK D. LUMSDEN, ANDREW D. CHRISTIANSON, Oak Ridge National Laboratory, JOHN A. SCHLUETER, Material Science Division, Argonne National Laboratory — The new linear chain coordination polymer $CuF_2(H_2O)_2(pyz)$(pyz=pyrazine) provides an interesting example for the study of low dimensional physics. $CuF_2(H_2O)_2(pyz)$ has a monoclinic structure where the Cu^{2+} ions form a 2 dimensional (2D) square lattice in the bc-plane. Short range magnetic order appears below 10 K followed by a transition to long range antiferromagnetic order with $T_N \sim 2.6$ K. To further understand the magnetic behavior of $CuF_2(H_2O)(pyz)$, we have performed neutron diffraction experiments on deuterated single crystals $CuF_2(D_2O)_2(d_4\text{-pyz})$. Below 2.6 K we observe magnetic Bragg peaks which are consistent with the propagation vector (1/2 1 0). Refinement of the data shows that the magnetic moment lies in the ac-plane. Fitting the temperature dependence of the magnetic order parameter to a power-law form in the reduced temperature range of 1-T/T_N = 0.01-0.4 yields a critical exponent, β, of 0.25±0.01. This result is consistent with the expectation for a 2D XY model where β=0.23 [1].

10:12AM V22.00012 Valence instability of Eu in $EuPd_3B_x$ $(0 < x < 0.53)$, ANDREAS LEITHE-JASPER, ROMAN GUMENIUK, MIRIAM SCHMITT, WILDER CARILLO-CABRERA, WALTER SCHNELLE, CHRISTOPH GEIBEL, HELGE ROSNER, MPI CPfS Dresden — In a joint theoretical and experimental study large series of intermetallic compounds $EuPd_3B_x$ and $GdPd_3B_x$ are characterized by X-ray diffraction, metallography, EPMA and chemical anlysis assessing the range of formation up to $x < 0.53$ and $x < 0.42$, respectively. Density functional based electronic structure calculations predict a valence change in $EuPd_3B_x$ above $x = 0.19(0.02)$ from a non-magnetic Eu^{3+} state into a magnetic Eu^{2+} state which is reflected in a discontinuity of the lattice parameter. Consistent with the calculations X-ray diffraction data show a kink in the lattice parameter at $x = 0.22(0.02)$. X-ray absorption spectroscopy measurements assign this kink to a transition into a heterogeneous mixed valence state of Eu. The influence of external pressure on the valence instability will be discussed.

10:24AM V22.00013 Efficient First-principles Wang-Landau Calculations , G. BROWN, Florida State University, A. RUSANU, KH. ODBADRAKH, M. EISENBACH, D.M. NICHOLSON, Oak Ridge National Laboratory — The Wang-Landau (WL) method of finding the density of states g(E) contributing to the partition function Z(kT) is useful for determining thermodynamic properties from first-principles energy calculations for magnetic systems. Since DFT calculations require significant computer resources, it is important to make the convergence of the WL method to a self-consistent g(E) as efficient as possible. We present approaches for making accurate initial estimates of g(E) based on similar Hamiltonians or estimates of g(E) for a different number of atoms. These approaches can include workstation-based calculations using classical Heisenberg Hamiltonians based on exchange parameters calculated from initial data from DFT WL calculations. In addition, we annunciate serveral insights we have gained into the convergence of the WL method. For instance, the minimum curvature of the calculated g(E) is limited by the update parameter and the maximum energy step of the Markov chain. This material is based upon work supported as part of the Center for Defect Physics, an Energy Frontier Research Center funded by the U. S. Department of Energy, Office of Science, Office of Basic Energy Sciences. This research used resources of the Oak Ridge Leadership Computing Facility at Oak Ridge National Laboratory, which is supported by the Office of Science of the Department of Energy.

10:36AM V22.00014 First principles calculations of magnetic properties of Fe and Fe_3C at finite temperature , MARKUS EISENBACH, GREGORY BROWN, AURELIAN RUSANU, DON M. NICHOLSON, Oak Ridge National Laboratory — We demonstrate a method to investigate finite temperature magnetism from first principles that harnesses massively parallel computers to obtain the free energy, specific heat, magnetization, susceptibility, and other quantities as function of temperature by combining classical Wang-Landau Monte-Carlo calculations with a first principles electronic structure code that allows the energy calculation of constrained magnetic states. Here we will present our calculations of finite temperature properties such as specific heat, magnetization and susceptibility of Fe and Fe_3C using this approach where we find the Curie temperatures to be in good agreement with experiment at 980K and 425K respectively. This work was conducted at Oak Ridge National Laboratory (ORNL), which is managed by UT-Battelle for the U.S. Department of Energy (US DOE) under contract DE-AC05-00OR22725 and sponsored in parts by the Center for Nanophase Material Sciences, Scientific User Facilities Division, the Center for Defect Physics, an Energy Frontier Research Center funded by the US DOE Office of Basic Energy Sciences and by the US DOE Office of Energy Efficiency and Renewable Energy, Industrial Technologies Program. This research used resources of the Oak Ridge Leadership Computing Facility at ORNL, which is supported by the US DOE, Office of Science.

10:48AM V22.00015 Fist Principles Approach to the Magneto Caloric Effect: Application to Ni_2MnGa , KHORGOLKHUU ODBADRAKH, DON NICHOLSON, AURELIAN RUSANU, MARKUS EISENBACH, GREGORY BROWN, BOYD EVANS III, ORNL — The magneto-caloric effect (MCE) has potential application in heating and cooling technologies. In this work, we present calculated magnetic structure of a candidate MCE material, Ni_2MnGa. The magnetic configurations of a 144 atom supercell is first explored using first-principle, the results are then used to fit exchange parameters of a Heisenberg Hamiltonian. The Wang-Landau method is used to calculate the magnetic density of states of the Heisenberg Hamiltonian. Based on this classical estimate, the magnetic density of states is calculated using the Wang Landau method with energies obtained from the first principles method. The Currie temperature and other thermodynamic properties are calculated using the density of states. The relationships between the density of magnetic states and the field induced adiabatic temperature change and isothermal entropy change are discussed. This work was sponsored by the Laboratory Directed Research and Development Program (ORNL), by the Mathematical, Information, and Computational Sciences Division; Office of Advanced Scientific Computing Research (US DOE), and by the Materials Sciences and Engineering Division; Office of Basic Energy Sciences (US DOE).

Thursday, March 24, 2011 8:00AM - 10:36AM –
Session V23 DCMP: Superconductivity: Josephson Effects II D165

8:00AM V23.00001 Lorentzian crater in superconducting microwave resonators with inserted nanowires , ALEXEY BEZRYADIN, MATTHEW W. BRENNER, SARANG GOPALAKRISHNAN, JASEUNG KU, University of Illinois at Urbana-Champaign, NAYANA SHAH, University of Cincinnati, PAUL M. GOLDBART, University of Illinois at Urbana-Champaign — We report on observations of nonequilibrium pulsing states in microwave (i.e., GHz) coplanar waveguide(CPW) resonators consisting of superconducting MoGe strips interrupted by a trench and connected by one or more suspended superconducting nanowires. The Lorentzian resonance peak shows a "crater" when driven past the critical current of the nanowire, leading to a "pulsing" state. In the pulsing state, the supercurrent grows until it reaches the critical current, at which point all stored energy quickly dissipates through Joule heating. We develop a phenomenological model of resonator-nanowire systems, which explains the experimental data quantitatively. For the case of resonators comprising two parallel nanowires and subject to an external magnetic field, we find field-driven oscillations of the onset power for crater formation, as well as the occurrence of a new state, in which the periodic pulsing effect is such that only the weaker wire participates in the dissipation process.

8:12AM V23.00002 Characterizing Chiral Domains in Sr2RuO4 via Nanoscale Josephson Junctions[1] , D. BAHR, University of Illinois, J.D. STRAND, Syracuse University, D.J. VAN HARLINGEN, University of Illinois, Y. MAENO, Kyoto University — There is substantial evidence that the ruthenate superconductor Sr_2RuO_4 has a chiral order parameter of the form $p_x \pm ip_y$ and forms chiral domains. In order to verify this picture and determine the size of the domains, we have fabricated Josephson junctions on the order of and smaller than the domain width of $\sim 1\mu$m implied by Josephson interferometer experiments. Using Focused Ion Beam milling, we have patterned Sr_2RuO_4-Cu-PbIn junctions ranging in size from 0.5μm x 0.5μm to 4μm x 4μm on the edge face of a Sr_2RuO_4 crystal. By measuring the magnetic field modulation of the Josephson critical current, we can probe the phase anisotropy across the junction and determine the size and dynamics of chiral domains. Our data is consistent with the predicted domain width but also exhibits signatures that suggest the formation of chiral domain structure along the c-axis. The theoretical model of domain wall movement proposed by Bouhon and Sigrist is supported by our data.

[1]Work supported by the Department of Energy Basic Energy Sciences grant DE-FG02-07ER46453.

8:24AM V23.00003 Josephson effect and Andreev scattering in a three-terminal quantum dot in the Kondo regime , AKIRA OGURI, Osaka City University, YOICHI TANAKA, RIKEN — We study low-temperature transport through a single quantum dot (QD) connected to three terminals, consisting of two superconducting (SC) leads and one additional normal lead. This system shows interesting behavior caused by an interplay between Josephson, Andreev and Kondo physics. The low-energy excitations of this system can be described by a local Fermi liquid theory for the renormalized Bogoliubov particles. We calculate the renormalized parameters using the Wilson numerical renormalization group approach. The Kondo temperature and the residual interaction between the renormalized Bogoliubov particles depend sensitively on the Josephson phase ϕ at the crossover region between the local Cooper paring and the Kondo singlet. This crossover reflects the quantum phase transition between non-magnetic singlet and magnetic doublet states, which takes place in the case where the addition normal lead is disconnected. We will also discuss the results for the Josephson current and the DC conductance due to the Andreev reflection.

8:36AM V23.00004 Dissipation of mobile vortices in self-dual Josephson junction arrays , SAID SAKHI, American University of Sharjah — Mutual U(1) $\times$ U(1) Chern-Simons Landau-Ginzburg theory appears as an effective field theory in self-dual Josephson junction arrays. In this theory two complex fields associated with disordering electric and magnetic charges are minimally coupled to two gauge fields related to the currents of Cooper pairs and vortices. The condensation of disorder fields is employed to explore the various phases (superconducting, insulating, and metallic) of the model. In this work we investigate the interplay between the dissipation of mobile vortices and the condensation of magnetic and charge excitations. We evaluate the electromagnetic response functions of the system, and we analyze the longitudinal and the Hall conductivities as a function of the strength of dissipation.

8:48AM V23.00005 Measurement of a weak-link Josephson junction in a p-wave superconducting ring , JOONHO JANG, RAFFI BUDAKIAN, DAVID FERGUSON, University of Illinois at Urbana-Champaign, VICTOR VAKARYUK, Argonne National Laboratory, PAUL GOLDBART, University of Illinois at Urbana-Champaign, YOSHITERU MAENO, Kyoto University, Japan — We report the fabrication of a weak-link Josephson junction in a micron-size Sr_2RuO_4 ring by focused ion beam milling, and the measurement of the current-phase relation (CPR) using cantilever torque magnetometry. In the presence of a magnetic field applied perpendicular to the crystal $c-$axis, a second harmonic term in the CPR appears which may be related to the underlying spin texture of the spin-triplet condensate. The observed CPR is similar to that previously reported for weak-link junctions in ^{3}He-B. By including the contribution from both the charge and the spin current into the Gibbs-free energy, we can accurately model the observed CPR of the Sr_2RuO_4 weak-link junction.

9:00AM V23.00006 Periodic critical current pattern in the superconductor-graphene-superconductor junction induced by the current in one of the leads , ULAS COSKUN, UT Dallas, IVAN BORZENETS, GLEB FINKELSTEIN, Duke University — We have formed superconducting metal contacts to graphene, resulting in supercurrent through graphene visible up to several degrees Kelvin. In our geometry, graphene bridges a gap between two closely spaced superconducting wires. We have found that passing a current along the length of one of the wires periodically modulates the magnitude of the supercurrent through graphene. We discuss the origins of the observed interference patterns

9:12AM V23.00007 Intrinsic Josephson Junctions with Intermediate Damping[1] , PAUL A. WARBURTON, SAJID SALEEM, JON C. FENTON, University College London, SUSIE SPELLER, CHRIS R.M. GROVENOR, University of Oxford — In cuprate superconductors, adjacent cuprate double-planes are intrinsically Josephson-coupled. For bias currents perpendicular to the planes, the current-voltage characteristics correspond to those of an array of underdamped Josephson junctions. We will discuss our experiments on sub-micron Tl-2212 intrinsic Josephson junctions (IJJs). The dynamics of the IJJs at the plasma frequency are moderately damped (Q $\approx$ 8). This results in a number of counter-intuitive observations, including both a suppression of the effect of thermal fluctuations and a shift of the skewness of the switching current distributions from negative to positive as the temperature is increased. Simulations confirm that these phenomena result from repeated phase slips as the IJJ switches from the zero-voltage to the running state. We further show that increased dissipation counter-intuitively increases the maximum supercurrent in the intermediate damping regime (PRL vol. 103, art. no. 217002). We discuss the role of environmental dissipation on the dynamics and describe experiments with on-chip lumped-element passive components in order control the environment seen by the IJJs.

[1]Work supported by EPSRC.

9:24AM V23.00008 Intrinsic Josephson effect in $Bi_2Sr_2CaCu_2O_{8+\delta}$ after doping by current injection , S. PROBST, X.Y. JIN, Y. SIMSEK, C. STEINER, C. BERGMANN, Y. KOVAL, P. MÜLLER, Department of Physics and Interdisciplinary Center for Molecular Materials (ICMM), Universität Erlangen-Nürnberg — By current injection we can change the properties of $Bi_2Sr_2CaCu_2O_{8+\delta}$ single crystals electronically in a wide range. In this work the properties of the same sample were changed multiple times in very small steps in order to investigate the doping process by current injection in greater detail. By measuring the IV characteristic of the intrinsic Josephson junctions as well as doping current and doping voltage simultaneously, the change of superconducting properties is monitored. Macroscopic quantum tunneling experiments in intrinsic Josephson junctions were performed. An exponential increase of the critical current density with hole concentration was observed. Simultaneously, the capacitance of the intrinsic Josephson junctions increases with the doping level by a factor of 5. We will discuss possible reasons for these results.

9:36AM V23.00009 Statistics of voltage fluctuations in resistively shunted Josephson junctions , MICHAEL MARTHALER, Institut fuer Theoretische Festkoerperphysik and DFG Center for Functional Nanostructures (CFN), Karlsruhe Institute of Technology, 76128 Karlsruhe, DMITRY GOLUBEV, Karlsruhe Institute of Technology, Institut fuer Nanotechnologie, 76021 Karlsruhe, Germany, YASUHIRO UTSUMI, Department of Physics Engineering, Faculty of Engineering, Mie University 1577, Kurimamachiya-cho, Tsu, Mi-e, 514-8507, Japan, GERD SCHÖN, Institut fuer Theoretische Festkoerperphysik and DFG Center for Functional Nanostructures (CFN), Karlsruhe Institute of Technology, 76128 Karlsruhe — The intrinsic nonlinearity of Josephson junctions converts Gaussian current noise in the input into non-Gaussian voltage noise in the output. For a resistively shunted Josephson junction with white input noise we determine numerically exactly the properties of the few lowest cumulants of the voltage fluctuations, and we derive analytical expressions for these cumulants in several important limits. The statistics of the voltage fluctuations is found to be Gaussian at bias currents well above the Josephson critical current, but Poissonian at currents below the critical value. In the transition region close to the critical current the higher-order cumulants oscillate and the voltage noise is strongly non-Gaussian. For coloured input noise we determine the third cumulant of the voltage.

9:48AM V23.00010 Josephson effect in S/F/S junctions: spin bandwidth asymmetry vs. Stoner exchange , HENRIK ENOKSEN, Norwegian University of Science and Technology, GAETANO ANNUNZIATA, Universita di Salerno, JACOB LINDER, Norwegian University of Science and Technology, MARIO CUOCO, CANIO NOCE, Universita di Salerno, ASLE SUDBO, Norwegian University of Science and Technology — We analyze the dc Josephson effect in a ballistic S/F/S junction in the quasiclassical Andreev approximation. We consider the possibility of ferromagnetism originating from a mass renormalization of carriers of opposite spin, i.e. a spin bandwidth asymmetry (SBAF). We provide a general formula for Andreev levels which is valid for arbitrary interface transparency, exchange interaction, and bandwidth asymmetry. We analyze the current-phase relation, the critical current, and the free energy in the short junction regime, showing that a larger number of $0-\pi$ transitions is expected when the ferromagnetism is driven by SBAF compared to Stoner magnetism. We compare the phase diagrams of two identical junctions differing only in the mechanism by which the mid layer becomes magnetic, pointing out that the phase difference across the junction in the ground state need not be the same, even for equal polarizations.

10:00AM V23.00011 Fluxon dynamics in two-band superconductor-based long Josephson junctions , BAL-RAM GHIMIRE, HAO-YU TSAI, JU KIM, Department of Physics and Astrophysics, UNIVERSITY OF NORTH DAKOTA TEAM — We investigate the phase dynamics of a long Josephson junction (LJJ) with two-band superconductors such as MgB_2 and iron pnictides. Due to two condensates in each superconductor layer, the phase dynamics of a two-band LJJ, described by the perturbed sine-Grodon equation, becomes more complex than that for the usual LJJ with one-band superconductors. This complexity arises from the presence of inter-band Josephson current that yields soliton-like excitation. This excitation represents a large stable variation of the phase difference of the two condensates. Accounting for the soliton- like excitation, we find that the fluxon dynamics in the LJJ with two-band superconductors is influenced by the modulation of Josephson current. The Josephson current modulation yields radiation emission by the moving fluxon. Also, we discuss the effects of this current modulation on the current- voltage characteristics of the LJJ.

10:12AM V23.00012 Enhancement of macroscopic quantum tunneling in Josephson junctions with multigap superconductors through zero-point fluctuations of Josephson-Leggett mode[1] , YUKIHIRO OTA, MASAHIKO MACHIDA, Japan Atomic Energy Agency, TOMIO KOYAMA, Tohoku Univ. — We theoretically study macroscopic quantum tunneling (MQT) in a hetero Josephson junction formed by a conventional single-gap superconductor and a multigap one such as MgB_2 and iron-based superconductors. In such a Josephson junction, multiple phase differences are defined and MQT dynamics are extended on a space expanded by the multiple phases. We clarify the quantum dynamics of the multiple phase differences and construct a theory for the MQT in Josephson junctions with multiple gaps. The dynamics of the phase differences are strongly affected by Josephson-Leggett mode, i.e., the fluctuation mode between the multiple phase differences and the escape rate characterizing MQT dynamics is calculated based on the effective action renormalized by the Josephson-Leggett mode. We show that the escape rate is drastically enhanced when the frequency of the Josephson-Leggett mode is less than the Josephson-plasma frequency.

[1]CREST(JST), JST-TRIP

10:24AM V23.00013 Parametric Amplification in Discrete Josephson Transmission Line , HAMID REZA MOHEBBI, A. MAJEDI MAJEDI, University of Waterloo, Institute for Quantum Computing — A Series-connected discrete Josephson transmission line (DJTL) which is periodically loaded by open stubs is studied to investigate various aspects of traveling-wave parametric amplification. The dispersion analysis is made to ensure the existence of three non-degenerate time-harmonic waves interacting with each other through the phase matching condition which is imposed by the cubic nonlinearity associated with each junction. Having weak nonlinearity and slow varying assumptions, we exploit the perturbation theory with the multiple scale technique to derive the three coupled nonlinear partial differential equations to describe their spatial and temporal amplitude variations in this parametric interaction. Cases of perfect phase-matching and slight mismatching are addressed in this work. The numerical analysis based on the spectral method in space and finite difference in time domain are used to monitor the unilateral gain, stability and bandwidth of the proposed structure. This structure can be used as a mesoscopic platform to study the creation of squeezed states of the microwave radiation. These properties make this structure desirable for applications ranging from superconducting optoelectronics to dispersive readout of superconducting qubits where high sensitivity, fast speed and low-noise operation is required.

Thursday, March 24, 2011 8:00AM - 10:00AM –
Session V24 FHP FIP: History of Physics and International Programs D167

8:00AM V24.00001 Castles in the Air: The Einstein-De Sitter Debate, 1916-1918 , CHARLES MIDWINTER, MICHEL JANSSEN, University of Minnesota — The Einstein De Sitter debate marked the birth of modern cosmology and the infamous cosmological constant. For Einstein, the controversy was essentially a philosophical one. Einstein's insistence on a static Universe and Mach's Principle guided him in the construction of his own cosmological model, and compelled him to criticize De Sitter's. For De Sitter, the debate began as idle conjecture. Before long, however, he began to wonder if the "spacious castles" he and Einstein had constructed might actually represent physical reality. We plan to write a volume that reproduces the documents relevant to the debate. Our commentary will retrace and explain the arguments of the historical players, complete with calculations. For the first time readers will be able to follow the arguments of Einstein and De Sitter in a detailed exploration of the first two relativistic cosmological models. Readers will see how Einstein's flawed criticisms of De Sitter were supported by Herman Weyl, and finally how Felix Klein settled the whole matter with a coordinate transformation.

8:12AM V24.00002 Ettore Majorana, Ugo Fano and Autoionization , ENNIO ARIMONDO, University of Pisa, CHARLES W. CLARK, Joint Quantum Institute, National Institute of Standards and Technology and University of Maryland, WILLIAM C. MARTIN, National Institute of Standards and Technology — In his brief career, Ettore Majorana posed some questions that remain of compelling interest today, such as the nature of the neutrino. Less remembered now is his virtuosity as an atomic theorist. His first published paper (1928) dealt successfully with complex atomic structures like those of Gd and U, using Fermi's statistical model which was only a few months old at the time. In the early 1930s he solved two outstanding problems of atomic spectroscopy, correctly interpreting them as involving multiply-excited discrete states of atoms that were embedded in single-electron continuua, and thus first identifying the phenomenon of autoionization in atomic spectra.[1] His unpublished notebooks[2] show that he grasped this phenomenon at a level of detail comparable to that of modern theory, which derives from the independent work of Ugo Fano.[3] We review Majorana's work on this subject and show how it still guides present understanding. Fano, Nuovo Cimento **12**, 154 (1935); *Phys. Rev.* **124**, 1866 (1961); *J. Res. Natl. Inst. Stand. Technol.* **110**, 583 (2005)

8:24AM V24.00003 The Golden Age of Radio: Solid State's Debt to the Rad Lab[1] , JOSEPH D. MARTIN, University of Minnesota — While MIT's Radiation Laboratory is rightly celebrated for its contributions to World War II radar research, its legacy extended beyond the war. The Rad Lab provided a model for interdisciplinary collaboration that continued to influence research at MIT in the post-war decades. The Rad Lab's institutional legacy–MIT's interdepartmental laboratories–drove the Institute's postwar research agenda. This talk examines how solid state physics research at MIT was shaped by a laboratory structure that encouraged cross-disciplinary collaboration. As the sub-discipline of solid state physics emerged through the late-1940s and 1950s, MIT was unique among universities in its laboratory structure, made possible by a large degree of government and military funding. Nonetheless, the manner in which MIT research groups from physics, chemistry, engineering, and metallurgy interfaced through the medium of solid state physics exemplified how the discipline of solid state physics came to be structured in the rest of the country. Through examining the Rad Lab's institutional legacy, I argue that World War II radar research, by establishing precedent for a particular mode of interdisciplinary collaboration, shaped the future structure of solid state research in the United States.

8:36AM V24.00004 Willie Hobbs Moore (1934-1994): The First Female African American Physicist , RONALD MICKENS, Clark Atlanta University — We discuss the life and career of Willie Hobbs Moore, the first African American woman to receive a doctorate degree in physics. This achievement occurred in June 1972 at the University of Michigan, Ann Arbor, MI. Her dissertation, directed by the renowned spectroscopist Samuel Krimm, was on the subject of "A Vibrational Analysis of Secondary Chlorides," and focused on a theoretical analysis of the secondary chlorides for polyvinal-chlorine polymers. From 1972–1977, she, Krimm, and collaborators published more than thirty papers on this and related research issues. In addition to an overview of her family background, her careers as a research physicist and scientist working in various industrial laboratories, we discuss the obstacles and successes she encountered at various stages of her life.

8:48AM V24.00005 Encounters with John Van Vleck: Elevating the Self-Esteem of an Experimentalist , JAMES WYNNE, IBM TJ Watson Research Center — As a Harvard freshman in 1960, John H. Van Vleck was assigned to guide me through physics course selections. As a Harvard first year graduate student in 1964, I took his course on Group Theory. He was an esteemed theoretician, and I was an experimentalist. Nevertheless, I liked him, and he both educated me and gave me good advice. Later, I learned that Van Vleck was responsible for bringing Nicolaas Bloembergen, my Ph. D. advisor, back to Harvard from Holland, with a faculty appointment in the Division of Engineering and Applied Physics. (Bloembergen had done his Ph.D. thesis with Ed Purcell, making NMR into a science, and Purcell was one of the best teachers I encountered in 9 years at Harvard.) Stepping forward in time to May, 1969, just after defending my doctoral thesis, I ran into Van Vleck in the hallway. I told him I had earned my Ph.D., and he asked me what I had done for my thesis. Feeling defensive while talking to a great theoretician, I started out cautiously to say that I had built a carbon dioxide laser. He immediately started praising me as the best of the breed, someone who could build things and actually make them work. The praise continued, he told some stories (which I will share), and I left the building on "Cloud 9." It was a really good day.

9:12AM V24.00006 US-Finland Planning Visit: Cooperative Research and Education Activities in Integrated Access Networks[1] , ARLENE MACLIN, Morgan State University, UNIVERSITY OF ARIZONA-CIAN COLLABORATION, AALTO UNIVERSITY IN FINLAND COLLABORATION — This planning grant visit sponsored by the NSF Office of International Science and Engineering occurred from October 3-10, 2010. The Dean of the School of Computer, Mathematical and Natural Sciences from Morgan State University (MSU), the PI and a faculty member from engineering at MSU along with a faculty member from the University of Arizona and two advanced level graduate students from the NSF-funded Center for Integrated Access Networks participated in this visit. The topic of novel low dimensional nano-materials was determined to be one possible area for future collaboration. As a result of this visit, a Materials World Network proposal has been submitted to the NSF involving MSU and CIAN in the US and Aalto University in Finland. A companion proposal on novel low dimensional nano- materials has also been submitted to the Academy of Finland. Another anticipated outcome of this collaboration of MSU with Aalto University and CIAN expands the outreach and diversity component to MSU, an institution serving largely an underrepresented minority student.

Session V25 DCMP: Superconductivity: HTSC Theory, Mostly Nematics and Inhomogeneous Systems D166

8:00AM V25.00001 The role of nematic fluctuations in the thermal melting of pair-density-wave phases in superconductors[1] , DANIEL BARCI, Department of Physics, Universidade Estadual do Rio de Janeiro, Brazil, EDUARDO FRADKIN, Department of Physics, University of Illinois — We study properties of phase transitions of the superconductor liquid crystal phases, and analyze the competition between the recently proposed Pair Density Wave (PDW) and nematic $4e$ superconductor (4eSC). Nematic fluctuations enhance the 4eSC and suppress the PDW phase. For a system decoupled from a lattice, the PDW state exists only at $T = 0$ and the low temperature phase is a nematic $4e$SC with short ranged PDW order.

8:12AM V25.00002 Nematicity in 3-band Hubbard model of cuprate superconductors , KYUNGMIN LEE, JUNPING SHAO, Cornell University, RICHARD SCALETTAR, University of California - Davis, MICHAEL LAWLER, SUNY Binghamton, EUN-AH KIM, Cornell University — The recent discovery of intra-unit-cell nematicity in STM studies of cuprate superconductors [1] underscores the importance of the role played by oxygen orbitals in CuO2 plane. Motivated by this observation we study 3-band Hubbard model using exact diagonalization. In particular, we investigate the effects various interaction parameters (Ud, Up, Vpd, Vpp) have on nematicity. Interestingly, we find that Ud, the on-site repulsion at copper sites, enhances nematicity in the strongly coupled regime.

[1] Lawler, M. J. *et al.* Intra-unit-cell electronic nematicity of the high-Tc copper-oxide pseudogap states. *Nature* **466**, 347 (2010).

8:24AM V25.00003 Mean-Field Nematic Phase Diagram for the Three-Band Hubbard Model , MARK H. FISCHER, LASSP, Department of Physics, Cornell University, MICHAEL J. LAWLER, Department of Physics, Applied Physics and Astronomy, Binghamton University, EUN-AH KIM, LASSP, Department of Physics, Cornell University — We map out the phase diagram of the three-band Hubbard model of a CuO_2 plane for nematic order in the parameter space of various on-site and nearest-neighbor interactions. For this, we define an intra-unit cell nematic order parameter in terms of a charge imbalance between the two oxygen sites in the unit cell and employ a self-consistent mean-field analysis. This study is motivated by recent STM experiments on high-T_c cuprate superconductors pointing towards intra-unit cell nematicity.

8:36AM V25.00004 Dynamical electronic nematicity from Mott physics , SATOSHI OKAMOTO, Materials Science and Technology Division, Oak Ridge National Laboratory, DAVID SENECHAL, Department de Physique and RQMP, Universite de Sherbrooke, MARCELLO CIVELLI, Laboratoire de Physique des Solides, Univ. Paris-Sud, ANDRE-MARIE TREMBLAY, Department de Physique and RQMP, Universite de Sherbrooke, and Canadian Institute for Advanced Research — We study the two-dimensional Hubbard model with small band anisotropy using dynamical-mean-field theory for clusters. We found that very large transport anisotropies can be induced by very small band anisotropy as in many strongly correlated materials. This happens when the interaction is large enough to yield a Mott transition. The maximum effect on conductivity anisotropy occurs in the underdoped regime as observed in high temperature superconductors. The anisotropy decreases at large frequency and is not associated with static stripe order. Thus we call the phenomenon "dynamical electronic nematicity". This work was supported by the Materials Sciences and Engineering Division, Office of Basic Energy Sciences, U.S. DOE (S.O.), NSERC (Canada) and the Tier I Canada Research Chair Program (A.- M.T.), with part of the computational resources by RQCHP and Compute Canada.

8:48AM V25.00005 Quantum Nematic Physics in the Hubbard Model of Cuprate Superconductors , SHI-QUAN SU, GONZALO ALVAREZ, MICHAEL SUMMERS, THOMAS MAIER, Oak Ridge National Lab — Recent experiments have provided strong evidence that quantum electronic nematic order plays an important role in characterizing the pseudogap region of the cuprate superconductors. Starting from the generic Hubbard model of the cuprates, we introduce a small anisotropy in the hopping integral to model a small orthorhombic distortion. We perform a dynamic cluster quantum Monte Carlo approximation of this model, in order to study the effects of this anisotropy on various properties. In particular, we investigate the effects on superconductivity and pseudogap behavior, as well as the competition between different effects.

9:00AM V25.00006 On the origin of quantum criticality found at finite doping in 2D Hubbard model[1] , SHUXIANG YANG, HERBERT FOTSO, JUANA MORENO, MARK JARRELL, Louisiana State University — To better understand the excitations responsible for quantum criticality (QC) found at finite doping in the 2D Hubbard model, we analyze the vertices for different scattering channels obtained from the Dynamical Cluster Continuous-Time Quantum Monte Carlo simulation. By decomposing these vertices using the parquet equations we find that both superconductivity and the charge instabilities responsible for the QC come from the crossed spin channel contribution, and thus are driven by the spin-fluctuations. On contrast, the spin instability comes from the fully irreducible spin vertex contribution.

[1]We acknowledge the support from NSF OISE-0730290 and DOE SciDAC DE-FC02-06ER25792

9:12AM V25.00007 Superconductivity from purely repulsive interactions in the 2D electron gas , SRINIVAS RAGHU, Rice University, STEVEN KIVELSON, Stanford University — We present a well-controlled perturbative renormalization group (RG) treatment of superconductivity from short-ranged repulsive interactions in a variety of model two dimensional electronic systems. Our analysis applies in the limit where the repulsive interactions between the electrons are small compared to their kinetic energy.

9:24AM V25.00008 Effect of competing orders on superconductivity in the Hubbard model , WEEJEE CHO, Stanford University, SRINIVAS RAGHU, Rice University, STEVEN KIVELSON, Stanford University — We study the superconducting transition in the repulsive Hubbard model incorporating different competing orders at the mean field level. To the model on the square lattice with nearest and next-nearest neighbor hopping amplitudes, we add appropriate modulations of the hopping terms or onsite energies, such that they produce the desired broken symmetry. We then study the superconducting instability in the (theoretically tractable) limit in which the onsite repulsion U is small compared to the bandwidth. We obtain the pairing symmetry and strength as a function of the magnitude of the order parameter. Specific cases of broken symmetry states we study include antiferromagnetism, ferromagnetism, nematic order, d-density wave, and orbital loop order.

9:36AM V25.00009 d-wave Cooper pairing in multiband models for the high-T_c cuprates , CARSTEN HONERKAMP, STEFAN UEBELACKER, RWTH Aachen — We investigate possible reasons for the significant differences of T_cs in high-T_c cuprate compounds, based on renormalization group treatments of downfolded models for the electronic structure. Generally, cuprates with a square like Fermi surface exhibit lower critical temperatures than materials with a more rounded Fermi surface, which contradicts with many theoretical studies of the one band Hubbard model. To resolve this contradiction we study multiband models which in addition to the d_{x2-y2} orbital contain $4s$ and d_{z2} orbitals using different approximation levels of the functional renormalization group technique. Our results suggest that the observed material trend can be explained in parts by the influence of orbital mixing, which can dominate over the effect of the Fermi surface shape.

9:48AM V25.00010 Inhomogeneity and d-wave superconductivity in the Hubbard model[1] , S. CHAKRABORTY, D. SÉNÉCHAL, A.-M.S TREMBLAY, Dept. de physique, RQMP, Sherbrooke — Whether or not inhomogeneity plays a significant role in determining the superconducting properties of the cuprate high-Tc superconductors remains an open issue, in spite of extensive theoretical and experimental focus. To this end, we study d-wave superconductivity in the checkerboard Hubbard model on a square lattice. We employ the Cellular Dynamical Mean Field theory method with an exact diagonalization solver at zero temperature. The d-wave order parameter is computed for various inhomogeneity levels over the entire doping range of interest. We find a monotonic decrease in the maximum amplitude of the superconducting order parameter with inhomogeneity. However, the order parameter increases with inhomogeneity in a small doping interval lying in the extreme overdoped regime. For any doping, an inhomogeneity-induced change in the height of the lowest energy peak in the antiferromagnetic spin susceptibility correlates with the change in amplitude of the order parameter.

[1]Supported by NSERC (Canada), CRC (A.-M.T.), RQCHP and Compute Canada.

10:00AM V25.00011 Disorder effects on pair binding in the checkerboard Hubbard model , PETER SMITH, MALCOLM KENNETT, Simon Fraser University — The checkerboard Hubbard model is an inhomogeneous fermionic Hubbard model in which hopping on plaquettes takes a different value to hopping between plaquettes. The pair binding energy in the clean checkerboard Hubbard model, interpreted as a tendency towards superconducting order, is positive over a wide part of the zero temperature phase diagram. We perform exact diagonalization studies of the checkerboard Hubbard model with on-site disorder. For systems up to twelve sites, we study the distribution of pair binding energies that results from the introduction of potential disorder and find that weak disorder enhances the region of the phase diagram over which there is a non-zero probability of pair binding, without greatly changing the average pair binding energy. We also study how stronger disorder destroys pair binding.

10:12AM V25.00012 Theoretical investigation of superconductivity and antiferromagnetism in trilayer cuprate superconductors , YAN CHEN, Fudan University, China — Recent ARPES experiment on the optimally doped trilayer cuprate superconductors Bi2223 has revealed a layer variation of both doping density and d-wave gap. In particular, the two outer layers are overdoped with a gap which is larger than the gap for optimally doped single layer cuprates while the inner layer is underdoped with an even larger gap. Here we propose a minimal model composed of three layer t-J model, single particle interlayer tunneling as well as Cooper pair tunneling terms. By using renormalized mean field method, both the superconducting (SC) and antiferromagnetic (AFM) properties are theoretically investigated. Both tunneling effects may influence the phase configurations of both d-wave SC and AFM order parameters on each layer which plays a crucial role in determining the electronic structures of trilayer cuprates. In particular, the inphase state for both SC and AFM phases is found to be relevant to the Bi2223 trilayer system. In such a state, the superconducting order parameter of inner plane will be further enhanced due to the constructive proximity effect from the two outer planes and the hole density of inner plane will be much suppressed. Furthermore we predict that the appearance of interlayer ferromagnetic correlations for such system which could be tested by future NMR experiments. **This work is in collaboration with Chun Chen and A. Fujimori.

10:24AM V25.00013 Confinement-deconfinement interplay in quantum phases of doped Mott insulators , PENG YE, Institute for Advanced Study, Tsinghua University, Beijing, 100084, P. R. China, CHU-SHUN TIAN, Institute of Theoretical Physics, Cologne University, D-50937 Cologne, Germany, XIAO-LIANG QI, Department of Physics, Stanford University, Stanford, CA 94305, USA, ZHENG-YU WENG, Institute for Advanced Study, Tsinghua University, Beijing, 100084, P. R. China — It is generally accepted that doped Mott insulators can be well described by the t-J model. In the latter, the electron fractionalization is dictated by the phase string effect. We found that in underdoped regime, the antiferromagnetic and superconducting phases are dual: in the former, holons are confined while spinons are deconfined, and vice versa in the latter. These two phases are separated by a novel phase, the so- called Bose-insulating phase, where both holons and spinons are deconfined. A pair of Wilson loops was found to constitute a complete set of order parameters determining this zero- temperature phase diagram. The quantum transitions between these phases are suggested to be of non-Landau-Ginzburg-Wilson type.

10:36AM V25.00014 FLEX calculation of the pairing state symmetry and quasiparticle excitations for $SrRu_2O_4$, JOHN DEISZ, Department of Physics, University of Northern Iowa — We calculate the superconducting phase diagram for a two-dimensional, three-band tight-binding model of $SrRu_2O_4$ using the fluctuation exchange approximation (FLEX). Electron interactions are modeled by an atomically-local interaction with intra-band, inter-band and exchange terms and an atomically-local spin-orbit interaction is included as well. Preliminary results suggest that FLEX produces a singlet-pairing state with $d_{x^2-y^2}$ orbital symmetry, a result that is not in agreement with many experimental results. However, we do find that the values for the interaction strengths that are required to generate $T_c \simeq 1.5\,K$ lead to normal state quasiparticle line widths that are in reasonable agreement with experimental results.

10:48AM V25.00015 Diagrammatic Quantum Monte Carlo Solution of Two dimensional Cooperon-Fermion model , KAIYU YANG, ETHZ & Boston College — We investigate the two-dimensional Cooperon-fermion model in the strong coupling limit with continuous-time diagrammatic determinant quantum monte carlo (DDQMC). We obtained the same Kosterlitz-Thouless transition temperature T_c for the fermion's off-diagonal long range order χ_{OD} ($\boldsymbol{k}$=0,$\omega = 0$) and cooperon's Greens function $G^b(\boldsymbol{k}$=0,$\omega = 0)$ as expected. The renormalized cooperon's band (band gap and mass) is examined carefully. The delocalization of the cooperons enhances the diamagnetism. When applied to study the diamagnetism of pseudogap state in high-T_c cuprate, the results we obtained is in good agreement with recent torque magnetization measurements.

Session V26 DMP DCOMP: Focus Session: Iron Based Superconductors – Doping Studies D162/164

8:00AM V26.00001 Isotope substitution induced lattice expansion in the iron based superconductors , MATS GRANATH, University of Gothenburg, OLEG KIM, ITAI PANAS, Chalmers University of Tech. — In the iron based superconductors there are indications of a wide range of exponents for the iron isotope effect on Tc in different families of these materials. In this work we explore to what extent this spread of exponents may be a result of different isotope induced lattice expansions in combination with an extreme sensitivity of Tc to the interatomic distances. We estimate the magnitude of anharmonicity in the dominant Fe-As(Se) bond based on a model fit of the temperature dependence of Raman phonon frequencies. Using a variational approach to treat the effect of the anharmonic potential we calculate the magnitude and sign of the expansion of lattice parameters and interatomic distances due to Fe isotope substitution in several different iron-based superconductors.

8:12AM V26.00002 Doping evolution of the electronic structure in $Ba(Fe_{1-x}Co_x)_2As_2$ as revealed by polarization dependent ARPES and soft X-ray absorption , PAOLO VILMERCATI, CHRISTINE CHENEY, University of Tennessee Knoxville, SUNG-KWAN MO, Lawrence Berkely National Laboratory, FEDERICA BONDINO, ELENA MAGNANO, Consiglio Nazionale delle Ricerche, MARCO MALVESTUTO, Sictrotrone Trieste, ATHENA SEFAT, MICHAEL MCGUIRE, BRIAN SALES, DAVID SINGH, DAVID MANDRUS, Oak Ridge National Laboratory, NORMAN MANNELLA, University of Tennessee Knoxville — Here we present a study based on ARPES and X-ray absorption spectroscopies in order to unveil the electronic structure evolution upon Co-doped in BaFe2As2 high Tc superconductors, for the doping levels x=(0,6,8,12,22)%. This study focuses on two points: i) the effective role of Co at different doping levels; ii) the shift upon doping of the band structure. X-ray absorption experiments carried out at the Co L23 edge highlight the chemical state of cobalt at the various doping levels, thus unveiling its role as charge donor. The orbital selectivity of polarization dependent ARPES is used to show the filling evolution of each band. The spectra have been collected in different geometries along the ΓX and ΓM high symmetry crystallographic directions and at two different photon energies. The experimental results show a general rearrangement of the charge within the various orbitals upon doping, with a non rigid band shift.

8:24AM V26.00003 Doping dependence of the optical spectra in $Fe_{1.02}Te_{1-x}Se_x$ [1] , CATALIN MARTIN, X. XI, K. MILLER, D. KOUKIS, University of Florida, J. HU, Z.Q. MAO, Tulane University, G.L. CARR, Brookhaven National Laboratory, D.B. TANNER, University of Florida — We measured the optical reflectivity and extracted the optical conductivity over a broad spectral range of the Fe-chalcogenide $Fe_{1.02}Te_{1-x}Se_x$, at various doping levels, from x=0.12 to x=0.45. Except for the highest concentration of Se (x=0.45), optical properties show unusual frequency and temperature dependence. The zero frequency Drude peak is absent in optical conductivity, a plasma edge cannot be unambiguously defined and both reflectivity and optical conductivity have non-monothonic temperature dependence. For the superconducting samples, we found a weak enhancement of the reflectivity in the far-infrared region upon cooling below Tc and its possible association with the superconducting gap will be discussed.

[1]Supported by the US DOE through contracts DE-FG02-02ER45984 and DE-AC02-98CH10886.

8:36AM V26.00004 Doping-Induced Evolution of Superconducting Order Parameter in Ba(Fe1-xNix)2As2 Single Crystals[1] , CONG REN, Laboratory for Superconductivity, Institute of Physics, China, ZHAOSHENG WANG, HUIQIAN LUO, HUAN YANG, LEI SHAN, HAIHU WEN, Laboratory for Superconductivity, IOP — We report a systematic investigation on the c-axis point-contact Andreev reflection (PCAR) in $BaFe_{2-x}Ni_xAs_2$ superconducting single crystals with the Ni concentrations from underdoped to overdoped regions ($0.075 \leq x \leq 0.15$). At low temperatures, an in-gap peak at low-bias voltage is observed in PCAR for overdoped samples, in contrast to the case of underdoped junctions, in which an in-gap plateau is observed. The spectra are fitted using a generalized Blonder- Tinkham-Klapwijk (BTK) formalism with two gaps: one isotropic and another angle dependent. The second gap, resulted from the fitting, shows a clear crossover from a nodeless in the underdoped side to a nodal feature in the overdoped region. This intriguing observation provides strong evidence of the doping induced evolution of the superconducting order parameter when the inter-pocket and intra-pocket scattering are tuned through doping, as expected in the $s_{\pm}$ scenario.

[1]This work is supported by the Natural Science Foundation of China, the Ministry od Science and Technology of China.

8:48AM V26.00005 First-principles study of light-element doping effects on iron-based superconductors , HIROKI NAKAMURA, MASAHIKO MACHIDA, Japan Atomic Energy Agency — Since the discovery of the iron-based superconductor, $LaFeAsO_{1-x}F_x$ whose Tc reached 26K, various types of iron-based superconductors have been fabricated to attain higher T_c. Recently, it is reported that Tc of an iron-based superconductor $LaFeAsO_{1-y}$ is enhanced to 35K by doping hydrogen. This result implies that atoms of light elements penetrate into the crystal of iron-based superconductors and transform their structures into more useful ones for superconductivity. In this talk, we investigate how the light elements are doped in the iron-based superconductors by using the first-principles density functional theory. Furthermore, we evaluate the effects of doping on the crystal structures and electronic states and explore the origin of the T_c enhancements.

9:00AM V26.00006 Electron spin resonance in iron pnictides , H.-A. KRUG VON NIDDA, J. DEISENHOFER, N. PASCHER, S. SCHAILE, E. DENGLER, A. LOIDL, Experimentalphysik V, Center for Electronic Correlations and Magnetism, Institute for Physics, Augsburg University, D-86135 Augsburg, Germany, H.S. JEEVAN, P. GEGENWART, I. Physik. Institut, Georg-August-Universitaet Goettingen, D-37077 Goettingen, Germany — We report on electron spin resonance studies in Eu based 122-superconductors where the Eu^{2+} ions serve as a probe of the normal and superconducting state. In polycrystalline $Eu_{0.5}K_{0.5}Fe_2As_2$ the spin-lattice relaxation rate $1/T_1^{\rm ESR}$ obtained from the ESR linewidth exhibits a Korringa-like linear increase with increasing temperature above T_c evidencing a normal Fermi-liquid behavior. Below T_c the spin lattice relaxation rate $1/T_1^{\rm ESR}$ follows a $T^{1.5}$-behavior without any appearance of a coherence peak. In superconducting $EuFe_2As_{1.8}P_{0.2}$ single crystals we find a similar Korringa slope in the normal state and observe anisotropic spectra for measuring with the external field parallel and perpendicular to the c-axis. In addition, we will discuss the ESR properties of selected systems from the 1111 and 11 families.

9:12AM V26.00007 Effect of Isoelectronic Doping at the As Site in Iron-based Superconducting Systems , GUANG-HAN CAO, Department of Physics, Zhejiang Uinversity — FeAs-based superconductivity can be induced with various doping strategies—either electron doping, hole doping or isoelectronic doping. In this talk, we will focus on the unique isoelectronic doping at the As site. By using different dopants such as P [1,2] or Sb [3], positive or negative chemical pressure can be generated onto the FeAs layers. The positive chemical pressure suppresses/destroys the spin-density-wave (SDW) ordering, and then superconductivity emerges around a quantum critical point. In contrast, the negative pressure tends to recover the suppressed/hidden SDW ordering. The isoelectronic doping also influences the electronic and magnetic state of 4f electrons in the rare-earth atomic layers and 3d electrons of the Fe planes, especially in the case of proximity between 4f and 3d energy levels. This was manifested by the observation of local-moment ferromagnetism of 4f electrons in $EuFe_2(As_{1-x}P_x)_2$, $CeFeAs_{1-x}P_xO$ and $CeFeAs_{1-x}P_xO_{0.95}F_{0.05}$ [4] systems. Our results demonstrate the intriguing interplay/competition of intersite RKKY coupling among 4f-moments, intrasite Kondo interaction between 4f- and 3d- electrons, and **k**-space Cooper pairing of 3d electrons. This work was done in collaboration with Zhu-An Xu and Jian-Hui Dai, and was supported by National Basic Research Program of China (Grant Nos. 2007CB925001 and 2010CB923003).

9:48AM V26.00008 Suppression of critical temperature in proton irradiated $Ba(Fe_{1-x}Co_x)_2As_2$, YASUYUKI NAKAJIMA, University of Tokyo, JST- TRIP, TOSHIHIRO TAEN, YUJI TSUCHIYA, University of Tokyo, TSUYOSHI TAMEGAI, University of Tokyo, JST- TRIP, HISASHI KITAMURA, TAKESHI MURAKAMI, NIRS — The study on the superconducting gap structure of iorn-pnictide superconductor is one of the most important issues to uncover the pairing mechanism of high temperature superconductivity. To elucidate the superconducting gap structure, a detailed study on the effect of defects is very crucial because the pair-breaking effects due to scattering centers are phase-sensitive. We report the suppression of T_c due to the pair- breaking effect introduced by 3 MeV proton irradiation in $Ba(Fe_{1-x}Co_x)_2As_2$ single crystals at under-, optimal-, and over-doping levels. We find that T_c decreases and residual resistivity increases monotonically with increasing the proton dose. We also find no resistive upturn at low temperatures, which suggests that the proton irradiation provides nonmagnetic scattering centers. The critical scattering rate for all samples estimated by three different ways is much higher than that expected in $s_{\pm}$-pairing scenario based on inter-band scattering due to antiferro-magnetic spin fluctuations.

10:00AM V26.00009 Nanometer Scale Phase Separation and Chemical Inhomogeneity in the Iron Chalcogenide Superconductor $Fe_{1+y}Te_xSe_{1-x}$, HEFEI HU, JIAN-MIN ZUO, University of Illinois at Urbana-Champaign, JINSHENG WEN, ZHIJUN XU, ZHIWEI LIN, QIANG LI, GENDA GU, Brookhaven National Laboratory, WAN KYU PARK, LAURA GREENE, University of Illinois at Urbana-Champaign — We report direct evidences of phase separation and chemical inhomogeneity in $Fe_{1+y}Te_xSe_{1-x}$ single crystals from scanning transmission electron microscopy (STEM) and electron energy loss spectroscopy (EELS). In STEM, images recorded using an annular dark field (ADF) detector show characteristic nanometer scale patterns of phase separation from the Z dependent contrast. The separation was observed in both non-superconducting samples with excess iron as well as superconducting samples. Using the line scan EELS technique, we determined ~20%, or less, fluctuation in Te concentration from the local average compositions by integrating the intensity of the Te-$M_{4,5}$ edge. The energy-loss near-edge structure (ELNES) of the Fe-$L_{2,3}$ edge changes as the composition varies, especially the L_3 and L_2 ratio, which is sensitive to the d-state occupancy of the Fe atom. The results suggest a miscibility gap in the $Fe_{1+y}Te_xSe_{1-x}$ system and changes in the d-electron states at the nanometer scale from the separated phases.

10:12AM V26.00010 Local topography and spectroscopy of the doped chalcogenide $FeTe_xSe_{1-x}$[1] , XIAOBO HE, GUORONG LI, JIANDI ZHANG, RONGYING JIN, Louisiana State University, Baton Rouge, LA 70803, USA, A.S. SEFAT, M.A. MCGUIRE, B.C. SALES, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, D. MANDRUS, University of Tennessee, Knoxville, TN, 37996, E.W. PLUMMER, Louisiana State University, Baton Rouge, LA 70803, USA — The atomically resolved structural and electronic properties of FeTe and $FeTe_{0.55}Se_{0.45}$ have been investigated using scanning tunneling microscopy/spectroscopy. The STM topography of the doped sample clearly distinguishes two types of atoms. Statistically the topography shows the correct concentration of the two species and reveals that they are not randomly distributed but prefer to congregate with tens of identical atoms in nanometer scale. Consequently, in contrast to extremely flat surface of parent compound FeTe, $FeTe_{0.55}Se_{0.45}$ shows structural phase separation globally breaking the pure *p4/nmm* symmetry. Surprisingly the local density of states on tellurium and selenium atoms in $FeTe_{0.55}Se_{0.45}$ are identical, but not the same as that in pure FeTe. This indicates an itinerant (rather than localized) electronic character in this doped system. This behavior is opposite to phase separation in many other doped materials.

[1]Supported by NSF DMR-1002622.

10:24AM V26.00011 Revealing the electronic structure of the iron pnictides with electron energy-loss spectroscopy , J.C. IDROBO, W. ZHOU, Vanderbilt U./ORNL, M.F. CHISHOLM, ORNL, M.P. PRANGE, Vanderbilt U./ORNL, A.S. SEFAT, M.A. MCGUIRE, B.C. SALES, ORNL, S.J. PENNYCOOK, ORNL/Vanderbilt U., S.T. PANTELIDES, Vanderbilt U./ORNL — We report electron energy-loss spectroscopy (EELS) studies of the parent compounds (LnFeAsO, Ln=La, Ce, Pr, Nd, Sm, Gd) using scanning transmission electron microscopy. We find that all the studied LnFeAsO present a Fe L-edge fine structure closer to that of metallic iron than iron oxides. We observe a direct correlation between the Fe valence state (obtained from EELS) and T_C, i.e. the smaller the calculated Fe valence state, the larger is the T_C for that compound. We also find an anomalous crystallographic orientation-dependence of the Ln M_{45} edge fine structure. In particular, we find difference in the apparent crystal field splitting of Ce and Gd f- bands when the spectra are collected parallel and perpendicular to the c-axis. This research was partially supported by NSF Grant No. DMR-0938330 (JCI, WZ), by ORNL's Shared Research Equipment (SHaRE) User Facility, which is sponsored by the Office of Basic Energy Sciences, U.S. Department of Energy (JCI) and the Office of Basic Energy Sciences, Materials Sciences and Engineering Division, U.S. Department of Energy (MC, ASS, MAM, BCS & SJP), DOE grant DE- F002-09ER46554 (MP, STP), and by the McMinn Endowment (STP) at Vanderbilt University.

10:36AM V26.00012 Doping dependent vortex pinning in single crystal $BaFe_2(As_{1-x}P_x)_2$, LEI FANG, Y. JIA, Argonne National Laboratory, Argonne, IL 60439, USA, C. CHAPARRO, Argonne National Laboratory and Department of Physics, University of Notre Dame, J. SCHLUETER, Argonne National Laboratory, Argonne, IL 60439, USA, Z.L. XIAO, Argonne National Laboratory and Northern Illinois University, H. HELMUT, A.E. KOSHELEV, U. WELP, G.W. CRABTREE, W.K. KWOK, Argonne National Laboratory, Argonne, IL 60439, USA — We report on magnetization measurements on doped single crystals of superconducting $BaFe_2(As_{1-x}P_x)_2$. For optimum doped crystals, we observe a second magnetization peak effect (fish tail). With further doping of phosphur for arsenic, the fish tail effect evolves into a peak effect close to H_{c2}, similar to that found in conventional type II superconductors. In heavily overdoped crystals, the magnetization loop is mostly reversible and no peak effect is observed. The evolution of the peak effect with doping is attributed to the reduction in defects as the crystal's purity is increased, going from optimum doping to over-doping. Possible pinning mechanism for the peak effect will be discussed within the framework of recent heat capacity and resistivity measurements.

Thursday, March 24, 2011 8:00AM - 10:48AM –

Session V27 GQI: Focus Session: Semiconductor Qubits- Dynamic Decoupling, Dephasing, and Relaxation C155

8:00AM V27.00001 Increasing Quantum Dot Electron Spin Coherence with Persistent Spin Narrowing[1] , BO SUN, University of Michigan, COLIN CHOW, Univeristy of Michigan, ALLAN BRACKER, DANIEL GAMMON, Naval Research Laboratory, LU SHAM, University of California San Diego, DUNCAN STEEL, University of Michigan — We demonstrate reproducible initialization of the Overhauser field in a single InAs self-assembled quantum dot using the hole assisted nuclear feedback mechanism. This fixes the mean the Overhauser field to a value determined by two pump lasers and dramatically reduces the statistical broadening of the electron spin resonance arising from averaging over the nuclear spin ensemble, (1/T2*). By initializing for tens of milliseconds, the prepared Overhauser field distribution lasts for well over a second even in the presence of a fluctuating electron spin. Furthermore, we find a mechanism which will initialize the nuclear spins using only a single laser, and that this mechanism involves the evolution of the nuclear spins "in the dark", that is, absent any optical field. This new method is directly compatible with the CW readout technique used in recent time-domain spin manipulation experiments.

8:12AM V27.00002 Effects of Multi-pulse Dynamical Decoupling Schemes on Dephasing in a GaAs Spin Qubit[1] , JAMES MEDFORD, CHRISTIAN BARTHEL, CHARLES MARCUS, Harvard University, MICAH HANSON, ARTHUR GOSSARD, Materials Department, University of California, Santa Barbara — Coherence time (T_2) of a singlet-triplet qubit in a GaAs double quantum dot is studied as a function of the number of π-pulses in a Carr-Purcell-Meiborn-Gill (CPMG) dynamical decoupling sequence. In this system, the dominant forms of dephasing are expected to be hyperfine coupling to the nuclei and electrical noise. For n_π ranging from 2 to 32, we find a power law dependence of T_2 with the number of pulses, $T_2 \propto n_\pi^\beta$, where n_π is the number of pulses and $\beta \sim 0.7$ is a fit parameter.

8:24AM V27.00003 The central spin problem: electron spin qubit evolution due to coherently evolving nuclear spins , IZHAR NEDER, MARK RUDNER, HENDRIK BLUHM, BERTRAND HALPERIN, AMIR YACOBY, Harvard University — In recent years, electron spin qubits in solid state quantum dots have emerged as promising candidates for the implementation of quantum information processing. We study the dephasing of two electron spins in a double quantum dot system due to the evolution of the underlying nuclear spins, as was measured in a recent spin echo experiments. We develop a semi-classical model for such a system, by treating the Overhauser field induced by the nuclear spins as a classical time-dependent vector. Comparing the outcome of this model to experimental echo signal of the electron qubit allows us to identify MNR-like signatures from the nuclear spin evolution, such as spin diffusion, coherent nuclear Larmor precession and the spread of the Larmor frequencies by various mechanisms.

8:36AM V27.00004 Generating Entanglement and Squeezed States of Nuclear Spins in Quantum Dots

, MARK RUDNER, Harvard University, LIEVEN VANDERSYPEN, TU Delft, VLADAN VULETIC, LEONID LEVITOV, MIT — Entanglement generation and detection are two of the most sought-after goals in the field of quantum control. Besides offering a means to probe some of the most peculiar and fundamental aspects of quantum mechanics, entanglement in many-body systems can be used as a tool to reduce fluctuations below the standard quantum limit. For spins, or spin-like systems, such a reduction of fluctuations can be realized with so-called squeezed states [1]. Here we present a scheme for achieving coherent spin squeezing of nuclear spin states in single electron quantum dots [2]. This work represents a major shift from earlier studies, which have explored classical "narrowing" of the nuclear polarization distribution through feedback involving stochastic spin flips. In contrast, we use the nuclear-polarization-dependence of the electron spin resonance (ESR) line to provide a non-linearity which generates a non-trivial, area-preserving, "twisting" dynamics which squeezes and stretches the nuclear spin Wigner distribution without the need for nuclear spin flips.

8:48AM V27.00005 Dephasing of two-spin qubits due to their charge and nuclear environments[1]

, GUY RAMON, Santa Clara University — We consider dephasing of qubits encoded in the singlet and unpolarized triplet states of pairs of spins localized in biased double quantum dots. The charge environment is modeled by both two-center charge traps in the insulator (where electrons tunnel between the two centers), and single charge traps located near the gate electrodes and QPCs (where electrons charge and empty the trap). The couplings of these trapped charges to the qubits are calculated by considering their charge distributions within a multipole expansion. It is demonstrated that the summation over these random telegraph processes in mesoscopic devices results in non-Markovian and non-Gaussian noise. For the nuclear environment we consider hyperfine-induced electron-spin dephasing in a nuclear spin bath with narrowed distribution. Nuclear state preparation using dynamical polarization cycles was experimentally achieved recently, and it is also essential to enable X-rotations for two-spin qubits. Our analysis is performed for both free induction and echo signals. The scaling of these dephasing mechanisms with the number of qubits is also discussed.

9:00AM V27.00006 Noisy (spin) neighbors of a solid state (spin) qubit[1]

, WAYNE WITZEL, MALCOLM CARROLL, Sandia National Laboratories, NM, LUKASZ CYWINSKI, Institute of Physics, Polish Academy of Sciences, SANKAR DAS SARMA, University of Maryland, College Park — Powerful computational methods have been developed in recent years for understanding decoherence induced by environmental spins. Specifically, the cluster correlation expansion [Phys. Rev. B 78, 085315 (2008)] and adaptations [Phys. Rev. Lett. 105, 187602 (2010)] provide successive approximations that approach the solution to the full quantum mechanical problem for small and large spin baths with good efficiency. We present our findings from these computations. These have implications for solid state spin qubit fabrication and materials choices. In silicon where nuclear spins may be eliminated through isotopic enrichment, we consider other sources of bath spins in the bulk and near interfaces. We also investigate the conditions under which we may abstract out an approximate noise model that is independent of operations applied to the qubit.

9:12AM V27.00007 Competing effects of hyperfine and spin-orbit interactions in two-electron spin qubits[1]

, ERNESTO COTA, Centro de Nanociencias y Nanotecnología, UNAM, Ensenada, Mexico, SERGIO ULLOA, Ohio University — We analyze the dynamics of a double quantum dot system with two electrons in a uniform magnetic field, taking into account the hyperfine interaction as well as the interdot tunneling-induced Rashba spin-orbit coupling. The former mixes the singlet and triplet (1,1) states while the latter accounts for mixing triplet states and the doubly occupied (0,2) singlet. We focus on the effects on experimental results in GaAs dots [1], involving the generation and control of a nuclear field gradient, necessary for full quantum control of this electron spin qubit. Using a complete description of the quantum states involved in the dynamics and numerical solution of the time-dependent Schrödinger equation, we study different pumping processes used to polarize (and read) the nuclear system, creating a large inhomogeneous nuclear field. We evaluate the fidelity of gate operations involving the two-electron qubit in the presence of competing spin-flip interactions as well as the implementation of these operations in quantum computation with characteristic experimental dot systems.

9:24AM V27.00008 Two-eletron spin relaxation in double quantum dots and P donors[1]

, CHIA-WEI HUANG, Department of Physics, Bar-Ilan University, Ramat Gan, 52900, Israel, MASSOUD BORHANI, XUEDONG HU, Department of Physics, University at Buffalo, SUNY, Buffalo, NY 14260-1500, USA — We study singlet-triplet relaxation of two electrons confined in a double quantum dot or bound to P donors in Silicon. Hyperfine interaction of the electrons with the host/phosphorus nuclei, in combination with the electron-phonon interaction, leads to relaxation of the triplet states. We calculate the triplet relaxation rates in the presence of an applied magnetic field. This relaxation mechanism affects, for example, the resonance peaks in current Electron Spin Resonance (ESR) experiments on P-dimers. Moreover, the estimated time scales for the spin decay put an upper bound on the gate pulses needed to perform fault-tolerant two-qubit operations in spin-based quantum computers. We have found the optimal regimes, which mitigate this relaxation mechanism, yet permit sufficiently fast two-qubit operations.

[1]We thank support by NSA/LPS thorugh ARO.

9:36AM V27.00009 Spin-orbit induced two-electron spin relaxation in double quantum dots[1]

, MASSOUD BORHANI, XUEDONG HU, SUNY at Buffalo, NY — We study the spin decay of two electrons confined in a double quantum dots via the spin-orbit interaction and acoustic phonons. We have obtained a generic form for the spin Hamiltonian for two electrons confined in (elliptic) harmonic potentials in doubles dots and in the presence of an arbitrary applied magnetic field. Our focus is on the interdot bias regime where singlet-triplet splitting is small, in contrast to the spin-blockade regime. Our results clarify the spin-orbit mediated two-spin relaxation in lateral/nanowire quantum dots, particularly when the confining potentials are different in each dot.

[1]We thank support by NSA/LPS thorugh ARO.

9:48AM V27.00010 Impurity effects on coupled quantum dot spin qubits in semiconductors , NGA NGUYEN, SANKAR DAS SARMA, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, Maryland 20742-4111, USA — Localized electron spins confined in semiconductor quantum dots are being studied by many groups as possible elementary qubits for solid-state quantum computation. We theoretically consider the effects of having unintentional charged impurities in laterally coupled two-dimensional double (GaAs) quantum dot systems, where each dot contains one or two electrons and a single charged impurity in the presence of an external magnetic field. We calculate the effect of the impurity on the 2-electron energy spectrum of each individual dot as well as on the spectrum of the coupled-double-dot 2-electron system. We find that the singlet-triplet exchange splitting between the two lowest energy states, both for the individual dots and the coupled dot system, depends sensitively on the location of the impurity and its coupling strength (i.e. the effective charge). We comment on the impurity effect in spin qubit operations in the double dot system based on our numerical results. This work is supported by LPS-CMTC and CNAM.

10:00AM V27.00011 Theory of anisotropic exchange in laterally coupled quantum dots , FABIO BARUFFA, Institute for Theoretical Physics, University of Regensburg, 93040 Regensburg, Germany, PETER STANO, Institute of Physics, Slovak Academy of Sciences, 84511 Bratislava, Slovak Republic, JAROSLAV FABIAN, Institute for Theoretical Physics, University of Regensburg, 93040 Regensburg, Germany — We consider an interacting pair of quantum dot electron spin qubits (a two electron double quantum dot). In this setup, two-qubit operations are generated by the (isotropic) exchange interaction, which results from the tunable inter-dot coupling. In the presence of spin-orbit interactions, additional effective inter-qubit coupling arises, termed anisotropic exchange. We show that in GaAs, where spin-orbit interactions are weak, the magnitude of the anisotropic exchange is proportional to the external magnetic field and therefore directly controllable, boosting prospects for spin-based quantum computing. We show how the form of anisotropic exchange follows from its spin-orbit origin and that its magnitude can be traced down to dipole moment matrix elements. Based on this findings, we propose an effective spin Hamiltonian suitable for practical modeling of two-electron spin dynamics. We prove the effective Hamiltonian quantitative accuracy confronting it with a microscopic numerical model.

10:12AM V27.00012 Many-body singlets of nuclear spins[1] , WANG YAO, The University of Hong Kong — We show that dynamic spin polarization by collective raising and lowering operators can drive a spin ensemble from arbitrary initial state to many-body singlets, the zero-collective-spin states with large scale entanglement. For an ensemble of N arbitrary spins, both the variance of the collective spin and the number of unentangled spins can be reduced to $O(1)$ (versus the typical value of $O(N)$), and many-body singlets can be occupied with a population of $\sim 20\%$ independent of the ensemble size. We implement this approach in a mesoscopic ensemble of nuclear spins through dynamic nuclear spin polarization by an electron. The result is of two-fold significance for spin quantum technology: (1) a resource of entanglement for nuclear spin based quantum information processing; (2) a cleaner surrounding and less quantum noise for the electron spin as the environmental spin moments are effectively annihilated.

[1]The work was supported by the Research Grant Council of Hong Kong.

10:24AM V27.00013 Atomistic theory of spin relaxation in self-assembled (In, Ga)As/GaAs quantum dots at zero magnetic field , LIXIN HE, Univ. Sci & Tech. of China, HAI WEI, MING GONG, G.-C. GUO — We investigated the spin-flip time (T_1) of electrons and holes mediated by acoustic phonons in self-assembled In(Ga)As/GaAs quantum dots at zero magnetic field, using an atomistic pseudopotential method. At low magnetic field, the first-order process is suppressed, and the second-order process becomes dominant. We find that the spin-phonon-interaction induced spin relaxation time is 40 - 80 s for electrons, and 1 -20 ms for holes at 4.2 K. The calculated hole-spin relaxation times are in good agreement with recent experiments, which suggests that the two-phonon process is the main relaxation mechanism for hole-spin relaxation in the self-assembled quantum dots at zero field. We further clarify the structural and alloy composition effects on the spin relaxation in the quantum dots.

10:36AM V27.00014 Optically controlled electron-nuclear spin dynamics in a quantum dot[1] , EDWIN BARNES, Condensed Matter Theory Center, Dept. of Physics, University of Maryland, SOPHIA ECONOMOU, Naval Research Lab — In recent years, a large number of experiments involving coherent and incoherent control of electron spins in quantum dots have revealed the important role of the nuclear spins of the host material. Experiments with optical controls, both pulsed and continuous wave, have shown that the feedback of the nuclear spins on the electron spin strongly affects the electron spin response. However, a microscopic theory of this mechanism is not available at present. We introduce a formalism that allows us to investigate this system without invoking any phenomenological spin-flip rates for the nuclei. We derive the electron-nuclear dynamics under the influence of external periodic pulsed control to second order in the electron-nuclear hyperfine coupling. Our formalism should have wide applications in both coherently and incoherently driven electron spins interacting with a nuclear spin bath, including self-assembled and gated quantum dots.

Session V28 DMP: Focus Session: Carbon Nanotubes and Related Materials: Devices III C156

8:00AM V28.00001 High Frequency Rectification by Carbon Nanotube Schottky Diodes[1] , ENRIQUE D. COBAS, STEVEN M. ANLAGE, MICHAEL S. FUHRER, Center for Nanophysics and Advanced Materials, University of Maryland, College Park, MD 20742-4111, USA — Carbon nanotubes (CNTs) display many properties that make them appealing for RF electronics, including room-temperature mean-free paths approaching 1 μm and a carrier mobility of 10^5 cm^2 / Vs. Further, small junction capacitances on the order of 10 aF promise cut-off frequencies approaching 1 THz, but high impedances make microwave measurements of individual CNTs challenging. We have fabricated single and few-tube CNT Schottky diodes on high-frequency compatible substrates and measured their ac rectification as a function of dc bias, ac power and frequency, up to 40 GHz. The bias dependence of the cut-off frequency is used to extract the effective junction capacitance for diodes of various channel lengths. This capacitance is found to have a weak dependence on applied bias and a strong relation to channel length. Electrostatic simulations corroborate that stray capacitance from the 1D channel to the metal electrode dominates over the effect of carrier depletion near the junction. The results demonstrate that chottky rectification is a viable method of probing transport in high-impedance semiconducting nanostructures.

8:12AM V28.00002 Logarithmic time response of carbon nanotube field-effect transistors , ANDREW TUNNELL, University of Maryland, VINCE BALLAROTTO, Laboratory for Physical Sciences, MERIJNTJE BRONSGEEST, JOHN CUMINGS, University of Maryland — When observing the source-drain current of a carbon nanotube field effect transistor (FET) held at constant bias, several different processes can produce a time response of the current, including fluctuations due to current noise, heating of contacts, and releasing of trapped charges in the gate dielectric. This third phenomenon is investigated by pulsing voltages on the gate and observing the source-drain current over time. Instead of a typical exponential decay with one or a few time constants, the current was observed to decrease linearly with the logarithm of time, possibly indicating exponential decay with multiple time constants. This trend was seen to continue for over 20 hours, which spans five orders of magnitude in time with respect to the measurement resolution. This trend of scaling logarithmically with time is also seen with the rate of current change with respect to a gate voltage pulse width. This behavior has been investigated in various FET geometries and different materials, all with comparable results. These measurements may be a new way to investigate and characterize the hysteresis in carbon nanotube FETs and the materials used in their fabrication.

8:24AM V28.00003 Mirage Effect From Thermally-Modulated Transparent Carbon Nanotube Sheet , ALI ALIEV, RAY BAUGHMAN — The single beam mirage effect, also known as photothermal deflection, is studied using a free-standing, highly-aligned carbon nanotube sheet as a heat source whose temperature can be modulated over a wide frequency range. The extremely low thermal capacitance and high heat transfer ability of these transparent forest-drawn carbon nanotube sheets enables high frequency modulation of sheet temperature over an enormous temperature range, thereby providing a sharp, rapidly changing gradient of refractive index in surrounding liquid or gas. The advantages of temperature modulation using carbon nanotube sheets are multiple: in inert gases the temperature can reach $>$2500 K; the obtained frequency range for photothermal modulation is $\sim$100 kHz in gases and over 100 Hz in high refractive index liquids; and the heat source is transparent for optical and acoustical waves. The remarkable light deflection in gases and liquids suggests possible application of carbon nanotube sheets for large laser projectors and cloaking systems.

8:36AM V28.00004 Application of Carbon Nanotube Assemblies for Sound Generation and Heat Dissipation , MIKHAIL KOZLOV, CARTER HAINES, JIYOUNG OH, MARCIO LIMA, SHAOLI FANG, University of Texas at Dallas — Nanotech approaches were explored for the efficient transformation of an electrical signal into sound, heat, cooling action, and mechanical strain. The studies are based on the aligned arrays of multi-walled carbon nanotubes (MWNT forests) that can be grown on various substrates using a conventional CVD technique. They form a three-dimensional conductive network that possesses uncommon electrical, thermal, acoustic and mechanical properties. When heated with an alternating current or a near-IR laser modulated in 0.01–20 kHz range, the nanotube forests produce loud, audible sound. High generated sound pressure and broad frequency response (beyond 20 kHz) show that the forests act as efficient thermo-acoustic (TA) transducers. They can generate intense third and fourth TA harmonics that reveal peculiar interference-like patterns from ac-dc voltage scans. A strong dependence of the patterns on forest height can be used for characterization of carbon nanotube assemblies and for evaluation of properties of thermal interfaces. Because of good coupling with surrounding air, the forests provide excellent dissipation of heat produced by IC chips. Thermoacoustic converters based on forests can be used for thermo- and photo-acoustic sound generation, amplification and noise cancellation.

8:48AM V28.00005 Thermoelectric Transport Through Arrays Of Carbon Nanotube Junctions , IRMA KULJANISHVILI, JIM CHOE, VENKAT CHANDRASEKHAR, SERHII SHAFRANIUK, Northwestern University — The work addresses the voltage-controlled thermal flow and electric current through the carbon nanotube (CNT) junction arrays. The CNT thermoelectric generation (TEG) promises a high efficiency for thermal and electric energy conversion in a variety of applications. [1] The energy generation had been studied using advanced methods of the condensed matter physics and nanotechnology. We will outline our experimental findings based on CNTs - TEG devices. We will report on our results that involve TEG-CNTs devices in array and /or single CNTs junctions geometries. We will describe fabrications protocols for preferential CVD growth of CNTs and nanoscale precision patterning of the catalyst on predefined device architectures. Electronic transport and optical properties of the CNTs-TEG nanostructures will also be discussed. I.K. and S.S. acknowledge support from the U.S. Army CECOM Acquisition Center #W909MY-10-C-0032. I.K. acknowledge collaboration with NanoInk Inc.

9:00AM V28.00006 Carbon nanotube quantum dot in a dissipative environment , HENOK MEBRAHTU, IVAN BORZENETS, YURIY BOMZE, Duke University, ALEX SMIRNOV, North Carolina State University, GLEB FINKELSTEIN, Duke University — We study conductance through a resonant level in a single-walled carbon nanotube quantum dot embedded in a dissipative environment. The dissipation is provided by environmental modes in the nanotube leads and the strength of the dissipation is experimentally controlled in several samples. At base temperature, dissipation suppresses the resonant tunneling peak height while maintaining resonant level width. We also observe a regime where the height and the width of a conductance peak demonstrate qualitatively different energy scaling.

9:12AM V28.00007 Energy Dissipation and Transport in Carbon Nanotube Devices , ERIC POP, University of Illinois Urbana-Champaign — Power consumption is a significant challenge in electronics, often limiting the performance of integrated circuits from mobile devices to massive data centers. Carbon nanotubes have emerged as potentially energy-efficient future devices and interconnects, with both large mobility and thermal conductivity. This talk will focus on understanding and controlling energy dissipation [1-3] and transport [4-6] in carbon nanotubes, with applications to low-energy devices, interconnects, heat sinks, and memory elements [7]. Experiments have been used to gain new insight into the fundamental behavior of such devices, and to better inform practical device models. The results suggest much room for energy optimization in nanoelectronics through the design of geometry, interfaces, and materials.

9:48AM V28.00008 Proximal heating by a current-carrying nanotube , KAMAL H. BALOCH, NORVIK VOSKANIAN, MERIJNTJE S. BRONSGEEST, JOHN CUMINGS, University of Maryland — The 1D nature of carbon nanotubes makes them an excellent candidate for thermal management and thermal logic devices. Using an established thermal measurement technique based on the melting of indium islands [1], we have studied the thermal characteristics of Joule-heated MWNTs. Our experimental observations contradict prevailing theoretical models for heat dissipation in CNT. Despite the high thermal contact resistance between the CNT and the substrate we observe that a current-carrying nanotube dissipates power readily into the substrate, suggesting an alternate mode of heat transport based on scattering of hot electrons in the CNT from the substrate phonons. Experimental results, simulations, and a review of the experimental technique will be presented in this talk.

[1] T. Brintlinger, et al., Nano Lett. **8**, 582 (2008).

10:00AM V28.00009 Correlated breakdown of carbon nanotubes in an ultra-high density aligned array , SHASHANK SHEKHAR, MIKHAIL EREMENTCHOUK, MICHAEL LEUENBERGER, SAIFUL KHONDAKER, NanoScience Technology Center and Department of Physics, University of Central Florida, 12424 Research Parkway, Orlando, 32826, USA. — Many proposed applications of single walled carbon nanotubes (SWNTs) require a massively parallel array and selective removal of metallic pathways from the array via electrical breakdown. Since experimental and theoretical studies of individual SWNTs demonstrate that the breakdown is due to Joule heating which occurs at defect sites, a straightforward extrapolation to an array would suggest that the breakdown would occur at random point inside each SWNT. Here we demonstrate that in a densely packed aligned array of SWNTs containing up to 30 SWNT/μm, the breakdown of one of the SWNTs leads to a highly correlated breakdown of neighboring SWNTs, thereby producing a "nano fissure" shaped pattern. We show theoretically that the correlated breakdown is due to the electrostatic field of broken nanotubes that produces locally inhomogeneous current distributions in the neighboring nanotubes triggering their breakdowns in the vicinity of the broken nanotubes. Our results suggest that the densely aligned array works like a correlated solid and have strong implications in the future development of fault-tolerant nano-electronic circuits based on SWNT array.

10:12AM V28.00010 Thermionic Emission Properties of Surface modified conical carbon nano tubes (CCNT) , ANDRIY SHEREHIY, GAMINI SUMANASEKERA, University of Louisville, Department of Physics and Astronomy, SANTOSHRUPA DUMPALA, MAHENDRA SUNKARA, University of Louisville, Department of Chemistry Engineering, ROBERT COHN, University of Louisville, Department of Electrical and Computer Engineering — We have studied field emission and thermionic emission properties of surface modified arrays of CCNTs. The CCNTs with narrow tip radii (about 10 nm) were synthesized using microwave plasma assisted chemical vapor deposition on platinum wire and planar graphite foils. They show enhanced field emission properties with geometrical enhancement factor as high as about 7000 and turn-on electric field as low as approximately 0.7 V/μm. The thermionic emission characteristics show work function of aproximately 4.2 eV which is considerably lower than that of aligned MWNT (4.8 eV). The reduced work function value was further confirmed using ultraviolet photoemission spectroscopy (UPS). The surface modified CCNT arrays were also studied and shown to exhibit poorer emission properties compared to pristine CCNTs. We have further coated CCNTs with diamond nanocrystals and doping of the nanocrystals is underway.

10:24AM V28.00011 Highly Efficient Field Emission from Carbon Nanotube-Nanohorn Hybrids Prepared by Chemical Vapor Deposition , RYOTA YUGE, NEC Corporation, JIN MIYAWAKI, Japan Science and Technology Agency, TOSHINARI ICHIHASHI, SADANORI KUROSHIMA, TSUTOMU YOSHITAKE, NEC Corporation, TETSUYA OHKAWA, YASUSHI AOKI, NEC Lighting, Ltd., SUMIO IIJIMA, Meijo University, MASAKO YUDASAKA, National Institute of Advanced Science and Technology — It is reported that the carbon nanotube (CNT) is one of the best cold cathode emitters for field emission display (FED) and field emission lamp (FEL) due to their large aspect ratio, high mechanical strength, and high electrical conductivity. For the manufacture of highly efficient field emission (FE) devices, we synthesized single-wall carbon nanotube (SWNT) on catalyst-supported single-wall carbon nanohorn (SWNH). We incorporated Fe acetate into SWNHs, heat-treated them, and obtained Fe oxide nano-particles attached to the tips of SWNHs (Fe@NHox). Using Fe@NHox as the catalyst, SWNTs were grown by ethanol-CVD technique (NTNH). In the obtained NTNH, the SWNTs diameters were 1–1.7 nm and the bundle diameters became almost uniform, $i.e.$, less than 10 nm, since the SWNTs were separated by SWNH aggregates. We also confirmed that a large-area FE device with NTNH cathodes made by screen printing was highly and homogeneously bright, suggesting the success of the hybrid strategy.

10:36AM V28.00012 Enhanced electron field emission from simultaneously purified and nitrogen incorporated CNTs via tip opening by Novel *in-situ* nitrogen ECR plasma[1] , SWATHI IYER, PAUL MAGUIRE, NIBEC, University of Ulster — We report a novel single step process by means of *in-situ* nitrogen ECR plasma treatment with very low power and treatment time for the simultaneous metal catalyst (iron) removal via tip opening and nitrogen functionalization/incorporation of the vertically aligned multiwalled carbon nanotubes synthesised using a microwave plasma enhanced chemical vapour deposition. Microscopic (SEM) and spectroscopic (NEXAFS, XPS and Raman) studies reveal negligible remaining Fe content (0%) and limited/no damage structure and alignment of the nanotubes. The incorporation of nitrogen was elucidated by the N-k edge NEXAFS spectra, where the sharp π* peak splits into three distinct peaks at energies 399, 399.5 and 401.1 eV. Increase in the at. % conc. of N 1s from 0.7 to 6.9 % and the disappearance of the peak at 780 eV by XPS and Raman corroborate the inclusion of nitrogen in the CNTs and the complete removal of iron metal catalyst. Metal catalyst removal and nitrogen addition by N-ECR plasma leads to enhanced field emission with very low turn on and threshold fields of 0.52 V/μm and 0.76 V/μm as compared to the recent studies of other nitrogen doped nanomaterials by plasma treatments.

[1]VCRS Scholarship

10:48AM V28.00013 Spin-polarized field emission from nanotubes[1] , JOSEPH DRISCOLL, BRANDON COOK, SERGIY BUBIN, KALMAN VARGA, Vanderbilt University Department of Physics and Astronomy — Time-dependent density functional theory has been used to calculate the spin-polarized field emission from carbon nanotubes with and without Fe adsorbates (atoms and clusters). Using our previously-developed approach [1], the electronic wave function was propagated in real time. Complex absorbing potentials have been employed to avoid artificial reflections from the boundaries and to allow long time simulations. It was observed that various adsorbates cause the separation of density into spin-polarized regions. The calculations predict that carbon nanotubes with various adsorbates can be used as spin-polarized current sources.

Thursday, March 24, 2011 8:00AM - 11:00AM –
Session V29 GQI DAMOP: Quantum Control and Measurement C148

8:00AM V29.00001 Robust high-fidelity universal quantum gates , RAN LI, Kent State University, FRANK GAITAN, Laboratory for Physical Sciences, University of Maryland — We show how a robust high-fidelity universal set of quantum gates can be produced using a single form of non-adiabatic rapid passage whose parameters are optimized to enhance gate fidelity and robustness. All gates in the universal set are found to: (i) operate with fidelities in the range 0.999 — 0.99999, and (ii) use control parameters requiring no more than 14-bit precision. Such precision is within the reach of commercially available arbitrary waveform generators, suggesting the feasibility of an experimental study of this approach to high-fidelity quantum control.

8:12AM V29.00002 Exact, Floquet-based, Single Qubit Control[1] , ANDREW SORNBORGER, University of Georgia, EMILY PRITCHETT, Institute for Quantum Computing — Single-qubit gate design using oscillatory controls is related to the Rabi problem of rotating a spin. In the classical solution one drives the spin with an oscillatory electromagnetic field orthogonal to a background field. Here, we introduce a new, general method for constructing continuous, oscillatory quantum controls based on Floquet's theorem. We then derive a family of exact, analytical solutions to the generalized Rabi problem of completely controlling a single-qubit in a fixed background field.

8:24AM V29.00003 Protection of quantum systems by nested Uhrig dynamical decoupling[1] , ZHEN-YU WANG, REN-BAO LIU, Department of Physics, The Chinese University of Hong Kong — Based on a theorem we establish on dynamical decoupling of time-dependent systems, we present a scheme of nested Uhrig dynamical decoupling (NUDD) to protect multi-qubit systems in generic quantum baths to arbitrary decoupling orders. This scheme uses only single-qubit operations. Higher order decoupling is achieved at the cost of a polynomial increase in pulse number. For general multi-level systems, this scheme protects a set of unitary Hermitian system operators which mutually either commute or anti-commute, and hence all operators in the Lie algebra generated from this set of operators, generating an effective symmetry group for the system up to a given order of precision. We also show how to implement NUDD with pulses of finite amplitude, up to an error in the second order of the pulse durations.

[1]This work was supported by Hong Kong GRF CUHK402209.

8:36AM V29.00004 Quantum noise of an electromagnetically controlled two level system , CHING-KIT CHAN, L.J. SHAM, Department of Physics, University of California San Diego — A coherent control of a spin is limited by both the decoherence due to coupling with the environment and noise coming from the quantized control. A quantum noise study is particularly important in fault tolerant quantum computation where a very high fidelity is demanded. Here, we present a time evolution study of a two level system interacting with a laser pulse and the electromagnetic vacuum based on the multimode Jaynes- Cummings model. We develop a diagrammatic formalism in which one can easily identify the coherent Rabi oscillation of the TLS and its relaxation from corresponding diagrams. In the small time limit ($t \ll T_1$), where the noise level is small but still an issue to fault tolerant quantum computing, this method gives a quantitative evaluation of the quantum noise of the TLS under an optical control with an arbitrary pulse shape. Furthermore, this approach can be naturally extended from the Markovian to the non-Markovian regime, resulting in dynamics different from that obtained in the optical Bloch analysis. All these calculations are done without any stochastic assumption.

8:48AM V29.00005 Optimal control of an ensemble of atoms in an optical lattice[1] , BOTAN KHANI, SETH MERKEL, JAY GAMBETTA, FELIX MOTZOI, FRANK K. WILHELM, University of Waterloo, QUANTUM DEVICE THEORY GROUP TEAM — Controlling quantum systems in a manner that is robust to experimental errors and inhomogeneities is vital for practical realization of quantum gates. We demonstrate numerically the control of motional degrees of freedom of an ensemble of neutral atoms in an optical lattice of shallow trapping potential. Taking into account the range of quasi-momenta across different Brillouin zones results in an ensemble whose members effectively have inhomogeneous control fields as well as spectrally distinct control Hamiltonians. We present a modified optimal control technique that yields high fidelity control pulses, irrespective of quasi-momentum, with average fidelities above 90%. The resultant controls show a broadband spectrum with gate times in the order of several Rabi oscillations to optimize gates with up to 75% dispersion in the energies from the band structure.

9:00AM V29.00006 High Fidelity State Transfer Over an Unmodulated Linear XY Spin Chain , C. ALLEN BISHOP, Department of Physics, Southern Illinois University Carbondale, YONG-CHENG OU, Department of Physics, Texas Tech University, ZHAO-MING WANG, Department of Physics, Ocean University of China, MARK BYRD, Department of Physics, Southern Illinois University Carbondale — We provide a class of initial encodings that can be sent with a high fidelity over an unmodulated, linear, XY spin chain. As an example, an average fidelity of 96% can be obtained using an 11-spin encoding to transmit a state over a chain containing 10,000 spins. An analysis of the magnetic-field dependence is given, and conditions for field optimization are provided.

9:12AM V29.00007 Geometric Phase Gates via Adiabatic Control Using Electron Spin Resonance , HUA WU, ERIK GAUGER, Department of Materials, Oxford University, Oxford OX1 3PH, UK, RICHARD GEORGE, Clarendon Laboratory, Department of Physics, Oxford University, Oxford OX1 3PU, UK, JOHN MORTON, Department of Materials, Oxford University, Oxford OX1 3PH, UK, MIKKO MÖTTÖNEN, 1)Department of Applied Physics/COMP, Aalto University, FI-00076 AALTO, Finland 2)Low Temperature Laboratory, Aalto University, FI-00076 AALTO Finland — High fidelity operations are essential elements of quantum information processing. In contrast with the dynamic pulses that are routinely used in electron spin resonance for spin qubit manipulation, geometric phase gates achieved via adiabatic control are less sensitive to certain kinds of noise and field inhomogeneities. Here, we employ theoretical and numerical tools to show that these geometric operations can be realized in electron spin systems with greater fidelities than composite dynamic pulses for large inhomogeneities in the microwave field. We further show that the adiabatic geometric phase is robust against fast fluctuations in the static magnetic field. Finally, we investigate adiabatic geometric phase operations experimentally, showing that we are able to apply such robust phase gates to the electron spin on the microseconds timescale.

9:24AM V29.00008 Nanoscale control of individual proximal NV spins via a scanning magnetic field-gradient , MICHAEL GRINOLDS, PATRICK MALETINSKY, SUNGKUN HONG, MIKHAIL LUKIN, RONALD WALSWORTH, AMIR YACOBY, Harvard University — Nanoscale ensembles of nitrogen-vacancy (NV) spins have been proposed for implementing quantum information protocols as well as performing sensitive nanoscale magnetometry. However, it has proven experimentally difficult to control individual NV spins without affecting the state of other, proximal spins, as spins are read-out optically and are often collectively driven by applied radio-frequency fields. We demonstrate that single-spin control in NV-spin ensembles can be achieved via a scanning magnetic field-gradient, which locally splits the electron spin resonances of proximal NVs. With this method, we achieve 9 nm spatial resolutions in imaging, characterization, and simultaneous manipulation of individual NVs, roughly two orders of magnitude better than the optical diffraction limit. We discuss applications of this individual control such as generating entangled spin-states and performing sensitive magnetometry.

9:36AM V29.00009 Nested Uhrig Dynamical Decoupling with Non-uniform Error Suppression , GREGORY QUIROZ, DANIEL LIDAR, University of Southern California — Here the performance of Nested Uhrig Dynamical Decoupling (NUDD) for qubit systems is analyzed when error suppression is non-uniform. The error suppression provided by NUDD is controlled by the sequence order of each nested sequence. The properties of the error suppression are characterized with respect to varying sequence order to verify the expected error suppression scaling of UDD, order $N+1$ error suppression with respect to the total time of evolution for an Nth order sequence. The system operators present in the system-environment evolution are isolated and used to quantify the order of error suppression associated with each system error operator. Using this as a measurement, error suppression is examined with respect to the strength of system-enviroment interaction, as well as the pure bath strength. In the case of single-qubit NUDD, known as Quadratic Dynamical Decoupling (QDD), the results show that the error suppression provided by the inner sequence scales exactly with that of UDD, while the outer sequence dynamics leads to error suppression greater than or equal to that expected from UDD. These results can be extended to multi-qubit systems where the error suppression scaling for the inner sequence applied to each qubit follows that of UDD and the outer sequence applied to each qubit gives an error suppression greater than or equal to $N+1$.

9:48AM V29.00010 Pulsed Quantum Optomechanics , MICHAEL R. VANNER, University of Vienna, IGOR PIKOVSKI, GARRETT D. COLE, MYUNGSHIK KIM, CASLAV BRUKNER, KLEMENS HAMMERER, GERARD J. MILBURN, MARKUS ASPELMEYER — By combining quantum optics with mechanical resonators an avenue is opened to extend investigations of quantum behavior into unprecendented mass regimes. The field resulting from this combination - "cavity quantum optomechanics" – is receiving a surge of interest for its potential to contribute to quantum measurement and control, studies of decoherence and non-classical state preparation of macroscopic objects. However, quantum state preparation and especially quantum state reconstruction of mechanical oscillators is currently a significant challenge. We are pursuing a scheme that employs short optical pulses to realize quantum state tomography, squeezing via measurement and state purifcation of a mechanical resonator. The pulsed scheme has considerable resilience to initial thermal occupation, provides a promising means to explore the quantum nature of massive oscillators and can be applied to other systems such as trapped ions. Our theoretical proposal and experimental results will be discussed.

10:00AM V29.00011 Quantum measurement with Mach-Zehnder Interferometer , YUNJIN CHOI, JUSTIN DRESSEL, ANDREW JORDAN, University of Rochester — We use an electronic Mach-Zehnder Interferometer (MZI) as a measurement device. We perform a measurement on a system by coupling with MZI using a phase shift induced by Clulombic coupling. By reading current and noise cross-correlations, strange conditioned averages can be constructed using the contextual values technique.

10:12AM V29.00012 Continuous phase amplification with a Sagnac interferometer , NATHAN WILLIAMS, DAVID STARLING, BEN DIXON, ANDREW JORDAN, JOHN HOWELL, University of Rochester — We describe a weak value inspired phase amplification technique in a Sagnac interferometer. We monitor the relative phase between two paths of a slightly misaligned interferometer by measuring the average position of a split-Gaussian mode in the dark port. Although we monitor only the dark port, we show that the signal varies linearly with phase and that we can obtain similar sensitivity to balanced homodyne detection. We derive the source of the amplification both with classical wave optics and as an inverse weak value.

10:24AM V29.00013 Conservation of Vacuum in an Interferometer , DOMINIC BERRY, University of Waterloo, ALEXANDER LVOVSKY, University of Calgary — Source efficiency and photon loss are major problems in optical metrology and quantum information. To understand how to address loss for these applications, it is vital to know how the loss behaves under linear optical (LO) processing including conditional measurements. We have developed a theory for the behavior of loss under LO processing, resolving many long-standing questions from previous work [1,2]. In particular, we have shown that, provided the efficiency of the sources is appropriately quantified, the efficiency of the state in any single mode cannot be increased beyond that of the highest-efficiency mode available at the input [1]. It is also not possible to increase efficiency in a catalytic way, using some high-efficiency modes to increase the efficiency of other modes [2]. The results provide a powerful unifying framework for quantifying efficiency by the incoherent vacuum contribution to optical states, even when entangled over multiple modes. The amount of vacuum is invariant under interferometers, and can only be increased by measurement.

10:36AM V29.00014 Dynamics of entanglement in two-dimensional spin system , QING XU, SABRE KAIS, Purdue University, GEHAD SADIEK, King Saud University and Ain Shams University — We consider the time evolution of entanglement in a finite two dimensional transverse Ising model. The model consists of a set of 7 localized spin-$\frac{1}{2}$ particles in a two dimensional triangular lattice coupled through exchange interaction J in presence of an external time dependent magnetic field $h(t)$. The magnetic field is presented in various function forms. We find that the magnetic field with sudden change does not provide a way to control or tuning the entanglement. While for the smoothly changing field, when its the character frequency is small, entanglement tends to follow the change of external magnetic field; when it gets larger, entanglement gradually loses pace with the field. It is also shown that the mixing of even a few excited states by small thermal fluctuation is devastating to the entanglement of the ground state.

10:48AM V29.00015 Probing Majorana edge states with a qubit , CHANG-YU HOU, FABIAN HASSLER, Institute Lorentz, Leiden University, JOHAN NILSSON, Department of Physics, University of Gothenburg, ANTON AKHMEROV, Institute Lorentz, Leiden University — A pair of counter-propagating Majorana edge modes can be described by an Ising conformal field theory. These modes appear in a chiral p-wave superconductor or in some superconducting system belonging to the same universality class. We show how a superconducting flux qubit attached to a such system couples to the two chiral edge modes via the disorder field of the Ising model. Thus, measuring the back-action of the edge states on the qubit allows to probe the properties of Majorana edge modes.

Thursday, March 24, 2011 8:00AM - 11:00AM –

Session V30 DCMP: Nanowires and Nanotubes: Thermal and Mechanical Properties C147/154

8:00AM V30.00001 Thermal boundary resistance between carbon nanotubes in nanocomposites with Monte Carlo simulations[1] , KHOA BUI, BRIAN GRADY, DIMITRIOS PAPAVASSILIOU, The University of Oklahoma — Enhancing the thermal conductivity of composites by incorporating carbon nanotubes (CNTs) has been an area of vigorous research recently. Measurements of the effective thermal conductivity (keff) for CNT-polystyrene composites at high CNT %wt found that the ratio (keff/kpolymer) at high concentration of CNTs is not as good as that at low CNT concentration [1]. It appears that the CNT dispersion pattern becomes worse, resulting in the formation of CNT bundles. In this work, we apply Monte Carlo simulations to investigate the keff at different weight fractions taking into account the bundle size and orientation, as well as the thermal boundary resistance. By validating with the experiment data, we found that the phonon transmission probability at the interface decreases by temperature. In addition, the poor enhancement of keff at high CNT concentration is because of the CNT-CNT contact resistance and because of the bundle geometry itself, which is equivalent to the presence of one low aspect ratio nanotube. 8:12AM V30.00002 Strain Engineering of the thermal conductance in Si nanowires , A. PAUL, K. MIAO, M. LUISIER, G. KLIMECK, Purdue University — Silicon nanowires (SiNWs) are promising semiconductor structures spanning a wide range of applications from CMOS devices to thermoelectric modules. Recently, SiNWs have shown tremendous potential as good thermoelectric materials with ZT coefficients larger than 1 [1]. This figure of merit can be further improved by tuning the thermal conductivity of the SiNWs. Here, we show that strain provides a natural way of tuning the thermal conductance of ultra-scaled SiNWs. We utilize a modified Valence Force Field (MVFF) model [2] to calculate the phonon dispersion in these SiNWs under strain and extract their thermal conductance using Landauer's approach. Our investigation shows that uniaxial tensile and hydrostatic compressive help reduce the thermal conductance of SiNWs. For example, a 3nm X 3nm, <100> oriented nanowire undergoing a 2% uniaxial tensile strain exhibits a thermal conductance reduced up to 2.6%, whereas a compressive hydrostatic strain of 2% gives a reduction of around 8%. Thus, strain engineering can prove beneficial in tuning the thermal conductance in Si nanowires and offers an efficient way to further improve the ZT figure of merit. 8:24AM V30.00003 Thermal Conductivity of Metallic Nanowires near Room Temperature , N. STOJANOVIC, J. BERG, Texas Tech University, D.H.S. MAITHRIPALA, University of Peradeniya, M. HOLTZ, Texas Tech University — In metallic structures with nanoscale dimension both electrical and thermal conductivities are significantly different from their bulk counterparts. The total thermal conductivity is generally the sum of the electronic and phonon contributions. We examine electron and phonon heat transport in metals, in the temperature range near to or above the Debye temperature, where it is generally assumed that phonon component is negligible for metals, an assumption that has not been subjected to rigorous experimental verification, particularly at the nanoscale, due to difficulties in direct measurement of thermal conductivity. Experimental evidence suggests that the Wiedemann-Franz (W-F) law breaks down at the nanoscale. The neglected phonon component is one factor that has been cited as contributing to the apparent discrepancy in W-F. Another factor is inelastic electron-phonon scattering that influences transport due to a temperature gradient, but not due to an electric field. We report experimental results for Al nanowires and develop a model based on the Boltzmann transport equation for size dependence of electrical and thermal conductivity in nanowires. The model is validated with available data reporting direct measurements of thermal conductivity of nanowires, ribbons, and thin films. The W-F law and Lorenz factor are examined and a modified version of W-F is presented, corrected for these two factors and valid from macro- to nanoscale provided characteristic sizes exceed the phonon mean free path.

8:36AM V30.00004 Diffusion-induced dephasing and bistability of nanoresonators , JUAN ATALAYA, Chalmers University of Technology, MARK I. DYKMAN, Michigan State University, ANDREAS ISACSSON, Chalmers University of Technology — We study dephasing of an underdamped harmonic oscillator due to frequency fluctuations. The spectrum of the response to an external field is sensitive to the nature of the fluctuations. For nanomechanical resonators, if the dephasing is due to diffusion of adsorbed particles along the resonator, the spectrum varies from a single Lorentzian peak to two closely spaced peaks depending on the parameters. If the dephasing depends on the oscillator state, the oscillator can exhibit bistability of forced vibrations. We study this bistability for a nanomechanical resonator with diffusing adsorbed particles. The vibrations affect the particles by driving them toward the antinodes of the vibrational mode. Unexpectedly, even though diffusion is a random process, the bistability arises if it is sufficiently strong, i.e., fast compared to the vibrations decay time. For fast diffusion, we find the bistable response in the mean-field approximation. We also study, analytically and numerically, the rate of fluctuation-induced switching between the coexisting stable states.

8:48AM V30.00005 Electrical Detection of Resonance of ZnO nanowires using Harmonic Detection of Radiation , DEEPIKA SAINI, RAMAKRISHNA PODILA, MALCOLM SKOVE, APPARAO RAO, Clemson University — ZnO nanowires exhibit semiconducting and piezoelectric properties making them a technologically promising material. We have measured the mechanical resonance of cantilevered ZnO nanowires using the Harmonic Detection of Resonance (HDR) method.[1] The resonance is induced by an oscillating electric field and detected by second harmonic electric response of the ZnO nanocantilever. The diameter of the nanowires used was about 200 nm and length varied from 60 to 300 μm. Other mechanical properties of the cantilever, such as Young's modulus, are calculated from the observed resonance frequency.

9:00AM V30.00006 Semiconducting nanowire electromechanics in the Coulomb blockade regime , HARI SOLANKI, SAJAL DHARA, ARNAB BHATTACHARYA, MANDAR DESHMUKH, Tata Institute, Mumbai, India — We fabricate and study Indium Arsenide (InAs) nanowire electromechanical resonators, in field effect transistor (FET) geometry, which allows us to tune the carrier density and tension in the wire at electromechanical resonance by tuning the dc gate voltage. At temperatures below 5K, quality factor (Q) of these resonators is $\sim$10000, two orders of magnitude larger than at room temperature, and the dynamic range reduces by an order of magnitude at low temperatures. Further in Coulomb blockade regime (charging energy $\sim$10 meV), using rectification technique, we have observed the modification in Coulomb diamond structure at the resonance frequency of the wire. Near the electromechanical resonance frequency, Coulomb peaks become broader symmetrically (independent of dc gate voltage and frequency sweep direction) and right at the resonance frequency their intensity is significantly reduced. This indicates a strong coupling between electron transport and mechanical vibration of the nanowire.

9:12AM V30.00007 Capacitive Spring Softening in Single-Walled Carbon Nanotube Nanoelectromechanical Resonators , CHUNG CHIANG WU, Department of EECS, University of Michigan — Due to their low mass density and high Young's modulus, single-walled carbon nanotubes (SWNTs) offer great promise as nanoelectromechanical (NEM) resonators with applications in ultrasmall mass and force sensing. Nanotube resonators can be actuated and detected simultaneously through electrostatic gate coupling. This gate induced frequency tuning of NEM resonators is known to be governed by two mechanisms: the elastic hardening effect and the capacitive softening effect. Although elastic hardening effect has been widely reported in SWNT resonators, the field-induced capacitive spring softening has rarely been observed. Here we report the capacitive spring softening effect observed in SWNT resonators. The nanotube resonators adopt dual-gate configuration with both bottom-gate and side-gate capable of tuning the resonance frequency through capacitive coupling. Interestingly, downward resonance frequency shifting is observed with increasing side-gate voltage, which can be attributed to the capacitive softening of spring constant. Furthermore, in-plane vibrational modes exhibit much stronger spring softening effect than out-of-plan modes. Our dual-gate design should enable the differentiation between these two types of vibrational modes, and open up new possibility for nonlinear operation of nanotube resonators. Other nonlinear effects in SWNT resonators will also be discussed.

9:24AM V30.00008 Vibrational Behaviour of Metal Nanowires under Tensile stress[1] , YASEMIN SENGUN, Department of Physics, Istanbul Technical University, Maslak, 34469, Istanbul, Turkey, SONDAN DURUKANOGLU, Faculty of Engineering and Natural Sciences, Sabanci University, Tuzla, 34956 Istanbul, Turkey — We present results of calculations on vibrational density of states (VDOS) of a thin Cu nanowire with <100> axial orientation and discuss on the effect of axial strain. The calculations are performed using real space Green's function method with the force constant matrix extracted from the interaction potentials based on the embedded atom method. It is shown that the characteristics of the VDOS of a strain-free nanowire are quite distinctive compared to that of a bulk atom. Among the striking features of this type nanowire is the existence of high frequency modes above the top of the bulk spectrum. From an examination of VDOS of local atoms it is seen that the corner and core atoms are the primary moderators for the anomalous increase in low frequency and high frequency modes, respectively. We, additionally, find that while the high frequency band above the top of the bulk phonon shifts to even higher frequencies, the characteristics at low frequencies remains almost the same upon stretching the nanowire along the axial direction.

[1]This work is supported by TUBITAK under Grant No. 109T105.

9:36AM V30.00009 Understanding and Controlling Intrinsic Dissipation in Driven Single Walled Carbon Nanotube Resonators[1] , RAJAMANI RAGHUNATHAN, P. ALEX GREANEY, JEFFREY C. GROSSMAN, Massachusetts Institute of Technology, Cambridge, MA 02139 — A "Phonostat" algorithm that can regulate total energy in a given internal degree of freedom within a molecular dynamics (MD) simulation is presented. The algorithm computes modal energies at every MD timestep, controls energy in a chosen vibrational mode with an external driving force and an internal damping. Using a test case of driven damped anharmonic oscillator, two different approaches of force correction are presented and various parameters that control the phonostat algorithm are analyzed. This algorithm is then employed to drive a chosen vibrational mode in carbon nanotube resonator to understand intrinsic dissipation under continuous driving, simultaneously computing its quality factor to mimic experimental conditions. The *gateway* modes that couple the driven mode to the thermal background are identified. Regulating these gateway modes hold the key to control intrinsic dissipation and improve quality factor for mass sensing application.

9:48AM V30.00010 Anomalous Electromechanical Resonance Behavior of Single-walled Carbon Nanotubes under High Bias Voltages , MEHMET AYKOL, WILLIAM BRANHAM, ZUWEI LIU, MOH AMER, I-KAI HSU, ROHAN DHALL, SHUN-WEN CHANG, STEPHEN CRONIN, University of Southern California — By monitoring the nanoelectromechanical response of suspended individual carbon nanotubes (CNT), we observe the onset of optical phonon (OP) emission in these CNTs under high bias voltages. An abrupt upshift in the mechanical resonance frequency is observed at high voltage biases. The underlying cause of this behavior is the sudden increase in the lattice temperature of the CNT that causes contraction of the lattice due to the negative thermal expansion coefficient. This, in turn, results in increased tension in the suspended nanotube and an upshift in the mechanical resonance frequency. The sudden increase in temperature is explained by the OP emission in CNT. This effect is also observed in the Raman spectra of CNTs as a sudden downshift in the G band OP frequencies at high bias voltages.

10:00AM V30.00011 Transport in partially equilibrated inhomogeneous quantum wires[1] , ALEX LEVCHENKO, Argonne National Laboratory, TOBIAS MICKLITZ, Freie Universitat Berlin, JEROME RECH, Centre de Physique Theorique Marseille, KONSTANTIN MATVEEV, Argonne National Laboratory — We study transport properties of weakly interacting one-dimensional electron systems including on an equal footing thermal equilibration due to three-particle collisions and the effects of large-scale inhomogeneities. We show that equilibration in an inhomogeneous quantum wire is characterized by the competition of interaction processes which reduce the electrons total momentum and such which change the number of right- and left-moving electrons. We find that the combined effect of interactions and inhomogeneities can dramatically increase the resistance of the wire. In addition, we find that the interactions strongly affect the thermoelectric properties of inhomogeneous wires and calculate their thermal conductance, thermopower, and Peltier coefficient.

10:12AM V30.00012 Energy loss of the electron system in individual single-walled carbon nanotubes[1] , DANIEL SANTAVICCA, JOEL CHUDOW, DANIEL PROBER, Yale University, MENINDER PUREWAL, PHILIP KIM, Columbia University — We characterize the energy loss of the non-equilibrium electron system in individual metallic single-walled carbon nanotubes at low temperature. Using Johnson noise thermometry, we demonstrate that, for a nanotube with ohmic contacts, the dc resistance at finite bias current directly reflects the average electron temperature. This enables a straightforward determination of the thermal conductance associated with cooling of the nanotube electron system. In analyzing the temperature- and length-dependence of the thermal conductance, we consider contributions from acoustic phonon emission, optical phonon emission, and hot electron outdiffusion [1]. In the same sample, we also characterize the radio frequency heterodyne response. Distinct responses are seen from bolometric detection and from the electrical nonlinearity due to non-ohmic contacts.

10:24AM V30.00013 Heat pumping in nanomechanical systems[1] , LILIANA ARRACHEA, Universidad de Buenos Aires, CLAUDIO CHAMON, Boston University, EDUARDO MUCCIOLO, University of Central Florida, RODRIGO CAPAZ, Universidade Federal de Rio de Janeiro — We propose using phonon pumping mechanism to transfer heat from a cold to a hot body. The mechanism is based on inducing a traveling modulation of the acoustic phonon velocity along the medium connecting the two bodies. This phonon pumping can cool nanomechanical systems without the need for active feedback. We have derived an estimate of the lowest achievable temperature. We have also analyzed this mechanism in the framework of simple one-dimensional microscopic models, which can be exactly solved with non-equilibrium Green function techniques.

10:36AM V30.00014 Phonon spectrum in a CdSe nanowire[1] , CHRIS BARRETT, Material Science and Engineering Department, University of California at Berkeley, LIN-WANG WANG, Material Sciences Division — It is important to calculate the phonon spectrum of realistic nanowires, e.g. to understand its thermo conductivity or to calculate the electron-phonon interaction. In this talk, we will present results of phonon spectrum calculation using valence force field (VFF) method. An important issue is to construct the VFF to describe the surface atomic displacement. We have developed a general VFF formalism to fit our VFF result with the density functional theory (DFT) calculated surface atom displacement energies. In particular, the (10-10) CdSe surface is modelled with Cd-Se dimerization. We will discuss the quality of such VFF model. The phonon spectrum of the nanowire will be presented, and its implication on the phonon transport and electron-phonon coupling will also be discussed.

10:48AM V30.00015 Curvature-induced Effects on the Phonon Modes in Sub-nanometer Diameter Single-walled Carbon Nanotubes , RAMAKRISHNA PODILA, Clemson University, RAHUL RAO, Air Force Research Laboratory, Materials and Manufacturing Directorate, WPAFB, OH, CODRUTA LOEBICK, NAN LI, Yale University, JASON REPPERT, Clemson University, LISA PFEFFERLE, Yale University, APPARAO M. RAO, Clemson Univeristy — Sub-nanometer diameter single-walled carbon nanotubes (sub-nm SWNTs) are of great interest for fundamental studies due to the effect of large curvature on their properties. We have recently synthesized high quality, narrow diameter distribution sub-SWNTs using CoMn catalysts supported on MCM-41 silica templates in a thermal chemical vapor deposition process [1]. The high curvature in the sub-nm SWNTs leads an unusual S-like dispersion of the G-band frequency due to the strong electron–phonon coupling. In addition, we observe diameter-selective intermediate frequency modes (IFMs) that are as intense as the low frequency radial breathing modes (RBMs). The effect of large curvature in the sub-nm SWNTs is also evident in the lower phonon dispersion of the double resonant Raman features compared to SWNTs with larger diameters. The origin of previously unidentified IFM features (600-1100 cm^{-1}) and the dispersion of high frequency phonons (1650 – 2300 cm^{-1}) will be discussed.

Thursday, March 24, 2011 8:00AM - 11:00AM –

Session V31 GERA: Energy Production: Combustion, Heat Engines, Solar Thermal and Thermoelectrics C145

8:00AM V31.00001 Electricity from Coal Combustion: Improving the hydrophobicity of oxidized coals , MOHINDAR SEEHRA, VIVEK SINGH, West Virginia University — To reduce pollution and improve efficiency, undesirable mineral impurities in coals are usually removed in coal preparation plants prior to combustion first by crushing and grinding coals followed by gravity separation using surfactant aided water flotation. However certain coals in the US are not amendable to this process because of their poor flotation characteristics resulting in a major loss of an energy resource. This problem has been linked to surface oxidation of mined coals which make these coals hydrophilic. In this project, we are investigating the surface and water flotation properties of the eight Argonne Premium (AP) coals using x-ray diffraction, IR spectroscopy and zeta potential measurements. The role of the surface functional groups, (phenolic -OH and carboxylic -COOH), produced as a result of chemisorptions of O_2 on coals in determining their flotation behavior is being explored. The isoelectric point (IEP) in zeta potential measurements of good vs. poor floaters is being examined in order to improved the hydrophobicity of poor floating coals (e.g. Illinois #6). Results from XRD and IR will be presented along with recent findings from zeta potential measurements, and use of additives to improve hydrophobicity. Supported by USDOE/CAST, Contract #DE-FC26-05NT42457.

8:12AM V31.00002 Electrorheology for Efficient Energy Production and Conservation , R. TAO, ENPENG DU, HONG TAO, XIAOJUN XU, Temple University, YUN LIU, NIST Center for Neutron Research — At present, most of our energy comes from liquid fuels. The viscosity plays a very important role in liquid fuel production and conservation. For example, reducing the viscosity of crude oil is the key for oil extraction and its transportation from off-shore via deep water pipelines. Currently, the dominant method to reduce viscosity is to raise oil's temperature, which does not only require much energy, but also impacts the environment. Recently, based on the basic physics of viscosity, we proposed a new theory and developed a new technology, utilizing electrorheology to reduce the viscosity of liquid fuels. The method is energy-efficient, and the results are significant. When this technology is applied to crude oil, the suspended nanoscale paraffin particle, asphalt particles, and other particles are aggregated into micrometer-size streamline aggregates, leading to significant viscosity reduction. When the temperature is below 0°C and the water content inside the oil becomes ice, the viscosity reduction can be as high as 75%. Our recent neutron scattering experiment has verified the physical mechanism of viscosity reduction. In comparison with heating, to reach the same level of viscosity reduction, this technology requires less than 1% of the energy needed for heating. Moreover, this technology only takes several seconds to complete the viscosity reduction, while heating takes at least several minutes to complete.

8:24AM V31.00003 Small angle neutron (SANS) and X-ray scattering (SAXS) investigation of microstructure and porosity with fractal properties of coal, shale, and sandstone from Indiana , NARAYAN CH DAS, HU CAO, H. KAISER, T.R. PRISK, PAUL E. SOKOL, Low Energy Neutron Source, Center for Exploration of Energy and Matter & Department of Physics, Indiana University, Bloomington, M. MASTALERZ, J. RUPP, Indiana Geological Survey, Indiana University, Bloomington — We have applied SAXS, SANS and adsorption isotherms to study the porosity, pore structure and interaction of confined fluids in the various Indiana rock samples. This study included a bituminous coal, a sandstone, and a grey shale from formations investigated as possible targets for CO2 sequestration. SAXS and SANS are demonstrated quantitative information about the microstructure and pore morphology of the coals and other rocks at length scale (1 nm to 0.3 micron) as well as the fractal nature of pore matrix interfaces. The different scattering cross sections of X-rays and neutrons provide information on the distribution of pore sizes in organic and inorganic components. Neutrons are relatively sensitive to the presence of either hydrocarbons or water in the pores, and always give a smaller Porod exponent that that for X-ray. Construction of LENS was supported by the NSF, the 21^{st} Century Science and Technology fund of Indiana, and the DOD. LENS operation is supported by Indiana University.

8:36AM V31.00004 Optimizing the performance of a heat engine: A simulation study , MULUGETA BEKELE, MEHARI BAYOU, YERGOU TATEK, MESFIN TSIGE — We performed a simulation study of a simple heat engine as it undergoes Carnot-type cyclic motion in a finite time over a wide range of piston speeds. There exists a specific piston speed at which the power delivered by the engine is maximum (P_{max}) and its corresponding efficiency is slightly larger than *half* of the Carnot efficiency (1/2 η_c). An optimization criterion leads to a trade-off between high power and high efficiency with respective values of 4/5 P_{max} and 3/4 η_c. In addition, we found the time taken at the optimized state to be twice the time taken when operating at maximum power.

8:48AM V31.00005 Analysis of Binary Cycle Efficiency Using Redlich-Kwong Equation of State , DEBORAH SAUNDERSON, ARIEF BUDIMAN, University of Calgary — Coal, natural gas and nuclear power plants operate using various forms of Rankine cycle. We present an efficiency maximization strategy of binary cycle, which has two Rankine cycles in tandem, using Redlich-Kwong equation of state for wide ranging working fluids: alkali metals, mercury, water, and ammonia. Binary cycle efficiency can approach the Carnot efficiency at a cost. The mercury/ammonia working fluid combination yields the highest efficiency for typical binary cycle conditions. We discuss practical implications given that mercury and ammonia create safety concerns, especially on finding other fluids having similar efficiency based on our simulations.

9:00AM V31.00006 Carbon dioxide adsorption on H_2O_2 treated single-walled carbon nanohorns[1] , ALDO MIGONE, VAIVA KRUNGLEVICIUTE, SHREE BANJARA, Department of Physics, Southern Illinois University Carbondale, MASAKO YUDASAKA, SUMIO IIJIMA, National Institute of Advanced Industrial Science and Technology, Japan — Carbon nanohorns are closed single-wall structures with a hollow interior. Unlike SWNTs, which assemble into cylindrical bundles, nanohorns form spherical aggregates. In our experiments we used dahlia-like carbon nanohorn aggregates. Our sample underwent treatment with H_2O_2 which opened access to the interior spaces of the individual nanohorns. We measured carbon dioxide adsorption at several temperatures between 167 and 195 K. We calculated the isosteric heat as a function of loading, and the binding energy values for CO_2 on the nanohorn aggregates from the isotherm data. Results on the H_2O_2-treated nanohorns will be compared with those obtained on other carbon substrates. We have also determined detailed equilibration profiles for CO_2 adsorption on the nanohorn aggregates; these results will also be presented.

[1]This work was supported by the NSF through grants DMR-1006428 and DMR-0705077.

9:12AM V31.00007 GOFs and ZIFs: Experimental Results and Analysis of Carbon Dioxide Sorption , JACOB BURRESS, JASON SIMMONS, NIST Center for Neutron Research, WEI ZHOU, University of Maryland, GADIPELLI SRINIVAS, JAMIE FORD, University of Pennsylvania, TANER YILDIRIM, NIST Center for Neutron Research — In recent years, growing concerns about global warming and the environment have spurred an accelerated development of materials technology for carbon dioxide (CO2) capture and storage. Two recent categories of materials being investigated for their CO2 storage capabilities are graphene oxide frameworks (GOFs) [1] and zeolitic imidazolate frameworks (ZIFs). We have synthesized graphene-oxide-frameworks (GOFs) by linking the OH groups on graphene oxide with benzene-boronic acids. Our initial GOF materials exhibit isosteric heats at low coverage of 32 kJ/mol for CO2. The nitrogen BET surface area of these initial materials is around 500 m2/g. Also, ZIFs are particularly useful for CO2 capture and storage due to high selectivities, CO2 uptakes and sample robustness. Neutron scattering and spectroscopic results of GOFs and select ZIFs with in-situ gas sorption will be presented. Neutrons are able to determine locations and strengths of binding sites. We will present detailed isotherms of carbon dioxide, methane and nitrogen at different temperatures of these interesting GOF and ZIF materials.

9:24AM V31.00008 Eutectics and Phase Diagrams of Molten Salts from Molecular Dynamics simulations , SAIVENKATARAMAN JAYARAMAN, ANATOLE VON LILIENFELD, AIDAN THOMPSON, Sandia National Laboratories — The use of alkali nitrate salt mixtures as heat transfer fluids in solar thermal power plants is limited by their relatively high melting point. Certain compositions of quaternary and higher dimensional mixtures of alkali and alkaline earth nitrates and nitrites have low melting points. However, the high dimensionality of the search space makes it difficult to find lowest melting compositions. Molecular simulations offer an efficient way to screen for promising mixtures. A molecular dynamics scheme general enough to identify eutectics of any HTF candidate mixture will be presented. The eutectic mixture and temperature are located as the tangent point between free energies of mixing for the liquid and a linear plane connecting the pure solid-liquid free energy differences. The free energy of mixing of the liquid phase is obtained using thermodynamic integration over "alchemical" transmutations sampled with molecular dynamics, in which particle identities are swapped gradually. Numerical results for binary and ternary mixtures of alkali nitrates agree well with experimental measurements.

9:36AM V31.00009 Energy Harvesting with Stochastic, Subharmonic and Ultraharmonic Vibrations[1] , JI-TZUOH LIN, BRUCE ALPHENAAR, University of Louisville — Non-linear bi-stable systems have been shown to provide improved efficiency for harvesting energy from random and broad band vibration sources. This paper explores the distinct frequency response in the broadened spectrum of a particular non-linear energy harvester, a piezoelectric cantilever with magnetic coupling. The cantilever response evolves dynamically with frequency around the main cantilever resonance. Both stochastic and multi-frequency vibration responses are observed, and account for some of the improved efficiency. In addition, sub-harmonics and ultra-harmonics of the main resonance, along with various combinations of these appear. Taken together, the sub-harmonic and ultra-harmonic response produces an average of four-fold increase in voltage production. For energy harvesting purposes, the mixtures of the stochastic and various harmonic features together with the un-damped resonant response enhances the performance well beyond that of a standard energy harvester. An analytical model of the bi-stable dynamics produces results consistent with those observed experimentally.

[1]The effort was funded by the U.S. Navy under Contract DAAB07-03-D-B010/TO-0198. Technical program oversight under Navy contract was provided by Naval Surface Warfare Center, Crane Division.

9:48AM V31.00010 Enhanced thermoelectric properties of n-type filled skutterudite Yb0.35Co4Sb12 by substitution on both the Co and Sb sites , TIANYI SUN, Boston College, GANG CHEN, MIT, ZHIFENG REN, Boston College — A dimensionless thermoelectric figure of merit (ZT) of about 1.2 was reported in Yb0.35Co4Sb12 at 550°C by ball milling and hot pressing. Through alloying on both the Co and Sb sites, we expect to achieve lower thermal conductivity while maintaining the power factor. The composition tuning is aimed for reducing the electrical conductivity and increasing the Seebeck coefficient, which will lead to a lower thermal conductivity, and ultimately higher ZT. In this report, we present the thermoelectric properties of skutterudites Yb0.35FexCo4-2xNixSb12 and Yb0.35Co4Sb12-yMy (M=Si, Ge, Sn, B, Al, Ga, In, etc.).

10:00AM V31.00011 Optimum Working Fluid Selection For Rankine Cycle Using Redlich-Kwong Equation of State , ARIEF BUDIMAN, DEBORAH SAUNDERSON, University of Calgary — Efficiency of Rankine cycle as a function of working fluid molecule is modeled using Redlich-Kwong equation of state. We have evaluated 12 molecules, ranging from water to ethylene glycol, and have parameterized their individual performance on several material parameters, including heat capacity and compressibility. This research aims to understand at the molecular level what drives some molecules to perform better at certain temperature and pressure range of the Rankine cycle. Immediate applications we are interested in are geothermal power, solar thermal energy conversion and waste heat recovery.

10:12AM V31.00012 Thermoelectric properties of correlated materials , JAN TOMCZAK, KRISTJAN HAULE, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA, TAKASHI MIYAKE, Nanosystem Research Institute, AIST, Tsukuba 305-8568, Japan, ANTOINE GEORGES, Centre de Physique Theorique, Ecole Polytechnique, CNRS, 91128 Palaiseau Cedex, France, GABRIEL KOTLIAR, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA — The discovery of large Seebeck coefficients in transition metal compounds such as FeSi, FeSb2, or the iron pnictides, has stirred renewed interest in the potential merits of electronic correlation effects for thermoelectric properties. The notorious sensitivity in this class of materials to small changes in composition (doping, chemical pressure) and external stimuli (temperature, pressure), makes a reliable and, possibly, predictive description cumbersome, while at the same time providing an arena of possibilities in the search for high performance thermoelectrics. Based on state-of-the-art electronic structure methods (density functional theory with the dynamical mean field theory) we here compute the thermoelectric response for several of the above mentioned exemplary materials from first principles. With the ultimate goal to understand the origin of a large thermoelectricity in these systems, we discuss various many-body renormalizations, and identify correlation controlled ingredients that are pivotal for thermopower enhancements.

10:24AM V31.00013 Electron correlation effect on temperature and magnetic-field dependences of thermopower[1] , MARI MATSUO, Japan Atomic Energy Agency and JST-CREST, SATOSHI OKAMOTO, Oak Ridge National Laboratory, WATARU KOSHIBAE, RIKEN, Japan, MICHIYASU MORI, SADAMICHI MAEKAWA, Japan Atomic Energy Agency and JST-CREST — We theoretically investigate the temperature T and the magnetic field dependences of thermopower. To focus on the strong electron correlation, the Hubbard model is solved in the dynamical mean field theory with the non-crossing approximation impurity solver. The thermopower shows a non-monotonic behavior as a function of T and asymptotes to the high-T values given by the Heikes formula, depending on the ratio of Coulomb repulsion and T. The large response to the magnetic-field, which is observed in the cobalt oxides [1], can be associated with the sharp quasiparticle peak intrinsic to the strongly correlated electron system. We discuss the effect of orbital degeneracy, which is another key factor to enhance the thermopower in the correlated system [2].

10:36AM V31.00014 Unusual Transport and Strongly Anisotropic Thermopower in $PtCoO_2$ and $PdCoO_2$, KHUONG ONG, Institute of High Performance Computing, DAVID SINGH, Oak Ridge National Laboratory, PING WU, Institute of High Performance Computing — Thermoelectrics provide a technology for producing electrical energy from solar and other heat sources. Thermoelectric performance requires materials with high thermopower, normally found in doped semiconductors, where the thermopower is generally nearly isotropic. We discovered using first principles calculations and Boltzmann transport theory that two oxides, $PtCoO_2$ and $PdCoO_2$, which are not semiconductors, but rather good metals, have exceptionally large thermopowers in one direction, and moreover that the thermopower in these materials is highly anisotropic. This places these compounds in a highly unusual transport regime. Besides providing a new direction for thermoelectric materials research, they may be very useful in probing the fundamental limits of conventional transport theory for metals.

10:48AM V31.00015 Analysis of Wind Forces on Roof-Top Solar Panel[1] , YOGENDRA PANTA, GANESH KUDAV, Department of Mechanical & Industrial Engineering, Youngstown State University, Youngstown, Ohio — Structural loads on solar panels include forces due to high wind, gravity, thermal expansion, and earthquakes. International Building Code (IBC) and the American Society of Civil Engineers are two commonly used approaches in solar industries to address wind loads. Minimum Design Loads for Buildings and Other Structures (ASCE 7-02) can be used to calculate wind uplift loads on roof-mounted solar panels. The present study is primarily focused on 2D and 3D modeling with steady, and turbulent flow over an inclined solar panel on the flat based roof to predict the wind forces for designing wind management system. For the numerical simulation, 3-D incompressible flow with the standard k-ε was adopted and commercial CFD software ANSYS FLUENT was used. Results were then validated with wind tunnel experiments with a good agreement. Solar panels with various aspect ratios for various high wind speeds and angle of attacks were modeled and simulated in order to predict the wind loads in various scenarios. The present study concluded to reduce the strong wind uplift by designing a guide plate or a deflector before the panel.

Thursday, March 24, 2011 8:00AM - 10:36AM –
Session V32 FIAP: Photonics: Metamaterials, Nanotechnology and Sensors C144

8:00AM V32.00001 Topological photonic systems: from integer to fractional quantum Hall states[1] , MOHAMMAD HAFEZI, Joint Quantum Institute, University of Maryland, MIKHAIL LUKIN, EUGENE DEMLER, Harvard University, JACOB TAYLOR, Joint Quantum Institute, NIST — Topological properties of systems lead to remarkable robustness against disorder. The hallmark of such behavior is the quantized quantum Hall effect, where the electronic transport in two-dimensional systems is protected against scattering from impurities and the quantized Hall conductance is the manifestation of a topological invariance. Here we suggest an analogous approach to quantum Hall physics to create robust photonic devices. Specifically, we show how quantum Hall and quantum spin Hall Hamiltonians can be implemented with linear optics using coupled resonator optical waveguides (CROW) in two dimensions. Key features of quantum Hall systems could be observed via reflection spectroscopy, including the characteristic Hofstadter "butterfly" and edge state transport. Furthermore, the addition of an optical non- linearity to our proposed system leads to the possibility of implementing a fractional quantum Hall state of photons, where phenomenon such as non-abelian statistics may be observable.

8:12AM V32.00002 Analytical and numerical analysis of a generic cloaking system[1] , PATTABHIRAJU MUNDRU, DENTCHO GENOV, Louisiana Tech University — We present a technique to realize a multi-shell generic cloaking system. By considering specific geometrical and material properties for the shells around the object, we were able to achieve a transparency conditions independent of object's optical properties in quasi-static regime. A complete suppression of dipolar scattering is demonstrated for an arbitrary object enclosed in such a system. We propose *tunable-low loss* realistic shell designs based on composite media and the effect of dispersion on the overall scattering cross-section is evaluated. Full wave analytical and numerical simulations based on the transparency conditions obtained in the quasi-static limit are performed. It is shown that strong reduction of the scattering by a factor of up to 10^3 can be achieved across the entire optical spectrum.

8:24AM V32.00003 Optical spin-orbit coupling and Darwin terms in epsilon-near-zero materials , ANDREW COOK, JENS NOECKEL, University of Oregon — In optical cavities formed from spatially inhomogeneous epsilon-near-zero (ENZ) metamaterials, optical spin-orbit coupling can be made nearly isospectral to relativistic electron spin-orbit coupling in atoms; the only difference is that the 3x3 classical spin-orbit operator shifts transverse fields by a different integer amount than the quantum operator. When the electric field is rescaled to account for unequal dispersive energy density in the electric and magnetic field quadratures, Maxwell's equations give a Darwin term with the same form as in quantum mechanical systems. These classical/QM similarities, combined with a pronounced importance of the Kerr nonlinearity, make ENZ materials ideal for coaxing electron-like behavior from light.

8:36AM V32.00004 Design of Optical Microcavities for Coupling to Nitrogen-Vacancy Centers in Diamond , JENNA HAGEMEIER, University of California Santa Barbara, California, USA, TOENO VAN DER SAR, Kavli Institute of Nanoscience, Delft University of Technology, The Netherlands, SUSANNA THON, HYOCHUL KIM, DUSTIN KLECKNER, University of California Santa Barbara, California, USA, WOLFGANG PFAFF, Kavli Institute of Nanoscience, Delft University of Technology, The Netherlands, ERWIN HEERES, TJERK OOSTERKAMP, Leiden Institute of Physics, Leiden University, The Netherlands, PIERRE PETROFF, Department of Materials and Department of ECE, University of California Santa Barbara, California, USA, RONALD HANSON, Kavli Institute of Nanoscience, Delft University of Technology, The Netherlands, DIRK BOUWMEESTER, University of California Santa Barbara, California, USA and Leiden University, The Netherlands — Nitrogen-Vacancy (NV) centers in diamond have emerged as promising candidates for solid state qubits. When placed in a confined optical field, such as exists in an optical microcavity, the properties of single quantum emitters can be drastically modified. In the weak coupling regime, the rate of spontaneous light emission from the quantum emitter can be enhanced via the Purcell effect. We demonstrate deterministic coupling between single NV centers and photonic crystal microcavities in Gallium Phosphide (GaP). Designs of novel optical cavities for coupling to NV centers in diamond will also be discussed.

8:48AM V32.00005 Radiation Tuning of Optical Nanoantennas for Design of Nanofilter Elements , MARJAN SABOKTAKIN, BRIAN EDWARDS, NADER ENGHETA, CHERIE KAGAN, University of Pennsylvania, PROF. KAGAN COLLABORATION, PROF. ENGHETA COLLABORATION — We experimentally and numerically explore the radiation characteristics of optical nanoantennas. These nanoantennas are dipole antennas with dimensions on the order of several tens of nanometers that are fabricated to form lumped capacitance and Inductance through the use of sandwich structures made of dielectric and plasmonic-material layers. We then investigate tuning the response of these optical nanoantennas by varying the material and/or thickness of the dielectric layer. After each experiment, experimental results are compared with numerical simulations to verify the validity of the results. We then exploit these characteristics in building a "lumped" nanofiltering device, and thereby extending the concept of antennas and circuit elements such as filters from the microwave regime to the visible regime.

9:00AM V32.00006 Confined Three-Dimensional Plasmon Modes inside a Ring-Shaped Nanocavity on a Silver Film Imaged by Cathodoluminescence Microscopy[1] , XINLI ZHU, JIASEN ZHANG, JUN XU, DAPENG YU, Department of Physics, Peking University — The confined modes of surface plasmon polaritons in boxing ring-shaped nanocavities have been investigated and imaged by using cathodoluminescence spectroscopy. The mode of the out-of-plane field components of surface plasmon polaritons dominates the experimental mode patterns, indicating that the electron beam locally excites the out-of-plane field component of surface plasmon polaritons. Quality factors can be directly acquired from the spectra induced by the ultrasmooth surface of the cavity and the high reflectivity of the silver reflectors. Because of its three-dimensional confined characteristics and the omnidirectional reflectors, the nanocavity exhibits a small modal volume, small total volume, rich resonant modes, and flexibility in mode control.

[1]This work is supported by NSFC (10804003, 61036005 and 11074015), the national 973 program of China (2007CB936203, 2009CB623703), MOST and NSFC/RGC (N HKUST615/06).

9:12AM V32.00007 Novel meta-surfaces for wave manipulation , SHULIN SUN, National Taiwan University, QIONG HE, SHIYI XIAO, Fudan University, QIN XU, LEI ZHOU, Fudan University — Meta-materials are man-made electromagnetic (EM) materials composed by subwavelength local resonance structures of electric and/or magnetic type, and thus possess arbitrary values of permittivity and permeability dictated by such resonance structures. Many novel EM properties, such as the negative refraction, the superlensing effect, and even the invisibility cloaking were predicted or discovered based on meta-materials. By carefully designing metamaterials with appropriate EM wave properties, one can employ metamaterials to efficiently manipulate various properties of EM waves, including the wave propagation, polarization, and so on. Here, we present our latest theoretical and experimental efforts in designing novel meta-surfaces (ultra-thin metamaterials) with anomalous EM wave properties to allow efficiently manipulating wave propagation directions. Furthermore, our system can also convert propagating wave to surface plasmon polariton. Microwave experiments are performed on realistic structures to successfully realize the theoretical predictions, and the obtained results are in agreements with FDTD simulations.

9:24AM V32.00008 Percolation and polaritonic effects in periodic planar nanostructures evolving from holes to islands[1] , YUN PENG, TRILOCHAN PAUDEL, WEN-CHEN CHEN, WILLIE PADILLA, ZHIFENG REN, Boston College, KRIS KEMPER, Boston College, South China Normal University — We study interaction of the electromagnetic radiation with a series of thin film periodic nanostructures evolving from holes to islands. We show, through model calculations, simulations and experiments, that the responses of these structures evolve accordingly, with two topologically distinct spectral types for holes and islands. We find also, that the response at the transitional pattern is singular. We show that the corresponding effective dielectric function follows the critical behavior predicted by the percolation theory, and thus the hole-to-island structural evolution in this series is a topological analog of the percolation problem, with the percolation threshold at the transitional pattern.

[1]This work was supported in part by a grant from DOE (Grant No. DE-FG02-00ER45805) (ZFR). W.-C.C. and W.J.P. acknowledge support from the Office of Navel Research under U. S. Navy Contract No. N00014-07-1-0819.

9:36AM V32.00009 ABSTRACT WITHDRAWN –

9:48AM V32.00010 An XPS study of gas phase interaction with Au nanoparticles coated TiO_2 nanosprings[1] , I. NIRAULA, B.A. FOUETIO, D.N. MCILROY, Dept. of Physics, Univ. of Idaho, Moscow, ID 83844, T. TURBA, M.G. NORTON, School of Mech. and Mat. Eng., Washington St. Univ., Pullman, WA 99164 — The interaction of CO and O_2on the surface of the Au nanoparticles (NPs) supported on TiO_2(Au/TiO_2) nanosprings (NS) by x-ray photoelectron spectroscopy will be discussed. The Au NPs were coated onto the TiO_2NS by plasma enhanced chemical vapor deposition, where the average particle size is 7-8 nm. The gas interactions with the Au NPs is evaluated by examining binding energy shifts of the Au 4f, C 1s, Ti 2p and O 1s electron core level states. For both of the gases, all of the core levels shifted to higher binding energy. Temperature dependent desorption, or the lack thereof, as determined by XPS analysis, indicates that the gas-substrate interaction is chemisorption, as opposed to physisorption. A detailed discussion on the mechanism of adsorption, as well as the roles of the Au NP and the TiO_2 substrate, will be presented.

[1]Univ. of Idaho, BANtech

10:00AM V32.00011 Paper based Flexible and Conformal SERS Substrate for Rapid Trace Detection on Real-world Surfaces[1] , SRIKANTH SINGAMANENI, CHANG LEE, LIMEI TIAN, Washington University in St. Louis — One of the important but often overlooked considerations in the design of surface enhanced Raman scattering (SERS) substrates for trace detection is the efficiency of sample collection. Conventional designs based on rigid substrates such as silicon, alumina, and glass resist conformal contact with the surface under investigation, making the sample collection inefficient. We demonstrate a novel SERS substrate based on common filter paper adsorbed with gold nanorods, which allows conformal contact with real-world surfaces, thus dramatically enhancing the sample collection efficiency compared to conventional rigid substrates. We demonstrate the detection of trace amounts of analyte (140 pg spread over 4 cm^2) by simply swabbing the surface under investigation with the novel SERS substrate. The hierarchical fibrous structure of paper serves as a 3D vasculature for easy uptake and transport of the analytes to the electromagnetic *hot spots* in the paper. Simple yet highly efficient and cost effective SERS substrate demonstrated here brings SERS based trace detection closer to real-world applications.

[1]We acknowledge the financial support from Center for Materials Innovation at Washington University.

10:12AM V32.00012 Sensitive detection of nitro aromatic explosives using novel polythiophene nanoparticles , SOUMITRA SATAPATHI, University of Massachusetts Lowell, B. HARIHARA VENKATARAMAN, University of Massachusetts Amherst, AKSHAY KOKIL, University of Massachusetts Lowell, LIAN LI, US Army Natick Soldier Research, Development & Engineering Center, Natick,, DHANDAPANI VENKATARAMAN, University of Massachusetts Amherst, JAYANT KUMAR, University of Massachusetts Lowell, CENTER FOR ADVANCED MATERIALS TEAM, UNIVERSITY OF MASSACHUSETTS LOWELL TEAM, UNIVERSITY OF MASSACHUSETTS AMHERST COLLABORATION — Fluorescent polythiophene nanoparticles were fabricated by surfactant assisted mini emulsion technique. The size distribution of the synthesized nanoparticles was characterized using dynamic light scattering (DLS) and scanning electron microscopy (SEM). The synthesized nanoparticles were also characterized using UV-Vis and fluorescence spectroscopy. Strong two-photon induced fluorescence was observed from these nanoparticles using 800 nm pulses from a femto second laser. The fluorescence response of these nanoparticles to nitro-aromatic explosives 2,4-dinitrotoluene and 2,4,6-trinitrotoluene in solution was investigated at different concentrations of the analytes. Strong fluorescence quenching was observed using both one photon and two-photon excitation source. The Stern Volmer constant is also higher.

10:24AM V32.00013 A novel nanostructure for ultrasensitive volatile organic compound sensing[1] , HUAIZHOU ZHAO, BINOD RIZAL, ZHIFENG REN, MICHAEL J. NAUGHTON, THOMAS C. CHILES, DONG CAI, Boston College — We have developed an arrayed nanocoaxial structure for the ultrasensitive sensing detection and identification of volatile organic compounds (VOC) by dielectric impedance spectroscopy. VOC molecules are absorbed into porous dielectric material in the annulus between nanoscale coax electrodes. A theoretical expression for the basic adsorption mechanism agrees with the experimental results. Detection sensitivities at parts-per-billion levels were demonstrated for a variety of VOCs. A limit-of-detection of ethanol reached $\sim$100 parts-per-trillion, following a Freundlich power-law isotherm across four decades of ethanol concentration. A linear dependence on VOC dielectric constant was observed. Dielectric impedance nanospectroscopy was also performed by scanning frequency from 10 mHz to 1 MHz, with distinctive spectra of different VOCs discovered. These were utilized to conduct colorimetric identification of VOCs. The results suggest our novel nanocoaxial sensor can be used as a sensitive, broadband, and multimodal sensing platform for chemical detection.

Session V33 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides: Vortices and Novel Mechanisms C143/149

8:00AM V33.00001 Effect of A-site size difference on polar behavior in MBiScNbO$_6$ (M=Na, K, and Rb) perovskite: Density functional calculations , SHIGEYUKI TAKAGI, ALASKA SUBEDI, Oak Ridge National Laboratory and University of Tennessee, VALENTINO COOPER, DAVID SINGH, Oak Ridge National Laboratory — We investigated the effect of A-site size difference in the double perovskites BiScO$_3$-MNbO$_3$ (M=Na, K, and Rb) using first-principles calculations. The materials studied have increasing ionic radii at the A-site ($r_{\mathrm{Na}^+} < r_{\mathrm{K}^+} < r_{\mathrm{Rb}^+}$) but are otherwise chemically similar. We find that the polarization of these materials is 70-90 μC/cm^2 along the rhombohedral direction, which increases as the A-site size difference becomes larger. The main contribution to the high polarization comes from large off-centerings of Bi ions, which are strongly enhanced by the suppression of octahedral tilts as the M-ion size increases. A high Born effective charge of Nb also contributes to the polarization and this contribution is also enhanced by increasing the M-ion size. This work was supported by ONR and DOE, BES, Materials Sciences and Engineering.

8:12AM V33.00002 First Principles Study of Flexoelectricity , JIAWANG HONG, DAVID VANDERBILT, Rutgers University — Flexoelectricity is the linear response of polarization to a strain gradient. Because strain gradients break inversion symmetry, flexoelectricity allows for charge to be extracted from deformations even in materials that are not piezoelectric. The flexoelectric effect is negligible on conventional length scales, but it becomes very strong at the nanoscale where large strain gradients can significantly affect the functional properties of dielectric thin films and superlattices. We present first-principles calculations of flexoelectric effects in nonpiezoelectric materials by introducing the strain gradient artificially in a slab geometry and obtain the flexoelectric coefficients. Furthermore, we model the results in terms of quantities, such as dynamical charges and higher[1] multipole moments that can be computed in the bulk, bringing us closer to a full theory of flexoelectricity.

8:24AM V33.00003 Coexistence of ferroelectricity and octahedral rotations in ABX$_3$ perovskites , NICOLE BENEDEK, CRAIG FENNIE, School of Applied and Engineering Physics, Cornell University — Nearly all cubic perovskite materials are unstable to energy-lowering structural distortions. The most intensively studied distortions are those that induce ferroelectricity and tilts or rotations of the anion octahedra. The phonon dispersion curves of many perovskites contain both types of instability, although competition between the different types of distortions usually leads to ground-state structures in which one type of instability has been eliminated. Hence, whereas there are many perovskites that are *either* ferroelectric or have rotated octahedra, there are very few perovskites that are *both* ferroelectric and have rotated octahedra. We use a combination of Density Functional Theory, group theoretical techniques and crystal chemistry arguments to study the competition between ferroelectric and octahedral rotation distortions in a family of ferroelectric perovskite fluorides and oxides. By considering both "long-range" distortions (phonons) and the local bonding environment of each ion, we are able to build up a picture of which factors favor one type of distortion over the other.

8:36AM V33.00004 Vortex Domains in Ferroelectric Nano-Structures

, JAMES F. SCOTT, Cambridge University — Recently the study of submicron-diameter ferroelectric disks and squares and rectangles fabricated from films of ca. 100-300 nm thick have revealed usual domain patterns, qualitatively different from the stripe domains commonly studied in macroscopic specimens in the past. These include doughnut-shaped domains, four-fold vertex closure domains, and fractal domains. The static configurations offer a variety of puzzles, and the structures differ from those in magnetic vortex domains, presumably due to the much larger anisotropy in ferroelectrics, which generally prohibits true vortex configurations with polarization forced out of plane. The dynamics also differ qualitatively from early studies: For decades ferroelectrics were thought to be highly Ising-like, but recent data and theoretical simulations favor Bloch walls and more Heisenberg-like kinetics. This talk will include data from Alina Schilling and Marty Gregg in Belfast, Marin Alexe in Halle, and modeling from Hlinka and Marton in Prague and Bellaiche and Prosandeev in Arkansas.

9:12AM V33.00005 Multiferroic Vortices and Graph Theory

, SANG-WOOK CHEONG, S.C. CHAE, Y. HORIBE, Rutgers Center for Emergent Materials, D.Y. JEONG, Department of Mathematics, Soongsil University, Korea , N. LEE, S. RODAN, T. CHOI, Rutgers Center for Emergent Materials — Hexagonal $REMnO_3$ (RE= rare earths) with RE=Ho-Lu, Y, and Sc, is an improper ferroelectric where the size mismatch between RE and Mn induces a trimerization-type structural phase transition, and this structural transition leads to three structural domains, each of which can support two directions of ferroelectric polarization. We reported that domains in h-$REMnO_3$ meet in cloverleaf arrangements that cycle through all six domain configurations, Occurring in pairs, the cloverleafs can be viewed as vortices and antivortices, in which the cycle of domain configurations is reversed. Vortices and antivortices are topological defects: even in a strong electric field they won't annihilate. Recently we have found intriguing, but seemingly irregular configurations of a zoo of topological vortices and antivortices in h-$REMnO_3$. These configurations can be neatly analyzed in terms of graph theory.

9:24AM V33.00006 Hidden Roto Symmetries in Crystals and Handed Structures[1]

, VENKATRAMAN GOPALAN, DANIEL LITVIN, Pennsylvania State University — Symmetry is a powerful framework to perceive and predict the physical world. The structure of materials is described by a combination of rotations, rotation-inversions and translational symmetries. By recognizing the reversal of static structural rotations between clockwise and counterclockwise directions as a distinct symmetry operation, here we show that there are many more structural symmetries than are currently recognized in right- or left-handed handed helices, spirals, and in antidistorted structures composed equally of rotations of both handedness. For example, though a helix or spiral cannot possess conventional mirror or inversion symmetries, they can possess them in combination with the rotation reversal symmetry. Similarly, we show that many antidistorted perovskites possess twice the number of symmetry elements as conventionally identified. These new symmetries, referred to as "roto" symmetries, predict new forms for roto properties that relate to static rotations, such as rotoelectricity, piezorotation, and rotomagnetism. They also enable a symmetry-based search for new phenomena, such as multiferroicity involving a coupling of spins, electric polarization and static rotations. This work is relevant to structure-property relationships in all material structures with static rotations.

9:36AM V33.00007 Spontaneous Vortex Nanodomain Arrays at Ferroelectric Heterointerfaces

, XIAOQING PAN, CHRISTOPHER NELSON, YI ZHANG, Dept. of Mater. Sci. & Eng., Univ. of Michigan, Ann Arbor, MI, BENJAMIN WINCHESTER, LONG-QING CHEN, Dept. of Mater. Sci. & Eng., Penn State Univ., University Park, PA, COLIN HEIKES, CAROLINA ADAMO, ALEXANDER MELVILLE, DARRELL SCHLOM, Dept. Sci. & Eng., Cornell Univ., Ithaca, NY, CHAD FOLKMAN, CHANG-BEOM EOM, Dept. of Mater. Sci. & Eng., Univ. of Wisconsin-Madison, Madison, WI — The polarization of $BiFeO_3$ subjected to different electrical boundary conditions by hetero-interfaces is imaged with atomic resolution using a Cs-corrected transmission electron microscope. Unusual nanodomains are seen and their role in providing polarization closure is understood through phase-field simulations. Hetero-interfaces are key to the performance of ferroelectric devices and this first observation of vortex arrays at ferroelectric hetero-interfaces reveals properties unlike the surrounding film including mixed Ising-Néel domain walls, which will affect switching behavior, and a drastic increase of in-plane polarization. Imaging this magnetic analogous effect at ferroelectric hetero-interfaces provides the ability to see device-relevant interface issues.

9:48AM V33.00008 Helical strain patterns and charge ordering in $YbFe_2O_4$

, ALEXANDER HEARMON, PAOLO RADAELLI, PRABHAKARAN DHARMALINGAM, Clarendon Laboratory, Oxford University, MATTHIAS GUTMANN, ISIS Facility, Rutherford Appleton Laboratory, FEDERICA FABRIZI, Clarendon Laboratory, Oxford University, DAVE ALLAN, Diamond Light Source Ltd — The RFe_2O_4 compounds exhibit simultaneously charge ordering (CO) of the Fe^{2+} and Fe^{3+} ions,[1] together with magnetic ordering of the Fe spins[2] and possible multiferroic behavior.[3] Synchrotron data collected below the 3D CO transition show intensity concentrated around peaks separated by $\sim 1/3$ c^* but slightly displaced in the (a^*, b^*) plane. Calculations modelling an oxygen displacement pattern are in excellent agreement with the data, suggesting an incommensurate charge ordering of the Fe ions close to the commensurate $\sqrt{3} \times \sqrt{3}$ structure, associated with a helical strain pattern. At high temperature, ordering wavevectors corresponding to many different displacement patterns are simultaneously populated by the system, leading to diffuse but highly structured features in reciprocal space.

10:00AM V33.00009 Three-dimensional distribution of ferroelectric vortices in multiferroic hexagonal $YMnO_3$

, MANFRED FIEBIG, HISKP, University of Bonn, Germany, ELISABETH SOERGEL, TOBIAS JUNGK, IAP, University of Bonn, Germany, NICOLA A. SPALDIN, Dept. Materials, ETH Zurich, Switzerland, KRIS DELANEY, MRL, UC Santa Barbara, USA — Multiferroics are a rich source for "unusual" forms of ferroelectric order. The spontaneous polarizations is induced by magnetism, charge order, geometric effects, etc., and may lead to novel domain states and functionalities. Recently it was shown that ferroelectric domains in hexagonal multiferroic $YMnO_3$ form vortex-like structures around the direction of polarization [1]. It was assumed that the sixfold character of the domain vortices reflects the uniaxial hexagonal structure. Here we show by piezoresponse force microscopy that high densities of sixfold vortices are also present *perpendicular* to the direction of the spontaneous polarization in spite of the merely twofold rotation-inversion symmetry in this direction [2]. We present a simple geometric explanation for this unexpected result and discuss the principal difference between the present case and vortex formation in discommensurate systems.

10:12AM V33.00010 Cloverleaf domain patterns in multiferroic $RMnO_3$ (R = Ho, Er, and Lu)

, Y. HORIBE, S.C. CHAE, N. LEE, S-W. CHEONG, Rutgers Center for Emergent Materials and Department of Physics & Astronomy, Rutgers University — Hexagonal $RMnO_3$ (R=rare earths) exhibits a unique improper ferroelectricity induced by structural trimerization. Intriguing domain pattern associated with ferroelectricity and trimerization, so-called "cloverleaf" domain pattern, has been reported in $YMnO_3$ [1] In this talk, we will report the domain structures in a series of $RMnO_3$ with different rare earth elements, obtained from the results of our transmission electron microscopy. Characteristic cloverleaf domain patterns are clearly observed in $RMnO_3$ (R = Ho, Er, and Lu). The results imply that the cloverleaf domain pattern is a common domain feature in the hexagonal manganites.

Thursday, March 24, 2011 8:00AM - 11:00AM –
Session V35 DCMP: Topological Insulators: ARPES & STM C140

8:00AM V35.00001 Local probing of Quantum Spin Hall edge states , MARKUS KÖNIG, ANDREI GARCIA, MATTHIAS BAENNINGER, Stanford University, CHRISTOPH BRÜNE, HARTMUT BUHMANN, LAURENS MOLENKAMP, University of Wuerzburg, DAVID GOLDHABER-GORDON, Stanford University — Since their recent experimental discovery, topological insulators have attracted a lot of interest. The two-dimensional manifestation of a topological insulator, the Quantum Spin Hall (QSH) state, is characterized by counter- propagating edge states with opposite spin-polarization, while the bulk is insulating. We use Scanning Gate Microscopy to demonstrate the edge state nature of transport in the QSH state. Utilizing the high spatial resolution of this technique, we gain insight into the spatial properties of the edge states. Furthermore, the experiments can yield information regarding the sensitivity of the QSH edge states to local perturbations, which can be useful for future applications.

8:12AM V35.00002 Visualizing Strong Scattering of Topological Surface States from Magnetic Impurities in Bi_2Te_3[1] , HAIM BEIDENKOPF, PEDRAM ROUSHAN, JUNGPIL SEO, LINDSAY GORMAN, Y.S. HOR, R.J. CAVA, ALI YAZDANI, Physics Department, Princeton University — Bi_2Te_3 is a topological insulator with a single Dirac cone in the band structure of its helical surface states. The associated spin texture protected by time reversal symmetry (TRS) is thought to suppress scattering off non-magnetic defects. We tested this using scanning tunneling microscopy and spectroscopy. At high energies, far above the Dirac point, backscattering off non-magnetic defects, such as step-edges, is facilitated by quasi-nesting conditions brought about by the hexagonal warped surface band. At lower energies at which the surface dispersion is linear backscattering is highly suppressed by the helical spin texture protected by TRS. In contrast, in Mn-doped Bi_2Te_3 the measured quasi- particle interference pattern shows the onset of strong scattering both in the warped region as well as in the conic one. The scattering processes involved are affected both by the spin texture as well as by the geometry of the scattering potential. Furthermore, close to the Dirac point the increased scattering in Mn-doped Bi_2Te_3 seems to promote localization of the surface states.

[1]Supported by NSF-DMR, and MRSEC through PCCM. Infrastructure at Princeton Nanoscale Microscopy Laboratory are also supported by grants from DOE, and the W.M. Keck foundation.

8:24AM V35.00003 Magnetic Versus Non-magnetic Scattering of Topological Surface States in Bi_2Te_3[1] , LINDSAY GORMAN, HAIM BEIDENKOPF, PEDRAM ROUSHAN, JUNGPIL SEO, Department of Physics, Princeton University, YEW SAN HOR, ROBERT CAVA, Department of Chemistry, Princeton University, ALI YAZDANI, Department of Physics, Princeton University — Due to their novel spin texture, the surface states of topological insulators are predicted to be impervious to backscattering from non-magnetic disorder. For impurities which break time-reversal symmetry, however, such backscattering is not forbidden by the topological character of the states. Here we use scanning tunneling microscopy to study scattering from impurities in doped Bi_2Te_3. In Mn-doped Bi_2Te_3, we have observed an interference pattern from the surface states throughout a broad range of energies, even in the region of linear dispersion near the Dirac point. We contrast these findings of the scattering of topological surface states from magnetic defects with similar measurements on Ca-doped Bi2Te3 using spectroscopic mapping. We will use the results of these experiments to probe whether the presence of magnetic impurities gives rise to backscattering in topological surface states.

8:36AM V35.00004 Scanning tunneling spectroscopic (STS) studies of MBE-grown topological insulators of Bi_2Se_3 epitaxial films on Si(111) , N.-C. YEH, M.L. TEAGUE, W.-H. LIN, H. CHU, Dept. of Physics, Caltech, Pasadena, CA 91125, F.X. XIU, L. HE, K.L. WANG, UCLA, Los Angeles, CA 90095 — We report STS studies of MBE-grown Bi_2Se_3 epitaxial films on Si(111) with varying thicknesses. The films were atomically flat on the scale of hundreds of nanometers, with occasional atomic steps of one c-axis lattice constant. In the case of thick Bi_2Se_3 films, the tunneling spectra were consistent with those found in single crystalline Bi_2Se_3, except that the Dirac point ($E_{Dirac} = -50 \sim$ -100 meV) of the MBE-film is generally much closer to the Fermi level ($E = 0$), in contrast to the large downshift of E_{Dirac} (= -400 $\sim$ -200 meV) commonly found in single crystalline bulk grown Bi_2Se_3. The STS spectra of the thinner films deviate from those of the thicker samples, probably the result of strain. Fourier transformed (FT) STS data as a function of energy reveals several quasiparticle scattering interference wave-vectors that are consistent with the topologically protected surface states with chiral spin texture, although the overall FT-STS maps are simpler than those reported on the $Bi_{0.92}Sb_{0.08}$ (111) surface due to simpler electronic band-structures of Bi_2Se_3. The effect of time reversal symmetry breaking on the FT-STS will be investigated by either magnetic doping or application of magnetic fields. This work was supported by a grant from FENA of FCRP and DARPA.

8:48AM V35.00005 Electron interference in the 3D topological insulator Bi_2Se_3 probed by scanning tunneling microscope , MAO YE, A. KIMURA, S. KIM, K. KURODA, Hiroshima University, E.E. KRASOVSKII, E.V. CHULKOV, Universidad del Pais Vasco, K. MIYAMOTO, M. NAKATAKE, T. OKUDA, Hiroshima University, Y. UEDA, Kure National College of Technology, H. NAMATAME, Hiroshima University, M. TANIGUCHI — Three-dimensional topological insulators (TIs) have aroused great attention to the new state of quantum matter originating from the surface state that forms a massless Dirac cone. Among the recently discovered TIs, Bi_2Se_3 is regarded as the most promising candidate [1]. However, recent magnetotransport measurements showed that the bulk conductance dominates even in low carrier samples [2], which raises the question of possible scattering channels responsible for the reduced surface mobility. Band structure calculations predict the Dirac point of the surface state to be located close to the bulk valence band maximum [1]. In order to clarify the surface state scattering feature, we have performed differential tunneling conductance mapping for the surface of Bi_2Se_3. The fast Fourier transformation image shows an electron interference pattern near the Dirac node, which provides the evidence of near-surface scattering of the spin polarized surface electrons at the Dirac point in Bi_2Se_3 into the spin-degenerate bulk continuum states.

9:00AM V35.00006 Power laws and STM image of standing wave of the topological surface states[1] , BANG-FEN ZHU, JING WANG, WEI LI, PENG CHENG, CANLI SONG, TONG ZHANG, XI CHEN, Department of Physics, Tsinghua University, XUCUN MA, KE HE, Institue of Physics, Chinese Academy of Science, JIN-FENG JIA, QI-KUN XUE, Department of Physics, Tsinghua University — We have theoretically and experimentally studied the quasiparticle interference pattern caused by scattering off the step edges of topological surface states in Bi_2Te_3 and Bi_2Se_3. We propose a general formalism to identify the power law that governs the decaying spatial oscillations of standing wave of the quasiparticle. With strong hexagonal warping of the surface states in Bi_2Te_3, the standing wave will have different decay index as the Fermi energy varies; while in Bi_2Se_3, the standing wave has only a single decay index due to weak warping effect. Using a scanning tunneling microscope, we directly observe the standing waves in the local density of states on both surfaces, which together with the analysis of such oscillations at different voltage confirms our theoretical predictions. We further show that, the characteristic scattering wavevectors of the standing wave of surface states caused by scattering off the nonmagnetic impurity in both Bi_2Te_3 and Bi_2Se_3can also be well explained by this general formalism.

9:12AM V35.00007 Multifunctional electronic structure in a topological insulator class , SUYANG XU, ZAHID HASAN, Princeton University — The discovery of topological properties in three dimensional bulk solids have opened up many new research avenues in condensed matter physics. Only a very few compounds have been identified to be topological insulators to this date. However, none of them is proven to be suitable for the majority of experimental configurations including giant magnetoelectric and anomalous optical rotation, unusual exciton condensation, or the neutral half-fermions and interface superconductivity. In fact the realization of even any one of these proposals requires a number of multiply-connected topological compounds with modulated surface band dispersions and naturally tuned in-gap Fermi level, as well as spin variations in the presence of long life-time of the surface states. Here, using conventional and spin-sensitive probes, we report the discovery of several classes of positive band-gap high figure of merit topological insulators with critically important functional properties such as high degree of bulk resistivity and insulation, electronic structure with both in-gap Dirac point and Fermi level crossing, long surface state life-times, as well as chirality inversion through the Dirac node. The unprecedented combinations of electronic, spin, life-time and resistive bulk transport featured by the topological insulators uncovered here not only provide a new platform for research on topological quantum phenomena but also pave the way for functional devices.

9:24AM V35.00008 Observation of novel interference patterns in BixFe1-xTe3 by Fourier transform scanning tunneling spectroscopy (FT-STS) , YOSHINORI OKADA, Boston College, CHETAN DHITAL, WEN-WEN ZHOU, HSIN LIN, SUSMITA BASAK, ARUN BANSIL, YAOBO HUANG, HONG DING, ZIQIANG WANG, STEPHEN WILSON, VIDYA MADHAVAN — We utilize Fourier transform scanning tunneling spectroscopy (FT-STS) to probe the surface of the magnetically doped TI, Bi2-xFexTe3. Our measurements show the appearance of a hitherto unobserved channel of electronic backscattering along the surface q-vector. By referencing the FT-STS with angle-resolved photoemission spectroscopy (ARPES) data, we formulate a simple model showing that these new vectors are fully consistent with spin-flip scattering. Our combined data therefore present compelling evidence for the first momentum resolved measurement of enhanced backscattering due to magnetic impurities in a prototypical TI.

9:36AM V35.00009 Local interaction of magnetic impurities and topological surface states[1] , WARREN MAR, KENJIRO K. GOMES, WONHEE KO, HARI C. MANOHARAN, Stanford University — Topological insulators have garnered much attention as a vehicle to explore exotic Dirac physics through the projection of unpaired Dirac cones into conducting surface states wrapping a spin-orbit twisted bulk band structure. We use an ultrahigh-vacuum low-temperature scanning tunneling microscope (STM) to gain access to and manipulate the chiral Dirac particles present on the Sb(111) surface. Understanding the interplay between local spins and Dirac fermions represents a key foundation to the development of new spintronic applications. Magnetic moments break time-reversal symmetry and provide an additional local quantum degree of freedom to engineer topological states. By dosing magnetic impurities of varying concentration and species, we show how STM can atomically manipulate individual magnetic adatoms on topological surfaces, and in the process gain insight into the physical bonding arrangement of magnetic impurities on top of and embedded inside the host crystal lattice. Using scanning tunneling spectroscopy, we map in real and momentum space how local spins interact with the chiral surface Dirac carriers.

9:48AM V35.00010 Visualizing spin-vortex evolution of a topological insulator[1] , YIHUA WANG, DAVID HSIEH, DAN PILON, MIT, LIANG FU, Harvard, DILLON GARDNER, YOUNG LEE, NUH GEDIK, MIT — Charge carriers on the surface of a topological insulator are predicted to form a spin-vortex in momentum space with the direction of spin rotation determined by whether the carriers are electron-like or hole-like. We show that the angular momentum of photon is extremely sensitive to the spin of carriers by performing time-of-flight based angle-resolved-photoelectron spectroscopy (TOF-ARPES) with photons of different helicity. We demonstrate the first reciprocal space volumetric mapping of the vectorial spin-texture of the surface states of Bi_2Se_3 and directly observe spin-vortex evolution from electron-like to hole-like states and the departure from perpendicular momentum-spin locking.

10:00AM V35.00011 Spin and angular reoslved photoemission studies of Bi2Se3[1] , ZHIHUI PAN, E. VESCOVO, G.D. GU, Brookhaven National Laboratory, D. GARDNER, S. CHU, Y. LEE, Massachusetts Institute of Technology, A.V. FEDOROV, Lawrence Berkeley National Laboratory, T. VALLA, Brookhaven National Labroatory — Topological insulators (TL) have attracted much attention because of their exotic properties. Bi_2Se_3 is a model TL with a relative large bulk gap and a simple surface state structure. By depositing various non-magnetic and magnetic impurities on the surface, we were able to fill the topological surface state and higher lying Rashba splitting surface states. The spin texture of the surface electronic structure was determined in spin resolved photoemission measurement.

[1]This work was supported by DOE

10:12AM V35.00012 Surface states never die by surface impurities in topological insulators[1] , HAN-JIN NOH, Department of Physics Chonnam National University, JINWON JEONG, EN-JIN CHO, Dep. of Phys. Chonnam National University, HAN-KOO LEE, HYEONG-DO KIM, Pohang Accelerator Laboratory Pohang University of Science and Technology — The metallic surface states in topological insulators are one of the most distinguished features among the characters of this newly discovered quantum state of matter. These states, if properly exploited, may open a new era in spintronics and quantum computing. However, full characterization and understanding of the surface states toward these goals are still far from satisfactory. Here, we focus on the robustness of the metallic surface states in a topological insulator $Bi_{0.9}Sb_{0.1}$, and demonstrate their durability over magnetic/non-magnetic surface impurities by measuring the scattering rates of the quasiparticles via angle-resolved photoemission spectroscopy.

[1]This work was supported by the National Research Foundation (NRF) of Korea Grant funded by the Korean Government (MEST) (Nos. 2008-0059108, 2010-0010771, and 2010-0028064)

10:24AM V35.00013 Experimental Realization of Three-dimensional Topological Insulator in Ternary Chalcogenides , K. KURODA, M. YE, A. KIMURA, Hiroshima Univ., Y. UEDA, Kure Nat. Coll. Tec., S.V. EREMEEV, Tomsk State Univ., E.E. KRASOVSKII, E.V. CHULKOV, DIPC, K. MIYAMOTO, T. OKUDA, K. SHIMADA, H. NAMATAME, M. TANIGUCHI, Hiroshima Univ. — Three-dimensional topological insulators (TIs) featured with spin-helical massless surface state have attracted a great attention. Up to now, the experimentally confirmed topological insulators are limited to some binary compounds, such as Bi_2Te_3, Bi_2Se_3 and so on. Recently, several ternary chalcogenides have been proposed as a new family of TI. In contrast to the layered binary chalcogenides, in ternary chalcogenides with a more substantial three dimensional character, the surface state depends on the topmost layer because the broken bonds at the surface may give rise also to trivial surface state. Therefore, the experimental realization of non-trivial surface state in TI has been strongly required. In this work, we have performed an angle resolved photoemission spectroscopy by using synchrotron radiation to prove the surface state in the ternary compounds. Especially, for one of the candidate materials, $TlBiSe_2$, two important aspects have been revealed: (i) The Dirac cone is more ideal than that of Bi_2Se_3. (ii) There are no bulk continuum states that energetically overlap with the Dirac point. This means that the scattering channel from the topological surface state to the bulk continuum is strongly suppressed in $TlBiSe_2$.

10:36AM V35.00014 STM/STS studies of the surface of Bi2Se3[1] , MEGAN ROMANOWICH, STUART TESSMER, Michigan State University, SERGEI URAZHDIN, West Virginia University, DUCK-YOUNG CHUNG, JUNG-HWAN SONG, MERCOURI KANATZIDIS, Northwestern University — Building upon previous work,[2] we apply scanning tunneling microscopy/spectroscopy to characterize the surface of the topological insulator Bi2Se3. We see clover-like defect states in the topographic scans and a residual image that appears in conductance scans, which we attribute to Bi substitutions in Se lattice sites. Spectroscopy reveals features in the density of states consistent with the topological surface state, with the defect states appearing as an additional enhancement. We will discuss the interaction of the topological surface state with the defect states.

10:48AM V35.00015 Scattering on Magnetic and Non-Magnetic Impurities on a Surface of a Topological Insulator[1] , T. VALLA, Z.-H. PAN, Brookhaven National Laboratory, D.R. GARDNER, S. CHU, Y.S. LEE, Massachusetts Institute of Technology — Dirac-like surface states on surfaces of topological insulators have a chiral spin structure that supresses back-scattering and protects the coherence of these states in the presence of potential scatterers. In contrast, magnetic scatterers are expected to open the back- scattering channel via the spin-flip processes and to degrade the state's coherence. We present angle-resolved photoemission spectroscopy studies of the electronic structure and the scattering rates upon adsorption of various magnetic and non-magnetic impurities on the surface of Bi_2Se_3, a model topological insulator. We uncovered an unusual insensitivity of the topological surface state to both non-magnetic and magnetic impurities. The electrons donated by the impurities fill the topological surface state and pairs of higher lying spin-orbit split surface bands, preserving the non-trivial spin texture of the surface.

Session V36 DCMP: Graphene: Optical Properties I C142

8:00AM V36.00001 Imaging stacking order in few-layer graphene , CHUN HUNG LUI, ZHIQIANG LI, ZHEYUAN CHEN, PAUL V. KLIMOV, LOUIS E. BRUS, TONY F. HEINZ, Columbia University — Few-layer graphene (FLG) has been predicted to exist in various crystallographic stacking sequences, which can strongly influence the material's electronic properties We demonstrate an accurate and efficient method of characterizing stacking order in FLG using the distinctive features of the Raman 2D-mode. Raman mapping allows us to visualize directly the spatial distribution of Bernal (ABA) and rhombohedral (ABC) stacking in tri- and tetra-layer graphene. We find that ∼15% of exfoliated graphene tri- and tetra-layers is comprised of micron-sized domains with rhombohedral stacking, rather than the Bernal stacking. These domains are stable and remain unchanged for annealing to temperatures exceeding 800 °C.

8:12AM V36.00002 Electric-field induced changes in the band structure of trilayer graphene: The effect of crystallographic stacking order , ZHIQIANG LI, CHUN HUNG LUI, KIN FAI MAK, Columbia University, EMMANUELE CAPPELLUTI, Institute for Complex Systems, TONY F. HEINZ, Columbia University — We have studied by means of infrared spectroscopy the influence of a strong perpendicular electric-field on the band structure of graphene trilayers with two different types of crystallographic stacking: ABA (Bernal) and ABC (rhombohedral) stacking. The symmetries of the two crystallographic structures are different, the former having mirror symmetry and the latter inversion symmetry. Distinct infrared response was observed when breaking their respective symmetries by the application of the electric field. We observed an electrically tunable band gap of over 100 meV in ABC trilayers, while no band gap was found for ABA trilayers. Our results will be compared to the induction of a band gap in AB bilayer graphene [K. F. Mak *et al*, PRL **102**, 256405 (2009); Y. Zhang *et al*, Nature **459**, 820 (2009)]

8:24AM V36.00003 Photoluminescence in highly doped graphene , BAISONG GENG, CHI-FAN CHEN, LIANG ZHENG TAN, Department of Physics, University of California at Berkeley, Berkeley, CA 94720, USA, BRYAN W. BOUDOURIS, Department of Chemistry, University of California at Berkeley, Berkeley, CA 94720, USA, JASON HORNG, CAGLAR GIRIT, ALEX ZETTL, MICHAEL F. CROMMIE, Department of Physics, University of California at Berkeley, Berkeley, CA 94720, USA, RACHEL SEGALMAN, Department of Chemistry, University of California at Berkeley, Berkeley, CA 94720, USA, STEVE G. LOUIE, FENG WANG, Department of Physics, University of California at Berkeley, Berkeley, CA 94720, USA — Pristine graphene is a zero-bandgap semiconductor. Usually no photoluminescence can be observed from such zero-bandgap material upon laser excitation. In highly doped graphene, however, we observed a strong broadband photoluminescence. We will discuss the mechanism of this photoluminescence in graphene, which arises from new recombination pathways enabled by strong electrical doping. We will also describe the polarization dependence of this newly observed photoluminescence.

8:36AM V36.00004 Response of graphene to intense optical irradiation , ADAM ROBERTS, College of Optical Science, University of Arizona, COLLIN REYNOLDS, DANIEL HEMMER, BRIAN LEROY, ARVINDER SANDHU, Department of Physics, University of Arizona — We investigate the modification of graphene under intense ultrashort laser irradiation. Our observations indicate that the graphene structure is very resilient and exhibits a high damage threshold, which is promising for high order non-linear applications. In the case of epitaxially grown samples, we find that single-shot damage threshold is $5x10^{10}Wcm^{-2}$ for 50 fs pulse duration. Raman and optical microscopy measurements of irradiated samples show that the carbon lattice completely disappears from the region where the laser intensity exceeds the threshold without leaving any visual or spectroscopic signature. Below the threshold, single-shot irradiation does not exhibit a significant defect formation. However, repeated laser irradiation below the threshold leads to formation of defects. The mechanisms underlying the defect formation and lattice reduction will be discussed.

8:48AM V36.00005 Mid Infrared Near Field Study of Monolayer Graphene , Z. FEI, G.O. ANDREEV, University of California - San Diego, W. BAO, University of California - Riverside, L.M. ZHANG, Boston University, Z. ZHAO, University of California - Riverside, G. DOMINGUEZ, M. THIEMENS, M.M. FOGLER, University of California - San Diego, C.N. LAU, University of California - Riverside, F. KEILMANN, Max-Planck-Institute of Quantum Optics, D.N. BASOV, University of California - San Diego — We have performed near-field spectroscopic studies of both monolayer suspended graphene (SG) and graphene on SiO_2/Si substrate (GOS) using scattering-type scanning near-field optical microscope (s-SNOM). Our data show that SG produces reliable near-field signal in mid-infrared frequencies. Images taken with high spatial resolution ($\sim$20nm) show nanoscopic features such as ripples and electronic inhomogeneities. The SiO_2/Si substrate contributes a phonon resonance in the near-field signal around 1130 cm^{-1}. This resonance is remarkably strengthened and broadened by just a single layer of graphene in the case of GOS. By probing the resonance spectrum we find over 400% contrast in near field signal between GOS and the bare substrate. The detailed analysis of the contrast suggests that GOS is slightly doped. This study therefore provides much needed insight into the thickness resolution of the s-SNOM technique, proving it can be sensitive to just a single layer of atoms, and advances the fundamental understanding of graphene-light interactions by probing in the near-field regime.

9:00AM V36.00006 Terahertz and Infrared Conductivity of Large-Area Graphene , LEI REN, QI ZHANG, TAKASHI ARIKAWA, LAYLA G. BOOSHEHRI, JUNICHIRO KONO, Department of Electrical and Computer Engineering, Rice University, ZHONG JIN, ZHENGZONG SUN, ZHENG YAN, JAMES M. TOUR, Department of Chemistry, Rice University — Graphene is predicted to offer new opportunities for terahertz (THz) science and technology. Its zero-gap linear band dispersion is expected to lead to exotic nonlinear electromagnetic properties, which can be probed through frequency-dependent conductivity measurements. Here, we use THz time-domain spectroscopy and Fourier-transform infrared spectroscopy to investigate carrier dynamics in large-area graphene grown by chemical vapor deposition. We studied both nitrogen-doped and nominally-undoped graphene; the latter had accidental doping presumably through air and acid exposure. Absorption increased with the number of graphene layers and was larger in the nominally-undoped samples especially in the 0.2-2.2 THz range. For the highest-mobility samples, we observed Drude-like frequency dependence in the THz range. Further measurements in a wider spectral range are in progress to understand the differences between these samples and the interplay between intra-band and inter-band dynamics.

9:12AM V36.00007 Carrier Cooling in Graphene Measured by THz Time-Domain Spectroscopy , JARED STRAIT, HAINING WANG, SHRIRAM SHIVARAMAN, VIRGIL SHIELDS, CARLOS RUIZ-VARGAS, JIWOONG PARK, MICHAEL SPENCER, FARHAN RANA, Cornell University — We present results on the ultrafast relaxation dynamics of photoexcited electrons and holes in graphene using optical-pump terahertz-probe spectroscopy. Measurements done at different temperatures show that the measured differential transmission as a function of the probe delay decays on time scales that become very long at low temperatures with decay times exceeding $\sim$150 ps at temperatures lower than $\sim$50K. We interpret these transients as carrier cooling due to a combination of electron-optical phonon and electron-acoustic phonon scattering. When the carrier temperature goes below $\sim$250 K, optical-phonon scattering ceases to effectively cool the carriers given the large optical phonon energies in graphene. Since acoustic phonon scattering is not efficient in removing the heat from the carriers, the carrier distribution cools very slowly. Our data is in agreement with the theoretical predictions [1].

9:24AM V36.00008 Ultrafast electron dynamics in freely suspended graphene , LEANDRO MALARD, KIN FAI MAK, TONY F. HEINZ, Columbia University — The optical conductivity of free-standing graphene under the non-equilibrium conditions was investigated by femtosecond pump-probe spectroscopy. The conductivity transient exhibited a strong dependence on pump fluence, with a crossover from enhanced to reduced absorbance occurring with increasing pump fluence. The observed phenomena can be understood by taking into account both the induced intra- and inter-band optical response. Intra-band transitions dominate the transient at low pump fluence (and electronic temperature) and inter-band transitions dominate at high pump fluence (and electronic temperature). Analysis within a model incorporating these two responses allows us to infer the variation of carrier scattering rate with electronic temperature. The temporal evolution of the conductivity transient is controlled by the anharmonic decay of the optical phonons; a lifetime of $\sim$1.4 ps was inferred for intrinsic, suspended graphene.

9:36AM V36.00009 Ultrafast dynamics of highly-excited Dirac fermions in monolayer graphene[1] , JUNHUA ZHANG, JÖRG SCHMALIAN, TIANQI LI, JIGANG WANG, Ames Laboratory and Department of Physics and Astronomy, Iowa State University — One of the striking optical properties of single-layer graphene is the universal absorbance in the near-infrared-to-visible spectral range due to the Dirac spectrum of the low-energy electronic structure. High-fluence laser pump can produce superdense Dirac-fermionic excitations at the order of 10 femtoseconds so to reach the non-linear saturation of absorption. We construct a simple model for the transient state of the photo-excited graphene to explore the non-linear saturation of photoexcitations and the transport property of carries. The comparison of our model calculations with the experimental results shows good agreements.

[1]Research supported by the U. S. DOE, office of BES, Materials Science and Engineering Division.

9:48AM V36.00010 Ultrafast relativistic response of Photo-excited Carriers in Graphene[1] , J. LEE, K.M. DANI, CINT, Los Alamos National Laboratory, R. SHARMA, Theoretical Division, Los Alamos National Laboratory, A.D. MOHITE, A.M. DATTELBAUM, H. HTOON, A.J. TAYLOR, R.P. PRASANKUMAR, CINT, Los Alamos National Laboratory, C.M. GALANDE, P.M. AJAYAN, Dept. of Mechanical Engineering and Materials Science, Rice University — Understanding the ultrafast non-equilibrium dynamics of photocarriers in graphene's unique relativistic band structure is important for the development of such high-speed, graphene-based photonic devices and also from a fundamental point of view. Here, we directly demonstrate the relativistic nature of a non-equilibrium gas of electrons and holes photogenerated in a graphene monolayer as early as 100 femtoseconds (fs) after photoexcitation. We photoexcited carriers in graphene and then measured the time-resolved, pump-induced change in reflection at various visible probe photon energies. We observe a nonlinear scaling in the Drude-like optical conductivity of the photocarriers with respect to their density, in striking contrast to the linear scaling expected from conventional materials with parabolic dispersion relations.

[1]Supported by University of California President's (UCOP) program on Carbon Nanostructures.

10:00AM V36.00011 Carrier Dynamics in Colloidal Graphene Quantum Dots , CHENG SUN, Michigan State University, XIN YAN, LIANG-SHI LI, Indiana University, JOHN A. MCGUIRE, Michigan State University — We describe carrier dynamics for single and multiple excitons in colloidal graphene quantum dots (GQDs). Strong confinement and corresponding size-tunable electronic structure make GQDs potentially useful sensitizers in photovoltaic devices. We have studied the optical response of GQDs consisting of 132 and 168 sp^2 hybridized carbon atoms dissolved in toluene with HOMO-LUMO transitions of 1.4-1.6 eV. From measurements of ultrafast ($\sim$100 fs) transient absorption over nanosecond timescales, we extract the single-photon absorption cross-section and observe carrier-induced Stark shifts of the order of 0.1 eV indicating strong carrier-carrier interactions, as expected for the relatively weak screening of a two-dimensional nanostructure. Multiexcitons are observed to decay nonradiatively on $\sim$1 to 20 ps timescales, while single excitons display dynamics on multiple timescales due to carrier cooling, singlet-to-triplet intersystem crossing, and, on nanosecond to microsecond timescales, radiative recombination.

Thursday, March 24, 2011 8:00AM - 11:00AM –

Session V37 DMP: Focus Session: Graphene Growth, Characterization, and Devices: Transport

C146

8:00AM V37.00001 Electronic Transport Properties of Graphene on Aluminum Nitride[1] , LIANG LI, JUN YAN, Center for Nanophysics and Advanced Materials, University of Maryland, College Park, MD 20742-4111, USA, R.D. VISPUTE, Blue Wave Semiconductors, Inc., MICHAEL FUHRER, Center for Nanophysics and Advanced Materials, University of Maryland, College Park, MD 20742-4111, USA — We have fabricated graphene field-effect transistors on aluminum nitride (AlN) gate dielectric over silicon back gates. AlN thin films are prepared on Si by pulsed laser deposition, and exfoliated graphene on SiO2 is transferred onto the AlN/Si surface by using thermal tape as a transfer medium. After transfer, Raman spectra and AFM measurement have been performed to confirm the quality of graphene on AlN. Electron transport measurements will be reported.

8:12AM V37.00002 Exploring Transport Effects in Nanoscale Graphene Devices , JEFF WORNE, CHARUDATTA GALANDE, HEMTEJ GULLAPALLI, PULICKEL AJAYAN, DOUGLAS NATELSON, Rice University — Graphene, the single- to few-atomic layers cousin to graphite, has become a very interesting topic of research owing to its unique mechanical, optical, thermal and electrical properties. Many of the properties of graphene can be traced to its structural uniformity, allowing both electrons and holes to travel long distances (up to several microns) before scattering. However, studying graphene on the micron level can mask its true nanoscale behavior. Using very short length scales allows for the investigation of the behavior of charge impurities, contact effects and ballistic transport. In this work, we fabricate sub-30 nanometer suspended graphene 3-terminal devices on gold and platinum electrodes. We present data from electrical measurements on charge impurities that are apparent at this length scale and the effect of electrode work function on contact resistance. We compare this to mechanically exfoliated graphene on a silicon/SiO2 substrate with gold electrodes.

8:24AM V37.00003 Electrical transport study of suspended graphene nanoribbons near the Dirac point[1] , MING-WEI LIN, CHENG LING, YIYANG ZHANG, HYEUN JOONG YOON, MARK MING-CHENG CHENG, ZHIXIAN ZHOU, Wayne State University — We have fabricated graphene nanoribbon Field-effect transistors from high-quality graphene nanoribbons produced by sonicating multiwall carbon nanotubes in an organic solvent. To minimize the influence of the underlying substrate, individual nanoribbons in the devices were suspended by removing the underneath silicon oxide using a wet etching method. Subsequently, in situ current annealing was carried out in high vacuum to further reduce the impurities adsorbed to the ribbon surfaces. The electrical transport properties of the devices were measured for a wide range of temperatures, revealing a range of unusual phenomena pertinent to the competing effects of improved overall charge homogeneity and reduced charge puddle sizes when the graphene nanoribbons are tuned close to the Dirac point. The electrical transport results on suspended graphene nanoribbon with varying disorder will be presented and discussed.

[1]ZZ acknowledges the support of the WSU new faculty startup funds.

8:36AM V37.00004 Effects of disorder on the transport properties of chemically derived graphene , GOKI EDA, JAMES BALL, YE XIAO, ROBERT MAHER, LESLEY COHEN, THOMAS ANTHOPOULOS, MANISH CHHOWALLA, Imperial College London — Transport properties of chemically derived graphene (CDG) are strongly influenced by the concentration of defects that are introduced during synthesis. We present a comprehensive transport study on a range of CDG films with varying degrees of disorder. The electric properties of CDG were found to be tunable over several orders of magnitude via controlled oxidation and reduction. The structural properties of CDG were monitored by analyzing the defect-related features in the Raman spectra and correlated with transport. The temperature dependence of the resistivity of these samples indicate that the conduction mechanism evolves from tunneling to hopping for strongly disordered samples and to activated transport for weakly disordered samples. Strong disorder causes localization of carriers and field-dependent modulation of hopping conduction. We discuss the temperature- and gate-bias-dependence of the resistivity of weakly disordered samples in terms of scattering dominated by midgap states, as is the case in ion irradiated graphene [2].

8:48AM V37.00005 Influence of Strain on Quantum Transport in Graphene , MD HOSSAIN, UIUC — Strain is unavoidable in graphene, either suspended or supported on a dielectric substrate such as SiO2. It is therefore crucial to identify the role of strain on transport properties in graphene. Experimentally, it is shown that local strain in graphene on a SiO2 substrate can modify graphene's conductance near the Fermi energy. The modification is attributed to the coupling of strain and phonon-mediated inelastic tunneling effects. However, conductance on the dielectric substrate is not ballistic and isolating the influence of strain is a difficult task. In this study, strain effects on ballistic conductance, an experimentally attainable transport property for suspended graphene, is studied using a combination of density functional theory and the Landauer-Buttiker formalism. It is found that, unlike in a CNT, regardless of the applied strain graphene's conductance at the Fermi energy is 0.21G0. Furthermore, for conducting electrons with energies higher or lower than the Fermi energy of the system, tensile hydrostatic strain is found to increase conductance but compressive hydrostatic strain decreases conductance. For an 8% compressive hydrostatic strain, conductance increases by as large as 30%. Surprisingly, for uni-axial strain, if the energy of the conducting electrons is higher than the Fermi energy, conductance remains approximately unchanged, whereas conductance by electrons less than the Fermi energy decreases (increases) with compressive (tensile) strain along the transport direction.

9:00AM V37.00006 ABSTRACT WITHDRAWN –

9:12AM V37.00007 Thermal and Electronic Transport Properties of Graphene Nanoribbons with Defects , JUSTIN HASKINS, Department of Chemical Engineering, Texas A&M University, ALPER KINACI, Department of Material Science, Texas A&M University, CEM SEVIK, TAHIR CAGIN, Department of Chemical Engineering, Texas A&M University — The interplay between graphene nanoribbon (GNR) structure and conductivity, both thermal and electrical, is probed with molecular dynamics and tight binding models. A variety of randomly oriented defects, vacancies and Stone-Wales, as well as edge terminations, zig-zag, armchair, and roughened, are studied in experimental sized systems (>100 nm long and >15 nm wide). It is found that GNR thermal conductivity responds similarly to edge roughness and moderate defect concentrations (0.0023) with a drastic reduction (81%) in lattice thermal conductivity, compared to pristine GNR value. Conversely, the presence of randomly oriented defects completely erodes the ballistic nature of the electrons, reducing conductance by two orders of magnitude, while edge roughened structures leave the electrical conductance intact.

9:24AM V37.00008 First principles study of transport properties of pristine and passivated bilayer graphene nanoribbons , XIAOLIANG ZHONG, RAVINDRA PANDEY, Michigan Technological University, SHASHI KARNA, Army research Laboratory — Transport properties of pristine and hydrogen passivated bilayers of zigzag-edged graphene nanoribbons (ZGNRs) coupled with gold electrodes are investigated using first-principles methods based on density-functional theory. The calculated ground state of the passivated bilayer 6-ZGNRs is non-magnetic and the antiferromagnetic coupling is energetically preferred for the pristine counterpart. The results of the bias and spin-dependent electron transmission and current calculated using the nonequilibrium Green's function formalism will be presented. The role of interlayer interaction in determining the I-V characteristics of bilayer graphene nanoribbons will also be discussed.

9:36AM V37.00009 1/f noise as a probe to investigate the band structure of graphene , ATINDRA NATH PAL, ARINDAM GHOSH, Department of Physics, Indian Institute of Science, Bangalore 560012, India — The flicker noise or low frequency resistance fluctuations in graphene depend explicitly on its ability to screen external potential fluctuations and more sensitive compared to the conventional time average transport. Here we show that the flicker noise is a powerful probe to the band structure of graphene that vary differently with the carrier density for the linear and parabolic bands. We have used different types of graphene field effect devices in our experiments which include exfoliated single and multilayer graphene on oxide substrate, freely suspended single layer graphene, and chemical vapor deposition (CVD)-grown graphene on SiO_2.We find this difference to be robust against disorder or existence of a substrate. Also, an analytical model has been developed to understand the mechanism of graphene field effect transistors. Our results reveal the microscopic mechanism of noise in Graphene Field Effect Transistors (GraFET), and outline a simple portable method to separate the single from multi layered graphene devices. 9:48AM V37.00010 Charge Trapping and Transport in Epitaxial Graphene , DAMON FARMER, IBM T.J. Watson Research Center — A thorough characterization of the electronic transport behavior of charge carriers in graphene that is epitaxially grown on the silicon face of 6H(0001) SiC is presented. A nonlinear temperature dependence of the carrier density is observed, and is attributed to the presence of charge traps in the material. Observation of this trapping effect has been previously unidentified, and gives critical information about the material properties of epitaxially grown graphene. The nature of the electrostatic screening associated with these traps is evaluated using zero screening, full screening, and RPA screening approximations, and it is found that the zero screening approximation best describes the measurements. Electrostatic homogeneity of this material allows for exceptionally low carrier densities to be attained, where the carrier mobility sharply increases. The entire mobility profile can be phenomenologically simulated assuming Coulomb and short-range scattering as the dominant scattering mechanisms at low temperatures. Based on this result, the temperature independent residual impurity concentration of this material can be directly extrapolated.

10:24AM V37.00011 ABSTRACT WITHDRAWN –

10:36AM V37.00012 Transport Through Andreev Bound States in a Graphene Quantum Dot , TRAVIS DIRKS, TAYLOR L. HUGHES, SIDDHARTHA LAL, BRUNO UCHOA, YUNG-FU CHEN, CESAR CHIALVO, PAUL M. GOLDBART, NADYA MASON, University of Illinois at Urbana-Champaign — We have performed transport measurements on a graphene-insulator-superconductor junction, and report the direct observation of sharp, gate-tunable Andreev bound states (ABS) in a graphene quantum dot (QD)[1]. The quantum dot is formed underneath the superconducting lead by local gating due to a work-function mismatch. We show that the ABS form when the discrete QD levels are proximity coupled to the superconducting contact. We find subgap resonant features which are remarkably narrow, can be tuned to zero energy by gating, and show a striking pattern as a function of applied bias and gate voltage.

Thursday, March 24, 2011 8:00AM - 11:00AM –

Session V38 DCP DBP: Focus Session: The Physics of Evolution II A130/131

8:00AM V38.00001 Natural Selection in Large Populations , MICHAEL DESAI, Harvard University — I will discuss theoretical and experimental approaches to the evolutionary dynamics and population genetics of natural selection in large populations. In these populations, many mutations are often present simultaneously, and because recombination is limited, selection cannot act on them all independently. Rather, it can only affect whole combinations of mutations linked together on the same chromosome. Methods common in theoretical population genetics have been of limited utility in analyzing this coupling between the fates of different mutations. In the past few years it has become increasingly clear that this is a crucial gap in our understanding, as sequence data has begun to show that selection appears to act pervasively on many linked sites in a wide range of populations, including viruses, microbes, *Drosophila*, and humans. I will describe approaches that combine analytical tools drawn from statistical physics and dynamical systems with traditional methods in theoretical population genetics to address this problem, and describe how experiments in budding yeast can help us directly observe these evolutionary dynamics.

8:36AM V38.00002 Understanding Biological Fitness From First Principles , EUGENE SHAKHNOVICH, Harvard University — This abstract not available.

9:12AM V38.00003 Geometry Genetics and Evolution[1] , ERIC SIGGIA, Rockefeller University — Darwin argued that highly perfected organs such as the vertebrate eye could evolve by a series of small changes, each of which conferred a selective advantage. In the context of gene networks, this idea can be recast into a predictive algorithm, namely find networks that can be built by incremental adaptation (gradient search) to perform some task. It embodies a "kinetic" view of evolution where a solution that is quick to evolve is preferred over a global optimum. Examples of biochemical kinetic networks were evolved for temporal adaptation, temperature compensated entrainable clocks, explore-exploit trade off in signal discrimination, will be presented as well as networks that model the spatially periodic somites (vertebrae) and HOX gene expression in the vertebrate embryo. These models appear complex by the criterion of 19th century applied mathematics since there is no separation of time or spatial scales, yet they are all derivable by gradient optimization of simple functions (several in the Pareto evolution) often based on the Shannon entropy of the time or spatial response. Joint work with P. Francois, Physics Dept. McGill University.

[1]With P. Francois, Physics Dept. McGill University

9:48AM V38.00004 TBD , TANJA KORTEMME, UCSF — This abstract not available.

10:24AM V38.00005 Dynamical Mueller's Ratchet: Population Size Dependence of Evolutionary Paths in Bacteria , DIRK LORENZ, Department of Physics and Astronomy, Rice University, JEONG-MAN PARK, Department of Physics, The Catholic University of Korea, MICHAEL DEEM, Departments of Physics and Astronomy and Bioengineering, Rice University, MICHAEL DEEM TEAM — Experimental evolution has recently enabled the complete quantitative description of small-dimensional fitness landscapes. Quasispecies theory allows the mathematical modeling of evolution on such a landscape. Typically, analytic solutions for these models are only exactly solvable for the case of an infinite population. Here we use a functional integral representation of population dynamics and solve it using the Schwinger Boson method. This allows us to compute the first-order correction to the average fitness for finite populations. We will use these results to explain the experimental observations of dynamics of evolution in finite populations.

10:36AM V38.00006 At the crossroads of biophysics and evolution: protein robustness and evolvability[1] , WOUTER HOFF, MASATO KUMAUCHI, Department of Microbiology and Molecular Genetics, Oklahoma State University — Proteins consist of only 20 different amino acids with modest chemical reactivity, but perform a breathtaking range of functions. How do proteins achieve such functional versatility? Novel insights are emerging from research at the interface of protein biophysics and molecular evolution. Proteins are robustness against point mutations: most mutations do not abolish function. How can such robustness be reconciled with the effective evolution of protein function? We examine these issues using photoactive yellow protein (PYP), a prototype of the PAS domain superfamily. High-throughput biophysical measurements of active site properties, functional kinetics, stability, and production level on libraries of PYP mutants reveal that almost all mutants retain photocycle activity, but that the majority of substitutions significantly alter functional properties. Thus, PYP combines robustness with evolvability. The data also reveal the mysterious role of the conserved residues that define protein superfamilies: most PAS-conserved residues are required for maintaining protein production. Asn43, the most conserved residue in PAS domains, regulates PYP signaling kinetics. This residue is often substituted by Ser, Asp, and Thr in PAS domains while retaining two side chain hydrogen bonds. Thus, not residue identity at position 43 but the pattern of side chain hydrogen bonds is conserved.

10:48AM V38.00007 Deciphering evolutionary instructions for specifying protein fold and function , WALRAJ GOSAL, RAMA RANGANATHAN, UT Southwestern Medical Center — Classical studies show that proteins have evolved to fold into functional native states that are, at best, only marginally stable through weak non-covalent interactions encoded by their primary sequences. How such fold and functional information is stored in a single amino acid sequence remains elusive. Using the statistical analysis of covariation between pairs of amino acids at all positions in a protein, here we identify groups of a few key physically-interconnected residues, which we term sectors. What information about the fold and function is captured by sectors? Using simulated-annealing Monte Carlo, we introduce variation in the sequence of a single member of the PDZ family in a manner that either preserves or disrupts sector correlations. Experimentally we show that function is specifically retained in designed proteins that obey sector correlations, and strikingly, even in the absence of a native state. Thus, we suggest that native-state stability is not a fundamental requirement for function, and is encoded in the sequence in an idiosyncratic manner in the PDZ family.

Thursday, March 24, 2011 8:00AM - 11:00AM –

Session V39 DBP: Cellular Biomechanics A124/127

8:00AM V39.00001 Three-dimensional traction force distribution in migrating amoeboid cells , BEGONA ALVAREZ, JUAN C. DEL ALAMO, RUDOLF MEILI, BALDOMERO ALONSO-LATORRE, RICHARD A. FIRTEL, JUAN C. LASHERAS — We have studied the 3D traction forces exerted by migrating *Dictyostelium* cells moving over flat elastic substrates. For that purpose, we have developed a method to calculate both vertical and tangential cell traction forces from measurements of 3D substrate deformation, based on the solution of the elastostatic equation for a linearly elastic medium. 3D substrate deformation is measured by applying correlation techniques to a volume of substrate containing fluorescent markers. We have performed experiments for wild-type (WT) and mutant cell lines with crosslinking defects to study how cytoskeletal organization affects the overall distribution of traction forces. We find that cells push the substrate downwards near their center and pull upwards at their periphery with forces of comparable magnitude. Our initial findings show that the effect of the crosslinking mutations on the tangential forces do not necessarily predict the effect on the vertical forces. For instance, myosin II-null cells show a significant reduction of the front-back organization of the tangential traction forces, while the distribution of vertical forces basically remains unaffected.

8:12AM V39.00002 The Physics Of Cell Crawling In Elastic Media , ELNAZ BAUM-SNOW, CHARLES WOLGEMUTH, University of Connecticut, Health Center — Understanding the motion of cells through deformable media, such as the extra-cellular matrix (ECM), is important for understanding many biological processes, such as cancer metastasis, wound healing, and organismal development. We propose a model to understand the cells' movements through ECM, described by an elastic medium. The deformations and the stress tensor are then calculated for different values of Young's modulus and Poisson's ratio. The results are then compared to the values measured experimentally.

8:24AM V39.00003 How Deep Cells Feel , AMNON BUXBOIM, EDWARD C. ECKELS, DENNIS E. DISCHER, University of Pennsylvania — Lacking eyes to see and ears to hear, cells can still sense their microenvironment by physically touching and deforming, thus sensing not only their immediate surroundings but also feeling beyond the cell-matrix interface. To elucidate how deeply cells feel we cultured mesenchymal stem cells on gels-made microfilms with controlled elasticity (E) and thickness (h). After 36hrs in culture cells spread area was smaller on thick and on soft than on thin and on stiff films, respectively, and correlated with nuclei morphology. Transition in spread area was obtained at <5 microns gel thickness. Transcription levels of Lamin-A predominantly decreased with E and in a similar fashion to Lamin-A expression levels increased with h. RNA levels of histones and of chromatin-remodeling enzymes were similar for stiff gels and for soft but thin films but suppression of cell contractility resulted in transcriptional profiles that were uncorrelated with matrix-emerging cues. We conclude that cells actively sense up to 20 microns into soft, adipose-like matrix. Cellular response to E and h includes cytoskeletal reorganization, NE remodeling with evidence of coupling between matrix-emerging signals and regulation of gene expression

8:36AM V39.00004 Delineating cell-matrix interaction at high resolution[1] , SHANG YOU TEE, JOHN CROCKER, PAUL JANMEY, University of Pennslyvania — It is increasingly evident that mechanic cues affect a wide variety of cells and can sometimes override biochemical cues to control cell division, cell death and even specify stem cell differentiation lineage. To understand how cells interact physically with their surrounding matrix, it is imperative to investigate the spatiotemporal distribution of forces and molecular players as cells undergo contractile activity. We examine human mesenchymal stem cell contractility at high temporal and spatial resolution on soft and hard substrates.

[1]We acknowledge NIH 5R01GM083272-03 funding.

8:48AM V39.00005 How substrate rigidity regulates the cellular motility , ALIREZA SARVESTANI, University of Maine — Mechanical stiffness of bio-adhesive substrates has been recognized as a major regulator of cell motility. We present a simple physical model to study the crawling locomotion of a contractile cell on a soft elastic substrate. The mechanism of rigidity sensing is accounted for using Schwarz's two spring model (Schwarz et al. (2006) BioSystems 83, 225-232). The predicted dependency between the speed of motility and substrate stiffness is qualitatively consistent with experimental observations. The model demonstrates that the rigidity dependent motility of cells is rooted in the regulation of actomyosin contractile forces by substrate deformation at each anchorage point. On stiffer substrates, the traction forces required for cell translocation acquire larger magnitude but show weaker asymmetry which leads to slower cell motility. On very soft substrates, the model predicts a biphasic relationship between the substrate rigidity and the speed of locomotion, over a narrow stiffness range, which has been observed experimentally for some cell types.

9:00AM V39.00006 Local nano-mechanical properties in cancer metastasis , LYNDON BASTATAS, Physics, Texas Tech University, RAUL MARTINEZ-ZAGUILAN, SOUAD SENNOUNE, Cell Physiology and Molecular Biophysics, Texas Tech University Health Sciences, SOYEUN PARK[1], Physics, Texas Tech University — We investigated whether the local nano-mechanical properties of cells can represent metastatic potential using the Atomic Force Microscope. As models, we used the lowly (LNCaP) and highly (CL1) metastatic prostate cancer cells. By varying the applied forces, we determined the heterogeneity in the local elastic properties of cells in the vertical direction. We also obtained the 2D array of the force-distance curves over the entire region of cells to investigate the lateral heterogeneity of local elastic moduli. By analyzing the force-distance curves using the Hertz and the advanced models, we delineated the 2D maps of elastic moduli and adhesiveness of cells. We found that the CL1 is more heterogeneous in the local elastic moduli compared to LNCaP. We also found that the CL1 adheres much better on the substrates than the LNCaP. The enhanced adhesion generates the tensional force and thus results in higher elastic moduli. We conclude that there is an optimal range of elastic moduli to make cells actively elicit the directional movements, leading to the enhance metastasis. We will discuss our results correlated with our intercellular calcium transit.

9:12AM V39.00007 Cell Shape Dynamics: From Waves to Migration , MEGHAN DRISCOLL, University of Maryland, COLIN MCCANN, University of Maryland and National Cancer Institute, National Institutes of Health, RAEL KOPACE, TESS HOMAN, JOHN FOURKAS, University of Maryland, CAROLE PARENT, National Cancer Institute, National Institutes of Health, WOLFGANG LOSERT, University of Maryland — We analyzed the dynamic shape of migrating Dictyostelium discoideum cells. We found that regions of high boundary curvature propagate from the front to the back of cells in an organized fashion. These waves of high curvature are stabilized by surface contact, and so, at the sides of cells, are stationary relative to the surface. The initiation of curvature waves, though, which usually occurs at the front of cells, is associated with protrusive motion. The protrusion location shifts rapidly in a ballistic manner at speeds nearly double that of cellular migration. To examine curvature waves in the absence of surface contact, we guided cells to extend over the edge of micro-cliffs. The curvature wave speed of cells extended over a cliff was triple the wave speed of cells migrating on a surface, which is consistent with the higher wave speeds observed near the non-adherent leading edge of cells.

9:24AM V39.00008 Self-organized cell motility , XINXIN DU, KONSTANTIN DOUBROVINSKI, Princeton University — Cell migration plays a key role in a wide range of biological phenomena, such as morphogenesis, chemotaxis, and wound healing. Cell locomotion relies on the cytoskeleton, a meshwork of filamentous proteins, intrinsically out of thermodynamic equilibrium and cross-linked by molecular motors, proteins that turn chemical energy into mechanical work. In the course of locomotion, cells remain polarized, i.e. they retain a single direction of motion in the absence of external cues. Traditionally, polarization has been attributed to intracellular signaling. However, recent experiments show that polarization may be a consequence of self-organized cytoskeletal dynamics. Our aim is to elucidate the mechanisms by which persistent unidirectional locomotion may arise through simple mechanical interactions of the cytoskeletal proteins. To this end, we develop a simple physical description of cytoskeletal dynamics. We find that the proposed description accounts for a range of phenomena associated with cell motility, including spontaneous polarization, persistent unidirectional motion, and the co-existence of motile and non-motile states.

9:36AM V39.00009 Differentiation and Behavior of Dental Pulp Stem Cells in Hydrogel Scaffolds of Various Stiffnesses , DIVYA BHATNAGAR, VLADIMIR JURUKOVSKI, MIRIAM RAFAILOVICH, MARCIA SIMON, Stony Brook University — Dental Pulp Stem Cells (DPSCs) are known to differentiate in bone, dentine, or nerve tissue through different environment signals. This work investigates whether differentiation could occur in the absence of chemical induction and through mechanical stimuli only. For this study, we chose enzymatically cross-linked gelatin hydrogels as our substrates. Rheological studies carried out by oscillatory shear rheometry indicated that the modulus of the hardest hydrogel was of the order of 8kPa where as the medium and the softest hydrogel had modulus of the order of 1kPa and 100Pa respectively. DPSC were then plated on all three substrates and cultured with and without dexamethasone induction media. After 21 days of incubation, SEM analysis indicated that the cells cultured in the induction media produced biomineralized deposits on hard, medium as well as soft hydrogels. On the other hand, the cells cultured without the induction media also produced large amounts of biomineralized deposits.The modulus of the cells was also measured using AFM. En mass cell migration was also studied to determine the average velocity of migration of DPSCs. We also investigated whether stem cells that are induced to differentiate by their scaffold environment would continue to differentiate and biomineralize when removed from the inducing scaffold.

9:48AM V39.00010 Model of myosin recruitment to the cell equator for cytokinesis: feedback mechanisms and dynamical regimes , ALEXANDER VEKSLER, Rice University, DIMITRIOS VAVYLONIS, Lehigh University — The formation and constriction of the contractile ring during cytokinesis, the final step of cell division, depends on the recruitment of motor protein myosin to the cell's equatorial region. During animal cell cytokinesis, cortical myosin filaments (MF) disassemble at the flanking regions and concentrate in the equator [1]. This recruitment depends on myosin motor activity and the Rho proteins that regulate MF assembly and disassembly. Central spindle and astral microtubules help establish a spatial pattern of differential Rho activity [2]. We propose a reaction-diffusion model for the dynamics of MF recruitment to the equatorial region. In the model, the central spindle and mechanical stress [3] promote self-reinforcing MF assembly. Negative feedback is introduced by MF-induced recruitment of inhibitor myosin phosphatase. Our model yields various dynamical regimes and explains both the recruitment of MF to the cleavage furrow and the observed damped MF oscillations in the flanking regions [1], as well as steady MF assembly [4]. Space and time parameters of MF oscillations are calculated. We predict oscillatory relaxation of cortical MF upon removal of locally-applied external stress. [1] Zhou & Wang, Mol. Biol. Cell **19**:318 (2008); [2] Murthy & Wadsworth, J. Cell Sci. **121**:2350 (2008); [3] Ren et al., Curr. Biol. **19**:1421 (2009); [4] Vale et al., J. Cell Biol. **186**:727 (2009)

10:00AM V39.00011 Biomechanics and dynamics of red blood cells probed by optical tweezers and digital holographic microscopy , NELSON CARDENAS, PATTRICK THOMAS, LINGFENG YU, Nanoscope Technologies LLC, SAMARENDRA MOHANTY — Red blood cells (RBC), with their unique viscoelastic properties, can undergo large deformations during interaction with fluid flow and migration through narrow capillaries. Both local and overall viscoelastic property is important for cellular function and change in these properties indicate diseased condition. Though biomechanics of the cells have been studied using variety of physical techniques (AFM, optically-trapped anchoring beads and microcapilary aspiration) in force regime $>$ 10pN, little is studied at low force regime $<$1pN. Such perturbations are not only hard to exercise on the cell membrane, but quantification of such deformations becomes extremely difficult. By application of low power optical tweezers directly on cell membrane, we could locally perturb discotic RBC along the axial direction, which was monitored dynamically by digital holographic microscopy-a real time, wide-field imaging method having nm axial resolution. The viscoelastic property of the RBC at low force regime was found to be significantly different from that of high-force regime. The results were found to be in good agreement with the simulation results obtained using finite element model of the axially-stretched RBC. The simulations and results of viscoelestic measurements will be presented.

10:12AM V39.00012 Effect of Surface Adhesion on Individual and Collective Migration[1] , WOLFGANG LOSERT, University of Maryland, COLIN MCCANN, University of Maryland and NCI, ERIN RERICHA, University of Maryland, CAROLE PARENT, LCMB, NCI, NIH — Cell-surface adhesion plays a critical role in amoeboid cell motion by supplying the traction allowing a cell to move itself forward. The amoeba Dictyostelium discoideum, a model system for individual and collective cell migration, naturally exhibits both cell-substrate and cell-cell adhesion during the aggregation process. We used both high- and low-magnification time-lapse microscopy to investigate the individual and collective migration of D. discoideum on substrates of varying adhesiveness, as well as on interfaces between surfaces. We find that surface adhesion can affect both individual cell migration as well as the behavior of cell groups. At the population scale, non-ideal surfaces slow down the initiation of aggregation and change the aggregation dynamics. At the scale of single cells, we measure both adhesion ability as well as the area of contact between cells and surface for individual cells and cells that are part of groups. We find that comparable forces are needed to pull cells off all surfaces, indicating that surface adhesion is actively regulated by migrating cells.

10:24AM V39.00013 Importance of spectrin network reorganization in computer simulations of RBC shapes[1] , ULF SCHILLER[2], TONY LADD, Department of Chemical Engineering, University of Florida, Gainesville — The shape of red blood cells (RBCs) has been the subject of intensive investigations in both experiments and theoretical models. Various computational models for RBCs have also been developed. However, a rigorous quantitative comparison of the observed shapes is still lacking. We have developed a flexible model that allows to study the influence of the various contributions to the membrane stress and their relevance for RBC shape. Our model reveals that a pure curvature model does not fully explain the experimentally observed discocyte shapes. We demonstrate that the in-plane stresses of the spectrin network have a crucial effect on the cell shapes and their transitions, and that the dynamic relaxation of the stresses due to spectrin reorganization is important. We present an extended model that incorporates the effects of dynamic spectrin remodeling and study their role on the dynamics of RBC shapes.

10:36AM V39.00014 The contribution of cytoskeleton networks to stretch is strain dependent[1] , KENECHUKWU DAVID NNETU, TOBIAS KIEßLING, ROLAND STANGE, JOSEF KÄS, University of Leipzig — The interaction between the cytoskeleton filaments in a cell provides it with mechanical stability and enables it to remodel its shape. The rheological response of cells has been characterized either as viscoelastic or soft-glassy which neglects the molecular origin of cell response. In this work, by using a large amount of cells ($>$10,000 in total) exceeding previous statistics by a decade, we link observed cell response to its molecular origin by showing that actin and microtubule networks maintain the mechanical integrity of cells in a strain dependent manner. While the actin network solely regulated cell deformation at small strain, the microtubule network was responsible for cell relaxation. At large strain, actin and microtubule networks dominated cell response with microtubules having a bipolar effect on cells upon stabilization. This effect could explain the relapse of some cancer after chemotherapy treatment using Taxol thus providing a bridge between soft condense matter physics and systems biology.

10:48AM V39.00015 Magnetic Carbon nanoparticles enabled efficient photothermal alteration of mammalian cells , L. GU, V. VARDARAJAN, A. KANNEGANTI, A. KOYMEN, S.K. MOHANTY, UT Arlington — While cw near-infrared (NIR) laser beams have been finding widespread application in photothermal therapy of cancer and pulsed NIR laser microbeams are recently being used for optoporation of exogeneous impermeable materials into cells. Since, carbon nanomaterials are very good in photothermal conversion, we utilized carbon nanoparticles (CNP) doped with Fe, so that they can be localized in a defined area by two fold selectivity, (i) external magnetic field for retention of the CNP in targeted area and (ii) surface functionalization for binding the targeted cells. Here, we report efficient photothermal therapy as well as poration of cells using magnetic CNPs with very low power continuous wave laser beam. Localization of CNPs on cell membrane under application of magnetic field was confirmed by scanning electron microscopy. At different power levels, cells could be damaged or microinjected with fluorescence protein-encoding plasmids or impermeable dyes. Monte Carlo simulation showed that the dose of NIR laser beam is sufficient to elicit response for magnetic CNP based photothermal treatment at significant depth. The results of our study suggest that magnetic CNP based photothermal alteration is a viable approach to remotely guide treatments offering high efficiency with significantly reduced cytotoxicity.

Session V40 DBP: Thesis Award Session: Nucleic Acids – Structure, Function, and the Genome

A122/123

8:00AM V40.00001 2010 Award for Outstanding Doctoral Thesis Research in Biological Physics Talk: How the Genome Folds , EREZ LIEBERMAN-AIDEN, Harvard Society of Fellows — I describe Hi-C, a novel technology for probing the three-dimensional architecture of whole genomes by coupling proximity-based ligation with massively parallel sequencing. Working with collaborators at the Broad Institute and UMass Medical School, we used Hi-C to construct spatial proximity maps of the human genome at a resolution of 1Mb. These maps confirm the presence of chromosome territories and the spatial proximity of small, gene-rich chromosomes. We identified an additional level of genome organization that is characterized by the spatial segregation of open and closed chromatin to form two genome-wide compartments. At the megabase scale, the chromatin conformation is consistent with a fractal globule, a knot-free conformation that enables maximally dense packing while preserving the ability to easily fold and unfold any genomic locus. The fractal globule is distinct from the more commonly used globular equilibrium model. Our results demonstrate the power of Hi-C to map the dynamic conformations of whole genomes.

8:36AM V40.00002 Recognition Tunneling towards Next Generation Single Molecule DNA Sequencing , SHUO HUANG, Arizona State University — A novel approach has been developed to trap and sequence DNA within a molecular junction formed by a pair of functionalized Au electrodes so individual DNA nucleotides could be recognized on small pieces of DNA with single base resolution. The cost of labeling reagents is totally eliminated since different nucleotides are recognized through their intrinsic physical properties. Unexpectedly long residence time of DNA (on the order of a second) in the molecular gap is observed which indicates that a pN force is required to achieve the sequencing speed as fast as 10 bases/Sec. Providing such ionic driving force, a nanopore device incorporated with recognition tunneling reader will provide a revolutionary way for fast, accurate and economic next generation DNA sequencing.

8:48AM V40.00003 Electronic Signatures of all Four DNA Nucleosides in a Tunneling Gap[1] , SHUAI CHANG, Arizona State University — New approaches to DNA sequencing are required to reduce costs and increase the availability of personalized genomics. Using Scanning Tunneling Microscope as a tool, we report measurements of the current signals generated as free nucleosides diffuse into a tunnel junction in which both electrodes are functionalized with a reagent that presents a hydrogen bond donor and acceptor to the nucleosides. This functionalization serves to both limit the range of molecular orientations in the tunnel gap and reduce the contact resistance, increasing the selectivity of the tunneling signal, so that a direct readout may be possible with a few repeated reads.

9:00AM V40.00004 Gel electrophoresis of partially denatured DNA: split-ends, bubbles, and squids , DAVID SEAN, GARY W. SLATER, University of Ottawa — Gel electrophoresis separates partially denatured DNA fragments based on chemical sequence. Upon an increase in temperature, AT-rich regions melt into two strands which is thought to be the main contributor to the rapid reduction of the fragment's mobility. The reduction in mobility is often predicted from the average number of denatured bases regardless of their positions. We re-visit the theoretical basis of this approach and determine that the analysis only holds for denatured domains that occur at the ends. Langevin Dynamics simulations are used to study the effect that the placement of the melted regions has on the mobility by discriminating between denatured domains which occur in the middle of the fragment (bubbles) and at the ends (split-ends). It is found that the split-ends dominate the blocking mechanism. In addition, we find a novel conformation (the "squid") which seems to be responsible for the blocking at high fields.

9:12AM V40.00005 Temperature dependence of two distinct DNA overstretching transitions , XINGHUA ZHANG, BioSyM, SMART, HONGXIA FU, Mechanobiology Institute, Singapore, National University of Singapore, PATRICK DOYLE, Department of Chemical Engineering, MIT, JIE YAN, Mechanobiology Institute, Singapore, National University of Singapore; Department of Physics, National University of Singapore — Recent experiments show that two distinct transitions are involved in the DNA overstretching that occurs at around 65 pN: a strand-unpeeling transition leading to strand separation from free DNA ends or nicks, and a B to S transition leading to an overstretched double-stranded DNA called "S-DNA." Here we show that the two transitions have distinct temperature dependence: in the strand-unpeeling transition, the transition force decreases when the temperature increases; while in the B to S transition, the temperature dependence of the transition force is opposite. Our results are in agreement with the notion that the two transitions involve distinct types of double-helix reorganization.

9:24AM V40.00006 An Analytic Theory for Single Molecule Manipulation of DNA[1] , CRISTIANO NISOLI, Theoretical Division and CNLS Los Alamos National Laboratory, Los Alamos NM — We introduce a minimal, analytically solvable model for thermo-mechanical behavior of DNA under tension and torque, and predict critical temperature for denaturation at unwinding and overwinding, phase diagrams for stable b–DNA, and supercoling-elongation curves as functions of applied torque, tension and temperature. Our results are in agreement with experimental data from experiments in single molecule manipulation. We also propose simple thermodynamical formulae for temperature, tension, torque, and supercoiling at criticality.

9:36AM V40.00007 Multimerization of DNA Origami Structures in Two Dimensions[1] , DANIEL SCHIFFELS, Ludwig-Maximilians-Universität München, DEBORAH FYGENSON, University of California Santa Barbara, TIM LIEDL, Ludwig-Maximilians-Universität München — DNA nanotechnology, here in particular DNA origami, is based on self-assembly and can be used to construct arbitrary three-dimensional structures with nanometer precision. The dimensions of such DNA origami structures are typically on the order of a hundred nanometers or smaller. To achieve large-scale two-dimensional lattices that could be employed as scaffolds for crystalline arrangement of biomolecules and proteins, individual DNA origami tiles need to be assembled hierarchically. We work on the multimerization of DNA origami structures into extended one- and two- dimensional lattices that can cover areas of several square micrometers. This is achieved by complementary single stranded DNAs (sticky ends) at specific positions on the DNA origami objects that we intend to grow into periodic structures. We study the effect of varying multimerization conditions such as annealing temperatures, length of sticky ends and salt concentration on the quality and size of the resulting lattice.

9:48AM V40.00008 Fluctuation Pressure Assisted Ejection of DNA From Bacteriophage , MICHAEL J. HARRISON, Michigan State University — The role of thermal pressure fluctuations excited within tightly packaged DNA while it is ejected from protein capsid shells is discussed in a model calculation. At equilibrium before ejection we assume the DNA is folded many times into a bundle of parallel segments that forms an equilibrium conformation at minimum free energy, which presses tightly against capsid walls. Using a canonical ensemble at temperature T we calculate internal pressure fluctuations against a slowly moving or static capsid mantle for an elastic continuum model of the folded DNA bundle. It is found that fluctuating pressures on the capsid from thermal excitation of longitudinal acoustic vibrations in the bundle whose wavelengths are exceeded by the bend persistence length may have root-mean-square values that are several tens of atmospheres for typically small phage dimensions. Comparisons are given with measured data on three mutants of lambda phage with different base pair lengths and total genome ejection pressures.

10:00AM V40.00009 Effects of sequence on DNA wrapping around histones[1] , VANESSA ORTIZ, Department of Chemical Engineering, Columbia University — A central question in biophysics is whether the sequence of a DNA strand affects its mechanical properties. In epigenetics, these are thought to influence nucleosome positioning and gene expression. Theoretical and experimental attempts to answer this question have been hindered by an inability to directly resolve DNA structure and dynamics at the base-pair level. In our previous studies we used a detailed model of DNA to measure the effects of sequence on the stability of naked DNA under bending. Sequence was shown to influence DNA's ability to form kinks, which arise when certain motifs slide past others to form non-native contacts. Here, we have now included histone-DNA interactions to see if the results obtained for naked DNA are transferable to the problem of nucleosome positioning. Different DNA sequences interacting with the histone protein complex are studied, and their equilibrium and mechanical properties are compared among themselves and with the naked case.

[1]NLM training grant to the Computation and Informatics in Biology and Medicine Training Program (NLM T15LM007359)

10:12AM V40.00010 A quantitative model of nucleosome dynamics , ROBERT FORTIES, JUSTIN NORTH, SARAH JAVAID, OMAR TABBAA, RICHARD FISHEL, MICHAEL POIRIER, RALF BUNDSCHUH, The Ohio State University — The expression, replication and repair of eukaryotic genomes require the fundamental organizing unit of chromatin, the nucleosome, to be unwrapped and/or disassembled. We have developed a quantitative model of nucleosome dynamics which provides a fundamental understanding of these DNA processes. We calibrated this model using results from high precision single molecule nucleosome unzipping experiments, and then tested its predictions for experiments in which nucleosomes are disassembled by the DNA mismatch recognition complex hMSH2-hMSH6. We found that this calibrated model quantitatively describes hMSH2-hMSH6 induced disassembly rates of nucleosomes with two separate DNA sequences and four distinct histone modification states. In addition, this model provides mechanistic insight into nucleosome disassembly by hMSH2-hMSH6 and the influence of histone modifications on this disassembly reaction. This model's precise agreement with current experiments suggests that it can be applied more generally to provide important mechanistic understanding of the numerous nucleosome alterations that occur during DNA processing.

10:24AM V40.00011 Fitness and structure landscapes for pre-miRNA processing , RALF BUNDSCHUH, Departments of Physics and Biochemistry, The Ohio State University, JULIETTE DE MEAUX, Fachbereich Biologie, Universitaet Muenster, MICHAEL LASSIG, Institut fuer theoretische Physics, Universitaet zu Koeln — The processing from pre-miRNA to mature miRNA in plants involves a mechanism, which depends on an extended stem in the secondary structure of the pre-miRNA. Here, we show how natural selection acts on this secondary structure to produce evolutionary conservation of the processing mechanism together with modularity of the pre-miRNA molecules, making this molecular function independent of others. Our main results are: 1. Selection on miRNA processing can be described by a fitness landscape which depends directly on the secondary structure of the pre-miRNA. 2. This fitness landscape predicts the divergence of the phenotype between orthologous pre-miRNA molecules from different species. 3. Actual pre-miRNA structures are modular: their phenotype is significantly less affected by deleterious mutations in the remainder of the molecule than for random RNA molecules.

10:36AM V40.00012 DNA-damage by free radicals in solution , P.K. BISWAS, Tougaloo College, RAMIN ABOLFATH, U. Texas at Dallas, R. RAJNARAYANAM, SUNY at Buffalo, K. CHO, U. Texas at Dallas, T. BRABEC, Ottawa U., L. PAPIEZ, U. Texas, UTSW — We employ a molecular simulation based on GROMACS-CPMD QM/MM method to study the initial damage to a fragment of DNA-molecule in the solution by ionizing radiation. We illustrate that the diatomic OH-radicals that are primary product of megavoltage ionizing radiation in water-based systems form a network of hydrogen bonds with the nearby water molecules. Our molecular simulation illustrates that the Hydrogen bonds strongly alter the relative orientation of the OH-radicals and DNA molecule. This results to an angular anisotropy in the chemical pathway and a lower efficiency in the hydrogen abstraction mechanisms than previously anticipated for identical system in the vacuum. We illustrate that the thermal fluctuations of the water molecules in the solution strongly compete with the H-abstraction that shows more energitically favorable in solution than in vacuum. As a result the chemical reaction takes place with slower rate in solution than in vacuum.

10:48AM V40.00013 Transport properties of nucleotides in a graphene nanogap for DNA sequencing[1] , J. PRASONGKIT, A. GRIGORIEV, R.H. SCHEICHER, Condensed Matter Theory Group, Dept of Physics and Astronomy, Uppsala University, Sweden, R. AHUJA, Condensed Matter Theory Group, Uppsala University, and Royal Institute of Technology (KTH), Stockholm, Sweden — The application of graphene nanogaps for DNA sequencing has been proposed [H. W. Ch. Postma, Nano Lett. 10, 420 (2010)]. We used density functional theory and the non-equilibrium Green's function method to study the electron transport properties of nucleotides located inside a graphene nanogap. Our setup considered different positions and orientations of the bases with respect to the graphene electrodes, and we analyzed how the transmission spectra depend on such shifts and rotations. Even when taking into account current changes due to base fluctuations, we find that each nucleotide possesses a different characteristic current magnitude, owing to its distinctive electronic properties. Based on our results, it thus seems that the electrical readout from a graphene nanogap could in principle be sufficiently sensitive to distinguish between the four nucleotides, and thus achieve the goal of rapid and economical whole-genome sequencing.

Session V41 DCP: Focus Session: The Role of Water in Energy Production and Utilization II

A115/117

8:00AM V41.00001 The structure of water/hydroxyl phases at metal interfaces , ANDREW HODGSON, The University of Liverpool — On all but the least reactive metals, the first contact layer with water is a mixture of water and hydroxyl, often formed by spontaneous dissociation [1]. Understanding the composition and stability of these layers is a key step in describing both the wetting and the redox behavior of the surface. Here we discuss the wetting of Cu(110) and the formation of mixed water-hydroxyl layers by reaction with adsorbed O. This surface does not conform to the traditional hexagonal symmetry associated with an ice Ih, and the hydrogen bonding structure must accommodate to the surface symmetry. A number of unusual structures are seen, including 1D chains of interlocking pentagons [2], an intact 2D network with a (7x8) unit cell at higher coverage [3] and several partially dissociated structures, including both 1D and 2D phases [4]. The composition of these structures and hydrogen bonding arrangements will be discussed, highlighting the way changing the composition and relative metal-adsorbate and adsorbate-adsorbate interactions drives the structural rearrangement of these phases.

8:36AM V41.00002 Quantum nature of the proton in water-hydroxyl overlayers on metal surfaces , ANGELOS MICHAELIDES, XINZHENG LI, London Centre for Nanotechnology and Department of Chemistry, University College London, MATTHEW PROBERT, Department of Physics, University of York, ALI ALAVI, Department of Chemistry, University of Cambridge — Using *ab initio* path integral molecular dynamics we show that water-hydroxyl overlayers on transition metal surfaces exhibit surprisingly pronounced quantum nuclear effects. The metal substrates serve to reduce the classical proton transfer barriers within the overlayers and, in analogy to ice under high pressure, to shorten the corresponding intermolecular hydrogen bonds. Depending on the substrate and the intermolecular separations it imposes, the traditional distinction between covalent and hydrogen bonds is lost partially (e.g. on Pt(111) and Ru(0001)) or almost entirely (e.g. on Ni(111)). We suggest that these systems provide an excellent platform on which to systematically explore the magnitude of quantum nuclear effects in hydrogen bonds.

8:48AM V41.00003 Water adsorption on oxygen covered Ru(0001) surfaces , SABINE MAIER[1], Lawrence Berkeley National Laboratory, PEPA CABRERA-SANFELIX, Donostia International Physics Center, San Sebastian, Spain, INGEBORG STASS, Lawrence Berkeley National Laboratory, DANIEL SANCHEZ-PORTAL, ANDRES ARNAU, Donostia International Physics Center, San Sebastian, Spain, MIQUEL SALMERON, Lawrence Berkeley National Laboratory — We present a combined scanning tunneling microscopy (STM) and density functional theory (DFT) study of the adsorption of water on a Ru(0001) surface covered with half monolayer of oxygen. The adsorption of water causes a shift of half of the oxygen atoms in the O(2x1) structure from hcp sites to fcc sites, creating a honeycomb structure where water molecules bind strongly to the exposed Ru atoms [1]. The energy cost of reconstructing the oxygen overlayer is more than compensated by the larger adsorption energy of water on the newly exposed Ru atoms. STM images reveal a (4x2) superstructure due to alternating orientations of the water molecules. Heating to 185 K results in the complete desorption of the water layer, leaving behind the oxygen honeycomb structure, which is metastable relative to the original (2x1). This stable structure is not recovered until after heating to temperatures close to 260K.

9:00AM V41.00004 Water monolayers on metals – a new framework[1] , PETER J. FEIBELMAN, Sandia National Laboratories — The first wetting layer on a solid embodies the boundary condition for water transport along its surface, is the template for ice nucleation, and governs aqueous surface chemistry. Today's talk is focused on the wetting of close-packed, precious metal surfaces, which are both relatively easily prepared, and susceptible to study by a host of surface science techniques. For decades, wetting layers on such surfaces have been thought to be "ice-like" – strained into registry with the metal lattice, but otherwise like the layers that stack to form the naturally occurring crystal, ice Ih. Interpretations of STM images of periodic wetting layers on Pt(111) [1], of TPD [2], and of IR absorption spectra [3] contradict the "ice-like" picture, but submit to a common, physics-based and DFT-supported interpretation. It is that several ice-like hexagonal rings of H_2O molecules, per repeated cell, are replaced by pentagons and heptagons, allowing a compact subset of H_2O's, with planes parallel to the metal surface, to approach the metal exceptionally closely and to anchor the wetting layer strongly to it. This motif, amounting to formation of energetically favorable di-interstitial "defects," appears to be general; similar molecular arrangements account for what we know experimentally (and, largely, could not previously explain) of water bonding to Ni, Ru, and Pd close-packed surfaces.

9:36AM V41.00005 First-principles simulation of water on graphene using different levels of theory[1] , P. GANESH, P.R.C. KENT, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, TN, DE-EN JIANG, Chemical Sciences Division, Oak Ridge National Laboratory, TN — We show results from molecular-dynamics simulations of water confined between flat graphene sheets using different levels of theory. DFT simulations using PBE exchange-correlation show strong layering near the graphene sheet, with the hydrogens closer to the graphene surface. Correlations die off to bulk values after ∼10Å from the surface. Inclusion of an empirical Grimme-type van der Waals potential has a small effect on the interfacial C-H distance but a seemingly large effect from the second coordination shell onwards from the surface. Existing reactive force-fields for water, e.g. ReaxFF, do not capture the structure of water on graphene accurately and require refitting to more closely reproduce the DFT results. Molecular dynamics results with available self-consistent vDW-DFx kernels and contrasts with existing classical water models will also be presented.

9:48AM V41.00006 How Water Meets Graphene , HUA ZHOU, PAUL FENTER, Argonne National Laboratory, JAKE MCDONOUGH, VOLKER PRESSER, YURI GOGOTSI, Department of Materials Science and Engineering, Drexel University, MATTHEW WANDER, KEVIN SHUFORD, Department of Chemistry, Drexel University — The interactions of electrolyte fluids with solids control many complex interfacial processes encountered in electrochemical energy storage systems. In this talk, we will demonstrate how to develop a fundamental atomic-scale understanding of interfacial structures at the water-graphene interface, a model fluid-solid interface combination. We have performed systematic measurements of high resolution X-ray reflectivity from epitaxial graphene films in contact with electrolytes including deionized water and aqueous salt solutions. The electron density profiles and structural models from the fully analyzed data reveal the intrinsic interfacial structures. It is noted that the interfacial water structure above the first graphene layer exhibits remarkable differences with those of subsequent graphene layers. The latter one, resembling water on freestanding graphene, is well predicted by parallel computational simulations. Moreover, the pH of aqueous solutions was found to have a subtle influence on the interfacial water structure above the first graphene layer. This may well be an indication of the interfacial structural distortions that might exist in this layer, and which may play an important role in controlling the chemical activity of monolayer epitaxial graphene.

10:00AM V41.00007 The Dynamics of Supercooled Water , FRANCESCO MALLAMACE, Dept of Physics, University of Messina, Italy — We present an overview of recent experiments performed on transport properties of water in the deeply supercooled region, a temperature region of fundamental importance in the science of water. We report data of nuclear magnetic resonance, quasi-elastic neutron scattering, Fourier-transform infrared spectroscopy, and Raman spectroscopy, studying water confined in nano-meter-scale environments (nano-tubes and the protein hydration water) and in bulk solutions. When contained within small pores, water does not crystallise, and can be supercooled well below its homogeneous nucleation temperature Th. On this basis it is possible to carry out a careful analysis of the well known thermodynamical anomalies of water. Studying the temperature and pressure dependencies of water dynamics, we show that the liquid-liquid phase transition (LLPT) hypothesis represents a reliable model for describing liquid water. In this model, water in the liquid state is a mixture of two different local structures, characterised by different densities, namely the low density liquid (LDL) and the high-density liquid (HDL). The LLPT line should terminate at a special transition point: a low-T liquid-liquid critical point. In particular We discuss the following experimental findings on liquid water: (i) a crossover from non-Arrhenius behaviour at high T to Arrhenius behaviour at low T in transport parameters; (ii) a breakdown of the Stokes-Einstein relation; (iii) the existence of a Widom line, which is the locus of points corresponding to maximum correlation length in the p-T phase diagram and which ends in the liquid-liquid critical point; (iv) the direct observation of the LDL phase; (v) a minimum in the density at approximately 70K below the temperature of the density maximum. In our opinion these results represent the experimental proofs of the validity of the LLPT hypothesis.

10:36AM V41.00008 Structural, Dynamic, and Spectroscopic Properties of the SCC-DFTB Water Model , LAURA KINNAMAN, KATHIE NEWMAN, STEVEN CORCELLI, University of Notre Dame — The interactions of water and many interfaces are not understood at a mechanistic level. The accuracy of simulations of the system are limited by the accuracy of the water model used. Classical models such as SPC/E use empirically derived parameters to match their behavior to desired bulk water properties, but cannot participate in reactions that require the making or breaking of bonds. Ab initio quantum mechanical methods such as Car-Parrinello (CP) do allow water to dissociate, but are computational intractable for large systems. A potential middle ground is the self-consistent charge density-functional tight-binding method (SCC-DFTB), which has a smaller associated computational cost, and therefore can access larger systems than CP, while still allowing for the making and breaking of bonds. The DFTB+ implementation of SCC-DFTB allows for 2nd and 3rd order expansions of the density fluctuations in the energy and, in the 3rd order expansion, an optional damping correction factor. For each of these models we compare the structural, dynamic, and spectroscopic properties of bulk SCC-DFTB water to classical SPC/E and experimental results.

10:48AM V41.00009 Interfacial water on TiO_2 anatase (101) and (001) surfaces: First-principles study with TiO_2 slabs dipped in bulk water[1] , YOSHITAKA TATEYAMA, MASATO SUMITA, International Centre for Materials Nanoarchitectonics (MANA), National Institute for Materials Science (NIMS), CHUNPING HU, Tokyo University of Science — Density functional molecular dynamics simulations using supercells with "bulk" water between the TiO_2 anatase (101) and (001) surfaces were carried out to elucidate the behaviour of water molecules and hydrogen bond networks on the interfaces of representative photocatalysts. It is demonstrated that the adsorption manners (molecular or dissociative) of water molecules on the vacuum surfaces still hold in the presence of "bulk" water on the interfaces. We also showed explicit atomistic structures of strong and weak hydrogen bonds on the TiO_2/water interfaces, which had been proposed experimentally so far. We then suggested a two-layer model for the interfacial water on both surfaces investigated. Our results also give insights into the H_2O or OH adsorption coverage on the interfaces and their hydrophobicity- hydrophilicity, which is important to understand the photocatalytic reaction mechanisms microscopically.

Session V42 DPOLY DBP: Focus Session: Supramolecular Self-Assembly–Controlling Network and Gel Formation II A302/303

8:00AM V42.00001 Control of semi-flexible polymer networks by architecture and dynamic cross-linking , FRED MACKINTOSH, Vrije Universiteit, Amsterdam — The rigidity of elastic networks depends sensitively on their internal connectivity and the nature of interactions between constituents. Particles interacting via central forces become rigid above the isostatic connectivity threshold first identified by Maxwell. Stiff or semi-flexible polymers, such as those that form the cellular cytoskeleton, develop a finite network shear modulus G at a lower threshold, although the degree to which the mechanics of such networks are governed by filament bending resistance remains a subject of considerable debate. Such networks also exhibit rich viscoelastic properties. For cytoskeletal networks, there is increasing evidence that the network response is governed by the compliance and dynamics of the cross-links, many of which are transient in nature. Here we study the effects of both local network architecture and dynamic cross-linking in disordered fibrous networks. Surprisingly, the network mechanics in both 2D and 3D are still governed by the central-force isostatic point, which acts as a zero-temperature critical point. Near this point, we find divergent strain fluctuations and an associated diverging length-scale, as well as an anomalous elastic regime that exhibits fractional power-law dependence of G on both fiber bending stiffness and stretch modulus. Furthermore, dynamic cross-linking gives rise to a broad, power-law viscoelastic regime at low frequency ω in which $G \sim \omega^{1/2}$.

8:36AM V42.00002 Macro- and microphase separation in multifunctional supramolecular polymer networks , ZOLTAN MESTER, University of California Santa Barbara, ARUNA MOHAN, Exxon-Mobil, GLENN FREDRICKSON, University of California Santa Barbara — We develop a field-based model for a binary melt of multifunctional polymers that can reversibly bond to form copolymer networks. The mean-field phase separation behavior of several model networks with heterogeneous bonding is calculated via the random phase approximation (RPA). The extent of bonding between polymers is controlled by specified bond energies. The phase boundary calculated via RPA is the stability limit of the homogeneous disordered phase to coexisting homogeneous macrophases, for low bond strengths, and to microphases, for high bond strengths. An isotropic Lifshitz point separates these two regions along the spindodal boundary. It is demonstrated that higher functionality and higher bond strength suppresses macrophase separation due to greater connectivity between unlike species. Gelation first occurs at a bond strength higher than the Lifshitz point for tri- or higher functional polymer components.

8:48AM V42.00003 Equilibrium and nonequilibrium gelation in TPR protein/linker mixtures[1] , TIANQI SHEN, ROBERT S. HOY, COREY S. O'HERN, Yale University — Using simulations we model gelation in two-component systems consisting of tetratricopeptide repeat (TPR) proteins and peptide cross linkers. These have recently been shown [1] to form strong, mechanically stable gels with remarkable shape recovery - but only within narrow parameter regimes. Within our minimal, coarse grained model, we elucidate the effects of the packing fraction ϕ, temperature T and concentration ratio r of TPR and cross linkers on the gel transition. Two gelation mechanisms are identified. At low ϕ and T, nonequilibrium microphase-separated gels may be formed by rapid temperature quenches. At higher ϕ and T, homogeneous equilibrium gelation occurs. At low r, gelation is suppressed due to depletion of linkers, while at high r gelation is suppressed due to the "coating" of proteins by linkers. The gel transition line in the (r, T) plane has an unusual, asymmetric form. We also briefly compare these results to those for a more realistic "patchy" model which incorporates the directional TPR-linker binding present in the experimental systems.

9:00AM V42.00004 Effects of inclusions on the dynamics of viscoelastic media , STEPHEN MIRIGIAN, MURUGAPPAN MUTHUKUMAR, University of Massachusetts — The modification of material properties due to the presence of inclusions in solutions and elastic composites are well known, modifying properties such as viscosity and elastic moduli. We calculate the mobility of such an inclusion in a viscoelastic medium as well as effective dynamic material properties due to the presence of such inclusions at various frequencies.

9:12AM V42.00005 Conformation and mechanical properties of diblock fibers[1] , SUMANTH SWAMINATHAN, Northwestern University, FRANCISCO SOLIS, Northwestern University / Arizona State University, MONICA OLVERA DE LA CRUZ, Northwestern University, OLVERA TEAM — We analyze the conformations of closed diblock fibers comprised of different bending rigidities and spontaneous curvatures. In each fiber, one block is a bare polymer while the other is an adsorbed protein-filament complex. The length fraction of each component and the total fiber length is controlled by tunable chemical potentials. We analytically calculate the shape of these two-component polymers for all values of the material parameters and chemical potentials. Our results yield: a complete analytical description of all possible two-component polymer conformations in two and three dimensions, a phase portrait detailing the parameter spaces in which these shapes occur, and the identification of spontaneous transitions between shapes driven by environmental changes.

9:24AM V42.00006 The Role of Multiple, Reformable Parallel Bonds on the Self-healing Behavior of Dual Crosslinked Nanogel Materials , ISAAC G. SALIB, GERMAN V. KOLMAKOV, CHET N. GNEGY, Chemical Engineering Department, University of Pittsburgh, KRZYSZTOF MATYJASZEWSKI, Department of Chemistry, Carnegie Mellon University, ANNA C. BALAZS, Chemical Engineering Department, University of Pittsburgh — Using computational modeling, we design novel self-healing materials composed of nanoscopic polymer gel particles, or nanogels. The particles are interconnected via both labile bonds (e.g., disulfide bonds) and stronger, less reactive bonds (e.g, C-C bonds) and therefore the nanogels form a "dual crosslinked" network. The stable bonds provide a rigid backbone while the labile bonds allow the material to undergo a dynamic reconfiguration in response to stress. We adapt the Hierarchical Bell Model (HBM) to describe the labile bonding interactions. The HBM effectively allows us to model cases where the ligands on neighboring nanogels interact through multiple sites. We show that the introduction of a small number of labile bonds that lie in parallel significantly increases the strength of the material relative to samples crosslinked solely by the stable bonds. We also isolate an optimal range of labile interconnections that provide high-strength, tough materials that are capable of self-repair.

9:36AM V42.00007 Forming Reversible Gels with Triblock Polyelectrolytes: a Field-theoretic Study , DEBRA AUDUS, GLENN FREDRICKSON, UC Santa Barbara — Recently, two research groups have formed reversible gels using triblock polyelectrolytes (Lemmers et al. 2010; Hunt et al., in preparation). This gel formation is driven by a phenomenon called complex coacervation, in which two oppositely charged homopolymers in solution phase separate into a polymer rich phase, known as a coacervate, and a solution phase. If instead, the polymers are triblocks with a neutral midblock and charged end blocks, under appropriate conditions they will microphase separate into micelles with cores of coacervated charged groups and coronas of neutral midblocks. These neutral midblocks act as bridges between the micelles, thereby creating a gel. One of the advantages of forming gels in this way is that the coacervate domains, and thus the gel, can be easily tuned by varying parameters such as pH, salt concentration and temperature. In order to understand the microstructures and solution sensitivity of these reversible gels, we have numerically simulated field-theoretic models of triblock polyelectrolyte mixtures in an implicit solvent. Because coacervation is driven by charge correlations, the usual mean-field assumption fails, and it is necessary to study the model beyond the level of SCFT.

9:48AM V42.00008 Supramolecular Arrest and Activation for the Network Formation of Acid Catalyzed Epoxy Polymerization , MATTHEW SPENCER, JAMES CRIVELLO, CHANG Y. RYU, Rensselaer Polytechnic Institute — Epoxy resins are limited currently as they must be externally activated by radiation in combination with a photo acid generator or implemented using the more ubiquitous two-component approach. Two component systems begin to react upon mixing are while UV cured epoxies are limited to situations where light can reach the monomer. We propose a novel one-component system that is externally activated with the application of heat. A considerable room temperature lifetime is attributed to the systems ability to sequester super acids through a system of hydrogen bonding coordination. The model system utilizes an alkyl glycidal ether which is made universal by the addition of crown ethers to non-ether epoxy monomers. Our supramolecular-based approach to retard and trigger the epoxy polymerization is likely to enable more widespread applications in microelectronic packaging.

10:00AM V42.00009 Polymer Phononic Meta-material Networks[1] , CHEONGYANG KOH, EDWIN THOMAS, DMSE, MIT — Phononic Meta-materials (PMM) offer unique opportunities for molding the flow of phonons through artificial structuring of the material at relevant length scales; however, most structures rely on combining mechanically "stiff" and "soft" materials to create the desired phononic properties, usually focusing on resonances to stop phonon flow. Such an approach suffers from lack of scalability, placing fabrication and material compatibility constraints on technological realization. Here, we show that these constraints are unnecessary and that phonon propagation behavior relies on the fundamental requirements of avoided crossings in the frequency dispersion relations. In particular, we demonstrate 1) polymer/air PMMs possessing i) multiple complete spectral gaps (MCSG), ii) negative index bands, iii) both a complete sub-wavelength transverse gap and Bragg-type longitudinal gap and 2) waveguides of pma2 *Frieze* group symmetry that possess MCGS; we verify their dispersion relation using Brillouin light scattering. This opens up the ability to develop novel integrated low-cost all-polymer phononic platforms for information processing via mesoscale polarization manipulation, filtering and superlensing.

10:12AM V42.00010 Formation of Anisotropic Block Copolymer Gels[1] , CHYA YAN LIAW, KENNETH SHULL, KEVIN HENDERSON, DERK JOESTER, Northwestern University — Anisotropic, fibrillar gels are important in a variety of processes. Biomineralization is one example, where the mineralization process often occurs within a matrix of collagen or chitin fibers that trap the mineral precursors and direct the mineralization process. We wish to replicate this type of behavior within block copolymer gels. Particularly, we are interested in employing gels composed of cylindrical micelles, which are anisotropic and closely mimic biological fibers. Micelle geometry is controlled in our system by manipulating the ratio of molecular weights of the two blocks and by controlling the detailed thermal processing history of the copolymer solutions. Small-Angle X-ray Scattering and Dynamic Light Scattering are used to determine the temperature dependence of the gel formation process. Initial experiments are based on a thermally-reversible alcohol-soluble system, that can be subsequently converted to a water soluble system by hydrolysis of a poly(t-butyl methacrylate) block to a poly (methacrylic acid) block.

10:24AM V42.00011 Microstructural Organization of Elastomeric Polyurethanes with Siloxane-Containing Soft Segments , TAEYI CHOI, The Pennsylvania State University, JADWIGA WEKLSER, AJAY PADSALGIKAR, Aortech Biomaterials, JAMES RUNT, The Pennsylvania State University — In the present study, we investigate the microstructure of two series of segmented polyurethanes (PUs) containing siloxane-based soft segments and the same hard segments, the latter synthesized from diphenylmethane diisocyanate and butanediol. The first series is synthesized using a hydroxy-terminated polydimethylsiloxane macrodiol and varying hard segment contents. The second series are derived from an oligomeric diol containing both siloxane and aliphatic carbonate species. Hard domain morphologies were characterized using tapping mode atomic force microscopy and quantitative analysis of hard/soft segment demixing was conducted using small-angle X-ray scattering. The phase transitions of all materials were investigated using DSC and dynamic mechanical analysis, and hydrogen bonding by FTIR spectroscopy.

10:36AM V42.00012 Viscoelastic Properties of Photo-crosslinked Shape Memory Elastomers[1] , JIAHUI LI, CHRISTOPHER LEWIS, DARCY CHEN, MITCHELL ANTHAMATTEN, University of Rochester — Lightly crosslinked polymer networks containing self-complementary hydrogen-bonding side-groups (e.g. ureidopyrimidinones, UPy) have been shown to exhibit unique shape-memory properties. Our synthetic approach, involving photo-crosslinking, enables both the crosslink density and UPy-content to be systematically varied. To better understand how hydrogen bond dynamics impact viscoelastic properties, dynamic mechanical analysis was performed on a series of photo-crosslinked elastomers. The presence of UPy side-groups imparts a broad dynamic transition over a frequency range that depends on the UPy content. The UPy side-group dynamics result in a high level of mechanical damping, and they enable damping characteristics to be tailored. Time temperature superposition (TTS) analysis was performed, and resulting shift factors show Arrhenius behavior. Activation energies were calculated, and elastomers with higher UPy content exhibit higher activation energies.

[1]Research was funded by NSF DMR-0906627.

10:48AM V42.00013 Origins and stability of the polydomain regime in isotropic-genesis nematic elastomers , BING LU, FANGFU YE, University of Illinois, XIANGJUN XING, Shanghai Jiao Tong University, PAUL GOLDBART, University of Illinois — We address the physical properties of nematic elastomers that have been randomly crosslinked in the high-temperature isotropic state. We do this by constructing a replica Landau theory in terms of a coupled pair of order-parameter fields: one for vulcanization, the other for nematic order. We focus on the correlations of the trapped-in nematic fluctuations as a diagnostic of the structure of the elastomer, determining them for a range of temperatures and disorder strengths. Our analysis shows that, in fewer than four spatial dimensions, the quenched randomness associated with the crosslinking prevents the emergence of long-range order, either of the mondomain nematic or of the spatially modulated type. It also shows that, for sufficiently strong disorder and low enough temperatures, the system exhibits unusual short-range oscillatory structure in the local nematic alignment.

Thursday, March 24, 2011 8:00AM - 11:00AM –
Session V43 DPOLY DBP: Focus Session: Translocation Through Nanopores II A306/307

8:00AM V43.00001 The Statistics of DNA Capture and Re-Capture by Solid-State Nanopores[1] , MIRNA MIHOVILOVIC, ERIN TEICH, NICK HAGERTY, JASON CHAN, DEREK STEIN, Brown University — We studied repeated electrophoretic translocations of the same DNA molecule through ∼10 nm nanopores using the voltage-reversal re-capture technique. Correlations were observed in the folding conformations of molecules re-captured within the Zimm relaxation time of the polymer. A trend was observed, whereby more compact conformations of DNA evolved over time. Consecutive event charge deficit measurements were narrowly distributed about a well defined mean, suggesting that the analysis of multiple translocations through a pore can be used to improve estimates of the length of long polymers.

[1]This work was supported by Intel Corporation and NSF through grant CBET-0846505.

8:12AM V43.00002 DNA translocation through a solid-state nanopore coated with a self-assembled monolayer , BINQUAN LUAN, GUSTAVO STOLOVITZKY, GLENN MARTYNA, IBM RESEARCH TEAM — The translocation of DNA through a solid-state nanopore can be dramatically affected by surface properties of a pore, such as charge density, roughness and hydrophobicity, since the pore surface serves as a boundary for the hydrodynamic flow accompanying with DNA motion. Recent experiment demonstrated the coating of a self-assembled monolayer (SAM) on the surface of a nanopore, allowing an active control on the surface property. Using all-atom molecular dynamics simulation, we investigated the tribological effect on DNA translocation through a solid-state nanopore coated with a SAM. When DNA is confined to the center of a pore, i.e. no direct interaction between DNA and pore surface, charge density and roughness of a pore surface can affect electroosmotic and hydrodynamic flows inside a nanopore, respectively. When allowing direct interaction between DNA and a SAM, adhesive interaction via hydrogen bonds can substantially increase friction force on DNA during translocation but repulsive interaction permits a fast translocation of DNA. We found two types of motion of DNA, stick-slip and steady-sliding, that are qualitatively explained using a Langevin-like model.

8:24AM V43.00003 Nanopore DNA translocation studies of tri-oligomer DNA with two hybridization segments[1] , VENKAT BALAGURUSAMY, PAUL WEINGER, XINSHENG LING, Brown University — We have earlier detected 12-base hybridizations in trimer DNA complexes formed by three single-stranded DNA oligomers hybridized at their ends sequentially, using nanopores of ∼ 10 nm diameter [1]. These complexes are connected to a polystyrene bead at one end to slow down their translocation. Here, we report translocation experiments at different voltages with nanopores ∼ 5 nm diameter. The measured time lapses between the passage of consecutive double-strand DNA segments in a trimer complex allow us to study the translocation dynamics. The measured mean-first-passage time between two consecutive hybridization segments is found to be consistent with theoretical estimates based on the Fokker-Planck equation.

8:36AM V43.00004 Dehydration and Ionic Conductance Quantization in Synthetic Nanopores[1]

, JAMES WILSON, University of California San Diego, MICHAEL ZWOLAK, MASSIMILIANO DI VENTRA — Synthetic nanopores and nanochannels create new opportunities - beyond biological ion channels - to study ionic transport at the nanoscale. One process that occurs at this scale is dehydration. Ions in water do not move freely, but are instead surrounded by tightly bound water molecules held by the charge-dipole interaction. These water molecules are organized into hydration layers. For the ion to move through a nanopore of sufficiently small radius, these hydration layers must be shed as there is not enough space within the pore to accommodate them. We use molecular dynamics simulations to develop a model of dehydration based on the energy cost associated with removing water molecules. We predict that the ionic current would show sudden drops as the pore radius is reduced due to the exclusion of the hydration layers. We also examine the effect of both the sign and magnitude of the ion charge, demonstrating that divalent ions will more clearly exhibit the effect of dehydration on the ionic current.

8:48AM V43.00005 Nanowire-nanopore transistor sensor for DNA detection during translocation

, PING XIE, Harvard University, QIHUA XIONG, Nanyang Technological University Singapore, YING FANG, National Center for Nanoscience and Technology China, QUAN QING, CHARLES LIEBER, Harvard University — Nanopore sequencing, as a promising low cost, high throughput sequencing technique, has been proposed more than a decade ago. Due to the incompatibility between small ionic current signal and fast translocation speed and the technical difficulties on large scale integration of nanopore for direct ionic current sequencing, alternative methods rely on integrated DNA sensors have been proposed, such as using capacitive coupling or tunnelling current etc. But none of them have been experimentally demonstrated yet. Here we show that for the first time an amplified sensor signal has been experimentally recorded from a nanowire-nanopore field effect transistor sensor during DNA translocation. Independent multi-channel recording was also demonstrated for the first time. Our results suggest that the signal is from highly localized potential change caused by DNA translocation in none-balanced buffer condition. Given this method may produce larger signal for smaller nanopores, we hope our experiment can be a starting point for a new generation of nanopore sequencing devices with larger signal, higher bandwidth and large-scale multiplexing capability and finally realize the ultimate goal of low cost high throughput sequencing.

9:00AM V43.00006 How to improve the sensitivity in transverse electronic measurements of DNA for nucleobase distinction?

, YUHUI HE, MING LIU, Institute of Microelectronics, Chinese Academy of Sciences, Beijing, China, ANTON GRIGORIEV, RALPH H. SCHEICHER, Cond. Mat. Theory Group, Dept of Physics and Astronomy, Uppsala University, Sweden, RAJEEV AHUJA, CMT Group at Uppsala; Dept of Mat. Sci. and Eng., Royal Inst. of Tech. (KTH), Stockholm, Sweden — In an attempt to realize third-generation whole-genome sequencing technologies, nanopores have been at the center of the research focus. Key issues with this approach involve how to slow down the translocation speed of DNA and how to achieve single-base resolution. We have previously proposed [arXiv:0708.4011; J. Phys. Chem. C 112, 3456 (2008)] the use of functionalized nanopore-embedded gold electrodes to address both these issues. More recently, we demonstrated [Appl. Phys. Lett. 97, 043701 (2010)] through molecular dynamics and electron transport simulations that the transverse differential conductance of a translocating DNA may allow for distinction between the four bases and can withstand electrical noise caused by DNA structure fluctuations. Our findings demonstrate several advantages of the transverse conductance approach, which may lead to realistic applications in rapid genome sequencing.

9:12AM V43.00007 Novel effects of chain flexibility, external force, and background stochasticity on polymer translocation[1]

, WOKYUNG SUNG, POSTECH — The polymer translocation through membranes and the polymer crossing over activation barriers in general, are ubiquitous in cell biology and biotechnological applications. Because they are interconnected flexible systems, polymers in translocation incur entropic barriers but can thermally surmount them with unusual sensitivity to background biases. In the presence of non-equilibrium noises characteristic of living environments, the translocation can speed up much when resonant activation occurs. As a related issue, I will also discuss the problem of polymer surmounting a potential barrier, where the chain flexibility enhances the crossing. Furthermore, when the chain flexibility leads to conformational changes, the crossing rate can be even more dramatically increased. This conformational flexibility and variability enhance the stochastic resonance, where the chain crossing dynamics at an optimal temperature and chain length is maximally coherent and resonant to a minute periodic force. Utilizing the self-organizing behaviors mentioned above, we may learn about bio-molecular machinery of living as well as clever means of manipulating it.

9:48AM V43.00008 Simulations of Single DNA Nucleotide Transport Through Nanoslits[1]

, BRIAN NOVAK, KAI XIA, DOREL MOLDOVAN, DIMITRIS NIKITOPOULOS, Louisiana State University, Mechanical Engineering, STEVEN SOPER, Louisiana State University, Chemistry and Mechanical Engineering — Transport of single molecules in nano-scale geometries might be used to identify them via their flight times. The motion of nucleotides in aqueous NaCl solution flowing through atomically smooth nanoslits composed of disordered carbon atoms was studied using nonequilibrium molecular dynamics simulations. The fluid was driven by gravity-like forces or the nucleotide was moved electrophoretically. Velocities were on the order of 1 m/s or 3 m/s, respectively. The relatively hydrophobic base parts of the nucleotides adsorbed to the walls multiple times while moving along the slit. The bases tended to adsorb/desorb with the sugar end of the base contacting the surface last/first. The distance required for separation of the flight time distributions (required channel length) was 8.8 μm for the gravity case. In the electrophoretic case with this surface, the nucleotides moved nearly as fast while adsorbed as while desorbed which made the separation more difficult than in the gravity case.

[1]Work supported in part by NSF-EPSCoR Grant # EPS-1003897 (LA-SiGMA) and by LONI.

10:00AM V43.00009 Heat Treatment to Shrink Solid-State Nanopores[1]

, JOSEPH BILLO, WASEEM ASGHAR, SAMIR M. IQBAL, Department of Electrical Engineering, Nanotechnology Research and Teaching Facility, University of Texas at Arlington — Solid-state nanopores have a promising application in the area of selective sensing of DNA. Therefore, it is imperative to have a simple and repeatable method for nano-fabrication of pores. This paper focuses on solid-state nanopore fabrication in a silicon-dioxide membrane with heat treatment. A 375 μm thick pre-oxidized silicon wafer with approximately 1 μm oxide is used. Photolithography followed by BHF etching, with well-cured photo-resist covering the back-side to preserve its oxide layer, was performed on the wafer in order to open square windows in the front-side oxide layer. Using the front-side oxide layer as a mask and the back-side oxide layer as an etch-stop, the silicon substrate underwent anisotropic etching to create SiO_2 membranes. The wafer was then cut into small squares approximately 1 cm on a side with each containing one membrane. A focused ion beam was used to open an initial pore in each membrane. Finally, a method for causing SiO_2 membranes to diffuse was used to shrink the pores to the desired diameter.

[1]This work was supported by the Metroplex Research Consortium for Electronic Devices and Materials, Dallas, TX.

10:12AM V43.00010 The Nanofluidic Field-Effect in Electrically Actuated Nanopores[1] , ZHIJUN JIANG, DEREK STEIN, Physics Dept., Brown University — We employed high-resolution milling techniques to create solid-state nanopores with integrated electrodes for exerting field-effect control over the transport of ions and single DNA molecules in solution. An embedded, annular gate electrode was used to voltage gate the ionic conductance through a nanopore. An absence of leakage currents confirms the electrostatic origin of this effect. The measurements also reveal strong dependencies on the pH and on the ionic strength of the fluid. These results reflect the crucial difference between the modulation of charge at a solid-liquid interface where surface chemistry plays an important role, versus at a chemically inert semiconductor interface. An electrochemical model of electrofluidic gating that captures the gate-field-induced shift in the chemical equilibrium of the ionizable surface groups describes our measurements quantitatively. We seek to electrostatically control the translocation of DNA through such gated nanopores, and thereby mimic the single-molecule regulatory capabilities of biological transmembrane channels.

[1]This work was supported by the NSF under grant DMR-0805176.

10:24AM V43.00011 FIB direct fabrication of sub-10 nm synthetic nanopores , JACQUES GIERAK, ALI MADOURI, ERIC BOURHIS, JEAN-YVES MARZIN, LPN-CNRS, GHANI OUKHALED, LAURENT BACRI, BENJAMIN CRESSIOT, JUAN PELTA, MPI-LAMBE, RALF JEDE, LARS BRUCHHAUS, Raith, LOÏC AUVRAY, MSC, LPN TEAM, MPI-LAMBE TEAM, RAITH TEAM, MSC TEAM — Nanopores in thin solid state membranes are used as single molecule electronic detectors or sensors. The membrane acts as a dividing wall in an electrolytic cell and draws charged molecules attracted by an electric field through the pore. Among the very few patterning techniques applicable to nanopores, one promising approach is to use a FIB system, which can produce small holes directly at specified locations with customized organization and shape into dielectric membranes. We detail an innovative FIB-based approach and the methodologies developed for sub-10 nm nanopore realization. Our method allows direct fabrication of nanometer-sized pores in relatively large quantities with excellent reproducibility. This approach offers the possibility to further process or to functionalize each pore on the same scale keeping the required nm-scaled positioning and patterning accuracies, for i.e. adding detection marks or local membrane thinning at nanopore site. Then we describe solutions for conditioning surface properties and for integrating such single nanopore devices for translocation experiments. Results involving DNA, proteins, polymers, colloids are presented.

10:36AM V43.00012 Incremental Mean First Passage Analysis of Unbiased Polymer Translocation[1] , GARY W. SLATER, HENDRICK W. DE HAAN, University of Ottawa — To provide a measure of how translocation progresses, we have recently developed a method of mapping the process as a series of mean first passage processes of increasing displacement. Starting with a simplified, "quasi-static" model of translocation, exact numerical and analytic calculations using this Incremental Mean First Passage Time (IMFPT) approach yield insight into the robustness of the scaling of the translocation time τ with polymer length N given by $\tau \sim N^2$ as predicted in early theoretical studies of translocation. This approach reveals fundamental differences in the dynamics between absorbing and reflective boundary conditions when only one monomer is in the pore - both experimentally relevant scenarios. IMFPT is also applied to Langevin Dynamics simulations of a full polymer to test the impact of including features neglected in the simplified model. While the scaling for much of the process is now $\tau \sim N^{2.2}$ due to internal degrees of freedom, the exponent as measured by only the net translocation time is shown to depend greatly on the details of the simulation setup as a result of non-equilibrium effects.

10:48AM V43.00013 Nanoscale fluid transportation through individual carbon nanotubes[1] , JIN HE, DI CAO, PEI PANG, TAO LUO, STUART LINDSAY, the Biodesign Institute, Arizona State University, PREDRAG KRISTIC, Oak Ridge National Laboratory, COLIN NUCKOLLS, Chemistry Department, Columbia Universtiy — There are great interest in both simulation and experiment of fluid flow on the nanoscale. Carbon nanotubes, with their extremely small inner diameter (usually below 2 nm) and atomic smooth inner surface, are ideal materials for studying nanoconfinement and ion and molecule nanoscale translocation. The excellent electrical properties of CNTs can also be integrated to achieve nanoelectrofluidic device. This presentation describes our recent progress in studying fluid transport through individual carbon nanotubes, including simultaneously ionic and electronic measurements during water, ion and molecule translocation.

Thursday, March 24, 2011 8:00AM - 11:00AM –

Session V44 DMP DPOLY: Focus Session: Organic Electronics and Photonics – Small molecule semiconductors and molecular electronics A309

8:00AM V44.00001 The Electronic Structure of a Local Charge-Transfer-Induced Spin Transition Molecular Adsorbate , XIN ZHANG, Nebraska Center for Materials and Nanoscience, Department of Physics and Astronomy, University of Nebraska-Lincoln, NING WU, ZHENGZHENG ZHANG, JEAN-FRANÇOIS LÉTARD, FRANÇOIS GUILLAUME, Université Bordeaux I, France, BERNARD DOUDIN, Université Louis Pasteur Strasbourg, FRANCE, PETER DOWBEN, University of Nebraska-Lincoln, UNIVERSITY OF NEBRASKA-LINCOLN COLLABORATION, UNIVERSITÉ BORDEAUX I COLLABORATION, UNIVERSITÉ LOUIS PASTEUR STRASBOURG COLLABORATION — The spin crossover phenomena has been identified in the [Fe(H_2B(pz)$_2$) bpy] where pz=(1-pyrazolyl)borate [Fe(H_2B(pz)$_2$) bpy], and but there is currently a lack of knowledge of the physical nature of this phenomena and the electronic structure of this organometallic compound has not been well characterized. We have investigated the interface electronic characteristics of molecular thin films of the metal-organic [Fe(H_2B(pz)$_2$) bpy] by ultraviolet photoelectron spectroscopy (UPS) and inverse photoemission (IPES). X-ray absorption spectroscopy (XAS) and Infrared spectroscopy (IR spectroscopy) were also used to study [Fe(H_2B(pz)$_2$) bpy]. The IPES results coincide with XAS, and the model calculations. The molecular vibrational modes have been identified from a comparison of the IR spectroscopy with model calculations.

8:12AM V44.00002 Raman scattering studies of organic semiconducting charge-transfer compounds , LAURIE MCNEIL, University of North Carolina at Chapel Hill, CHRISTIAN KLOC, Nanyang Technological University (Singapore) — Organic semiconductors offer the possibility of devices with greater mechanical flexibility and lower production costs compared to existing materials. Reports of carrier mobilities in monomolecular organic semiconductors in the 10-50 cm^2/V-s range and success in fabricating electronic devices from organic materials has increased the interest in their properties for electronic applications. However, the range of properties displayed by the monomolecular crystals is rather narrow. Charge-transfer compounds composed of two different organic molecules in which one acts as a donor and the other as an acceptor may represent the next generation of organic semiconductors. Control of their properties by modification of the molecules or changes in stoichiometry and crystalline structure makes them particularly attractive for a wide range of applications provided that the relationship between the structure and constituents of the compounds and their physical properties can be elucidated. Raman scattering studies of single crystals of two representative charge-transfer compounds, perylene-TCNQ and anthracene-TCNQ, will be presented. Theoretical calculations suggest that these materials have the potential for ambipolar charge transport, and so intermolecular interactions in these compounds are of particular interest.

8:24AM V44.00003 Observation of optically forbidden states in $PC_{60}BM$ due to interfacial distortion , HEMANT SHAH, BRUCE ALPHENAAR, University of Louisville — PCBM is a fullerene derivative used extensively in organic solar cells. $PC_{60}BM$ shows strong absorbance at wavelengths below 400 nm. A series of sub-gap transitions exist, but are symmetry forbidden in C_{60}, and only weakly observed in the $PC_{60}BM$ absorbance. Recent theoretical calculations predict that the symmetry rules for C_{60} can be lifted by the proximity of a metallic substrate due to perturbation of the electronic spatial distribution. Here we describe capacitive photocurrent measurements of $PC_{60}BM$ in which the optically forbidden features are strongly observed. In agreement with the theoretical predictions, this is thought to be due to the influence of a high conductivity ITO layer in contact with the $PC_{60}BM$. The influence of the ITO is tested by introducing a thin insulator (Al_2O_3) of varying thickness between the $PC_{60}BM$ and the ITO. The photocurrent due to the symmetry forbidden states drops strongly compared to the above gap photocurrent with increasing separation. Implications of these results on the polythiophene/fullerene blends will also be discussed. DOE-3048103802-08-073, NSF- DMR-0906961

8:36AM V44.00004 Free exciton emission and vibrations in pentacene monolayers[1] , RUI HE, Columbia University — Pentacene is a benchmark organic semiconductor material because of its potential applications in electronic and optoelectronic devices. Recently we demonstrated that optical and vibrational characterizations of pentacene films can be carried out down to the sub-monolayer limit. These milestones were achieved in highly uniform pentacene films that were grown on a compliant polymeric substrate. Films with thickness ranging from sub- monolayer to tens of monolayers were studied at low temperatures. The intensity of the free exciton (FE) luminescence band increases quadratically with the number of layers N when N is small. This quadratic dependence is explained as arising from the linear dependence of the intensity of absorption and the probability of emission on the number of layers N. Large enhancements of Raman scattering intensities at the FE resonance enable the first observations of low-lying lattice modes in the monolayers. The measured low- lying modes (in the 20 to 100cm^{-1} range) display characteristic changes when going from a single monolayer to two layers. The Raman intensities by high frequency intra-molecular vibrations display resonance enhancement double-peaks when incident or scattered photon energies overlap the FE optical emission. The double resonances are about the same strength which suggests that Franck-Condon overlap integrals for the respective vibronic transitions have the same magnitude. The interference between scattering amplitudes in the Raman resonance reveals quantum coherence of the symmetry-split states (Davydov doublet) of the lowest intrinsic singlet exciton. These results demonstrate novel venues for ultra-thin film characterization and studies of fundamental physics in organic semiconductor structures.

9:12AM V44.00005 The interaction of charge carriers with lattice phonons in oligoacene crystals , VEACESLAV COROPCEANU, YUAN LI, YUANPING YI, ROBERT BROWN, JEAN-LUC BREDAS, Center for Organic Photonics and Electronics and School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA 30332-0400, USA — We use density functional theory calculations to investigate the non-local electron-phonon interactions between charge carriers and lattice phonons (i.e., the modulation of transfer integrals by vibrations) in oligoacene crystals as a function of molecular size from naphthalene through pentacene. The results point to a significant coupling to both translational and librational intermolecular phonon modes as well as to intra-molecular vibrational modes. The impact of the interplay among these mechanisms on charge transport is investigated by treating the lattice dynamics classically. The impact of quadratic electron-phonon interaction on charge transport is studied as well.

9:24AM V44.00006 Spectroscopy of organic semiconductors from first principles , SAHAR SHARIFZADEH, Molecular Foundry, LBL, ARIEL BILLER, LEEOR KRONIK, Weizmann Institute of Science, JEFFERY NEATON, Molecular Foundry, LBNL — Advances in organic optoelectronic materials rely on an accurate understanding their spectroscopy, motivating the development of predictive theoretical methods that accurately describe the excited states of organic semiconductors. In this work, we use density functional theory and many-body perturbation theory (GW/BSE) to compute the electronic and optical properties of two well-studied organic semiconductors, pentacene and PTCDA. We carefully compare our calculations of the bulk density of states with available photoemission spectra, accounting for the role of finite temperature and surface effects in experiment, and examining the influence of our main approximations – e.g. the GW starting point and the application of the generalized plasmon-pole model – on the predicted electronic structure. Moreover, our predictions for the nature of the exciton and its binding energy are discussed and compared against optical absorption data. We acknowledge DOE, NSF, and BASF for financial support and NERSC for computational resources.

9:36AM V44.00007 Angle resolved photoemission study of rubrene single crystal , YONGLI GAO, HUANJUN DING, IRFAN IRFAN, University of Rochester, COLIN REESE REESE, Stanford University, ANTTI MAKINEN, Naval Research Laboratory, ZHENAN BAO, Stanford University — We report the direct experimental observation of the band structure of a bulk organic single crystal. The electronic structure of rubrene single crystal grown by physical vapor transport method was studied with angle-resolved photoemission spectroscopy. Highly reproducible dispersive features were observed with nice symmetry about the Brillouin zone center and boundaries, representing the band structure measured for a bulk organic single crystal. The high quality of the surface was confirmed with scanning tunneling microscopy. The energy dispersion of the highest occupied molecular orbitals derived bands showed strong anisotropic behavior in the a-b plane of the unit cell. The measured band structure, however, differs unexpectedly from theoretical calculations in terms of the amount of the dispersion and the separation of the bands.

9:48AM V44.00008 Charge localization and inhibition of self-assembly in tetraphenyl porphyrin on Cu(111) , GEOFFREY ROJAS, XUMIN CHEN, DONNA KUNKEL, JIE XIAO[1], PETER A. DOWBEN, AXEL ENDERS, University of Nebraska-Lincoln, ENDERS RESEARCH TEAM, DOWBEN RESEARCH TEAM — A study of the nature of the electronic structure and inter-molecular interaction of the adsorbed tetraphenyl porphyrin (H_2TPP)/Cu(111) system using scanning tunneling spectroscopy (STS) and inverse photoemission spectroscopy (IPES) is presented. By studying STS and IPES spectra as a function of increasing coverage, significant upshifts in the local shockley surface state near the adsorbate as a well interfacial HOMO-LUMO gap state are observed in monolayer-thick films. This, combined with observations of changes in the local workfunction and distortions of the Cu(111) surface within 1 Å of the molecules, indicates strong molecule-interface electronic interaction and stronger bonding. Such strong electron transfers and resulting charge dipoles are the origin of observed inter-molecular Coulomb repulsion, thereby preventing self-assembly of first-monolayer H_2TPP/Cu(111) systems, while allowing for self-assembly of second-monolayer and higher, where no such surface states are observed.

[1]Now at the University of Erlangen-Nuremberg

10:00AM V44.00009 Scanning Tunneling Spectroscopy measurements of the Electronic Structure of C60 films on the Cu(100) surface[1] , D.R. DAUGHTON, J.A. GUPTA, The Ohio State University, Department of Physics — Successful implementation of organometallic electronic and photoelectronic device architectures requires understanding and engineering of molecule-electrode interfaces. Here we investigate the electronic structure of a monolayer film of C60 on a Cu(100) surface with low temperature (5 K) scanning tunneling microscopy (STM) and spectroscopy. C60 adopts four unique orientations on the Cu(100) surface, and shifts in the molecular orbital resonances for the four geometries indicate different degrees of electronic molecule-surface hybridization. At higher bias, Stark-shifted image state resonances are shown to spatially vary across the molecular film. Modulation of the image state energies are attributed to shifts in the interfacial dipole that derive from the interplay of interfacial charge transfer, surface reconstruction, and orientational ordering of the molecular film. These observations suggest the need for nanoscale interface characterization for optimizing the performance of molecular electronic devices.

[1]Funding by the Arnold and Mabel Beckman Foundation.

10:12AM V44.00010 Highly Conducting Contacts for Single Molecule Transport Measured by STM-Break Junction[1] , JONATHAN R. WIDAWSKY, ZHAN-LING CHENG, RACHID SKOUTA, SEVERIN T. SCHNEEBELI, HECTOR VAZQUEZ, MARK S. HYBERTSEN, RONALD BRESLOW, LATHA VENKATARAMAN, Columbia University and CFN, Brookhaven National Laboratory — We present a novel method to directly link single alkane chains to gold electrodes using trimethyl tin ($SnMe_3$) linkers. We characterize electron transport through single molecule junctions using the STM-based break-junction technique, where a gold point contact is repeatedly formed and broken in a solution of the $SnMe_3$-alkanes while conductance is measured. Based on analysis of more than 10,000 individual junctions, we find that we create single molecule junctions which are $\sim$100 times more conducting than those with alkanes terminated with any other linker previously studied. The contact resistance, determined by extrapolating to zero carbons, is 4kΩ, two orders of magnitude lower than analogous values found using amine linkers. Strong evidence supports the hypothesis that *in situ* cleaving of the $SnMe_3$ end groups facilitates the formation of a direct bond between the carbon backbone and gold leads, thereby enhancing conductance. We corroborate this result by comparing the conductance of junctions formed from SnMe3- and Ph_3PAu-terminated benzenes.

10:24AM V44.00011 34 nm Charge Transport through DNA[1] , JASON SLINKER, The University of Texas at Dallas, NATALIE MUREN, SARA RENFREW, JACQUELINE BARTON, California Institute of Technology — Long-range charge transport through DNA has broad-reaching implications due to its inherent biological recognition capabilities and unmatched capacity to be patterned into precise, nanoscale shapes. We have observed charge transport through 34 nm DNA monolayers (100 base pairs) using DNA-mediated electrochemistry. Cyclic voltammetry of multiplexed gold electrodes modified with 100mer DNAs reveal sizable peaks from distally-bound Nile Blue redox probes for well matched duplexes but highly attenuated redox peaks from 100mer monolayers containing a single base pair mismatch, demonstrating that the charge transfer is DNA-mediated. The 100mers on the gold surface are efficiently cleaved by the restriction enzyme RsaI. The 100mers in the DNA film thus adopt conformations that are readily accessible to protein binding and restriction. The ability to assemble well-characterized DNA films with these 100mers permits the demonstration of charge transport over distances surpassing most reports of molecular wires.

10:36AM V44.00012 Electrical properties of metal-molecule-silicon structures with varying molecular backbones, dipoles, and atomic tethers , CURT A. RICHTER, NADINE GERGEL-HACKETT, MARIONA COLL, CHRISTINA A. HACKER, Semiconductor Electronics Division, NIST — We present the results of an extensive experimental investigation of metal-monolayer-silicon junctions. By varying the molecular dipole, the molecular backbone, the Si-molecule linkage, and the Si-doping, we indentified critical features that determine the electrical transport and injection properties of the junctions. Two basic structures were used. One is an enclosed planar structure in which an organic monolayer is directly assembled on silicon and contacted with evaporated silver. The other was made via Flip Chip Lamination, a novel approach that relies on the formation of monolayers on a gold surface first, which enables the study of a wider range of molecular layers on silicon of very high-quality. Two charge transport regimes dominate: (1) a Schottky barrier limited regime where the molecular dipole results in silicon band bending at the junction interface, and (2) a tunneling regime where the molecular dipole creates a small local electric field that screens the electrical transport. Transition Voltage spectroscopy was used to identify electrical differences between π-conjugated and alkyl backbones attributed to the extended π-delocalization and variations due to the chemical nature of Si-atom linkage.

10:48AM V44.00013 Engineering controlled Au/GaAs junctions with partial molecular monolayers , C. MARGINEAN, J.P. PELZ, The Ohio State University, H. HAICK, D. CAHEN, Weizmann Institute — Advances in molecular electronics offer the possibility to use molecular-based components to enhance integrated circuits and other electronic devices. Therefore, the studies of the electronic transport properties of junctions containing molecular layers are of great interest. The local hot-electron transmittance at buried metal-dicarboxylic acid-semiconductor [1] interfaces was directly investigated with nanometer spatial resolution and meV- level energy resolution using BEEM by spatially mapping hot-electrons that were injected into the top metal thin film and passed through the diode [2]. That study found that the dominant electronic transport mechanism for some dicarboxylic ligands was though pinholes rather than direct tunneling through the molecular film, and that the effective Schottky barrier height (SBH) at the pinholes was increased by a negative electric dipole moment in the surrounding molecular film [2]. We present the results of finite element electrostatic calculations of Au/discontinuous-molecular film/GaAs structures with both positive and negative dipole films, and show that the expected decrease (or increase) of the effective SBH is consistent with BEEM measurements of these types of samples. Work supported by NSF Grant No. DMR-0805237. [1] H. Haick et al., Adv. Mater. 16, 2145 (2004). [2] H. Haick, et. al., Phys. Stat. Sol. (A) 2031, 3438 (2006).

Session V45 DAMOP: Rotation and Artificial Gauge Fields: Vortices and Quantum Hall Physics

A310

8:00AM V45.00001 Acoustic Hawking radiation in dynamically expanding Bose-Einstein condensate , TAKAO MORINARI, Yukawa Institute for Theoretical Physics, Kyoto University — Black holes are not just an absorver but emit radiation. Verification of this phenomenon, called Hawking radiation, for real black holes is almost hopeless because the characteristic temperature is much lower than the cosmic microwave background radiation. There are attempts to verify Hawking radiation physics using acoustic black holes. In this paper, I will present a numerical simulation result for a dynamically expanding Bose-Einstein condensate of cold atoms. The result shows that the radiation spectrum obeys the Planck distribution function with the temperature on the order of 0.1nK and the particle creation occurs near the horizon. I will discuss the result from the view point of the phase coherence of Bose-Einstein condensate.

8:12AM V45.00002 Interferometry with Synthetic Gauge Fields[1] , BRANDON ANDERSON, JACOB TAYLOR, VICTOR GALITSKI, University of Maryland and Joint Quantum Institute — We propose a compact atom interferometry scheme for measuring weak, time-dependent accelerations. Our proposal uses an ensemble of dilute trapped bosons with two internal states that couple to a synthetic gauge field with opposite charges. The trapped gauge field couples spin to momentum to allow time dependent accelerations to be continuously imparted on the internal states. We generalize this system to reduce noise and estimate the sensitivity of such a system to be $S \sim 10^{-7} \frac{\mathrm{m/s^2}}{\sqrt{\mathrm{Hz}}}$.

[1]US-ARO and JQI

8:24AM V45.00003 Pulling Fluxes Away from Particles in Quantum Hall States of Atomic Gases[1] , WEIRAN LI, TIN-LUN HO, The Ohio State University — Quantum Hall states are often described as states with magnetic fluxes attached to the particles. In the case of rapidly rotating atomic gases, we show that by deforming the trapping potential of a rotating cluster, one can in fact pull the fluxes away from the particles in their quantum Hall state, as a consequence of the balance between rotational energy and interaction energy. This phenomenon can be revealed clearly from the density profile of the clusters after releasing the atoms from the trap, as well as from photoassociation experiments which measure the short range correlations.

[1]Work supported by Grants from DARPA and ARO through the OLE Program

8:36AM V45.00004 Lattice Quantum Hall Effect , LAYLA HORMOZI, Joint Quantum Institute, NIST and University of Maryland, GUNNAR MOLLER, University of Cambridge, STEVEN SIMON, University of Oxford — We study the groundstate of a two-dimensional system of interacting ultra-cold atoms (bosons and fermions), trapped in the periodic potential of an optical lattice, under the influence of a strong synthetic magnetic field. In the absence of inter-particle interactions, the energy spectrum is depicted by the Hofstadter butterfly — a fractal structure seemingly very different from the Landau levels in the continuum. However, when the number of flux quanta per lattice cell is close to a rational fraction, the energy splittings in the Hofstadter butterfly resemble Landau levels. Inspired by this similarity we establish a mapping between the wavefunctions of the non-interacting system in the lattice near rational fractions and the corresponding wavefunctions in the continuum. Using these single-particle wavefunctions we calculate pseudopotential coefficients for the interacting system. These effective interaction potentials can then be used to construct trial wavefunctions for the groundstate of the interacting system on a lattice. For the case of bosons with contact interaction, in addition to the interaction obtained by Palmer et al. [1], we find anomalous terms in the pseudopotential coefficients resembling the umklapp process.
[1] R. N. Palmer, A. Klein and D. Jaksch, Phys. Rev. A 78, 013609 (2008).

8:48AM V45.00005 Fractionalization via Z_2 Gauge Fields at a Cold Atom Quantum Hall Transition , YAFIS BARLAS, KUN YANG, National High Magnetic Field Laboratory — We study a single species of fermionic atoms in an "effective" magnetic field at total filling factor $\nu_f = 1$, interacting through a p-wave Feshbach resonance, and show that the system undergoes a quantum phase transition from a $\nu_f = 1$ fermionic integer Quantum Hall state to $\nu_b = 1/4$ bosonic fractional Hall state as a function of detuning. The transition is in the $(2+1)$D-Ising universality class. We formulate a dual theory in terms of quasiparticles interacting with a Z_2 gauge field, and show that charge fractionalization follows from this topological quantum phase transition. The resultant effective theory contains the lattice Z_2 gauge theory action along with a "Hopf" term which encodes the quasiparticle statistics. The transition occurs in the Z_2 sector and is a confinement-deconfinement transition for the quasiparticles.

9:00AM V45.00006 Bogoliubov theory of interacting bosons on a lattice in a synthetic magnetic field , STEPHEN POWELL, RYAN BARNETT, Condensed Matter Theory Center and Joint Quantum Institute, University of Maryland, RAJDEEP SENSARMA, Condensed Matter Theory Center, University of Maryland, SANKAR DAS SARMA, Condensed Matter Theory Center and Joint Quantum Institute, University of Maryland — We present a theoretical study of the effect of a magnetic field on a bosonic superfluid in a tight-binding lattice, motivated by advances in the synthesis of gauge potentials for ultracold atoms. An analysis based on the magnetic symmetry group shows that the superfluid has simultaneous spatial order, and that this depends on commensuration between the magnetic field and lattice. We predict clear signatures of many-body effects in time-of-flight images, and use a Bogoliubov expansion to calculate quasiparticle spectra that may be measured using Bragg spectroscopy. This work has been supported by JQI-NSF-PFC, ARO-DARPA-OLE, and Atomtronics-ARO-MURI.

9:12AM V45.00007 How does a synthetic non-Abelian gauge field influence the bound states of two spin-$1/2$ fermions?[1] , JAYANTHA VYASANAKERE, VIJAY SHENOY, Indian Institute of Science, Bangalore — We study the bound states of two spin-$1/2$ fermions interacting via a contact attraction (characterized by the scattering length) in the singlet channel in $3D$ space in presence of a uniform non-Abelian gauge field. The configuration of the gauge field that generates a Rashba type spin-orbit interaction is described by three coupling parameters $(\lambda_x, \lambda_y, \lambda_z)$. For a generic gauge field configuration, the critical scattering length required for the formation of a bound state is *negative*, i.e., shifts to the "BCS side" of the resonance. Interestingly, we find that there are special high-symmetry configurations (e.g., $\lambda_x = \lambda_y = \lambda_z$) for which there is a two body bound state for *any* scattering length however small and negative. Our results show that the BCS-BEC crossover is drastically affected by the presence of a non-Abelian gauge field. We discuss possible experimental signatures of our findings both at high and low temperatures.

9:24AM V45.00008 Dynamic vortex unbinding following a quantum quench in bosonic mixtures , LUDWIG MATHEY, Joint Quantum Institute, KENNETH GUENTER, JEAN DALIBARD, Laboratoire Kastler Brossel, ENS, ANATOLI POLKOVNIKOV, Boston University, CHARLES CLARK, Joint Quantum Institute — We study the many-body dynamics of a mixture of two hyperfine states of bosonic atoms in 2D, following a pi/2-pulse. Using both a numerical implementation of the Truncated Wigner approximation and an analytical approach, we find that a dynamic phase transition can be triggered, in which the system relaxes from a superfluid to a disordered state via vortex unbinding. This process can be dynamically suppressed, which creates a long-lived metastable supercritical state. We discuss the realization and detection of these effects.

9:36AM V45.00009 Macroscopic superposition states of cold bosons in an asymmetric double well with Orbital Degrees of freedom[1] , MIGUEL-ANGEL GARCIA-MARCH, LINCOLN D. CARR, Colorado School of Mines — We study the dynamics of ultracold bosons in three-dimensional double wells when they are allowed either to condense in single-particle ground states or to occupy excited states. On the one hand, the introduction of second level single-particle states opens a range of new dynamical regimes. On the other, since the second level eigenstates can carry angular momentum, NOON-like macroscopic superposition (MS) states of atoms with non-zero angular momentum can be obtained. This leads to the study of the dynamics of atoms carrying vorticity while tunneling between wells. We obtain new tunneling processes, like vortex hopping and vortex-antivortex pair superposition along with the sloshing of atoms between both wells. The resulting vortex MS states are much more robust against decoherence than the usual NOON states, as all atoms in the vortex core region must be resolved, not just a single atom.

9:48AM V45.00010 Optical Lattice Hamiltonians for Relativistic Quantum Electrodynamics , ELIOT KAPIT, ERICH MUELLER, Cornell University — We show how interpenetrating optical lattices containing Bose-Fermi mixtures can be constructed to emulate the thermodynamics of 2+1d quantum electrodynamics (QED3). We present a model of neutral atoms on planar lattices whose low energy effective action reduces to that of photons coupled to Dirac fermions. We overview the properties of QED3 and discuss how two of its most interesting features, chiral symmetry breaking and Chern-Simons physics, could be observed experimentally in our cold atom system.

10:00AM V45.00011 Vortex Dynamics and Hall Conductivity of Hard Core Bosons , ASSA AUERBACH, Technion - Israel Institute of Technology, NETANEL LINDNER, California Institute of Technolgoy, DANIEL AROVAS, University of California at San Diego — Magneto-transport of hard core bosons (HCB) is studied using an XXZ quantum spin model representation, appropriately gauged on the torus to allow for an external magnetic field. We find strong lattice effects near half filling. An effective quantum mechanical description of the vortex degrees of freedom is derived. Using semiclassical and numerical analysis we compute the vortex hopping energy, which at half filling is close to magnitude of the boson hopping energy. The critical quantum melting density of the vortex lattice is estimated at 6.5x10-5 vortices per unit cell. The Hall conductance is computed from the Chern numbers of the low energy eigenstates. At zero temperature, it reverses sign abruptly at half filling. At precisely half filling, all eigenstates are doubly degenerate for any odd number of flux quanta. We prove the exact degeneracies on the torus by constructing an SU(2) algebra of point-group symmetries, associated with the center of vorticity. This result is interpreted as if each vortex carries an internal spin-half degree of freedom ('vspin'), which can manifest itself as a charge density modulation in its core. Our findings suggest interesting experimental implications for vortex motion of cold atoms in optical lattices, and magnet-transport of short coherence length superconductors.

10:12AM V45.00012 Birefringent break up of Dirac fermions in a square optical lattice[1] , NAZANIN KOMEILIZADEH, KAMRAN KAVEH, PETER M. SMITH, MALCOLM P. KENNETT, Simon Fraser University — We introduce a model of spinless fermions on a square lattice in a spatially periodic magnetic field. This model has Dirac points in its spectrum when there is an average flux of half a flux quantum per plaquette. The dispersion in the vicinity of these Dirac points has the unusual feature that the double degeneracy of Dirac cones is broken. This corresponds to a situation in which the low energy excitations have two different "speeds of light." This is a consequence of broken chiral symmetry in the model, which occurs in the kinetic energy term, and hence leaves the spectrum gapless in the vicinity of the Dirac points. This chiral symmetry breaking is fundamentally different from spontaneous chiral symmetry breaking that leads to mass generation in field theoretic models. We investigate the effects of several perturbations on the spectrum such as staggered potentials, nearest neighbor interactions, and domain wall topological defects. We provide a physical setting in which this model might be realized, namely for fermions in an optical lattice in an artificial magnetic field.

10:24AM V45.00013 Generation and Characterization of Free Electron Vortices , BENJAMIN MCMORRAN, AMIT AGRAWAL, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, IAN ANDERSON, Surface and Microanalysis Science Division, National Institute of Standards and Technology, GREGG GALLATIN, HENRI LEZEC, JABEZ MCCLELLAND, JOHN UNGURIS, Center for Nanoscale Science and Technology, National Institute of Standards and Technology — Free electron vortex beams – composed of electron wavefunctions imprinted with a helical phase – are remarkable for their unique topology, quantized orbital angular momentum, and magnetic moment. We recently produced free electron vortex beams in a transmission electron microscope (TEM) using nanofabricated diffraction holograms. We used this technique to generate well-defined free electron vortices in various orbital states, demonstrating beams with up to 100 $\hbar$ of orbital angular momentum per electron.The helical phase of the electrons was measured directly using interferometric techniques. The orbital magnetic moment of the electron vortex scales with the topological charge of the vortex, and leads to interesting behavior in magnetic fields. As one example of several immediate applications for the electron vortex beam, we discuss how these beams can provide elementally sensitive magnetic imaging capabilities in a TEM by using the transfer of quantized orbital angular momentum to induce preferred atomic excitations in a sample.

10:36AM V45.00014 Vortex structures in ultra-rapidly rotating two-component Bose-Einstein condensates[1] , C.-H. HSUEH, National Taiwan Normal University, I.-G. LIU, S.-C. GOU, National Changhua University of Education, W.C. WU, National Taiwan Normal University — We investigate the vortex structures in rotating two-component Bose-Einstein condensates with a rotating frequency larger than the harmonic trapping frequency. Representative cases for the three phases, miscible, symmetric phase-separated, and asymmetric phase-separated, are studied. It is shown that the three different phases are manifested in the vortex structures to which at the cannular region around the center, vortices of each component form an annular structure and interlace with those of the other component. To determine the vortex structure in an authentic equilibrium state, the result obtained via imaginary-time propagating method is used as the initial state of the stochastic Gross-Pitaevskii equation and one keeps it propagating until the density profile saturates.

Session W1 DCMP: Superconducting Qubits: Advances in Single-Shot QND Readout Ballroom A1

11:15AM W1.00001 DC-SQUID Quantum Non-Demolition Readout of Superconducting Flux Qubits , KEES HARMANS, Kavli Institute, Delft University of Technology — Extracting state information from a quantum system is a central theme in quantum mechanics. As the process of state extraction by a detector implies system-detector entanglement, reverse action from the detector onto the quantum object can not be avoided. Consequently, detectors that minimise this back action are crucial. For superconducting flux qubits [1] commonly a DC-SQUID detector is used, either in an AC dispersive scheme or in a switching mode. The latter can be by AC bifurcation or by direct DC switching. The DC approach combines simplicity in use with complexity in dynamical behaviour. This complexity results from the fast Josephson phase dynamics and the significant generation of quasi-particles in the dissipative detector ON-state. This gave rise to the long-standing belief that it can not act as a "good" detector. This includes it to fail as a Quantum Non-Demolition (QND) detector, i.e. the preservation of the state of the quantum object after a state readout. In a recent experiment for relatively weak qubit-SQUID interaction strength [2] we investigated the detection properties of such a DC-switching SQUID, finding a remarkably good QND fidelity. This was achieved by shunting the SQUID by a low-value resistor, thus strongly suppressing the generation of quasi-particles. Also the detector ON-time was minimised to a few tens of ns using a nearby cryogenic amplifier. The QND-ness was obtained from measuring the correlation between two successive readouts, and found to reach 75% QND fidelity. The weak qubit-detector interaction leads to a limited readout contrast. We will discuss the results as well as its consequences, including the potential for combining high contrast and good QND fidelity.

11:51AM W1.00002 Novel approaches to high fidelity qubit state measurement in circuit quantum electrodynamics , ERAN GINOSSAR, Yale University — Qubit state measurement ('readout') in solid state systems is an open problem, which is currently the subject of intensive experimental and theoretical research. Achieving high fidelity in a single-shot measurement is an interesting quantum control problem, as well as an important component for the successful implementation of quantum information protocols. For superconducting qubits we can distinguish between linear dispersive and nonlinear methods, the latter relying on the bistability of a nonlinear resonator. In the context of circuit quantum electrodynamics, the transmon qubit is strongly coupled to a linear resonator and described by a generalized Jaynes-Cummings model (JCM) with external drive and dissipation. Recent novel approaches to achieve high-fidelity readout in the dispersive regime rely on the intrinsic nonlinearity of the JCM and its ultimate linearity in the high excitation regime. In the degenerate regime we rely on the photon blockade and precise transient dynamics of the system. This regime presents a theoretical challenge and the driven damped JCM model exhibits a dynamical phase transition. Another proposed approach extends the Josephson Bifurcation Amplifier and employs the dynamical effects of frequency chirping of the drive on the coupled qubit-resonator system. We will discuss the physics of these different regimes and describe the readout schemes which have been demonstrated by recent experiments and quantum simulations, as well as the role of quantum fluctuations and optimal control.

12:27PM W1.00003 Observation of quantum jumps in a superconducting quantum bit[1] , R. VIJAY, Quantum Nanoelectronics Laboratory, University of California, Berkeley CA 94720 — Superconducting qubit technology has made great advances since the first demonstration of coherent oscillations more than 10 years ago. Coherence times have improved by several orders of magnitude and significant progress has been made in qubit state readout fidelity. However, a fast, high-fidelity, quantum non-demolition measurement scheme which is essential to implement quantum error correction has so far been missing. We demonstrate such a scheme for the first time where we continuously measure the state of a superconducting quantum bit using a fast, ultralow-noise parametric amplifier. This arrangement allows us to observe quantum jumps between the qubit states in real time. The key development enabling this experiment is the use of a low quality factor (Q), nonlinear resonator to implement a phase-sensitive parametric amplifier operating near the quantum limit. The nonlinear resonator was constructed using a two junction SQUID shunted with an on-chip capacitor. The SQUID allowed us to tune the operating band of the amplifier and the low Q provided us with a bandwidth greater than 10 MHz, sufficient to observe jumps in the qubit state in real time. I will briefly describe the operation of the parametric amplifier and discuss how it was used to measure the state of a transmon qubit in the circuit QED architecture. I will discuss measurement fidelity and the statistics of the quantum jumps. I will conclude by discussing the implications of this development for quantum information processing and further improvements to the measurement technique.

1:03PM W1.00004 Probing the quantum fluctuations of a nonlinear resonator with a superconducting qubit , PATRICE BERTET, CEA Saclay — Coupling a superconducting quantum bit to a superconducting resonator offers the opportunity to investigate the interaction between light and an atom in regimes hardly accessible otherwise [1]. Making the resonator nonlinear has enabled important recent progress in the readout of qubits. Indeed, when pumped by a microwave field of well-chosen amplitude and frequency, nonlinear resonators (NRs) provide parametric amplification close to the quantum limit. In other drive conditions, the intra-cavity field can take two stable values between which the resonator can switch stochastically. Both regimes have been shown to yield a high-fidelity qubit readout [2,3]. Qubits can also be used to obtain interesting insight into the physics of NRs. In this work we use a transmon qubit [4] coupled to such a pumped NR as a probe of its quantum fluctuations. The qubit-NR coupling is manifested by the appearance around the qubit spectral line of two sidebands that we interpret as processes in which the driven resonator fluctuations are effectively cooled down or heated with the assistance of the qubit. The ratio of the sidebands amplitudes gives thus a direct experimental access to the pumped NR effective temperature which is found to be in quantitative agreement with the theory, bringing a clear support to the quantum description of a driven nonlinear resonator [5].

Session W2 DCMP: CVD Graphene: Synthesis, Properties and Applications Ballroom A2

11:15AM W2.00001 Chemical Vapor Deposition of Large-size Monolayer Graphene and Properties[1] , RODNEY RUOFF, The University of Texas at Austin — Graphene is of interest in part due to its electronic and thermal transport, mechanical properties including high stiffness and the possibility of high strength and toughness, high specific surface area, and that it can act as an atom thick layer, barrier, or membrane. Our top-down micromechanical exfoliation approaches conceived of in 1998 [1, 2] yielded multilayer graphene. Two main areas of our research are: (i) CVD growth of large area graphene films on metal substrates, characterization and properties of such films, and (ii) The generation, study, and use of colloids containing graphene-based platelets. We present our work on CVD growth of graphene on metal substrates, including the first achievement of large area growth of monolayer graphene [3], studies on understanding growth [related references: 3-6]. Properties such as TCE [7], thermal conductivity [8], and mechanical properties [related reference: 9], will be presented. An excellent review of graphene is [10]. A history of experimental work on graphene (from its discovery in 1969 until now) will be available on our web site: http://bucky-central.me.utexas.edu/ prior to the meeting. Ruoff group publications: http://bucky-central.me.utexas.edu/publications.htm.

11:51AM W2.00002 Roll-to-roll production of 30-inch graphene films for transparent electrodes[1] , BYUNG HEE HONG, Sungkyunkwan University — The outstanding electrical1, mechanical and chemical properties of graphene make it attractive for applications in flexible electronics. However, efforts to make transparent conducting films from graphene have been hampered by the lack of efficient methods for the synthesis, transfer and doping of graphene at the scale and quality required for applications. Here, we report the roll-to-roll production and wet-chemical doping of predominantly monolayer 30-inch graphene films grown by chemical vapour deposition onto flexible copper substrates. The films have sheet resistances as low as ∼125 Ohm/sq with 97.4% optical transmittance, and exhibit the half-integer quantum Hall effect, indicating their high quality. We further use layer-by-layer stacking to fabricate a doped four-layer film and measure its sheet resistance at values as low as ∼30 Ohm/sq at ∼90% transparency, which is superior to commercial transparent electrodes such as indium tin oxides. Graphene electrodes were incorporated into a fully functional touch-screen panel device capable of withstanding high strain.

12:27PM W2.00003 Structural and electronic properties of graphene grown by chemical vapor deposition (CVD) , YONG CHEN, Purdue University — Graphene grown by chemical vapor deposition (CVD) has brought many exciting opportunities for both fundamental studies and practical applications. In this talk, I will present our studies of the structural and electronic properties of graphene synthesized by ambient CVD based growth on polycrystalline Ni and Cu foils. Our earlier work on graphene layers and large scale graphitic thin films grown on Ni and transferred to insulators [1,2] show that such films can have excellent electronic properties, despite their structural non-uniformity. We also characterized the wrinkles in such films, yielding insights on their growth and buckling processes [3]. On Cu foils, we have synthesized wafer-scale graphene films consisting of predominantly monolayer graphene [4]. We have studied the electronic transport properties [4], including field effect, "half-integer" quantum Hall effect (electronic hall-mark of graphene) and weak localization (probing carrier scattering) in such synthetic graphene transferred to SiO2/Si substrates and characterized its structural properties by Raman mapping, transmission electron microscopy (TEM) and scanning tunneling microscopy (STM). We have also studied thermal transport in CVD graphene using both electrical and Raman measurements [5]. Finally, one of the outstanding issues in large scale CVD graphene, which can be monolayer but generally polycrystalline, is the role of grain boundaries. I will present our recent studies of single crystal graphene grains (hexagonally-shaped with edges macroscopically aligned close to zigzag directions) grown on Cu, and how individual grain boundaries affect the electronic transport properties [6]. Work in collaboration with Q. Yu, H. Cao, L. Jauregui, J. Tian, N. Guisinger, R. Colby and E.A.Stach.

1:03PM W2.00004 Atomistic view in the initial stages of growth of epitaxial graphene on metal substrates[1] , ZHENYU ZHANG, Oak Ridge National Laboratory / U of Tennessee — For both fundamental studies and potential development of graphene electronics, it is pressing to search for reliable methods for mass production of quality graphene. Epitaxial growth of graphene on catalytic metal substrates combined with post-growth transfer has become a promising route towards this goal [1,2]. However, to better control the quality and yield of graphene, a comprehensive understanding of the growth kinetics is essential. In particular, how the carbon atoms adsorbed on the metal surface (or dissolved into the metal) meet to nucleate into stable carbon islands will greatly influence both the growth rate and quality of larger carbon entities such as graphene sheets. In this talk, we first show that the delicate competition between carbon-carbon bonding and carbon-metal bonding dictates the initial nucleation sites of graphene on metal surfaces [3]. These results are discussed in connection with the experimental findings that on Ir(111) and Ru(0001) substrates graphene nucleates from the step edges [4,5]. We also predict that on Cu(111) nucleation should take place everywhere on a terrace [3]. Next we study larger carbon clusters on Cu(111) and explicitly compare the stability of linear and compact structures. We find that the linear carbon "nanoarches" are more stable than compact islands consisting of up to 13 carbon atoms, and these nanoarched structures may serve as the missing bridge between carbon dimers and larger graphene nanodomes. Based on these improved understanding of the atomistic rate processes involved, we propose a few kinetic pathways that may lead to better growth control of bilayer graphene and graphene nanoribbons as elemental building blocks for developing graphene electronics.

1:39PM W2.00005 Graphene synthesis, characterization, and processing: an atomic-scale investigation , NATHAN GUISINGER, Argonne National Laboratory — Graphene is nature's ideal two-dimensional conductor that is comprised of a single sheet of hexagonally packed carbon atoms. Since the first electrical measurements made on graphene, researchers have been trying to exploit the unique properties of this material for a variety of applications that span numerous scientific and engineering disciplines. In order fully realize the potential of graphene, large scale synthesis of high quality graphene and the ability to control the electronic properties of this material on a nanometer length-scale remain key challenges. This talk will focus on atomic-scale characterization of graphene synthesis on various materials (SiC, Cu(111), Cu foil, etc) via scanning tunneling microscopy. These fundamental studies explore growth dynamics, film quality, and the role of defects. The chemical modification of graphene following exposure to atomic hydrogen will be discussed, while additional emphasis will be made on graphene's unique structural (not electronic) properties.

Thursday, March 24, 2011 11:15AM - 2:15PM –
Session W3 DCMP DMP: Advances in ZnO Physics and Applications Ballroom A3

11:15AM W3.00001 Hybrid functional studies of defects and impurities in ZnO[1] , JOHN LYONS, University of California, Santa Barbara — Zinc oxide is regarded as a highly promising material for light-emitting diodes and lasers. Its features include a direct band gap of 3.4 eV, a large exciton binding energy of 60 meV, and the availability of high-quality single-crystal substrates. Despite the rapid development, fundamental issues regarding p-type doping remain unresolved. The most significant barrier to realizing ZnO-based optoelectronic devices is the difficulty in producing reliable and reproducible p-type material. Among the possible acceptor impurities, N has been considered the most promising because it has an atomic size close to that of O. In addition, N has been conclusively shown to act as a shallow acceptor in other II-V semiconductors, such as ZnSe. In spite of many published reports on p-type conductivity in N-doped ZnO, reproducibility and stability are still major issues, and devices based on $p-n$ homojunctions have remained elusive. In this work, we study the properties of the nitrogen acceptor using advanced density functional techniques. Our first principles calculations are based on hybrid functionals, which include a portion of exact exchange and correct the band gap of semiconductors, allowing us to accurately predict defect and impurity transition levels. Contrary to the conventional wisdom, we find the N acceptor has an exceedingly high ionization energy of 1.3 eV above the valence band, meaning that N cannot lead to hole conductivity in ZnO [1]. We have also analyzed the optical transitions (absorption and luminescence) and charge distribution associated with the N impurity, which offer characteristic signatures that can be compared to experimental results.

11:51AM W3.00002 Limits of Conductivity in ZnO Thin Films: Experiment and Theory , DAVID C. LOOK, Wright State University — Transparent conductive oxides (TCOs) have major (multi-$B) roles in applications such as flat-panel displays, solar cells, and architectural glass. The present workhorse TCO is indium-tin-oxide (ITO), but the recent huge demand for ITO has made In very expensive; moreover, it is toxic. The most commonly suggested replacement for ITO is ZnO, doped with Al, Ga, or In, and indeed the ISI lists 628 papers on Group-III-doped ZnO in 2009. However, to our knowledge, none of these papers has included calculations of donor N_D and acceptor N_A concentrations, the fundamental components of conductivity in semiconductors. We have developed a simple model for the calculation of N_D and N_A from temperature-dependent measurements of carrier concentration n, mobility μ, and film thickness d. With the inclusion of phonon scattering in the model, excellent fits of n and μ are obtained from 15 – 300 K. Experimentally, we have shown that highly conductive ZnO films can be grown by pulsed laser deposition in a pure Ar ambient, rather than the usual O_2. In a 278-μm-thick film, we have achieved a room-temperature resistivity $\rho = 1.96 \times 10^{-4}$ Ω-cm, carrier concentration n = 1.14 x 10^{21} cm^{-3}, and mobility μ = 28.0 cm^2/V-s. From our model, we calculate $N_D = 1.60 \times 10^{21}$ and $N_A = 4.95 \times 10^{20}$ cm^{-3}; however, the model also predicts that a significant reduction of N_A would give $\mu = 42.5$ cm^2/V-s and $\rho = 7.01 \times 10^{-5}$ Ω-cm, a world record. Such a reduction in N_A may be possible by in-diffusion of Zn after growth, since there is evidence that one of the major acceptor species in these films is the Zn-vacancy/Ga_{Zn} complex. We can also decrease the resistivity by annealing in forming gas, and have recently attained $\rho = 1.46 \times 10^{-4}$ Ω-cm, n = 1.01 x 10^{21} cm^{-3}, and $\mu = 42.2$ cm^2/V-s, giving $N_D = 1.13 \times 10^{21}$ and $N_A = 1.09 \times 10^{20}$ cm^{-3}. In very thin films, quantum effects must be considered.

12:27PM W3.00003 The Electronic Properties of Native Point Defects at ZnO Surfaces and Interfaces[1] , LEONARD BRILLSON, The Ohio State University — Despite nearly sixty years of research, several fundamental issues surrounding ZnO remain unresolved. Among the key roadblocks to ZnO optoelectronics have been the difficulty of p-type doping and the role of compensating native defects. Oxygen vacancies (V_O), Zn interstitials (Zn_I), and residual impurities such as H, Al, Ga, and In are reported to be donors in ZnO, while Zn vacancies (V_{Zn}) are considered to be acceptors. Electrically active complexes of V_O, Zn_I, and V_{Zn} can also exist. Although their impact on free carrier compensation and recombination is recognized, the physical nature of the donors and acceptors dominating carrier densities in ZnO and their effects on carrier injection at contacts is unresolved. The impact of these electronic states on ZnO carriers at the nanoscale is only now being explored. We can now address these issues using a combination of depth-resolved and scanned probe techniques. Taken together, we clearly identify the optical transitions and energies of V_{Zn} and V_{Zn} clusters, effects of annealing on their spatial distributions in ion-implanted ZnO, and how V_{Zn} and V_{Zn} clusters modify the near- and sub-surface carrier densities. Indeed, these native point defects can directly impact the activation of extrinsic dopants. We have now discovered that nanostructures form spontaneously on ZnO polar surfaces and create sub-surface V_{Zn} locally because of Zn diffusion that feeds the nanostructure growth. Overall, this work reveals the interplay between ZnO electronic defects, polarity, and surface nanostructure.

[1]National Science Foundation Grant DMR-0803276 (Verne Hess and Charles Ying)

1:03PM W3.00004 Realization of high performance random laser diodes[1] , S.F. YU, Hong Kong Polytechnic University — For the past four decades, extensive studies have been concentrated on the understanding of the physics of random lasing phenomena in scattering media with optical gain. Although lasing modes can be excited from the mirrorless scattering media, the characteristics of high scattering loss, multiple-direction emission, as well as multiple-mode oscillation prohibited them to be used as practical laser cavities. Furthermore, due to the difficulty of achieving high optical gain under electrical excitation, electrical excitation of random lasing action was seldom reported. Hence, mirrorless random cavities have never been used to realize lasers for practical applications – CD, DVD, pico-projector, etc. Nowadays, studies of random lasing are still limited to the scientific research. Recently, the difficulty of achieving 'battery driven' random laser diodes has been overcome by using nano-structured ZnO as the random medium and the careful design of heterojunctions. This lead to the first demonstration of room-temperature electrically pumped random lasing action under continuity wave and pulsed operation. In this presentation, we proposed to realize an array of quasi-one dimensional ZnO random laser diodes. We can show that if the laser array can be manipulated in a way such that every individual random laser can be coupled laterally to and locked with a particular phase relationship to its adjacent neighbor, the laser array can obtain coherent addition of random modes. Hence, output power can be multiplied and one lasing mode will only be supported due to the repulsion characteristics of random modes.

1:39PM W3.00005 Nanogenerators and Piezotronics , ZHONG LIN WANG, Georgia Institute of Technology — Developing wireless nanodevices and nanosystems is of critical importance for sensing, medical science, environmental/infrastructure monitoring, defense technology and even personal electronics. It is highly desirable for wireless devices to be self-powered without using battery. This is a new initiative in today's energy research for mico/nano-systems in searching for sustainable self-sufficient power sources [1]. We have invented an innovative approach for converting nano-scale mechanical energy into electric energy by piezoelectric zinc oxide nanowire arrays [2]. As today, a gentle straining can output 1-3 V from an integrated nanogenerator, using which a self-powered nanosensor has been demonstrated. A commercial LED has been lid up [3-5]. Due to the polarization of ions in a crystal that has non-central symmetry, a piezoelectric potential *(piezopotential)* is created in the crystal by applying a stress. The effect of piezopotential to the transport behavior of charge carriers is significant due to their multiple functionalities of piezoelectricity, semiconductor and photon excitation. Electronics fabricated by using inner-crystal piezopotential as a "gate" voltage to tune/control the charge transport behavior is named *piezotronics [6,7].Piezo-phototronic effect* is a result of three-way coupling among piezoelectricity, photonic excitation and semiconductor transport, which allows tuning and controlling of electro-optical processes by strain induced piezopotential [8].

Thursday, March 24, 2011 11:15AM - 2:15PM –
Session W4 DCMP GSNP: Glassy Dynamics and Jamming Ballroom A4

11:15AM W4.00001 Growing length-scales at the glass and jamming transition , GIULIO BIROLI, IPhT CEA Saclay — Growing timescales are usually associated to growing length-scales. The glass transition is no exception. Recent experimental, numerical and theoretical results unveiled that the slowing down of the dynamics is accompanied by growing dynamic and static correlation lengths.
The aim of this talk is to present an overview of what has been recently understood about growing length-scales at the glass transition and their role in glassy dynamics. I will also discuss the main open questions and the predictions of different theoretical approaches.

11:51AM W4.00002 Structural rearrangements that govern flow in colloidal glasses , PETER SCHALL, University of Amsterdam — We use colloidal glasses to obtain insight into the flow of amorphous materials. In three dimensions and real time, we track the individual colloidal particles in a flowing glass, and we visualize structural rearrangements that occur during flow. The individual particle trajectories are used to identify regions of non-affine deformation, in which shear concentrates. Under slow shear, we observe thermally activated 'shear transformation zones' embedded in an otherwise elastic amorphous material. Connections between these zones result in flow, which is homogeneous on macroscopic length scales. We calculate correlation functions for the fluctuations of non-affine displacements, and find a remarkable scaling, indicating that the flow of glasses is highly correlated in space. By reconstructing the entire three-dimensional strain distribution, we demonstrate that these system-spanning correlations arise from the elastic interactions between shear transformations.

12:27PM W4.00003 Order in amorphous solids , JORGE KURCHAN, PMMH-ESPCI — A solid is a system which has density modulations that are not erased by thermal motion, even on long timescales. The typical example is a crystal. Particles with soft, inter-penetrable cores may form such a solid. The remarkable fact that one can build a hard building with soft bricks can only be explained by the cooperation between an infinite number of particles. If soft particles may form a true, glassy solid phase, then we are forced to accept that an infinite coherence length must also exist for them. And yet, when we look at glass configurations, they appear definitely disordered, liquid-like. This is the mystery of glasses, which motivates the quest for a hidden order. I shall describe a coherence length that is accessible experimentally, and should diverge in an ideal glass state.

1:03PM W4.00004 Low frequency vibrational modes and particle rearrangements in colloidal glasses[1] , KE CHEN, University of Pennsylvania — We investigate the correlation between low frequency vibrational modes and fragile regions in two dimensional binary colloidal glasses, consisting of thermosensitive microgel particles. The sample packing fraction is tuned by small changes in temperature. The particles remain in their equilibrium positions in jammed states, and rearrangements are observed during temperature changes when packing fraction is changing. Using the particle displacement covariance matrix, we extract the intrinsic vibrational modes of the "shadow" colloidal network (i.e., with same geometric configuration and interactions but absent damping). Spatial correlations are observed between low frequency quasi-localized modes and rearranging clusters. The low frequency modes are found to contribute much more to particle rearrangement than high frequency modes. The number of rearranging clusters, as well as the size of particle rearrangements, increases as the system approaches jamming transition.

1:39PM W4.00005 Space-time phase transitions in models of glasses , JUAN P. GARRAHAN, University of Nottingham — Glass forming systems have a much richer dynamical phase structure than their thermodynamics would suggest. I will show how to explore this by means of large-deviation methods. In particular, I will demonstrate the existence of space-time phase transitions in kinetically constrained models of glasses. Similar space-time transitions seem to be present in atomistic models of supercooled liquids. In contrast to equilibrium phase transitions, which occur in configuration space, these transitions occurs in trajectory space, and are controlled by variables that drive the system out of equilibrium. Glass formers appear to live at, or close to, first-order coexistence between two distinct dynamical phases: an active and equilibrium phase, and an inactive and non-equilibrium one. This space-time coexistence helps explain observed fluctuation effects such as dynamic heterogeneity and transport decoupling. The connection of the glass transition to a true order-disorder dynamical transition offers the possibility of a unified picture of glassy phenomena.

Thursday, March 24, 2011 11:15AM - 2:15PM –
Session W5 FIAP FEd: Educating Physicists for Industrial Careers Ballroom C1

11:15AM W5.00001 SPIN-UP and Preparing Undergraduate Physics Majors for Careers in Industry[1] , RUTH HOWES, Ball State University — Seven years ago, the Strategic Programs for Innovations in Undergraduate Physics (SPIN-UP) Report produced by the National Task Force on Undergraduate Physics identified several key characteristics of thriving undergraduate physics departments including steps these departments had taken to prepare students better for careers in industry. Today statistical data from AIP shows that almost 40% of students graduating with a degree in physics seek employment as soon as they graduate. Successful undergraduate physics programs have taken steps to adapt their rigorous physics programs to ensure that graduating seniors have the skills they need to enter the industrial workplace as well as to go on to graduate school in physics. Typical strategies noted during a series of SPIN-UP workshops funded by a grant from NSF to APS, AAPT, and AIP include flexible curricula, early introduction of undergraduates to research techniques, revised laboratory experiences that provide students with skills they need to move directly into jobs, and increased emphasis on "soft" skills such as communication and team work. Despite significant success, undergraduate programs face continuing challenges in preparing students to work in industry, most significantly the fact that there is no job called "physicist" at the undergraduate level.

[1]supported by grant NSF DUE-0741560

11:51AM W5.00002 From Grad School to the Glass Industry: One Perspective , PAUL MEDWICK, PPG Industries, Inc. — This presentation will reflect one physicist's thoughts regarding a research and development career in the glass industry.

12:27PM W5.00003 Applying Physics: Opportunities in Semiconductor Technology Companies , GREG REDINBO, Varian Semiconductor — While many physicists practice in university settings, physics skills can also be applied outside the traditional academic track. Identifying these opportunities requires a clear understanding of how your physics training can be used in an industrial setting, understanding what challenges technology companies face, and identifying how your problem solving skills can be broadly applied in technology companies. In this talk I will highlight the common features of such companies, discuss what specific skills are useful for an industrial physicist, and explain roles (possibly unfamiliar) that may be available to you.

1:03PM W5.00004 How a Physicist Can Add Value In the Oil and Gas Industry , MARTIN POITZSCH, Schlumberger-Doll Research — The talk will focus on some specific examples of innovative and fit-for-purpose physics applied to solve real-world oil and gas exploration and production problems. In addition, links will be made to some of the skills and areas of practical experience acquired in physics education and research that can prove invaluable for success in such an industrial setting with a rather distinct and unique culture and a highly-collaborative working style. The oil and gas industry is one of the largest and most geographically and organizationally diverse areas of business activity on earth; and as a 'mature industry,' it is also characterized by a bewildering mix of technologies dating from the 19th century to the 21st. Oil well construction represents one of the largest volume markets for steel tubulars, Portland cement, and high-quality sand. On the other hand, 3D seismic data processing, shaped-charge perforating, and nuclear well logging have consistently driven forward the state of the art in their respective areas of applied science, as much or more so than defense or other industries. Moreover, a surprising number of physicists have made their careers in the oil industry. To be successful at introducing new technology requires understanding which problems most need to be solved. The most exotic or improbable technologies can take off in this industry if they honestly offer the best solution to a real problem that is costing millions of dollars in risk or inefficiency. On the other hand, any cheaper or simpler solution that performs as well would prevail, no matter how inelegant! The speaker started out in atomic spectroscopy (Harvard), post-doc'ed in laser cooling and trapping of ions for high-accuracy time and frequency metrology (NIST), and then jumped directly into Drilling Engineering with Schlumberger Corp. in Houston. Since then, his career has moved through applied electromagnetics, geological imaging, nuclear magnetic resonance logging, some R and D portfolio management, and more recently, management of applied physics research for evaluating reservoir rocks and fluids and enhancing the productivity of reservoirs.

1:39PM W5.00005 Internet Courses for Career Path Redirections , DAVID ATTWOOD, University of California, Berkeley — The Internet provides a cost-efficient means to reach out to larger audiences, not only to graduate students soon to enter the work force, but also to practicing scientists and engineers who wish to update their own knowledge base and perhaps consider new career directions. In this presentation we describe experience with several graduate courses at the University of California, Berkeley, that were broadcast live over the internet and posted first as Google videos and later at www.youtube.com. Full graduate class lectures, typically 28 per class, together with all presentation materials available for download, plus homeworks (and solutions upon request) are found at www.coe.berkeley.edu/AST/srms and www.coe.berkeley.edu/AST/sxr2009. The video lectures are also available at www.youtube.com by clicking on "videos" and then searching "david attwood". Based on e-mail queries and personal feedback it is clear that the lectures are widely viewed, both as training lectures in industry and as classes at various universities worldwide.

Thursday, March 24, 2011 11:15AM - 2:15PM –

Session W6 DAMOP: Alkaline Earth Atoms and SU(N) Magnetism Ballroom C2

11:15AM W6.00001 Two-orbital SU(N) magnetism with ultracold alkaline-earth atoms , ALEXEY GORSHKOV, California Institute of Technology — Fermionic alkaline-earth atoms have unique properties that make them attractive candidates for the realization of atomic clocks and degenerate quantum gases. At the same time, they are attracting considerable theoretical attention in the context of quantum information processing. In this talk, we demonstrate that when such atoms are loaded in optical lattices, they can be used as quantum simulators of unique many-body phenomena. In particular, we show that the decoupling of the nuclear spin from the electronic angular momentum can be used to implement many-body systems with an unprecedented degree of symmetry, characterized by the SU(N) group with N as large as 10. Moreover, the interplay of the nuclear spin with the electronic degree of freedom provided by a stable optically excited state should enable the study of physics governed by the spin-orbital interaction. Such systems may provide valuable insights into the physics of strongly correlated transition-metal oxides, heavy-fermion materials and spin-liquid phases. [Reference: Nature Phys. 6, 289 (2010)]

11:51AM W6.00002 Double-degenerate Bose-Fermi mixture of strontium , FLORIAN SCHRECK, IQOQI, OEAW — We report on the attainment of a double-degenerate Bose-Fermi mixture of strontium. A sample of fermionic ^{87}Sr atoms is spin-polarized and sympathetically cooled by interisotope collisions with the bosonic isotope ^{84}Sr. A degeneracy with $T/T_F = 0.30(5)$ is reached for a ^{87}Sr Fermi sea of 2×10^4 atoms together with an almost pure ^{84}Sr BEC of 10^5 atoms. The rich electronic structure and the large nuclear spin of ^{87}Sr make it a promising candidate for quantum simulation of SU(N) magnetism and quantum information processing.

12:27PM W6.00003 Degenerate Fermi Gas of Strontium-87[1] , THOMAS KILLIAN, Rice University — Degenerate Fermi gases of alkaline earth metal atoms such as strontium and ytterbium open new possibilities in the study of many-body physics because of the existence of isotopes with large nuclear spin I (e.g. I=9/2 in strontium-87). With the closed-shell electronic ground state in these atoms, the nuclear spin is decoupled from other degrees of freedom. Interactions between atoms are spin-independent, leading to a large SU(N=2I+1) symmetry of the Hamiltonian. This results in a large degeneracy of the ground state, which has been predicted to result in novel spin liquid and valence bond states. Strong attractive interactions would favor formation of N-particle singlets, in analogy to the formation of baryons in quantum chromodynamics. (For a short overview, see C. Wu, *Physics* **3**, 92 (2010).) We will describe the experimental realization of a degenerate Fermi gas of strontium-87 and characterization of an optical Feshbach resonance in this system that would be needed to manipulate the atom-atom interactions.

[1]This work was supported by the National Science Foundation and the Welch Foundation

1:03PM W6.00004 Realization of an SU(6) invariant Fermi system , YOSHIRO TAKAHASHI, Kyoto University — We report the realization of a novel Fermi system with an enlarged spin symmetry of SU(6) in a cold atomic gas of ytterbium ^{173}Yb with nuclear spin I=5/2, which will open up a new opportunity for exotic many-body physics . While the achievement of quantum degeneracy of ^{173}Yb with 6 spin components was already reported three years ago, an important technique of the separate imaging of the nuclear spin components was not developed. Recently we have made this possible by exploiting an optical Stern-Gerlach effect using a spatially inhomogeneous laser beam. The metallic state to Mott insulator transition for SU(6) Fermi gas is also investigated by loading ^{173}Yb atoms into a 3D optical lattice. We find some results suggesting the formation of SU(6) Mott state at low lattice temperatures expected for SU(N) systems. The similar adiabatic cooling effect is also observed in the Bose-Fermi mixture of spinless boson of ^{174}Yb and the SU(6) Fermi system of ^{173}Yb. In addition, an all-optical sympathetic evaporative cooling method is applied to the two fermionic isotopes of ytterbium ^{171}Yb with the nuclear spin I=1/2 and ^{173}Yb, and we successfully cool the mixture below the Fermi temperatures. The same scattering lengths for different spin components make this mixture featured with the novel SU(2) x SU(6) symmetry. The mixture is loaded into a 3D optical lattice to implement the SU(2) x SU(6) Hubbard model. In particular, we find interaction-induced suppression of Bloch oscillations for the mixture in the 3D lattice.

1:39PM W6.00005 Exotic magnetism and new states of matter with alkaline earth atoms[1] , MICHAEL HERMELE, Department of Physics, University of Colorado at Boulder — A crucial basic property of antiferromagnetic insulators with SU(2) symmetry is that adjacent spins can (and tend to) combine to form singlets, or valence bonds. The classical analog of this fact is that adjacent spins prefer to be antiparallel. These two facts underly much of our thinking about ground states of quantum antiferromagnets. Ultracold alkaline earth atoms can be used to realize magnetic insulators with SU(N) symmetry, where a minimum of N spins is required to form a singlet, and where N can be as large as 10. These systems belong to a largely unexplored class of quantum magnets. In this talk, I will discuss some of the remarkable new states of matter that are strong candidates to arise in these systems, including chiral spin liquids with fractional and non-Abelian statistics. I will also briefly discuss the issue of temperature, and point out an advantage of high-spin alkaline earths as compared to spin-1/2 magnetic systems.

Session W8 GMAG DAMOP: Bose-Einstein Condensation of Magnons and Related Phenomena

Ballroom C4

11:15AM W8.00001 Spin Dimers: from BEC to Luttinger liquids[1] , THIERRY GIAMARCHI, University of Geneva — Localized spin systems, and in particular dimer systems, provide a fantastic laboratory to study the interplay between quantum effects and the interaction between excitations. Magnetic field and temperature allow an excellent control on the density of excitations and various very efficient probes such as neutrons and NMR are available. They can thus be used as "quantum simulators" to tackle with great success questions that one would normally search in itinerant interacting quantum systems. In particular they have provided excellent realizations of Bose-Einstein condensates [1,2]. This allowed not only to probe the properties of interacting bosons in a variety of dimensions but also to study in a controlled way additional effects such as disorder. If the dimensionality is reduced they also allow to test in a quantitative way Luttinger liquid physics [3,4,5]. I will discuss these various cases, and show that we have now good theoretical tools [6] to make quantitative comparisons with the experiments. Finally, how to go from this low dimensional case where the spins behave essentially as fermions, to the higher dimensional case where they behave as (essentially free) bosons, is a very challenging, and experimentally relevant issue.

11:51AM W8.00002 Luttinger–liquid and BEC physics in spin ladders[1] , CHRISTIAN RUEGG, Paul Scherrer Institute — Spin ladder materials serve as model systems in which the fundamental phases, exotic order, and elementary excitations of low-dimensional quantum magnets can be studied experimentally and compared quantitatively to predictions by theory. We have utilised the optimal energy scale of the exchange interactions and excellent low dimensionality of the metal–organic spin ladder material $(C_5H_{12}N)_2CuBr_4$ to study spin Luttinger–liquid (LL) and magnon Bose–Einstein Condensate (BEC) physics realized at low temperatures and in high magnetic fields in this magnetic insulator. Furthermore, the inherent chemical flexibility and the structural tunability of such metal–organic compounds enable studies of the effects of bond randomness and of non–magnetic and magnetic dopants on the spin LL and magnon BEC. Bose glass phases form and the localized impurities dominate the physics near the intrinsic quantum critical points of the ladder. Measurements of the elementary excitations, phase diagrams, and thermodynamic and magnetic properties of the LL and BEC have also been extended recently to $BiCu_2PO_6$ in which these phenomena are combined intriguingly with frustration of the magnetic exchange interactions.

12:27PM W8.00003 Bose-Einstein Condensation and Asymmetry induced by Quantum Fluctuations in $NiCl_2$-4SC$(NH_2)_2$[1] , VIVIEN ZAPF, National High Magnetic Field Lab, Los Alamos National Lab — I will review Bose-Einstein condensation (BEC) in quantum magnets, in particular the compound $NiCl_2$-4SC$(NH_2)_2$. This compound exhibits field-induced XY antiferromagnetism of the S = 1 Ni system for magnetic fields along the tetragonal c-axis between H_{c1} = 2.1 and H_{c2} = 12.6 T, and the axial symmetry of the spin environment allows us to understand the quantum phase transitions at H_{c1} and H_{c2} in terms of BEC of the spin system. Here the tuning parameter for the BEC transition is the magnetic field and not the temperature. It turns out that mass of the bosons that condense can be strongly suppressed by quantum fluctuations, resulting in a remarkable asymmetry between the properties at H_{c1} and H_{c2}. Here I will present magnetization, thermal conductivity and specific heat data to probe BEC and in particular the effect of quantum fluctuations on the boson mass.

1:03PM W8.00004 Spin Superfluidity and Magnone BEC in He-3[1] , YURY BUNKOV, Institut Neel, Grenoble — The spin superfluidity – superfluidity in the magnetic subsystem of a condensed matter – is manifested as the spontaneous phase-coherent precession of spins first discovered in 1984 in ^{3}He-B. This superfluid current of spins – spin supercurrent – is one more representative of superfluid currents known or discussed in other systems, such as the superfluid current of mass and atoms in superfluid ^{4}He; superfluid current of electric charge in superconductors; superfluid current of hypercharge in Standard Model of particle physics; superfluid baryonic current and current of chiral charge in quark matter; etc. Spin superfluidity can be described in terms of the Bose condensation of spin waves – magnons. We discuss different states of magnon superfluidity with different types of spin-orbit coupling: in bulk ^{3}He-B; magnetically traped "Q-balls" at very low temperatures; in ^{3}He-A and ^{3}He-B immerged in deformed aerogel; etc. Some effects in normal ^{3}He can also be treated as a magnetic BEC of fermi liquid. A very similar phenomena can be observed also in a magnetic systems with dinamical frequensy shift, like $MnC0_3$. We will discuss the main experimental signatures of magnons superfluidity: (i) spin supercurrent, which transports the magnetization on a macroscopic distance more than 1 cm long; (ii) spin current Josephson effect which shows interference between two condensates; (iii) spin current vortex – a topological defect which is an analog of a quantized vortex in superfluids, of an Abrikosov vortex in superconductors, and cosmic strings in relativistic theories; (iv) Goldstone modes related to the broken $U(1)$ symmetry – phonons in the spin-superfluid magnon gas; etc. For recent review see Yu. M. Bunkov and G. E. Volovik J. Phys. Cond. Matter. **22**, 164210 (2010)

Thursday, March 24, 2011 11:15AM - 2:15PM –
Session W9 DFD: Self Assembly II followed by Vesicles and Micelles II D220

11:15AM W9.00001 Self-assembly of two-dimensional systems with off-center core-corona architecture , DANIEL SALGADO, CARLOS MENDOZA, Instituto de Investigaciones en Materiales, UNAM — Physical systems with core-corona architecture, such as dendritic polymers or hyper-branched star polymers which are characterized by two repulsive length scales, related to the hard and soft repulsions, respectively, show the spontaneous formation of stripe phases. Here we study, by using Monte Carlo simulations, how robust is the stripe formation process upon a shift in the center of the core with respect to the corona in a two-dimensional system of colloidal particles. We find that for sufficiently large shifts, the strip phases are replaced by a sort of plastic (or glassy) colloidal crystal consisting of a regular lattice of coronas inside of which disordered aggregates of cores coexist. The model investigated in this work could be useful for the design of colloidal plastic crystals.

11:27AM W9.00002 Limit of validity of Ostwald's rule of stages in a model of solution crystallization[1] , LESTER HEDGES, STEPHEN WHITELAM, Molecular Foundry, Lawrence Berkeley National Laboratory — Many systems take "nonclassical" crystallization pathways, forming ordered solids via intermediates that do not share the architecture of the stable material. We possess only rules-of-thumb to explain such dynamics. Chief among them is Ostwald's rule of stages, which states that the phase that first emerges is the one closest in free energy to the parent phase. Although widely applicable, the rule breaks down in many experiments and computer simulations. It is therefore clear that the rule is without firm theoretical foundation, but it is not clear when it should apply. To this end we test Ostwald's rule of stages in a lattice model of solution crystallization. We find that rule holds in certain regions of parameter space and breaks down in others. We argue that its breakdown can be predicted using simple arguments. In addition, we find that crystallization pathways depend qualitatively on both the thermodynamic landscape prescribed by inter-particle interactions and on the relative rates of particle rotations and translations.

[1]Supported by the Center for Nanoscale Control of Geologic CO2, a U.S. D.O.E. Energy Frontier Research Center, Contract No. DE-AC02-05CH11231.

11:39AM W9.00003 Mesophase behavior and rheology of polyhedral particles[1] , UMANG AGARWAL, FERNANDO ESCOBEDO, School of Chemical and Biomolecular Engineering, Cornell University — Translational and orientational excluded volume fields can guide assembly of particles with anisotropic shape to diverse morphologies. A roadmap elucidating correlations between phase behavior and particle shape may help devising efficient strategies for self-assembly of desired nanocrystal superlattices. To explore these complex correlations we performed detailed Monte Carlo simulations of six convex multi-faceted shapes belonging to the diverse class of space-filling polyhedrons. Simulations predict formation of various novel liquid-crystalline and plastic-crystalline phases at intermediate volume fractions. By correlating these findings with particle anisotropy and order of rotational symmetry, simple guidelines for predicting phase behavior of polyhedral particles are proposed. Moreover, detailed analysis of the structures of mesophases reveals importance of dynamical order in defining these phases and preliminary information about kinetics of these transitions is also obtained. Finally, to elucidate the effect of particle shape anisotropy on rheology, preliminary results will be reported from non equilibrium molecular dynamics simulations of the isotropic and cubatic(LC) phase of cuboidal particles.

11:51AM W9.00004 Triblock Janus Spheres , QIAN CHEN, SUNG CHUL BAE, STEVE GRANICK, University of Illinois at Urbana Champaign — We show that spheres that attract one another on two polar regions but repel at the middle band ("triblock Janus") assemble into nontrivial reticulated networks. We have constructed such spheres and have visualized their aqueous assembly dynamics on the single-particle level. The building blocks are simple micron-sized colloidal spheres whose interactions (electrostatic repulsion in the middle, hydrophobic attraction at the poles) are likewise simple, but their self-assembly into this open structure contrasts with previously-known close-packed periodic arrangements of spheres. This strategy of "convergent" self-assembly from facilely fabricated colloidal building blocks encodes the target supracolloidal architecture not in localized attractive spots but rather in large redundantly attractive regions of the building blocks. The idea extends to designing other supracolloidal networks.

12:03PM W9.00005 Novel structure formation of dipolar Janus particles (JP) in electrolytes: A molecular dynamic (MD) simulation study , MAHDY MALEKZADEH, BAMIN KHOMAMI, Materials Research and Innovative Laboratory (MRAIL), Department of Chemical and Biomolecular Engineering, University of Tennessee, Knoxville — There have been tremendous number of experimental studies and number of simulations in recent years trying to elucidate the underlying principals which determine structure formation of colloidal systems of JP. However most of simulations utilize relatively simple models and lack inclusion of long range columbic interactions. In this work MD simulations have been performed to understand effects of surface charge density and volume fraction (0.01-0.17) on structure formation and radial pair distribution function (RDF) of JPs of 6 nm in diameter with opposite charges on each hemisphere. Inclusion of long range columbic interaction via Ewald summation leads to formation of novel structures such as rings, chains and layered large spheres (about hundreds of nanometers) in accord to experimental observations. Moreover based on possibility of defect formation during synthesis, defects were introduced into each JP by slightly altering the uniform charge distribution on each hemisphere. Our results show in presence of small amount of defects ($<$10%) no significant changes occur in RDF, however increasing defect sites up to around 20% will significantly changes structure formation and combination of aforementioned structures concur to SFM and SEM images.

12:15PM W9.00006 Glassy Dynamics in the Rotator Phase of Two-Dimensional Janus Crystals , JING YAN, SHAN JIANG, JONATHAN WHITMER, STEPHEN ANTHONY, ERIK LUIJTEN, Department of Materials Science and Engineering and Department of Engineering Sciences and Applied Mathematics, Northwestern University, STEVE GRANICK, Departments of Materials Science and Engineering, Physics, and Chemistry — Janus particles, spheres with two different sides, represent the simplest building blocks whose interparticle interaction is orientation dependent. When confined on regular lattices, they epitomize basic physical problems from the arrangement of spins in magnetic materials, to rotating molecules in plastic crystals. Here we study both in experiment and in simulation, the heterogeneous dynamics in a two-dimensional crystal of amphiphilic Janus spheres. Single particle tracking reveals that orientation along can generate phenomenology resembling conventional translational supecooled liquids and glasses. Characteristic cage break events, which requires anti- correlated rotation of particles sitting on neighboring lattices, were indentified and characterized in detail. Recent experiments aiming at selectively perturbing the system using external field, such as magnetic field, will also be discussed.

12:27PM W9.00007 Chiral Control of Interfacial Tension , MARK ZAKHARY, THOMAS GIBAUD, EDWARD BARRY, ROBERT MEYER, ZVONIMIR DOGIC, Brandeis University — The interfacial tension between molecular species in self-assembling systems plays a crucial role in determining the physical properties of the mesoscopic assemblages. The predominant method for controlling interfacial tension is the addition of surfactant molecules, which preferentially adsorb onto the interface and modify the interactions between the two phases. In this talk, using a model colloidal membrane composed of chiral, rod-like *fd* viruses, I will present a new method for controlling interfacial tension which does not require additional surfactant components, but instead utilizes the intrinsic chirality of the constituent rods. I will demonstrate that chirality can be used to continuously tune the interfacial tension of a membrane and to drive a dramatic phase transition from two-dimensional membranes to one-dimensional twisted ribbons. Using a wide variety of microscopic techniques, this transition is characterized over all relevant length-scales, ranging from nanometers to microns.

12:39PM W9.00008 ABSTRACT WITHDRAWN –

12:51PM W9.00009 Dynamics of a compound vesicle in shear flow , SHRAVAN VEERAPANENI, NYU, YUAN-NAN YOUNG, NJIT, PETIA VLAHOVSKA, Brown University, JERZY BLAWZDZIEWICZ, Texas Tech University — The dynamics of compound vesicle (a lipid bilayer membrane enclosing a fluid with a suspended particle) in shear flow is investigated using both numerical simulations and theoretical analysis. We find that the non-linear coupling (via hydrodynamic interaction) between the inclusion motion and the confining membrane deformation gives rise to new features in the vesicle dynamics. Transition from tank–treading to tumbling can occur even in the absence of any viscosity mismatch. An initially non-concentric inclusion induces transient vesicle waltzing. A swinging-like vesicle motion is observed if the enclosed particle is an ellipsoid. The rheology of a suspension of compound vesicles is also strongly affected by the inclusion confinement. Our results highlight the complex effects of internal cellular structures on cell dynamics in external flow.

1:03PM W9.00010 Exploring Structure, Shape, and Dynamics of Elastin-like Polypeptide Nanoparticles , KIRIL A. STRELETZKY, Cleveland State University, KAITLIN VANDEMARK, ALI GHOORCHIAN, NOLAN HOLLAND, Cleveland State University — Environmentally responsive nanoparticles synthesized from elastin-like polypeptides (ELP) present a promising system for applications as biosensors, drug delivery vehicles, and viscosity modifiers. These nanoparticles undergo a transition from a soluble state at room temperature to micellar aggregates above the transition. The size, shape, and dynamics of micelles above the transition as well as effects of the solvent salt concentration and pH on the transition are important to understand from a fundamental science point of view as well as for potential applications. The system has been characterized with high resolution multiangle Dynamic and Static Light Scattering Spectroscopies. It was confirmed that the system undergoes a transition from mixture of ELP extended trimers and their non-spherical formations to a solution of micelles. It was discovered that micellar size and structure are very sensitive to solution's pH. The micelles were generally found to exhibit properties of the hyperbranched spheres below pH of 10 and above pH of 10.3 with their shape becoming significantly elongated in the pH window of 10 to 10.3. It was also found that the size of micelles strongly depends on salt concentration displaying at least two size regimes (20-45nm at 0-20mM and 100-150nm at 25-40mM) with different salt concentration dependences.

1:15PM W9.00011 The Lipid domain Phase diagram in a Dipalmitoyl-PC/Docosahaexnoic Acid-PE/Cholesterol System[1] , CHAI LOR, LINDA HIRST[2], University of California, Merced — Lipid domains in bilayer membrane and polyunsaturated fatty acids (PUFAs) are thought to play an important role in cellular activities. In particular, lipids containing docosahaexnoic acid are an interesting class of PUFAs due to their health benefits. In this project, we perform oxidation measurements of DHA-PE to determine the rate of oxidation in combination with antioxidants. A ternary diagram of DPPC/DHA-PE/cholesterol is mapped out to identify phase separation phenomena using atomic force microscope (AFM). Fluorescence microscopy is also used to image lipid domains in a flat bilayer with fluorescent labels. As expected, we observe the phase, shape, and size of lipid domains changes with varying composition. Moreover, we find that the roughness of the domains changes possibly due to overpacking of cholesterol in domains. This model study provides further understanding of the role of cholesterol in the bilayer membrane leading towards a better understanding of cell membranes.

[2]Ph.D

1:27PM W9.00012 Interfacial Microrheology with a Magnetic Needle Viscometer and Two-Particle Correlated Motion , JAMES SEBEL, KENNETH W. DESMOND, ERIC R. WEEKS, Emory University — We measure the viscoelastic moduli of thin films using two different methods. First, we use a magnetic needle viscometer. Our apparatus employs Helmholtz coils to control the position and orientation of the needle in the film. By driving the needle we can produce a response in the film which allows us to probe the bulk viscoelastic properties of the film. Second, we use two particle microrheology to probe the local properties of the film. Tracking the correlated motion between two particles as they undergo Brownian motion probes the local viscoelastic properties of any heterogeneous domains. Examining the correlations between pairs of particles with large separations helps us infer information about the bulk properties. Coupling this technique with the magnetic needle viscometer provides information on the effect local viscoelastic properties have on the bulk properties.

1:39PM W9.00013 Ion-Specific Induced Charges at Aqueous Soft Interfaces[1] , WENJIE WANG, ALEX TRAVESSET, DAVID VAKNIN, Ames Laboratory, and Department of Physics, Iowa State University, Ames, Iowa 50011 — Surface-sensitive X-ray scattering and spectroscopic techniques are employed to monitor ion binding specifically to Langmuir monolayers of densely packed carboxyl or phosphate groups. By systematically varying pH of Fe^{3+}, Fe^{2+} and La^{3+} solutions, we show that the critical surface pressure at the tilted (L2) to untilted (LS) transition is ionic specific and pH dependent. While the maximum density of surface bound La^{3+} per carboxylic group is ~ 0.3, the amount necessary to neutralize the fully charged surface, for Fe^{3+} it is nearly 0.6. Furthermore, the binding of Fe^{3+} is accompanied with a significant accumulation of Cl^- co-ions implying interfacial charge inversion. Similar experiments with charged phosphate groups at the interface show that the bindings of Fe^{2+} and La^{3+} are electrostatically driven. Our results have implications on biomineralization processes and ionic functions at cell membranes.

1:51PM W9.00014 Structural characterization of a multiple stacked supported bilayer system , CURT DECARO, JUSTIN BERRY, LAURENCE LURIO, Northern Illinois University, YICONG MA, GANG CHEN, SUNIL SINHA, University of California San Diego, LOBAT TAYEBI, ATUL PARIKH, University of California Davis — Supported Lipid Bilayers are a popular model system for cell membranes since their defined orientation allow characterization with probes such as AFM, x-ray and neutron scattering. A significant concern, however, is that strong interactions with the substrate can suppress dynamics within the bilayer. One method that has been successful at overcoming this limitation is to cushion the supported bilayer on a softer material. In the present work, we have stacked up to five successive bilayers of DPPE on top of each other, in effect using the lower bilayers as cushions. X-ray reflectivity shows that each stack preserves the orientation of the first, and that each bilayer exhibits full coverage of the one below. The roughness of each bilayer is found to increases with distance from the substrate as would be expected if thermal fluctuations are increasing with distance from the substrate. We also find that upon heating from the gel to the fluid state that an unbinding transition is observed.

2:03PM W9.00015 Shape and Size of highly concentrated micelles in CTAB/NaSal solutions by small angle neutron scattering (SANS) , HU CAO, HELMULT KAISER, NARAYAN DAS, PAUL SOKOL, Center for the Exploration of Energy and Matter, Indiana University, Bloomington, IN 47408, JOSEPH GLADDEN, Dept. of Physics and Astronomy, University of Mississippi, University, MS 38677 — Highly concentrated micelles CTAB/NaSal with a fixed salt/surfactant ratio of 0.6 have been studied by small angle neutron scattering (SANS) as a function of temperature and concentrations. A modeling analysis with a combination of ellipsoid, Gaussian size distribution and Hard Sphere Model (HSM) on SANS data suggests that these micelle solutions have an ellipsoidal structure, which is independent on the concentrations and temperature. However, the micelle size decreases monotonically as increasing the temperature or concentration. Besides, it was found that the number density of particles increases as increasing the temperature, while the total volume keeps unchanged. These observations indicate that large micelles at low temperature begin to break to form small ones as increasing the temperature and these broken surfactant molecules aggregate again under the effect of strongly binding counterions to form more micelles.

Session W10 DCMP: Adsorption, Wetting, and Complex Interfaces D221

11:15AM W10.00001 Surface Tension Anisotropy of Lennard-Jones Systems , EMRE ESENTURK, University of Pittsburgh — Anisotropy in the surface tension plays a significant role in the evolution of interfaces and in determining the equilibrium shapes of materials (dendritic growth, motion of grain boundaries). We present a discrete version of integral Phase Field Model with non-local potential for the crystal-melt interfaces of Lennard-Jones Systems. The model provides a methodology to understand the process of transfer of microscopic anisotropy to macroscopic scale. We calculate the surface tension and the anisotropy of the crystal-melt interface in the [100] and [110] directions and compare our results with recent simulations.

11:27AM W10.00002 Adsorption of Methane and Propane on a LJ Wall and on Molybdenum Surface: A Simulation Study , ALI ABU NADA, Southern Illinois University at Carbondale, GARY LEUTY, MESFIN TSIGE, University of Akron — Atomic-scale MD simulations were used to study multilayer adsorption as a function of temperature for two different alkanes (CH_4 and C_3H_8) on a fixed Lennard-Jones wall and on the (001) surface of molybdenum. In sets of simulations on the molybdenum surface, the substrate atoms were made to interact via a Lennard-Jones potential in one study and via an embedded-atom model (EAM) potential in the next. The results show that CH_4 and C_3H_8 on the flat wall possess a highly ordered packing arrangement exhibiting a higher degree of order than films adsorbed on the molybdenum substrate. Additionally, the number of ordered layers seen in the case of adsorption of CH_4 was noted to be greater than the number of ordered layers in the case of adsorption of C_3H_8. In each case, the first layer appears frozen, implying there is no translational motion for the molecules in this layer, and we can confidently surmise that the first adsorbed layer exists in the solid phase far above the bulk melting temperature.

11:39AM W10.00003 Evaporation kinetics of CO_2 laser heated fused silica[1] , SELIM ELHADJ, M.J. MATTHEWS, S.T. YANG, D. COOKE, J.S. STOLKEN, M.D. FEIT, LLNL — Laser-based machining strategies of optical surfaces remain mostly empirical, yet, systematic and controlled studies that relate gas chemistry and surface temperature to evaporation kinetics are limited, especially at extreme temperatures (>2800K) reached during laser irradiation. We present experimental results of CO_2 laser heating of silica in oxidizing and non-oxidizing environments, along with analysis of surface shape from which a near-equilibrium evaporation model is derived. Based on this model, temperature dependent enthalpies of evaporation are determined and compared to published results. This model reproduces experimental laser-etch rates, while still accounting for laser, mass transport, and gas chemistry parameters. Although heat and mass transport processes are complex and tightly coupled, general conditions for which such an approach can be used to guide laser-based evaporation will be presented.

11:51AM W10.00004 ABSTRACT WITHDRAWN –

12:03PM W10.00005 Simulation study on structure of water in aqueous solutions confined between graphene electrodes under very high applied electric field[1] , GARY LEUTY, MESFIN TSIGE, The University of Akron, SAIKAT TALAPATRA, Southern Illinois University at Carbondale — Arising from questions regarding electric double-layer capacitors utilizing graphene electrodes and aqueous electrolyte (KOH solution), atomistic MD simulations of electrolyte confined between graphene electrodes were performed to understand the behavior of electrolyte as a function of electric field strength and solution concentration, from pure water to 6M KOH. It was noted that the strength of the electric field had a demonstrable effect on the structure of pure water between the electrodes (as has previously been seen in highly confined multilayer water systems), creating regularly spaced channels and densely packed sheets of highly ordered molecules. We also saw a clear effect due to the presence of electrolyte ions and their separation from the water due to the action of the field; different field strengths appear to greatly alter the distribution of ions, which in turn affects the structure and ordering of the water. Time dependence in the strength of the electric field was also studied to determine what effect, if any, it has on induced structure.

12:15PM W10.00006 Thermodynamics and kinetics of wetting transition of an oily fluid on surfaces with nanoscale roughness: A molecular dynamics study , ELIZABETH SAVOY[1], FERNANDO ESCOBEDO, Cornell University — Surface wettability has garnered significant interest in recent years, as design and manufacture of nanoscale features allows fabrication of highly non-wetting surfaces. Such behavior is more difficult to achieve for low surface-tension fluids such as oils, and requires novel approaches. One approach is to create roughness features that provide an energy barrier to the fluid's transition from the composite to fully wetted state. We use molecular dynamics of small droplets in combination with various simulation techniques, such as umbrella sampling and forward flux sampling, to probe the energy landscape associated with the wetting transition and compute transition rates and their dependence on key topological parameters such as feature height. We find that the drop does not transition with a flat liquid-vapor interface when it penetrates and wets the subsurface features (as is often assumed in continuum treatments) and that the hysteresis in the wetting and dewetting transitions is associated with differences in the evolution of that interface.

12:27PM W10.00007 Understanding and designing of steam-phobic surfaces[1] , ILA BADGE, SUNNY SETHI, ALI DHINOJWALA, The University of Akron — The wetting behavior of a surface under steam condensation depends on its intrinsic wettability and micron or nanoscale surface roughness. A typical superhydrophobic surface may not be suitable as a steam-phobic surface due to nucleation and growth of water inside the valleys and thus, failure to form air-liquid- solid composite interface. Here, we present the results of steam condensation on chemically modified nano-structured carbon nanotube carpets. The combination of surface chemistry and surface roughness provides a mechanism to retain superhydrophobicity of the nanotube surfaces under steam condensation. Ability of withstand steam temperature and pressure also implies improved hydrostatic stability of the surface.

12:39PM W10.00008 Effects of host relaxation on gas uptake in porous media , MILTON COLE, Pennsylvania State University, ANNIE GROSMAN, University of Paris VI, SUSANA HERNANDEZ, University of Buenos Aires, ANGELA LUEKING, Penn State University — We have recently predicted [1] an *imbibition transition* as a prototype of a general phenomenon-substrate relaxation due to adsorption. That transition is exemplified by a graphene sheet's lifting off of a surface in order to intercalate gas. Other relevant phenomena include the expansion of nanotube bundles or MOFs to accommodate imbibed gases. In our new work, we first analyze the relaxation problem, in general, and then address infinite cylindrical and slit pore geometries, for which simplifications occur because there is just one finite dimension. Research supported by DOE.

12:51PM W10.00009 Surface metal-oxygen bond length on hydrated rutile(110) and cassiterite(110) surface - A measure of the local environment , NITIN KUMAR, Department of Physics, Penn State University, PAUL KENT, Center for Nanophase Materials Sciences and Chemical Sciences Division, Oak Ridge National Laboratory, ANDREI BANDURA, St. Petersburg State University, DAVID WESOLOWSKI, Chemical Sciences Division, Oak Ridge National Laboratory, JAMES KUBICKI, Department of Geosciences, Penn State University, JORGE SOFO, Department of Physics, Penn State University — We study the dynamics of water on the surface of rutile (110) and cassiterite (110) using ab-initio molecular dynamics simulation. The water molecule covalently attach with the fivefold coordinated metal atoms on the surface. It can remain in a molecular form or it can dissociate to form hydroxyls on the surface. The distance between the metal and the oxygen depends on the protonation state of the latter. Moreover, we find that the local environment is not only limited to the number of covalently bonded hydrogen but it also depends on number of hydrogen bonds and the species participating in it. In general, the metal oxygen distance shows much larger fluctuations in rutile compared with cassiterite. The half width half maximum (HWHM) of the metal oxygen distance histogram, for the terminal oxygen, is 0.27 Angstrom for rutile and 0.16 Angstrom for cassiterite. Also, for bridging oxygen HWHM is 0.18 and 0.12 Angstrom for rutile and cassiterite, respectively.

1:03PM W10.00010 Water-Thin-Film Adsorption on Alpha-Quartz (0001) Surface[1] , YUN-WEN CHEN, YAN WANG, HAI-PING CHENG, Department of Physics and Quantum Theory Project, University of Florida — We investigated thin water films adsorbed on quartz (0001) surfaces using first-principles density functional theory calculations. Interfacial structure and energetics were studied through a layer-by-layer deposition. From monolayer to multilayer, the low energy state configurations and adsorption sites show a transition due to formation of a highly stable bilayer membranelike structure. The water adsorption energy on a quartz surface coated by this membrane is of typical hydrogen bond strength for both dry and fully hydroxylated surfaces. The interactions between the surface and the water films are short-ranged due to shielding of the bilayer.

1:15PM W10.00011 Mn Adsorption on MgO/Ag(100): DFT and DFT+U Calculations , HOSSEIN HASHEMI, Martin-Luther-Universität Halle-Wittenberg, Friedemann-Bach-Platz 6, D-06099 Halle, Germany, BARBARA JONES, IBM Almaden Research Center, San Jose, CA 95120-6099, USA — The adsorption properties of a Mn adatom on MgO ultrathin films deposited on a Ag(100) substrate are determined from first principles DFT calculations and compared with the corresponding adsorption characteristics from DFT+U calculations. First, we investigate the properties of a pure Ag (100) surface and a MgO/Ag(100) system. The structural relaxation, work function and surface energy for the Ag(100) surface, as a function of thickness dependence, is discussed. Next, we discuss the addition of a Mn adatom. Regular (U=0) DFT calculations show that the most stable site for Mn adsorption on MgO/Ag(100) is the bridge site, followed closely by the Oxygen site, and a very unlikely position, the Mg site. We have also investigated the role of strong electron correlations in the substrate on the chemisorption properties of a Mn adatom. DFT+U calculations predict the Oxygen site to be the most stable site, instead of the bridge site, in contrast to U=0 DFT calculations. The energies, geometry, and magnetic properties of the Mn adatom are all influenced by adding a Coulomb energy. Altogether our results show that the on-site Coulomb repulsion in the Mn d band plays an important role in the description of adsorption on MgO/Ag(100).

1:27PM W10.00012 Stabilizing Graphitic Thin Films of Wurtzite Materials by Epitaxial Strain[1] , DANGXIN WU, FENG LIU, University of Utah — Recent theoretical and experimental work showed that (0001) ultrathin films of wurtzite materials transform into a stable graphite-like structure if their thickness is reduced to only a few atomic layers. Using first-principles calculations of both freestanding and substrate-supported thin films, we predict that the thickness range of stable graphitic films can be greatly extended by epitaxial tensile strain but reduced by compressive strain. The band gap of the resulting graphitic films can be tuned by strain and film thickness either above or below that of the bulk wurtzite phase. Our prediction suggests a plausible physical mechanism to be explored by future experiments for strain engineering of graphitic films from wurtzite materials with a wide range of potential applications.

1:39PM W10.00013 Simulating phase formation during exothermic reactions in Al/Ni and Al/Zr multilayered foils[1] , RONG-GUANG XU, Department of Physics and Astronomy, Johns Hopkins University, MICHAEL L. FALK, Department of Materials and Engineering, Department of Mechanical Engineering and Department of Physics and Astronomy, Johns Hopkins University, HONG-WEI SHENG, Department of Computational and Data Sciences, George Mason University, JOHNS HOPKINS UNIVERSITY TEAM, GEORGE MASON UNIVERSITY COLLABORATION — Reactive multilayered foils are composed of thousands of alternating micro- to nano- scale layers of elements which have a large negative enthalpy of mixing. When a small pulse of energy (such as an electric spark or a thermal pulse) is provided, highly exothermic, self-propagating chemical reactions can be triggered. Both theoretical models and experimental data indicate that even a relatively small amount of premixing can have a dramatic effect on the heats and velocities of the propagating reaction front. We have implemented molecular dynamics simulation to study the phase transformation sequence during multilayered reactions and to elucidate how premixing can affect the sequence of phase formation during such reactions.

1:51PM W10.00014 Chemical Reactivity at the Ti/CuO Interface[1] , A. CHOURASIA, J. EDMONDSON, Texas A&M Univ.-Commerce — The chemical reactivity between titanium and copper oxide at the Ti/CuO interface has been investigated using x-ray photoelectron spectroscopy. About 15 nm thick copper film was deposited on silicon substrates by the e-beam method. Such samples were oxidized in an oxygen environment in a quartz tube furnace at 400 °C. The formation of CuO was checked by the XPS spectral data. Thin films of titanium were then deposited on these CuO samples. The titanium 2p, oxygen 1s and copper 2p regions were investigated by XPS. The magnesium anode (energy = 1253.6 eV) has been used for this purpose. The spectral data show chemical reactivity at the Ti/CuO interface. The samples were annealed afterwards in air at 400 °C. The spectral data were recorded at different take-off angles. Comparison of the data with the pre-annealed samples shows diffusion of Cu through the titanium overlayer alongwith the formation of CuO.

2:03PM W10.00015 Composite TiO2-Carbon nano films with enhanced photocatalytic activity[1] , DINKO CHAKAROV, RAJA SELLAPPAN, Chalmers University of Technology — Composite TiO2-carbon thin films prepared by physical vapor deposition techniques on fused silica substrates show enhanced photocatalytic activity, as compared to pure TiO2 films of similar thickness, towards decomposition of methanol to CO2 and water. Raman and XRD measurements confirm that annealed TiO2 films exhibit anatase structure while the carbon layer becomes graphitic. Characteristic for the composite films is an enhanced optical absorption in the visible range. The presence of the carbon film causes a shift of the TiO2 absorption edge and modifies its grain size to be smaller. The observed enhancement is attributed to synergy effects at the carbon-TiO2 interface, resulting in smaller crystallite size and anisotropic charge carrier transport, which in turn reduces their recombination probability.

Session W11 FIAP: Electronic Structure: Thermodynamics and Optical Properties D222

11:15AM W11.00001 Comparison of Experimental and Theoretical Vibrational Spectra for Pentacene Derivatives , GREGORY MASLAK, MARK STEWART, LILLIE GHOBRIAL, WES LAURION, Dept. of Physics, SUNY Oswego, JINYUE JIANG, LI TAN, Dept. of Engineering Mechanics, UNL, CAROLINA C. ILIE, Dept. of Physics, SUNY Oswego — The practical use of pentacene in the area of organic field-effect transistors is limited by its sensitivity to oxygen and poor solubility in organic solvents. To overcome these disadvantages, new organic semiconductors as 2,3,9,10-tetrakis(3,5-di-t-butylphenylethynyl)-6,13- bis (trimethylsilylethynyl) pentacene are synthesized. The new pentacene derivatives may be useful for electronic devices such as organic field-effect transistors or organic light-emitting diodes. Here we compare the calculated vibrational spectra to the experimental data in order to characterize the new derivative. The methods and similarities between the theoretical calculations and the experimental data are discussed.

11:27AM W11.00002 Optical characterization of p-doped InP epitaxial layers in mid and far infrared region[1] , R.C. JAYASINGHE, Y.F. LAO, A.G.U. PERERA, Georgia State University, M. HAMMAR, Royal Institute of Technology, Kista, Sweden, C.F. CAO, Chinese Academy of Sciences, Shanghai, China, H. WU, Zhejiang University, Hangzhou, China — The optical properties of p-doped Indium Phosphide (InP) epitaxial thin films with 1, 3, and 24 $\times$ 10^{18} cm^{-3} carrier concentrations were investigated by infrared reflection, transmission, and absorption measurements in 5 - 40 μm wavelength range. The absorption spectra were modeled by complex dielectric function using the classical Lorentz–Drude model. The phonon absorption in InP was modeled using eight Lorentzian oscillators. This method gives a straightforward approach for modeling the experimental absorption spectra when compared to the two-phonon absorption spectroscopy technique. The calculated spectra are in a good agreement with experimental spectra. The effects of doping on fitting parameters are also investigated.

11:39AM W11.00003 Photoluminescence intensity oscillations with magnetic field in InGaAs quantum wells[1] , LARS SCHWEIDENBACK, ANDREAS RUSS, TARIQ ALI, JOSEPH MURPHY, ALEXANDER CARTWRIGHT, ATHOS PETROU, SUNY Buffalo, ALEXANDER GOVOROV, Ohio University, CONNIE LI, AUBREY HANBICKI, BEREND JONKER, Naval Research Laboratory, GEORGE KIOSEOGLOU, University of Crete — We have observed magnetic field oscillations in the photoluminescence (PL) intensity from InGaAs quantum wells (QWs) with indium compositions of 5% and 15% with laser excitation close to the bandgap for temperatures < 20 K. For all samples the intensity maxima occur at 2.2 and 4.5 tesla when the magnetic field is applied perpendicular to the QW plane. Experiments in which the sample normal (z-axis) is tilted with respect to the applied magnetic field B show that the PL intensity maxima positions depend on the magnetic field component B_z. Time-resolved PL comparison with GaAs QWs yields much longer recombination times for the InGaAs QWs. Furthermore, cross sectional scanning tunneling microscopy studies indicate the formation of Indium rich InGaAs clusters in the InGaAs QWs. We interpret the observed oscillations in terms of the Aharonov-Bohm effect and quasi-indirect excitons with ring-like trajectories of carriers. The oscillation period corresponds to orbits with radius equal to 24 nm.

[1]Work at SUNY was supported by ONR and NSF

11:51AM W11.00004 Optical two-dimensional Fourier transform spectroscopy of single GaAs quantum wells , YURI D. GLINKA, ZHENG SUN, XIAOQIN LI, Physics department, University of Texas-Austin, TX 78712 USA, ALLAN BRACKER, Naval Research Lab, Washington, DC 20375 USA — Optical two-dimensional Fourier transform spectroscopy is applied to study the coherent coupling between light-hole and heavy-hole excitons in single GaAs quantum wells instead of those consisted of ten or four periods of GaAs separated by $Al_{0.3}Ga_{0.7}As$ barriers measured previously. The effect of the confinement energy as well as Coulomb and disorder correlation lengths on coherent coupling dynamics is discussed. The financial support from ARO, NSF, and Welch foundation is gratefully acknowledged.

12:03PM W11.00005 Origin of the Terahertz Absorption Peak in Single-Walled Carbon Nanotubes , QI ZHANG, LEI REN, H. GOJUKI, E.H. HAROZ, T. ARIKAWA, J. KONO, ECE Dept., Rice University, C.L. PINT, R.H. HAUGE, Chemistry Dept., Rice University, A.K. WOJCIK, A.A. BELYANIN, Dept. of Physics, Texas A&M Univ., ECE DEPT., RICE UNIVERSITY TEAM, CHEMISTRY DEPT., RICE UNIVERSITY COLLABORATION, DEPT. OF PHYSICS, TEXAS A&M UNIV. COLLABORATION — Single-walled carbon nanotubes (SWNTs) are promising for high-frequency electronics and terahertz (THz) applications, as well as for fundamental studies of finite-frequency dynamics of one-dimensional electronics. Previous studies of dynamic conductivities of various types of SWNTs have revealed a pronounced and broad absorption peak around 4 THz, whose origin has been a matter of controversy. Both the effects of curvature-induced band gaps and plasmonic absorption due to finite lengths have been proposed to be important, but a consensus has not emerged. We have studied 4THz peak in highly aligned and length-controlled SWNT films and metallically-enriched SWNT films through FTIR and THz time-domain spectroscopy. We provide evidence that this peak is observable only when the THz polarization is parallel to the nanotubes and only in metallic tubes. We will discuss the origin of this absorption peak in light of these new findings.

12:15PM W11.00006 UV light emission from ZnO nanostructures in SiO_2 synthesized by ion implantation and thermal annealing , BIMAL PANDEY, AKHILESH SINGH, PRAKASH POUDEL, ARUP NEOGI, DUNCAN WEATHERS, University of North Texas — Zinc Oxide (ZnO) nanostructures were synthesized by the implantation of low energy (35 keV) ZnO molecular ions into thermally grown SiO_2 at a fluence of 5×10^{16} ions/cm^2. Implanted samples were annealed in an oxygen environment to allow the growth of ZnO precipitates. X-ray photoelectron spectroscopy (XPS), Fourier transform spectroscopy (FTIR) and energy dispersive x-ray spectroscopy (EDS), confirm the formation of ZnO. High resolution transmission electron microscopy (HRTEM) shows the formation of nanostructures having diameters ranging from 2 nm to 5 nm in the SiO_2. Photoluminescence (PL) measurements show excitonic and band-edge emission in the ultraviolet region at temperatures ranging from 4 K - 300 K. Time-resolved PL measurements performed at 4K showed an electron-hole recombination lifetime on the order of a few hundred picoseconds.

12:27PM W11.00007 Ab initio calculation of indirect light absorption by free carriers in transparent conducting oxides[1] , HARTWIN PEELAERS, EMMANOUIL KIOUPAKIS, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara, CA 93106-5050 — Phonon-assisted absorption of light by free carriers is an important optical process in many materials and a challenging problem for computational condensed-matter physics. As transparent conducting oxides play an important role as contacts to light emitters and photovoltaic devices, it is important to consider not only the optical absorption across the band gap, but also the absorption by free carriers due to indirect processes mediated by phonons and defects. Here we calculate these losses using a full ab initio methodology as opposed to a phenomenological Drude model containing empirical parameters. These calculations involve the electron-phonon coupling matrix elements, which are dominated by the longitudinal optical phonon modes. We also compare with the Fröhlich model, which describes the electron-phonon matrix elements in the long-wavelength limit.

[1]This work was supported by DOE, the UCSB SSLEC, and the BAEF.

12:39PM W11.00008 Optical absorption of light carrying orbital angular momentum by semiconductors: free-particle quantum kinetics , P.I. TAMBORENEA, G.F. QUINTEIRO, Departamento de Física and IFIBA, Universidad de Buenos Aires, Argentina — We develop a free-carrier theory of the optical absorption of light carrying orbital angular momentum (twisted light) by bulk and quasi-two-dimensional semiconductors. We obtain the optical transition matrix elements for Bessel-mode twisted light and use them to calculate the wave function of photo-excited electrons to first-order in the vector potential of the laser [1]. We then pose the problem of the quantum kinetics of interband transitions in terms of the Heisenberg equations of motion of the electron populations, and interband and intraband coherences [2]. We solve the equations of motion in the low-excitation regime, and obtain analytical expressions for the coherences and populations; with these, we calculate the orbital angular momentum transferred from the light to the electrons and the paramagnetic and diamagnetic electric current densities.

[1] G. F. Quinteiro and P. I. Tamborenea, EPL **85**, 47001 (2009).

12:51PM W11.00009 Optical harmonics generation in semiconductor quantum dots: A tunable terahertz source , YAN XIE, Beijing Computational Science Research Center, WEIDONG CHU, SUQING DUAN, WEI ZHANG, Institute of Applied Physics and Computational Mathematics — The high-order harmonic generation (HHG) study have been extended to semiconductor quantum dots (QDs) and coupled QDs (CQDs), the so-called "artificial atoms and molecules." One motivation of the study of the HHG in QDs is to find an efficient way of terahertz wave generation due to their controllable energy spectra and wave functions. With the help of Floquet theory, we show that the HHG in quantum dot structures can be changed from only odd orders to both odd and even orders by controlling the coupling parameters. The selection rules of the odd-even HHG in a noninversion-symmetric multilevel system are determined by the parity of emitted photon numbers during allowable virtual steps. On the other hand, by mapping the optical problem to a transport problem, we find that the terahertz generation efficiency is determined by the bandwidth of the quasienergy spectrum. Our studies are useful for engineering tunable terahertz sources based on semiconductor quantum dots.

1:03PM W11.00010 Ultrafast Quantum Control in Semiconductor Nanostructures using Twisted Light , GUILLERMO QUINTEIRO, PABLO TAMBORENEA, Univ de Buenos Aires, JAMAL BERAKDAR, Martin Luther Univ — We investigate possible uses of twisted light (TL) —or light carrying orbital angular momentum (OAM)— as a tool to control semiconductor-based nanostructures. Two systems are considered, namely quantum dots (QD) and quantum rings (QR). For both structures we employ a simplified two-band model in the effective-mass approximation, having a conduction and a heavy-hole valence bands. In the case of disk-shaped QDs, we predict that the TL would allow to induce optical transitions which are normally regarded to be forbidden. The OAM l and other parameters of the TL beam can be used to precisely control the final state of the electron. In the case of QRs, we study induced electric currents. We analyze the evolution of the system in terms of Heisenberg equations of motion. We find an analytical solution that resembles the standard Optical Bloch Equations. Using this solution, we find the evolution of the z-component of OAM and the electric current circulating the ring. Our results indicate that the electric current could be as large as μA, in the time-scale of pico-seconds. For an appropriate radius of the ring, the photo-induced magnetic field would be large enough to switch within picoseconds the magnetic moment of particles placed within the ring.

1:15PM W11.00011 Far-infrared absorption of PbSe nanorods , BYUNG-RYOOL HYUN, ADAM BARTNIK, Cornell University, WEON-KYU KOH, University of Pennsylvania, NIKOLAY AGLADZE, JUN YANG, AL SIEVERS, Cornell University, CHRISTOPHER MURRAY, University of Pennsylvania, FRANK WISE, Cornell University, OPTICS COLLABORATION, SYNTHESIS COLLABORATION, SPECTROSCOPY COLLABORATION — The far-infrared absorption spectra of PbSe nanodots and nanorods are measured as a function of aspect ratio, and show the expected splitting of the single Frohlich sphere mode in nanocrystals into two modes parallel and perpendicular to the nanorod axis. We analyze this splitting by modeling the dependence of the nanocrystal's local field factor on its shape. Excellent agreements is found with the features measured in experiment. We predict that this shape-dependent local field factor will cause a two-order of magnitude increase of the third-order susceptibility of long nanorods in the near-infrared.

1:27PM W11.00012 Bright spot pattern generation in GaAs/AlGaAs multiple quantum wells[1] , ANGELO MASCARENHAS, BRIAN FLUEGEL, National Renewable Energy Laboratory, D.W. SNOKE, Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, Pennsylvania 15260, USA — Exciton photoluminescence pattern generation is investigated in multiple quantum wells. High-contrast outer rings and localized bright spots are generated using efficient field-assisted upconversion of laser light whose photon energy lies below the energy of the luminescing quantum well transition. Time-resolved images of the bright spot reveal that the ring transients are driven by carrier diffusion both from the laser excitation spot as well as from the bright spot. These dynamics are not explained simply by two-dimensional rate equations for generation and diffusion. The behavior must be understood as a result of three-dimensional transport in the vertically extended samples.

1:39PM W11.00013 Nonlinear optical properties of polychlorotriphenylmethyl radicals: a computational study , CLAUDIA CARDOSO, BRUCE FORBES MILNE, FERNANDO NOGUEIRA, Centro de Física Computacional, Faculdade de Ciências e Tecnologia, Universidade de Coimbra — The special interest in molecular design for the development of novel second-order nonlinear optical (SONLO) materials is driven by their potential applications in new optoelectronic technologies. Various strategies are currently employed to enhance the molecular SONLO activity, and studies revealed that species having open-shell electronic states exhibit larger β values than analogous closed-shell systems. Their open-shell electronic structure leads to accessible low-lying charge transfer electronic states which enhance the β values with respect to their closed-shell counterparts. We present the results of a Density Functional Theory calculations of a series of substituted polychlorinated triphenylmethyl radicals. This family of radicals has been measured by Ratera et al using Hyper-Rayleigh Scattering and showed to have enhanced β values. The present study compares results obtained within LDA and several hybrid functionals, namely long-range corrected functionals. The effect of solvents was also considered through the use of the polarizable continuum model.

1:51PM W11.00014 Binding energies of indirect excitons in double quantum well systems , ALEX ROSSOKHATY, Russian Academy of Sciences, Chernogolovka, STEFAN SCHMULT, WERNER DIETSCHE, KLAUS VON KLITZING, Max-Planck-Institute for Solid State Research, Stuttgart, IGOR KUKUSHKIN, Russian Academy of Sciences, Chernogolovka — A prerequisite towards Bose-Einstein condensation is a cold and dense system of bosons. Indirect excitons in double GaAs/AlGaAs quantum wells (DQWs) are believed to be suitable candidates. Indirect excitons are formed in asymmetric DQW structures by mass filtering, a method which does not require external electric fields. The exciton density and the electron-hole balance can be tuned optically. Binding energies are measured by a resonant microwave absorption technique. Our results show that screening of the indirect excitons becomes already relevant at densities as low as $5{\times}10^9 \mathrm{cm}^{-2}$ and results in their destruction.

Session W12 FIAP: Electronic Transport in Novel Materials and Nanostructures D223/224

11:15AM W12.00001 ABSTRACT WITHDRAWN –

11:27AM W12.00002 Random Telegraph Noise in Silicon Nanowire BioFETs , NITIN RAJAN, Yale University, DAVID ROUTENBERG, Scripps Research Institute, JIN CHEN, Stanford University, MARK REED, Yale University — Noise spectroscopy is important for nanostructures because it represents a highly sensitive and non-destructive means of studying surface states/defects. In this study we characterize the low frequency noise of top-down fabricated silicon nanowire FETs with exposed channels at low temperature. For some devices, we observe a change in the noise spectra as temperature is lowered, from 1/f to Lorentzian. This indicates the presence of random telegraph signals (RTS) due to an interface trap which we confirm from the time-domain measurements. By making measurements at different temperatures, we can probe into the dynamic properties of the trap. In this way, the activation energies for the emission and capture of electrons are determined. The nature and position of the trap is deduced from the gate voltage dependence of the emission and capture time constants. We also observe an increase in the relative RTS noise amplitude as temperature is decreased and report on very large (>100%) relative noise amplitudes for measurements carried out at low temperature.

11:39AM W12.00003 Distinct microwave photoresistivity peak in a high-mobility quantum Hall system[1] , A.T. HATKE, M.A. ZUDOV, University of Minnesota, L.N. PFEIFFER, K.W. WEST, Princeton University — We report on a distinct resistivity peak in a microwave-irradiated high-mobility two-dimensional electron system at low temperatures. This peak appears in the regime of well separated Landau levels near the second harmonic of the cyclotron resonance and is in addition to microwave-induced resistance oscillations. This talk will focus on the generic characteristics of this peak, such as its dependence on microwave power and temperature.

[1]This work is supported by DOE DE-SC0002567 and NSF DMR-0548014.

11:51AM W12.00004 Theory of nonlinear transport in separated Landau levels of two-dimensional electron systems[1] , M. KHODAS, University of Iowa, H.-S. CHIANG, A.T. HATKE, M.A. ZUDOV, University of Minnesota, L.N. PFEIFFER, K.W. WEST, Princeton University — Recent experiments have shown that the differential magnetoresistivity of a high mobility two-dimensional electron system (2DES) is strongly suppressed under applied dc bias. This phenomenon is most pronounced when the Landau level width becomes smaller than the cyclotron energy. Using the quantum kinetics approach we calculate the characteristic current responsible for the suppression and compare the results to the experimental data obtained on a high mobility 2DES at low temperatures.

12:03PM W12.00005 ABSTRACT WITHDRAWN –

12:15PM W12.00006 ABSTRACT WITHDRAWN –

12:27PM W12.00007 Terahertz Spectroscopy of Semiconductor Materials and Nanostructures , WILLIAM BAUGHMAN, SHAWN DAVID WILBERT, LEE BUTLER, NICK HARRIS, GANG SHEN, NABIL DAWAHRE, JOSEPH BREWER, PATRICK KUNG, SEONGSIN MARGARET KIM, The University of Alabama — Terahertz (THz) time-domain spectroscopy is an attractive method to obtain the electronic transport properties in a variety of semiconductor materials and nanostructures. Unlike traditional techniques, THz spectroscopy does not require the realization of electrical contacts or even direct contact to the material probed. Here, we report the use of THz time-domain spectroscopy to determine the dielectric constant of a variety of semiconductor materials in the THz spectral range, and extract the refractive index, absorption coefficient and electrical conductivity. We also present a comparison of the results obtained from other techniques, including four-point probe resistivity measurements.

12:39PM W12.00008 Statistics of excitations in the electron glass model , MATTEO PALASSINI, University of Barcelona — We study the statistics of elementary excitations in the classical electron glass model of localized electrons interacting via the unscreened Coulomb interaction in the presence of disorder. We reconsider the long-standing puzzle of the exponential suppression of the single-particle density of states near the Fermi level, by measuring accurately the density of states of charged and electron-hole pair excitations via finite temperature Monte Carlo simulation and zero-temperature relaxation. We also investigate the statistics of large charge rearrangements after a perturbation of the system, which may shed some light on the slow relaxation and glassy phenomena recently observed in a variety of Anderson insulators. In collaboration with Martin Goethe.

12:51PM W12.00009 Kondo Effect in a mesoscopic system[1] , SEUNGJOO NAH, MICHAEL PUSTILNIK, Georgia Institute of Technology — At low temperatures, transport and thermodynamic properties of Coulomb blockade systems are characterized by the energy scale T_K (the Kondo temperature). We show that the Kondo temperature is subject to strong mesoscopic fluctuations. In a quantum dot system with many single-particle energy levels, the Kondo temperature acquires a log-normal distribution.

[1]This work was supported by the NSF (DMR-4106B23).

1:03PM W12.00010 Two-Dimensional Electrostatic Lattices for Excitons , MIKAS REMEIKA, LEONID BUTOV, University of California, San Diego — We report on a method for the realization of two-dimensional electrostatic lattices for excitons in quantum well structures. The lattice structure is set by an electrode pattern and the amplitude of the lattice potential is controlled by applied voltages. We demonstrate square, hexagonal, and honeycomb lattices created by this method.

1:15PM W12.00011 Non-Markovian effects in the quantum noise of interacting nanostructures , CLIVE EMARY, TU Berlin, DAVID MARCOS, RAMON AGUADO, ICMM, TOBIAS BRANDES, TU Berlin — We present a theory of finite-frequency noise in non-equilibrium conductors, and in particular, interacting nanostructures. We employ a quantum master equation approach and treat correlations between the system and the reservoirs in a nonMarkovian fashion. These correlations are pivotal in properly describing current fluctuations in situations where the measuring frequency is larger than both the applied voltage and the temperature. We explicitly show the importance of nonMarkovian effects in different contexts, including the finite-frequency current noise through a double quantum dot charge qubit and the short-time counting statistics of quantum dots.

1:27PM W12.00012 Nonlinear Insulator in Complex Oxides , ZHIQI LIU, T. VENKATESAN, A. ARIANDO, NANOCORE, NUS TEAM, NTU COLLABORATION — For complex oxides, the very concept of an insulator must be re-examined as they behave differently from conventional insulators such as SiO_2 due to the presence of multiple defect levels within bandgap. As the semiconductor industry is moving to such oxides for high-k materials, we need to truly understand the insulating properties of them under various electrical excitations. We report a class of material which we coin as nonlinear insulators that exhibit reversible electric-field-induced metal-insulator transitions (MIT). We show this behaviour for an insulating $LaAlO_3$thin film with a large bandgap of $\sim$5.6 eV in a metal/$LaAlO_3$/Nb-$SrTiO_3$ heterostructure. The reversible MIT is attributed to the formation of a quasi-conduction band (QCB) in the defect states of $LaAlO_3$ that forms a continuum state with the conduction band of the Nb-$SrTiO_3$. An opposing voltage is required to deplete the charges from the QCB. The implications of these nonlinear insulators are far-reaching. For example, the use of multi-component oxides as insulators in devices (e.g., high-k dielectrics in silicon CMOS devices) must be exercised with caution.

1:39PM W12.00013 Tailoring the Crystal Structure of Individual Silicon Nanowires by Polarized Laser Annealing , CHIA-CHI CHANG, Department of Physics, University of Southern California, HAITIAN CHEN, CHUN-CHUNG CHEN, CHONGWU ZHOU, STEPHEN CRONIN, Department of Electrical Engineering, University of Southern California — We study the effect of polarized laser annealing on the crystalline structure of individual amorphous and nano-crystalline silicon nanowires (Si NWs) using Raman spectroscopy. The crystalline fraction of annealed NWs increases dramatically from 0 to 0.93 with increasing incident laser power. We observe Raman line shape narrowing and frequency hardening upon laser annealing due to the increase in crystal grain size. The Raman anti-Stokes:Stokes intensity ratio is used to determine the local heating temperature caused by the intense focused laser spot, which shows a strong polarization dependence on both single crystal bulk Si and nano-crystalline Si NWs. This method provides a new approach to control the crystal structure rather than by simply adjusting the laser power. Furthermore, strain induced linewidth broadening and frequency softening was also observed in bent nano-crystalline Si NWs, and the deformation stress can be released via laser annealing.

1:51PM W12.00014 A novel method for measuring electrical conductance in thin solid films that is insensitive to contact effects , TAMAR MENTZEL, MOUNGI BAWENDI, MARC KASTNER, Massachusetts Institute of Technology — The synthesis of novel materials has been a primary driver in the emerging fields of organic-based electronics and nanoelectronics. One major obstacle to the research and development of novel materials is the ability to electrically characterize the material without introducing a significant contact resistance or damaging the material. In organic materials, the contact material has been found to alter the morphology of and to penetrate into the organic molecules, to form Schottky barriers, and to be thermally and mechanically unstable. Throughout nanoelectronics, unstable contacts and large contact resistances arise because of the reduced contact area as devices shrink in size. I will present a novel method for measuring electrical conductance in thin solid films that is insensitive to contact effects. In place of standard current measurements, a nanoscale metal-oxide-semiconductor field-effect transistor (MOSFET) is used to sense charge diffusion in a thin film of amorphous germanium. The contact resistance between the amorphous germanium and a pair of gold electrodes can be modulated *in situ* without affecting the conductance measurement. Moreover, our technique enables the measurement of conductance as low as 10^{-19} S with application of only 1 V to the film. This method can be used to electrically characterize any thin film which is sensitive to contact effects or where the resistance is too high to measure with conventional methods.

2:03PM W12.00015 Spectrometry of electron pumping by surface acoustic waves , M.J. BENESH, M. KATAOKA[1], C.J.B. FORD, C.H.W. BARNES, J.P. GRIFFITHS, G.A.C. JONES, I. FARRER, D.A. RITCHIE, University of Cambridge — Surface acoustic waves (SAWs) generate an electrostatic potential wave when applied to a GaAs/AlGaAs heterostructure. Electrons may be captured in a SAW minimum, creating a dynamic quantum dot (QD). SAW-defined QDs may be useful for certain quantum computing schemes, since, for example, they provide reliable single-electron transport and reduce the need for fast gate switching. Surface gates above a 2D electron gas (2DEG) are used to define a quasi-1D channel (Q1DC) at a potential far above the Fermi level. A SAW pulse captures electrons from the 2DEG and pumps a number of them controllably through the Q1DC. As a SAW minimum rises up the potential slope at the channel entrance, the QD is squeezed and some electrons are ejected back into the 2DEG with energies above the Fermi level. In our experiment, we probe the range of energies at which the electrons are emitted using a narrow potential barrier as an energy spectrometer. We can also measure electrons that have been pumped through the channel. We compare these results with a model for the SAW capture/pumping process.

Session W13 GSNP DBP: Applications of Statistical and Nonlinear Physics in the Life Sciences

D225/226

11:15AM W13.00001 Mean-field theory of four species in cyclic competition[1] , C.H. DURNEY, S.O. CASE, M. PLEIMLING, R.K.P. ZIA, Virginia Tech — We consider a simple model of cyclic competition of M species: When a pair of individuals from species k and $k+1$ interact, the latter transforms into the former. Even with no spatial structure, such systems often display interesting and counterintuitive behavior. With possible applications in both biological systems (e.g., Min proteins, E. Coli, lizards) and game theory (e.g., rock-paper-scissors), the $M = 3$ case has attracted considerable recent attention. We study a $M = 4$ system (with no spatial structure) and find major differences, e.g., (1) the presence of macroscopically many absorbing states, (2) coexistence of species, and (3) violation of the "law" of survival of the weakest - a central theme in the $M = 3$ case. Like the game of Bridge, the system typically ends with "partner pairs." After describing the full stochastic model and its master equation, we present the mean-field approximation. Several exact, analytic predictions will be shown. Their limitations and implications for the stochastic system will also be discussed.

[1]Supported in part by NSF-DMR-0705152, 0904999, 1005417.

11:27AM W13.00002 Stochastic evolution of four species in cyclic competition: exact and simulation results[1] , S.O. CASE, C.H. DURNEY, M. PLEIMLING, R.K.P. ZIA, Virginia Tech — We study a stochastic system with N individuals, consisting of four species competing cyclically: $A + B \longrightarrow A + A$, $\cdots$, $D + A \longrightarrow D + D$. Randomly choosing a pair and letting them react, N is conserved but the fractions of each species evolve non-trivially. At late times, the system ends in a static, absorbing state – typically, coexisting species AC or BD. The master equation is shown and solved exactly for $N = 4$, providing a little insight into the problem. For large N, we rely on simulations by Monte Carlo techniques (with a faster dynamics where a reaction occurs at every step). Generally, the results are in good agreement with predictions from mean field theory, after appropriate rescaling of Monte Carlo time. The theory fails, however, to describe extinction or predict their probabilities. Nevertheless, it can hint at many remarkable behavior associated with extinction, which we discover when studying systems with extremely disparate rates.

[1]Supported in part by NSF-DMR-0705152, 0904999, 1005417.

11:39AM W13.00003 Random inheritance in a stochastic Lotka-Volterra model , ULRICH DOBRAMYSL, Department of Physics, Virginia Tech, GABRIEL MARTINEZ, Department of Computer Science, Virginia Tech, UWE C. TÄUBER, Department of Physics, Virginia Tech — We introduce a stochastic two-species Lotka-Volterra predator-prey model that includes random inheritance features. Specifically, each individual particle takes on a predation rate value which is determined when the particle is created and is dependent on the particle's parent. Thus we arrive at a simple model for evolution due to selection pressure. We employ Monte Carlo simulations to study the time evolution of the predation rate distribution as a function of the prescribed variability. We find that this model yields a steady state with optimized rates for both predator and prey species. Contrary to, e.g., gene expression models, the rates do not experience fixation at extreme values. An approximate description of the resulting data is achieved by means of an effective master equation approach for the predation rate distribution.

11:51AM W13.00004 Time-dependent mechanical response of a network model for the cytoskeleton[1] , NASRIN AFZAL, MICHEL PLEIMLING, Virginia Tech — Motivated by a series of experiments that study the response of the cytoskeleton in living cells to time-dependent mechanical forces, we investigate through Monte Carlo simulations a three-dimensional network subjected to time-dependent perturbations. After having prepared the system in a relaxed state, time-dependent shear or stress is applied and the response is monitored. We discuss the possible implications of our results for the time-dependent mechanical response of the cytoskeleton.

[1]Supported in part by the US National Science Foundation through Grant DMR-0904999.

12:03PM W13.00005 Hopf Bifurcations in a Model for Circadian Rhythms in Arabidopsis Thaliana , ORRIN SHINDELL, RANDALL TAGG, University of Colorado Denver — Arabidopsis thaliana is a plant used for many fundamental studies, including circadian rhythms. Numerically integrating the 7-equation kinetic model of Locke et al. [J. Theor. Bio. 234 (2005) 383], we have mapped regions of parameter space where circadian expression of key mRNA and proteins undergoes limit cycle oscillation. We seek to relate this to the work of Fukuda et al. [Phys. Rev. Lett. 99 (2007) 098102], where a coupled system of cells individually described by Stuart-Landau equations is used phenomenologically to describe experimentally observed spatio-temporal patterns in the plant leaves. To that end we have done a weakly nonlinear analysis of the system of kinetic equations. We also comment on possible experimental directions to further connect the kinetic models to dynamics in this multi-cellular system.

12:15PM W13.00006 Translation with secondary structure: Dynamic blockages in totally asymmetric simple exclusion process , LEAH SHAW, College of William and Mary — The totally asymmetric simple exclusion process (TASEP) is often used as a model for protein synthesis, with the lattice and particles representing the mRNA and ribosomes, respectively. Here we model the effect of secondary structure (folding) of the mRNA by introducing a dynamic blockage region in the lattice. If the region is unoccupied by particles, the blockage can close and prevent upstream particles from moving into it, representing the folding of that section of mRNA. Reopening of the blockage, allowing particles to pass, represents unfolding. We study the effects of the blockage size, closing/opening probabilities, and TASEP parameters on the particle current and blockage switching rates.

12:27PM W13.00007 Rescue Interventions in Biological and Physical Networks , SEAN CORNELIUS, Northwestern University — Gene knockout experiments on single cells have established that expression of most genes is not needed for optimal growth. Yet, environmental and genetic perturbations to these organisms are known to be accompanied by the transient activation of a large number of latent metabolic pathways, suggesting that the temporarily activated reactions increase growth in the presence of perturbations. We have tested this hypothesis computationally and found, surprisingly, that the availability of latent pathways tends in fact to inhibit growth after genetic perturbations. This adverse effect indicates that latent pathway activation is derivative of a suboptimal response and that consequently, growth can actually be improved by removing these pathways from the network. In this talk, I will relate this counterintuitive effect to very recent research showing that a loss in network performance inflicted by an external perturbation can be mitigated by the application of additional perturbations. The challenge is to identify such "rescues" under constraints that limit the type of perturbations that can be made. I will present an approach to identify such eligible rescues for general networks modeled as dynamical systems, and present computational examples for biological and physical networks.

12:39PM W13.00008 Feedback control for stabilizing chaotic spiral waves during cardiac ventricular fibrillation[1] , ILIJA UZELAC, JOHN WIKSWO, Vanderbilt University, RICHARD GRAY, Food and Drug Administration — The cardiac arrhythmias that lead to ventricular fibrillation (VF) arise from electrical spiral waves (SW) rotating within the heart with a characteristic period τ. A single drifting SW can degenerate into a chaotic system of multiple SWs and VF. Hence early SW detection and termination is crucial to prevent VF. Time-delayed feedback control (TDFC) is well known approach for stabilizing unstable periodic orbits embedded in chaotic attractors. We hypothesize that cardiac SWs can be stabilized by TDFC with a time-delay of τ. Implementing this approach will require precise, closed-loop control of the charge delivered to the heart during the defibrillation process. To do this, we have developed a 2 kW arbitrary-waveform voltage-to-current converter (V2CC) with a 1 kHz bandwidth that can deliver up to 5 A at 400 V for 500 ms, and a photodiode system for recording in real time an optical electrocardiogram, OECG(t). The feedback signal driving the V2CC will be the time-difference (OECG(t) - OECG(t-T), where we hypothesize that T is τ, the period of the SW. This may dramatically decrease defibrillation voltages by using a defibrillation waveform customized to the VF event, unlike commercial capacitor defibrillators.

[1]Supported in part by NIH R01 HL58241-11 through ARRA 2009

12:51PM W13.00009 Experimental and theoretical evidence for fluctuation driven activations in an excitable chemical system[1] , HAROLD HASTINGS, SABRINA SOBEL, Hofstra University, RICHARD FIELD, University of Montana, SCOTT MINCHENBERG, NICOLE SPINELLI, KEITH ZAUDERER, Hofstra University — An excitable medium is a system in which small perturbations die out, but sufficiently large perturbations generate large "excitations." Biological examples include neurons and the heart; the latter supports waves of excitation normally generated by the sinus node, but occasionally generated by other mechanisms. The ferroin-catalyzed Belousov-Zhabotinsky reaction is the prototype chemical excitable medium. We present experimental and theoretical evidence for that random fluctuations can generate excitations in the Belousov-Zhabothinsky reaction. Although the heart is significantly different, there are some scaling analogies.

[1]This material is based upon work supported by the Department of Energy under Award Number DE-FG02-08ER64623.

1:03PM W13.00010 The statistical physics of decision-making in insect colonies , PATRICK M. HOGAN, Department of Computer Science, University of Sheffield, UK, THOMAS SCHLEGEL, NIGEL R. FRANKS, School of Biological Sciences, University of Bristol, UK, JAMES A.R. MARSHALL, Department of Computer Science, University of Sheffield, UK — We apply the stochastic methods of statistical physics to analyse collective-decision making in social insect colonies, allowing us to derive the colony-level behaviour from an individual-level model. This contrasts with the traditional approach where a differential equation model, with or without arbitrary noise terms, is assumed. Social insect colonies vary in size from on the order 100 to 10,000,000 individuals, and such a statistical physics approach allows us explicitly to derive equations for both the average behaviour and the noise in the system, across this entire scale. We develop such a framework by building upon an existing stochastic model of opinion formation to model the decision-making processes in emigrating ant colonies. This new model is both driven by and evaluated against results from experiments with rock ants. This allows us to elucidate rigorously the role played by the individual-level phenomena of direct switching in the colony-level decision-making process, which optimality theory has predicted to be of crucial importance, and which we compare with our experimental results. This illustrates the power of the stochastic methods of statistical physics for understanding social insect colonies as complex systems.

1:15PM W13.00011 Thermodynamic efficiency out of equilibrium , DAVID SIVAK, GAVIN CROOKS, Lawrence Berkeley National Laboratory — Molecular-scale machines typically operate far from thermodynamic equilibrium, limiting the applicability of equilibrium statistical mechanics to understand their efficiency. Thermodynamic length analysis relates a non-equilibrium property (dissipation) to equilibrium properties (equilibrium fluctuations and their relaxation time). Herein we demonstrate that the thermodynamic length framework follows directly from the assumptions of linear response theory. Uniting these two frameworks provides thermodynamic length analysis a firmer statistical mechanical grounding, and equips linear response theory with a metric structure to facilitate the prediction and discovery of optimal (minimum dissipation) paths in complicated free energy landscapes. To explore the applicability of this theoretical framework, we examine its accuracy for simple bistable systems, parametrized to model single-molecule force-extension experiments. Through analytic derivation of the equilibrium fluctuations and numerical calculation of the dissipation and relaxation time, we verify that thermodynamic length analysis (though derived in a near-equilibrium limit) provides a strikingly good approximation even far from equilibrium, and thus provides a useful framework for understanding molecular motor efficiency.

1:27PM W13.00012 A simple model for the transmission of malaria , ADRIANA DICKMAN, PUC Minas — We study a simple lattice model describing the transmission of malaria. The transmission of the disease to humans occurs through contact with an infected mosquito, while a healthy mosquito can become infected through contact with an infected human. Recovered individuals are susceptible to re-infection. The mosquitoes diffuse through the lattice, spreading the disease. We show preliminary results for the model obtained via site approximation (mean-field theory).

1:39PM W13.00013 Genearlized force-extension relation for DNA confined in sub-100nm nanoslits , YENG-LONG CHEN, PO-KENG LIN, CHIA-FU CHOU, Institute of Physics and Research Center for Applied Sciences, Academia Sinica — We generalize the force-extension relation of DNA molecules confined in persistence length scale nanoslits. In strong confinement with slit geometry, the segmental correlation length of DNA molecules have two components – in the confined and unconfined dimensions. In the confined dimension, the segmental correlation length is controlled by the slit height. In the unconfined dimension, the segmental correlation length increases as the slit height decreases. We characterize this effect, and generalize how this affects the entropic elasticity of confined DNA molecules. In addition, we investigate the structure of dense strongly confined semi-flexible polymers.

Thursday, March 24, 2011 11:15AM - 2:15PM –

Session W14 GSNP: Focus Session: Extreme Mechanics: Elasticity and Deformation III D227

11:15AM W14.00001 A general theory of mechanical instabilities in soft solids , EVAN HOHLFELD, Department of Physics, Harvard University and Chemical Sciences Division, LBNL, L. MAHADEVAN, Engineering and Applied Sciences, Kavli Institute for Nanobio Science and Technology, Harvard University — Some instabilities in soft solids, e.g. buckling and wrinkling, can be detected in linearized analysis. Surprisingly, linearly stable configurations can still have nonlinear instabilities with strictly zero energy barrier. Two examples are cavitation (formation of voids) and sulcification (formation of sharply creased free surface folds), wherein singularities nucleate and grow when a critical strain is achieved. Here we present the first general theory of stability in nonlinearly elastic materials. The theory predicts when singularities spontaneously form, irrespective of linearized analysis, and how these can be controlled with geometry. Such "hidden" instabilities arise from the scale-free geometric and constitutive nonlinearities common in soft materials, and can be understood as scale symmetry breaking processes in simple cases. More deeply, even buckling and wrinkling can be traced back to scale-free linear instabilities (loss of ellipticity at an interface) as was first explained by M. A. Biot. We illustrate the theory with simulations and experiments on sulcification. Time allowing we will also discuss fracture and delamination.

11:27AM W14.00002 Elastocapillary imbibition , CAMILLE DUPRAT, JEFFREY ARISTOFF, HOWARD STONE, Department of Mechanical and Aerospace Engineering, Princeton University, PRINCETON UNIVERSITY TEAM — The deformation of elastic structures under capillary forces (elastocapillarity), and their interaction with fluid flow (elastohyrodynamics), are relevant to many biological, geophysical and engineering processes. Here, we present the dynamics of surface-tension-driven flow into a gap between flexible boundaries (i.e. elastocapillary imbibition). We examine two model systems of elastocapillary imbibition, with and without gravitational effects, using a combination of experiment, theory, and numerical simulation. We identify the characteristic length and time scales, and demonstrate how the prescence of flexible boundaries leads to a departure from classical imbibition. The time to reach equilibrium (if one exists) is determined, and a criterion for the coalescence of the boundaries is established. Good agreement between experiment and theory is obtained.

11:39AM W14.00003 Buckling of swelling gels under constraints , HOWON LEE, University of Illinois at Urbana-Champaign, JIAPING ZHANG, YONGHAO AN, HANQING JIANG, Arizona State University, NICHOLAS FANG, Massachusetts Institute of Technology — Buckling is a traditional topic in mechanics and has been thought to be well studied for the last hundred years. Recently, buckling has drawn new attention in a different perspective; a novel scheme for pattern transformation. Here we present an experimental study on buckling using swelling of gels under constraints. Under critical conditions combined with proper mechanical constraints, non-homogenous stress develops as gel swells, which gives rise to buckling instability. We developed a fabrication technique to make a 3D cylinder-shaped microgel, the bottom end of which is tightly fixed on a rigid substrate to impose constraints. Equilibrium swelling study of such gel structure allowed us to determine a critical geometrical condition for buckling. Furthermore, exploiting slow gel swelling process, we recorded time evolution of buckling as gel swells to study post-buckling morphologies. Numerical simulation also showed close relationship between geometric parameters and resulting buckling pattern. We believe our study on buckling of swelling gels will not only help us better understand the mechanics of soft materials, but it will also contribute to increasing the breadth of possible application of soft materials in many emerging fields such as photonic crystals.

11:51AM W14.00004 Optimal control of growing sheets , GARETH JONES, L. MAHADEVAN, Harvard University — There has been much recent interest in plates and sheets that have the ability to actively swell, grow and bend. In this presentation an inhomogeneously growing plate is modeled by prescribing the in-plane growth strain and the active change-of-curvature function. The plate will then change shape to accommodate the induced strains. For applications of this phenomenon, an important problem is how best to choose these functions in order for the plate to deform to a given target shape. In seeking an answer to this question, we have developed a computational approach, where the growth strains will be found as solutions to a numerical optimization procedure. Example results will be presented which will provide some insight into the mechanical behavior of growing thin structures.

12:03PM W14.00005 Decoupling thermal, chemical, and mechanical strain components in thin films , MEREDITH SILBERSTEIN, ETHAN CRUMLIN, YANG SHAO-HORN, MARY BOYCE, MIT Mechanical Engineering — Many electrochemical systems have performance which is affected by internal strains due to thermal and/or chemical stimuli. The bi-material curvature method is a means to quantify these thermal and chemical strains and their coupling with mechanical stress. In this method, a thin layer of the material of interest is deposited on a substrate of intermediate thickness. The composite assumes a curvature that depends on the mismatch strains between the substrate and film. The Stoney formula provides an explicit expression for the film stress as a function of the elastic substrate properties, film and substrate thickness, and curvature. Here we study two distinct materials systems: Nafion used as the polymer electrolyte in low temperature fuel cells, and epitaxial perovskite thin films used as a catalyst for the oxygen reduction reaction in solid oxide fuel cells. The thermal, chemical, and mechanical strains are quantitatively determined as functions of temperature and atmospheric conditions by monitoring the curvature evolution with changes in these parameters. The extent of coupling of the thermal and chemical strains with mechanical stress is evaluated by conducting the experiment at multiple substrate thicknesses.

12:15PM W14.00006 Plane deformations generating a prescribed finite rotation field , GREGORY RIZZA, JANET BLUME, Brown University — Compatibility conditions for various strain measures are well known in both small and finite strain kinematics. For many problems, such conditions enable boundary value problems to be formulated using strains, stresses, or a generating potential function, as the fundamental dependent variable(s). These methods are effective, as most strain fields fully determine the generating deformations up to an arbitrary rigid deformation. Our research is concerned with the compatibility issue for the rotation field. Although it is not a direct measure of the distortion in a deformation, the rotation associated with a deformation and its variation from point to point within a body turns out to carry quite a bit of information about the actual deformation. For the case of plane deformation, we have been able to show that any suitably smooth plane proper orthogonal tensor field may serve as a finite rotation tensor for a generating deformation. We have developed several examples demonstrating this relationship between material deformation and rotation fields. Our results demonstrate in the case of plane deformation, any skew-symmetric two-dimensional tensor field can serve as a plane rotation field. The relation between the position-dependence of a rotation field and generating deformation information has implications in both mechanical twinning and shear banding.

12:27PM W14.00007 Mechanics of Suture Joints , YANING LI, JUHA SONG, CHRISTINE ORTIZ, MARY BOYCE, MIT, ORTIZ GROUP/DMSE/MIT TEAM, BOYCE GROUP/ME/MIT TEAM — Biological sutures are joints which connect two stiff skeletal or skeletal-like components. These joints possess a wavy geometry with a thin organic layer providing adhesion. Examples of biological sutures include mammalian skulls, the pelvic assembly of the armored fish Gasterosteus aculeatus (the three-spined stickleback), and the suture joints in the shell of the red-eared slider turtle. Biological sutures allow for movement and compliance, control stress concentrations, transmit loads, reduce fatigue stress and absorb energy. In this investigation, the mechanics of the role of suture geometry in providing a naturally optimized joint is explored. In particular, analytical and numerical micromechanical models of the suture joint are constructed. The anisotropic mechanical stiffness and strength are studied as a function of suture wavelength, amplitude and the material properties of the skeletal and organic components, revealing key insights into the optimized nature of these ubiquitous natural joints.

12:39PM W14.00008 Mechanical and thermal stability of adhesive membranes with nonzero bending rigidity , TUOMAS TALLINEN, Harvard University / University of Jyvaskyla, JAN ASTROM, CSC - The Finnish IT Center for Science, PEKKA KEKALAINEN, JUSSI TIMONEN, University of Jyvaskyla — Membranes at a microscopic scale are affected by thermal fluctuations and self-adhesion due to Van der Waals forces. Methods to prepare membranes of even molecular scale, e.g. graphene, have been recently developed, and the question of their mechanical and thermal stability is of crucial importance. To this end we modeled microscopic membranes with a short-range attractive interaction and applied Langevin dynamics. Their behavior was also analyzed under external loading. Even though these membranes folded during isotropic compression as a result of energy minimization, the process at high confinement did not differ much from crumpling of macroscopic thin sheets. The main difference appeared when the external load was released. In such cases, for membranes of sufficiently large size L, folded or scrolled conformations emerged. At high enough temperature T entropic effects made such conformations unfavorable, however. Possible conformations of free-standing membranes ("phase diagrams") were determined in the TL-plane.

12:51PM W14.00009 Universal Shapes formed by Interacting Cracks , MELISSA FENDER, North Carolina State University, FREDERIC LECHENAULT, University of Montpellier, KAREN DANIELS, North Carolina State University — Brittle failure through multiple cracks occurs in a wide variety of contexts, from microscopic failures in dental enamel and cleaved silicon to geological faults and planetary ice crusts. In each of these situations, with complicated curvature and stress geometries, pairwise interactions between approaching cracks nonetheless produce characteristically curved fracture paths known in the geologic literature as en passant cracks. While the fragmentation of solids via many interacting cracks has seen wide investigation, less attention has been paid to the details of individual crack-crack interactions. We investigate the origins of this widely observed crack pattern using a rectangular elastic plate which is notched on each long side and then subjected to quasistatic uniaxial strain from the short side. The two cracks propagate along approximately straight paths until the pass each other, after which they curve and release a lenticular fragment. We find that, for materials with diverse mechanical properties, the shape of this fragment has an aspect ratio of 2:1, with the length scale set by the initial cracks offset s and the time scale set by the ratio of s to the pulling velocity. The cracks have a universal square root shape, which we understand by using a simple geometric model and the crack-crack interaction.

1:03PM W14.00010 Pericyte Actomyosin-Mediated Contraction at the Cell-Material Interface can Modulate the Microvascular Niche , ADAM ZEIGER, MIT, MACIEJ KOTECKI, Tufts University, JOHN MALONEY, MIT, IRA HERMAN, Tufts University, KRYSTYN VAN VLIET, MIT — Here we employ the experimental finding that pericytes can wrinkle a freestanding, underlying membrane via actin-mediated contraction. Pericytes were cultured on deformable silicone substrata. Local stiffness of subcellular domains was investigated by using AFM-enabled nanoindentation. Substratum contraction was quantified by normalized change in wrinkle contour lengths, and a model was used to relate local strain energies to pericyte contractile forces. The nature of pericyte-generated wrinkling and contractile protein-generated force transduction was further explored by the addition of pharmacological cytoskeletal inhibitors that affected contractile forces and the effective elastic moduli of pericyte domains. Actin-mediated forces are sufficient for pericytes to exert an average contraction of 38% on the substrata employed in these in vitro studies. Pericyte generated contractile forces thus serve as a direct mechanical stimulus to adjacent vascular endothelial cells, potentially altering the effective mechanical stiffness of nonlinear-elastic extracellular matrices, to modulate pericyte-endothelial cell interactions that directly influences physiologic angiogenesis.

1:15PM W14.00011 Extraordinary Elasticity of the Distorted Kagome Lattice , ANTON SOUSLOV, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA 19104, KAI SUN, Joint Quantum Institute and Condensed Matter Theory Center, University of Maryland, College Park, MD 20742, XIAOMING MAO, TOM LUBENSKY, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA 19104 — J. C. Maxwell discovered that a system of particles in d-dimensions will be marginally rigid, or *isostatic*, if each particle interacts on average with $2d$ of its neighbors. Isostatic models have been used to describe such diverse soft phenomena as the jamming transition and the elasticity in networks of semi-flexible polymer gels. We develop models based on the isostatic kagome lattice, which has a subextensive number of floppy phonon modes. We show that these can be extended into soft deformations by changing the particle configurations while keeping the bond lengths fixed. Thus, we create families of novel isostatic lattices, which exhibit highly tunable elastic properties as a consequence of isotropic linear elasticity with a zero bulk modulus. They have a negative Poisson ratio, or auxetic (anti-rubber) behavior. Further, we find no bulk soft phonons at large length scales due to conformal symmetry. We discuss the intimate relationship between various symmetries and soft response in these models as well as the relation of these models to other marginally rigid systems.

1:27PM W14.00012 Suppression of Viscous Fingers in Miscible Hele-Shaw Flow , RADHA RAMACHANDRAN, JUSTIN BURTON, SIDNEY NAGEL, University of Chicago — The flow of two immiscible fluids between closely-spaced parallel plates can be highly unstable and produce a series of complex fingering patterns when the less viscous injected fluid invades the more viscous one. Air displacing granular material in such a Hele-Shaw geometry shows similar patterns with sharp features consistent with the granular/air surface tension being virtually zero [1]. Here we investigate the flow of two *miscible* fluids in a radial Hele-Shaw cell, with an inner liquid displacing an outer one of higher viscosity. We use two glycerol- water mixtures so that the viscosity can be tuned by varying the glycerol concentration. We vary the plate spacing and flow rate as well as the fluid viscosites. The non-equilibrium interfacial tension between these two miscible fluids is expected to be nearly zero. However, extrapolating to zero surface tension in the linear theory for Hele-Shaw flow does not describe our results. Specifically, flow becomes *stable* even when the inner liquid has a much lower viscosity than the outer one. At higher velocity, it is possible to see small amplitude fingering patterns develop.

1:39PM W14.00013 Patterns on thin sheets: buckling, wrinkling, crumpling, folding , BENNY DAVIDOVITCH, University of Massachusetts — Recent experiments on thin sheets under various geometric confinements and distributions of exerted forces found a multitude of pattern types. I will discuss the possibility of classifying this diverse phenomenology by generalizing concepts of primary and secondary instabilities, and basic types of symmetry breaking.

1:51PM W14.00014 Mechanics and chemical thermodynamics of a temperature-sensitive hydrogel[1] , SHENGQIANG CAI, Harvard University, ZHIGANG SUO — A temperature-sensitive hydrogel is a network of polymers containing monomers, whose interaction with water molecules can be tuned dramatically by changing temperature. In most cases, the swelling ratio of a temperature-sensitive hydrogel changes discontinuously upon heating above or cooling below a critical temperature, which is called volume phase transition. Interestingly, the coexistence of swollen phases and shrunk phases are frequently observed in the experiments for temperature-sensitive hydrogels and additionally, people have also discovered that a uniaxial force can induce phase transition in a temperature-sensitive gel bar .In order to understand these phenomena, we studied the mechanics and chemical thermodynamics of a temperature-sensitive hydrogel bar, by using the free-energy landscape of a bar made from PNIPAM gel. Following Gibbs, we plot the phase diagram of a temperature-sensitive hydrogel bar under uniaxial force.

2:03PM W14.00015 Mechanics of Curved Folds[1] , MARCELO A. DIAS, CHRISTIAN D. SANTANGELO, University of Massachusetts Amherst — Despite an almost two thousand year history, origami, the art of folding paper, remains a challenge both artistically and scientifically. Traditionally, origami is practiced by folding along straight creases. A whole new set of shapes can be explored, however, if, instead of straight creases, one folds along arbitrary curves. We present a mechanical model for curved fold origami in which the energy of a plastically-deformed crease is balanced by the bending energy of developable regions on either side of the crease. Though geometry requires that a sheet buckle when folded along a closed curve, its shape depends on the elasticity of the sheet.

Session W15 DMP GMAG FIAP: Focus Session: Spins in Semiconductors - Spin-Orbit Effects and Confinement D171

11:15AM W15.00001 Chern Number Spins of Mn Acceptor Magnets in GaAs , C. M. CANALI[1], Linnaeus University, Kalmar, Sweden — State-of-the-art STM techniques have made it possible to substitute transition metal impurities for individual atoms in semiconductor crystals and have provided detailed information on the nature of the bound acceptor or donor states. Individual coupled acceptor (or donor)-impurity centers represent a new class of nanomagnets which we refer to as *acceptor or donor magnets*. Here we determine the effective total spin $J$of local moments formed from acceptor states bound to Mn ions in GaAs by evaluating their magnetic Chern numbers. When individual Mn atoms are close to the sample surface, the total spin changes from $J = 1$ to $J = 2$, due to quenching of the acceptor orbital moment. For Mn pairs in bulk, the total Jdepends on pair orientation in the GaAs lattice and on the separation between the Mn atoms. We point out that Berry curvature variation as a function of local moment orientation can profoundly influence the quantum-spin dynamics of these magnetic entities.

11:51AM W15.00002 Effect of magnetic field on the local density of states of Mn acceptor magnets in GaAs , M.R. K. MAHANI, C.M. CANALI, Linnaeus University, Kalmar, Sweden, A.H. MACDONALD, University of Texas at Austin — Advances in atomic manipulation, real-space imagining and spectroscopic power of STM techniques have recently made it possible to investigate the local electronic properties of a few substitutional Mn impurities inserted in the GaAs surfaces [1]. Theoretical work [2] predicts that the local density of states in the vicinity of the Mn impurities should depend strongly on the direction of the Mn magnetic moment. In contrast, recent STM experiments [3] from several groups find a negligible dependence of the tunneling LDOS on the magnetic field direction for applied fields up to 7 T. Based on tight- binding calculations we interpret these findings by arguing that large LDOS signals require large angle moment rotations, and that the strength of the magnetic field used in present experiments is not strong enough to substantially modify the magnetic anisotropy landscape of Mn impurities near the GaAs surface.

12:03PM W15.00003 Effects of Anisotropy in Magnetic Quantum Dots , RAFAL OSZWALDOWSKI, IGOR ZUTIC, University at Buffalo, ANDRE PETUKHOV, South Dakota School of Mines and Technology — Magnetic ordering in semiconductor Quantum Dots (QDs) doped with Mn is mediated by the confined carriers (typically holes), which interact with Mn through exchange interaction. The ordering can be affected by the QD flat shape [1], and, by the resultant anisotropic g-factor of holes [2]. A reduction of the in-plane symmetry of the QD by an external potential may influence the magnetic alignment as well [3]. We study the magnetic ordering at different degrees of anisotropy. The ordering arises in absence of external magnetic field, e.g., through formation of magnetic polarons. A typical number of Mn in a QD is large, so we replace their spins by classical magnetic moments. We emphasize the limit of full isotropy (electrons) and extreme anisotropy (holes in a flat QD). Supported by DOE-BST, ONR, AFOSR, and NSF-ECCS CAREER.

12:15PM W15.00004 Incorporation of Mn into Ge Quantum Dots: Growth Strategies to Control Structure and Magnetism[1] , CHRISTOPHER NOLPH, PETRA REINKE, Department of Materials Science and Engineering, University of Virginia — Manganese doped, magnetic germanium quantum dots are important building blocks for the future of spintronic devices. Our goal is to understand and control how the manipulation of the Mn-environment within the Si(100)-Ge wetting layer-Ge QD systems influence the magnetic properties. We investigate several pathways for Mn-doping of Ge QDs which suppress detrimental germanide formation. The first pathway uses a surface-driven approach: Mn is deposited on the Ge QD surface, forms well-defined clusters on the QD and dissolve during annealing. The second pathway uses co-deposition of Ge and Mn (i) throughout the entire QD growth process, and (ii) only during the formation of the wetting layer. The highest concentration of Mn is about 20%, and the Ge QD growth is only marginally perturbed, albeit germanides begin to form. All processes are observed with scanning tunneling microscopy, which yields morphological and electronic structure information of the reaction sequence. A comprehensive model of all processes will be presented. Preliminary magnetism results, obtained with a vibrating sample magnetometer, indicate a ferromagnetic material with a Curie temperature up to 100K.

12:27PM W15.00005 Control and properties of magnetic nanostructures in nitride semiconductors , ALBERTA BONANNI, Johannes Kepler University, Linz-Austria — We review [1] studies of MOVPE (Ga,Fe)N [2-7] and (Ga,Mn)N [8,9], combining magnetic [2-4,6,8,9], magnetooptical [3], and XANES [4,5,8] investigations with a comprehensive structural and chemical characterization by SIMS, TEM, EDS [2,4,6,8,9], synchrotron-XRD [4,6,8], EXAFS [5,8], and PEEM [7]. We show that the Fe ions aggregate into Fe_xN nanocrystals either by crystallographic or by chemical phase separation, controlled by the growth conditions and by co-doping. Depending on the degree of nitridation, these nanocrystals are either ferromagnetic or antiferromagnetic.

1:03PM W15.00006 From simplicity to complexity: Can transcendental equation and transfer matrix enlighten us about the nature of Rashba physics? , CHIH-PIAO CHUU, University of Texas at Austin, TX, ROLAND WINKLER, Northern Illinois University, IL, QIAN NIU, University of Texas at Austin, TX — We present an analytic model of Rashba spin-splitting of conduction electrons in asymmetric quantum wells based on transcendental equation and transfer matrix approaches. The sources of asymmetries of quantum wells, such as interface discontinuity, conduction and valence band profiles, external field or presence of a potential gradient, related to Rashba spin-splitting will be discussed. We will use type I and type II semiconductor heterostructure quantum wells for demonstration.

1:15PM W15.00007 Signatures of the crystal symmetry after Dyakonov-Perel spin relaxation of photoexcited hot electrons in semiconductor heterostructures[1] , LAN QING, HANAN DERY, Department of Physics and Astronomy, University of Rochester, Rochester, New York 14627 — We reveal unique manifestations of the intimate relation between the crystal structure of zincblende semiconductors and their spin-orbit coupling. We show that reflection of photoexcited hot electrons is capable of tipping the direction of the optically injected net spin vector away from the propagation axis of the exciting circularly polarized beam. The effect is robust even in case of complete electron reflection from a non magnetic target (e.g., GaAs/AlAs). The tipping angle of the net spin vector after spin relaxation is determined by the effective Dyakonov-Perel magnetic field as well as by the momentum alignment and spin-momentum correlation of the initial photoexcited electron population. All of these crystal-structure dependent mechanisms contribute due to the reflection plane induced symmetry breaking. We perform Monte Carlo simulations to calculate the tipping angle and also provide qualitative derivations of the effect. Results are shown for non-magnetic semiconductor heterostructures and for hybrid semiconductor/ferromagnet systems.

1:27PM W15.00008 The spin dynamics in the strong spin-orbit coupling regime-A collective Rabi oscillation[1] , XIN LIU, XIONG-JUN LIU, JAIRO SINOVA, Department of Physics, Texas A&M University, College Station, TX 77843-4242, USA — We study the spin evolution in a high-mobility two dimensional electron gas (2DEG) with generic spin-orbit interactions(SOI). A fully understanding of the D'yakonov-Perel's(DP) mechanism is presented by using the microscopic linear response theory from the diffusive to the ballistic regime. We derive a set of spin dynamical equations which capture the characters of the purely exponential and damped oscillatory spin evolution modes in different spin-orbit coupling(SOC) regimes. It is shown that the oscillatory spin dynamics appear when the electron life time is larger than the half of the spin precession time due to the SOI. The Rabi oscillation between two spin bands is the physical origination of the damped oscillatory modes.

1:39PM W15.00009 Rasbha Spin-Orbit Interaction in Digital Alloys , JOSEPH PINGENOT, KIERAN MULLEN, The University of Oklahoma Department of Physics and Astronomy — The Rashba spin-orbit interaction couples the electron spatial wavefunction to its spin through breaking the inversion symmetry of a structure. From work by Lange[1], the Rashba spin-orbit effect can be divided into a structural component, originating primarily in the valence band offsets within the nanostructure, and an electric field component, originating primarily in the internal self-consistent electric field and in an applied electric field. A common growth technique, digital alloying, breaks the well into discrete steps and then varies the material composition for each step by constructing a well within the step such that the average material across the step corresponds to the desired percentage, e.g. a $Ga_{0.5}In_{0.5}As$ well would be pure GaAs through half the step, followed by pure InAs for the rest of the step. With digital alloying, the electron wavefunction is approximately the same as is obtained by using a real alloy. The Rashba spin-orbit couplings, however, are considerably smaller for the digital alloy than the real alloy. This comes about because the digital alloy has a series of positive and negative interfaces at each step, whereas the real alloy has a series of identical steps. We calculate the Rashba coefficient for a variety of realistic well geometries, for both digitial and continuous alloying, and discuss how the consequences for experiment. [1] Jens Lange, *Quantentransport in Halbleiter-Heterostrukturen* (1996).

1:51PM W15.00010 Superconductivity in the repulsive Rashba model , LUYANG WANG, OSKAR VAFEK, National High Magnetic Field Laboratory and Department of Physics, Florida State University — We study the superconducting instability of a two dimensional Rashba spin-orbit coupled system with a weak repulsive interaction by a two step renormalization group (RG) method introduced by Raghu et.al. (PRB 81, 224505 (2010)). We present the superconducting transition temperature Tc in terms of the correlation functions of the non-interacting system. The RG flows in the Cooper channel break down below some scale, which we identify with Tc and verify that the Tc is independent of the intermediate cutoff. Finally, we present results of Tc as a function of spin-orbit coupling strength.

2:03PM W15.00011 Kohn-Luttinger superconductivity of two-dimensional electrons in the presence of Rashba spin-orbit coupling , ALI ASHRAFI, DMITRII MASLOV, Department of Physics, University of Florida — We consider a two-dimensional(2D) system of fermions with weak short-range repulsive interac- tion in the presence of Rashba Spin-Orbit coupling(SOC). We show that although Kohn-Luttinger instability in 2D in the absence of SOC occurs only to third order in the interaction, it occurs to second order in the presence of SOC. The critical temperature of the p-wave transition is calculated.

Session W16 DMP GMAG: Focus Session: Bulk Properties of Complex Oxides - Other D173

11:15AM W16.00001 Magnetic Force Microcopy of the Magnetostructural Phases of Mn3O4

, XU WANG, MINJUNG KIM, RAFFI BUDAKIAN, S. L. COOPER, University of Illinois at Urbana-Champaign — In this talk, we report temperature- and field- dependent magnetic force microscopy (MFM) studies of Mn3O4. The spinel Mn3O4 has novel phase structure at low temperatures due to a three-way competition between spin-orbital coupling, geometric frustration and external magnetic field. This competition could lead to complex magnetic pattern formations. A particularly interesting phase exists where the crystal lattice undergoes a transition to resolve the spin frustration due to internal and external magnetic fields. In this phase the spins were expected to be in a disordered state, but local magnetic ordering has not been explored in previous studies. We present results from our investigation of Mn3O4 phase space using a variable temeprature MFM. Measurements were made at temperatures between 4K and 75K and in magnetic fields up to 5 tesla.

11:27AM W16.00002 Magnetic excitations in the geometric frustrated multiferroic $CuCrO_2$

, MATTHIAS FRONTZEK, GEORG EHLERS, ANDREY PODLESNYAK, MASAAKI MATSUDA, ANDREW CHRISTIANSON, NScD, Oak Ridge National Laboratory, 37831 Oak Ridge, USA, RANDY FISHMAN, Materials Science and Technology Division, Oak Ridge National Laboratory, 37831 Oak Ridge, USA, JASON HARALDSEN, Theoretical Division, Los Alamos National Laboratory, 87545 Los Alamos USA, SERGEI BARILO, Institute of Solid State and Semiconductor Physics, Minsk 220 072, Belarus — The delafossite $CuCrO_2$, crystallizing in the rhombohedral $R\bar{3}M$ space group, is an interesting case of a multiferroic compound due to its apparent strong coupling of spin and charge. In contrast to other multiferroic compounds $CuCrO_2$ shows a spontaneous electric polarization upon antiferromagnetic ordering at $T_N \approx 24$ K without an accompanying structural phase transition. Further, $CuCrO_2$ is a rare example where the magnetoelectric properties are tunable by both an electric and a magnetic field. In our contribution we present inelastic neutron scattering experiments on $CuCrO_2$ single crystals. The measured magnetic excitation spectra have been modeled by Monte-Carlo spin wave calculations and allowed the determination of the relevant exchange interaction and anisotropy terms. We will present evidence for a weak ferromagnetic Cr-Cr-interlayer exchange interaction and show that this interaction is relevant for the multiferroic properties of $CuCrO_2$.

11:39AM W16.00003 Charge dynamics in frustrated charge ordered system with strong electron correlation

, MAKOTO NAKA, SUMIO ISHIHARA, Department of Physics, Tohoku University — Electronic ferroelectricity is known as phenomena where the electric polarization is caused by the electronic charge order without inversion symmetry. This is seen in some transition metal oxides, e.g. $LuFe_2O_4$, and charge transfer organic salts. It is suggested from the theoretical works [1,2] that large charge fluctuation and frustration are responsible for the electric polarization. This charge fluctuation is expected to govern dynamical properties and external field effects. Actually, the relaxer like large dielectric fluctuation in some electronic ferroelectricity is observed. Motivated by these experimental and theoretical results, we study charge dynamics in charge ordered fermion system on the layered triangular lattice. We adopt the V-t model where the inter-site electron transfers and the inter-site Coulomb interactions are taken into account. We analyze this model by utilizing the exact diagonalization method and focus on effects of frustration in the charge dynamics. In the 3-fold charge ordered phase associated with the electric polarization, the optical conductivity shows multiple-peak structure in a wide energy range. In the non-polar 2-fold charge ordered phase, a precursor of the 3fold charge order appears in the low energy charge fluctuation around the phase boundary. [1] A. Nagano et al. Phys. Rev. Lett. **99** 217202. [2] M. Naka et al. Phys. Rev. B. **77** 224441.

11:51AM W16.00004 Photo induced spin-state change in itinerant correlated electron systems

, SUMIO ISHIHARA, YU KANAMORI, Tohoku University, HIROAKI MATSUEDA, Sendai National College of Technology — Recently developed ultrafast optical techniques open up a new frontier for research of the phase transition. This is the so-called photo-induced phase transition (PIPT). The spin-state transition between different magnitudes of the spin-angular moment is one of the targets. In particular, the photo-induced spin-state transition is seen in the cobalt oxides with a perovskite structure. The ultrafast optical measurements in the low-temperature low-spin insulators show transient metallic spectra which are completely different from the spectra in the high-temperature high-spin phase. We study theoretically the photo-induced spin-state change in itinerant correlated electron systems. We derive the model Hamiltonians where numbers of photo-excited electron-hole pair are fixed. A bound state of the photo-doped hole and the high-spin state are created inside of the low-spin sites. This bound state brings about a characteristic peak structure in the optical pump-probe spectra which are completely different from the spectra in thermally excited states. The present theory provides a possible scenario in recently observed photo-induced hidden state in perovskite cobaltites.

12:03PM W16.00005 Rapidly fluctuating orbital occupancy above the orbital ordering transition in spin-gap compounds[1]

, FRANCISCO RIVADULLA, BEATRIZ RIVAS-MURIAS, Physical Chemistry Dept. and Center for Research in Biological Chemistry and Molecular Materials, Univ. Santiago Compostela, Spain, HAIDONG ZHOU, National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL 32306-4005, USA, JOSE RIVAS, Applied Physics Department, University of Santiago de Compostela, Spain — Low-dimensionality spin systems develop a spin-dimer phase within a molecular orbital that competes with long-range antiferromagnetism below TS. Very often, preferential orbital occupancy and ordering are the actual driving force for dimerization, as in the orbitally-driven spin-Peierls (MgTi2O4, CuIr2S4, La4Ru2O10, NaTiSi2O6, etc.). Through a microscopic analysis of the thermal conductivity in La4Ru2O10, we show that the orbital occupancy fluctuates rapidly above TS, resulting in an orbital-liquid state. Strong orbital-lattice coupling introduces dynamic bond-length fluctuations that scatter the phonons to produce a glass-like thermal conductivity above TS. This phonon-glass to phonon-crystal transition occurs in other spin-dimer systems, like NaTiSi2O6, pointing to a general phenomenon.

12:15PM W16.00006 Influence of particle size on the magnetic and magnetocaloric properties of nanocrystalline $La_{2/8}Pr_{3/8}Ca_{3/8}MnO_3$

, P. LAMPEN, N.S. BINGHAM, M.H. PHAN, H. SRIKANTH, University of South Florida, T.H. HOANG, H.D. CHINH, Hanoi University of Technology — Bulk manganites $La_{5/8-y}Pr_yCa_{3/8}MnO_3$(LPCMO) exhibit a complex phase diagram due to coexisting and competing charge-ordered (CO) and ferromagnetic (FM) phases. Of particular interest is the CO phase that is unstable under various perturbations, such as carrier doping, strain, magnetic and electric field. We report systematic studies of the influence of particle size on the magnetic and magnetocaloric properties of nanocrystalline LPCMO (y=3/8) synthesized by sol-gel method. The nanocrystalline samples with mean particle sizes of 30 nm, 150 nm, and 250 nm were structurally characterized by XRD, SEM, and TEM. Magnetic and magnetocaloric measurements were conducted using a Quantum Design PPMS. We find that the 150 nm and 250 nm samples exhibit features similar to their bulk counterpart. However, the case is very different for the 30 nm sample where only a paramagnetic to ferromagnetic transition occurs. Size reduction has been found to suppress the CO phase, decrease the magnetization, and strongly modify the magnetocaloric effect in LPCMO.

12:27PM W16.00007 Studies on manganese substituted cobalt ferrite prepared by autocombustion route

, Y. KOLEKAR, Pune University, R. KAMBALE, Shivaji University, Kolhapur, R. GUPTA, P. KAHOL, K. GHOSH, Missouri State University — Compositions of Co1.2-xMnxFe1.8O4 (0 = x = 0.4) were synthesized by autocombustion route keeping oxidizer to fuel ratio at 1. Structural and compositional characterizations of all the samples were performed by XRD, SEM and EDS. Magnetization measurements showed that the Ms increases form 106.5 emu/g for x = 0.0 to 138.5 emu/g for x = 0.2 and then decreases from x = 0.3 (124.71 emu/g for x = 0.3 and 97.78 emu/g for x =0.4), whereas the coercivity (Hc) decreases with manganese (Mn) substitution, except for x = 0.3. Room temperature dielectric properties such as relative dielectric permittivity (er), dielectric loss and ac conductivity, were studied as a function of frequency in the range from 20 Hz to 1 MHz. These studies indicates that the relative dielectric permittivity increasing (from er = 600 for x =0.0 to er = 2400 for x = 0.4) with the increase of Mn content in cobalt ferrite and also all samples show the usual dielectric dispersion which may be due to the Maxwell-Wagner-type of interfacial polarization. Dr. Y. D. Kolekar gratefully acknowledges the award of BOYSCAST fellowship by Department of Science and Technology, India. *On leave from Department of Physics, University of Pune, Pune- 411 007, India.

12:39PM W16.00008 Single magneto-chiral domain observed in langasite $Ba_3NbFe_3Si_2O_{14}$ by non-resonant magnetic X-ray scattering , LAURENT CHAPON, ALESSANDRO BOMBARDI, FEDERICA FABRIZI, CHRIS STOCK, DES MCMORROW, PAOLO RADAELLI, SANG-WOOK CHEONG — The helical magnetic ground state of the chiral langasite compound $Ba_3NbFe_3Si_2O_{14}$ has been investigated using a left-handed single crystal using non resonant x-ray magnetic scattering. This technique, when combined with circularly polarized x-ray and a full polarization analysis of the scattered beam, is sensitive to the chirality of the spiral order previously reported in this compound and it allows an unique determination of the chirality of the magnetic ground state. A topographic map of the sample surface shows that the crystal is made of a single magneto-chiral domain. Azimuthal scans revealed that the long range magnetic order with wave-vector k=(0,0,1/7) is characterized by an elliptical modulation rather than a circular one, as initially reported. We also discuss the possible spin-driven ferroelectric state in this compound.

12:51PM W16.00009 Simple point-ion electrostatic model explains the cation ordering in A2BO4 spinel oxides[1] , VLADAN STEVANOVIC, MAYEUL D'AVEZAC, ALEX ZUNGER, NREL, Golden CO — The A2BO4 spinel oxides are distinguished by having either a normal or an inverse distribution of the A, B cations over the octahedrally and tetrahedrally coordinated sites. While normal spinel represents a single structure (A-octahedral, B-tetrahedral) the inverse spinel is similar to a 50-50 alloy with octahedral sublattice occupied randomly by A and B. We show that a simple point-ion electrostatic (PIE) model parameterized by the oxygen displacement parameter u and by the relative formal cation valencies ZA vs ZB provides a simple rule: if ZA>ZB the structure is normal for u>0.2592 and inverse for u<0.2578, while if ZA<ZB the structure is normal for u<0.2550 and inverse for u>0.2578. This rule is illustrated for the known spinel oxides, proving to be 98 % successful (PRL 105, 075501). Moreover, in inverse spinels the PIE model also explains the origin of the experimentally observed ordered phase that emerges from the random alloy at low T.

1:03PM W16.00010 Anionogenic Magnetism: Mixed Alkali – Alkaline Earth Metal Oxides , SHIVAKUMARA GIRIYAPURA, SYARIF RIYADI, Solid State Materials for Electronics, Zernike Institute for Advanced Materials, University of Groningen, Groningen,The Netherlands, BAOMIN ZHANG, ROBERT A. DE GROOT, Electronic Structure of Materials, IMM, Radboud University Nijmegen, Nijmegen, The Netherlands, THOMAS T.M. PALSTRA, GRAEME R. BLAKE, Solid State Materials for Electronics, Zernike Institute for Advanced Materials, University of Groningen, Groningen,The Netherlands, S S M E TEAM, IMM COLLABORATION — The scientific and technological potential of materials in which magnetism arises from p-electrons is little explored. Accordingly, we have synthesized the solid solution $Ba_{1-x}K_x(O_2^{2-})_{1-x}(O_2^{-})_x$ which contains a nominal mixture of magnetic superoxide and non magnetic peroxide anions. Magnetization measurements reveal short range antiferromagnetic ordering below ∼65 K for all compositions, with an increasing tendency toward ferromagnetic interactions at lower temperatures, characterized by the opening of magnetic hysteresis loops in applied fields.Field induced reorientation of the dioxygen dumbbells probably occurs, altering the magnetic exchange interactions between nearest neighbor anions.

Session W17 GMAG DMP: Focus Session: Magnetic Oxide Thin Films - Cobaltate and Ferrous Oxide Thin Films D174

11:15AM W17.00001 Fist-principles design of magnetic oxides , ARTHUR ERNST, Max Planck Institute of Microstructure Physics — First-principles design of magnetic oxides is one of most ambitious challenges in modern computational physics. The electronic and magnetic properties of these materials are substantially affected by strongly localized electrons, complex crystalline structures, and mixed valencies of magnetic ions. In my talk I shall present an ab-initio Green function method within density functional theory which provides an accurate description of the electronic structure of these materials. In particular, the treatment of strongly localized electrons is improved considerably by applying a self-interaction correction (SIC), thereby removing the spurious interaction of an electron with itself. By localizing a particular electronic configuration using the SIC, we simulate various valencies of magnetic ions. A mixed-valency state can then be efficiently treated within the coherent potential approximation which is implemented in our multiple-scattering Green function code that can be used as well for simulations of any kind of substitutional disorder. In my talk I shall demonstrate the power of our approach on complex magnetic oxidic surfaces and interfaces. In particular, I shall discuss effective exchange interactions in systems with mixed valency and the influence of structural imperfections, such as defects and relaxations, on the electronic and magnetic properties of these materials.

11:51AM W17.00002 Cobalt spin state and hyperfine interaction in ferromagnetic insulating $LaCoO_3$ thin films[1] , RENATA WENTZCOVITCH, HAN HSU, University of Minnesota, PETER BLAHA, TU Vienna, CHRIS LEIGHTON, University of Minnesota — At low temperatures, bulk $LaCoO_3$ is a non-metallic diamagnet. In contrast, thin-film $LaCoO_3$ experiencing a tensile epitaxial strain is a ferromagnetic insulator in the same temperature range. It is difficult to properly describe this phenomenon with density functional theory (DFT) calculations, even with the Hubbard U correction. Previous calculations have found ferromagnetic conducting thin-film $LaCoO_3$ with all Co ions in the intermediate-spin (IS) state, incompatible with experimental data. In this work, using the DFT+U approach, we show that a strained $LaCoO_3$ thin film can be stabilized in a ferromagnetic insulating state. We also predict the electric field gradient (EFG) at the Co nucleus in the magnetic thin film, which can be helpful in identifying Co spin states via nuclear magnetic resonance (NMR) spectroscopy.

[1]This work is primarily supported by the MRSEC Program of NSF under DMR-0212302 and DMR-0819885, and partially supported by EAR-0810212 and EAR-1047629. P.B. was supported by the Austrian Science Fund (P20271-N17). Calculations were performed at MSI.

12:03PM W17.00003 First-principles study of strain-induced ferromagnetism in $LaCoO_3$, HOSUNG SEO, ALEXANDER DEMKOV, The University of Texas at Austin — We study theoretically the effect of biaxial strain on magnetic properties of $LaCoO_3$ (LCO) using density functional theory combined with the Hubbard U method. LCO is normally a non-magnetic insulator with trivalent cobalt ions in low-spin state (t_{2g}^6). Owing to close interplay between orbital, spin, and lattice degrees of freedom, it shows rich magnetic behavior such as temperature-induced spin state transition. Recently, the ferromagnetic tensile-strained LCO films have been reported. The underlying physics of the ferromagnetic state is, however, unclear. Using a large tetragonal cell we calculate full structural response of the system to applied strain for non-magnetic and magnetic solutions. We show that beyond tensile strain of 3.8% the ferromagnetic solution with Co ions in intermediate-spin state (t_{2g}^5 e_g^1) is stabilized accompanied by partial untilting of CoO_6 octahedral network. We also perform the calculation for compressive-strained structures and the difference between these and the tensile strained structures will be presented.

12:15PM W17.00004 Spin-polarized scanning tunneling spectroscopic (SP-STS) studies of the intrinsic electronic heterogeneity in ferromagnetic (FM) cobaltites and manganites , JING SHI, LI ZHANG, WEI-HSUN LIN, HAO CHU, CAMERON HUGHES, NAI-CHANG YEH, California Institute of Technology — The perovskite manganites $Ln_{1-x}A_xMnO_3$ and cobaltites $Ln_{1-x}A_xCoO_3$ (Ln: trivalent rare earth ions; A: divalent alkaline earth ions) exhibit interesting magnetotransport properties in their FM state: the former show colossal magnetoresistance (CMR) and the latter display giant anomalous Hall effect (AHE), where the AHE coefficient peaks near the Curie temperature (T_C). These novel phenomena are associated with the intrinsic electronic heterogeneity resulting from strongly correlated multi-valence multi-spin electronic configurations. We perform SP-STS studies on epitaxial films of $La_{0.7}Ca_{0.3}MnO_3$ and $La_{1-x}A_xCoO_3$ (A = Sr, Ca; $0.4 \leq x \leq 0.6$). In the manganites electronic heterogeneity on the scale of $\sim 10^2$ nm is found to develop below T_C and diminish with increasing magnetic field. A surface FM insulating phase is manifested by the spin filtering effect and is attributed to the MnO_2 surface layer. Similar studies are conducted on the cobaltites to reveal possible correlation between magnetic clustering effects and the Berry phase.

12:27PM W17.00005 Epitaxial growth and characterization of strained $LaCoO_3$ on Si (100) , AGHAM POSADAS, University of Texas at Austin, MORGANN BERG, HOSUNG SEO, DAVID SMITH, ALEXANDER KIRK, DMITRY ZHERNOKLETOV, ROBERT WALLACE, ALEX DE LOZANNE, ALEXANDER DEMKOV — $LaCoO_3$ is a correlated oxide that normally has a diamagnetic ground state in bulk. The material undergoes a spin-state transition and becomes paramagnetic at higher temperatures. In this work, we report the epitaxial growth of strained $LaCoO_3$ on silicon via a fully-relaxed $SrTiO_3$ buffer layer using molecular beam epitaxy (MBE). We confirm that the strained $LaCoO_3$ becomes ferromagnetic with a Curie temperature of 85 K, similar to recent reports for films grown by pulsed laser deposition. We will discuss the issues related to the MBE growth of $LaCoO_3$ and show results of x-ray diffraction, x-ray photoelectron spectroscopy, transmission electron microscopy, and SQUID magnetometry measurements on $LaCoO_3$ films grown on silicon.

12:39PM W17.00006 Control of the Octahedral Tilts in Lanthanum Cobaltite and the Impact on Magnetic Properties , MICHAEL BIEGALSKI, HAILE AMBAYE, VALERIA LAUTER, HANS CHRISTEN, Oak Ridge National Labratory — Strain can be accommodated in two ways in perovskite materials, either via the extension of bond lengths or the rotation of the relatively rigid BO_6 octahedra. To explore the effects of octahedral tilts on magnitism, we have used epitaxy to control the octahedral tilting in the unit cell of $La_{0.5}Sr_{0.5}CoO_3$ by growth on cubic $La_{0.3}Sr_{0.7}Al_{0.65}Ta_{0.35}O_3$ (LSAT) and orthorhombic $NdGaO_3$. From X-ray diffraction, the films grown on LSAT were shown to have a cubic structure whereas the films grown on $NdGaO_3$ show an orthorhombic distortion. Due to the large paramagnetic response of the $NdGaO_3$ polarized neutron reflectometery was used to probe the magnetic structure of the films. The polarized neutron reflectometry demonstrates that changes in the crystal structure due to the epitaxially imposed symmetries alter the magnetism in these materials.

12:51PM W17.00007 Magnetic Phase Separation in Oxygen Doped $SrCoO_{3-y}$[1] , F.J. RUECKERT, C.K. XIE, Y.F. NIE, B.O. WELLS, J.I. BUDNICK, W.A. HINES, University of Connecticut, B. DABROWSKI, Northern Illinois University — $SrCoO_{3-y}$ forms the perovskite structure with oxygen vacancies and is ferromagnetic for $y<0.25$. We have performed a study on polycrystalline samples, controlling the oxidation state using electrochemistry. Under these conditions we have found that magnetically the system segregates into separate, stable phases that correspond to $SrCoO_{2.75}$($T_C = 165$ K), $SrCoO_{2.875}$($T_C = 220$ K), and $SrCoO_3$ ($T_C = 280$ K), with two phase behavior for intermediate oxygen concentrations. Surprisingly, these same samples show only a single structural phase that evolves smoothly. We have recently learned to grow high quality epitaxial films of $SrCoO_y$, allowing for more typical single crystal diffraction experiments. Our initial results indicate that magnetic phase separation is suppressed in the films.

1:03PM W17.00008 Examining the Magnetic Properties of $LaCoO_3$ Thin Films Using Magnetic Force Microscopy[1] , MORGANN BERG, AGHAM POSADAS, ALEX DE LOZANNE, ALEXANDER DEMKOV, Department of Physics, The University of Texas at Austin — In contrast to the non-magnetic ground state of bulk $LaCoO_3$ (LCO) at low temperatures, ferromagnetism has been observed in elastically strained thin film specimens. The origins of ferromagnetism in strained LCO thin films have been obscured by conflicting experimental results. Pulsed laser deposition (PLD) is the current standard of preparation techniques used to grow thin films of LCO, but results from thin film LCO samples prepared by PLD have been questioned on the basis of chemical inhomogeneity and film defects. Using magnetic force microscopy, we investigate the microscale magnetic properties of strained thin films of LCO prepared by molecular beam epitaxy and deposited on lanthanum aluminate and strontium titanate substrates. We observe these properties across a temperature range surrounding the Curie temperature ($T_c \sim 80$K) and compare our results to global magnetic characteristics of these films as measured by a SQUID magnetometer.

[1]Supported by NSF-DMR and NSF-IGERT.

1:15PM W17.00009 Magnetic resonance at the Verwey transition in epitaxial Fe_3O_4[1] , M. PECHAN, B. KASTER, J. DOU, Dept. of Physics, Miami University, Oxford, OH, P. JAYATHILAKA, C. BAUER, C. MILLER, Dept. of Physics, Center for Integrated Functional Materials, University of South Florida, Tampa, Florida — Fe_3O_4 is of interest due to its potential applications in the field of spintronics. Previous studies on magnetite films and Fe_3O_4/Cr/NiFe spin valves indicate the presence of a uniaxial anisotropy when the magnetite is grown in a magnetic field. Two 170 nm thick films of Fe_3O_4 were reactively sputtered simultaneously onto (100) MgO substrates without and with an applied field (100 Oe). Epitaxy was confirmed by in-plane x-ray diffraction and optimal oxygen stoichiometry is confirmed by the 119 K Verwey transition temperature (T_V). Ferromagnetic resonance (FMR) measurements at 35 GHz in the plane of the film revealed four-fold anisotropy confirming high quality (100) epitaxy, with an additional uniaxial contribution present in the field-grown sample. Temperature dependent FMR on the sample grown without field clearly reflects T_V in the linewidth and in-plane and out-of-plane anisotropies. The in-plane uniaxial anisotropy for the sample grown with field exhibits an even stronger temperature response at T_V. Detailed discussions of thermal variations of magnetization, anisotropy and relaxation processes will be presented.

[1]Supported by the US Dept. of Energy at MU, and NSF at USF.

1:27PM W17.00010 LuFe2O4 nanostructures on MgO(111) substrate[1] , XIAOSHAN XU[2], Oak Ridge National Lab, WENBIN WANG, University of Tennessee, GAI ZHENG, PAUL SNIJDER, THOMAZ WARD, JIAN SHEN, Oak Ridge National Lab — $LuFe_2O_4$ nanostructures have been deposited on MgO(111) substrate using pulsed laser deposition. Substrate temperature and gas pressure are found to be very critical to form the $LuFe_2O_4$ phase. Scanning electron microscopy (SEM) and atomic force microscopy (AFM) show very well crystalized morphology with triangular symmetry. The common orientations of the nanosctructurals are consistent with epitaxial growth. X-ray diffraction data show that (001) face of $LuFe_2O_4$ is parrallel to the substrate face MgO(111).

1:39PM W17.00011 Edge-Imposed Domain Ordering in Antiferromagnetic LaFeO3 Nanostructures[1] , J.K. GREPSTAD, E. FOLVEN, T. TYBELL, Norwegian University of Science and Technology, A. SCHOLL, A. YOUNG, Advanced Light Source, LBNL, S.T. RETTERER, Oak Ridge National Laboratories, Y. TAKAMURA, University of California, Davis — The antiferromagnetic (AFM) domain structure of submicron-sized $LaFeO_3$ nanostructures was imaged with photoemission electron microscopy in combination with x-ray magnetic linear dichroism. These nanostructures were defined in epitaxial $LaFeO_3$ thin films using e-beam lithography and Ar^+ ion implantation to locally destroy the magnetic order in the surrounding matrix. Extended domains were found to form along the perimeter of rectangular-shaped islands, when their edges were aligned with the in-plane <100> axes of the cubic $SrTiO_3$ substrate. The AFM spin axis of these domains was confined to lie within the film plane, aligned with the edges of the nanostructures. This domain configuration predominated for nanoislands scaled down to 500x500 nm^2. However, no edge-imposed domain ordering was observed for rectangular islands rotated by 45° with respect to the in-plane crystalline axes, suggesting a magnetocrystalline origin of the extended edge-bound AFM domains. These findings may prove important to spintronic devices relying on exchange-biased nanostructures, where domain engineering in antiferromagnets remains relatively unexplored and has the potential to provide new device opportunities.

1:51PM W17.00012 Fe_3O_4/ZnO: a high-quality magnetic oxide-semiconductor heterostructure , ANDREAS MUELLER, MARKUS PAUL, DOMINIK KUFER, SEBASTIAN BRUECK, Experimentelle Physik 4, Universitaet Wuerzburg, EBERHARD GOERING, Max-Planck-Institut fuer Metallforschung, Stuttgart, MARTIN KAMP, Technische Physik, Universitaet Wuerzburg, JO VERBEECK, HE TIAN, Electron Microscopy For Materials Science, University of Antwerp, MICHAEL SING, RALPH CLAESSEN, Experimentelle Physik 4, Universitaet Wuerzburg — Magnetite (Fe_3O_4) is ranked among the most promising materials to use as a spin injector into a semiconducting host. We demonstrate epitaxial growth of Fe_3O_4 films on ZnO which presents a further step towards incorporation of magnetic materials into semiconductor technology. X-ray spectroscopy results evidence that the iron-oxide is phase-pure and nearly stoichiometric magnetite. Diffraction measurements indicate highly oriented epitaxy and almost complete structural relaxation. The microstructure consists of domains separated by anti-phase boundaries or twin boundaries as a result of island-like growth. The magnetic behavior shows a rather slow approach to saturation at high fields in comparison with bulk crystals, which is likely due to antiferromagnetic coupling at the anti-phase boundaries.

2:03PM W17.00013 The control of Morin transition temperature on hematite α-Fe_2O_3(0001) thin film , SEONGHUN PARK, J.-H. PARK, POSTECH, B.-G. PARK, J.-Y. KIM, PAL — The Morin transition of α-Fe_2O_3(0001) thin film was investigated by using soft x-ray absorption spectroscopy (XAS).The epitaxial thin films were grown by cycles of evaporation and post-oxydation method on Al_2O_3(0001) substrate. The x-ray diffraction (XRD) revealed that the strain is changed with variation of the thickness and the buffer layer. The Morin temperature were measured by x-ray magnetic linear dichroism (XMLD).Interestingly, the Morin transition temperature increased up to room temperature in hematite thin film. In addition, the Co metal overlayer suppressed the Morin transition temperature. Finally, we discuss the magnetic anisotropy including the strain and the interlayer exchange interaction.

Session W18 DCOMP: Many Body D172

11:15AM W18.00001 Exact asymptotes of static and dynamic correlation functions of the 1D Bose gas , ADITYA SHASHI, Rice University, LEONID GLAZMAN, Yale University, JEAN-SEBASTIEN CAUX, Institute for Theoretical Physics, Universiteit van Amsterdam, Amsterdam, The Netherlands, ADILET IMAMBEKOV, Rice University — Recent experiments with ultracold atomic gases have provided realizations of one-dimensional systems of bosons with contact interactions, described by the Lieb-Liniger model. These experiments have revived interest in the correlation functions for this model. Since a fully analytical calculation of the correlation functions is still lacking, our results [1] represent a significant step forward. We have combined field theoretical approaches with an analysis of the finite size scaling of exact form factors of the Lieb-Liniger model to analytically calculate "non-universal" prefactors in the long-distance behavior of correlation functions as well as prefactors of singularities in dynamic response functions such as the density structure factor and spectral function. We have also proved the existence of singularities within a continuum spectrum.

11:27AM W18.00002 Correlation functions of nonlinear Luttinger liquids as Fredholm determinants , YINBIN MA, ADILET IMAMBEKOV, Rice University — One dimensional quantum liquids are often described within an effective linear hydrodynamic approach known as Luttinger liquid theory. As the principal simplification, a generic spectrum of the constituent particles is replaced by a linear one, which leads to a linear hydrodynamic theory. It has been shown recently [1] that the nonlinearity of the generic spectrum leads to a significant modification of the dynamic response functions. Their description can be achieved within the universal framework of nonlinear Luttinger liquid theory. We show here that correlation functions within such approach can be expressed as Fredholm determinants, and evaluate them in low energy regions for arbitrary interaction strength and small temperatures.

[1] "Universal theory of nonlinear Luttinger liquids," A. Imambekov and L.I. Glazman, Science 323, 228 (2009)

11:39AM W18.00003 Ab initio Low-Dimensional Physics Opened Up by Constrained RPA for Energy and Space: Applications to LaFeAsO and κ-$(BEDT\text{-}TTF)_2X$, KAZUMA NAKAMURA, University of Tokyo, JST-CREST, YOSHIHIDE YOSHIMOTO, Tottori University, YOSHIRO NOHARA, MASATOSHI IMADA, University of Tokyo — Studies on outstanding electron correlation effects such as non-Fermi liquid behavior and unconventional superconductivity discovered in systems with low-dimensional anisotropy have continuously been at a front of condensed matter physics. Analyses for 1D or 2D simplified models have played a primary role in understanding essence of correlation effects, but to a large extent, the studies rely on ad hoc adjustable parameters as in the Hubbard models. We develop a new ab initio downfolding scheme for deriving effective low-energy models with low spatial dimensions [1]. The scheme is based on constrained random-phase-approximations by imposing constraints not only in "energy" but also in "space". We show real applications for 2D-layered superconductors of LaFeAsO and κ-$(BEDT\text{-}TTF)_2X$. The derived interactions in the effective models become short ranged essentially within up to next-nearest neighbors and thus justify multiband 2D Hubbard models as effective models for these materials from first principles. This work is supported from MEXT Japan under grant numbers 22740215 and 22104010.

11:51AM W18.00004 Beyond Landau Adiabacity: Weak Interaction Quenches in a Fermi Gas

, STEFAN KEHREIN, University of Munich (LMU), Germany, MICHAEL MOECKEL, Max Planck Institute of Quantum Optics, Garching, Germany — The crossover from Landau's Fermi-liquid paradigm with adiabatic switching on of the interaction to a sudden interaction quench is investigated [Phys. Rev. Lett. 100, 175702 (2008); Ann. Phys. 324, 2146 (2009); New J. Phys. 12, 055016 (2010)]. The real time dynamics for weak interactions is calculated in a systematic expansion and one finds three clearly separated time regimes: (i) An initial buildup of correlations where the quasiparticles are formed. (ii) An intermediate quasi-steady prethermalized regime resembling a zero temperature Fermi liquid with a nonequilibrium quasiparticle distribution function. (iii) The long-time limit described by a quantum Boltzmann equation leading to thermalization of the momentum distribution function. This thermalization behavior is contrasted with interaction quenches in 1d models.

12:03PM W18.00005 Dynamical Freezing of Response in Driven Many-Body Quantum System

, ARNAB DAS, Theoretical Division (T-4), Los Alamos National Laboratory, MS-B213, Los Alamos, NM 87545 — We show, that the response of a periodically driven quantum many- body system may freeze drastically, when driven with certain combinations of driving parameters (amplitude and frequency). We demonstrate this effect with analytical results for a broad class of integrable quantum spin models (illustrated particularly for one-dimensional Transverse Ising Model)and direct numerical integration data for large system-size. We show that the immunity of the freezing behavior to external noise can be controlled arbitrarily by controlling the strength of the local (on-site) field.

12:15PM W18.00006 Bethe-Salpeter Equation calculations of transition metal $L_{2,3}$ edge x-ray spectra including multiplet effects[1]

, J. VINSON, U. Washington, E.L. SHIRLEY, NIST, J.J. REHR, U. Washington — Calculations of x-ray spectra at transition metal $L_{2,3}$ edges often present theoretical difficulties due to strong core-hole multiplet effects. Here we discuss an *ab initio* method for treating these effects following the Bethe-Salpeter Equation (BSE) approach of Shirley.[2] The method builds in spin-orbit interactions, intra-atomic Coulomb integrals, core-hole screening, and band-structure effects, and thus accounts for multiplet effects without the need for phenomenological ligand-field parameters. The method has been implemented in the core-level BSE code OCEAN,[3] which uses as input wavefunctions from planewave, pseudopotential DFT calculations and PAW transition matrix elements. Examples are presented for several transition metal systems and compared with experiment.

12:39PM W18.00008 Real Space Green's Function Calculations of RIXS[1]

, J.J. KAS, J.J. REHR, U. Washington, J.A. SOININEN, U. Helsinki — We present an *ab initio* theory of resonant inelastic x-ray scattering (RIXS) based on the real-space multiple scattering Green's function (RSGF) formalism and a quasi-boson model Hamiltonian. It is shown that the RIXS spectrum is quasi-local in nature, depending primarily on the Green's function close to the absorbing site. Based on several assumptions, we derive an approximation to the RIXS spectrum in terms of a convolution of the x-ray absorption and x-ray emission spectra. In addition, quasi-particle self-energy and other many-body effects are calculated using a many-pole model dielectric function, and included via a convolution of the RIXS spectrum with an energy dependent spectral function. Core hole effects are also investigated. The method is implemented in an extension of the RSMS code FEFF90[2] and illustrated with several examples. Results are found to be in qualitative agreement with experiment.

12:51PM W18.00009 Finite-Temperature Constraint-Pairing Mean Field Theory[1]

, JIANMIN TAO, GUSTAVO SCUSERIA, Rice University — Recently Tsuchimochi and Scuseria have developed a constrained-pairing mean-field theory (CPMFT), based on the Hartree-Fock-Bogoliubov theory. Application to molecular systems shows that CPMFT can accurately describe the binding energy curve in the dissociation of molecules, where electron correlation is strong. However, because CPMFT is a zero-temperature theory, it is not suitable for the description of high-temperature superconductivity and normal state of high-temperature superconductors. Here a finite-temperature generalization is formulated for the thermodynamic state of quantum many-body systems.

1:03PM W18.00010 Fermionic duality approach to strongly-interacting lattice models[1]

, JOE MITCHELL, TIGRAN SEDRAKYAN, VICTOR GALITSKI, University of Maryland — We derive an exact Grassmann path-integral representation for strongly interacting fermion systems that is dual to the conventional Hubbard-Stratonovich approach. In contrast to the latter, we decouple the interaction Hamiltonian by introducing additional (dual) fermionic fields. This fermionic decoupling naturally forms in particle-hole channels and leads to alternative order parameters given in terms of the dual fields. The new formalism is tested by calculating the partition function in a simple solvable model with four-fermion interaction and is argued to be very effective for strong or repulsive interactions.

1:15PM W18.00011 ABSTRACT WITHDRAWN –

1:27PM W18.00012 Breakdown of the coherent state path integral: two simple examples[1]

, JUSTIN WILSON, VICTOR GALITSKI, Dept. of Physics, University of Maryland — We show how the time-continuous coherent state path integral breaks down for both the single-site Bose-Hubbard model and the spin path integral. Specifically, when the Hamiltonian is quadratic in a generator of the algebra used to construct coherent states, the path integral fails to produce correct results following from an operator approach. As suggested by previous authors, we note that the problems do not arise in the time-discretized version of the path integral. Further, a naïve use of the semiclassics agrees with our conclusions.

Session W19 GMAG DMP: Focus Session: Novel Magnetic Devices D170

11:15AM W19.00001 Novel Spintronic Device-Terahertz Magnon-Photon Laser , BORIS TANKHILEVICH, Terahertz Technologies LLC — A novel spintronic -based method of generating THz radiation is proposed. The method is based on pumping of non-equilibrium electrons into the upper (spin-down) sub-band of spin-polarized half-metallic ferromagnets or ferromagnetic semiconductors, which makes it possible to build tunable, narrow-band, high-power THz sources. Non-equilibrium electrons pumped into the spin-down subband rapidly emit non-equilibrium magnons with THz frequency, pass into highly excited states of the spin-up subband, and fall into the ground state due to interaction with the equilibrium spin-up electrons or by emitting optical phonons. The mechanism of magnon generation is similar to a three-level conventional laser, and at a critical pumping intensity, which depends on the magnon damping, magnon lasing begins. In this regime the number of excited magnons increases exponentially with time. Merging of two THz magnons with frequency f generates a THz photon with frequency 2f. Thus, a magnon laser becomes a THz photon laser. The proposed one-stage device is capable of generating THz power being of orders of milliwatt and is tunable by tuning the magnetic field and/or the bias. The device has nano-dimensions and can be mass produced on a large scale. Recently THz radiation by spin-polarized current in a ferromagnetic structure was observed. However, the material used in this experiment has not met the conditions for magnon lasing.

11:27AM W19.00002 Micro-Structured Ferromagnetic Tubes for Spin Wave Excitation , ALEXANDER KOZHANOV, DANIEL OUELLETTE, MARK RODWELL, University of California Santa Barbara, DOK WON LEE, SHAN X. WANG, Stanford University, S. JAMES ALLEN, University of California Santa Barbara — Small scale magnetostatic spin wave devices are potentially important for on-chip filters for communication systems and spin wave logic devices. Low efficient coupling the electronic signals into the spin waves as well as coupling-out makes it difficult to build logical circuits especially when structures are scaled down to nanometer sizes. In this work we study the effect of external biasing magnetic field on the propagation of backward volume magnetostatic spin waves (BVMSW) in ferromagnetic CoTaZr stripe with micron sized ferromagnetic tubes fabricated at the ends. Spin waves are excited by shorted coplanar waveguides signal line of which is placed inside the tubes. Ferromagnetic tubes placed at the ends of the stripe form closed magnetic circuit that traps the RF magnetic field produced by the coupling loop. Transmission S-parameters of fabricated structures were measured using a vector network analyzer in the frequency range (0.5-20) GHz and biasing magnetic fields (0-1000) Oe. Experimental data is analyzed with use of theoretical model for BVMSW in ferromagnetic stripe. This work is supported by the Nanoelectronics Research Initiative (NRI) - Western Institute of Nanoelectronics (WIN).

11:39AM W19.00003 Ferromagnetic STM tip operating as a Spin-diode[1] , POLIANA H. PENTEADO, University of São Paulo, FABRICIO M. SOUZA, Federal University of Uberlândia, ANTÔNIO C. SERIDONIO, UNESP, RENATO M. COUTINHO, EDSON VERNEK, Federal University of Uberlândia, J. CARLOS EGUES, University of São Paulo — We study spin-dependent transport in a system composed of a ferromagnetic STM tip coupled to an adsorbed atom (adatom) and to a host metallic (non-magnetic) surface. Electrons can tunnel directly from the tip to the surface or through the adatom. Our calculation is based on the nonequilibrium Green functions technique (Keldysh formalism). We self-consistently calculate the adatom spin occupation and its magnetization as a function of the tip position. We find that the adatom becomes magnetized when the tip approaches it; this magnetization switches sign as the voltage changes from forward to reverse bias. We also calculate the spin-resolved currents. If the tip is near the adatom, we obtain the spin-diode effect [PRB **75**, 165303 (2007)] - i. e., unpolarized current for positive bias and polarized current for reverse bias - when the adatom is singly occupied. We also observe Friedel oscillations in the current as the tip-adatom distance increases [F. M. Souza, P. H. Penteado, et al. - to be submitted].

11:51AM W19.00004 Spin voltage generation across rare earth spin filter barriers[1] , GUOXING MIAO, MIT, JOONYEON CHANG, KIST, JAGADEESH MOODERA, MIT — When a metal is in close contact with a rare-earth based magnetic compound, strong exchange interaction exists between the localized 4f electrons and the free moving conduction electrons. One important consequence is that the spin degeneracy among the conduction electrons is lifted, showing up as an effective Zeeman splitting higher than tens of Tesla in low dimensional systems such as graphene and other 2DEG. We perform our work using a vertical transport geometry, which consists of double spin filtering barriers based on a ferromagnetic Eu chalcogenide - EuS. A thin Al metallic layer is sandwiched in the middle and its conduction electrons thus experience the strong spin splitting, which is subsequently detected via the spin filtering effect. A spontaneous spin dependent voltage appears across such a device, and its polarity is directly determined by the EuS/Al interface. The voltage level difference between the spin-parallel and -antiparallel configurations is as large as a few mV. Such spin splitting also induces a clear universal behavior in the observed TMR bias dependence. Such spin voltage effect offers a possibility of directly converting magnetic exchange energy into electrical power.

12:03PM W19.00005 Generation of spin currents due to mechanical rotation , MAMORU MATSUO, Kyoto Univ., ASRC-JAEA, JUN'ICHI IEDA, ASRC-JAEA, CREAST-JST, EIJI SAITOH, ASRC-JAEA, IMR Tohoku Univ., CREST-JST, SADAMICHI MAEKAWA, ASRC-JAEA, CREST-JST — In the frontier of spintronics, much attention is paid on the control and generation of spin currents. Due to the exciting progress of nanomechatrononics, the importance of mechanical manipulation of electron spin will increase. We discuss theoretically effects of mechanical rotation on spin currents using generally covariant Dirac equation with gauge fields in the non-relativistic limit. We derive semi-classical equations of motion for a wavepacket of electrons in two dimentional planes subject to the spin-orbit interaction argumented by a mechanical rotation. We show that a circular spin current is created by the mechanical rotation with a magnetic field. The magnitude of the spin current becomes $10^8 \mathrm{A/m}^2$ in Pt with the magnetic field $\approx 1\mathrm{T}$ and the rotational velocity $\approx 1\mathrm{kHz}$.

12:15PM W19.00006 Magnetic Field Effects on Mechanical Cantilevers with Deposited Thin Film Micromagnets[1] , ROSA ELIA CÁRDENAS, FRANCISCO MÁRQUEZ, JOHN T. MARKERT, The University of Texas at Austin, Department of Physics — We report on the techniques used to deposit magnetic material onto mechanical cantilevers. The deposition of the magnetic material, permalloy, onto the cantilevers was achieved by using a precise masking technique before mounting the cantilevers inside an electron beam evaporation chamber. This method resulted in a mechanical cantilever with a deposited micromagnet on its tip. A typical size of the resulting micromagnet is 200 nm thick by 20 microns wide by 10 microns in height. Using a laser interferometer, the driven response of the cantilevers with the deposited micromagnets are currently being studied in vacuum as a function of the external magnetic field. We will analyze the magnetic-field-dependent changes in the resonant frequencies and the quality factors of the cantilevers to determine the micromagnet net moment and anisotropy constants.

12:27PM W19.00007 Torque magnetometry of permalloy-coated microcantilevers using higher order vibrational modes , JOSEPH LOSBY, JACOB A.J. BURGESS, Department of Physics, University of Alberta and National Institute for Nanotechnology, DOUGLAS VICK, National Institute for Nanotechnology, JOHN P. DAVIS, Department of Physics, University of Alberta, WAYNE K. HIEBERT, National Institute for Nanotechnology, MARK R. FREEMAN, Department of Physics, University of Alberta — There has been an accumulation of recent interest in the development of magnetometry techniques facilitating the use of nano- and micro-resonators. A finite element model describing the interaction of a magnetic cantilever driven at its fundamental resonance frequency by an external field is described and illustrated for the simple case of a straight domain wall propagating across the cantilever during magnetization reversal. The experimental results are compared to the finite element mechanical transformation of Landau-Lifshits-Gilbert based micromagnetic simulations. This idea is then extended to higher order (flexural and torsional) modes, with the intent of moving towards increased sensitivity and functionalization of magnetometers for the observation of quasi-static magnetization processes.

12:39PM W19.00008 Forces due to Patterned Magnetic Traps within Microfluidic Channels , M. HOWDYSHELL, G. VIEIRA, A. CHEN, M. SIMON, M. POIRIER, R. SOORYAKUMAR — An array of microscopic ferromagnetic disks patterned onto a silicon surface has been previously utilized to trap and transport magnetic microspheres as well as magnetically labeled biological cells across the surface. The transport is activated through programmable weak external magnetic fields that do not damage the cells and enable remote control on the magnitude and direction of the fields. In this talk we present results in which the array of magnetic bits is imprinted within microfluidic channels where now competing hydrodynamic drag forces come into play. The trapping forces on individual microspheres are directly determined from the flow rates required to overcome the local magnetic forces. These findings are compared to results derived from micromagnetic simulations of the magnetic profile of individual disks. The fluid flow within the channel is also used to stretch DNA molecules tethered between two microparticles. With one of the ends trapped on a magnetic disk, the extension is controlled by the fluid flow rate. Comparisons to DNA stretching achieved with conventional magnetic tweezers reported in the literature serve as an additional calibration of the measured forces.

12:51PM W19.00009 Giant Magnetioimpedance in Co-Based Amorphous Ribbons Coated in Magnetic Nanoparticles for Biosensing Applications , N. LAURITA, A. CHATURVEDI, K. STOJAK, S. CHANDRA, M.H. PHAN, H. SRIKANTH, University of South Florida — Giant magnetoimpedance (GMI) is a large change in the ac impedance of a ferromagnetic conductor subject to a dc magnetic field. It forms the basis for developing highly sensitive magnetic sensors. We report studies aimed at developing GMI as a magnetic biosensing technique. We have investigated the GMI effect and its field sensitivity in Co-based amorphous alloys with and without coated magnetic nanoparticles. Fe_3O_4 and $CoFe_2O_4$ nanoparticles (mean size, 5-10 nm) were patterned onto the ribbon surfaces and the number of particle layers was varied from 10 to 80. The influences of particles size, concentration, and layer thickness on the GMI and field sensitivity have been investigated systematically. The coating of the nanoparticles has been shown to enhance the GMI and field sensitivity, both of which increase with increase of particle concentration and layer thickness. Overall, our studies demonstrate the possibility of using GMI as a magnetic biosensor with high sensitivity for applications in biomolecular detection.

1:03PM W19.00010 Correlation between magnetic softness, sample surface and magnetoimpedance in $Co_{69}Fe_{4.5}X_{1.5}Si_{10}B_{15}$ (X = Ni, Al, Cr) amorphous ribbons , A. CHATURVEDI, T. DHAKAL, S. WITANACHCHI, M.H. PHAN, H. SRIKANTH, University of South Florida, A.T. LE, Hanoi University of Technology, Vietnam — In this work we have studied the giant magnetoimpedance (GMI) effect and its field sensitivity (η) in $Co_{69}Fe_{4.5}X_{1.5}Si_{10}B_{15}$ (X = Ni, Al, Cr) amorphous ribbons in the frequency (f) range of 0.1 to 10 MHz. We find that at f $<$ 5 MHz, the GMI effect and η reach the largest values for the Al-containing sample and the smallest values for the Ni-containing sample, while an opposite trend is observed at f $>$ 5 MHz. Magnetization and atomic force microscopy (AFM) experiments reveal that the largest values of the low-frequency GMI effect and η for the Al-containing sample result from the largest value of magnetic permeability, while the largest values of the high-frequency GMI effect and η for the Ni-containing sample are attributed to the smallest surface roughness of this sample. These results point to the importance of the sample surface in determining high-frequency GMI behavior. A correlation between the sample surface and high-frequency GMI is established in the investigated ribbons.

1:15PM W19.00011 Modulating the Magnetic Field to Improve Magnetic Sensors , ALAN EDELSTEIN, JONATHAN PETRIE, JONATHAN FINE, GREG FISCHER, US Army Research Laboratory, JAMES BURNETTE, NIST Gaithersburg, GOPAL SRINIVASAN, SANJAY MANDAL, Oakland University, US ARMY RESEARCH LABORATORY COLLABORATION, NIST GAITHESBURG COLLABORATION, OAKLAND UNIVERSITY COLLABORATION — The sensitivity of most magnetic sensors is affected by $1/f$ noise. Modulating the magnetic field to be detected by magnetic sensors can improve their performance by minimizing the effect of this $1/f$ noise and, in some cases, also have them operate in a narrow frequency band where they have higher sensitivity. We present approaches for modulating the field. One approach is the MEMS flux concentrator can be used with small magnetic sensors and another, based on using a rotating disc containing flux concentrators that can be used with large magnetic sensors, such as magnetoelectric sensors, that have an increased sensitivity at their mechanical resonance frequency. Sidebands observed around the modulation frequency demonstrate the applicability of these approaches. The MEMS flux concentrator has improved the signal to noise ratio in the power spectrum by a factor of 15. The sensors have the potential to achieve sensitivities of a few $pT/Hz^{1/2}$ at 1 Hz.

1:27PM W19.00012 Ultra high sensitivity, room temperature magneto-optic field sensor made of ferromagnetic bismuth rare-earth iron garnet thick films , DONG HO WU, ANTHONY GARZARELLA, Naval Research Laboratory, VINCE FRATELLO, Integrated Photonics, Inc — The ferrimagnetic bismuth rare-earth iron garnet $(BiGdLu)_3(FeGa)_5O_{12}$ thick film has a specific Faraday rotation θ_S of 0.09 $^\circ$/mm at 1550 nm and excellent transparency at infrared wavelengths. Using the thick film we recently have demonstrated a magneto-optic (MO) field sensor with a sensitivity of about $10^{-14}T/Hz^{1/2}$, comparable with SQUID. The sensor is made of all dielectric materials including the bismuth rare-earth iron garnet and optical fibers, and is operated at room temperature without any cooling requirement. The MO field sensor is capable to measure a magnetic field over a very large dynamic range (from a very weak field to a very high magnetic field exceeding several hundred Tesla) and over a very wide frequency range, which may be from DC to a few hundred GHz. However, presently, our MO sensor's frequency range is limited from DC to 2 GHz. We think that this limited frequency range is due to the presence of magnetic domains in the bismuth rare-earth iron garnet film. In this presentation we will report our experimental results obtained from this MO field sensor as well as the effect of magnetic domains.

1:39PM W19.00013 Spin-Flipping at Sputtered Co(90)Fe(10)/Cu Interfaces[1] , HOANG YEN THI NGUYEN, RAKHI ACHARYYA, WILLIAM P. PRATT JR., JACK BASS, Michigan State University — Knowledge of the spin-flipping probability, $P_{F/N} = 1 - \exp[-\delta(F/N)]$, at ferromagnetic/non-magnetic (F/N) interfaces in the Current-Perpendicular-to-Plane (CPP) geometry is minimal [1,2]. We use a new technique [2] to find δ(CoFe/Cu) at 4.2K, where CoFe = Co(90)Fe(10). With thin (3 nm) CoFe layers, the spin-diffusion length of CoFe $\sim$ 12 nm doesn't mask spin-flipping due to δ. Our most important samples, sensitive to δ(CoFe/Cu), have the form FeMn/Py/Cu/X/Cu/Py/FeMn. Here Py = Ni(80)Fe(20), the antiferromagnet FeMn pins the two Py layers to flip at a much higher field than X = $[CoFe(3)/Cu(1.4)]_n CoFe(3)$, and 1.4 nm of Cu couples the CoFe layers ferromagnetically so X reverses as a unit. We measure, versus the number of repeats n, the change in specific resistance, $A\Delta R$ = AR(AP) – AR(P), between states where the X moment is anti-parallel (AP) or parallel (P) to the pinned Py moments. CPP current flows through area A. Our resulting best estimate is δ(CoFe/Cu) $\approx$ 0.2. [1] J. Bass and W.P.Pratt Jr., J. Phys. Cond. Matt. **19**, 183201 (2007). [2] B. Dassonneville et al., Appl. Phys. Lett. **96**, 022509 (2010).

1:51PM W19.00014 Magnetic Properties of Niobium-Permalloy hybrid system , JIYEONG GU, JILL PESTANA, DAVID CHRISTIANSEN, Department of Physics and Astronomy, California State University, Long Beach — Ferromagnet/superconductor hybrid system has been studied intensively due to the proximity effect between ferromagnetism and superconductivity. Not only the superconducting property changes because of the different magnetic configuration, the presence of the superconductivity can also often drastically change the magnetic properties of the ferromagnets. In our current work we focused on the investigation of the magnetic property change of the Nb-Py (Permalloy; NiFe) hybrid system through the superconducting transition. Nb-Py bilayer and trilayers were fabricated using Multi-target sputtering system. Magnetization was measured by Physical Property Measurement System using the Vibrating Sample Magnetometer (VSM) or Alternating Current Measurement System (ACMS) options. In addition to the magnetometry measurement, we also measured magneto optical Kerr effect. Magnetization changed when the system goes through the superconducting transition; however the result varied depending on many parameters, such as magnetic measurement history, cooling or warming rate, and measurement method. Magnetic responses obtained from different methods would be compared and discussed.

2:03PM W19.00015 Localized magnetism on the surface of niobium: experiments and theory[1] , THOMAS PROSLIER, Argonne natl lab, JOHN ZASADZINSKI, Illinois Institute of technology, GIANLUIGI CIOVATI, Jefferson lab, MIKE PELLIN, Argonne natl lab — The presence of magnetic impurities in native niobium oxides have been confirmed by Point contact spectroscopy (PCT), SQUID magnetometry and Electron paramagnetic resonance (EPR). All niobium (Nb) samples displayed a small impurity contribution to the magnetic susceptibility at low temperatures which exhibited Curie-Weiss behavior, indicative of weakly coupled localized paramagnetic moments. By examining Nb samples with widely varying surface-to-volume ratios it was found that the impurity contribution is correlated with surface area. Tunneling measurements which use the native oxide layers as barriers exhibit a zero-bias conductance peak which splits in a magnetic field > 4T, consistent with the Appelbaum model for spin flip tunneling. Viewed together the experiments strongly suggest that the native oxides of Nb are intrinsically defective, and consistently exhibit localized paramagnetic moments caused by oxygen vacancies in Nb_2O_5. The computation of the surface impedance (R_S) in presence of magnetic impurities in the Shiba approximation reveals the saturation at low temperature of Rs, suggesting that magnetic impurities are responsible for the so-called residual resistance.

Session W20 DMP GERA FIAP: Focus Session: Thermoelectric Materials: Clathrates and Oxides D168

11:15AM W20.00001 The Atomic Structure of Ga and Ge in Ba-Ga-(Si,Ge) Clathrate , A.N. MANSOUR, NSWCCD, J.B. MARTIN, W. WONG-NG, NIST, G.S. NOLAS, USF — Compression studies on $Sr_8Ga_{16}Ge_{30}$ type I clathrate revealed a 3 fold increase in "ZT" [J. F. Meng et al., J. Appl. Phys., 89, 1730 (2001)]. Substitution of Si for Ge in Ba-Ga-Ge clathrate could mimic the effect of bulk compression, and subsequently enhance "ZT". Recent studies on Si substituted Ba-Ga-Ge clathrate have shown a decrease in the lattice constant and an increase in the power factor with Si substitution. However, the effects of Si on the electronic and local atomic structures of Ga and Ge have not been investigated in detail. We have used XAS to characterize the electronic and local atomic structures of Ga and Ge for a number of samples with varying degree of Si substitution. Analysis of Ga and Ge K-edge XANES spectra revealed that the partial density of p-states was modified for both Ga and Ge with Si substitution with the changes being more pronounced in the case of Ga. Comparisons of Fourier transforms of EXAFS spectra revealed that the local structure of Ga is significantly changed with Si substitution while changes in the local structure of Ge with Si substitution are moderate.

11:27AM W20.00002 Examining Lattice Disorder in Type-I Clathrate $Ba_8Ga_{16}Sn_{30}$ using EXAFS[1] , SCOTT MEDLING, MICHAEL KOZINA, FRANK BRIDGES, UC Santa Cruz, KOICHIRO SUEKUNI, Japan Advanced Institute of Science and Technology, TOSHIRO TAKABATAKE, Hiroshima University — Semiconducting type I clathrates, such as $Ba_8Ga_{16}Ge_{30}$ (BaGaGe) and $Ba_8Ga_{16}Sn_{30}$ (BaGaSn), have a cage-like crystal structure with "rattler" atoms (Ba) located near the center of cages (Ga-Ge/Sn). Such compounds have a low thermal conductivity which is attributed mainly to vibrations of the "rattler" atoms inside the cages which strongly scatter phonons. BaGaSn has a surprising lower thermal conductivity than BaGaGe. To better understand why, we studied samples of BaGaSn using Extended X-ray Absorption Fine Structure (EXAFS). The analysis shows that the average Ga-Sn distance is shorter and the average Sn-Sn distance is longer than the distances found from diffraction; also, the Ba-Ga and Ba-Sn distances have greatly increased disorder. This suggests that the cage-like structure is severely distorted, in contrast to BaGaGe; such a large distortion will strongly scatter phonons, decreasing the thermal conductivity, but unfortunately also will reduce the electrical conductivity. We compare our results for BaGaSn with earlier results for BaGaGe and discuss them in light of recent transport measurements.

11:39AM W20.00003 Structural, Electronic and Vibrational Properties of $Na_xSi_{136}(0 < x < 24)$ Clathrates , CRAIG HIGGINS, EMMANUEL NENGHABI, CHARLES MYLES, Texas Tech University, KOUSHIK BISWAS, Oak Ridge National Laboratory, MATT BEEKMAN, University of Oregon, GEORGE NOLAS, University of South Florida — CRAIG HIGGINS, EMMANUEL NENGHABI[†], CHARLES W. MYLES, Texas Tech U.; KOUSHIK BISWAS, Oak Ridge National Lab; MATT BEEKMAN, U. of Oregon; GEORGE S. NOLAS, U. of South Florida - Na_xSi_{136} is a Type II clathrate with important thermoelectric properties. It's face-centered cubic lattice contains polyhedral "cages" of silicon atoms with Na atom "guests" in the cages. This material is very interesting because powder X-ray diffraction experiments[1] for differing Na content x have shown that, for increasing x in the range $0 < x < 8$, lattice contraction occurs. After all Si_{28} cages in the unit cell are filled ($x = 8$) and x is increased further, causing a filling of the Si_{20} cages, a contrasting lattice expansion results. Using the local density approximation, we have calculated the x dependences of the structural, electronic and vibrational properties of Na_xSi_{136}. Results are presented for the x dependences of the lattice constant, electronic bands, and vibrational modes. Our results for the x dependence of the lattice constant are in agreement with our X-ray data[1]. [†]Deceased. [1]M. Beekman, E.N. Nenghabi, K. Biswas, C.W. Myles, M. Baitinger, Y. Grin, G.S. Nolas, Inorg. Chem. 49, 5338–5340 (2010).

11:51AM W20.00004 NMR relaxation and phonon rattling in type-I $Ba_8Ga_{16}Sn_{30}$ clathrates , XIANG ZHENG, SERGIO Y. RODRIGUEZ, JOSEPH H. ROSS, JR., Department of Physics and Astronomy, Materials and Engineering Program, Texas A&M University — The atomic motion of guest atoms inside clathrate cages has been considered as one of the important reasons for the observed glasslike thermal behavior. ^{69}Ga and ^{71}Ga Nuclear Magnetic Resonance (NMR) studies of type-I $Ba_8Ga_{16}Sn_{30}$ clathrates show a clear low temperature spin-lattice relaxation peak attributed to the influence of Ba rattling dynamics on the framework-atom resonance. Analysis indicates that the quadrupolar relaxation is the leading contribution. The data are analyzed using a two-phonon Raman process, according to a recent theory involving localized one dimensional anharmonic oscillators. Excellent agreement is obtained using this model, with the parameters corresponding to a double well with very large anharmonicity. We have extended the theory to include a two dimensional anharmonic well, with similar parameters providing the best fit to the data. We also examine the Einstein type peak observed in heat capacity using this model, and compare to previous reported results obtained using different models for the anharmonic oscillator. This work is supported by Robert A. Welch Foundation (A-1526).

12:03PM W20.00005 Zintl stabilization and site preference in Ba-Cu-Ge clathrates , SERGIO Y. RODRIGUEZ, XIANG ZHENG, LAZIZ SARIBAEV, JOSEPH H. ROSS, JR., Department of Physics and Astronomy, Texas A&M University — Sn, Ge and Si clathrates have cage-like structures, and many exhibit enhanced thermoelectric performance. To understand Cu substitution and Zintl stabilization in $Ba_8Cu_xGe_{46-x}$ type-I clathrates with $4 \leq x \leq 6$, we performed NMR measurements coupled with first principles calculations. The ^{63}Cu NMR resonance exhibits a lineshape characteristic of Cu occupation of the high-symmetry 6c site. All electron computational results showed that the lowest energy configuration is the one with all the Cu atoms located in the 6c site, in agreement with NMR and crystallographic analysis. From bandstructure calculations we find that the preferred structure is a semiconductor, consistent with the observed Zintl stabilization in this material. A direct band gap of about 0.27 eV is found within the Generalized Gradient Approximation formalism. The preferred compositions follow quite closely the valence-counting scheme. From an Atoms In Molecules analysis it is seen that the Ba charge is less than 2^+, even though the simple electron-counting argument works well. The framework is seen to be composed of a sp^3 bonded network, with strongly polar bonds for Cu. Ba atoms in the large cages are least strongly bond in the plane of the hexagonal faces, corresponding to ease of rattling as seen for other clathrates. This work is supported by Robert A. Welch Foundation (Grant A-1526).

12:15PM W20.00006 Thermoelectric properties of low-dimensional clathrates from first principles , DEEPA KASINATHAN, HELGE ROSNER, MPI CPfS — Type-I inorganic clathrates are host-guest structures with the guest atoms trapped in the framework of the host structure. From a thermoelectric point of view, they are interesting because they are semiconductors with adjustable bandgaps. Investigations in the past decade have shown that type-I clathrates $X_8Ga_{16}Ge_{30}$(X = Ba, Sr, Eu) may have the unusual property of "phonon glass-electron crystal" for good thermoelectric materials. Among the known clathrates, $Ba_8Ga_{16}Ge_{30}$ has the highest figure of merit (ZT 1). To enable a more widespread usage of thermoelectric technology power generation and heating/cooling applications, ZT of at least 2-3 is required. Two different research approaches have been proposed for developing next generation thermoelectric materials: one investigating new families of advanced bulk materials, and the other studying low-dimensional materials. In our work, we concentrate on understanding the thermoelectric properties of the nanostructured Ba-based clathrates. We use semi-classical Boltzmann transport equations to calculate the various thermoelectric properties as a function of reduced dimensions. We observe that there exists a delicate balance between the electrical conductivity and the electronic part of the thermal conductivity in reduced dimensions. Insights from these results can directly be used to control particle size in nanostructuring experiments.

12:27PM W20.00007 Nanostructured Oxides and Sulfides for Thermoelectrics , KUNIHITO KOUMOTO, Nagoya University — Thermoelectric power generation can be applied to various heat sources, both waste heat and renewable energy, to harvest electricity. Even though each heat source is of a small scale, it would lead to a great deal of energy saving if they are combined and collected, and it would greatly contribute to reducing carbon dioxide emission. We have been engaged in developing novel thermoelectric materials to be used for energy saving and environmental protection and are currently developing nanostructured ceramics for thermoelectric conversion. We have demonstrated a quantum confinement effect giving rise to two dimensional electron gas (2DEG) in a 2D superlattice, STO/STO:Nb (STO: strontium titanate), which could generate giant thermopower while keeping high electrical conductivity. One unit-cell thick Nb-doped well layer was estimated to show ZT=2.4 at 300K. Then, a "synergistic nanostructuring" concept incorporating 2DEG grain boundaries as well as nanosizing of grains has been applied to our STO material and 3D superlattice ceramics was designed and proposed. It was verified by numerical simulation that this 3D superlattice ceramics should be capable of showing ZT=1.0 at 300K which is comparable to or even higher than that of conventional bismuth telluride-based thermoelectrics. We have recently proposed titanium disulfide-based misfit-layered compounds as novel TE materials. Insertion of misfit-layers into the van der Waals gaps in layer-structured titanium disulfide thus forming a natural superlattice gives rise to internal nanointerfaces and dramatically reduces its lattice thermal conductivity. ZT value reaches 0.37 at 673 K even without optimization of electronic properties. Our challenge to further increase ZT by controlling their electronic system and superlattice structures will be presented.

1:03PM W20.00008 Electronic Structure Determination of the Thermoelectric $CuRh_{1-x}Mg_xO_2$ using Soft X-Ray Spectroscopies , ERIC MARTIN, PAOLO VILMERCATI, CHRISTINE CHENEY, Dept. of Physics and Astronomy, University of Tennessee, TAKAO SASAGAWA, Materials and Structures Laboratory, Tokyo Institute of Technology, NORMAN MANNELLA, Dept. of Physics and Astronomy, University of Tennessee — Magnesium-doped rhodium oxides with formula unit $CuRh_{1-x}Mg_xO_2$ and delafossite-type structure exhibit a high thermoelectric figure of merit at elevated temperatures. The electronic structure of $CuRh_{1-x}Mg_xO_2$ has been studied with x-ray emission spectroscopy (XES), x-ray absorption spectroscopy (XAS), and photoemission spectroscopy (PES). The data reveal that the states at the Fermi level are Rh-derived. Measurements carried out by changing the orientation of the linear photon polarization further indicate that the Rh states have a more localized character along the c-axis, consistent with the layered crystal structure. Given the similarity of the electronic configurations of Co and Rh, these data provide solid experimental evidence that the orbital degrees of freedom of the d^6ionic configuration of the states rooted in transport are key for explaining the thermoelectric properties of oxide materials.

1:15PM W20.00009 Thermal Conductivity of Aluminum Oxide from First Principles[1] , MOSES NTAM, JIANJUN DONG, Auburn University, BIN XU, University of Texas at Arlignton — Alumina (Al_2O_3) is a well-known ceramic material. First-principles study of lattice thermal conductivity can assist our understanding in extreme conditions that are difficult to achieve experimentally, as well as analyze the fundamental difference between other materials. We combine density functional theory and the Peierls–Boltzmann transport theory to predict the temperature and pressure dependencies of lattice thermal conductivity of the corundum phase. We use a real space super cell method to extract second force constants and third order lattice anharmonicity tensors. These are then used to directly evaluate the phonon scattering rates due to lattice anharmonicity. Our preliminary results show that at a density of 4.23 g/cm^3 Al_2O_3 has thermal conductivities of 14.8Wm^{-1}K^{-1} at 300K and 5.31Wm^{-1}K^{-1} at 1000K. Moreover, we calculated the thermodynamic properties such as thermal expansion coefficient, bulk modulus and heat capacity, which are in excellent agreement with available measurements and previous theoretical calculations.

[1]NSF EAR-0757847

1:27PM W20.00010 Thermoelectric properties of $Ca_3Co_4O_9$ thin film[1] , ROBERT KLIE, QIAO QIAO, AHMET GULEC, TADAS PAULAUSKAS, University of Illinois - Chicago, STANISLAW KOLESNIK, BOGDAN DABROWSKI, Northern Illinois University, CIHAT BOYRAZ, MEHMET OZDEMIR, DIPANJAN MAZUMDAR, ARUN GUPTA, University of Alabama — Thermoelectric oxides have attracted increasing attention due to their high thermal power and temperature stability. In particular, $Ca_3Co_4O_9$(CCO), a misfit layered structure consisting of single layer hole-doped CoO_2 sandwiched between insulating Ca_2CoO_3 rocksalt layers, exhibits a high Seebeck coefficient at 1000 K. It was suggested that the Seebeck-coefficient can be further increased by growing doped thin films with controlled defects structures. This study combines pulsed layer deposition thin film synthesis of pristine CCO on several oxide substrates, as well as CCO thin films doped with Ti, Bi or La, with aberration-corrected scanning transmission electron microscopy and electron energy loss spectroscopy (EELS) to examine the effects of interfacial strain and doping on the atomic and electronic structures of CCO. The thermoelectric properties will be measured and correlated to the local changes in the atomic and electronic structures. We will further evaluate the role of CoO_2 stacking faults, as well as film thickness on the thermoelectric properties of CCO.

1:39PM W20.00011 Improvement of the thermoelectric properties of substituted $SrTiO_3$ by synthesis conditions[1] , S. KOLESNIK, S. BOONA, Department of Physics, Northern Illinois University, DeKalb, IL, B. DABROWSKI, Department of Physics, Northern Illinois University, DeKalb, IL, Materials Science Division, Argonne National Laboratory, Argonne IL, K. SWIERCZEK, K. WOJCIECHOWSKI, AGH University of Science and Technology, Cracow, Poland — We have studied thermoelectric properties of polycrystalline $Sr_{1-x}La_xTiO_3$ and $SrTi_{1-x}Nb_xO_3$ (x<=0.2) synthesized by a solid state synthesis method in a H_2/Ar atmosphere. The incorporation of La and Nb into the crystal structure was confirmed by x-ray diffraction and energy dispersive x-ray spectroscopy. By increasing the synthesis temperature (up to $\sim$1570^{o}C) and decreasing the partial pressure of oxygen, we were able to optimize the thermoelectric properties of the studied materials. The determined values of the thermoelectric figure of merit ZT$\sim$0.1 at 400 K and $\sim$0.3 at 800 K are comparable to those of single crystals of La- and Nb- substituted compounds. Our results show that the synthesis conditions play a crucial role in tailoring of the thermoelectric properties of substituted strontium titanates.

1:51PM W20.00012 Thermoelectric Properties of a-InGaZnOx , D.S. WILLIAMS, STEPHAN PIOTROWSKI, B.E. WHITE, Binghamton University — Primarily known as an active layer in thin film transistors, the electrical and thermal properties of a-InGaZnOx indicate promise as a thermoelectric material. In contrast to most phonon-blocking, electron-transmitting thermoelectric materials, a-InGaZnOx is a structurally amorphous material that maintains relatively high electron mobility (10-50 cm2/V-s) and optical transparency. Here we report on the electrical conductivity, thermal conductivity, and Seebeck coefficient of this material as a function of charge carrier concentration. Carrier concentration is modulated through thin film annealing in a reducing ambient. Room temperature thermal conductivity is found to be 0.35 W/m-K with a Seebeck coefficient of approximately 200μV/K. These data suggest room temperature thermoelectric figures of merit in the range of 0.1-0.3 are achievable with these materials, offering the possibility of transparent thermoelectric energy generation.

Session W21 GIMS: Novel Imaging Techniques and Calorimetry D161

11:15AM W21.00001 Particle distribution and dynamics in a complex fluid suspension studied by an image-analysis light-scattering technique , SAAD ALGARNI, H. KASHURI, GERMANO IANNACCHIONE, WPI — A relatively unique approach is described to analyze the scattered laser light from a complex fluid suspension for both static and dynamic behavior. Recent development of speckle analysis using CCD recorded direct imaging of the scattered coherent light has opened many new avenues for the application of static and dynamic light scattering experiments. The straightforward nature of this approach is somewhat offset by the constraints of the CCD chip size and placement to probe wide (or narrow) ranges of the wave vector. An alternative, and greatly simplified variation of this technique, is to convert the scattered light into diffuse scattering using a translucent screen placed at a desired location down beam then imaging the resulting pattern on the screen. A thru-beam stop and axis scales can be easily placed on the screen and recorded to improve the image quality and later analysis. One of many possible applications is the study of the particle (7nm diam aerosil SiO2 spheres) distribution and dynamics due to Brownian motion as well as sedimentation in a complex fluid (glycerol).

11:27AM W21.00002 ABSTRACT WITHDRAWN –

11:39AM W21.00003 3D Optical Field Mapping of a Focused Cylindrical Vector Beam Using Rayleigh Nanoparticles[1] , LIANGCHENG ZHOU, Lehigh University, QIWEN ZHAN, University of Dayton, H. DANIEL OU-YANG, Lehigh University — We report a novel method of mapping the optical field distribution of a focused cylindrical vector beam (CVB) using optically trapped Rayleigh nanoparticles. By using an ensemble method to measure the potential energy of nanoparticles in a CVB trap, optical trapping energy as low as 0.05 k_BT was measured. We demonstrated that the absolute intensity of a highly localized optical field is measured *in situ* using low concentration of polystyrene nanoparticles sized at 48 nm acting as optical nanoprobes. Their collective behavior in the focal volume gives very accurate reading of the optical field distribution, which shows excellent consistency with numerical simulations.

11:51AM W21.00004 High Resolution Micro-Optical Wall Shear Stress Sensor Based on Whispering Gallery Modes of Dielectric Microspheres , ULAS AYAZ, TINDARO IOPPOLO, VOLKAN OTUGEN, Southern Methodist University — We report the performance of a photonic wall shear stress sensor based on Whispering gallery mode (WGM) shifts of dielectric microsphere resonators. In particular, issues related to the sensitivity, resolution, frequency response and cross-axis sensitivity of the sensor are investigated experimentally. The sensor used in this prototype is a dielectric hollow microsphere made of Polydimethylsyloxane (PDMS). The wall shear stress acting on a sensing element of 125 μm diameter, is transmitted mechanically to the microsphere and the transmitted stress leads to shifts in the WGMs of the microsphere. By monitoring these WGM shifts, the magnitude as well as the direction of the wall shear stress are measured. Measurement resolutions better than 1 mPa have been observed.

12:03PM W21.00005 An effect of probe current on ADF image intensity of Si crystal , SUHYUN KIM, Tokyo Institute of Technology, YOSHIFUMI OSHIMA, YASUMASA TANISHIRO, KUNIO TAKAYANAGI — Annular dark field (ADF) scanning transmission electron microscope has been used to identify elements in the crystal. To analyze ADF image intensity more quantitatively, simulation of ADF image is required. However, the simulation has been known to overestimate the intensity because source size used in the simulation is assumed to be a point. Therefore, finite effective source size has been taken into an account by convolving Gaussian function to simulation. And, the Gaussian convolution has been usefully used to solve the mismatch in intensity, providing us a way of quantitative analysis for ADF image. Here, we quantitatively estimated an effective size of the cold field emission source. We obtained different Gaussian convolution size for ADF image acquired with various probe current by comparing ADF image contrast between experiment and simulation. As a result, we found that the effective source size which is needed for explaining contrast of ADF image decreased with decreasing probe current.

12:15PM W21.00006 Fast and Computationally Efficient Boundary Detection Technique for Medical Images , ARPITA DAS, PARTHA GOSWAMI, SUSANTA SEN, Calcutta University, India — Detection of edge is a fundamental procedure of image processing. Many edge detection algorithms have been developed based on computation of the intensity gradient. In medical images, boundaries of the objects are vague for gradual change of intensities. Therefore need exists to develop a computationally efficient and accurate edge detection approach. We have presented such algorithm using modified global threshold technique. In our work, the boundaries are highlighted from the background by selecting a threshold (**T**) that separates object and background. In the image, where object to background or vice-verse transition occurs, pixel intensity either rises greater or equal to **T** (background to object transition) or falls less than **T** (object to background). We have marked these transition regions as object boundary and enhanced the corresponding intensity. The value of **T** may be specified heuristically or by following specific algorithm. Conventional global threshold algorithm computes the value of **T** automatically. But this approach is not computationally efficient and required a large memory. In this study, we have proposed a parameter for which computation of **T** is very easy and fast. We have also proved that a fixed size memory [256×4Byte] is enough to compute this algorithm.

12:27PM W21.00007 Integrated instrument for holographic optical trapping and multicolor holographic video microscopy , BHASKAR JYOTI KRISHNATREYA, DAVID G. GRIER, Department of Physics and Center for Soft Matter Research, New York University, New York, NY 10003 — We designed and constructed an integrated holographic materials characterization and processing workstation that combines dynamical holographic optical trapping with multicolor holographic video microscopy. Unlike previously described systems, which are based on conventional light microscopes, our holographic workstation features a rigid, compact, adaptable, and modular design that can be replicated easily using standard off-the-shelf optical components. We demonstrate enhanced efficiency in micro-manipulation of colloidal materials using our instrument. By illuminating these colloidal particles with multiple laser wavelengths concurrently and analyzing the multicolor holograms independently for each color, we can acquire complementary information about the particles' size, position, and composition, and also gain insights into their material-dependent properties.

12:39PM W21.00008 Graded Index Lens Design for Aqueous Applications[1] , THEODORE MARTIN, MICHAEL NICHOLAS, GREGORY ORRIS, Naval Research Laboratory, LIANG-WU CAI, Kansas State University, DANIEL TORRENT, JOSE SANCHEZ-DEHESA, Universidad Politecnica de Valencia — A graded refractive index (GRIN) provides a means of controlling wave propagation within the bulk of a material without relying on curved interfaces between dissimilar materials. We report the design and experimental testing of a GRIN metamaterial that behaves as a lens for acoustic waves in water. The graded index is achieved using a regular array of cylindrical scatterers with an anisotropic distribution of sizes. The metamaterial lens operates at sonic frequencies and has flat interfaces. We demonstrate that this metamaterial design focuses acoustic signals in the same manner as an ideal optical lens. By comparing with calculations using multiple scattering theory and finite difference time domain methods we show that the elastic properties of the scatterers are important for achieving an accurate model of the transmitted signal. We consider perturbations of the metamaterial design and their impact on the transmission.

12:51PM W21.00009 WASTED at work: the Webcam Alpha Spectrometer Experiment Demonstrator , ARTHUR PALLONE, NICOLE NEWTON[1], Murray State University — Ion beam analysis (IBA) methods are commonly used to determine the composition or other properties of samples. The scanning of micrometer diameter and smaller ion beams across sample surfaces produces spatial distribution maps of those properties for the samples. Electron microscope providers offer radiation-hardened CMOS camera options to directly image sample areas as a complement to scanning the electron beam. A modified webcam operated in the radiographic mode of transmission ion microscopy (TIM), with alpha particles in place of electrons, has been shown to be an effective low-cost alternative to that camera for TIM. IBA under ambient pressure is still not commonly practiced. Even less common is the use of a radioactive source of ions, such as Po-210, in IBA. The synthesis of these three ideas – the direct imaging by a modified webcam of Po-210 alpha particles that first pass through a sample under ambient pressure – is explored with the Webcam Alpha Spectrometer Experiment Demonstrator (WASTED). A description of the experiment, first results, conclusions and future work will be presented.

1:03PM W21.00010 Fourier phase contrast microscopy technique for real time imaging of phase and fluorescence features simultaneously[1] , CHANDRA YELLLESWARAPU, ALEXEY VERAKSA, BHARGAB DAS, DEVULAPALLI RAO[2], University of Massachusetts Boston, DEPARTMENT OF PHYSICS TEAM, DEPARTMENT OF BIOLOGY COLLABORATION — Understanding of biological cell response is facilitated by microscopy techniques, but has been limited by our ability to image cell structure and function at the same time. Current procedure is to obtain separate images, such as phase and fluorescence features, using different imaging techniques one after the other and digitally register the resulting images together. Mostly this procedure requires switching between the light sources and the associated optical paths, making it difficult to image biological events at short time scales. Recently we developed a novel optical Fourier phase contrast microscopy technique for real time display of phase and fluorescence features of biological specimens at the same time. We were able to image the brightfield+fluorescence, phase+fluorescence, and edge enhanced+fluorescence features of the *Drosophila* embryo at once without the need for digital image registration and fusion. This comprehensive microscope has the capability of simultaneously providing both structural and functional information.

1:15PM W21.00011 Atomic Resolution imaging with non-contact Atomic Force Microscope (nc-AFM) in a closed liquid cell , UMIT CELIK, Istanbul Technical University, DEMET CATCAT, NanoMagnetics Instruments Ltd./Hacettepe University, H. OZGUR OZER, Istanbul Technical University, AHMET ORAL, Sabanci University, ISTANBUL TECHNICAL UNIVERSITY TEAM, NANOMAGNETICS INSTRUMENTS LTD. TEAM, HACETTEPE UNIVERSITY TEAM, SABANCI UNIVERSITY TEAM — We have designed a non-contact Atomic Force Microscope, which can achieve true atomic resolution in a closed liquid cell, which does not suffer from evaporation of fluids during imaging. We have designed a closed liquid cell, where we can flow the fluid using a syringe or a peristaltic pump. The AFM cantilever holder was designed to eliminate acoustical resonances. We can obtain resonance curves without spurious acoustic peaks in liquid using a piezoactuator. We have used an RF modulated 635 nm low noise diode laser. RF modulation is effective to reduce the optical feedback noise and the optical interference noise. Deflection noise density of designed system is $\sim$20 fm/$\sqrt{\text{Hz}}$ in air and $\sim$25 fm/$\sqrt{\text{Hz}}$ in water. The observed frequency noise at the PLL output was $\sim 1\text{Hz}_{pp}$ in water using a 300kHz, 32N/m cantilever oscillated at 0.9nm amplitude with Q$\sim$11. Force sensitivity of our system is demonstrated by imaging cleaved mica surface in water environment with atomic resolution.

1:27PM W21.00012 Scanning Tunneling Microscope Study of Atomic Steps in Gold Films on Muscovite Mica[1] , OLESYA SITNIKOVA, RAMESH MANI, Georgia State University — We are carrying Scanning Tunneling Microscope (STM) studies of gold on Muscovite mica to observe the atomic step migration and test the functionality of our STM. The experiment was performed by using a RHK ultra-high-vacuum STM. The gold sample was prepared in low pressure vacuum chamber, and the films were grown at constant rate of 0.1 nm/sec to the desired thickness. After deposition, the films were thermally annealed to produce flat terraces which are being studied. The migration of atomic steps over time is being observed and the results are presented.

1:39PM W21.00013 X-Ray Fluorescence Imaging of Ancient Artifacts , ROBERT THORNE, ETHAN GEIL, Cornell University, KATHRYN HUDSON, CHARLES CROWTHER, Oxford University — Many archaeological artifacts feature inscribed and/or painted text or figures which, through erosion and aging, have become difficult or impossible to read with conventional methods. Often, however, the pigments in paints contain metallic elements, and traces may remain even after visible markings are gone. A promising non-destructive technique for revealing these remnants is X-ray fluorescence (XRF) imaging, in which a tightly focused beam of monochromatic synchrotron radiation is raster scanned across a sample. At each pixel, an energy-dispersive detector records a fluorescence spectrum, which is then analyzed to determine element concentrations. In this way, a map of various elements is made across a region of interest. We have succesfully XRF imaged ancient Greek, Roman, and Mayan artifacts, and in many cases, the element maps have revealed significant new information, including previously invisible painted lines and traces of iron from tools used to carve stone tablets. X-ray imaging can be used to determine an object's provenance, including the region where it was produced and whether it is authentic or a copy.

1:51PM W21.00014 Measuring the Imaginary Part of the Permittivity Using Calorimetry[1] , HEKTOR KASHURI, KRISHNA SIGDEL, KLAIDA KASHURI, GERMANO S. IANNACCHIONE — Modulated or AC calorimetry is a well established technique for measuring the temperature dependence of the heat capacity of many complex fluids. Employing a dielectric or RF heating method, the heat capacity, thermal conductivity, and the dielectric properties of the sample are all probed simultaneously. Combining the results obtained by this technique for the liquid crystal 4-n-pentyl-4-cyanophenyl (5CB) with those obtained by our novel AC calorimetric technique employing RF (dielectric) heating, we have been able to directly measure the temperature dependence of the imaginary part of the permittivity of this liquid crystal. Measurements were performed over a temperature range from 303 to 313 K, spanning the nematic to isotropic phase transition, as well as radio frequencies from 10 to 30 MHz

2:03PM W21.00015 Calorimetry of epitaxial thin films[1] , FRANCES HELLMAN, DAVID COOKE, University of California at Berkeley, JAMES GROVES, BRUCE CLEMENS, Stanford University — Thin film growth allows for the manipulation of material on the nanoscale, allowing for the creation of metastable phases not seen in the bulk. Heat capacity provides a direct way of measuring thermodynamic properties of these new materials, but traditional bulk calorimetric techniques are inappropriate for such a small amount of material. Micro- and nanocalorimetry techniques exist for the measurements of thin films but rely on an amorphous membrane platform, limiting the types of films which can be measured. In this work, ion-beam-assisted deposition is used to provide a biaxially-oriented MgO template on a suspended membrane microcalorimeter. Synchrotron X-ray diffraction was used to successfully assess the biaxial order of the MgO template. X-ray diffraction was also used to prove the high level of epitaxy of a film grown onto this MgO template. The contribution of the MgO layer to the technique will be discussed. An $Fe_{.49}Rh_{.51}$ film grown epitaxially onto the device was measured, comparing favorably to literature data on bulk crystals. This shows the viability of the MgO microcalorimeter as a way of measuring the thermodynamic properties of epitaxial thin films.

11:15AM W22.00001 Bound states and E8 symmetry effects in perturbed quantum Ising chains , JONAS KJALL, University of California, Berkeley, FRANK POLLMANN, University of California, Berkeley and Academia Sinica, JOEL MOORE, University of California, Berkeley and Lawrence Berkeley National Laboratory — In a recent experiment on $CoNb_2O_6$, Coldea et al. found for the first time experimental evidence of the exceptional Lie algebra E_8. The emergence of this symmetry was theoretically predicted long ago for the transverse quantum Ising chain in the presence of a weak longitudinal field. We consider an accurate microscopic model of $CoNb_2O_6$ incorporating additional couplings and calculate numerically the dynamical structure function using a recently developed matrix-product-state method. We compare the signatures of this model to those found in the transverse Ising chain in a longitudinal field and to experimental data, with focus on how far the effects of integrability extends and how robust they are to the additional interactions. The excitation spectra show bound states characteristic of the weakly broken E_8 symmetry and a bound state continuum carrying spectral weight comparable to the higher bound states.

11:27AM W22.00002 Comparison between two simple models for the magnetoelectric interaction in multiferroics , G.E. BARBERIS, IFGW, Unicamp, Brazil, C.J. CALDERON FILHO, IFGW Unicamp, Brazil — We developed numerical calculations to simulate the magnetoelectric coupling in multiferroic compounds, using the Monte Carlo technique. Two simple models were used to simulate the compounds. In the first one, the magnetic ions are represented by a spin 1/2 2D Ising lattice of ions, and the electric lattice by classical moments, coupled one to one with the magnetic moments. The coupling between both lattices allows to the leading lattice, that is, the magnetic one, to change the orientation of the electrical dipoles in one direction perpendicular to the magnetic dipoles. This direction was chosen to accomplish the symmetry requirements of the magnetoelectric effect. In the second case, the magnetic lattice is also a 2D Ising lattice, but the electric momenta are in a lattice that also behaves as an Ising lattice, perpendicular to the magnetic moments. In this case, the one-to-one coupling of the electric and magnetic momenta is represented by a two-valued energy parameter, allowing the possibility of independent transition temperatures for both lattices. Both models contain three independent parameters. We studied the physical properties obtained with both models, as functions of the ratio of the three parameters. The results in both cases allowed us to compare changes in the physics of the models, and with the physics of compounds measured experimentally.

11:39AM W22.00003 The itinerant ferromagnetic phase of the Hubbard model , GIUSEPPE CARLEO, SAVERIO MORONI, FEDERICO BECCA, STEFANO BARONI, SISSA and CNR-IOM DEMOCRITOS - Trieste, Italy — Using a newly developed quantum Monte Carlo technique, we provide strong evidence for the stability of a saturated ferromagnetic phase in the high-density regime of the two-dimensional infinite-U Hubbard model. By decreasing the electron density, a discontinuous transition to a paramagnetic phase is observed, accompanied by a divergence of the susceptibility on the paramagnetic side. This behavior, resulting from a high degeneracy among different spin sectors, is consistent with an infinite-order phase transition. The remarkable stability of itinerant ferromagnetism renews the hope to describe this phenomenon within a purely kinetic mechanism and will facilitate the validation of experimental quantum simulators with cold atoms loaded in optical lattices.

11:51AM W22.00004 Two species Bosonic Hubbard model in a two-dimensional optical lattice , KALANI HETTIARACHCHILAGE, VALY ROUSSEAU, JUANA MORENO, MARK JARRELL, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, Louisiana 70803, USA — We study a two-component hardcore bosonic Hubbard model in a two- dimensional optical lattice by performing Quantum Monte Carlo (QMC) simulations. Our model contains a repulsive interspecies interaction between the two species of bosons and a hopping term between nearest neighbors. The phase diagram shows magnetic orderings, insulatings and superfluid phases as a function of doping for balanced populations. We predict the appearance of a first order phase transition from an antiferromagnetic phase to a superfluid phase near half filling. A phase transition from superfluid to an exotic phase occurs away from half filling at very low temperature.

12:03PM W22.00005 An Anomalously Elastic, Intermediate Phase in Randomly Layered Planar Magnets, Superfluids, and Superconductors , THOMAS VOJTA, Missouri University of Science and Technology, PAUL GOLDBART, University of Illinois at Urbana-Champaign, PRIYANKA MOHAN, RAJESH NARAYANAN, Indian Institute of Technology Madras, JOHN TONER, University of Oregon — We show that layered quenched randomness in planar magnets leads to an unusual intermediate phase between the conventional ferromagnetic low-temperature and paramagnetic high-temperature phases. In this intermediate phase, which is part of the Griffiths region, the spin-wave stiffness perpendicular to the random layers displays anomalous scaling behavior, with a continuously variable anomalous exponent, while the magnetization and the stiffness parallel to the layers both remain finite. Analogous results hold for superfluids and superconductors. We study the two phase transitions into the anomalous elastic phase, and we discuss the universality of these results, and implications of finite sample size as well as possible experiments.

12:15PM W22.00006 Quantum fidelity in the thermodynamic limit[1] , MAREK RAMS, BOGDAN DAMSKI, Los Alamos National Laboratory — A quantum phase transition happens when dramatic changes in the ground state properties of a quantum system can be induced by a tiny variation of an external parameter (e.g., a magnetic field in spin systems). Quantum fidelity – the overlap between two ground states calculated at slightly different values of the external parameter – provides the most basic probe into the dramatic change of the wave-function. In this talk I will discuss quantum fidelity focusing on thermodynamic regime. I will present novel analytical results for quantum fidelity of the Ising chain, a paradigmatic model of quantum phase transitions, and discuss a theory extending these findings to systems characterized by other universality classes. In particular, I will show how quantum fidelity approaches a non-analytic limit, quantify how the Anderson catastrophe takes place in quantum critical systems, and discuss scaling properties of quantum fidelity when it cannot be approximated by the popular fidelity susceptibility approach. This approach provides a promising way of characterizing quantum phase transition in strongly correlated systems. The work is summarized in M.M. Rams, B. Damski, arXiv:1010:1048

12:27PM W22.00007 Finite-Temperature Fidelity Susceptibility for One-Dimensional Quantum Systems[1] , JESKO SIRKER, TU Kaiserslautern — We calculate the fidelity susceptibility χ_f for the Luttinger model and show that there is a universal contribution linear in temperature T (or inverse length $1/L$) by using conformal field theory. Furthermore, we develop an algorithm - based on a lattice path integral approach - to calculate the fidelity $F(T)$ in the thermodynamic limit for one-dimensional quantum systems. We check the Luttinger model predictions by calculating $\chi_f(T)$ analytically for free spinless fermions and numerically for the XXZ chain. Finally, we study χ_f at the two phase transitions in this model.

12:39PM W22.00008 Thermodynamics of itinerant metamagnetic transitions , ANDREW BERRIDGE, University of St Andrews — Itinerant metamagnetic transitions may be driven by features in the electronic density of states. These features produce signatures in the entropy and specific heat near to the transition. We study these signatures for a variety of different cases, identifying the key features which differ from naive expectations, such as enhanced critical fields and 'non-Fermi liquid' temperature dependencies above the transition. We will consider the generic case of a logarithmically divergent density of states, as caused by a van Hove singularity in 2D. We also study a specific model for the bandstructure of $Sr_3Ru_2O_7$, a material with a well-studied metamagnetic transition and quantum critical endpoint. We consider how far the behaviour of the system can be explained by the density of states rather than quantum fluctuations, and the distinctive features of this mechanism. The most intriguing feature of $Sr_3Ru_2O_7$ is an unusual phase with a higher entropy than its surroundings, we consider how this may arise in the context of a density of states picture and find that we can reproduce the observed thermodynamic behaviour and first-order phase transitions.

12:51PM W22.00009 Low-energy behavior of the generalized Golden chain at an integrable point , PAATA KAKASHVILI, EDDY ARDONNE, NORDITA — Recently, properties of collective states of interacting non-Abelian anyons have attracted a considerable attention. In particular, it has been shown to that the generalization of the Golden chain, a chain of interacting Fibonacci anyons, has a rich phase diagram with various critical and gapped phases. In additions, several integrable points have also been studied. We identify a new integrable point in the parameter space of the model and diagonalize the Hamiltonian exactly using the Bethe Ansatz method. To describe the corresponding low-energy conformal field theory, we perform the finite-size analysis to calculate the central charge and critical exponents.

1:03PM W22.00010 Tensor renormalization group: Local magnetizations, correlation functions, and phase diagrams of systems with quenched randomness[1] , CAN GÜVEN, MICHAEL HINCZEWSKI, University of Maryland, A. NIHAT BERKER, Sabanci University — The tensor renormalization-group method, developed by Levin and Nave, brings systematic improvability to the position-space renormalization-group method and yields essentially exact results for phase diagrams and entire thermodynamic functions. The method, previously used on systems with no quenched randomness, is extended in this study to systems with quenched randomness [1]. Local magnetizations and correlation functions as a function of spin separation are calculated as tensor products subject to renormalization-group transformation. Phase diagrams are extracted from the long-distance behavior of the correlation functions. The approach is illustrated with the quenched bond-diluted Ising model on the triangular lattice. An accurate phase diagram is obtained in temperature and bond-dilution probability for the entire temperature range down to the percolation threshold at zero temperature.

1:15PM W22.00011 Nature of Fermi Systems near l=0 Pomeranchuk Instability: A Tractable Crossing Symmetric Equation Approach , KELLY REIDY, KHANDKER QUADER, Kent State University, KEVIN BEDELL, Boston College — In Fermi liquids, a Pomeranchuk instability occurs when one of the Landau parameters $F_\ell^{a,s} \to -(2\ell+1)$. The Pomeranchuk instabilities at $F_0^{a,s} = -1$ are related to respectively to a ferromagnetic transition (a), and to a density wave or charge instability resulting in phase separation (s). We use the tractable crossing symmetric equations (TSCE) method to explore the nature of quantum fluctuations, excitations and pairing in a 3D Fermi system, around these points. We obtain interesting limiting results at zero and finite momentum (q), and in the limits of large and small coupling strengths. We develop methods to deal with a set of finite-q singularities in the competing quantum fluctuation terms contained in TSCE; these may have physical significance. Using graphical and numerical methods to solve coupled non-linear integral equations that arise in the TSCE scheme, we obtain results for the behavior of spin and density excitations, and pairing properties around the instability points. Our results may have relevance to ferromagnetic superconductors.

1:27PM W22.00012 Microscopic model for the $Sr_{n+1}Ir_nO_{3n+1}$ Ruddlesden-Popper series of materials , JEAN-MICHEL CARTER, HAE-YOUNG KEE, University of Toronto — The $Sr_{n+1}Ir_nO_{3n+1}$ family of materials displays an insulator to metal transition as the number of layers (n) increases. The presence of large spin-orbit coupling is believed to be a significant ingredient for the novel $J_{eff} = 1/2$ state found in Sr_2IrO_4. We offer a microscopic tight-binding Hamiltonian with spin-orbit coupling and Hubbard interactions, and compare our results with experimentally observed phases.

1:39PM W22.00013 Protecting clean critical points by local disorder correlations[1] , J.A. HOYOS, Universidade de São Paulo, NICOLAS LAFLORENCIE, Universite Paris-Sud, ANDRÉ VIEIRA, Universidade de São Paulo, THOMAS VOJTA, Missouri University of Science and Technology — We show that a broad class of quantum critical points can be stable against locally correlated disorder even if they are unstable against uncorrelated disorder. Although this result seemingly contradicts the Harris criterion, it follows naturally from the absence of a random-mass term in the associated order-parameter field theory. We illustrate the general concept with explicit calculations for quantum spin-chain models. Instead of the infinite-randomness physics induced by uncorrelated disorder, we find that weak locally correlated disorder is irrelevant. For larger disorder, we find a line of critical points with unusual properties such as an increase of the entanglement entropy with the disorder strength. We also propose experimental realizations in the context of quantum magnetism and cold-atom physics.

1:51PM W22.00014 Quantum antiferromagnet on a Bethe lattice at percolation I. Low-energy states, DMRG, and diagnostics , HITESH CHANGLANI, SHIVAM GHOSH, C.L. HENLEY, Cornell University — We investigate ground and excited state properties of randomly diluted spin-1/2, exchange-coupled Heisenberg antiferromagnets on the Bethe lattice with coordination 3. In the case of square lattice percolation clusters, previous Quantum Monte Carlo (QMC) calculations [1] found that the singlet-triplet gaps scaled "anomalously," being much smaller than the $1/N$ scaling expected from the tower of "quantum rotor" states (due to $E = M^2/2N\chi$). The low energies were attributed to the interaction of distant "dangling spins," forced by the local imbalance of even and odd sites. In the present study we further study this effect on the Bethe lattice, using Exact Diagonalization and density-matrix RG. (DMRG applies naturally since the Bethe lattice lacks loops). We introduce inter-site correlation and susceptibility matrices as diagnostics to identify the spatial locations of the low-energy degrees of freedom, and to understand interactions between them. These matrices have been computed within the harmonic spin-wave theory, in order to highlight the deviations seen in the spin-1/2 system. In addition to the above, we propose a simple effective Hamiltonian which explains the magnitude of the singlet-triplet gap.

2:03PM W22.00015 Quantum antiferromagnet on a Bethe lattice at percolation II.Effective Hamiltonian for dangling spins , SHIVAM GHOSH, HITESH CHANGLANI, SUMIRAN PUJARI, C.L. HENLEY, Cornell University — The lowest energy excitations of spin 1/2 Heisenberg antiferromagnets on percolation clusters (about the Neel ordered state) were believed to be "quantum rotor states" scaling with cluster size as 1/N, until Wang and Sandvik [Wang et al, Phys. Rev. B 81, 054417 (2010)] discovered a class of states in the diluted square lattice that had even lower energies and had a different finite size scaling of the gap exponent. They conjectured these anomalous states were due to local even/odd sublattice imbalances, leading to emergent local moments called "dangling spins" that interact over large distances, mediated through intervening spins. We have pursued this question on the z=3 Bethe lattice at the percolation threshold. Exact diagonalization shows, forevery cluster, a split-off group of low-energy states having the same quantum numbers as can be made using the dangling spins. We identify these with the Wang-Sandvik anomalous states and model their energies using an effective pair Hamiltonian coupling the "dangling spins." The couplings are a function of separation and geometry; the parameters are solved by fitting to a database of different clusters.The separation dependence of these interactions can be related to the gap scaling with N. We will also compare the effective Hamiltonian predictions to the intersite susceptibility matrix of each cluster.

Session W23 DCMP: Superconductivity: Mesoscopic and Nanometer Scale Phenomena D165

11:15AM W23.00001 Fluxoid Quantization in Superconducting Al Nano-Rings[1] , STEPHEN SNYDER, ALLEN GOLDMAN, University of Minnesota — The Little-Parks experiment on superconducting cylinders is an important demonstration of fluxoid quantization in superconductors. The transition temperature oscillations in magnetic field have a period of $h/2e$ for the micro cylinders in their studies, which was further evidence for Cooper paring at the time [W. A. Little, R. D. Parks, PRL 1964, 9, 9]. However recent theoretical works have suggested that in superconducting loops smaller than the coherence length this period changes from $h/2e$ to h/e, for details see [F. Loder, et al. PRB, 2008, 78, 174526] and references therein. We present experimental work in an effort to achieve this limit with Al nano-rings prepared by electron beam lithography. The rings presented here are smaller than others reported in the literature by as much as a factor of two or three [H. Wang, et al. PRB, 2007, 75, 064509].

[1]This work was supported by the U.S. Department of Energy under Grant No. DE-FG02-02ER46004.

11:27AM W23.00002 Destructive regime in Al loops prepared by e-beam lithography , NEAL STALEY, YING LIU, Department of Physics and Materials Research Institute, The Pennsylvania State University — For doubly connected superconductors, cylinders, loops, or rings, the fundamental fluxoid quantization leads to oscillations in the superconducting transition temperature (T_c) with the applied flux. This is known as the Little-Parks effect. For sufficiently small loops, with a circumference smaller than $\pi\xi(0)$, where $\xi(0)$ is the zero temperature coherence length, superconductivity is completely destroyed near the half-flux quanta. This "destructive regime" emerges because of the competition between the kinetic energy carried by the supercurrent, and the condensation energy of the system. Theoretically, it has been shown that adding a tail to the loop can increase the condensation energy and possibly eliminate the destructive regime. We present electrical transport measurements on Al loops defined by e-beam lithography with a size comparable to $\xi(0)$. The loops were varied to have different condensation energies by adding explicit tails, and by lengthening and shortening the measurement leads. We observed strongly enhanced Little-Parks oscillations due to the reduction of the sample size, and the transition to the destructive regime when the size of sample was further reduced. These experimental results will be examined in the context of the competition between the kinetic and condensed energies. Work supported by NSF.

11:39AM W23.00003 Superconducting nanowires as nonlinear inductive elements for qubits[1] , JASEUNG KU, University of Illinois at Urbana-Champaign, VLADIMIR MANUCHARYAN, Yale University, ALEXEY BEZRYADIN, University of Illinois at Urbana-Champaign — We report microwave transmission measurements of superconducting Fabry-Perot resonators, having a superconducting nanowire placed at a supercurrent antinode. As the plasma oscillation is excited, the supercurrent is forced to flow through the nanowire. The microwave transmission of the resonator-nanowire device shows a nonlinear resonance behavior, significantly dependent on the amplitude of the supercurrent oscillation. We show that such amplitude-dependent response is due to the nonlinearity of the current-phase relationship of the nanowire. The results are explained within a nonlinear oscillator model of the Duffing oscillator, in which the nanowire acts as a purely inductive element, in the limit of low temperatures and low amplitudes. The low-quality factor sample exhibits a "crater" at the resonance peak at higher driving power, which is due to dissipation. We observe a hysteretic bifurcation behavior of the transmission response to frequency sweep in a sample with a higher quality factor. The Duffing model is used to explain the Duffing bistability diagram.

11:51AM W23.00004 Electrical transport properties of topological insulator Bi2Te3 nanowires contacted with superconducting electrodes[1] , MINGLIANG TIAN, JIAN WANG, MEENAKSHI SINGH, MOSES CHAN, PENN STATE UNIVERSITY TEAM — Single-crystal Bi2Te3 nanowires were fabricated by template-assisted electrochemical deposition. The electrical transport properties of the nanowires in the temperature range 1.8-300 K were investigated by connecting nonsuperconducting or superconducting electrodes. When the wire was connected to focused-ions beam deposited W-electrodes, a series of exotic quasi-periodic oscillations were found and the amplitude of the oscillations was unusually enhanced near 3.5 K below the Tc, 4.5 K, of W-electrodes. When the wire was connected to nonsuperconducting Pt electrodes, the wire showed positive magnetoresistance accompanied with random fluctuations.

[1]This work was supported bythe center for nanoscale science (Penn State MRSEC) funded by NSF under Grant No. DMR-0820404.

12:03PM W23.00005 Observation of Little-Parks Oscillations of the Kinetic Inductance at Low Temperatures Using a GHz Resonator with Two Parallel Superconducting Nanowires[1] , ANDREY BELKIN, MATTHEW BRENNER, THOMAS AREF, JASEUNG KU, ALEXEY BEZRYADIN, University of Illinois at Urbana-Champaign — Little-Parks (LP) effect manifests the phenomenon of the fluxoid quantization in doubly connected superconductors. Usually it is observed at high temperatures, i.e. slightly below the critical temperature (Tc). We demonstrated that a thin-film Fabry-Perot superconducting resonator with a pair of nanowires inserted at the point of supercurrent antinode can be used to reveal LP effect even at temperatures much lower than Tc. As magnetic field (H) is applied, the Meissner current develops, changing the kinetic inductance of the wires and, correspondingly, the resonance frequency of the resonator and its transmission S21 measured at the fixed frequency. The periodicity of the LP effect is revealed as a periodic set of distorted parabolas S21(H) corresponding to the states with different vorticities. The transition from one state to another corresponds to a Little's phase slip. We suggest a theoretical explanation to the shape of the observed parabolas. We also report a statistical analysis of the jumps between the parabolas.

12:15PM W23.00006 Spin Resonance and dc Current Generation in a Quantum Wire , PENG ZHOU[1], ARTEM ABANOV[2], WAYNE SASLOW[3], VALERY POKROVSKY[4], Texas A&M Univ. — We show that in a quantum wire the spin-orbit interaction leads to a narrow spin resonance at low temperatures, even in the absence of an external magnetic field. A relatively weak dc magnetic field of a definite direction strongly increases the resonance absorption. Linearly polarized resonance radiation produces dynamic magnetization as well as electric and spin currents. The effect strongly depends on the external magnetic field.

12:27PM W23.00007 Large oscillations of the magnetoresistance in nano-patterned high-temperature superconducting films , ILYA SOCHNIKOV, AVNER SHAULOV, YOSEF YESHURUN, Bar-Ilan University, GENNADY LOGVENOV, IVAN BOZOVIC, Brookhaven National Laboratory — Measurements on nano-scale structures made of high-temperature superconductors are expected to shed light on the origin of superconductivity in these materials. The size of loops made of these compounds was so far limited to the submicron scale. We report the results of measurements on loops of $La_{1.84}Sr_{0.16}CuO_4$, with dimensions down to tens of nanometers. We observe oscillations in the loops resistance as a function of the magnetic flux through the loops. The oscillations have a period of $h/2e$ and their amplitude is much larger than the amplitude of resistance oscillations expected from the Little-Parks effect [1-2]. Unlike the Little-Parks oscillations, caused by periodic changes in the superconducting transition temperature, the oscillations we observe are caused by periodic changes in the interaction between thermally-excited moving vortices and the oscillating persistent current induced in the loops. Despite the enhanced amplitude of these oscillations, we have not detected oscillations with a period of h/e, as recently predicted for nanoscale loops of superconductors with d-wave symmetry, or with a period of $h/4e$, as predicted for superconductors that exhibit stripes. 12:39PM W23.00008 Penetration Depth of Superconductors with Random Superfluid Density , THOMAS LIPPMAN, KATHRYN MOLER, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, 2575 Sand Hill Road, Menlo Park, CA 94025, USA. — Electronic inhomogeneity is inevitable in doped superconductors, due simply to the random nature of the doping process. We argue that when the superconducting coherence length is not much larger than the lattice scale, this creates spatial randomness in the superconducting properties. In particular, we expect the superfluid density to be stochastic, which modifies the measured diamagnetic response. We approximate the London equation with random superfluid density as a modified equation for the disorder averaged field response, and speculate on implications for the interpretation of measurements of the penetration depth.

12:51PM W23.00009 MBE Growth for Qubit Devices , ANTHONY MEGRANT, ALEX KOZHANOV, LUDWIG FEIGL, MARTIN WEIDES, JIAN ZHAO, YI YIN, JAMES WENNER, ANDREW CLELAND, CHRIS PALMSTROM, JOHN MARTINIS — A major component of the UCSB research program is to find and understand proper growth conditions and procedures for epitaxial Re and sapphire thin films. Separately, we are taking what we have learned from this research and applying it to develop growth-optimized procedures in our dedicated MBE chamber for qubit devices. I will report on important parameters that need to be adjusted to obtain optimum growth, some of which include: temperature, deposition rate and surface preparation. Measurement tools such as in-situ RHEED and ex-situ XRD and AFM are used to characterize the quality of the films, as well as the fabrication of resonators to measure the quality factor.

1:03PM W23.00010 Single Electron Turnstiles: Improving Performance for a Quantum Metrological Current Standard , THOMAS AREF, Aalto Univ, Low Temp Lab, Espoo, Finland, VILLE MAISI, MIKES, Espoo, Finland, OLLI-PENTTI SAIRA, Aalto Univ, Low Temp Lab, Espoo, Finland, ANTTI KEMPPINEN, MIKES, Espoo, Finland, JUKKA PEKOLA, Aalto Univ, Low Temp Lab, Espoo, Finland — A top priority in metrology is to develop measurement standards that are based on fundamental physical constants. Although such standards exist for resistance and voltage (the quantum Hall effect and the Josephson effect respectively), no such standard exists for the unit of current, the ampere, at the present time. The best candidate for a quantum metrological standard for current is a single electron turnstile. Such turnstiles allow electrons through one at a time. When operated at a specific frequency, they produce a proportional current traceable to the single electron charge. Our turnstiles are based on a normal metal copper island contacted through insulating barriers by superconducting aluminum electrodes. By engineering improvements such as on-chip filtering and increased charging energy, we have improved our turnstiles to suppress both first order leakage and second order Andreev currents thus approaching the required accuracy for a new quantum metrological current standard. This current standard would allow the closing of the quantum metrological triangle created by voltage, resistance and current.

1:15PM W23.00011 Tunneling spectroscopy of the Andreev Bound States in a Carbon Nanotube[1] , JEAN-DAMIEN PILLET, CEA-Saclay, CHARIS QUAY, CRISTINA BENA, LPS Orsay, ALFREDO LEVY YEYATI, Universidad Autónoma de Madrid, PHILIPPE JOYEZ, CEA-Saclay — Carbon nanotubes are not intrinsically superconducting but they can carry a supercurrent when connected to superconducting electrodes. This supercurrent is mainly transmitted by discrete entangled (electron-hole) states confined to the nanotube, called Andreev Bound States. These states are a key concept in mesoscopic superconductivity as they provide a universal description of Josephson-like effects in quantum-coherent nanostructures (e.g. molecules, nanowires, magnetic or normal metallic layers) connected to superconducting leads. We report here the first tunneling spectroscopy of individually resolved ABS, in a nanotube-superconductor device. Analyzing the evolution of the ABS spectrum with a gate voltage, we show that the ABS arise from the discrete electronic levels of the molecule and that they reveal detailed information about the energies of these levels, their relative spin orientation and the coupling to the leads.

1:27PM W23.00012 Quantum impurity model for microwave photons , MOSHE GOLDSTEIN, Department of Physics, Yale University, 217 Prospect Street, New Haven, CT 06520, USA, MICHEL DEVORET, Departments of Physics and Applied Physics, Yale University, New Haven, CT 06520, USA, MANUEL HOUZET, SPSMS, UMR-E 9001, CEA-INAC/UJF-Grenoble 1, F-38054 Grenoble, France, LEONID GLAZMAN, Department of Physics, Yale University, 217 Prospect Street, New Haven, CT 06520, USA — We consider propagation of microwave photons along an array of superconducting grains with a set of weakly-coupled grains at its center. Quantum fluctuations of charge on the weakly- coupled grains make the process of "photon splitting" effective. In such a process, an incoming photon may be split into a number of photons of lower energy. The minimal number of photons created in such process depends on the symmetry properties of the corresponding quantum impurity model. As an example, we consider a specific circuit allowing quantum fluctuations between two charge configurations of two weakly- coupled grains, thus mimicking the behavior of an anisotropic Kondo impurity. Both ferromagnetic and antiferromagnetic Kondo regimes may be reached this way. We relate the rate of conversion of the incoming photons into the lower-energy ones to the dynamic spin susceptibility of the Kondo model.

1:39PM W23.00013 Elliptic billiard is a nontrivial integrable system , TAO MA, ROSTISLAV SEROTA, University of Cincinnati — We investigate the semiclassical energy spectrum of quantum elliptic billiards. The nearest neighbor spacing distribution, level number variance and spectral rigidity support the notion that the elliptic billiard is a generic integrable system. A classical simulation shows that all periodic orbits, except two, are not isolated. From Fourier analysis of the spectrum, all peaks correspond to periodic orbits. The two isolated periodic orbits have relatively small contribution to the fluctuations of the level density as compared to non-isolated periodic orbits. We argue that elliptic billiard is a nontrivial classically integrable system that enables us to gain new insights into their properties.

1:51PM W23.00014 Measurement of the statistical properties of the persistent current in normal metal rings , MANUEL CASTELLANOS BELTRAN, WILL SHANKS, DUSTIN NGO, Yale University, ANIA BLESZYNSKI-JAYICH, UCSB, JACK HARRIS, Yale University — A striking manifestation of quantum mechanics at the mesoscopic scale is the existence of an equilibrium persistent current in normal metal rings threaded by a magnetic flux. A theory of non-interacting diffusive electrons predicts that the amplitude of these currents is a stochastic function of the disorder profile of the specific ring. Thus the persistent current is different from sample to sample, with a Gaussian distribution. Due to the difficulty of measuring these currents, experiments to determine the form of the persistent current distribution had not yet been performed. However, our group recently developed a technique for measuring persistent currents in normal metal rings with high SNR, low measurement back-action, excellent background rejection, and over a large range of magnetic fields. We have measured a total of roughly 100 independent realizations of persistent current amplitudes in single rings. Within the statistical limits of our data, we corroborate that the first five cumulants are consistent with a Gaussian distribution. As a further test of the higher-order statistical properties of the persistent current, we also show that the quadrature amplitudes of the current's Aharonov-Bohm oscillations are uncorrelated.

Session W24 DCOMP: Density Functional Theory I D167

11:15AM W24.00001 A conventional, massively parallel eigensolver for electronic structure theory[1] , V. BLUM, M. SCHEFFLER, Fritz Haber Institute, Berlin, Germany, R. JOHANNI, H. LEDERER, RZ Garching, TH. AUCKENTHALER, TH. HUCKLE, H.-J. BUNGARTZ, TU Munich, L. KRÄMER, P. WILLEMS, B. LANG, BU Wuppertal, V. HAVU, TKK Helsinki — We demonstrate a robust large-scale, massively parallel conventional eigensolver for first-principles theory of molecules and materials. Despite much research into $O(N)$ methods, standard approaches (Kohn-Sham or Hartree-Fock theory and excited-state formalisms) must still rely on conventional but robust $O(N^3)$ solvers for many system classes, most notably metals. Our eigensolver overcomes especially parallel scalability limitations, where standard implementations of certain steps (reduction to tridiagonal form, solution of reduced tridiagonal eigenproblem) can be a serious bottleneck already for a few hundred CPUs. We demonstrate scalable implementations of these and all other steps of the full generalized eigenvalue problem. Our largest example is a production run with 1046 Pt (heavy-metal) atoms [1] with converged all-electron accuracy in the numeric atom-centered orbital code FHI-aims,[2] but the implementation is generic and should easily be portable to other codes. [1] P. Havu *et al.*, Phys. Rev. B **82**, 161418 (2010). [2] V. Blum *et al.*, Comp. Phys. Comm. **180**, 2175 (2009).

11:27AM W24.00002 GPAW on Blue Gene/P[1] , NICHOLS ROMERO, Argonne National Laboratory, JUSSI ENKOVAARA, CSC - IT Center for Science Ltd., MARCIN DULAK, CHRISTIAN GLINSVAD, ASK LARSEN, JENS MORTENSEN, Technical University of Denmark, SAMEER SHENDE, University of Oregon, VITALI MOROZOV, JEFFREY GREELEY, Argonne National Laboratory — Density function theory (DFT) is the most widely employed electronic structure method due to its favorable scaling with system size and accuracy for a broad range of molecular and condensed-phase systems. The advent of massively parallel supercomputers have enhanced the scientific community's ability to study larger system sizes. Ground state DFT calculations of systems with $O(10^3)$ valence electrons can be routinely performed on present-day supercomputers. The performance of these massively parallel DFT codes at the scale of 1 - 10K execution threads are not well understood; even experienced DFT users are unaware of Amdahl's Law and the non-trivial scaling bottlenecks that are present in standard $O(N^3)$ DFT algorithms. The GPAW code was ported an optimized for the Blue Gene/P. We present our algorithmic parallelization strategy and interpret the results for a number of benchmark tests cases. Lastly, I will describe opportunities for computer allocations at the Argonne Leadership Computing Facility.

11:39AM W24.00003 Application of partition density-functional theory to model systems[1] , LARRY BOYER, George Mason University, MICHAEL MEHL, Naval Research Laboratory — Elliott et al.[2] have introduced a method called partition density-functional theory (PDFT) for expressing the Kohn-Sham charge density as a sum of overlapping fragment densities, which promises accuracy and efficiency along with a framework for developing and testing useful approximations for kinetic-energy functionals, T[n]. They illustrate their method using results obtained for non-interacting electrons in a one-dimensional model potential. Following their approach, we apply PDFT to similar models which examine its usefulness in developing approximations for T. We also discuss how PDFT compares with the self-consistent atomic deformation[3] method.

11:51AM W24.00004 Simple Impurity Embedded in a Spherical Jellium: Approximations of Density Functional Theory compared to Quantum Monte Carlo Benchmarks , MICHAL BAJDICH, MSTD, ORNL, Oak Ridge, TN 37831, JEOGNIM KIM, NCSA, UIUC, Urbana, IL 61801, USA, PAUL R.C. KENT, CNMS, ORNL, Oak Ridge, TN 37831, FERNANDO A. REBOREDO, MSTD, ORNL, Oak Ridge, TN 37831 — We study the electronic structure of a simple Gaussian impurity embedded in a spherical jellium in order to mimic the localization effects present in d- and f-electron compounds. We use quantum Monte Carlo benchmarks to validate approximations of density functional theory (DFT), such as local density approximation (LDA) and generalized gradient approximation (GGA) as well as the Hartree–Fock (HF) method. We identify distinct transitions between delocalized and localized states in the phase space of realistic densities ($1 \leq r_s \leq 5$) and moderate depths of the Gaussian impurity. We also extend the previous fixed-node diffusion Monte Carlo calculations of impurity-free jellium spheres and extract very accurate jellium surface exchange-correlation energies. Computer resources supported by DOE, Office of Science under contract DE-AC05-00OR22725 (NCCS). Research sponsored by DOE, BES, Materials Sciences and Engineering Division (FAR) and LDRD program (MB) and DOE SUF, CNMS (PRCK).

12:03PM W24.00005 Periodic Density Functional Theory Solver using Multiresolution Analysis with MADNESS[1] , ROBERT HARRISON, Oak Ridge National Laboratory, WILLIAM THORNTON, University of Tennessee — We describe the first implementation of the all-electron Kohn-Sham density functional periodic solver (DFT) using multi-wavelets and fast integral equations using MADNESS (multiresolution adaptive numerical environment for scientific simulation; http://code.google.com/p/m-a-d-n-e-s-s). The multiresolution nature of a multi-wavelet basis allows for fast computation with guaranteed precision. By reformulating the Kohn-Sham eigenvalue equation into the Lippmann-Schwinger equation, we can avoid using the derivative operator which allows better control of overall precision for the all-electron problem. Other highlights include the development of periodic integral operators with low-rank separation, an adaptable model potential for nuclear potential, and an implementation for Hartree Fock exchange.

12:15PM W24.00006 A Robust Spectrum Slicing Method Applied to the Kohn-Sham Equation for the Liquid/Solid Silicon Interface[1] , GRADY SCHOFIELD, JAMES CHELIKOWSKY, University of Texas at Austin — A difficult aspect of solving the Kohn Sham equation is the super-linear scaling of eigensolvers with the number of valence orbitals desired. We present a robust spectrum slicing technique that calculates the valence orbitals in a divide and conquer fashion through the use of smooth Chebyshev-Jackson filters. This algorithm allows for a "parallel" implementation of the eigensolver. Our calculations are done in the real-space density functional framework implemented in the program PARSEC. We apply this method to examine the liquid-solid silicon interface.

12:27PM W24.00007 Beyond the LDA in density functional theory: empirical Laplacian-based models for the exchange-correlation energy[1]

, ANTONIO C. CANCIO, CHRISTOPHER E. WAGNER, Ball State University — We report recent work in developing a GGA-level density functional theory using primarily the Laplacian of the density $\nabla^2 n$ as an input beyond the LDA. Our starting point and motivation is a model fit to the exchange-correlation energy density of the valence shell of the Si crystal and other systems, as calculated by quantum Monte Carlo simulations, which show a strong, roughly linear dependence of this quantity on the Laplacian. The model respects the Lieb-Oxford bound for large positive Laplacian but suffers from a pole at negative values. A better treatment of $\nabla^2 n$ in this limit can be used to construct an all-electron extension of our model, and as an added benefit, avoid the singularity in the Kohn-Sham potential that gradient-based models suffer due to the cusp in electron density at the nucleus. Using an expansion in $1/\nabla^2 n$ we fit exchange energy densities in the cusp region accurately; obtaining reasonable potentials is a harder task but made easier by keeping the gradient of the density.

12:39PM W24.00008 Better GGA and meta-GGA Functionals: VT84, meta-VMT, meta-VT84[1]

, ALBERTO VELA, Cinvestav, Mexico DF Mexico, J. MARTIN DEL CAMPO, J.L. GAZQUEZ, Univ. Autonoma Metropolitana I., Mexico, S.B. TRICKEY, Physics, QTP, Univ. Florida — The goal of fast DFT calculations on large families of highly complicated systems (e.g. large clusters, biomolecules) implicitly conflicts with the heavy emphasis of recent years on inclusion of exact exchange. In response we have worked on improving non-empirical GGA X functionals. Here we report extension of our VMT GGA functional (J. Chem. Phys. **130** 244103 (2009)) to satisfy a relevant asymptotic constraint, yielding the VT{84} X functional. With the PBE C functional, VT{84} gives about 10% improvement over VMT in energetics on the G3 223 molecule set. At the meta-GGA level of complexity, we have both meta-VMT and meta-{84}. The former is about 10% better on the G3 set than the TPSS meta-GGA, while meta-VT{84} gives roughly 10% further improvement over meta-VMT. Details of these assessments, including improvements in chemical shifts, will be presented.

12:51PM W24.00009 All-Electron and Pseudopotential Orbital-Free Density Functional Calculations[1]

, VALENTIN KARASIEV, T. SJOSTROM, S.B. TRICKEY, Physics, QTP, Univ. Florida — Generalized gradient approximation (GGA) and modified-conjoint GGA kinetic energy functionals, proposed recently, have been implemented in an all-electron diatomic molecule code and in a periodic boundary condition code which uses local pseudopotentials. Self-consistent OF-DFT calculations confirm earlier non-self-consistent results. The GGA KE functionals give qualitatively incorrect total energy surfaces in the attractive region (isolated molecule) and the equilibrium crystalline cell volume is strongly expanded. In contrast, the mcGGA functional predicts a qualitatively correct energy surface for isolated systems, and the equilibrium geometry for pseudopotential calculations is in agreement with the Kohn-Sham results. We show the closeness in behavior between GGA-based functionals and simpler approximations defined by mixing of the Thomas-Fermi and the von Weizsäcker KE functionals. Effects of the pseudopotential in OF-DFT calculations also are discussed.

1:03PM W24.00010 Contributions to the Non-interacting Free Energy Density Functional[1]

, S.B. TRICKEY, Physics, QTP, U. Florida, JAMES DUFTY, Physics, U. Florida, T. SJOSTROM, Physics, QTP, U. Florida — Phenomenological models for the T=0 non-interacting kinetic energy density functional often use a linear combination of the von Weizsäcker (vW) and Thomas-Fermi (TF) functionals. A more systemmatic approach, for any temperature follows from extracting the vW functional from the exact free energy density functional, and analyzing the remainder in a local density approximation. We show that the vW functional is a lower bound for the free energy functional, extending a well-known T=0 result and indicating its priority in the decomposition. The exact remainder involves gradients of the off-diagonal one-body Fermi density matrix, for which a local density approximation is ambiguous. We discuss the extent to which a TF contribution can be extracted. Extension of the original vW phenomenological approach gives complementary insight. Modeling the orbitals as modulated plane waves, with coefficients identified in terms of the density and its gradients leads to vW and TF functionals plus higher-order gradient and temperature corrections.

1:15PM W24.00011 Finite-size correction in many-body electronic structure calculations of spin polarized systems[1]

, FENGJIE MA, SHIWEI ZHANG, HENRY KRAKAUER, Department of Physics, The College of William and Mary — We extend the post-processing finite-size (FS) correction method, developed by Kwee, Zhang, and Krakauer[2], to spin polarized systems. The method estimates the FS effects in many-body (MB) electronic structure calculations by a modified density functional theory (DFT) calculation, without having to repeat expensive MB simulations. We construct a unified FS DFT exchange-correlation functional for spin unpolarized and fully spin polarized systems, and then interpolate the results to arbitrary spin polarizations using the formula of Perdew and Wang[3] or that of Perdew and Zunger.[4] The application of this FS correction method to several typical magnetic systems with varying supercell sizes demonstrates that it consistently removes most of the FS errors, leading to rapid convergence of the MB results to the infinite size limit.

1:27PM W24.00012 Generalization of the Hohenberg-Kohn theorem to the case of the presence of a magnetic field[1]

, VIRAHT SAHNI, Brooklyn College, CUNY, XIAOYIN PAN, Ningbo University — We generalize the HK theorem for the nondegenerate ground state of electrons in an external electrostatic field $\mathbf{E}(\mathbf{r}) = -\boldsymbol{\nabla} v(\mathbf{r})$ to the presence of an additional external magnetostatic field $\mathbf{B}(\mathbf{r}) = \boldsymbol{\nabla} \times \mathbf{A}(\mathbf{r})$. We prove that the nondegenerate ground state wave function Ψ is a functional of the ground state density $\rho(\mathbf{r})$, the physical current density $\mathbf{j}(\mathbf{r})$, and a gauge function $\alpha(\mathbf{R})$, with $\mathbf{R} = \{\mathbf{r}\}$. In other words, the basic variables, viz. those that uniquely determine the external potentials $\{v(\mathbf{r}), \mathbf{A}(\mathbf{r})\}$, are $\{\rho(\mathbf{r}), \mathbf{j}(\mathbf{r})\}$. As the choice of $\alpha(\mathbf{R})$ is arbitrary, it is possible to construct a $\{\rho(\mathbf{r}), \mathbf{j}(\mathbf{r})\}$ functional theory, as well as the corresponding Kohn-Sham and quantal density functional theories.

[1]Supported by RF CUNY and National NSF, China.

1:39PM W24.00013 Quantal density functional theory (QDFT) in the presence of a magnetic field[1] , XIAOYIN PAN, TAO YANG, Ningbo University, VIRAHT SAHNI, Brooklyn College, CUNY — We present the QDFT of electrons in an external electrostatic $\mathbf{E}(\mathbf{r}) = -\boldsymbol{\nabla} v(\mathbf{r})$ and magnetostatic $\mathbf{B}(\mathbf{r}) = \boldsymbol{\nabla} \times \mathbf{A}(\mathbf{r})$ field. This is the mapping from the interacting system of electrons to one of noninteracting fermions with the same density $\rho(\mathbf{r})$ and physical current density $\mathbf{j}(\mathbf{r})$. The mapping, based on the 'quantal Newtonian' first law, is in terms of 'classical' fields and quantal sources, the fields being separately representative of electron correlations due to the Pauli exclusion principle and Coulomb repulsion, and correlation-kinetic and correlation-magnetic effects. The theory is valid for ground and excited states. It is explicated by application to a ground state of the exactly solvable Hooke's atom in the presence of a magnetic field.

[1]Supported by National NSF, China and RF CUNY.

1:51PM W24.00014 Quantum Continuum Mechanics for Many-Electron Systems in a Strong Magnetic Field[1] , STEFANO PITTALIS, University of Missouri-Columbia, U.S.A., I.V. TOKATLY, Universidad del Pais Vasco and KERBASQUE, Basque Foundation for Science, Spain, G. VIGNALE, University of Missouri-Columbia, U.S.A. — A quantum continuum mechanics approach for the determination of the excitation energies of many-electron systems in strong magnetic field is introduced by means of linear response theory (LRT) and time-dependent deformation-functional theory (TD-DefT). In the high-frequency (anti-adiabatic) limit the collective modes of the system appear as the small oscillations of an elastic body in the presence of non-inertial forces reminiscent of the Coriolis and centrifugal forces. Interestingly, the complexity of the problem does not increase significantly with the particle number and only ground state properties are needed as an input. Further results, together with elementary and illustrative examples, may be presented as well.

2:03PM W24.00015 First principles finite temperature magnetism of defects in Fe using Wang-Landau method[1] , AURELIAN RUSANU, Materials Science and Technology Division, ORNL, D.M. NICHOLSON, Computational Science and Mathematics Division, ORNL, KH. ODBADRAKH, Materials Science and Technology Division, ORNL, GREGORY BROWN, Florida State University, MARKUS EISENBACH, National Center for Computational Sciences, ORNL — Magnetic structure of materials with defects presents a strong dependence on local atomic arrangements. This dependence affects mechanical, magneto-caloric, and magnetization properties. Insights into thermodynamic and magnetic fluctuations at defects in Fe are obtained from first principle analysis by deploying the first principle local self consistent multiple scattering method(LSMS) and Wang-Landau statistical method. The computation of thermodynamic properties requires the sampling of a large number of configurations. To reduce the computational effort a Heisenberg model will be used to speed the configuration sampling procedures. The approach will be demonstrated for Fe systems and will address the magnetic structure of defects.

Session W25 DCMP: Novel Superconductors I D166

11:15AM W25.00001 Parallels and contrasts in the pairing mechanism between cuprate and organic superconductors , THOMAS MAIER, Oak Ridge National Laboratory — The organic superconductors share many characteristics with the cuprates, such as the existence of antiferromagnetism, unconventional superconductivity and Mott insulating behavior. In addition, despite their complexity, their physics can be approximated by a single-band Hubbard model on a two-dimensional lattice. Here, we will present dynamic cluster quantum Monte Carlo simulations of a half-filled "dimer" Hubbard model on an anisotropic triangular lattice, which find a transition from an antiferromagnetic phase to a d-wave superconducting phase with increasing frustration. In particular, we will discuss commonalities and differences in the nature of the superconducting behavior between the dimer Hubbard model of the organic compounds and the standard Hubbard model of the cuprate materials.

11:27AM W25.00002 Can simple hydrocarbon molecular solids superconduct? A theoretical investigation of superconductivity in K_3Picene , XUHUI LUO, UIC & NIST, SERDAR OGUT, UIC, TANER YILDIRIM, UPenn & NIST — Unlike many well established high temperature (T_c) superconductors such as cuprates, M_3C_{60}, MgB_2 and iron-pnictides, the possibility of superconductivity in molecular hydrocarbon solids remains a controversial issue. This topic became active again by a recent study reporting superconductivity up to $T_c \sim$ 17 K in potassium doped Picene [1], a wide-bandgap semiconducting solid hydrocarbon. However, there is no theoretical study about possible mechanism of superconductivity. In this talk, we present a detailed first-principles study of the electron-phonon (el-ph) coupling in doped organic molecular solids. Due to large system size, the calculation of el-ph coupling using the standard linear response theory is not feasible. Hence, we have developed a finite-displacement method where both the phonon energies and el-ph coupling can be easily calculated for large systems. We have tested our code for well-established superconductors such as K_3C_{60} and MgB_2. As a comparison, we have also studied the el-ph coupling in alkali-doped Pentacene, a similar well-studied hydrocarbon in which no superconductivity has been observed. We discuss the effect of charge transfer as well as pressure on $T_c$for solid Picene and make predictions for future possible experiments.
[1] Mitsuhashi et al. Nature, 464, p. 76 (March, 2010).

11:39AM W25.00003 Electronic structure and magnetic properties of the hydrocarbon K_3picene superconductor near the metal-insulator transition , MINJAE KIM, B.I. MIN, Department of Physics, PCTP, Pohang University of Science and Technology, GEUNSIK LEE, HEE JAE KWON, Y.M. RHEE, JI HOON SHIM, Department of Chemistry, Pohang University of Science and Technology — Superconductivity has recently been observed in K-doped picene, K_3picene, which is a first organic superconductor in the hydrocarbon system with high transition temperature Tc=18K [1]. We have investigated the electronic structures and magnetic properties of K_3picene by density-functional theory. We have shown that the metal-insulator transition (MIT) is driven in K_3picene by 5% volume enhancement with a formation of local magnetic moment. Active bands for superconductivity near the Fermi level (E_F) are found to have hybridized character of LUMO and LUMO+1 picene molecular orbitals. Fermi surfaces of K_3picene manifest neither prominent nesting feature nor marked two-dimensional behavior. By estimating the ratio of the Coulomb interaction $U$and the band width $W$of the active bands near E_F , U/W, we have demonstrated that K_3picene is located in the vicinity of the Mott transition.

11:51AM W25.00004 Slow-Motion ^1H NMR Study of κ-$(ET)_2Cu[N(CN)_2]Br$[1] , J.C. GEZO, TAK-KEI LUI, R.W. GIANNETTA, C.P. SLICHTER, Loomis Laboratory of Physics, University of Illinois at Urbana-Champaign, J.A. SCHLEUTER, Materials Sciences Division, Argonne National Laboratory — The recent discovery of an anomalous Nernst signal in the pseudogap phase of organic superconductor κ-$(ET)_2Cu[N(CN)_2]Br$ suggests the presence of magnetic flux vortices above T_c.[2] We report spin-locked and line-narrowed proton NMR data on the pseudogap phase of this material. These experiments are sensitive to magnetic fluctuations, and probe far slower timescales (10^{-6}-10^{-3}s) than the previously explored NMR parameter space. Other experiments[3] have suggested that vortices leave an NMR fingerprint at these low frequencies.

12:03PM W25.00005 NMR Study of κ-$(ET)_2Cu[N(CN)_2]Br$[1] , TAK-KEI LUI, J.C. GEZO, R.W. GIANNETTA, C.P. SLICHTER, University of Illinois at Urbana-Champaign, IL 61801, J.A. SCHLUETER, Material Sciences Division, Argonne National Laboratory, Argonne, IL 60439 — We report measurements of the ^{13}C spin-lattice relaxation rate, $(T_1T)^{-1}$ of κ-$(ET)_2Cu[N(CN)_2]Br$, an organic superconductor with $T_C = 11.9\,K$. The shape of the $(T_1T)^{-1}$versus T graph suggests the existence of a finite spin singlet-triplet gap[2]. Knight shifts were measured to search for a two-component electronic system. We also report measurements using an "S-shape" pulse sequence[3] that inverts half of the absorption line, permitting one to study slow motions and spin density waves.

12:15PM W25.00006 13C NMR measurements of Zeeman limited superconductivity in κ-(BEDT-TTF)2Cu(NCS)2 , JEFFREY WRIGHT, UCLA , JAMES BRUGGER, UCLA Dept. of Physics & Astronomy, JOHN SCHLUETER, Argonne National Laboratory, REIZO KATO, RIKEN, STUART BROWN, UCLA — The class of superconductors formulated by the BEDT-TTF molecule offers a unique ability to study superconductivity which is Zeeman limited, utilizing their qausi-2D layered structure. The critical field H_{c2}, which usually limits superconductivity due to orbital screening currents, can be suppressed by aligning the applied magnetic field parallel to the conducting layers. In this orientation, the field penetrates in the form of Josephson vortices, and the dominant effect of the magnetic field is from the Zeeman interaction with quasiparticles. We present 13C NMR measurements of the spin lattice relaxation rate as a function of applied field on a single crystal of κ-(BEDT-TTF)2Cu(NCS)2 after aligning the field in this orientation. A quadratic dependence is observed: $R(B) \sim B^2$, which gives clear evidence of k-space nodes in the superconducting gap. Extending these measurements to field strengths near and above the Pauli limit, we observe a phase transition within the superconducting state at B=21.5T, and we comment on the compatibility of these results with the sought after FFLO state.

12:27PM W25.00007 Upper Critical Field in the Molecular Organic Superconductor $(DMET)_2I_3$[1] , PASHUPATI DHAKAL[2], Boston College, HARUKAZU YOSHINO, Osaka City University, JEONG IL OH, Boston College, KOICHI KIKUCHI, Tokyo Metropolitan University, MICHAEL J. NAUGHTON, Boston College — We report the temperature dependence of the upper critical magnetic field in the quasi-one-dimensional molecular organic superconductor $(DMET)_2I_3$, for magnetic field applied along the intrachain, interchain, and interplane directions. The upper critical field tends to saturation at low temperature for field in all directions and does not exceed the Pauli paramagnetic limit. Thus the superconductivity appears to be conventional spin singlet, in contrast to the status of the isostructural Bechgaard salts. Furthermore, we will discuss a magnetic field-induced dimensional crossover effect in the normal metallic state leading to a magnetoresistance minimum for the field parallel to the most conducting plane. This result will be useful to understand the nature of superconductivity in the molecular organic conductors.

[2]Current Address: Jefferson Lab, Newport News, VA

12:39PM W25.00008 London penetration depth of λ-$(BETS)_2GaCl_4$ superconductor , JASON MURPHY, H. KIM, K. CHO, M.A. TANTAR, Iowa State University/Ames Laboratory, A. KOBAYASHI, University of Tokyo, Japan, H. KOBAYASHI, Department of Chemistry, Nihon University, Japan, R. PROZOROV, Iowa State University/Ames Laboratory — After many years of study, it is still unclear whether the superconductivity of organic charge transfer salts is conventional or not. In particular, symmetry of the superconducting gap is an important unresolved question. The gap anisotropy and nodal structure can be probed via precision measurements of London penetration depth, $\lambda(T)$, for which tunnel-diode resonator has been developed over past 20 years. Here we report $\lambda(T)$ in λ-$(BETS)_2GaCl_4$ crystals ($T_c \sim 5$ K) measured down to 400 mK. We find that different samples exhibit different widths of superconducting transition, ΔT_c. It is known for organic superconductors that cooling rate from room temperature is important for the properties probed at the low temperatures. We discuss observed variation of ΔT_c with the cooling rate as well as sample size and aspect ratio. Results are compared with thermal conductivity measurements [1].

[1] M. A. Tanatar, T. Ishiguro, H. Tanaka, H. Kobayashi, Phys.Rev. B **66**, 134503 (2002).

12:51PM W25.00009 Thermodynamic study of the superconducting gap structure of $(TMTSF)_2ClO_4$, SHINGO YONEZAWA, YOSHITERU MAENO, Department of Physics, Graduate School of Science, Kyoto University, KLAUS BECHGAARD, Department of Chemistry, Oersted Institute, Copenhagen, Denmark, DENIS JEROME, Laboratoire de Physique des Solides, Univ. Paris-Sud, Orsay, France — We have studied the superconducting (SC) gap structure of the quasi-one-dimensional molecular conductor $(TMTSF)_2ClO_4$ based on our high-resolution heat capacity measurement. We developed a new calorimeter, which allowed us field-angle resolved calorimetry using one single crystal weighing as small as 76 μg. From our results, we investigate the SC gap structure in the k-space as well as in the spin space. Comparison between the SC phase diagram deduced from the present results and those obtained from previous resistivity measurements are also discussed.

1:03PM W25.00010 Superconducting energy gap features of MgB_2 thin films on different substrates and orientations , WENQING DAI, QI LI, Department of Physics, The Pennsylvania State University, University Park, PA 16802, KE CHEN, XIAOXING XI, Department of Physics, Temple University, Philadelphia, PA 19122 — We report a detailed study of tunneling spectra of MgB_2/I/Pb planar junctions with MgB_2 films on various substrates and of various doping levels. Planar trilayer junctions were fabricated using MgB_2 films with native oxide barrier grown by the Hybrid Physical-Chemical Vapor Deposition technique. Both π and σ bands contribute to the tunneling spectra of tilted-axis films on MgO (211) substrate and mainly π band was observed on c-axis MgB_2 films on SiC (0001), MgO (111) and c-sapphire substrates. We observed σ gap value of $\sim$7.9 meV in MgB_2 films on SiC substrates which display higher T_c due to the lattice strain. This is larger than 7.4 meV on unstrained substrates. However, the π gap value of all samples is $\sim$2.3 meV. We concluded that the strain in MgB_2 films on SiC substrates mainly affects the σ band of MgB_2. In addition, small amount of nitrogen gas was added during film growth to introduce more scattering in MgB_2 films. We systematically studied the change of two gaps with nitrogen doping from the tunneling spectra of MgB2/I/Pb junctions.

1:15PM W25.00011 Measurements of Multiple Gap Substructure in MgB_2 Below 1 Kelvin[1] , STEVEN CARABELLO, JOSEPH LAMBERT, ROBERTO RAMOS, Department of Physics, Drexel University — The two superconducting energy gaps of magnesium diboride (MgB_2) are well established. First-principles calculations have also predicted substructure within the sigma- and pi-band gaps. However, due to anticipated intraband impurity scattering, there is controversy as to whether these finer structures can be observed in real samples. Prior experimental evidence above 1 Kelvin has provided evidence supportive of these features. We have performed tunneling spectroscopy experiments on MgB_2/insulator/Pb Josephson junctions on SiC substrates, at temperatures as low as 20 mK. By measuring differential conductance at low temperatures, and by using extremely clean MgB_2 thin films, we have resolved features within the energy gaps to under 1 meV. We report results of these experiments, which are in remarkable agreement with theoretical predictions for this substructure.

[1]We wish to thank Profs. Xiaoxing Xi and Ke Chen for providing high quality MgB_2 Josephson junctions and many helpful insights.

1:27PM W25.00012 Time Dependent Transport Properties of Superconducting MgB_2 , MURAT OLUTAS, ATILGAN ALTINKOK, ATILLA KILIC, KIVILCIM KILIC, Abant Izzet Baysal University — The time dependent transport properties of polycrystalline superconducting MgB_2 sample was investigated in details by means of current-voltage (I – V curves) measurements with different current sweep rates (dI/dt) and transport relaxation (V – t curves) measurements. The corresponding measurements were carried out as functions of temperature (T), transport current (I) and external magnetic field (H). Upon cycling of the transport current, it was observed that the hysteresis effects in I – V curves are negligible. Further, for slow or fast sweep rates (dI/dt) of the transport current, the measured voltage dissipation at a given transport current is approximately stable and does not change much with time. Analysis of the I – V curves shows that the pinning potential is also practically independent of dI/dt. The time evolution of sample voltage reveals that the increase in sample voltage is quite a sharp and non-linear. The V – t curves were interpreted in terms of re-organization of flux lines and suppression of the effective superconducting order parameter along the sample as the time progresses. The quenched state created in V – t curves was correlated to the supercooling of flux lines. Finally, the experimental results of polycrystalline MgB_2 sample were compared to previous similar studies on superconducting $Y_1Ba_2Cu_3O_{7-x}$ and $Bi_{1.7}Pb_{0.3}Sr_2Ca_2Cu_3O_x$ polycrystalline samples.

1:39PM W25.00013 Measurement of Hc1 in MgB2 thin films and multilayer structures by a microwave absorption technique , CHENGGANG ZHUANG, KE CHEN, Temple Univ., SOM TYAGI, Drexel Univ., XIAOXING XI, Temple Univ. — For superconducting RF applications, Gurevich suggested a route to enhance the vortex penetration field, Hc1, and thermal breakdown field by a multilayer structure consisting of alternating insulator and superconductor layers with thicknesses smaller than the penetration depth. We have measured Hc1 of MgB2 thin films and multilayer structures by measuring the microwave absorption of the sample at 9.3 GHz in a TE102 rectangular cavity under an applied magnetic field. The magnetic fluxon penetration into the sample as the applied field is increased to greater than Hc1 leads to an increase in the microwave absorption. Preliminary results indicate an enhancement of Hc1 in the MgB2 thin films from the bulk value, consistent with Gurevich's thickness effect model, which is very promising for RF applications of MgB2.

1:51PM W25.00014 Magnetic force microscopy study of the penetration depth in MgB_2 thin films , JEEHOON KIM, LEONARDO CIVALE, MPA Division, Los Alamos National Laboratory, EVGUENI NAZARETSKI, Brookhaven National Laboratory, Upton, NY, NESTOR HABERKORN, MPA Division, Los Alamos National Laboratory, JOSH THIBODAUX, ILYA VEKHTER, Dept of Physics and Astronomy, Louisiana State University, BRIAN MOECKLY, Superconductor Technologies, Inc., Santa Barbara, JOE D. THOMPSON, ROMAN MOVSHOVICH, MPA Division, Los Alamos National Laboratory — We performed magnetic force microscopy (MFM) investigations of superconducting vortices in thin films of MgB_2. Our MFM instrument has the capability of scanning multiple samples. Prior to imaging vortices in MgB_2, vortex imaging in a Nb thin film was performed to characterize the cantilever's tip. This procedure allows extraction of the penetration depth with only one fitting parameter. Images of two MgB_2 films with different thickness were taken as a function of temperature, together with periodic checks of the condition of the magnetic tip via imaging of vortices in the Nb reference sample, during a single cooldown. The temperature dependent penetration depth determined by MFM will be compared to that obtained via SQUID magnetometry on the same samples.

2:03PM W25.00015 Metastable Vortex Lattice Phases in MgB_2 , C. RASTOVSKI, K. SCHLESINGER, P. DAS, M.R. ESKILDSEN, University of Notre Dame, IN, US, L. DEBEER-SCHMITT, Oak Ridge National Laboratory, TN, USA, N. ZHIGADLO, J. KARPINSKI, ETH Zurich, Switzerland — We present small-angle neutron scattering (SANS) studies of vortex lattice (VL) metastability in MgB_2. Three different VL phases are observed, all of which have a triangular symmetry. At low fields the VL is aligned with the crystalline a-axis. At intermediate fields the VL rotates away from the a-axis, leading to two degenerate domain orientations. Once the rotation reaches 30° a single domain, high field VL is reformed, now aligned along the a^*-axis. Metastable configurations are obtained when crossing the equilibrium VL transition lines by cooling or heating in a constant field. At any given field and temperature the equilibrium VL can be obtained by inducing vortex motion. We have explored the details of how the metastable VL transitions to the ground state, and established that the equilibrium VL phase propagate from the edge of the sample towards the center as the magnetic field is reduced. We have successfully prepared samples with a coexistence of metastable and ground state VL domains, and explored how large field changes are necessary to completely suppress the metastable VL phase. The SANS results are compared to measurements of the critical current obtained from magnetization measurements. This work was supported by DOE BES award no. DE-SC0005051.

Thursday, March 24, 2011 11:15AM - 2:15PM –

Session W26 DMP DCOMP: Focus Session: Iron Based Superconductors – Tuning Magnetism and Superconductivity D162/164

11:15AM W26.00001 ABSTRACT WITHDRAWN –

11:27AM W26.00002 Superconductivity in (Sr,Ba)Fe2As2 single crystals by Pt substitution[1] , TYLER DRYE, SHANTA SAHA, KEVIN KIRSHENBAUM, NICHOLAS BUTCH, JOHNPIERRE PAGLIONE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park, MD, PETER ZAVALIJ, Department of Chemistry and Biochemistry, University of Maryland, College Park, MD — Iron-based superconducting materials with the ThCr2Si2 tetragonal crystal structure appear to show a maximum superconducting transition temperature of Tc $\sim$ 20-25 K when transition metals (e.g., Co, Ni, Ru, Rh, Pd, or Ir) are substituted for Fe, effectively doping d-electrons and suppressing the antiferromagnetic order of the parent compounds. However, this trend is known to be broken in the case of SrFe2-xNixAs2 and SrFe2-xPdxAs2, which both have lower optimal Tc values near 10 K. We will present our recent work on Pt substitution in single crystalline BaFe2As2 and SrFe2As2, which induces a maximum Tc of 23 K and 17 K, respectively. The relation between Pt substitution in these systems and the related cases of isoelectronic Ni and Pd substitution will be discussed.

[1]This work was supported by AFOSR MURI Grant FA9550-09-1-0603.

11:39AM W26.00003 Tetragonal lattice collapse in $SrFe_2As_2$ - a combined experimental and theoretical study , HELGE ROSNER, DEEPA KASINATHAN, MIRIAM SCHMITT, ALIM ORMECI, KATRIN MEIER, ULRICH SCHWARZ, MPI CPfS Dresden, MICHAEL HANFLAND, ESRF Grenoble, KLAUS KOEPERNIK, IFW Dresden, YURI GRIN, ANDREAS LEITHE-JASPER, MPI CPfS Dresden — In a joint experimental and theoretical study we investigate the crystal structure of the Fe pnictide compounds $SrFe_2As_2$ under applied hydrostatic pressure. Applying high pressure X-ray diffractyion, for a critical pressure of about 10 GPa we observe a sudden collapse of the tetragonal c axis, accompagnied by a small expansion of the basal plane. This results in a drastic reduction of the c/a ratio and a significant decrease of the unit cell volume. This tetragonal collapse is well described by DFT band structure calculations and can be assigne d to the formation of an additional As-As bond along the tetragonal c axis.

11:51AM W26.00004 Structural tuning of superconductivity and magnetism in intermetallic iron-pnictide materials[1] , JOHNPIERRE PAGLIONE, University of Maryland — The relationship between superconductivity, magnetism and crystallographic structure remains as one of the intriguing properties of the new family of iron-based superconducting materials. A well established requirement for high-temperature superconductivity in these systems is a substructure of iron ions tetrahedrally coordinated with either pnictogen or chalcogen anions stacked together to form a layered material, suggesting that both tetrahedral geometry and quasi-two-dimensionality are key ingredients. Through an investigation of solid solutions of (Ba,Sr,Ca)Fe_2As_2 series of parent compounds, we present a study of the importance of internal tetrahedral structure in stabilizing both magnetic and superconducting ground states in these materials, revealing an intimate relationship between the energy scale that dictates magnetic order and the internal structure of the $FeAs_4$ tetrahedra even far above the magnetic ordering temperature. In addition, interlayer coupling is investigated by exploiting the "collapse" of the tetragonal unit cell of $CaFe_2As_2$ under pressure, where interlayer pnictogen-pnictigen bonding changes dramatically. We investigate the effect of this collapse on superconductivity via chemical substitution, demonstrating an intriguing interplay of structure, magnetic and superconducting properties.

[1]This work is supported by AFOSR-MURI grant #FA9550-09-1-0603.

12:27PM W26.00005 Magnetic ordering in $EuCo_2As_2$[1] , BALAZS SIPOS, ATHENA S. SEFAT, BRIAN C. SALES, OAK RIDGE NATIONAL LABORATORY, OAK RIDGE, TENNESSEE 37831, USA TEAM — We have synthesized and studied $EuCo_2As_2$ single crystals by resistivity, magnetoresistance, and susceptibility measurements. We found antiferromagnetic (AFM) ordering of the Eu spins at $T_N = 50$ K. Upon applying a magnetic field $H \| ab$ at $T = 2$ K this phase exhibits a metamagnetic (MM) transition at $H_{MM} = 3.5$ T. In case of $H \| c$ the magnetisation increases linearly up to 7 T. The same AFM to MM transition was found at 0.5 T in $EuFe_2As_2$ where it was found to be due to the reorientation of the Eu spin. We found that replacing Fe with Co strengthens the coupling between the Eu moments resulting in a higher T_N and H_{MM}.

12:39PM W26.00006 High Magnetic Field Studies of Pressure-induced Superconductor $EuFe_2As_2$, NOBUYUKI KURITA, MOTOI KIMATA, KOTA KODAMA, ATSUSHI HARADA, HIROYUKI SUZUKI, TAKEHIKO MATSUMOTO, SHINYA UJI, TAICHI TERASHIMA, National Institute for Materials Science, KEIZO MURATA, Graduate School of Science, Osaka City University — We have performed resistivity and susceptibility measurements of the pressure-induced superconductor $EuFe_2As_2$ under high magnetic fields up to 27 T. The upper critical field B_{c2} and its pressure evolution up to 3.2 GPa were determined in a wide temperature range down to 1.6 K. At 2.5 GPa, nearly the optimal pressure with T_c=30 K, $B_{c2}(0)$ obtained by the onset of resistive transitions are 25 T and 22 T for $B \parallel ab$ and $B \parallel c$, respectively, which are appreciably smaller than those for other Fe-based superconductors with similar T_c. The small $B_{c2}(0)$ values and the peculiar $B_{c2}(T)$ curves in $EuFe_2As_2$ can be explained by a multiple pair-breaking model including the exchange field due to the magnetic Eu^{2+} moments. We will also present the results of quantum oscillations observed above the optimal pressure.

12:51PM W26.00007 Pressure shift of the superconducting T_c of $(Pr_{1-x}Sr_x)FeAsO$ and $Sm(O_{1-x}F_x)FeAs$, KALYAN SASMAL, Department of Physics, TcSUH, University of Houston, G. MU, H.-H. WEN, Institute of Physics, Chinese Academy of Sciences, B. LORENZ, Department of Physics, TcSUH, University of Houston, CHING-WU CHU, Department of Physics, TcSUH, University of Houston and Lawrence Berkeley National Laboratory — Pressure plays important role in discovery and unraveling physics of novel superconductors.High Tc iron-based layered compounds can be obtained by hole/electron-doping.To determine if a symmetry between electron and hole-doping exists,we investigated pressure-induced shift in T_c by carryingout resistivity measurements under hydrostatic pressure on hole-doped $Pr_{1-x}Sr_xFeAsO$ up to 1.8GPa using piston-cylinder clamp cell device.The coexistence of superconductivity & spin-density wave behavior were observed and pressure effects on both being investigated. Four probe resistance measurements show T_c increases ($+dT_c/dP$) with pressure for under-doped $Pr_{1-x}Sr_xFeAsO$ similar to high-T_c cuprates. High pressure can compress crystalline structure of material and force its layers to be closer,which might increase material's T_c by improving pressure-induced charge transfer between (Fe_2As_2) and (Pr/Sr)O layers. The pressure effect on T_c of $Pr_{1-x}Sr_xFeAsO$ is being compared with that of electron doped $Sm(O_{1-x}F_x)FeAs$. The results suggest a symmetry appear to exist between electron and hole-doping Fe-pnictide superconductors.

1:03PM W26.00008 Pressure induced superconductivity in LaFeAsO: the role of anionic height and magnetic ordering[1] , RAVHI KUMAR, HiPSEC and Dep. Physics, University of Nevada Las Vegas, JAMES HAMLIN, Department of Physics, University of California San Diego, YUMING XIAO, STANISLAV SINOGEIKIN, PAUL CHOW, HPCAT and Carnegie Institution of Washington, BRIAN MAPLE, Department of Physics, University of California San Diego, YUSHENG ZHAO, HiPSEC and Dep. Physics, University of Nevada Las Vegas, ANDREW CORNELIUS, HiPSEC and Dep.Physics, University of Nevada Las Vegas — We have investigated the pressure effect on the crystal structure and magnetic ordering of LaFeAsO at low emperature ($\sim$18K) using high pressure powder x-ray diffraction (HPXRD) and nuclear forward scattering (NFS) to pressures up to 40 GPa. We demonstrate a continuous suppression of the long range antiferromagnetic ordering in this compound under pressure. Furthermore we show here a direct correlation between the pressure induced changes in the anionic height parameter to the transition temperature (Tc) and is first observed in the 1111 class of iron arsenide compounds under pressure. Our findings suggest that pressure induced suppression of magnetic ordering and the anionic height variation both play important roles in the origin of pressure induced superconductivity in LaFeAsO.

[1]HiPSEC is supported by NNSA, and DOE (DE-FC52-06NA26274).

1:15PM W26.00009 The Pressure Effects on $SmFeAsO_{0.85}$ and $PrFe_{0.925}Co_{0.075}AsO$ Superconductors , X.L. DONG, W. LU, J. YANG, W. YI, Z.C. LI, C. ZHANG, Z.A. REN, G.C. CHE, L.L. SUN, F. ZHOU, X.J. ZHOU, Z.X. ZHAO, National Laboratory for Superconductivity, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, CAS, Beijing 100190 — We have measured magnetic susceptibility of iron pnictide superconductors $SmFeAsO_{0.85}$ and $PrFe_{0.925}Co_{0.075}AsO$ under hydrostatic pressure up to 1.15 GPa. Our results indicate that the pressure dependences of T_C and superfluid density in both systems are positively correlated which suggests that these quaternary iron-based superconductors are not conventional BCS ones.

1:27PM W26.00010 Valence change of europium and its relation to superconductivity in $EuFe_2As_{1.4}P_{0.6}$ and compressed $EuFe_2As_2$, LILING SUN, JING GUO, GENFU CHEN, XIANHUI CHEN, XIAOLI DONG, WEI LU, CHAO ZHANG, ZHENG JIANG, YANG ZUO, SHUO ZHANG, YUYING HUANG, QI WU, XI DAI, YUANCHUN LI, JING LIU, ZHONGXIAN ZHAO — Superconductivity can be realized in Eu-containing pnictides by applying chemical (internal) and physical (external) pressure, the intrinsic physical mechanism of which attracts much attention in the studies of pnictide superconductors. Here we present the experimental evidence for the pressure-induced valence change of europium in $EuFe_2As_{1.4}P_{0.6}$ exposed to ambient pressure and $EuFe_2As_2$ to high pressure by x-ray absorption measurements on L_3-Eu edge. We found that the absorption spectrum of $EuFe_2As_{1.4}P_{0.6}$ showed a clear spectra weight transfer from divalent to trivalent state. Furthermore, a similar behavior of valence transition as in $EuFe_2As_{1.4}P_{0.6}$ was also observed in $EuFe_2As_2$ when pressure was applied. This is the first to report the observation of valence change in pnictide superconductors and the analysis of its influence on superconductivity in $EuFe_2As_{1.4}P_{0.6}$ and compressed $EuFe_2As_2$.

1:39PM W26.00011 Pressure effects on strained $FeSe_{0.5}Te_{0.5}$ thin films , MELISSA GOOCH, BERND LORENZ, Department of Physics and TcSUH at the University of Houston, SUNXIANG HUANG, CHIA-LING CHIEN, Department of Physics and Astronomy at John Hopkins University, PAUL CHU, Department of Physics and TcSUH at the University of Houston; Lawrence Berkeley National Laboratory — FeSe is the simplest structure in the family of the iron pnictides, with a reported superconducting transition of 8K for the α-PbO- type structure. With the substitution of Te for Se, $FeSe_{0.5}Te_{0.5}$, was found to have an increased superconducting transition up to 15.2 K. To investigate the strain effect on the superconducting properties of the $FeSe_{0.5}Te_{0.5}$, thin films were grown under different conditions. The Tc and the normal state properties show a correlation to the induced strain of the system. The application of external pressure resulted in an increase of T_c, but at different rates depending on the pre-existent strain in the system.

1:51PM W26.00012 Enhanced SDW transition temperature under hydrostatic pressure in Fe1.02Se0.10Te0.90 , NAOYUKI KATAYAMA, University of Virginia, KAZUYUKI MATSUBAYASHI, University of Tokyo, JUSCELINO LEAO, NIST, SUNGDAE JI, University of Virginia, SUNG CHANG, NIST, YOSHIYA UWATOKO, TAKU SATO, University of Tokyo, SEUNGHUN LEE, University of Virginia, UNIVERSITY OF VIRGINIA TEAM, UNIVERSITY OF TOKYO COLLABORATION, NIST COLLABORATION — We will present the spin glass (SG) to spin density wave (SDW) transition in Fe1.02Se0.10Te0.90 under hydrostatic pressure. At ambient pressure, the present compound shows SG transition, characterized by a broad weak magnetic peak. By applying hydrostatic pressure, SG develops to SDW at Pc $\sim$ 0.5 GPa and the sharp strong magnetic Bragg peak appears. The SDW transition temperature is increased up to $\sim$ 250 K at 8 GPa, which is sharply contrast to the results of pressure experiments in LaFeAsO families and BaFe2As2 families.

2:03PM W26.00013 Competition between magnetic order and superconductivity in Fe oxypnictides , SAMUELE SANNA, Physics Department and CNISM University of Pavia, Italy, P. CARRETTA, G. PRANDO, A. RIGAMONTI, R. DE RENZI, T. SHIROKA, G. LAMURA, M. PUTTI, A. MARTINELLI, R. CIMBERLE, M. TROPEANO, C. FERDEGHINI, A. PALENZONA, UNIVERSITY OF PAVIA TEAM, UNIVERSITY OF PARMA TEAM, UNIVERSITY OF GENOVA AND SPIN-CNR TEAM, ETH OF ZURICH TEAM — We have microscopically investigated the interplay between magnetism (M) and superconductivity (SC) of the RFeAsO (1111) oxy-pnictide for R=La, Sm and Ce as a function of F doping, isoelectronic Fe/Ru substitution and external pressure. In contrast to earlier data, our results suggest a unique behaviour in different 1111 families at the M-SC crossover, showing a sharp crossover between the two types of order as a function of F doping [1-3]. In the optimally e^--doped $SmFe_{1-x}Ru_xAsO_{0.85}F_{0.15}$ compound, magnetic order appears in the FeAs layers for $0.1 < x < 0.5$, together with a concomitant dramatic reduction of the superconducting transition temperature [3]. Both these features suggest a strong competition between the magnetic and superconducting order parameters within the FeAs layers of 1111 oxypnictides.

Session W27 GQI: Focus Session: Semiconductor Qubits- Optical Control, Donors, and Hybrid Systems C155

11:15AM W27.00001 Ultrafast optical entanglement control between two quantum dot spins

, SAM CARTER, DANNY KIM, ALEX GREILICH, ALLAN BRACKER, DANIEL GAMMON, Naval Research Laboratory — A single electron spin in an InAs quantum dot is very attractive as a qubit since this system is potentially scalable and allows complete quantum control on an ultrafast timescale using optical pulses. While great progress has been achieved with single spin qubits, it is essential for quantum information applications to move toward entangled multi-qubit systems. Two-qubit systems have been studied in electrostatically-defined quantum dots, but their optical functionality remains unexplored. Here we demonstrate ultrafast optical control of two interacting qubits consisting of two electron spins in separate InAs dots. We initialize the system into a spin singlet state using a cw laser. We then manipulate the entangled state of the two spins with single qubit gates (acting only on one spin) by using pulses faster than the exchange interaction. This allows us to generate all four Bell states. Two-qubit gates are obtained either by the natural exchange precession or by using a longer laser pulse that induces a phase shift in the precession. The two-qubit exchange rate (30 GHz) here gives SWAP gate times of 16 ps, the fastest of any candidate for quantum information processing.

11:27AM W27.00002 Complete ultrafast optical coherent control and spin echo of single InAs quantum dot spins

, KRISTIAAN DE GREVE, PETER MCMAHON, DAVID PRESS, Ginzton Labs, Stanford University, THADDEUS LADD[1], Ginzton Labs, Stanford University and National Institute of Informatics (NII), Tokyo, CHRISTIAN SCHNEIDER, DIRK BISPING, MARTIN KAMP, LUKAS WORSCHECH, SVEN HOEFLING, ALFRED FORCHEL, Technische Physik, Physikalisches Institut, Wilhelm Conrad Röntgen Research Center for Complex Material Systems, Universität Würzburg, YOSHIHISA YAMAMOTO, Ginzton labs, Stanford University and National Institute of Informatics (NII), Tokyo — We report on recent progress on the complete ultrafast optical coherent control of individual InAs quantum dot spin qubits. We demonstrate Rabi-oscillations and Ramsey-fringes, and implement a spin echo to overcome time-averaged dephasing.[2] We probe the hyperfine interaction of a single spin using optical pulse control. Interesting non-Markovian dynamics could be observed in the single electron spin free-induction decay, resulting from feedback between the strong electron spin Overhauser shift and spin dependent nuclear relaxation.[3]

11:39AM W27.00003 Control of exciton relaxation channels in quantum dot molecules

, KUSHAL C. WIJESUNDARA, JUAN E. ROLON, SERGIO E. ULLOA, ERIC A. STINAFF, Department of Physics and Astronomy, and Nanoscale and Quantum Phenomena Institute, Ohio University, Athens, OH 45701, USA, ALLAN BRACKER, DAN GAMMON, Naval Research Laboratory, Washington, DC 20375, USA — We observe modulations in radiative lifetimes and intensities of the spatially indirect exciton as the InAs/GaAs coupled quantum dot system is tuned between molecular and atomic like states. With standard time-resolved single photon counting techniques the measured lifetimes were found to vary between 0.3 and 2.0 ns which resulted in modulations of the observed photoluminescence intensity of the indirect exciton. These modulations can be attributed to phonon mediated relaxations and carrier tunneling processes in good agreement with the modeled results. We clearly see the structure of the acoustic phonon distribution as shown in recent theoretical predictions. Tuning the relative energy levels in coupled quantum dots results in controllable modulation of exciton relaxation channels that may provide new directions in engineering decoherence in these systems.

11:51AM W27.00004 Charge dynamics and phonon induced oscillatory relaxation rates of indirect excitons in quantum dot molecules[1]

, J.E. ROLON, K.C. WIJESUNDARA, E.A. STINAFF, S.E. ULLOA, Ohio University — Optoelectronic control of quantum dots is a thriving area of research with impact on fundamental physics and quantum information devices. Time-resolved photoluminescence experiments, carried out in charge tunable coupled quantum dots, have demonstrated non-monotonic behavior of neutral indirect exciton lifetimes over a wide range of applied electric fields [1]. We present a model for neutral indirect exciton lifetimes in electric field tunable quantum dot molecules. Our model includes field-dependent oscillatory phonon-induced relaxation rates [2], carrier tunneling rates, and carrier relaxation into nearby charged exciton states. To this end we have used a multi-excitonic Hamiltonian, and calculated the exciton population dynamics using a master equation with electric field dependent rates. We find that lifetime suppression is dominated by scattering with LA phonons at low fields, and that the maximum lifetime gives information on the effective dimensions of the molecule. In contrast, at high fields the lifetime suppression is dominated by the interplay of carrier population exchange with nearby charged excitons. This prompts for ways of controlling exciton lifetimes and possible decoherence in quantum dots. [1] K. C. Wijesundara et al., (unpublished), [2] J. I. Climente et al., Phys. Rev. B 74, 035313 (2006).

12:03PM W27.00005 Ultralong Coherence of Phosphorus Donors in High-Purity ^{28}Si Silicon

, S.A. LYON, A.M. TYRYSHKIN, Princeton University, S. TOJO, K.M. ITOH, Keio University, J.J.L. MORTON, Oxford University, T. SCHENKEL, Lawrence Berkeley National Laboratory, M.L.W. THEWALT, Simon Fraser University, H. RIEMANN, N.V. ABROSIMOV, Institute for Crystal Growth, IKZ, P. BECKER, PTB Braunschweig, H.-J. POHL, VITCON Projectconsult GmbH — We report on electron spin coherence measurements for phosphorus donors in high purity, highly-enriched ^{28}Si, with residual ^{29}Si of less than 50 ppm. At this low ^{29}Si density, spectral diffusion processes by nuclear spin flip-flops are suppressed, and therefore other relaxation processes become prominent. By examining a series of ^{28}Si crystals with a donor concentration of 1×10^{14} to 3×10^{15}/cm^3, we identified three decoherence mechanisms, all related to dipole interactions between donors: (1) instantaneous diffusion, caused by flips of donor spins induced by the applied microwave pulses; (2) spectral diffusion caused by T_1-induced flips of neighboring donors; (3) spectral diffusion caused by donor spin flip-flops. We demonstrate how all three mechanisms can be suppressed, leading to measured coherence times extrapolating to T_2 $\sim$10 sec. The work was funded by DOE and LPS.

12:15PM W27.00006 Electrical Control of the high spin system Mn2+ in ZnO

, RICHARD GEORGE, JOHN MORTON, ARZHANG ARDAVAN, University of Oxford, JAMES EDWARDS, University of Cambridge — We examine the high spin impurity Mn^{2+} in single crystal ZnO (S=5/2, I=5/2), and report a strong linear coupling (K = 52.3 rad/V/m) of the manganese electrical and magnetic moments that preserves quantum coherence. We combine pulsed EPR and electric field techniques to manipulate the Mn states and study electron spin lifetimes, finding T_{2e} and T_{1e} times of 0.8ms and 100ms at 2K in the natural material. We investigate the 'forbidden' transitions that become allowed in the low symmetry environment and use these to manipulate the nuclear spin state on a sub-microsecond timescale that is inaccessible via ENDOR and RF techniques. Finally, we explore the existence of subspaces that are robust against strain-induced decoherence and the application of this material as an entanglement-based field sensor.

12:27PM W27.00007 Electron spin coherence and electron nuclear double resonance of Bi donors in natural Si , JOHN MORTON, STEPHANIE SIMMONS, RICHARD GEORGE, Oxford University, WAYNE WITZEL, Sandia National Labs, H. RIEMANN, NIKOLAI ABROSIMOV, N. NOTZEL, Institute for Crystal Growth, Berlin, MIKE THEWALT, Simon Fraser University — We have shown that the electron spin coherence times of Si:Bi donors in natural silicon are limited by the same mechanism of spectral diffusion as seen in Si:P, though the smaller Bohr radius of the Bi donor leads to $\sim 30\%$ longer T_2 times (up to 0.8 ms). We have mapped out the 36 ENDOR transitions observable at X-band arising from the $I = 9/2$ nuclear spin of ^{209}Bi, going up to 1.3 GHz. We also demonstrate the transfer of electron spin coherence to and from the ^{209}Bi nuclear spin with a fidelity of $\sim 63\%$. Using pulsed ESR at W-band (100 GHz), we observe optically-induced dynamic nuclear polarisation, consistent with the mechanism of exciton capture proposed in by T. Sekiguchi *et al.*. Finally, we explore the zero-field splitting of 7.5 GHz in this system, within the context of coupling to superconducting resonators.

12:39PM W27.00008 Neutral donors interacting with a two-dimensional electron gas measured by electrically detected magnetic resonance up to 94GHz , C.C. LO, J. BOKOR, University of California, Berkeley, V. LANG, R.E. GEORGE, J.J.L. MORTON, University of Oxford, A.M. TYRYSHKIN, S.A. LYON, Princeton University, T. SCHENKEL, Lawrence Berkeley National Laboratory — Electrically detected magnetic resonance of a silicon field-effect transistor with channel-implanted donors is measured in a W-band (94 GHz, 3.36 T) resonant microwave cavity. It is found that the two-dimensional electron gas (2DEG) resonance signal intensity increases by two orders of magnitude compared with conventional low-field X-band (9.7 GHz, 0.35 T) measurements. On the other hand, the neutral donor resonance signals increase by over one order of magnitude. We interpret the results in terms of direct spin-dependent scattering and a polarization transfer from the donors to the 2DEG spin system.

12:51PM W27.00009 Electrical Manipulation of Spin Qubits in Li-doped Si , ANDRE PETUKHOV, LUKE PENDO, ERIN HANDBERG, South Dakota School of Mines, VADIM SMELYANSKIY, NASA Ames Research Center — We propose a complete quantum computing scheme based on Li donors in Si under external biaxial stress. The qubits are encoded on the ground state Zeeman doublets and coupled via long-range spin-spin interaction mediated by acoustic phonons. This interaction is unique for Li donors in Si due to their inverted electronic structure. Our scheme takes advantage of the fact that the energy level spacing in $1s$ Li-donor manifold is comparable with the magnitude of the spin-orbit interaction. As a result the Li spin qubits can be placed 100 nm apart and manipulated by a combination of external electric field and microwave field impulses. We present a specially-designed sequence of the electric field impulses which allows for a typical time of a two-qubit gate ~ 1 μs and a quality factor $\sim 10^{-6}$. These estimates are derived from detailed microscopic calculations of the quadratic Stark effect and electron-phonon decoherence times.

1:03PM W27.00010 Entanglement in a Solid State Spin Ensemble , STEPHANIE SIMMONS, RICHARD BROWN, Oxford University, HELGE RIEMANN, NIKOLAI ABROSIMOV, Leibniz Institut, PETER BECKER, PTB Braunschweig, HANS-JOACHIM POHL, VITCON Projectconsult GmbH, MIKE THEWALT, Simon Fraser University, KOHEI ITOH, Keio University, JOHN MORTON, Oxford University — Entanglement is a both a fascinating phenomenon and a critical ingredient in most emerging quantum technologies. Spin ensembles manipulated using magnetic resonance have demonstrated the most advanced quantum algorithms to date, however these studies contain no entanglement and hence constitute classical simulations of quantum algorithms. Here we report the on-demand generation of entanglement between an ensemble of electron and nuclear spins in isotopically engineered phosphorus-doped silicon. High field/low temperature electron spin resonance (3.4 T, 2.9 K) was used in conjunction with a hyperpolarisation sequence to reduce the spin entropy to a level sufficient to form an inseparable state. The generated entanglement was confirmed by measuring the state's density matrix which displayed a fidelity of 98% compared to the ideal state at this field and temperature. The entanglement operation was performed simultaneously, with high fidelity, to 10^{10} spin pairs, and represents an essential requirement of a silicon- based quantum information processor.

1:15PM W27.00011 Optimized Electron-spin-cavity coupling in a double quantum dot[1] , XUEDONG HU, University at Buffalo, SUNY, YU-XI LIU, Tsinghua University, China, FRANCO NORI, RIKEN, Japan — We search for the optimal regime to couple an electron spin in a semiconductor double quantum dot to a superconducting stripline resonator via the electrically driven spin resonance technique. In particular, we calculate the spin relaxation rate in the regime when spin-photon coupling is strong, so that we can identify system parameters that allow the electron spin to reach the strong coupling limit.

[1]We thank support by NSA/LPS through ARO.

1:27PM W27.00012 Near Field Photon Emission and Revival in Quantum Dot Qubits[1] , S. TAFUR, M.N. LEUENBERGER, Dept of Physics, University of Central Florida — Modeling the spontaneous emission of photons coupled to the electronic states of quantum dots is important for understanding quantum interactions and entanglement in condensed matter as applied to proposed solid-state quantum computers, quantum networks, single photon emitters, and single photon detectors. A quantum dot initially in an excited state can be experimentally observed to decay to its ground state and the observed homodyne tomography of the emitted photon can yield information about the qubit state of the emitter. Though the characteristic lifetime of photon emission is traditionally modeled via the Weisskopf-Wigner approximation, we seek to model the fully quantized spontaneous emission, including near field effects, of a photon from the excited state of a quantum dot beyond the Markovian limit. We further investigate subsequent interactions between the emitted photon and adjacent quantum dots in an effort to describe multipartite entanglement. We propose the use of discretized central-difference approximations of space and time partial derivatives, similar to finite-difference time domain models, to describe single photon states via single photon operators. Additionally, within the future scope of this model, we seek results in the Purcell and Rabi regimes for spontaneous emission events from quantum dots embedded in micro-cavities.

[1]NSF (Grant No. ECCS-0725514), DARPA/MTO (Grant No. HR0011-08-1-0059), NSF (Grant No. ECCS-0901784), and AFOSR (Grant No. FA9550-09-1-0450)

1:39PM W27.00013 A Theoretical Model of Single Photon Source at Room Temperature , AHMED ELHALAWANY, MICHAEL LEUENBERGER, University of Central Florida — In this work we present a theoretical model for an electrically injected single photon source at room temperature. The source is made of three regions. The region containing the source is n-doped, the middle region is an intrinsic semiconductor heterostructure. The region containing the drain is p-doped. The conguration of the intrinsic region is designed to trap a single pair of electron and hole; this is due to Pauli Exclusion Principle and Coulomb blockage. This is achieved by applying a reverse voltage to neutralize the intrinsic electric field between the n- and p-doped regions. Based on the calculated tunneling time of the electron/hole, the reverse voltage will be switched o. For the kinetics at the room temperature operation is calculated by means of the Master equations. For this we use an eective Hamiltonian in the tight-binding approximation. The results show that a single electron and a single hole are trapped simultaneously for an adequate period of time until they recombine.

1:51PM W27.00014 Phonons and solid-state qubits for quantum technology , Ö.O. SOYKAL, RUSKO RUSKOV, University of Maryland, College Park, MD 20742, CHARLES TAHAN, Laboratory for Physical Sciences, College Park, MD 20740 — Phonons in the context of quantum information processing are traditionally negatives. They induce relaxation or decoherence of or between qubit states. Learning to control phonons for positive purposes, both as supporting technology for quantum information processing, and for other quantum devices is of great possible interest. Already, acoustic waves are used as a supporting technology in microelectronics and optoelectronics (e.g. their slow speed can be useful in certain contexts). Here we consider some methods for making phonons useful and describe the physics of such systems in several potential solid-state systems including silicon. Our results may also be of interest to the optomechanics community.

2:03PM W27.00015 Towards electrons floating over diamond[1] , M.P. RAY, J.W. BALDWIN, M.K. ZALALUTDINOV, J.L. SHAW, J.E. BUTLER, B.B. PATE, Naval Research Laboratory, T.I. FEYGELSON, SAIC Inc. — The opportunities for development of a 2D electron system of image potential surface electrons over negative electron affinity diamond are examined. Image potential surface electron states, located spatially outside the solid, are well established on a variety of surfaces (metals, semiconductors and dielectrics). In particular, laterally confined electrons above liquid helium have been demonstrated and proposed for advanced computing applications [1,2]. Unlike the surface of liquid helium, the electron affinity of the diamond surface can be varied [3], providing the ability to lithographically pattern surface electron 'pools' and 'wires'. We present candidate structures for lateral charge control that make use of buried and surface features patterned in and on diamond. Electronic properties and spectroscopy of electrons over diamond in our fabricated structures are discussed.

Thursday, March 24, 2011 11:15AM - 2:15PM –
Session W28 DCMP: Graphene: Nanoribbons and Electronic Transport C156

11:15AM W28.00001 Low Bias Negative Differential Resistance in Graphene Nanoribbon Superlattices[1] , GERSON J. FERREIRA, Universidade de São Paulo, MICHAEL N. LEUENBERGER, University of Central Florida, DANIEL LOSS, University of Basel, J. CARLOS EGUES, Universidade de São Paulo — We theoretically investigate negative differential resistance (NDR) for ballistic transport in semiconducting armchair graphene nanoribbon superlattices at low bias voltages V_{SD}. We combine the modulated graphene-Dirac hamiltonian with the Landauer formalism to calculate the current I_{SD} through the system. This description is expected to be valid at low biases and for narrow samples. We find three distinct transport regimes in which NDR occurs: (i) a "classical regime" in which the transport across the crossings of barrier and valley bandgaps is suppressed; (ii) a quantum regime dominated by superlattice miniband conduction, with current suppression arising from the misalignment of miniband states with increasing V_{SD}; (iii) a Wannier-Stark ladder regime with current peaks occurring at the crossings of Wannier-Stark rungs from distinct ladders. We emphasize that all the above mechanisms show NDR at voltages lower than 500 mV. Interestingly, within the miniband transport regime the NDR occurs at biases as low as 10 mV, i.e., comparable to the miniband width.

11:27AM W28.00002 A finite difference method for transport of massless Dirac fermions: The case of graphene nanoribbons[1] , CAIO LEWENKOPF, Universidade Federal Fluminense - Brazil, ALEXIS HERNANDEZ, Pontificia Universidade Catolica do Rio de Janeiro - Brazil — We develop a new finite difference scheme to numerically compute the scattering matrix of two-dimensional massless Dirac fermions propagating in a ribbon geometry. The method is nonlocal, avoids the fermion doubling problem, and is suitable for introducing different kinds of boundary conditions. To illustrate its utility we compute the Landauer conductance of a monolayer graphene sheets with zig-zag boundary conditions in presence of a perpendicular magnetic field. The method is particularly useful in the study of long range disorder effects (much larger than the lattice spacing) in large graphene strips. In passing, we also show how the method works in the description of electronic transport at the surface of three-dimensional topological insulators.

11:51AM W28.00004 Graphene edge from A to Z , YUANYUE LIU, SOMNATH BHOWMICK, BORIS I. YAKOBSON, Rice University — We introduce an energy decomposition anzats, which leads to an analytical expression for the edge energy G(X) of arbitrary direction-cut angle X in two dimensional materials [1]. We further show that thermodynamic conditions at the edge simply add a "chemical phase shift" C, G(X) = cos(X + C), making the favorable shapes controllable, according to the Wulff construction. Direct atomistic computations and analysis for graphene, as well as 2D boron nitride (h-BN), and zinic oxide (ZnO) support the universal nature of the relationship.

[1] Y. Liu, A. Dobrinsky, and B.I. Yakobson, Phys. Rev. Lett., in press (Dec 10 2010 issue).

12:03PM W28.00005 Boron nitride nanoribbons become metallic , ALEJANDRO LOPEZ-BEZANILLA, JING-SONG HUANG, HUMBERTO TERRONES, BOBBY SUMPTER, Oak Ridge National Laboratory — Boron nitride (BN) sheets can be grown on nickel substrates, similar to graphene, and BN domains coexist with graphene. The synthesis of zig-zag BN nanoribbons (zBNNRs) brings interesting possibilities regarding edge chemistry: since both boron and nitrogen atoms are exposed on each edge the functionality of the nanostructure is enriched. We report first principles calculations on the electronic properties of zBNNR nanoribbons with several types of functionalization. Sulfur and oxygen edge doping and topological one-dimensional defects are studied and the possibility of having half metallicity is also analysed. Sulfur and oxygen edge passivation converts zBNNRs into a metallic material which offers several possibilities for new applications in electronics, molecular sensing and spintronics.

12:15PM W28.00006 Graphene valley pseudospin filter using an extended line defect[1] , DANIEL GUNLYCKE, CARTER WHITE, Naval Research Laboratory — Although graphene exhibits excellent electron and thermal transport properties, it does not have an intrinsic band gap, required to use graphene as a replacement material for silicon and other semiconductors in conventional electronics. The band structure of graphene with its two cones near the Fermi level, however, offers opportunities to develop non-traditional applications. One such avenue is to exploit the valley degeneracy in graphene to develop valleytronics. A central component in valleytronics is the valley filter, just as the spin filter is central in spintronics. Herein, we present a two-dimensional valley filter based on scattering of electrons and holes off a recently observed extended line defect [Nat. Nanotech. **5**, 326 (2010)] within graphene. The transmission probability depends strongly on the valley pseudospin and the angle of incidence of the incident quasiparticles. Quasiparticles arriving at the line defect at a high angle of incidence lead to a valley polarization of the transmitted beam that is near 100 percent.

12:27PM W28.00007 Zero Landau level in folded graphene nanoribbons[1] , ELSA PRADA, Instituto de Ciencia de Materiales de Madrid-CSIC, PABLO SAN-JOSE, Instituto de Estructura de la Materia-CSIC, LUIS BREY, Instituto de Ciencia de Materiales de Madrid-CSIC — Graphene nanoribbons can be folded into a double layer system keeping the two layers decoupled. In the Quantum Hall regime folds behave as a new type of Hall bar edge. We show that the symmetry properties of the zero Landau level in metallic nanoribbons dictate that the zero energy edge states traversing a fold are perfectly transmitted onto the opposite layer. This result is valid irrespective of fold geometry, magnetic field strength and crystallographic orientation of the nanoribbon. Backscattering suppression on the N=0 Hall plateau is ultimately due to the orthogonality of forward and backward channels, much like in the Klein paradox.

12:39PM W28.00008 Effective time-reversal symmetry breaking in the spin relaxation in a graphene quantum dot , PHILIPP STRUCK, GUIDO BURKARD, University of Konstanz — We study the relaxation of a single electron spin in a circular gate-tunable quantum dot in gapped graphene [1]. Direct coupling of the spin to out-of-plane phonons via the intrinsic spin-orbit coupling leads to a lowered relaxation time T_1 at intermediate B-fields. At low fields, T_1 increases as $\propto B^{-2}$ due to the suppression of the phonon density of states at long wavelengths in a finite system. We also find that Rashba spin-orbit induced admixture of opposite spin states in combination with the emission of in-plane phonons provides various further relaxation channels via deformation potential and bond-length change. In the absence of valley mixing, spin relaxation takes place within each valley separately and thus time-reversal symmetry is effectively broken, thus inhibiting the van Vleck cancellation at $B = 0$ known from GaAs quantum dots. Both the absence of the van Vleck cancellation as well as the out-of-plane phonons lead to a behavior of the spin relaxation rate at low magnetic and intermediate fields which is markedly different from the known results for GaAs. At high fields there is a crossover to $T_1 \propto B^{-2}$ or $\propto B^{-4}$.

12:51PM W28.00009 Sensory Organ Like Response of Zigzag Edge Graphene Nanoribbons[1] , VIJAY SHENOY, Indian Institute of Science Bangalore, SOMNATH BHOWMICK[2], Indian Institute of Science — Using a continuum Dirac theory, we study the density and spin response of zigzag edge terminated graphene ribbons subjected to edge potentials and Zeeman fields. Our analytical calculations of the density and spin responses of the closed system (fixed particle number) to the static edge fields, show a highly nonlinear Weber-Fechner type behavior where the response depends logarithmically on the edge potential. The dependence of the response on the size of the system (e.g. width of a nanoribbon) is also uncovered. Zigzag edge graphene nanoribbons, therefore, provide a realization of response of organs such as the eye and ear that obey Weber-Fechner law. We validate our analytical results with tight binding calculations. These results are crucial in understanding important effects of electron-electron interactions in graphene nanoribbons such as edge magnetism etc., and also suggest possibilities for device applications of graphene nanoribbons.

1:03PM W28.00010 Transport Through Graphene Surface States , DOUGLAS MASON, ERIC HELLER, Harvard University — Of particular interest to models of transport through graphene has been the theoretical prediction of long-lived surface states on zigzag cuts. These states may have a strong influence on transport through finite graphene structures since, unlike infinite nanoribbon surface states, they can absorb and emit electrons traveling through the bulk of the structure. We will be presenting a novel approach to these surface states and postulate on their role in recent transport calculations.

1:15PM W28.00011 Quantum charge pumping in graphene nanoribbons[1] , TEJINDER KAUR, Ohio University, LILIANA ARRACHEA, Universidad de Buenos Aires, Argentina, NANCY SANDLER, Ohio University — The mechanism to generate DC currents in open-quantum systems by applying local de-phased time-dependent potentials is known as charge pumping. For graphene ribbons, pumping techniques provide an alternative route for current production that overcomes the role of contacts. We have analyzed the properties of zero-bias current through graphene nanoribbons using a tight-binding Hamiltonian description and the Keldysh formalism, which provides the proper description for these systems in the quantum non-equilibrium regime. After reviewing results for quantum pumping in a one-dimensional chain attached to two reservoirs, with two local single-harmonic potentials oscillating in time, we will introduce results for finite-width ribbons of square and graphene lattices. A discussion on the differences in transmission functions and DC currents between these two cases will be presented and the role of edge termination in graphene ribbons will be addressed.

1:27PM W28.00012 Electronic properties of graphene nanoflakes: energy gap engineering , CARLOS RAMOS, EDUARDO CIFUENTES, ROMEO DE COSS, Cinvestav Unidad Merida, EDGAR MARTINEZ, Universidad Autonoma de Nuevo Leon — Graphene nanostructures show an energy gap resulting of the finite size, and are of current interest because of the potential applications in electronic devices. Thus, we discuss some recent progress in the synthesis of graphene nanoflakes obtained from the reaction of polyaromatic hydrocarbons. We are presenting ab-initio results for the electronic properties of graphene nanoflakes with a hexagonal-zigzag (HZ) structure and different effective radius (R). The calculations were performed using the Density Functional Theory as implemented in the pseudopotential-LCAO method. We find that the, Kohn-Sham gap decreases with size as R^{-1}, while the quasi-particle energy gap follow the $R^{-0.8}$ scaling rule. A formula to evaluate the energy gap of a HZ graphene nanoflake of arbitrary size is provided. This research was supported by Conacyt-México under Grant No. 83604.

1:39PM W28.00013 Electric and Magnetic Field Induced Insulating States in High Quality Bilayer Graphene pnp Junctions , LEI JING, JAIRO VELASCO, PHILIP KRATZ, Univ. of California, Riverside, GANG LIU, UCLA, WENZHONG BAO, MARC BOCKRAT, CHUN NING LAU, Univ. of California, Riverside — Band gap opening in bilayer graphene has generated significant interest in both technological application and fundamental research. By applying external electric and magnetic field, we observe an insulating state in our dual-gated bilayer graphene device. In addition, we also observe Quantum Hall plateaus with fractional values of e^2/h at large magnetic field, which arises from edge state equilibration at the interface of differentially doped regions, in agreement with theoretical predictions.

1:51PM W28.00014 Electron-Hole Asymmetry and Electron-Electron Interaction in Bilayer Graphene , K. ZOU, X. HONG, J. ZHU, Department of Physics, The Pennsylvania State University — We report precision measurements of the effective mass m^* in high-quality bilayer graphene samples using the temperature dependence of Shubnikov-de Haas oscillation. In the measured density range of $0.7\text{x}10^{12}/\text{cm}^2 < n < 4.1\text{x}10^{12}/\text{cm}^2$, both the hole mass $m^*_{\rm h}$ and the electron mass $m^*_{\rm e}$ increase with increasing n, with $m^*_{\rm h}$ being roughly 20-30% larger than $m^*_{\rm e}$ at the same density. We compare our results to tight-binding calculations and provide an accurate determination of several hopping parameters. The measured m^* is substantially suppressed compared to non- interacting values, demonstrating the importance of electron- electron interaction in bilayer graphene.

2:03PM W28.00015 Magneto-transport study of band structure of tri-layer graphene , RYUTA YAGI, SEIYA FUKADA, MIDOR SHIMOMURA, Hiroshima University — We have studied magneto-transport of high-quality tri-layer graphene samples. It has been observed Shubnikov-de Haas oscillations with two different frequencies that corresponded to two bands in tri-layer graphene. Detailed analysis of gate voltage dependence of the frequencies showed that sum of the carrier density for each band gave approximately the nominal carrier density tuned by the gate voltage. From temperature dependence of magnitude of the oscillation we have estimated cyclotron masses.

Session W29 GQI: Symmetric Discrete Structures for Finite Dimensional Quantum Systems

C148

11:15AM W29.00001 Pairwise complementary observables and their mutually unbiased bases , BERGE ENGLERT, National University of Singapore — Pairs of complementary observables (PCO) characterize all quantum degrees of freedom and are central to a technical formulation of Bohr's principle of complementarity. A defining property of such pairs are their mutually unbiased bases (MUB) of eigenstates. MUB have found many applications for tasks in quantum information processing. Maximal sets of PCO and MUB are known, by explicit construction, for degrees of freedom that live in finite-dimensional Hilbert space whose dimension is a power of a prime; continuous sets of MUB are also known for most continuous degrees of freedom. I will review the situation and mention a couple of open problems.

11:51AM W29.00002 Quantum States as Probabilities from Symmetric Informationally Complete Measurements[1] , ÅSA ERICSSON, Institute Mittag-Leffler — If you pick d^2 symmetrically spread vectors in a d-dimensional Hilbert space, you get a symmetric informationally complete set of quantum states (or SIC for short). SICs have applications within quantum information science, such as to quantum state tomography and quantum cryptography, and are also of interest for foundational studies of quantum mechanics. In this talk I will review the representation of quantum states as probability distributions over the outcomes of a SIC measurement. Not all probability distributions correspond to quantum states, thus quantum state space is a restricted subset of all potentially available probabilities. We will explore how this restriction can be characterized. A recent publication (Fuchs and Schack, arXiv:0906.2187) advocates the SIC-representation and suggests that the Born rule rewritten in this language can be taken as a postulate for quantum mechanics. This motivates the introduction of so-called maximally consistent sets (Appleby, Ericsson, and Fuchs, arXiv:0910.2750); one such set is quantum state space.

12:27PM W29.00003 The Lie Algebraic Significance of Symmetric Informationally Complete Measurements , STEVEN FLAMMIA, Caltech — Examples of symmetric informationally complete positive operator valued measures (SIC-POVMs) have been constructed in every dimension less than 68. However, it remains an open question whether they exist in all finite dimensions. A SIC-POVM is usually thought of as a highly symmetric structure in quantum state space. However, its elements can equally well be regarded as a basis for the Lie algebra gl(d,C). We examine the resulting structure constants, which are calculated from the traces of the triple products of the SIC-POVM elements and which, it turns out, characterize the SIC-POVM up to unitary equivalence. We show that the structure constants have numerous remarkable properties. In particular we show that the existence of a SIC-POVM in dimension d is equivalent to the existence of a certain structure in the adjoint representation of gl(d,C). We hope that transforming the problem in this way, from a question about quantum state space to a question about Lie algebras, may help to make the existence problem tractable. This is joint work with M. Appleby and C. Fuchs.

1:03PM W29.00004 Experimental access to higher-dimensional discrete quantum systems, towards realizing SIC-POVM and MUB measurements, using integrated optics[1] , CHRISTOPH SCHAEFF, IQOQI — The aim of our work is to access and explore higher-dimensional photonic quantum systems. In terms of stability and complexity, normal bulk-optic setups greatly limit the capabilities of reaching higher-dimensional systems. However, the recent development in integrated photonic circuits has opened new possibilities [1]. Our approach is to use integrated photonic circuits on-chip, as well as in fiber, to reach photonic states of higher dimension. We are working toward a fully integrated realization of a multiport [2], a device which can apply any unitary transformation based on tunable internal parameters. Our first step is to realize a multiport in dimension four, implementing any unitary transformation on Qubits, Qutrits and Ququarts. Furthermore, we have built an integrated source using purely in-fiber components for creating higher-dimensional entangled photons. The combination of this source with the multiport yields a very general system applicable to a variety of experiments in higher dimensional Hilbert spaces. It is possible to realize different experimental setups by setting the device for different incoming entangled states, and subsequently applying unitary transformations. For example, this opens the possibility to observe new types of higher-order perfect correlations [3], or to realize full SIC-POVM measurements in higher dimensions.

1:39PM W29.00005 Isotropic States in Discrete Phase Space , WILLIAM WOOTTERS, Williams College — An energy eigenstate of a harmonic oscillator is isotropic in phase space, in the sense that the state looks the same along any ray emanating from the origin. It is possible to extend this notion of "isotropic" to quantum systems with finite-dimensional state spaces—the rays are then rays in discrete phase space. In this talk I present examples of discrete isotropic states and discuss their properties. One can show that every isotropic state minimizes a specific information-theoretic measure of uncertainty with respect to a complete set of mutually unbiased bases. Numerical results on a certain class of isotropic state vectors suggest that their components, in any of those same mutually unbiased bases, exhibit a semicircular distribution when the dimension of the state space is large.

Thursday, March 24, 2011 11:15AM - 2:15PM –

Session W30 DCMP: Nanowires and Nanotubes: Optical Properties and Spectroscopy C147/154

11:15AM W30.00001 ABSTRACT WITHDRAWN –

11:27AM W30.00002 Low temperature electron transport spectroscopy of mechanically templated carbon nanotube quantum dots[1] , SAIFUL KHONDAKER, University of Central Florida, PAUL STOKES, UNIVERSITY OF CENTRAL FLORIDA TEAM — We report on the low temperature electronic transport measurements of mechanically templated carbon nanotube quantum dots (QDs). The devices were fabricated by precise dielectrophoretic placement of single walled carbon nanotubes (SWNTs) between 1 μm spaced Pd electrodes and over a local Al/Al_2O_3 bottom gate. The local gate defines the quantum dot due to the bending of SWNT at the edges of the gate, as well as controls its operation [1]. We performed detailed transport spectroscopy measurements of the templated SWNT QDs to determine how the tunnel barriers evolve with both the global back gate and local gate voltage. We will present models to explain the evolution of these devices as a function of local gate and back gate voltage. This study may allow for future size tunabiliy of SWNT QDs by further control over the tunnel barrier transparency and source, drain, and gate capacitance to fabricate room temperature single electron transistors.

11:39AM W30.00003 Tunneling spectroscopy using carbon nanotubes quantum dots[1] , YANJING LI, NADYA MASON, University of Illinois — Tunneling spectroscopy is an important measurement technique, encompassing, for example, planar tunneling, scanning tunneling microscopy and superconducting tunnel probes. Here, we demonstrate that carbon nanotube quantum dots (QDs) can be used as tunneling probes. The sharp features in the density of states of the QDs in the Coulomb blockade regime can map out the density of states and the energy distribution function of the system to be studied. We present preliminary data showing tunneling from a carbon nanotube quantum dot into mesoscopic metal wires that have been driven out of equilibrium by a bias voltage. Previous measurements of these systems using superconducting probes [1-2] showed that the electron energy distribution functions and electron interactions can be determined. With the present measurements, the use of a QD instead of a superconductor allows us to probe at significantly higher temperatures and biases.

11:51AM W30.00004 Photoconductivity Spectroscopy of Colloidal Lead Selenide Nanowires , RION GRAHAM, KA LEUNG, DONG YU, UC Davis — PbSe, with a large Bohr exciton radius of 46 nm, is ideally suited to study strong quantum confinement effects. Photoconductivity spectroscopy of single PbSe nanowire devices can remove the inhomogeneous broadening of ensemble measurements and allows for extraction of fine electronic structures in two dimensionally confined semiconductors. We have grown PbSe nanowires via a colloidal, oriented attachment mechanism, with diameters down to 6nm. Using a tunable wavelength laser, we have measured photoconductivity of single nanowire field effect transistors (FETs) as a function of excitation energy, temperature, and nanowire diameters.

12:03PM W30.00005 The optical properties of SnO_2 nano-wires by THz time-domain spectroscopy , DONGWOOK LEE, Nanyang Technological University, XINGQUAN ZOU, CHUANWEI CHENG, SARITHA K. NAIR, HONGJIN FAN, ELBERT E.M. CHIA — As feature seizes of devices are reduced below a hundred nanometers and chip frequencies reaches high GHz, a convenient method of characterizing thin films in the GHz to THz frequency range has been required. THz time-domain spectroscopy provides a non-destructive, non-contact, and high-sensitive tool to characterize thin films as well as nano-materials. The optical properties of SnO_2 nano-wires, which were grown on z-cut quartz, have been investigated by THz time-domain spectroscopy. The real and imaginary parts of the complex refractive index and optical conductivity are measured at THz frequency.

12:15PM W30.00006 Direct mapping of the exciton-polariton dispersion in tree-like ZnO micro-structures[1] , XIANGSHUN LU, Dept. of Physics, Univ. of Arkansas, HUAJUN ZHOU, Z. RYAN TIAN, Dept. of Chemistry and Biochemistry, MIN XIAO, Dept. of Physics, Univ. of Arkansas — We report a direct observation of branches of the exciton polaritons in tree-like ZnO micro-structures using second-harmonic generation (SHG) spectroscopy. Within the tunable range of a mode-locked Ti:Sapphire laser with pulse width of 100 femto-second, we are able to tune the second harmonic energy of the incident laser across the A, B and C excitons of ZnO. Under the resonant enhancement of the strong coupling between photons and excitons, we obtain for the first time the direct mapping of the branches of exciton-polariton dispersion at the room as well as liquid nitrogen temperatures. We also observed strong modulation of the polariton spectra by the whispering-gallery modes (WGMs) formed inside the tree-like micro-structure. The disappearance of the SHG in tree-like ZnO near/above the energy of the excitonic band gap indicates the much higher efficiency of energy conversion, comparing to the simple ZnO rod, and reveal the practical and important applications of the tree-like micro-structures in solar cell.

[1]We thank the partial funding support from NSF/MRSEC.

12:27PM W30.00007 Optical anisotropy of transparent multiwalled carbon nanotube sheets , JULIA BYKOVA, University of Texas at Dallas, Richardson, Texas, YAKOV LESNICHII, ALEKSEY ARSENIN, DMITRY FEDYANIN, Moscow Institute of Physics and Technology, Moscow, Russia, JONATHON SMITH, University of Texas at Dallas, Richardson, Texas, WILLIAM HOLMES, Solarno Inc., Irving, Texas, ANVAR ZAKHIDOV, University of Texas at Dallas, Richardson, Texas; Solarno Inc., Irving, Texas — Replace this text with your abstract body. The oriented carbon nanotube (CNT) sheets absorb polarized light anizotropically depending on its relative orientation to the incident light. Oriented aerogel of multi-walled carbon nanotubes (MWNT) created by dry-drawing of spinnable CNT forests has been shown to be a relatively good polarizer [1] even at high temperatures [2]. In this presentation it is shown how the qualitative factor of polarization (QFP) depends on the CVD synthesis conditions and CNT sheets process. The optimized QFP of MWNT sheet is found to be 2-3 times higher than reported before for CNT-based polarizers. Systematic characterization by UV-Vis spectroscopy, elipsometry combined with SEM showed how the polarization properties can be improved by annealing, stretching and electrical field, which enhance the anisotropy of MWCNT sheets. This work is supported by AFOSR grant FA 9550-09-10384 and AFRL/Rice grant via CONTACT consortium of Texas. [1] M. Zhang et al., Science, 309 (2005) 1215 [2] A. Aliev at al. Phys Let A, 372 (2008) 4938

12:39PM W30.00008 Synthesis and Optical Properties of Free Standing Titania Nanotubes Arrays for Photovoltaic and Photocatalytic Applications , DALMAU REIG-I-PLESSIS, MOHAMED ABD ELMOULA, EUGEN PANAITESCU, DONALD HEIMAN, LATIKA MENON, Northeastern University — Titanium oxide nanostructures, nanotubes arrays in particular, are key components for several emerging technologies, notably dye sensitized solar cells and supported gold nanoparticle catalysts. Free standing nanotube ordered arrays were produced by anodization of titanium foil in non-aqueous solutions. For optical measurement purposes the arrays were flaked off the titanium substrate. Flakes as large as several square centimeters, with a thickness of 30-50 μm were obtained, and coated either with N719 dye, or with gold nanoparticles (2-7nm). Both annealed (crystalline) and non-annealed (amorphous) samples were characterized by means of SEM and TEM imaging coupled with EDS and XRD spectroscopy. Subsequent optical measurements on gold decorated nanotubes offered insight on the gold-titania interaction, while measurements on both naked and dye coated tubes provided information on diffraction and thin film effects. These effects caused a significant wavelength dependent difference in the reflection spectrum depending on whether illumination was incident on the open or closed side of the tubes.

12:51PM W30.00009 Electro-Optic Effects in Colloidal Dispersion of Metal Nano-Rods with Nematic Ordering[1] , OLEG D. LAVRENTOVICH, Liquid Crystal Institute, Kent State University, ANDRII B. GOLOVIN, JIE XIANG, HEUNG-SHIK PARK, LUANA TORTORA, YURIY A. NASTISHIN, SERGIJ V. SHIYANOVSKII, Liquid Crystal Institute, Kent State University — In modern transformation optics, one explores metamaterials with properties that vary from point to point in space and time, suitable for applications in devices such as an "optical cloak" [1] and an "optical black hole" [2]. We propose an approach to construct spatially varying and switchable metamaterials that are based on colloidal dispersions of gold (Au) nano-rods (NRs) in dielectric fluids [3], in which dielectrophoretic forces, originating in the electric field gradients, create spatially varying configurations of aligned NRs. We quantify the electric field induced orientational order and concentration distribution of Au NRs and the describe the ensuing optical effects. We demonstrate that the gradient electric-field induces a nematic birefringent phase in the toluene dispersions of AuNR and determine how the refractive indices change in space. [1] W. 1:03PM W30.00010 Measurement of carrier lifetimes in silicon vapor-liquid-solid wires , BRIAN BRYCE, Cornell University, MARK REUTER, BRENT WACASER , IBM Thomas J. Watson Research Center, SANDIP TIWARI, Cornell University — Minority carrier lifetimes are critically important to many semiconductor devices. For example, optimal photovoltaic design is almost completely dependent on knowledge of carrier lifetimes. We have extended traditional microwave photoconductance methods for use on aggregated films of nanowires. Using these methods we have measured the carrier lifetimes of both gold and aluminum catalyzed silicon vapor-liquid-solid wires in the 100-800 nm range. This approach allows for rapid characterization of wire quality prior to device design and fabrication.

1:15PM W30.00011 Exciton dynamics for single walled carbon nanotubes in the presence of a single ion , BENJAMIN TAYO, SLAVA ROTKIN, Lehigh University — We study the dynamics of excitons in single walled carbon nanotubes in the presence of a single ion placed on the surface of the tube. The scattering process is described in three main stages. First, we solve the Schrödinger equation in the tight binding approximation to calculate the quasiparticle wave functions and energies. Second, we use quasiparticle wave functions and energies in the Bethe-Salpeter equation to calculate exciton binding energies and wave functions. Finally, we use the exciton energies and wave functions to investigate the process of exciton-ion scattering. We model the potential of the single ion by that of a point charge. Our studies show exciton trapping in the presence of the ion.

1:27PM W30.00012 The emissivity of an incandescent carbon nanotube[1] , B.C. REGAN, SCOTT SINGER, MATTHEW MECKLENBURG, EDWARD WHITE, UCLA Department of Physics and Astronomy, and CNSI — A classical thermal emitter has physical dimensions large compared to the wavelength λ of the emitted light, and radiates power in proportion to its surface area. To explore the non-classical limit, we build tiny incandescent lamps with individual multi-walled carbon nanotubes as their filaments. We image a filament with atomic resolution in a transmission electron microscope, determining its length L and radius r. Separately we apply Joule heating to reach temperatures ~ 2000 K, where the nanotube radiates in the visible ($L \sim \lambda \gg r$), and collect the light with an optical microscope. Comparing the filament's brightness with its tiny physical dimensions, we find that a single carbon nanotube is surprisingly black.

[1]Supported by NSF CAREER award #0748880.

1:39PM W30.00013 Polarized Light Emission from a Single Hot Carbon Nanotube[1] , S.B. SINGER, MATTHEW MECKLENBURG, EDWARD WHITE, B.C. REGAN, UCLA Department of Physics and Astronomy, and CNSI — We fabricate nanoscale lamps, incandescent in the visible, which have a filament consisting of a single multiwall carbon nanotube. The radius r of the nanotube is much smaller than the wavelength λ of the emitted light, making it a very unusual thermal emitter. Transmission electron microscopy is used to determine the nanotube's axis as well as the parameters of the tube's geometry. We image both light polarizations on a CCD camera simultaneously and observe a degree of polarization between 70% and 85% along the tube's axis at visible wavelengths–highly polarized, yet less so than is expected for a conducting antenna. Furthermore, the polarization's variation with wavelength trends opposite to that predicted by classical models and analogy with graphene.

[1]Supported by NSF Career Award #0748880.

1:51PM W30.00014 Photoconductivity of complexes of chrysotile with tetra(4-sulfonatophenyl) porphyrins created via ionic self-assembly[1] , WESLEY CHU, WALTER SMITH, Haverford College, YE LU, A.T. JOHNSON, University of Pennsylvania, GIOVANNA DE LUCA, LUIGI SCOLARO, Università di Messina — Tetrakis(4-sulfonatophenyl) porphine (TPPS4) molecules form complexes with chrysotile nanotubes in a chloroform-methanol solvent; the self-assembly is driven by Coulombic attractions. The UV/vis absorption spectrum indicates J-aggregation. In AFM, the complexes appear as straight, long tubes when deposited onto oxidized silicon substrates. Preliminary experiments conducted in a dry nitrogen atmosphere (0.2% oxygen concentration) show that the aggregates are photoconductive. When illuminated for long periods at 428 nm, the photoconductivity grows slowly, and there is also a growth of persistent photoconductivity. These observations are similar to those for nanorods self-assembled from TPPS4 (without chrysotile),[2] though the current levels are much lower in the chrysotile complexes.

2:03PM W30.00015 A confinement phase in carbon nanotubes as captured by the extended massive Schwinger model , TAKASHI OKA, HIDEO AOKI, The University of Tokyo — We propose that the strong-coupling excitons in carbon nanotubes with electric fluxes confined in one dimension can be a condensed-matter candidate for a confinement phenomenon. Namely, we show that the system, with the Coulomb interaction proportional to $|x|$, is in a confinement phase with many properties similar to QCD in 4D. Low-energy physics is described by the massive Schwinger model with multi-species fermions labelled by the band and valley indices. We propose two means to detect this. One is an optical measurement of the exciton spectrum, where the confinement phase should be hallmarked by an absence of continuous component in the exciton spectrum. The spectrum is actually calculated with the 't Hooft-Berknoff equation utilizing the light-front field theory, where the Gell-Mann-Oakes-Renner relation is shown to be satisfied by dark excitons. The second way is through the nonlinear transport, which is shown to be related to Coleman's "half-asymptotic" state. (arXiv:1007.5393)

Session W31 GERA: Energy Production & Distribution, Nuclear, Hydrogen, Bio and Infrastructure C145

11:15AM W31.00001 Phonon dynamics of UO_2 at high temperature[1] , J.W.L. PANG, ORNL, A. CHERNATYNSKIY, U. Florida, B.C. LARSON, ORNL, S.R. PHILLPOT, U. Florida, W.J.L. BUYERS, Can. Inst. for Adv. Res. — Inelastic neutron scattering and numerical simulations are being used to investigate the fundamental aspects of phonons and thermal transport in UO2 as part of a DOE-EFRC "Center for Materials Science of Nuclear Fuel" project. Understanding thermal transport associated with nuclear fuel environments requires a correct accounting for a wide range of phonon scattering processes, including anharmonic phonon-phonon, phonon-fission product, and phonon-defect cluster. Reactor and spallation neutron measurements of phonon dispersion, phonon linewidths and density of states in UO_2 at room and high temperature are in progress for direct comparison with atomic potential lattice-dynamics simulations of phonon dispersion, phonon group velocity, phonon linewidth, and phonon density of states. Direct comparisons between experimental measurements and numerical simulations in UO_2 as a function of temperature will be presented.

11:27AM W31.00002 An *Ab Initio* Study of α –Pu[1] , SARAH C. HERNANDEZ, ASOK K. RAY, University of Texas at Arlington — Hybrid density functionals, which replace a fraction of density functional theory exchange with exact Hartree-Fock exchange has been used to study the electronic, geometric, and magnetic properties of α – Pu. Different fractions of Hartree-Fock exchange have been used and the computations have been performed using the all-electron full-potential linearized augmented plane wave plus local orbitals basis method. Pu has been studied at the non-magnetic, ferromagnetic and anti-ferromagnetic configurations with spin-orbit coupling, orbital polarization, and *full* geometry optimizations. The variations of the optimized lattice constants, magnetic moments, bulk moduli, density of states, and the degree of $5f$ electron localization with the amount of Hartree – Fock exchange will be reported. Results will be compared with those of δ – Pu for which the performance of the hybrid functionals did *not* seem superior to that of the pure density functionals.[2]

11:39AM W31.00003 Electron Correlation and Tranport Properties in Nuclear Fuel Materials[1] , QUAN YIN, KRISTJAN HAULE, GABRIEL KOTLIAR, Rutgers University, SERGEY SAVRASOV, WARREN PICKETT, University of California, Davis — Using first principle LDA+DMFT method, we conduct a systematic study on the correlated electronic structures and transport properties of select actinide carbides, nitrides, and oxides, many of which are nuclear fuel materials. Our results capture the metal–insulator Mott transition within the studied systems, and the appearance of the Zhang-Rice state in uranium dioxide. More importantly, by understanding the physics underlying their transport properties, we suggest ways to improve the efficiency of currently used fuels.

11:51AM W31.00004 Reaction Rate Measurement at the Californium User Facility (CUF) for unfolding the neutron spectrum[1] , MOHAMMAD HANNAN, RUBEN ORTEGA, The University of Texas- Pan American — Neutron Activation Analysis was used to determine Reaction Rate measurement of several activation detectors at the ORNL Californium User Facility (CUF). The irradiations were performed with 34 mg Cf^{252} neutron source strength.. Ten source capsules $>$ 34 mg were positioned concentrically around a sample cavity. We have determined absolute activity per atom of 9 detectors: Au^{197} (n,γ) Au^{198}, Al^{27}(n,α)Na^{24}, Al^{27}(n,p) Mg^{27}, Fe^{56}(n,p) Mn^{5}, Fe^{54}(n,p) Mn^{54}, In^{115} (n,γ)In^{116}, Ti^{46}(n,p)Sc^{46}, Ni^{60} (n,p) Co^{60}, Fe^{58}(n,γ) Fe^{59}. The errors are within 1.5-8% except Ni^{60} and Fe^{58} have errors of 46% and 32 %. These high errors may be attributed to the counting statistics. These reaction rate values will be used to unfold the neutron spectrum of the CUF using the MAXED 2000, a computer code for the de convolution of multi sphere neutron spectrometer data and the results are discussed.

12:03PM W31.00005 A first-principles investigation of III-V semiconductor-water interfaces for solar hydrogen production , BRANDON WOOD, TADASHI OGITSU, ERIC SCHWEGLER, LLNL — Photoelectrochemical devices promise sustainable hydrogen production using sunlight and water. Currently, the highest efficiency devices use III-V semiconductor photoelectrodes; however, stability of these materials under operating conditions remains an issue. In an effort to understand the chemical properties of the electrode-water interface, we have performed first-principles molecular dynamics simulations on model III-V surfaces in realistic aqueous environments. The structure, stability, and chemical activity of these surfaces are investigated, with the aim of understanding the reactive states precursory to photoexcitation and hydrogen evolution. Our results show that surface oxide nucleation is key to facilitating surface reactivity, and that the surface oxygen bonding arrangement is important for determining of the available pathways for water dissociation and corrosion. This points to the importance of III-V surface oxides as intermediates in the water-dissociation component of hydrogen evolution. Prepared by LLNL under Contract DE-AC52-07NA27344.

12:15PM W31.00006 Hydrogen Generation and Photoelectrochemical Effect of InGaN alloys , KRISHNA ARYAL, BED PANTHA, RAJENDRA DAHAL, JING LI, JINGYU LIN, HONGXING JIANG, Texas Tech University — Generation of hydrogen gas, a clean source of energy with the highest conversion efficiency, via water splitting, using renewable resources has attracted tremendous research work in recent years. For producing hydrogen gas, a promising method using semiconductor materials is direct photoelectrolysis by solar water splitting. $In_xGa_{1-x}N$ alloys grown by metal organic chemical vapor deposition (MOCVD) are very promising candidates for water splitting because of their direct band gap which can be tuned to the entire solar spectrum through band gap engineering. It was found that n-GaN has a higher photocurrent density (J_{ph}) at zero bias, while an InGaN alloy provides much higher hydrogen generation rate (R_H) with a small external bias. R_H of about 0.024 mL/min.cm^2 was obtained using an $In_{0.18}Ga_{0.82}N$ as working electrode. The characteristics of time dependent J_{ph} for a prolonged period of time (up to 7 days) showed higher chemical stability of the InGaN electrodes in aqueous solution of HBr.

12:27PM W31.00007 Sieving hydrogen based on its high compressibility , HANGYAN CHEN, DEYAN SUN, Department of Physics, East China Normal University, Shanghai, China, XINGAO GONG, Department of Physics, Fudan University, Shanghai, China, ZHIFENG LIU, Department of Chemistry and Center for Scientific Modeling and Computation, Chinese University of Hong Kong, Hong Kong, China — Based on carbon nanotube intramolecular junction and a C60, a molecular sieve for hydrogen is presented. The small interspace between C60 and junction provides a size changeable channel for the permselectivity of hydrogen while blocking Ne and Ar. The sieving mechanism is due to the high compressibility of hydrogen.

12:39PM W31.00008 ABSTRACT WITHDRAWN —

12:51PM W31.00009 Combining micro-structures and micro-algae to increase lipid production for bio-fuel , SAURABH VYAWAHARE, EMILLY ZHU, TROY MESTLER, ANDRÉ ESTÉVEZ-TORRES, ROBERT AUSTIN, Physics Department, Princeton University, Princeton NJ 08544 — 3rd generation bio-fuels like lipid producing micro-algae are a promising source of energy that could replace our dependence on petroleum. However, until there are improvements in algae oil yields, and a reduction in the energy needed for processing, algae bio-fuels are not economically competitive with petroleum. Here, we describe our work combining micro-fabricated devices with micro-algae *Neochloris oleoabundans*, a species first isolated on the sand dunes of Saudi Arabia. Inserting micro-algae of varying fitness into a landscape of micro-habitats allows us to evolve and select them based on a variety of conditions like specific gravity, starvation response and Nile Red fluorescence (which is a marker for lipid production). Hence, we can both estimate the production of lipids and generate conditions that allow the creation and isolation of algae which produce higher amounts of lipids, while discarding the rest. Finally, we can use micro-fabricated structures and flocculation to de-water these high lipid producing algae, reducing the need for expensive centrifugation and filtration.

1:03PM W31.00010 Structure and diffusion of furans and other cellulose-derived compounds in solvents via MD simulation , BROOKS RABIDEAU, AHMED ISMAIL, RWTH Aachen University, Aachen, Germany — There is now a large push towards the development of energy sources that are both environmentally friendly and sustainable; with the conversion of cellulose derived from biomass into biofuels being one promising route. In this conversion, a variety of intermediary compounds have been identified, which appear critical to successful expansion of the process to an industrial scale. Here we examine the structure and diffusion of these furans and acids derived from cellulose within ionic liquids via molecular dynamic simulation. Ionic liquids have shown the ability to dissolve cellulose with certain 'green' benefits over existing, conventional solvents. Specifically, we study the solvation properties of these chemicals by examining the pair correlation functions of solute with solvent, and by exploring the agglomeration and separation of these chemicals from the solvent as well as the hydrogen bonding between species. Additionally, we determine the diffusion constant of these compounds in ionic liquid and aqueous solvents.

1:15PM W31.00011 Molecular-dynamics study of proton transport near an ionomer-electrode interface[1] , PHILIP TAYLOR, ELSHAD ALLAHYAROV, Case Western Reserve University — Coarse-grained molecular-dynamics simulations have been used to study the behavior of an ionomer electrolyte in response to an induced current. We observe the changes in the distribution of charge concentration and local electrostatic field in the region near an electrode in contact with a Nafion-like ionomer. We have also analyzed how the morphology of the sulfonate clusters and the transport of water molecules depends on the current strength. In this study we insert protons at the electrode interface of the material and remove them at a plane some distance into the material. When a steady state is achieved we note the new charge distribution and average voltage difference between the faces of the simulation cell. We also note the change in distribution of water molecules within the material in response to the induced current of protons. We compare these results with those predicted by one-dimensional theoretical models.

1:27PM W31.00012 Origin of colossal ionic conductivity in YSZ/STO multilayers , TIMOTHY PENNYCOOK, MARK OXLEY, Vanderbilt Univ., Oak Ridge National Laboratory, MATTHEW BECK, Vanderbilt Univ., JAVIER GARCIA-BARRIOCANAL, FLAVIO BRUNO, CARLOS LEON, JACOBO SANTAMARIA, Complutense Univ., Madrid, MARIA VARELA, Oak Ridge National Laboratory, STEPHEN PENNYCOOK, Oak Ridge National Laboratory, Vanderbilt Univ., SOKRATES PANTELIDES, Vanderbilt Univ., Oak Ridge National Laboratory — A colossal eight order of magnitude increase in the ionic conductivity of yttria- stabilized zirconia (YSZ) near room temperature was recently reported in YSZ/strontium titanate (STO) epitaxial heterostructures [1]. We present density functional theory results that explain the enhancement in terms of strain- and interface-induced disorder of the YSZ O-sublattice [2]. We further present experimental confirmation of O disorder using a combination of scanning transmission electron microscopy and electron energy loss spectroscopy. The O K-edge fine structure shows blurred-out features indicative of disorder [3]. Atomic-resolution elemental mapping clearly resolves the O sublattice in the STO but is blurred out in the YSZ, indicating disorder. This work is supported by DOE grant DE-FG02-09ER46554 and DOE Materials Sciences and Engineering Div. 1 J. Garcia-Barriocanal et al. Science 321, 676 (2008); 2 T.J. Pennycook et al., Phys. Rev. Lett. 104, 115901 (2010); 3 T.J. Pennycook et al., European Phys. J.

1:39PM W31.00013 Microscopic Understanding of Reactivity of Clinkers for Green Cement , ENGIN DURGUN, HEGOI MANZANO, ROLAND J. M. PELLENQ, JEFFREY C. GROSSMAN, Massachusetts Institute of Technology — Cement is the cause of up to 10 percent of global CO2 emissions, and yet, while it is one of the most common materials in use, we have remarkably little understanding of its microscopic properties. Toward this end, we use quantum mechanical simulations to examine the electronic properties and structure of cement crystals and to understand the surface reactivity of various clinker phases. Using these results, our aim is to clarify the mechanisms of cement dissolution, which is the initial stage of hydration and also one of the key processes that leads to the need for high temperature/energy manufacturing. As a first step we modeled the crystal structure of two major clinker phases, alite and belite and analyzed both electronic and mechanical properties. Next, we cleaved the clinker crystal in the simulation along different symmetry directions in order to obtain a prediction of the most stable surfaces. Dissolution occurs at the surface so accurate determination of the surface pattern is crucial. Using the computed surface energies, we can predict the full structure of the clinker nanocluster. This allows us to examine the interaction of water molecules with different nanocluster phases, in order to shed light on the dissolution mechanism and use this new understanding to predict possible novel routes for modifying and controlling the dissolution reactions.

1:51PM W31.00014 Comparison of Solar and Wind Power Output and Correlation with Real-Time Pricing[1] , KATHRYN E. HOEPFL, ALVIN D. COMPAAN, Dept. of Physics & Astronomy, University of Toledo, ANDREW SOLOCHA, Dept. of Finance, University of Toledo — This study presents a method that can be used to determine the least volatile power output of a wind and solar hybrid energy system in which wind and solar systems have the same peak power. Hourly data for wind and PV systems in Northwest Ohio are used to show that a combination of both types of sustainable energy sources produces a more stable power output and would be more valuable to the grid than either individually. This method could be used to determine the ideal ratio in any part of the country and should help convince electric utility companies to bring more renewable generation online. This study also looks at real-time market pricing and how each system (solar, wind, and hybrid) correlates with 2009 hourly pricing from the Midwest Interconnect.

[1]KEH acknowledges support from the NSF-REU grant PHY-1004649 to the Univ. of Toledo and Garland Energy Systems/Ohio Department of Development.

2:03PM W31.00015 Monte Carlo optimization of a matrix-based power-grid islanding algorithm , IBRAHIM ABOU HAMAD, PER ARNE RIKVOLD, Physics Department, Florida State University, SVETLANA V. POROSEVA, Mechanical Engineering Department, University of New Mexico — Spectral matrix methods are widely used for intelligent intentional islanding of power grids, the purposeful partitioning of a utility system to limit cascading disturbances. However, these methods may produce unbalanced islands of generators and loads when applied recursively. While some of the resulting islands have surplus generating capacity, others are deficient. We here implement a Monte Carlo simulated-annealing optimization procedure to load-balance the islands and increase their internal connectivity or modularity. After a matrix-based initial agglomeration of nearby loads and generators, Monte Carlo is used to redistribute loads among neighboring islands. The resulting network of islands is treated as a new network with the first-generation islands as the new nodes ("supergenerators" and "superloads"), and the same agglomeration and MC procedures are iteratively applied. We show here that combining matrix-based agglomeration and Monte Carlo methods results in well balanced, internally connected islands.

Session W32 FIAP DCOMP: Focus Session: Frontiers in Computational Thermodynamics of Materials I C144

11:15AM W32.00001 Modeling the interactions of adsorbates with each other and with metal surfaces , JOHN KITCHIN, Carnegie Mellon University — The interactions of molecules with metallic surfaces are fundamental to the ability of metals to catalyze reactions. One often thinks of a metal like platinum as the catalyst, but under reaction conditions the reactivity of the metal surfaces is modified by the molecules that adsorb on them. We have used quantum chemical calculations in conjunction with cluster expansions to probe the adsorption behavior of atomic adsorbates such as C, N, O, and S on late transition metal surfaces such as Rh, Ir, Pd, Pt, Cu, Ag, and Au(111). There are remarkable similarities in the adsorption behavior of these adsorbates that can be interpreted in terms of a simple adsorbate-induced surface electronic structure modification mechanism that is common to all the adsorbates and surfaces. The variations between the adsorbates and metals are readily explained in terms of the size of the metal and adsorbate orbitals and the geometry dependent overlap of these orbitals. We have constructed a new Solid State Table of these orbital radii from the quantum chemical calculations that can be used in conjunction with a simple model to rapidly estimate the electronic structure of metal and alloy surfaces with adsorbates on them.

11:51AM W32.00002 An Automatic Symmetry-Leveraging Approach for Solving Incomplete Many-Atom Crystal Structures , BRYCE MEREDIG, CHRIS WOLVERTON, Northwestern University — We present a new first principles-based method, called a symmetry-leveraging genetic algorithm (SLGA), for fully and automatically solving large crystal structures when experimental diffraction studies do not identify all internal atomic positions. Such incomplete structural refinements may occur when crystals contain light atoms or when the characterization is performed under extreme conditions such as high pressure. We apply our method to solve the crystal structure of the promising hydrogen storage candidate magnesium imide (MgNH), which has remained a mystery for over 40 years. We also confirm *via* a fully automated procedure a recent specialized "by hand" prediction for the high-pressure phase of ammonia borane, NH_3BH_3. The MgNH prediction, which involves 36 atoms and a notoriously complex configuration space, to the best of our knowledge represents the largest-ever crystal structure solution derived from first-principles calculations without making simplifying assumptions about atom connectivity. The 32-atom NH_3BH_3 prediction is nearly as demanding. Our approach, which takes full advantage of existing experimental information to solve for structural unknowns, has great potential for completing thousands of partially determined crystal structures.

12:03PM W32.00003 Finite Temperature Lattice Vibrations and the Magnetic Structure of Fe and Ni[1] , G. MALCOLM STOCKS, Oak Ridge National Laboratory, YANG WANG, Pittsburgh SuperComputer Center, ROGER STOLLER, Oak Ridge National Lab., AURELIAN RUSANU, University of Tennessee, MARKUS EISENBACH, DONALD NICHOLSON, GERMAN SAMOLYUK, Oak Ridge National Lab. — Modern *ab initio* theories of the magnetic phase transition (Curie Temperature, T_C) of Fe and Ni based on the Disordered Local Moment (DLM) type models generally rely on (constrained) density functional theory calculations performed at 0K and assume that the atoms occupy their equilibrium lattice sites. Here we point out that finite temperature lattice vibrations can result in large fluctuations in the local moments associated with individual site beyond those already accounted for in these approaches. These conclusions are based on large cell ($\sim 10^4$ – atoms) *ab initio* calculations of the magnetic state of Fe and Ni based on the O[N] Locally Self-consistent Multiple Scattering (LSMS) method. Atom positions are obtained from freezes of individual time steps of molecular dynamics simulations based on classical interaction potentials. Calculations are performed for a range of temperatures up and beyond T_C that illustrate the extent of the moment fluctuations. We discuss the consequences of these findings for the adequacy of existing theories T_C.

12:15PM W32.00004 Combined Experimental and Theoretical Studies of Core-Shell Nanostructures in Al-Sc-Li Alloys , COLIN OPHUS, ABHAY GAUTAM, Lawrence Berkeley National Lab, EMMANUELLE MARQUIS, University of Michigan, VELIMIR RADMILOVICH, ULRICH DAHMEN, Lawrence Berkeley National Lab, MARK ASTA, University of California, Berkeley — We have used two aging treatments of Al-Li-Sc alloys to create highly monodisperse, coherent $L1_2$ structure core-shell precipitates. We perform detailed analyses of the compositional distributions in the precipitate structures with electron microscopy and atom probe tomography. By combining this information with first principles calculations and Monte Carlo simulations based on the cluster expansion formalism, we compute bulk and interfacial thermodynamic properties relevant to precipitate formation. We specifically focus on understanding how the presence of Li modifies the nucleation rate relative to that of pure Al3Sc precipitates.

12:27PM W32.00005 New structures in Pd-rich ordered alloys[1] , JACQUELINE CORBITT, GUS HART, Brigham Young University - Provo — An intriguing intermetallic structure with 8:1 stoichiometry was discovered in the 1950s in the Pt-Ti system. Since then, a handful of other Pt/Pd/Ni binary systems have been observed to exhibit this curious structure (e.g., Pt_8Zr, Pd_8Mo, Ni_8Nb, etc). This ordered structure can significantly increase the hardness of an alloy by forming precipitates. Recent calculations and experiments suggest that the 8:1 structure may form in about 20 previously unsuspected Pt/Pd binary systems. Using first-principles calculations, cluster expansion, Monte Carlo modeling, we have explored possible precipitate hardening (via the 8:1 structure) in Pd-Nb, Pd-Mg and Pd-Cu.

12:39PM W32.00006 Pseudo-Random Number Generation for Brownian Dynamics and Dissipative Particle Dynamics Simulations on GPU Devices , CAROLYN PHILLIPS, JOSHUA ANDERSON, SHARON GLOTZER, University of Michigan — Brownian Dynamics (BD) and Dissipative Particle Dynamics (DPD) are implicit solvent methods commonly used in models of soft matter and biomolecular systems. The interaction of the numerous solvent particles with larger particles is coarse-grained as a Langevin thermostat is applied to individual particles or to particle pairs. The Langevin thermostat requires a pseudo-random number generator (PRNG) to generate the stochastic force applied to each particle or pair of neighboring particles during each time step. In a GPU parallel computing environment, small batches of random numbers must be generated over thousands of threads and millions of kernel calls. We introduce a PRNG scheme, in which a micro-stream of pseudorandom numbers is generated in each thread and kernel call. These high quality, statistically robust micro-streams are more computationally efficient than other PRNG schemes in memory-bound kernels, and uniquely enable the DPD simulation method . This scheme has been implemented in HOOMD-blue, a GPU-accelerated open-source general purpose molecular dynamics simulation package. By enabling BD and DPD to be performed in HOOMD-blue, a broad range of mesoscale coarse-grained simulations can now be accelerated in a massively parallel architecture.

12:51PM W32.00007 Efficient ab initio molecular dynamics using exact reweighting , VIDVUDS OZOLINS, University of California, Los Angeles, MARK ASTA, University of California, Berkeley — Density-functional theory (DFT) based *ab initio* molecular dynamics (AIMD) is a promising method for calculating high-temperature thermodynamic properties of solids and liquids. Nevertheless, computational expense associated with AIMD simulations has prevented general adoption of these methods. We show that substantial savings of computational effort can be realized by using less expensive (and less accurate) Hamiltonians to generate long MD trajectories and by recalculating statistically independent snapshots with high-accuracy DFT methods. A formally exact reweighting formula, based on the Jarzynski switching approach, is used to obtain thermal averages and thermodynamic properties in the high-accuracy DFT ensemble. If under-converged AIMD simulations with low energy cutoffs and coarse k-point meshes are used to generate trajectories, this approach can lead to savings of CPU time of a factor of 10 to 100, depending on the relevant correlations times. We also present extensions of the reweighting method to calculate impurity free energies and free energy barriers for interstitial diffusion. Robust methods for estimation of statistical errors based on random subsampling and variance extrapolation are discussed.

1:03PM W32.00008 Ab Initio Simulations of Hydrogen in Crystalline and Amorphous Metal Membranes , WILLIAM HUHN, MIKE WIDOM, Carnegie Mellon University — Solid metallic membranes are used to separate hydrogen from other gases for clean energy applications. In order to create cheaper, more effective membranes for hydrogen separation, it is desirable to model hydrogen transport through the membrane. Amorphous metal membranes in particular have potential for this type of application due to low expense and high theoretical hydrogen capacity. We computationally model hydrogen absorption and transport through materials in order to find materials that can be used to construct effective membranes for hydrogen capture. In this talk, we will obtain hydrogen binding sites and diffusion barriers in order to model the hydrogen diffusion through various nickel-based amorphous alloys and compare them to associated crystalline structures as well as elemental palladium, which is favored for this application despite its high expense. Ab initio methods (specifically the Vienna Ab Initio Simulation Package, VASP) are used to develop the hydrogen binding energy spectrum, from which thermodynamic models can be constructed. Kinetic Monte Carlo methods are used to model the hydrogen transport through the bulk, from which we can obtain the permeability.

1:15PM W32.00009 The enigmatic Ag-Pt phase diagram and yet another derivative structure algorithm , GUS L.W. HART, LANCE J. NELSON, RODNEY W. FORCADE, Brigham Young University — The Ag-Pt phase diagram as published in the most recent phase diagram compilations (Massalski, Pauling File) is entirely speculative below 1000° C. The phase diagrams and our calculations both suggest a stable $L1_1$ phase at 50 at.-% Pt. However, an experimental study published after the compilations supports a significantly different phase diagram. In this new phase diagram, the only stable phases at low temperatures are the elemental fcc Ag and Pt phases and one ordered phase at the unusual concentration of 53 ± 0.5 at.-% Pt. The experimental study shows that the homogeneity range for the ordered phase is narrow (almost like a line compound), and its X-ray data suggests that the unit cell of this phase contains 32 atoms with a stoichiometry of 15:17. We developed a new derivative structure enumeration algorithm specifically designed for large unit cells with known concentrations. This is necessary because our old algorithm enumerated all concentrations and was therefore limited to smaller unit cells. We have explored, via first-principles, the structural details of this enigmatic phase in the Ag-Pt phase diagram. I will discuss our first-principles results for Ag-Pt, and I will discuss the how the new algorithm is useful for large unit cells when partial structural information is known.

Thursday, March 24, 2011 11:15AM - 2:15PM –

Session W33 DCMP: Insulators and Dielectrics I C143/149

11:15AM W33.00001 An *Ab Initio* Study of $PuO_{2\pm0.25}$, $UO_{2\pm0.25}$, and $U_{0.5}Pu_{0.5}O_{2\pm0.25}$[1] , LI MA, ASOK RAY, University of Texas at Arlington — Hybrid density functional theory has been used to systematically study the electronic, geometric, and magnetic properties of strongly correlated materials $PuO_{2\pm x}$, $UO_{2\pm x}$, and $U_{0.5}Pu_{0.5}O_{2\pm x}$ with x=0.25. The calculations have been performed using the all-electron full-potential linearized augmented plane wave plus local orbitals basis (FP-L/APW+lo) method. Each compound has been studied at the ferromagnetic (FM) and anti-ferromagnetic (AFM) configurations with and without spin-orbit coupling (SOC) and *full* geometry optimizations. The optimized lattice constants, bulk moduli, and band gaps will be reported. Total energy calculations indicate that the ground states are AFM for all compounds studied here and the band gaps are typically higher than 1.0 eV, and characteristic of semiconductors. The total energy is lowered significantly and the band gaps increase with the inclusion of SOC. The chemical bonds between the actinide metals and oxygen atoms are primarily ionic in character.

11:27AM W33.00002 Characterization of point defects in UO2 by positron annihilation spectroscopy: a first-principles study , MARC TORRENT, GERALD JOMARD, Commissariat a l Energie Atomique et Aux Energies Alternatives, Paris, France — abstract- Positron Annihilation Spectroscopy is a powerful experimental tool for probing defects in crystalline materials. The correct identification of defects with PAS requires the knowledge of accurate positron lifetimes for the various kinds of defects. That can be provided by numerical calculations in the framework of the Two-Component Density-Functional Theory. This method accurately treat on the same footing, the electrons and positron densities as well as the atomic structure. We have implemented this formalism within the Projector Augmented-Wave method in the ABINIT code, optimizing the electrons and positron densities self-consistently and calculating positron-induced forces accurately. That allows to properly determining the relaxed geometries of defects that trapped positron. We have applied the TC-DFT to various point defects in UO2. The use of the PAW method allows considering large super cells to simulate point defects, we have typically used cells that contain 32 UO2 unit formulas. We use the LDA+U framework in order to treat strong electronic correlations. This work is a first attempt to help for the interpretation of PAS experiments on UO2 but it seems really promising.-

11:39AM W33.00003 Effect of Dielectric Materials on the Topological Insulator Bi_2Se_3 Surface States , JIWON CHANG, LEONARD REGISTER, SANJAY BANERJEE, BHAGAWAN SAHU, Microelectronics Research Center, The University of Texas at Austin — We study the effects of crystalline dielectric materials on the electronic surface states of a strong topological band insulator (TI) Bi_2Se_3 using a density functional based electronic structure method [1]. We will discuss the sensitivity of Dirac point degeneracy and linear band dispersion of the TI with respect to different dielectric surface terminations as well as different relative atom positions of the dielectric and the TI. Both passivated and non-passivated substrate surfaces will be considered. Two representative dielectrics SiO_2 and boron nitride will be chosen to understand the physics of interplay of interface potential, linear band dispersion and the chemical environments of the TI surface states. Our findings have implications in interpreting experiments and designing novel nanoelectronics device concepts based on TIs.

11:51AM W33.00004 First-Principles Investigation of Low Energy E' Center Precursors in Amorphous Silica , NATHAN ANDERSON, School of Materials Engineering, Purdue University, RAVI VEDULA, School of Electrical and Computer Engineering, Purdue University, PETER SCHULTZ, Sandia National Laboratories, RENEE VAN GINHOVEN, Pacific Northwest National Laboratory, ALEJANDRO STRACHAN, School of Materials Engineering, Purdue University — We show that oxygen vacancies are not necessary for the formation of E' centers in amorphous SiO2 and that a single O-deficiency can lead to two charge traps. Employing molecular dynamics with a reactive potential and density functional theory we generate an ensemble of stoichiometric and oxygen-deficient amorphous SiO2 atomic structures and identify low-energy network defects. Three-coordinated Si atoms appear in several low-energy defects both in stoichiometric and O-deficient samples where, in addition to the neutral oxygen vacancy, they appear as isolated defects. Various charge transition levels for each defect are also presented.

12:03PM W33.00005 Structure and energetics of ferroelectric domain walls in $LiNbO_3$ from atomic level simulations[1] , DONGHWA LEE, Lawrence Livermore National Laboratory, HAIXUAN XU, Oak Ridge National Laboratory, VOLKMAR DIEROLF, Lehigh University, VENKATRAMAN GOPALAN, Pennsylvania State University, SIMON PHILLPOT, University of Florida, UNIVERSITY OF FLORIDA TEAM, LEHIGH UNIVERSITY COLLABORATION, PENNSYLVANIA STATE UNIVERSITY COLLABORATION — Due to its unique ferroelectric and nonlinear optical properties, $LiNbO_3$ has a wide range of applications in optoelectronics and nonlinear optics. These unique properties of $LiNbO_3$ are, however, quite sensitive to point defects and ferroelectric domain walls. Therefore, detailed characterization of the ferroelectric domain walls and their interaction with the defects at atomistic scale is highly important The local structure and energetics of the ferroelectric domain walls in $LiNbO_3$ are examined using density functional theory (DFT) and atomistic-level simulation methods. The energetics and electric dipoles associated with the pertinent point defects and domain walls in $LiNbO_3$ are investigated in detail. In particular, the variation of polarization due to 180˚ ferroelectric domain walls, the coupling of defect-domain wall interactions and their effects on domain wall motion are discussed

12:15PM W33.00006 Study of Defects That Trap Excitons in Yttrium Aluminum Garnets Doped With Rare-Earth Elements[1] , FARIDA SELIM, CHRIS VARNERY, GARY COLLINS, DAVID MCKAY, SHERIF REDA, Washnigton State University — Excitons play a fundamental role in transporting energy in photonic materials. Understanding and controlling excitons dynamics through their interactions with activating impurities and lattice defects is key to improving scintillation and optical properties. Singles crystals of yttrium aluminum garnet (YAG) crystals doped with rare-earths were studied by positron annihilation, thermolunuinescence and optical spectroscopy. Evidence of defect complexes was found in the YAG structure. Positron lifetime measurements were performed to characterize those defects. Effects of dopants on the optical properties and lattice defects were investigated.

12:27PM W33.00007 Charge-Flow Regulation at Material Interfaces in Atomistic Models[1] , STEVEN VALONE, Los Alamos National Laboratory — An important class of materials problems of great interest consists of composites of metals and metal oxides. At sharp metal/metal oxide interfaces, the oxygen concentration is varying radically over short distances. For this reason, at the atomistic level, variable-charge atomistic models are required that control charge flow at these interfaces. Charge flow is controlled through chemical potential equalization among its constituents. Existing models of chemical potential, such as the Iczkowski-Margrave (IM) model, are linear in the charge as is appropriate for metals. Here a new, "fragment" model Hamiltonian is constructed at the atomistic level commensurate with the IM model, as opposed to the one-electron model Hamiltonians that underlie tight-binding and related methods. Essential properties of the fragment model Hamiltonian include an alternative charge dependence compared to the IM model, charge-flow regulation, absent in the IM model, preservation of a sense of covalent-ionic balance, and capture of important theoretical limits.

12:39PM W33.00008 Infrared laser ablation of polystyrene from microseconds to picoseconds , RICHARD HAGLUND, SERGEY AVANESYAN, KENNETH SCHRIVER, Vanderbilt University, MALTE DUERING, BARRY LUTHER-DAVIES, Australian National University, HEE PARK, AppliFlex LLC, SINGARAVELU SENTHILRAJA, Old Dominion University, MICHAEL KLOPF, Jefferson National Acceleratory Facility, MICHAEL KELLEY, College of William and Mary — We describe experiments on both resonant and non-resonant infrared pulsed laser of polystyrene across time scales varying from microseconds to picoseconds for the purpose of determining the ways in which the rate of energy deposition changes the response of both the ablated material and the residual substrate. RIR-PLD has been shown to be a relatively low-temperature process leading to evaporation and deposition of intact molecules. We compare the characteristics of ablation craters and ablation plumes deposited by Nd:YAG and Er:YAG lasers, picosecond and nanosecond optical parametric oscillators, and two different infrared free-electron lasers with differing pulse profiles. The films were characterized by profilometry, digital optical microscopy, scanning electron microscopy, and Fourier-transform infrared spectroscopy. Based on the experiments and computational modeling, we discuss the constraints on laser parameters that produce non-destructive ablation by resonant infrared excitation.

12:51PM W33.00009 The effect of substrate temperature on the structure and morphology of titanium nitride compounds grown by DC magnetron sputtering , MOHAMMAD R. HANTEHZADEH, REZA BAVADI, Plasma Physics Research Center, Science and Research branch, Islamic Azad University — The TiN thin films were deposited on p-type silicon (100) substrates using reactive planar DC magnetron sputtering system. The target was 99.99% pure Ti. The reactive sputter gas was a mixture of Ar (99.999%) and N_2 (99.999%) with the ratio Ar (97%) and N_2(3%) by volume. Structural characterization of the coating was done using X-ray diffraction (XRD). The surface roughness of the coating was determined using an Atomic Force Microscope (AFM). The reflectivity of thin films was investigated by a spectrophotometer system. The X-ray diffraction measurements showed that by increasing the substrate temperature during the growth, change in crystalline structure will occur. The crystallite size of the films determined by Scherer's equation, and the crystallite size measured by AFM also increased by increasing the substrate growth temperature. The surface reflectivity measurements indicate that by increasing the substrate growth temperature, the optical properties of the films changes. The change in optical properties and crystalline structure of the films indicate that substrate growth temperature plays an important role in structure and morphology of the grown layers.

1:03PM W33.00010 Growth of Erbium doped Yttrium oxide thin films by atomic layer deposition , NICHOLAS BECKER, THOMAS PROSLIER, J. KLUG, J. ELAM, Argonne National Laboratory, T. SANAMYAN, M. DUBINCKII, J. GIROLAMI, M. PELLIN, Argonne National Laboratory — Er-doped Yttrium oxide (Er^{3+}:Y_2O_3) has gained recent attention for its possible use in optoelectronic devices. Here we report the use of atomic layer deposition (ALD) to synthesize thin films of Yttrium oxide with various doping levels of Erbium ions (Er^{3+}) using different chemistries. ALD uses self-limiting surface reactions to deposit highly conformal thin films over large areas and substrates of arbitrary shape. This allows for the uniform layered doping of Yttrium oxide with Er^{3+}. The spatial separation of the Erbium ions can be controlled using organometallic precursors with varying ligand sizes. The doping concentration (volume ratio of Er^{3+} sites to Y^{3+} sites) is controlled by the ratio of the precursor pulses. We comprehensively studied ALD-grown films of Er^{3+}:Y_2O_3 obtained from the Erbium precursors Er(MCp)$_3$ and Er(BA)$_3$ and the Yttrium precursors Y(MCp)$_3$ and Y(Cp)$_3$ using either water or hydrogen peroxide as an oxygen source. Detailed description of the studied optical and spectroscopic properties, stoichiometry, and physical characteristics of these films will be presented.

1:15PM W33.00011 Atomic Layer Deposition of AlOx for Metal-AlOx-Metal Trilayers and Resonators , A. KOZEN, L. HENN-LECORDIER, X. CHEN, M. SCHROEDER, University of Maryland, C. MUSGRAVE, University of Colorado, G. RUBLOFF, University of Maryland — The dielectric layer in conventional Josephson junction qubits is fabricated by thermal oxidation of aluminum. These dielectrics suffer from high loss tangents thought to be due to defect-related quantum two level systems. Our collaborators have identified the -OH rotor associated with hydroxyl species in the AlOx as a prime defect candidate. We demonstrate the fabrication of the AlOx dielectric in MIM structures using atomic layer deposition (ALD) from trimethylaluminum and both H2O and D2O precursors. ALD enables precise control of film growth at the atomic scale, while comparison of D2O vs H2O as the oxidation precursor should reveal the role of this defect in the loss tangent. We have developed the D2O based ALD process, observed similar kinetics and properties for D2O and H2O based ALD for AlOx, and characterized the materials by SIMS, XPS, and electrical measurements of MIM capacitor structures. Correlation between room temperature electrical measurements and low temperature resonator performance will be discussed.

1:27PM W33.00012 Improvements of Defect Analysis by Space-Charge Wave Spectroscopy[1] , KAY-MICHAEL VOIT, University of Osnabrueck, BURKHARD HILLING, HEINZ-JÜRGEN SCHMIDT, MIRCO IMLAU — We report on our recent advancements in space-charge wave spectroscopy, which can be used to investigate defect structures in classical high-resistive semiconductors and insulators. It permits to estimate the effective trap concentrations as well as the effective donor density N_{eff} and the product $\mu\tau$ of electron mobility and life-time in the conduction band. We present a novel method of space-charge wave excitation, using a superposition of a running and a static sinusoidal illumination pattern. Thus we acquire – in contrast to the former oscillating pattern – a distinct direction of movement. The proposed new technique can be regarded as an effective amelioration, as the theoretical analysis is no longer limited by numerous presumptions like low modulation depth or small oscillation amplitudes. It not only overcomes these limits of the experimental configuration improving accuracy of SCW spectroscopy, but it also provides additional information, such as the sign of the charge carriers.

1:39PM W33.00013 First-principles studies of Ce and Eu doped inorganic scintillator gamma ray detectors[1] , ANDREW CANNING, ANURAG CHAUDHRY, Lawrence Berkeley National Laboratory, UC Davis, ROSTYSLAV BOUTCHKO, STEPHEN DERENZO, Lawrence Berkeley National Laboratory — We have performed DFT based band structure calculations for new Ce and Eu doped wide band gap inorganic materials to determine their potential as candidates for gamma ray scintillator detectors. These calculations are based on determining the 4f ground state level of the Ce and Eu relative to the valence band of the host as well as the position of the Ce and Eu 5d excited state relative to the conduction band of the host. Host hole and electron traps as well as STEs (self trapped excitons) can also limit the transfer of energy from the host to the Ce or Eu site and therefore limit the light output. We also present calculations for host hole traps and STEs to compare the energies to the Ce and Eu excited states.

1:51PM W33.00014 Novel Approaches in Energy Conversion by Molecular Charge Transfer from Diamond Surfaces[1] , FRANZ A.M. KOECK, Arizona State University, JEFF SHARP, Marlow Industries, Inc, ROBERT J. NEMANICH, Arizona State University — Vacuum thermionic energy conversion is based on electron transfer from a hot emitter across a vacuum gap to the collector. Our approach for an efficient emitter utilizes nanostructured, negative electron affinity doped diamond films. With a low effective work function of less than 1.3 eV thermionic emission commences at 260 C and observes the law of Richardson – Dushman with a significant emission current $>$ 5 mA at 500 C. Pairing this emitter with a similar collector results in a potential across the gap and introduction of an ohmic load establishes a current indicative of energy conversion. Utilizing ionization processes of gaseous species at the emitter surface can enhance inter-electrode charge transfer and increase output power. In the ionization process an electron is trapped in an occupied molecular orbital establishing a negative ion state. The electron affinity and negative ion binding energy determines stability of the transient negative species, and we present results for H2 and CH4. As these species are introduced in the inter-electrode gap an increase in output power is observed with a concurrent shift of maximum output power to lower load resistance.

2:03PM W33.00015 Diamond Based Electron Emitters for Photon Enhanced Thermionic Energy Conversion[1] , TIANYIN SUN, FRANZ A. KOECK, ROBERT J. NEMANICH, Arizona State University — Energy conversion cells utilize either direct photon illumination or indirect thermal energy for electron excitation. Nitrogen-doped, hydrogen terminated nanocrystalline diamond films display a negative electron affinity and have shown low temperature thermionic emission which can be employed for energy conversion in a vacuum thermionic emission cell. However, the low work function of such films suggests that the current could be enhanced through visible light illumination to induce photoelectron emission. We present measurements of the spectrum of emitted electrons from N-doped diamond films for light illumination between 600 and 340nm, while the film is heated from ambient to 500C. Features due to thermionic and photo-emission are identified, and a complex interaction is observed between the two processes at various temperatures and illumination wavelengths. The results indicate the potential application of diamond emitters as combined thermal and photon energy converters, and we present a new approach to enhance the performance of diamond-film energy converters.

11:15AM W34.00001 Evolution of CdSe/ZnS Quantum Dot Ensembles Under Prolonged Excitation[1] , GEORGIY SHCHERBATYUK, RICHARD INMAN, SAYANTANI GHOSH, University of California, Merced — We study the spectral evolution of self-assembled ensembles of CdSe/ZnS core/shell quantum dots (QDs) under photo-excitation in ambient conditions. We use spatially-resolved photoluminescence (PL) scanning microscopy in conjunction with spectrally-resolved time-resolved spectroscopy to measure variations in spectral intensity, emission wavelength and recombination lifetimes. Our results indicate that the spectral intensity of the ensemble undergoes both photo-induced brightening and darkening, and these rates have a complicated dependence on the concentration of the QD samples. They initially decrease with decreasing concentration but are greatly enhanced in the dilute limit. The photo-exposure also causes a rapid spectral red-shift followed by a slow blue-shift. The recombination lifetimes increase with the red-shift for all concentrations but do not correlate to the blue-shift in a straightforward manner in different samples. We conclude the possible explanation of this behavior is the inter-play of photo-induced surface trap discharging and preferential photo-oxidation of the smaller QDs in the ensemble.

11:27AM W34.00002 Photoluminescence spectroscopy and lifetime measurements from self assembled semiconducting quantum dot- metal nanoparticle hybrid arrays , M. HARIDAS, J.K. BASU, Indian Institute of Science — We demonstrate how the emission properties of a hybrid array consisting of semiconducting quantum dot (QD) and metal nanoparticles (NP) can be controlled by varying the density and distance between QD and NP independently. Our hybrid system consists of chemically synthesized cadmium selenide quantum dots (CdSe QDs) and polymer capped gold nanoparticles (Au NP) embedded in a block copolymer matrix having the topology of cylinders oriented perpendicular to the substrate. We have prepared hybrid arrays with two different densities of CdSe QDs (ρ_{QD}) each having same Au NP densities (ρ_{Au}). The photoluminescence measurements (PL) from such hybrid system shows enhancement in emission with increase in ρ_{Au}, compared to the CdSe QD film and the enhancement factor is lower for hybrid films with high ρ_{QD}. The lifetime measurement shows double exponent PL decay with systematic reduction in exciton lifetime for hybrid arrays with respect to ρ_{Au}. The film with high ρ_{QD} shows larger reduction in lifetime. Similarly, the amplitudes of the two relaxations switch over with increase in ρ_{Au}. It is clear that the shorter time becomes the dominant relaxation mode with increasing ρ_{Au}. Observed phenomena have been explained in terms of exciton plasmon interaction.

11:39AM W34.00003 Manipulating coupling between a single semiconductor quantum dot and single gold nanoparticle[1] , FARBOD SHAFIEI, DANIEL RATCHFORD, SUENNE KIM, XIAOQIN LI, Department of Physics, University of Texas at Austin, STEPHEN GRAY, Chemistry Division and Center for Nanoscale Materials, Argonne National Laboratory — We report the manipulation of coupling in a simple model system, a single semiconductor quantum dot (QD) near a single metallic nanoparticle, and study the resulting changes in QD photoluminescence (PL) dynamics. We used atomic force microscopy nanomanipulation to controllably push a Au NP proximal to a CdSe/ZnS QD. We observed gradual and reversible changes in the QD PL lifetime and blinking dynamics. In some cases, the total lifetime reduced from 30 ns to well below 1 ns. This decrease is accompanied by the disappearance of blinking behavior as the nonradiative energy transfer from QD to the Au NP becomes the dominant decay channel. In comparison to previous studies, our experiments report changes in the PL dynamics of the same QD, therefore, eliminating the ambiguity of variable properties of individual QDs.

11:51AM W34.00004 Carbon Nanotube CdSe Nanoparticle Hybrid Materials: Synthesis and Optical Properties , AUSTIN AKEY, CHENGUANG LU, IRVING P. HERMAN, Columbia University — Carbon nanotubes present remarkable opportunities as a base for construction of advanced nanomaterials with uniques properties. We report novel heterostructures composed of single-walled carbon nanotubes and monodisperse cadmium selenide nanoparticles (3.5 to 6 nm in diameter). The optical properties of the hybrid material differ significantly from those of the unbound nanoparticles and nanotubes, pointing to the existence of strong electronic/optical interaction effects between the two. Specific differences in absorption/emission behavior and the photoluminescence Stokes shift in the nanoparticles will be presented, along with experiments exploring the underlying mechanisms of this interaction. We believe this system exhibits "hot" excitation-transfer behavior from the nanoparticles to the nanotubes, which makes it of great interest for photovoltaic applications. This work is primarily supported by the Nanoscale Science and Engineering Center at Columbia University, which is supported by the Nanoscale Science and Engineering Initiative of the NSF under Award Number CHE-0641523.

12:03PM W34.00005 Enhanced Optical Absorption of Glancing Angle Deposited Semiconducting Nanostructures for Photovoltaic Solar Cell Applications , HILAL IS, MEHMET CANSIZOGLU, Department of Applied Science, University of Arkansas at Little Rock, Little Rock, AR, 72204, MIRIA FINCKENOR, NASA Marshall Space Flight Center, AL 35812, TANSEL KARABACAK, Department of Applied Science, University of Arkansas at Little Rock, Little Rock, AR, 72204 — Semiconducting nanostructures with controlled geometries can provide enhanced optical absorption and effective collection of photo-charges for high efficiency photovoltaic solar cells and photoconductive devices. Glancing angle deposition (GLAD) provides a unique capability of producing nanostructured arrays of various materials with controlled shapes, size, and separation. In this study, as a model system, we fabricated arrays of semiconducting indium sulfide nanostructures by GLAD in the shapes of springs, screws, rods, and zigzags. We show that GLAD nanostructures have significantly lower reflectance and higher optical absorption compared to conventional flat thin films. In addition, we observed a superior photoconductivity (PC) response of about 80% for nanorod array samples, which is believed to be mainly due to their high optical absorption. On the other hand, PC response was less than 1% for conventional thin films of indium sulfide.

12:15PM W34.00006 In-Situ Studies of Photoluminescence Quenching in Single Crystal Quantum Dot Sensitized Solar Cells , DOUGLAS SHEPHERD, Department of Physics, Colorado State University, YONG-QI LIANG, School of Energy Resources, University of Wyoming, JUSTIN SAMBUR, Department of Chemistry, Colorado State University, BRUCE PARKINSON, School of Energy Resources, University of Wyoming, MARTIN GELFAND, Department of Physics, Colorado State University, ALAN VAN ORDEN, Department of Chemistry, Colorado State University — Single crystal quantum dot sensitized solar cells (QDSSC) are a promising photovoltaic system in which collection of multiple charge carriers per photon has recently been reported.[1] Utilizing time-correlated single photon counting we have studied both the fluorescence intensity and fluorescence decay time from CdSe quantum dots coupled to both single crystal TiO_2 and ZnO substrates through short and long chain ligands. We find that for all configurations the fluorescence decay time is quenched compared to unbound quantum dots in solution, while the photovoltaic properties of the system strongly depend on the chain-length of the ligand. These results suggest there exist interactions between either the individual quantum dots or the quantum dots and substrate that may compete with the charge injection process in QDSSCs.

12:27PM W34.00007 Particle Morphology and Interfacial Energy Transfer in CdSe/CdS Nanocrystals , NICHOLAS BORYS, MANFRED WALTER, University of Utah, JING HUANG, DMITRI TALAPIN, University of Chicago, JOHN LUPTON, University of Utah — CdSe/CdS core-shell nanocrystal heterostructures are unique systems to study nanoscale energy migration. We perform single-particle excitation spectroscopy at low temperatures by monitoring both the luminescence intensity and energy of the core as a function of optical excitation energy in three different heterostructure shapes: spherical particles, rods, and tetrapods. In the tetrapod and rod structures, the shapes of the PLE spectra fall into one of two classes while the spherical particles all exhibit one universal form, which we attribute to the general shape and quantum confinement symmetry of the CdS shell. We confirm this assignment by correlated single particle SEM and PLE measurements. By resolving the core emission energy as a function of excitation energy, we identify two distinct exciton species in the tetrapods indicating the presence of a barrier that prevents charge transfer across the heterostructure interface [1].

12:39PM W34.00008 Copper-doped core-shell ZnSe/CdSe nanocrystals with efficient and widely tunable photoluminescence , RANJANI VISWANATHA, SERGIO BROVELLI, VICTOR I. KLIMOV, Chemistry Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545 — We report synthesis and spectroscopic studies of Cu-doped ZnSe/CdSe nanocrystals (NCs) with a wide range of shell thicknesses. Incorporation of copper ions into the NCs introduces an atomic-like state within the NC band gap. This results in a three-level system in which emission occurs due to the transition coupling the NC lowest-energy conduction-band level to the localized hole state associated with the Cu ions. Cu is incorporated into the NC core while the shell remains nominally undoped, which allows us to manipulate the shell thickness (and thus emission color) without affecting the overall level of NC doping. We demonstrate a wide-range spectral tunability of photoluminescence (PL) (from 3.1 eV to 1.25 eV), and "giant" Stokes shifts ($\sim$ 0.8 eV), which reduce emission losses due to reabsorption. We show that hole trapping at the Cu sites occurs primarily from the top of the valence band (i.e., no hot-hole transfer processes are detected) and that the main nonradiative mechanism is electron trapping at surface defects, which can be suppressed at cryogenic temperatures, resulting in PL quantum yields of $\sim$40%. High intrinsic emission efficiencies, wide-spectral tunability, and a large Stokes shift make these novel NCs attractive candidates for radiation detection, light-emitting diodes, and lasers.

12:51PM W34.00009 Breakdown of Volume Scaling in Auger Recombination in CdSe/CdS Heteronanocrystals: The Role of the Core-Shell Interface , SERGIO BROVELLI, FLORENCIO GARCÍA-SANTAMARÍA, RANJANI VISWANATHA, HAN HTOON, SCOTT CROOKER, VICTOR I. KLIMOV — Spatial confinement of electronic excitations in semiconductor nanocrystals (NCs) results in a significant enhancement in nonradiative Auger recombination (AR) of multiexcitons, which is detrimental to promising NC lasing applications. In standard NCs, AR times scale linearly with NC volume. We investigate multiexciton dynamics in NCs composed of CdSe cores and CdS shells of tunable thickness. Thicker shells dramatically reduce AR, particularly during initial shell growth, which cannot be explained by traditional volume scaling alone. Rather, low-temperature fluorescence-line-narrowing studies strongly suggest that suppressed AR derives primarily from the formation of an alloy layer at the CdSe/CdS interface, and a corresponding "smoothing" of the confinement potential (CP). These findings support the recent theory, which predicts that the change from abrupt to smoothly-varying CPs reduces the high-spatial-frequency Fourier components of the exciton wave function, thereby minimizing overlap with the high-energy states involved in nonradiative Auger decay. Our results highlight the importance of NC interfacial structure in the AR process in zero-dimensional NCs and provide general guidelines for the design of new nanostructures with suppressed AR for future lasing applications.

1:03PM W34.00010 Complete suppression of Blinking and convergence to a single emissive state in giant nanocrystal quantum dots , ANTON MALKO, SIDDHARTH SAMPAT, The University of Texas at Dallas, Department of Physics, YOUNG-SHIN PARK, JAVIER VELA, YOUNGFEN CHEN, JENNIFER HOLLINGSWORTH, VICTOR KLIMOV, HAN HTOON, Los Alamos National Laboratory, Chemistry Division and Center for Integrated Nanotechnologies — We report a systematic study of photoluminescence (PL) emission intensities and lifetimes of individual core-shell CdSe/CdS "giant" nanocrystal quantum dots (gNQDs) as a function of the shell thickness. We observed a complete suppression of blinking for gNQDs overcoated with more than 16 monolayers (ML) of CdS shell. An analysis of the photon emission statistics reveals a highly super-Poissonian distribution for thin shell (4-12 ML) gNQDs and near perfect Poissonian distribution for non-blinking, thick-shell gNQDs. Measurements of PL decay rates as a function of PL intensity show that while PL lifetimes vary continuously with PL intensity for thin-shell gNQDs, only one PL decay constant is observed for the thicker shell gNQDs. This result clearly indicates that while the thin-shell gNQDs possess continuous distribution of emission states, PL of the non-blinking, thick-shell gNQDs originates from a single emissive state.

1:15PM W34.00011 A comparative study of carrier multiplication in PbS and PbSe nanocrystals[1] , JOHN STEWART, LAZARO PADILHA, DOH LEE, BISHNU KHANAL, JEFFREY PIETRYGA, VICTOR KLIMOV, Los Alamos National Laboratory — In this talk I will present our recent studies of carrier multiplication (CM) in PbS and PbSe nanocrystals (NCs). CM is a process in which absorption of a single photon produces multiple excitons. In our experiments, we evaluate its efficiency based on the amplitude of the Auger decay signature of multiexcitons in carrier dynamics recorded using both transient absorption and time-resolved photoluminescence. In the case of PbSe NCs, we have measured the CM quantum efficiencies and Auger lifetimes for a large range of NC sizes, including very large particles with a band gap around 0.5 eV. Using excitation at 3.1eV we observe that the quantum efficiency is low for small NCs and increases monotonically toward the bulk value for larger dots. Despite many apparent similarities in the band structure of PbSe and PbS NCs, our preliminary studies of PbS nanoparticles hint at a quite different spectral behavior of quantum efficiencies compared to PbSe NCs. In particular, while the quantum efficiencies are similar for smaller NCs, we see discrepancies for the larger NCs for which the energy gap approaches the bulk limit. We discuss these discrepancies in the context of our comparative studies of intraband relaxation and Auger recombination in these two types of the NCs.

[1]Center for Advanced Solar Photophysics

1:27PM W34.00012 Carrier recombination pathways in Copper Indium Sulfide (CIS) nanocrystals , ANSHU PANDEY, LIANG LI, JEFFREY M. PIETRYGA, VICTOR I. KLIMOV — Ternary and Quaternary compounds are rapidly gaining interest because of potential applications in areas such as thin-film photovoltaics and light-emitting diodes. We will discuss carrier dynamics in Copper Indium Sulfide (CIS) nanocrystals (NCs), one of the better studied members of the ternary-quaternary family. While as-prepared CIS NCs exhibit photoluminescence (PL) quantum yields less than 10%, overgrowth with a few monolayers of CdS or ZnS increases PL quantum efficiency to more than 80%. We investigated the reasons for this dramatic improvement in efficiency through time-resolved PL and transient absorption measurements. Our results suggest that while electrons in CIS NCs remain delocalized, the holes are rapidly localized due to trapping at defects. PL emission arises through the radiative recombination of a delocalized electron with a hole at the interior defect site (radiative decay center). We also observe surface defects that serve primarily as centers for nonradiative recombination. Overcoating of CIS NCs with CdS or ZnS eliminates surface traps and results in a long single-exponential PL decay that appears to be unique among visible-emitting NCs.

1:39PM W34.00013 Nonradiative Energy Transfer in Assemblies of Nanostructures with Mixed Dimensionality , PEDRO LUDWIG HERNANDEZ-MARTINEZ[1], HILMI VOLKAN DEMIR[2], Department of Physics, Department of Electrical and Electronics Engineering, UNAM, Bilkent University, Ankara 06800, Turkey — We study the exciton-exciton interaction and nonradiative energy transfer in nanostructure assemblies with mixed dimensionality. We investigate possible combinations in terms of dimensionality for these nanostructures, and analyze the resulting nonradiative energy transfer rates as a function of dimensionality. Depending on the direction of the energy transfer, arrangements of such nanostructures have potential applications in both photovoltaics [1] and light generation [2].

1:51PM W34.00014 Charge and Shape Effects on the Carrier Dynamics of 25 Atom Au Nanoclusters , MATTHEW SFEIR, Brookhaven National Laboratory, HUIFENG QIAN, RONGCHAO JIN, Carnegie Mellon University — We study a series of semiconducting gold clusters that exhibit strong quantum confinement effects on their optical properties. In contrast to larger metallic nanoparticles, the surface plasmon resonance disappears a large optical gap ($>$ 1.3 eV) is formed. Recent synthetic advances have permitted the study of truly monodisperse clusters with precise control on the atomic scale. Using femtosecond and nanosecond transient absorption spectroscopy, we have investigated the excited state relaxation dynamics of spherical and prolate 25 atom isomers. We have determined that these particles exhibit long excited state lifetimes and that the carrier dynamics that are strongly influenced by the charge state and the physical arrangement of the atoms.

2:03PM W34.00015 Transparent Conducting Metallic Film for Applications in Photovoltaics and Optoelectronic Devices , TRILOCHAN PAUDEL, PIOTR PATOKA, WEN-CHEN CHEN, MICHAEL GIERSIG, WILLIE PADILLA, ZHIFENG REN, KRIS KEMPA — Oxides such as Indium-Tin Oxide (ITO) known as transparent conducting oxide (TCO) have been used for a long time in most of the thin film solar cell fabrications. It simultaneously works as an electrically conducting and optically transparent electrode. However, the electrical conductivity and optical transparency are not good enough. Here, we discuss our experimental and simulated results on nanostructured metallic films as a possible alternative replacement to TCO. This structure may possibly outperform the conventional ITO for applications in photovoltaics and optoelectronic devices such as LEDs.

Thursday, March 24, 2011 11:15AM - 2:15PM –
Session W35 DCMP: Topological Insulators: Superconductivity C140

11:15AM W35.00001 New forms of superconductivity and magnetism in a doped topological insulator , L. ANDREW WRAY, Lawrence Berkeley National Lab, SUYANG XU, Princeton University, HSIN LIN, Northeastern University, M. ZAHID HASAN, Princeton University — Topological insulators achieve a phase of matter characterized by the quantum topology of electron kinetics rather than by broken symmetries. The topological insulator state gives rise to spin-helical surface states that dramatically alter the surface physics and allow new phenomena in the presence of purturbations such as superconductivity and magnetism. We have used angle resolved photoemission spectroscopy to map electron dynamics at the surface of a topological insulator in the presence of magnetic surface ions and with doping compositions that superconduct. Our measurements establish that bulk Cu-doped $Cu_{0.12}Bi_2Se_3$ realizes a new form of superconductivity (Wray et al, Nat. Phys. 6, 855 (2010)) and is likely to host localized non-Abelian Majorana fermions on the crystal surface. We observe that surface-deposited ions lead to the formation of new topoligically-derived surface Dirac bands, and our data suggest that magnetic moments of deposited Fe undergo a phase transition to align along the out-of-plane axis (arXiv:1009.6216).

11:27AM W35.00002 Coupling superconductors to topological insulators , MENNO VELDHORST, MARCEL HOEK, MARIEKE SNELDER, Faculty of Science and Technology and MESA+ Institute for Nanotechnology, University of Twente, the Netherlands, XIAOLIN WANG, Institute for Superconducting and Electronic Materials, University of Wollongong, Wollongong, NSW, Australia, HANS HILGENKAMP, ALEXANDER BRINKMAN, Faculty of Science and Technology and MESA+ Institute for Nanotechnology, University of Twente, the Netherlands — The recent discovery of the topological insulators sparked an enormous attention. The experimental investigation of topological insulators with surface sensitive spectroscopic techniques evidently exposed the helical Dirac fermions living at the surface of a bulk insulator. In transport experiments, intrinsic bulk conduction challenges the observation of the topological surface states. We have observed electrical transport through the surface states of Bi_2Te3 by utilizing the electrical field effect and by utilizing intrinsically transparant interfaces to metallic electrodes. Of particular interest is coupling topogical insulators to superconductors, where at the interface the elusive Majorana fermion is predicted to recide. We fabricated superconductor – topological insulator – superconductor Nb-Bi_2Te_3-Nb junctions and observed a supercurrent over a length scale of more than a micrometer. Shapiro steps appear under microwave irradiation. The supercurrent is found to be surprisingly robust in large magnetic fields.

11:39AM W35.00003 Stability of surface Majorana modes in superconducting doped topological insulators , ASHVIN VISHWANATH, PAVAN HOSUR, POUYAN GHAEMI, ROGER MONG, University of California at Berkeley — In recent years, several model condensed matter systems have been predicted to harbor Majorana fermion zero modes. One such system is the surface of a strong topological insulator with proximity-induced superconductivity. A vortex in this surface superconductor was shown to host a topologically protected Majorana mode. Since then, bulk superconductivity has been induced in several strong topological insulators via doping or application of pressure. Here, we address the question of whether a vortex in these superconductors will trap Majorana zero modes at the surface. Viewed as a 1D system, the vortex can be characterized by a Z_2 topological invariant which denotes the presence or absence of a Majorana mode at its end. For weak pairing, we find that, the transition point between the two topological phases is determined by a Fermi surface property in the normal state. Hence, the phase transition can be achieved by simply varying the Fermi level. At the transition, the vortex supports gapless Majorana excitations along its length. Using this criterion, we discuss whether surface Majorana modes exist in the experimentally established superconductors $Cu_x Bi_2Se_3$, p-doped $TlBiTe_2$ and $Pd_x Bi_2Te_3$. Interestingly, the Fermi surface criterion also allows superconducting vortices in systems with non-topological band structures to be associated with surface Majorana modes.

11:51AM W35.00004 Surface Spectral Function in the Superconducting State of a Topological Insulator[1] , TING-KUO LEE, LEI HAO, Academia Sinica, Taiwan — We discuss the surface spectral function of superconductors realized from a topological insulator, such as the copper-intercalated Bi_2Se_3. These functions are calculated by projecting bulk states to the surface for two different models proposed previously for the topological insulator. Dependence of the surface spectra on the symmetry of the bulk pairing order parameter will be discussed with particular emphasis on the odd-parity pairing. Exotic spectra like an Andreev bound state connected to the topological surface states will be presented.

[1]We wish to acknowledge the support of NSC under Grant No. 98-2112-M-001-017-MY3.

12:03PM W35.00005 Superconductivity in Topological Parent Compound Induced via Pressure[1] , C.Q. JIN, Institute of Physics, CAS, China, J.L. ZHANG, S.J. ZHANG, H.M. GONG, W. ZHANG, P.P. KONG, J. ZHU, R.Z. YU, L.X. YANG, S.M. FENG, Q.Q. LIU, X.C. WANG, R.C. YU, Institute of Physics, Chinese Academy of Sciences, China, W.G. YANG, L. WANG, HPSync, APS, ANL, USA, S.C. ZHANG, Department of Physics, Stanford University, USA, X. DAI, Z. FANG, Institute of Physics, Chinese Academy of Sciences, China — We report successful observation of pressure induced superconductivity in topological compound of Bi_2Te_3 single crystal induced via pressure [1]. The combined high pressure structure investigations with first-principles calculations indicated that the superconductivity occurs at the ambient phase of topologically nontrivial. The results suggest topological superconductivity can be realized in the parent state of Bi_2Te_3 topological material. Ref: [1] J. L. Zhang et al., "Pressure induced superconductivity in the parent compound of Bi_2Te_3" (submitted)..

12:15PM W35.00006 Detecting Majorana Bound States , COLIN BENJAMIN, Univ. of Georgia, Athens, GA, USA, JIANNIS PACHOS, Univ. of Leeds, UK — We propose a set of interferometric methods on how to detect Majorana bound states induced by a topological insulator. The existence of these states can be easily determined by the conductance oscillations as function of magnetic flux and/or electric voltage. We study the system in the presence and absence of Majorana bound states and observe strikingly different behaviors. Importantly, we show that the presence of coupled Majorana bound states can induce a persistent current in absence of any external magnetic field.

12:27PM W35.00007 Chain of Majorana States from Superconducting Dirac Fermions at a Magnetic DomainWall , TITUS NEUPERT, Condensed Matter Theory Group, Paul Scherrer Institute, CH-5232 Villigen PSI, Switzerland, SHIGEKI ONODA, AKIRA FURUSAKI, Condensed Matter Theory Laboratory, RIKEN, Wako, Saitama 351-0198, Japan — We study theoretically a strongly type-II s-wave superconducting state of two-dimensional Dirac fermions in proximity to a ferromagnet having in-plane magnetization. It is shown that a magnetic domain wall can host a chain of equally spaced vortices in the superconducting order parameter, each of which binds a Majorana-fermion state. The overlap integral of neighboring Majorana states is sensitive to the position of the chemical potential of the Dirac fermions. Thermal transport and scanning tunneling microscopy experiments to probe the Majorana fermions are discussed.

12:39PM W35.00008 Global Properties of 3D Topological Insulator Surface/Superconductor Junctions , MATTHEW GILBERT, Department of Electrical and Computer Engineering, University of Illinois, 1406 W. Green St., Urbana IL 61801, TAYLOR HUGHES, CHING-KAI CHIU, Department of Physics, University of Illinois, 1110 West Green St., Urbana IL 61801, ANDREI BERNEVIG, Department of Physics, Princeton University, Princeton, NJ 08544 — The ability to precisely find and manipulate non-Abelian anyons[1] has long been sought after as a potential means for the realization of robust quantum information processing. The simplest of these particles, Majorana fermions, have been predicted to exist in a new class of materials commonly referred to as topological insulators[2] when they are coupled with s-wave superconducting contacts.[3] This proposal is the focus of intense experimental research whose aim is to prove the existence of Majorana fermions trapped at the surface of topological insulators paired with superconductors. We will present our initial theoretical investigations into the surface properties of 3D topological insulator/superconductor junctions.

12:51PM W35.00009 Order parameter and triplet correlations near a superconductor-topological insulator interface , MAHMOUD LABABIDI, ERHAI ZHAO, George Mason University — At the interface between a 3D topological band insulator and an s- wave superconductor forms a remarkable 2D superconductor that can host Majorana fermions at vortex cores. Going beyond the original work of Fu and Kane [Phys. Rev. Lett. 100, 096407 (2008)], we present a microscopic theory for the proximity effect near the TI-S interface. We compute the superconducting order parameter as a function of the distance away from the interface by self-consistently solving the Bogoliubov-de Gennes equation. We discuss the suppression of the order parameter by the topological insulator. Moreover, we show that triplet superconducting correlations of $p_x \pm ip_y$ orbital symmetry are induced near the interface by the spin-orbit coupling inside the topological insulator.

1:03PM W35.00010 Superconductivity and Majorana fermion creation at the quantum spin Hall insulator edge , ANNICA M. BLACK-SCHAFFER, NORDITA — We focus on properties related to Majorana fermion creation in a self-consistent study of a microscopic interface between a quantum spin Hall insulator (QSHI) and a superconductor (SC). For a spin-singlet s-wave SC we show that large odd-in-momentum, or p-wave, order parameters exist for all doping levels of the QSHI and that they can be related to different spinless Cooper pair amplitudes. This result demonstrates that it is natural that the Majorana mode at a SC-ferromagnet (SF) interface survives even at zero doping. Despite the induced p-wave order parameters, the induced superconducting gap in the QSHI always retains its s-wave character, thus validating the commonly used effective model for superconductivity in a topological insulator. We also self-consistently model an SFS Josephson junction along the QSHI edge and report on Majorana mode occurrence in the junction, the current-phase relation, and novel odd-frequency spin-triplet correlations.

1:15PM W35.00011 Measurements of Electrical Noise at the Interface between Bi2Se3 and a Superconductor , J.S. LEE, D.M. ZHANG, A.R. RICHARDELLA, NITIN SAMARTH, Physics Dept., Penn State University, University Park PA 16802 — The narrow band gap semiconductor Bi_2Se_3 is a promising candidate for exploring exotic quantum states that might arise at the interface between topological insulators and superconductors (Phys. Rev. Lett. **100**, 096407 (2008)). Motivated by proposed approaches for detecting such states (Phys. Rev. B **79**, R161408 (2009)), we have embarked on measurements of electrical noise in mesoscopic Bi_2Se_3 devices with superconducting electrodes. Present measurements focus on CVD-grown Bi_2Se_3 nanoribbons which show proximity-induced superconductivity below ~ 5 K when contacted by (dirty) W electrodes. The measurements are carried out using a balanced bridge technique over a temperature range of $0.5\mathrm{K} \leq \mathrm{T} \leq 40$ K and in magnetic fields up to 80 kOe. We observe 1/f noise over a wide range of temperature and discuss the variation in noise spectral density across the normal-superconductor transition as well as its dependence upon excitation current and magnetic field. We will also describe extensions of these studies to mesoscopic devices lithographically patterned from thin films of Bi_2Se_3 grown by molecular beam epitaxy. Supported by NSF and ONR.

1:27PM W35.00012 Study of the interface of superconductor and topological insulator , DONG QIAN, XIAOMEI WANG, CHUNLEI GAO, CANHUA LIU, JINFENG JIA, Shanghai Jiao Tong University — State-of-art Molecular beam epitaxy (MBE) has been carried out to grow high quality topological insulator (TI) films on some BCS s-wave superconductor (SC) substrates. The growth dynamics and the electronics structures of the SC/TI interface were studied using high energy reflected electron diffraction and ultralow-temperature scanning tunneling microscopy (STM). Electronic structure, superconducting gap, vortex dynamics would be reported in this presentation. The superconducting state of the topological insulator due to approximate effect and the formation of Majorana Fermion would be discussed.

1:39PM W35.00013 Self-consistent study at the superconductor-3D topological insulator interface , XIAOTING ZHOU, CHEN FANG, JIANGPING HU, Purdue University — We perform a theoretical study of the interface between a 3D topological insulator (TI) and an s-wave conventional superconductor (both in normal and superconducting state) using the BdG self-consistent formulation. The robustness of the TI surface state when in contact with a metal is discussed and the topological superconductivity on the interface induced by the proximity effect is studied in detail. We find that in general a mixed singlet and triplet pairing can be observed on the interface as the spin-orbit coupling breaks the SU(2) symmetry in TI. The Majorana edge states of such a mixed pairing 2D topological superconductor are also studied.

1:51PM W35.00014 Proximity induced superconductivity in Bi_2Se_3 nanoribbons , D.M. ZHANG, J. WANG, J.S. LEE, H.R. GUTIERREZ, M.H.W. CHAN, N. SAMARTH, Physics Dept., Penn State University, University Park PA 16802 — Proposals for possible realizations of Majorana fermions in condensed matter provide a strong motivation for interfacing superconductors with topological insulators (PRL **100**, 096407 (2008)). We describe experiments that accomplish an important first step in this context: the realization of proximity-induced superconductivity in a candidate topological insulator. We have measured the bias-dependent differential conductance in Bi_2Se_3 nanoribbons contacted with superconducting electrodes over a temperature range 0.5 K $\leq T \leq$ 6 K in magnetic fields up to 8 T. We observe signatures of both proximity-induced superconductivity and incoherent multiple Andreev reflections in these mesoscale devices. In addition, we find periodic magneto- resistance oscillations for magnetic field perpendicular to both the nanoribbon axis and the superconducting contacts. The temperature- and field-dependence of the magneto-resistance oscillation amplitude and period are suggestive of dissipative vortex dynamics in the vicinity of the contacts. Supported by NSF-MRSEC, NSF-NNIN and ONR.

2:03PM W35.00015 Majorana Fermions in a Spin Ladder System , WADE DEGOTTARDI, SMITHA VISHVESHWARA, University of Illinois at Urbana-Champaign, DITPIMAN SEN, Centre for High Energy Physics, Indian Institute of Science, KITAEV LADDER COLLABORATION — We consider a two-legged spin chain version of Kitaev's honeycomb model. Like its parent, this model supports Z_2 vortices at every plaquette. The topological phase of the system is sensitive to, *inter alia*, the spatial pattern of these vortices. The topological phases are gapped in the bulk but possess isolated zero energy Majorana modes at each end. The existence of such Majorana modes can be inferred from a new topological invariant. We show that there is an intimate relation between the existence of Majorana modes and the spontaneous breaking of the global Z_2 symmetry.

Thursday, March 24, 2011 11:15AM - 2:15PM –

Session W36 DMP: Focus Session: Graphene Structure, Dopants, and Defects: Graphene Oxide and Fluoride C142

11:15AM W36.00001 Properties of Dilute Fluorinated Graphene , XIA HONG, The Pennsylvania State University — I will discuss our recent studies on dilute fluorinated graphene (DFG). Fluorine adatoms are covalently added to a graphene sheet using a controlled and reversible approach to create a dilute coverage on the order of $10^{12}/\text{cm}^2$, as determined by scanning tunneling microscopy studies. These adatoms are atomically sharp defects, interact strongly with the electronic states of graphene and drastically modify the transport properties of pristine graphene. This unusual 2D system exhibits several remarkable properties. Mid-gap state scattering dominates conduction at high temperature, the magnitude of which is determined by the adatom density and is correlated with Raman spectra. The temperature-dependent conductivity of the DFG sample follows weak localization at high carrier density and variable-range hopping at low carrier density. The transition is strongly correlated with the fluorine adatom density. In the variable-range hopping regime, DFG samples exhibit very large, negative magnetoresistance, which shows unusual staircase-like field dependence at low temperature. In the weak localization regime, we observe anomalous phase breaking behavior. I will discuss possible origins of these observations in the context of magnetism and localization. (In collaboration with S.-H. Cheng, C. Herding, and J. Zhu.)

11:51AM W36.00002 Electronic and structural properties of fluorinated graphene[1] , CHAD E. JUNKERMEIER, STEFAN C. BADESCU[2], THOMAS L. REINECKE, NRL, Washington, DC — Experiments have shown that the electronic structure of graphene can be tailored from that of a semimetal to that of a wide bandgap semiconductor through adsorption of fluorene. This makes fluorinated graphene C_xF ($x \geq 1$) attractive for electronics applications. Here we present first-principle calculations that reveal the dependence of C_xF electronic structure on the degree of fluorination in the range $1 \leq x \leq 8$. We present a systematic analysis of bandgap opening and p-doping, as well as of adsorption energies, lattice constants, bulk modulus and surface corrugation for single-face and two-face functionalization. We rationalize these with a band-interpolation scheme in terms of localized orbitals that clarify the C-C, C-F and F-F bonding. We discuss the relevance of tunable Young modulus for nanomechanical resonators.

[2]Currently at AFRL, Dayton, Ohio

12:03PM W36.00003 Patterning nanoroads and quantum dots on fluorinated graphene , MORGANA RIBAS, Rice University, ABHISHEK SINGH, Indian Institute of Science and Rice University, PAVEL SOROKIN, BORIS YAKOBSON, Rice University — Graphene nanoroads [1] and quantum dots [2] patterned on functionalized graphene combine metallic and semiconducting properties on a same mechanically intact sheet. Using density functional methods we investigate different stoichiometric phases of fluorinated graphene and find that the complete "2D-teflon" CF phase is thermodynamically more stable. The formation of fluorinated graphene favors the nucleation of aromatic "magic" clusters, but unlike hydrogenated graphene [3] it does not have a nucleation barrier. The CF is an insulator and turns out to be a perfect matrix-host for patterning nanoroads and quantum dots of pristine graphene. Depending upon the edge orientation and width the electronic and magnetic properties of the nanoroads can be tuned. The HOMO-LUMO energy gaps are size dependent and show a typical confinement of Dirac fermions. Furthermore, we study the effect of different coverage of F on graphene (CF and C_4F) on the band gaps, and show their suitability to host quantum dots of graphene with unique electronic properties. References: [1] Singh, A. K.; Yakobson, B. I., Nano Lett. 2009, 9 (4), 1540.[2] Singh, A. K.; Penev, E. S.; Yakobson, B. I., ACS Nano 2010, 4 (6), 3510. [3] Lin, Y.; Ding, F.; Yakobson, B. I., Phys. Rev. B 2008, 78 (4), 041402.

12:15PM W36.00004 Anomalous Phase Breaking in Dilute Fluorinated Graphene , XIA HONG, SHIH-HO CHENG, JUN ZHU, Department of Physics, The Pennsylvania State University — Quantum interference induced weak localization and phase breaking measurements are sensitive tools to probe the existence of magnetic impurities in mesoscopic systems. In this work, we study the low-field magnetoresistance of dilute fluorinated graphene (DFG), with a fluorine adatom density of $\sim 10^{12}/\text{cm}^2$. In the DFG samples, the phase breaking time τ_ϕ follows T^{-1} at high temperature and saturates at $T \sim 10$ K. The former is consistent with electron-electron interaction. The latter cannot be accounted for by conventional theories based on sample size and charge inhomogeneity. We show the dependence of the saturated τ_ϕ on the carrier density and fluorine coverage and discuss the effects of spin-flip scattering and localization in phase breaking. Our observations point to the presence of adatom induced local magnetic moments in dilute fluorinated graphene.

12:27PM W36.00005 Functionalization of exfoliated graphene by grafting aryl groups , HANG ZHANG, ELENA BEKYAROVA, ZENG ZHAO, WENZHONG BAO, JHAO-WUN HUANG, MIKHAIL ITKIS, SANDIP NIYOGI, XIAOLIU CHI, HUAZHOU WEI, FENGLIN WANG, ROBERT HADDON, CHUN NING LAU — We studied the transport properties of aryl functionalized exfoliated graphene. For the functionalization the graphene devices were immersed in a solution of diazonium salt. The attachment of aryl free radical to the basal carbon atoms changes the hybridization of the graphitic atoms from sp2 to sp3 thereby modifying the lattice's electronic structure. We observe that this opens a Coulomb gap at low temperatures and transport measurements indicate a variable range hopping mechanism. In suspended graphene, which allows for functionalization on both sides, we observe a large transport gap.

12:39PM W36.00006 Field emission from atomically thin edges of reduced graphene oxide , HISATO YAMAGUCHI, Rutgers Univeristy, KATSUHISA MURAKAMI, Osaka University, GOKI EDA, Imperial College London, TAKESHI FUJITA, Tohoku University, JULIEN BOISSE, Rutgers University, PENGFEI GUAN, Tohoku University, FUJIO WAKAYA, Osaka University, KYEONGJAE CHO, YVES CHABAL, University of Texas at Dallas, MINGWEI CHEN, Tohoku University, MIKIO TAKAI, Osaka University, MANISH CHHOWALLA, Rutgers University — Point sources show the best electron emission properties due to local field enhancement at the tip. A drawback of tip emitters is that they must be positioned sufficiently apart to achieve field enhancement, limiting the number of emission sites and therefore the overall current. In contrast, we report ultra-low threshold voltage emission of multiple electron beams from atomically thin edges of individual reduced graphene oxide (rGO) sheets. The emission sites observed by field emission (FEM) and field ion (FIM) microscopies are atomically spaced along the edge. FEM measurements indicate evidence for interference, suggesting that the emitted electron beams are coherent. Based on our spectroscopy, high-resolution transmission electron microscopy and theory results, field emission is attributed to the aggregation of oxygen groups in the form of cyclic edge ethers. Such closely spaced electron beams from rGO offer prospects for novel applications and understanding the physics of linear electron sources.

12:51PM W36.00007 Electronic structure of graphite oxide , HAE KYUNG JEONG, Daegu University, CHEOLSOO YANG, Samsung Electronics, BONG SOO KIM, KI-JEONG KIM, Pohang Accelerator Laboratory (PAL) — We have investigated the electronic structure of graphite oxide by photoelectron spectroscopy at the Pohang Accelerator Laboratory, Korea. The typical sp^2 hybridization states found in graphite were also seen in graphite oxide. However, the π state disappeared near the Fermi level because of bonding between the π and oxygen-related states originating from graphite oxide, indicating electron transfer from graphite to oxygen and resulting in a downward shift of the highest occupied molecular orbital (HOMO) state to higher binding energies. The band gap opening increased to about 1.8 eV, and additional oxygen-related peaks were observed at 8.5 and 27 eV.

This research was supported by the Basic Science Program through the National Research Foundation of Korea (NRF), funded by the Ministry of Education, Science and Technology (2010-0004592), and partly by the MEST (2009-0087138). Experiments at the PLS were supported in part by POSTECH and MEST.

1:03PM W36.00008 Computational Studies for Reduced Graphene Oxide in Alcohol- and Hydrogen-Rich Environments , RAMIN ABOLFATH, CHENG GONG, MUGE ACIK, YVES CHABAL, KYEONGJAE CHO, University of Texas at Dallas — We employ *ab-initio* molecular dynamic simulations to analyze the chemical reaction mechanisms for the oxygen removal process of graphene oxide upon annealing in the presence of water molecules and compare various thermal pathways in alcohol- and hydrogen-rich environments. Our first principles calculation shows damage-repair mechanisms of sp^2-C bonds in the etch holes of reduced graphene oxide and formation of dangling and/or sp^3-C bonds. The initial oxygen-abstraction results in the propagation of broken bonds and multi-site sp^2-C bond damage driven by the cascade of chemical reactions. The interplay between the environmentally induced damages and self-repair mechanisms of sp^2-C bonds determines the quality of the sheets after chemical treatments in alcohols or with hydrogen-rich environment. Water molecules form C=O and C-H bonds in the etch holes. We show that the alcohol- and hydrogen-rich environment provide an efficient transformation of C=O to the C-O bonds, and the removal of oxygen that is rarely observed with alcohol-rich environment alone.

1:15PM W36.00009 Electron Phonon Coupling Mechanism in Thermally Reduced Graphene , MUGE ACIK, GEUNSIK LEE, CECILIA MATTEVI, MANISH CHHOWALLA, KYEONGJAE CHO, YVES J. CHABAL, THE UNIVERSITY OF TEXAS AT DALLAS COLLABORATION, RUTGERS UNIVERSITY COLLABORATION — Infrared absorption of atomic and molecular vibrations in solids can be affected by electronic contributions through non-adiabatic interactions, such as the Fano effect. Typically, the IR absorption lineshapes are modified or IR forbidden modes are detectable as a modulation of the electronic absorption. In contrast to such known phenomena, we report here the observation of a giant IR absorption band in reduced graphene oxide (GO), arising from the coupling of electronic states to the asymmetric stretch mode of a yet unreported structure [1], consisting of oxygen atoms aggregated at edges of defects. DFT calculations show that free electrons are induced by the displacement of the oxygen atoms, leading to a strong IR absorption that is in-phase with the phonon mode. This new phenomenon is only possible when all other oxygen-containing chemical species including hydroxyl, carboxyl, epoxide and ketonic functional groups are removed from the region adjacent to the edges, i.e. clean graphene patches are present. *The authors acknowledge funding from the NRI SWAN program and Texas Instruments. [1] Acik, M.; Lee, G.; Mattevi, C.; Chhowalla, M.; Cho, K.; Chabal, Y. J. *Nature Materials.* **9,** 840-845 (2010)

1:27PM W36.00010 Grain-boundary unzipping by oxidation in polycrystalline graphene[1] , SIMONE ALEXANDRE, UFMG-Brazil, ALINE LUCIO, UFLA-Brazil, RICARDO NUNES, UFMG-Brazil — The need for large-scale production of graphene will inevitably lead to synthesis of the polycrystalline material [1,2]. Understanding the chemical, mechanical, and electronic properties of grain boundaries in graphene polycrystals will be crucial for the development of graphene-based electronics. Oxidation of this material has been suggested to lead to graphene ribbons, by the oxygen-driven unzipping mechanism [3]. A cooperative-strain mechanism, based on the formation of epoxy groups along lines of parallel bonds in the hexagons of graphene's honeycomb lattice, was proposed to explain the unzipping effect in bulk graphene [3] In this work we employ *ab initio* calculations to study the oxidation of polycrystalline graphene by chemisorption of oxygen at the grain boundaries. Our results indicate that oxygen tends to segregate at the boundaries, and that the unzipping mechanism is also operative along the grain boundaries, despite the lack of the parallel bonds due to the presence of fivefold and sevenfold carbon rings along the boundary core.

1:39PM W36.00011 Influence of Gate Voltage on the diffusion of Oxygen on Graphene , ALEJANDRO SUAREZ, Department of Physics, The Pennsylvania State University, LJUBISA RADOVIC, Department of Energy and Mineral Engineering, The Pennsylvania State University, EZRA BAR-ZIV, Ben-Gurion University of the Negev, Beer-Sheva, Israel, JORGE SOFO, Department of Physics, The Pennsylvania State University — We calculate the surface diffusion of Oxygen on Graphene using Density Functional Theory. We find the activation energy for diffusion to be 0.71 eV. Charging the graphene plane causes the diffusion barrier to change substantially. Electron doping graphene lowers the diffusion barrier, resulting in activation energies as low as 0.15 eV for a carrier concentration of 7.6x10^{13} cm^{-2}. This barrier reduction yields diffusion coefficients reaching over nine orders of magnitude lower than that of diffusion on neutral graphene. After study of the change in charge density distribution and local density of states, this effect is explained by a mixture of bond weakening under the equilibrium state and bond strengthening during the transition state. With this large fluctuation in diffusivity, patterning of oxidized regions in graphene may be achieved through variation of the gate voltage.

1:51PM W36.00012 Coulomb blockade and hopping conduction in graphene quantum dots array , DAEHA JOUNG, LEI ZHAI, SAIFUL KHONDAKER, Nanoscience Technology Center, Department of Physics, Department of Chemistry, University of Central Florida, Orlando, Florida 32826 — We show from the low temperature electron transport measurements that the transport properties of chemically reduced graphene oxide (RGO) sheets can be explained as a sequential tunneling of charges through a two dimensional polydispersed array of graphene quantum dots (GQD), where graphene domains act like QDs while oxidized domains behave like tunnel barriers between QDs. As the temperature is decreased to lower than 15 K, a complete suppression of current (I) below a threshold voltage (V_t) was observed due to Coulomb blockade (CB) of charges through GQD array. For $V >$ V_t, the current follows a scaling behavior, I $\propto [(V - V_t)/V_t]^{\alpha}$ with α ~ 2.8, implying a quasi 2D GQD array. Temperature dependent current – gate voltage ($I - V_g$) curves show reproducible Coulomb oscillations due to a single electron tunneling through GQD array that washes out between 70 and 120 K corresponding to charging energies of 6.2 $\sim$ 10 meV giving estimated GQD sizes of 5 - 8 nm. Temperature dependent resistance data show Efros-Shklovskii variable range hopping (ES VRH) arising from CB, structural and size induced disorder.

2:03PM W36.00013 Ink jet printed graphene oxide (GO) coplanar waveguide (CPW) structures for measurement of microwave propagation in GO , KATE DUNCAN, STCD CERDEC, EDWIN BARRY, MARK GRIEP, WMRD ARL, JOHHNY DANIEL, DEREK MORRIS, STCD CERDEC, SHASHI KARNA, WMRD ARL — Chemically reduced graphene (CGR) has been successfully inkjet printed using a commercially available printer. The CGR with sheet sizes below 200 nm were dispersed in a mixture of water and ethanol. Coplanar waveguide (CPW) structures were deposited on CGR and plastic substrates, scattering (S) parameters were measured in order to extract material parameter for incorporation into simulation tools. Measurements and modeling of microwave propagation in graphene shall be presented.

Thursday, March 24, 2011 11:15AM - 2:15PM –

Session W37 DMP: Focus Session: Graphene: Growth, Characterization, and Devices: Quantum Hall Effect C146

11:15AM W37.00001 A study of the quantum Hall effect in CVD graphene synthesized on Cu , TIAN SHEN, Department of Physics, Purdue University, West Lafayette, IN, 47907 / PML, NIST, Gaithersburg, MD, 20899, WEI WU, Center for Advanced Materials, and ECE, University of Houston, Houston, Texas, 77204, HELIN CAO, YONG CHEN, Department of Physics, Purdue University, West Lafayette, IN, 47907, DAVID NEWELL, CURT RICHTER, PML, NIST, Gaithersburg, MD, 20899, QINGKAI YU, Center for Advanced Materials, and ECE, University of Houston, Houston, Texas, 77204 — Graphene films grown by Chemical Vapor Deposition (CVD) have provided a viable way to large area, low cost graphene-based electronics. Graphene CVD grown on Cu was transferred to SiO2/Si substrates and Hall-bar devices with sizes as large as 150 μm were fabricated, exhibiting carrier mobility of $\sim$3000cm^2/Vs. At low temperatures, the half integer quantum-Hall effect (QHE) and Shubnikov-de Haas (SdH) oscillations confirmed the single layer quality of the transferred graphene films. Systematic measurements in the quantum Hall region such as the DC/AC current dependence, temperature dependence, and AC frequency dependence were carried out, and their impact on the breakdown of the QHE was investigated. From weak localization peak fitting, the phase coherence length of the CVD graphene is determined to be $\sim$3μm at 1.6K.

11:27AM W37.00002 Strain-induced pseudo-magnetic fields and charging effects on CVD-grown graphene , R.T.-P. WU, M.-L. TEAGUE, N.-C. YEH, Dept. of Physics, Caltech, Pasadena, CA 91125, S. YEOM, B.L. STANDLEY, D.A. BOYD, M.W. BOCKRATH, Dept. of Applied Physics, Caltech, Pasadena, CA 91125 — Atomically resolved imaging and spectroscopic characteristics of chemical vapor deposition (CVD) grown graphene on Cu are studied using scanning tunneling microscopy and spectroscopy. CVD-grown graphene remaining on Cu exhibits large ripples and appears strongly strained. Different regions show different lattice structures and electronic density of states (DOS). Ridges appear along the boundaries of different lattice structures, which reveal excess charging effects. The large, non-uniform strain induces pseudo-magnetic fields up to $\sim$50 Tesla, yielding integer and fractional quantum Hall effects (IQHE and FQHE) as quantized conductance peaks in the DOS. For CVD-grown graphene transferred from Cu to SiO_2, the average strain and the resulting charging effects and pseudo-magnetic fields are much reduced. Fourier transformation of the local DOS of strained samples as well as data on the effects of real magnetic fields versus pseudo-magnetic fields will be presented. This work was jointly supported by NSF and NRI.

11:39AM W37.00003 Transport phenomena of suspended graphene in the quantum Hall regime , HSIN-YING CHIU, CHING-TZU CHEN, DAVID DIVINCENZO, PHAEDON AVOURIS, IBM Thomas J. Watson Research Center — Towards the goal of making qubits in graphene, it is important to develop graphene quantum point contact for quantum-gate operations. Klein tunneling effect implies that confining charge carriers in graphene using external potential is challenging. Hence, we resort to electric-field controlled band gap opening for charge confinement. We have successfully fabricated high quality suspended few-layer graphene devices with local electrostatic gates. In this talk, we present our observation of voltage-controlled band gap opening and anomalous quantum Hall features upon applying vertical electrical filed, revealing rich physics of symmetry breaking in the few-layer graphene system.

11:51AM W37.00004 Measurement of the 1/3 Fractional Quantum Hall Effect Energy Gap in Multi-terminal Suspended Graphene Devices , FERESHTE GHAHARI KERMANI, YUE ZHAO, PAUL CADDEN-ZIMANSKY, Columbia University, KIRILL BOLOTIN, Vanderbilt University, PHILIP KIM, Columbia University — In recent investigations of transport properties in two-terminal high mobility suspended graphene devices, a quantized conductance corresponding to the 1/3 FQHE state has been observed. However, due to the inherent mixing between longitudinal and transverse resistivities in this two-terminal measurement, quantitative characterization of the observed FQHE states such as the FQHE energy gap is difficult. In this talk, we present the measurement of multi-terminal IQHE and FQHE states in ultraclean suspended graphene samples in low density regime. The energy gap of the 1/3 FQHE, measured by its temperature-dependent activation, is found to be much larger than the corresponding state found in the 2DEGs of high-quality GaAs heterostructures, indicating that stronger e-e interactions are present in graphene.

12:03PM W37.00005 Symmetry breaking of zero energy landau level in monolayer graphene , YUE ZHAO, Physics Department, Columbia University, PAUL CADDEN-ZIMANSKY, FERESHTE GHAHARI, PHILIP KIM — We experimentally study the nature of the symmetry breaking of the zero energy landau level (LL) in monolayer graphene using Corbino geometry and Hall bar geometry devices. At high magnetic fields, in the absence of the edge state channel connection in Corbino devices, we observe a gap opening in $\nu = 0$ QH state whose gap is independent of in-plane magnetic field. In Hall-bar geometry devices where edge state connection is allowed, we observe similar QH Insulator behavior independent of the in-plane magnetic field, indicating that the observed insulating behavior at the charge neutrality point of monolayer graphene at high magnetic field is originated from the degeneracy lifting of the zero LL via the valley pseudospin polarization rather spin polarization.

12:15PM W37.00006 Fractional quantum Hall effect in graphene on boron nitride , CORY DEAN, Columbia University, Electrical Engineering & Mechanical Engineering, ANDREA YOUNG, PAUL CADDEN-ZIMANSKY, Columbia University, Department of Physics, LEI WANG, Columbia University, Electrical Engineering, HECHEN REN, Columbia University, Department of Physics, KENJI WATANABE, Advanced Materials Laboratory, National Institute for Materials Science, Japan, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, PHILIP KIM, Columbia University, Department of Physics, JAMES HONE, Columbia University, Mechanical Engineering, KEN SHEPARD, Columbia University, Electrical Engineering — Graphene is a remarkable 2D material exhibiting many unique and surprising many-body effects resulting from strong electron interactions. A continuing challenge remains the fabrication of ultra-high mobility devices that allow the intrinsic character of graphene to be fully explored. In my talk I will discuss our recent advancements in fabricating very-high quality graphene devices on boron nitride. Magnetoresistance measurements under very large applied fields will be presented including our recent observation of the fractional quantum Hall effect in multi-terminal devices over a broad range of carrier densities.

12:27PM W37.00007 Transport on gated C-face epitaxial graphene , CLAIRE BERGER, CNRS-Institut Neel, Grenoble and Georgia Tech, School of Physics, Atlanta — We present transport and electronic properties on single layer and multilayered epitaxial graphene layers grown on 4H-SiC-(000-1) (C-face) by the Confinement Controlled Sublimation method [1]. Single layers present all the characteristics of isolated graphene layers. In particular quantum Hall effect plateaus develop at half-integer values, concomitant with vanishing longitudinal resistivity. High mobility up to μ=14,000 cm^2/V.s at 300 K is achieved despite contamination and substrate steps. Multilayered epitaxial graphene (MEG) on the C-face consists of non-graphitic rotationally stacked graphene layers, exhibiting the band structure of a single graphene layer [2]. Transport in MEG presents also graphene characteristics. In some cases transport anomalies are observed indicating a much richer picture.

1:03PM W37.00008 Quantum Hall Effect of Hybrid Monolayer-bilayer Graphene Structures: Observation of Broken electron-hole Symmetry , YONG P. CHEN, JIFA TIAN, ISAAC CHILDRES, HELIN CAO, Department of Physics, Purdue University — Quantum Hall Effect (QHE) in both monolayer (1L) and bilayer (2L) graphene has been well studied in the past few years. Little attention has been paid to the magneto-transport across the 1L ∼2L graphene interface. Here, we present the magnetotransport measurements of several exfoliated graphene quasi-Hall bar devices which consist of partly 1L and partly 2L graphene. We focused on the Hall resistance (R_{xy}) across the interface between 1L and 2L graphene when the carrier types and densities are changed using a back gate voltage. We observed that when the carrier type is p type (hole), R_{xy} typically shows QHE of bilayer graphene with filling factor of 4N, N being integers. When the carrier type is changed into n type (electron), the corresponding R_{xy} typically shows QHE of single layer graphene with filling factor of 4(N+1/2), N being integers. We discuss possible explanations for the observed broken electron-hole symmetry in such hybrid structures.

1:15PM W37.00009 Multi-terminal transport property on hybrid structure of monolayer and bilayer graphene , YONGJIN JIANG, Zhejiang Normal University, JIANGPING HU, Purdue University — We study the transport properties of Hybrid structures formed by monolayer and bilayer graphene. The energy spectrum and edge states of various junctions in strong magnetic field are analyzed. The transport properties are affected by the mixing effect of interfaces and the scattering between edge states, and display many novel features in multi-terminal measurements, Our results explains recent experimental results on such hybrid structure systems.

1:27PM W37.00010 Electric field induced transition between spin to valley polarized ν=0 quantum Hall state in dual-gated graphene bilayers[1] , KAYOUNG LEE, SEYOUNG KIM, BABAK FALLAHAZAD, EMANUEL TUTUC, The University of Texas at Austin — Graphene bilayers in Bernal stacking exhibit a transverse electric field dependent energy gap, thanks to the on-site electron energy asymmetry between the two layers. In a perpendicular magnetic field, the applied transverse electric field (E) will induce a quantum Hall state (QHS) at the charge neutrality point (filling factor ν=0) marked by a insulating behavior of the longitudinal resistance (ρ_{xx}), and a plateau in the Hall conductivity. Using dual-gated graphene bilayers, we investigate here the E-field dependence of the ν=0 QHS in high perpendicular magnetic fields (B), up to 30T. The temperature dependence of ρ_{xx} measured at ν=0 shows an insulating behavior, which is strongest in the vicinity of E=0 as well as at large E-fields. At a fixed B-field, as a function of the applied E-field the ν=0 QHS undergoes a transition, marked by a ρ_{xx}minimum, as well as a temperature independent ρ_{xx} at a finite E-field value. This observation can be explained by a transition from a spin polarized ν=0 QHS at small E-fields, to a valley (layer) polarized ν=0 QHS at large E-fields. The E-field value at which the transition occurs follows a linear dependence on the applied perpendicular magnetic field, with a slope of ∼18 mV/nm·T.

[1]We thank NRI and NSF for support.

1:39PM W37.00011 Giant Spin-Hall Effect and Nonlocal Transport in Graphene , DMITRY ABANIN, Princeton, K.S. NOVOSELOV, A.K. GEIM, Manchester, L.S. LEVITOV, MIT — Graphene provides a unique opportunity to explore quantum-relativistic phenomena in a condensed matter laboratory. Interesting phenomena associated with the parity anomaly, including quantum Hall effect in the absence of magnetic field and quantum spin-Hall effect in quantizing magnetic fields, have been theoretically proposed, but could not be observed so far largely due to disorder and density inhonogeneity. We show that weak magnetic field induces large bulk non-quantized spin-Hall effect in graphene. The effect occurs due to Zeeman spin splitting which generates the imbalance of the Hall resistivities of the two spin species. The spin-Hall effect is robust in the presence of disorder and interactions. It will manifest itself in large nonlocal transport mediated by long-lived spin currents, as well as in spin injection and spin accumulation experiments. The effect peaks at the Dirac point, and can serve as a hallmark of the relativistic character of carriers in graphene and other Dirac materials.

1:51PM W37.00012 Quantum Hall effect and Landau level crossing in trilayer graphene , THITI TAYCHATANAPAT, Department of Physics, Harvard University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, PABLO JARILLO-HERRERO, Department of Physics, MIT — We report the experimental observation of quantum Hall effect in Bernal stacked trilayer graphene (TLG) on hexagonal boron nitride substrate. The mobility of our TLG reaches 110,000 $cm^2/V{\cdot}s$ allowing us to observe the Shubnikov-de Haas oscillation at a magnetic field as low as 300 mT and broken- symmetry states at high magnetic field. In addition, the unique band structure of Bernal stacked TLG which consists of monolayer-like and bilayer-like subbands at low energy allows us to observe the Landau level crossing between these two subbands. The positions of these crossings in magnetic field and filling factors enable us to estimate relevant Slonczewski-Weiss-McClure parameters.

2:03PM W37.00013 Suspended graphene electromechanics in quantum Hall regime , VIBHOR SINGH, GANESH SUBRAMANIAN, BUSHRA IRFAN, HARI SOLANKI, MANDAR DESHMUKH, Tata Institute, Mumbai, India — There has been a keen interest in the NEMS community in probing the coupling between charge and mechanical degrees in NEMS resonators. These experiments show that electron transport and mechanical motion of the resonator influence each other. Motivated by this, we have probed the electron transport in the ultra clean graphene devices in quantum Hall regime at low temperature while it is mechanically perturbed. There can be several mechanisms that can lead to the resistance change due to mechanical vibrations like, by strain due to deformation of the flake, redistribution of the carrier density etc, electron scattering within the flake due to changes in the energy landscape. In our study we find that upon mechanical vibrations the resistance of the device changes. We try to understand these changes caused by the non-linear dependence of resistance on carrier density.

Thursday, March 24, 2011 11:15AM - 2:15PM –

Session W38 DMP DPOLY: Focus Session: Organic Electronics and Photonics – Charge transport A130/131

11:15AM W38.00001 Charge Transport in Functionalized Fluorinated Pentacenes , OANA JURCHESCU, DANIEL DAVID, CLAIRE MCLELLAN, Wake Forest University, BALAJI PURUSHOTHAMAN, University of Kentucky, SHUBIN LIU, University of North Carolina, VEACESLAV COROPCEANU, Georgia Institute of Technology, JOHN ANTHONY, University of Kentucky, LAURIE MCNEIL, University of North Carolina — We report on charge transport in fluorinated functionalized pentacenes and discuss the effect of trialkylsilyl and the number of fluorine atoms. We show that modifications in the chemical composition influence the molecular packing, crystal formation and electrical properties, allowing us to measure mobilities from 10^{-5} to 1.7 cm^2/Vs. The mobilities correlate with the packing, demonstrating that tuning the solid-state order to induce pi-stacking improves electrical properties. By combining Raman measurements with theoretical calculations predicting the vibrational spectrum, we explore the vibrational modes of the crystals, providing information about the intermolecular coupling and electron-phonon interactions governing charge transport. We calculate the intermolecular electronic couplings and band structures by using density functional theory, and study the effect of fluorination and trialkylsilyl substitution on crystal packing and the electronic properties.

11:27AM W38.00002 Semicrystalline high performance poly (thienothiophene) thin films: crystallites and defects , CHENCHEN WANG, Applied Physics, Stanford University, JAVIER DACUÑA, Electrical Engineering, Stanford Univerisity, BJÖRN BRÄUER, Stanford Institute of Materials and Energy Science, DAN DARANCIANG, Department of Chemistry, Stanford Univerisity, ALBERTO SALLEO, Material science and engineering, Stanford Univerisity — Effects of liquid crystalline temperature annealing and surface treatment on Poly(2,5-bis(3-alkylthiophen-2-yl)thieno[3,2-b]thiophenes) (PBTTT) thin films were studied. Time resolved terahertz spectroscopy (TRTS), which measures the local carrier mobility, suggests that the mobility improvement of annealed PBTTT on octadecyltrichlorosilane (OTS), compared with as cast film, is mainly due to superior local carrier mobility. Scanning transmission x-ray microscopy (STXM), which measures the in-plane molecular orientation with 30nm spatial resolution, shows similar domain size of annealed films on both OTS and SiO_2, and implies that the higher mobility of film on OTS cannot be accounted for by domain size. These results are also supported by the mobility edge model, which extracts trap density and quasi-free carrier mobility in crystallites from transistor characterization. Annealing film on OTS improves mobility in crystallites, but has little effects of reducing trap density. The modeling shows great elimination of interface trap density of film on OTS, compared with film on SiO_2, which might be the main reason for its higher mobility.

11:39AM W38.00003 First-principles study of polythiophene and polyselenophene crystals for organic electronics[1] , TAKAO TSUMURAYA, JUNG-HWAN SONG, A.J. FREEMAN, Northwestern University — Semiconducting polymers, like regioregular poly(3-hexylthiophene)/poly(3-hexylselenophene) (rr-P3HT/rr-P3HS) are currently the most widely studied materials in a variety of applications for polymer based bulk-heterojunction (BHJ) solar cells and organic field-effect transistors (OFET). [1,2] For both applications, the performance of devices has been attributed to thin film structures of rr-P3HT/rr-P3HS on substrates. To understand their mechanisms, the crystal structure has been extensively investigated by using various experimental techniques. However the crystal structure has yet to be unambiguously characterized. Here, we proposed several possible structures and investigated their stabilities from first-principles density functional calculations based on the all-electron FLAPW method. [3] We found that two base-centered monoclinic structures belonging to space group $A2$ are in the degenerate lowest energy structures. The electronic and transport properties are also discussed. Lastly, we report on the differences in electronic and crystal structure between rr-P3HT and rr-P3HS.

11:51AM W38.00004 Analysis of Metallic Conduction at the Interface of TTF and TCNQ Crystals[1] , VIKTOR ATALLA, Fritz-Haber-Institut der Max-Planck-Gesellschaft, 14195 Berlin, MINA YOON, ORNL, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der Max-Planck-Gesellschaft, 14195 Berlin — Organic materials are promising candidates for a next generation of electronic devices, since they offer a variety of new intriguing electronic phenomena while being environmentally friendly, low cost, and mechanically flexible. Here we study the donor/acceptor interface of TTF and TCNQ organic molecular crystals which was found to exhibit metallic conduction whereas the individual crystals are large band-gap semiconductors. Using density functional theory (DFT) we first compare the performance of different exchange-correlation (XC) functionals for TTF and TCNQ dimers. All employed XC functionals consistently give electron transfer from TTF to TCNQ and the van der Waals (vdW) corrected molecular binding distances are within ≈ 0.1 Å of the MP2 value, indicating that within DFT the system can be qualitatively described by semilocal functionals. We construct interfaces between the two types of crystals and calculate their electronic structures. On a PBE + vdW level we find indications for metallic conduction at the interface, due to metallic bands that are exclusively induced from the interface layers of TTF and TCNQ molecules.

12:03PM W38.00005 Charge Trapping in Organic Thin-Film Transistors , CLAIRE MCLELLAN, JACK OWEN, Wake Forest University, MARSHA GRIMMINGER, JOHN ANTHONY, University of Kentucky, OANA JURCHESCU[1] — Charge trapping in the bulk of the organic semiconductors and at interface with the gate dielectric and/or contacts is one of the determining factors governing charge transport in organic thin-film transistors (OTFTs). We explore the current-voltage characteristics in different charge density regimes and extract the field-effect mobility. The dependence of mobility on gate/drain voltage give us valuable insight into the mechanism of charge transport and the relevance of trapping states. We perform measurements on devices fabricated using different methods, such as spin-coating, drop-casting or spray-coating, on a silicon gate electrode, silicon dioxide gate dielectric, and gold source and drain contacts. We demonstrate that the performance of OTFTs is strongly dependent on processing details. We show that even when using the same processing method, we are able to systematically tune the charge trapping states by chemically modifying the contact and dielectric surfaces with self-assembly monolayers.

[1]Wake Forest University

12:15PM W38.00006 Organic electrical double layer transistors gated with ionic liquids[1] , WEI XIE, C. DANIEL FRISBIE, Department of Chemical Engineering and Materials Science, University of Minnesota — Transport in organic semiconductors gated with several types of ionic liquids has been systematically studied at charge densities larger than 10^{13} cm^{-2}. We observe a pronounced maximum in channel conductance for both p-type and n-type organic single crystals which is attributed to carrier localization at the semiconductor-electrolyte interface. Carrier mobility, as well as charge density and dielectric capacitance are determined through displacement current measurement and capacitance-voltage measurement. By using a larger-sized and spherical anion, tris(pentafluoroethyl)trifluorophosphate (FAP), effective carrier mobility in rubrene can be enhanced substantially up to 3.2 cm^{2}V^{-1}s^{-1}. Efforts have been made to maximize the charge density in rubrene single crystals, and at low temperature when higher gate bias can be applied, charge density can more than double the amount of that at room temperature, reaching 8*10^{13} cm^{-2} holes (0.4 holes per rubrene molecule).

[1]NSF MRSEC program at the University of Minnesota

12:27PM W38.00007 Hopping transport in electrolyte-gated P3HT organic field effect transistors[1] , SHUN WANG, MINGJING HA, MICHAEL MANNO, C. DANIEL FRISBIE, C. LEIGHTON, Department of Chemical Engineering and Material Science, University of Minneosta — Using ion-gel-gated poly (3-hexylthiophene) (P3HT), we successfully fabricated p-type organic field effect transistors (OFET) with on/off ratios of 10^5 and mobility of the order of 1 cm^2/V s at room temperature. We studied charge transport in the electrochemically doped P3HT as a function of gate voltage, temperature, magnetic field, film thickness, and roughness. Carrier concentrations were obtained from both gate charging current and Hall effect measurements. The resistance vs. temperature (down to 5K for large gate voltages) characteristics indicate 2D hopping transport. Large positive magnetoresistance at temperatures lower than 50 K was observed, but with anomalously low anisotropy due to high roughness.

[1]Work supported by NSF MRSEC.

12:39PM W38.00008 Charge transport and velocity distribution in ambipolar organic thin film Transistors based on a diketopyrrolopyrrole-benzothiadiazole copolymer , TAE-JUN HA, The University of Texas at Austin, PRASHANT SONAR, SAMARENDRA PRATAP SINGH, Institute of Materials Research and Engineering(A*STAR), ANANTH DODABALAPUR, The University of Texas at Austin — There have been reports of charge transport mechanisms in organic thin film transistors (OTFTs) focusing on steady-state characteristics but these measurements provide limited information. Time-resolved measurements can provide additional information in understanding transport mechanisms but existing reports have focused on unipolar organic characteristics. No previous reports on ambipolar organic devices have involved entire velocity distribution and charge transport mechanisms. Recently, we have fabricated ambipolar OTFTs based on a diketopyrrolopyrrole-benzothiadiazole copolymer (PDPP-TBT) with a field-effect mobility of more than 0.2 cm^2 $V^{-}1$ $s^{-}1$. Velocity distributions are measured by performing specialized dynamic measurements while keeping the RC-time constant of the measurement circuit small. This yields a distribution in arrival times of charge carriers from source to drain which can be converted to velocity distributions. We will also describe dynamic transport measurements on high-k-dielectric PDPP-TBT OTFTs.

12:51PM W38.00009 Organic field effect transistor fabricated by directly grown poly (3 hexylthiophene) crystalline nanowires on solution processed carbon nanotube aligned array electrodes , BIDDUT SARKER, Nanoscience Technology Center, Department of Physics, University of Central Florida, Orlando, FL 32826, JIANHUA LIU, LEI ZHAI, Nanoscience Technology Center, Department of Chemistry, University of Central Florida, Orlando, FL 32826, SAIFUL KHONDAKER, Nanoscience Technology Center, Department of Physics, and School of Electrical Engineering and Computer Science, University of Central Florida — We demonstrate convenient and highly reproducible approach to fabricate organic field effect transistors (OFETs) using the direct growth of crystalline P3HT nanowires on aligned array SWNT interdigitated electrodes. Compared to the OFETs with metal electrodes, the OFETs with SWNT electrodes show high mobility and high current on-off ratio with a maximum of 0.13 cm^2/Vs and 3.1×10^5, respectively. The improved device characteristics are also demonstrated by the absence of short channel effect which is dominant in gold electrode OFETs. Such remarkable improvement of the device performance as high mobility, high current on-off ratio, absence of short channel effect and better charge carrier injection can be attributed to the improved contact via strong $\pi-\pi$ interaction SWNT electrodes with the crystalline P3HT nanowires as well as the improved morphology of P3HT due to one dimensional crystalline structure. .

1:03PM W38.00010 Interfacial Width Measurements of Dielectric/P(NDI2OD-T2) Using Resonant Soft X-ray Reflectivity[1] , HONGPING YAN, ZIRAN GU, ELIOT GANN, BRIAN COLLINS, NC State Univ., SUFAL SWARAJ, SOLEIL, CHENG WANG, Advanced Light Source, TORBEN SCHUETTFORT, CHRIS MCNEILL, Univ. of Cambridge, HARALD ADE, NC State Univ. — Interfaces between a conjugated polymer and a dielectric play a critical role in organic thin-film transistors, yet it's difficult to measure. Resonant Soft X-ray Reflectivity (R-SoXR) is a unique and relatively simple method to investigate such interfaces. By tuning the soft X-ray energies, we are able to selectively and quantitatively characterize the interfacial width and thicknesses of the films. In an effort to relate performance to interface structure, we have used R-SoXR to investigate polystyrene (PS) or poly(methyl methacrylate) (PMMA) as the top layer and poly{[N,N9-bis(2-octyldodecyl)-naphtha-lene-1,4,5,8-bis(dicarboximide)-2,6-diyl]-alt-5, 59-(2,29-bithiophene)} (P(NDI2OD-T2)) as bottom layer supported on a Si substrate. We found that the device with PS as dielectric has a higher threshold voltage, which correlates to the increased interfacial trapping due to increased interfacial roughness. The extension of R-SoXR to the energy of fluorine K absorption edge is also demonstrated.

[1]NSF DMR-0906457, DOE DE-FG02-98ER45737

1:15PM W38.00011 Temperature Induced Structure Evolution of Regioregular Poly (3-hexylthiophene) in Dilute Solution and its Influence on Thin Film Morphology , CHARLES HAN, YE HUANG, HE CHENG, Joint Laboratory of Polymer Science and Materials, ICCAS, Beijing, China, JOINT LABORATORY OF POLYMER SCIENCE AND MATERIALS, ICCAS, BEIJING, CHINA TEAM — The structure evolution of regioregular Poly (3-hexylthiophene) (P3HT) in THF dilute solution, and its influence on thin film morphology were studied. A thermal treatment at high temperature effectively re-disperses P3HT micro-sized aggregates, and introduces two modes in DLS measurements. The structures of these 2 modes are identified, and the two structures of P3HT in dilute solution can greatly influence the morphology on subsequent thin films produced. Since the P3HT structures are carried into the film morphology, proper understanding and control of the structures in solution are important and can enhance electronic and opto-physical properties of the final devices.

1:27PM W38.00012 Effect of Cooling Rate on Microstructure and Charge Transport in Semiconducting Polymer Thin Films[1] , EVAN KANG, EUNSEONG KIM, KAIST, CENTER FOR SUPERSOLID AND QUANTUM MATTER RESEARCH TEAM — Thermal annealing of polymer thin films often enhances charge carrier mobility which can be attributed to self-healing of the film morphology. We have investigated the effect of cooling rate following the annealing treatment on the thin film microstructure and the charge transport properties using a high performance semiconducting polymer, poly(2,5-bis(3-alkylthiophen-2-yl)thieno[3,2-b]thiophene) (PBTTT). The cooling rate plays a key role in determining the microstructure and performance of polymer thin films. Differential scanning calorimeter measurement shows that fast cooling suppresses the crystallization process. The microstructure of thin films is investigated by using 2D X-ray diffraction and atomic force microscopy. Slow cooling results in well-connected large domains with enhanced three dimensional ordering whereas fast cooling leads to misalignment of small domains with relatively rough surface. Transport characteristics at various temperatures show increase in the charge carrier mobility and decrease in the activation energy when the cooling rate is slowed. This change in the mobility and activation energy becomes saturated with cooling rate below 15 $^\circ$C/min.

[1]E. S. H. K. and E. K. gratefully acknowledge financial support from the National Research Foundation of Korea through the Creative Research Initiatives (CSQR).

1:39PM W38.00013 Exponential behavior of the Ohmic transport in organic films , CORNELIU COLESNIUC, Department of Physics and Center for Advanced Nanotechnology, University of California San Diego, La Jolla, California 92093 , RUDRO BISWAS, Department of Physics, Harvard University, Cambridge, Massachusetts 02138, SAMUEL HEVIA, Facultad de Física, Universidad Católica de Chile, Casilla 306, Santiago, Chile 6904411, ALEXANDER BALATSKY, Theoretical Division and Center for Integrated Nano-Technologies, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, IVAN SCHULLER, Department of Physics and Center for Advanced Nanotechnology, University of California San Diego, La Jolla, California 92093 — An exponential dependence of conductance on thickness and temperature was found in the low voltage, Ohmic regime of copper (CuPc) and cobalt (CoPc) phthalocyanine, sandwiched between palladium and gold electrodes, unlike ever claimed in organic materials. A comparison with conventional models fails to explain all the data with a single set of parameters. On the other hand, a model which incorporates tunneling between localized states with thermally-induced overlap agrees with the data, and decouples the contributions to conductance from the electrode-film interface and the bulk of the film. Work supported by AFOSR, DOE and the UCOP program on carbon nanostructures.

1:51PM W38.00014 Atomistic Molecular Dynamics Simulation of the Surface Properties of P3HT Films[1]

, YENENEH YIMER, SIMA MOFAKHAM, ALI DHINOJWALA, MESFIN TSIGE, Department of Polymer Science, University of Akron — In recent years P3HT has attracted much interest mainly because of its potential applications in solar cells, light emitting diodes and field effect transistors. The performance of these devices is strongly dependent on the structural packing, morphology and interfacial properties of the P3HT. In order to improve the devices efficiency, understanding the structural and dynamical properties of P3HT at the atomic level is important. Most studies on P3HT have mainly focused on understanding its bulk properties. However, the orientation of P3HT chains at the polymer/air interface has not been well investigated. Using molecular dynamics simulations we have studied the interfacial properties of free-standing P3HT films. The simulation results show that at the air/polymer interface the alkane side groups of the P3HT chains orient mainly to the interface in qualitatively good agreement with SFG experimental results. The surface tension of P3HT in its melt state shows strong dependence on temperature and chain length and is directly related to the roughness of the P3HT surface.

2:03PM W38.00015 Switching or triggering by light organic materials in the 100 nm size range

, VINA FARAMARZI, JEAN FRANCOIS DAYEN, BERNARD DOUDIN, IPCMS/CNRS/UDS, DMONS TEAM — We investigate optoelectronic fabrication and characterization of organic electronics devices in the 100 nm range. This intermediate size has advantages in simplicity of device fabrication and robustness of observed properties. For this aim high aspect ratio lateral electrodes separated by a sub 100nm gap were produced by means of simple optical lithography techniques [1]. The electrical measurements set-up is integrated with an inverted optical microscope, allowing simultaneous optical and electrical measurements followed by temperature and magnetic field studies. We demonstrate that electrical contacts are suitable for a wide range of current measurements going from 10^{-13} to 10^{-2} A. This versatility makes the nanotrench design compatible for studying a broad variety of nanoparticles and molecular systems. Electrical transport properties of different devices are presented, e.g molecular switches, Iron based spin-transition nanoparticles, Conductive molecular chains and 2D nanoparticle networks. The promising reproducible results reveal novel intrinsic transport properties and confirm the high interest and reliability of this approach for further studies in the field of molecular electronics and spin dependent transport in molecular structures.

Session W39 DBP: Experimental Techniques in Biophysics A124/127

11:15AM W39.00001 ABSTRACT WITHDRAWN –

11:27AM W39.00002 Spatially resolved absorption spectroscopy of bio - assemblies on a micron scale

, SILKI ARORA, Department of Physics and College of Optics, University of Central Florida, JENNIFER MAUSER, DEBOPAM CHAKRABARTI, Burnett School of Biomedical Sciences, University of Central Florida, ALFONS SCHULTE, Department of Physics and College of Optics, University of Central Florida — We have developed a novel approach to measure optical absorption spectra with spatial resolution at the micron scale. The setup employs a confocal microscope with a broadband white light excitation beam in transmission geometry. An aperture controls the amount of illuminating light and localizes the area of excitation. The setup is employed to measure the absorption spectrum of single red blood cells ($\sim$ 7 microns diameter) under solution conditions. The spatial resolution in the lateral direction is found to be better than three microns. Through measurements of the transmitted intensity in met- myoglobin and calcein dye nanoliter solutions at fixed path lengths, we establish that the absorbance varies linearly with concentration over the range from 0.1 to 2 mM. Our instrument enables measurements of spatial variations in the optical density of small samples and may find application in monitoring biological assemblies at the single cell level.

11:39AM W39.00003 Stochastic super resolution imaging by diffusive probes

, THOMAS DORN, JOHN EWALT, FRANCISCO MARQUEZ, GEORGE SHUBEITA, UT-Austin, Physics — Optical microscopy is a powerful tool for the imaging of cells and bio-materials, however the resolution is limited by diffraction and thus objects closer than a few hundred nanometers cannot be individually resolved. We report a novel stochastic super-resolution technique which relies on diffusing probes in which the resolution is determined by probe size and Forster radius of energy transfer. By recording a time-series of images similar to other super-resolution techniques, the centers of bright spots can be determined with sub-pixel accuracy by fitting to the point spread function. The centroids can then be used to reconstruct a super-resolution image.

11:51AM W39.00004 Near-field Approaches to Subcellular Tissue Abalation

, DEEPA RAGHU, George Washington University, JOAN HOFFMANN, Applied Physics Laboratory, BENJAMIN GAMARI, University of Massachusetts, ANDREW GOMELLA, MARK REEVES, George Washington University — We report on the development of a near-field approach to MALDI (Matrix-assisted laser desorption and Ionization). In this technique analytes embedded in an energy- absorbing matrix are ablated from the surface of a sample. In the infrared region, the matrix can be water by exciting the 3-micron vibrational mode of the water molecule. We use a 3-micron wavelength lasers, coupled with a near-field scanning microscope to ablate material from cells of different membrane stiffness. We have been able to reproducibly ablate features as small as 1 micron in diameter in cell and have characterized the power-dependence of the ablation process. We will review our findings and describe demonstrations of tissue modification by this approach at length scales smaller than a single cell. This approach has the potential to allow the identification and mapping of proteins expressed in intact cells and tissues, which is of great interest as protein expression connects genomic information with the functioning of an organism.

12:03PM W39.00005 Rotational Diffusion of Plasmon-Resonant Gold Nanorods for Depth-Resolved Microrheology Using Optical Coherence Tomography[1]

, AMY OLDENBURG, RAGHAV CHHETRI, University of North Carolina at Chapel Hill, KRYSTIAN KOZEK, AARON JOHNSTON-PECK, JOSEPH TRACY, North Carolina State University — The ability to perform microrheology in optically thick samples would enable analysis of bulk tissues. Optical coherence tomography (OCT) provides imaging several mean free scattering path lengths into tissue. In this study we report the use of plasmon-resonant gold nanorods as microrheological sensors in OCT. Nanorods exhibit a longitudinal mode that is excited when they are oriented parallel to the polarization of the incident light, which is favorable for passive microrheology using polarized light to monitor their rotational diffusion. We demonstrate measurements of the rotational diffusion of unconfined, colloidal gold nanorods using polarization-sensitive OCT, and validate the Stokes-Einstein relationship for the nanorods in simple fluids of varying viscosity. We then show that OCT provides depth-resolved imaging of fluid viscosity through measurements of the rotational diffusion rate of the nanorods.

12:15PM W39.00006 Monte-Carlo Study of Binding Kinetics in Surface Plasmon Resonance Systems , MATTHEW RAUM, UWE TÄUBER, Virginia Tech, Department of Physics, KIMBERLY FORSTEN-WILLIAMS, Virginia Tech, Department of Chemical Engineering — Surface plasmon resonance (SPR) has become a standard tool for studying ligand-receptor binding reactions in real-time. Ideally the data obtained with this technique allows measurement of kinetic reaction rates (rather than merely the equilibrium constant for the reaction). In typical experimental configurations one species is immobilized near the active surface while its binding partner is initially suspended in solution, flowing across the active surface. It is generally appreciated that reaction rates observed in SPR experiments are affected by mass transport if the time scales for reaction and transport in the system are comparable. The issue of ensuing effective reaction rates has been treated through different approaches in the literature. The goal of this research is a quantitative study of how faithfully intrinsic binding rates can be measured in SPR devices. We employ a lattice Monte Carlo method to simulate SPR experiments in order to test the efficacy of common SPR analytical techniques. We point out where existing analytical techniques succeed or fail in measuring binding and dissociation rates, and investigate the influence of secondary parameters in the system (such as the flow rate) on experimental data.

12:27PM W39.00007 Fluorescence Correlation Spectroscopy of Tryptophan-containing Proteins in Sugar Solutions using Two Photon Excitation[1] , DAVID SIDEBOTTOM, NATHAN HOLMAN, YULI WANG, MICHAEL NICHOLS, Creighton University — Simple sugars are often incorporated in cryopreserving media to aid in the preservation of biomaterials and functional proteins. However, the mechanism by which sugars provide protection is still openly debated. As part of a project to investigate the behavior of proteins in sugar solutions, we are developing Fluorescence Correlation Spectroscopy (FCS), using a novel two photon excitation at 532 nm, as a selective probe of protein dynamics for tryptophan-containing proteins. Our goal is to monitor possible alterations in the protein's hydrodynamic radius caused by preferential binding of sugars to its surface.

12:39PM W39.00008 Continuous Nano-Particle Transport in a Standing Wave Optical Line Trap , VASSILI DEMERGIS, ERNST-LUDWIG FLORIN, The University of Texas at Austin — Since the introduction of the single beam optical trap (SBT) by Ashkin et. al. in 1986, trapping and manipulation of micron-sized particles by optical forces has become instrumental in many areas of research. However, controlled transport of large numbers of particles is difficult using a SBT. Here we introduce a technique for controlled transport that we call an Optical Capillary (OC), named for its ability to strongly confine and continuously transport nanometer-sized particles. The OC, generated by an optical standing wave pattern, is especially strong along the optical axis due to the compensation of the axial scattering force. We utilize the lateral scattering forces to control the transport of particles along a line perpendicular to the optical axis. The measured velocity profiles of single particles in the OC agree with our model predictions.

12:51PM W39.00009 Laser- based Insect Tracker (LIT) , LEONARDO MESQUITA, SHIVA SINHA, ROB DE RUYTER VAN STEVENINCK, Indiana University Bloomington, Dep. of Physics — Insects are excellent model systems for studying learning and behavior, and the potential for genetic manipulation makes the fruitfly especially attractive. Many aspects of fruitfly behavior have been studied through video based tracking methods. However, to our knowledge no current system incorporates signals for behavioral conditioning in freely moving flies. We introduce a non-video based method that enables tracking of single insects over large volumes (>8000cm3) at high spatial (<1mm) and temporal (<1ms) resolution for extended periods (>1 hour). The system uses a set of moveable mirrors that steer a tracking laser beam. Tracking is based on feedback from a four-quadrant sensor, sampling the beam after it bounces back from a retro reflector. Through the same mirrors we couple a high speed camera for flight dynamics analysis and an IR laser for aversive heat conditioning. Such heat shocks, combined with visual stimuli projected on a screen surrounding the flight arena, enable studies of learning and memory. By sampling the long term statistics of behavior, the system augments quantitative studies of behavioral phenotypes. Preliminary results of such studies will be presented.

1:03PM W39.00010 Power dependent study of kinetics of TRF2 recruitment in cells due to DNA damage caused by ultrafast near-IR Laser , MANAS BHALERAO, UT Arlington, NAZMUL HUDA, DAVID GILLEY, IUPUI, SAMARENDRA MOHANTY, UT Arlington — Ultrafast laser microbeam is finding widespread applications in eliciting highly localized damage to cellular components allowing study of in-situ repair machinery. While the high peak power density that exists in ultrafast laser can cause various types of DNA damage including double strand breaks (DSB), tuning the power of these laser microbeams may cause specific type of DNA damage. Here, we report wavelength and dose dependent parametric study of kinetics of TRF2 recruitment in cells due to DNA damage caused by ultrafast near-IR Laser. A tunable Ti: Sapphire laser beam was coupled via laser port of an inverted microscope. Spot and line laser micro-irradiation pattern in nuclear sites of HT1080 cells expressing YFP-tagged TRF2 was achieved by piezo-scanning mechanism. The recruitment of TRF2-YFP was found to depend highly on the peak irradiance of the near-IR laser microbeam, the required threshold irradiance being much higher than that observed for DSB. Further, recruitment kinetics revealed that the time constant for TRF2 recruitment depends on the laser irradiance parameters. The time required for TRF2 recruitment was found to decrease with increased peak irradiance. We will present these results and also elucidate on physical mechanism of DNA damage caused by ultrafast laser microbeam.

1:15PM W39.00011 Background Elimination and Noise Reduction by Mechanical Modulation Raman Spectroscopy , KATHLEEN HINKO, CHIEZE IBENECHE, ANDREA KEIDEL, TOBIAS BARTSCH, ERNST-LUDWIG FLORIN, University of Texas at Austin — Raman spectroscopy is widely used by biophysicists for the molecular identification of cellular substructures. However, there are high levels of background and noise associated with Raman spectra from other molecules in the microscopic detection volume. We present two methods of mechanical modulation for background subtraction and noise reduction in a Raman microscope: (1) a three-axis stage modulation for fixed objects and (2) a separate optical trap modulation for objects in solution. With our technique, we completely eliminate the background in our spectra and improve the signal-to-noise ratio by two orders of magnitude. We applied this technique to lipid vesicles and fission yeast cells in solution. Additionally, we obtained mechanical modulation Raman spectra of fission yeast in three dimensions and observed spatial differences in the molecular composition for different metabolic states of a single yeast cell.

1:27PM W39.00012 Ultraweak bioluminescence dynamics and singlet oxygen correlations during injury repair in sweet potato , MARIUS HOSSU, LUN MA, WEI CHEN, UT Arlington — Ultraweak bioluminescence at the level of hundreds of photons per second per square centimeter after cutting injury of sweet potato was investigated. A small emission peak immediate after cutting and a later and higher peak were observed. Selective singlet oxygen inhibitors and sensors have been use to study the contribution of singlet oxygen during the curing process, demonstrating increased presence of singlet oxygen during and after the late bioemission peak. It was confirmed that singlet oxygen has direct contribution to ultraweak bioluminescence but also induces the formation of other exited luminescent species that are responsible for the recorded bioluminescence.

1:39PM W39.00013 Obtaining optical properties using Representative Layer Theory[1] , NEEMA RAZAVI, BRAIN YUST, DHIRAJ SARDAR, University of Texas San Antonio — Reliable and minimally invasive methods for diagnosis of toxicity and onset of disease are important for advances in clinical practices. This is commonly achieved through the optical properties, such as a change in the absorption or scattering strength of the diseased tissue. Thus, being able to quantitatively characterize these changes is important to advancements in medical diagnostic methods. By adapting the Representative Layer Theory to the integrating sphere technique, very thin biological samples may be optically characterized, yielding a quick and easy method for monitoring optical changes as a function of disease progression. Samples, consisting of cells, dyes, and nanoparticles of known concentrations were optically characterized at multiple wavelengths. Optical properties obtained by the Representative Layer Theory are compared to those obtained through other methods, such as Kubelka-Munk and Inverse Adding Doubling which are known to have sample thickness limitations.

1:51PM W39.00014 An *in vitro* approach to understanding intracellular motor-based cargo transport , RAFAEL LONGORIA CASASA, University of Texas at Austin, Physics Department, HAYLEY MANNING, GEORGE SHUBEITA, University of Texas at Austin, Physics Department — Microtubule-based molecular motors are responsible for the long range transport of intracellular cargoes. Most cargoes move bidirectionally yet reach their destination in the cell. The mechanism by which the seemingly random bidirectional motion of cargoes is regulated by the cell to produce directed transport remains unclear. Two distinct models have been proposed: coordination via a tug-of-war, the dynamics of which depend only on the properties of the motors; and coordination via non-motor proteins. However, no direct evidence for either one has been found yet. We present an experimental method that can address the different predictions of these models. We reconstitute *in vitro* transport of endogenous motor-driven lipid droplets purified from *Drosophila* embryos. Global transport dynamics are observed under varied medium conditions by DIC microscopy. Combined with stall force measurements using an optical trap, these investigations relate the global dynamics to local changes in force production of the motors which give us a direct handle to differentiate between the different models of transport.

2:03PM W39.00015 Nonlinear optical microscopy in biology: Combining second-harmonic generation and two-photon fluorescence imaging , KOEN CLAYS, University of Leuven, Belgium — Optical microscopy has been since long a truly enabling visualization technique in the biological and biomedical sciences. Linear optical microscopy relies on simple linear optical effects. Nonlinear optical microscopy relies on the nonlinear optical properties of endogenous or exogenous chromophores to produce a better image. Two-photon fluorescence (TPF), a third-order nonlinear optical effect and observed at the focal spot only due to the quadratic intensity dependence, results in inherently higher resolution than possible for one-photon fluorescence, observed over the complete Rayleigh range. Second-harmonic generation (SHG) is a second-order nonlinear optical effect only observed for non-centrosymmetric arrangements of non-centrosymmetric chromophores. While this does put a restriction on the chromophores that can be used, it also results in structural information about symmetry when used in combination with TPF. TPF, being a third-order nonlinear process, is not restricted by any symmetry consideration. We will review the molecular design criteria for exogenous probes for combined SHG and TPF nonlinear microscopy, provide examples of optimized chromophores and show microscopy images demonstrating the use of such chromophores in nonlinear microscopy.

Thursday, March 24, 2011 11:15AM - 2:03PM –

Session W40 DPOLY: Polymer Blends A122/123

11:15AM W40.00001 Entanglement Dynamics in Miscible Polyisoprene / Poly(p-*tert*-butyl styrene) Blends , HIROSHI WATANABE, Kyoto University — Viscoelastic and dielectric behavior was examined for well entangled, miscible blends of high-M *cis*-polyisoprene (PI) and poly(p-*tert*-butyl styrene) (PtBS). The dielectric data of the blends, reflecting the global motion of the PI chains having the type-A dipoles, indicated that PI and PtBS were the fast and slow components therein. At high temperatures T, the blends exhibited two-step entanglement plateau. The high frequency (ω) plateau height was well described by a simple mixing rule of the entanglement length based on the number fraction of the Kuhn segments. At low T, the blend exhibited the Rouse-like power-law behavior of storage and loss moduli, $G' = G'' \sim \omega^{0.5}$, in the range of ω where the high-ω plateau was supposed to emerge. This lack of the high-ω plateau was attributed to retardation of the Rouse equilibration of the PI chain over the entanglement length due to the hindrance from the slow PtBS chains: The PI and PtBS chains were equilibrated cooperatively, and the retardation due to PtBS shortened the plateau for PI to a width not resolved experimentally. A simple model for this cooperative equilibration formulated on the basis of the dielectric data described the viscoelastic data surprisingly well.

11:27AM W40.00002 Local Relaxation Behavior and Dynamic Fragility in Hydrogen Bonded Polymer Blends[1] , JAMES RUNT, Penn State University, KEVIN MASSER, Penn State Univerity, HANQING ZHAO, PAUL PAINTER, Penn State University — The dynamics of intermolecularly hydrogen bonded polymer blends of poly(p-(hexafluoro-2-hydroxyl-2-propyl)styrene) with poly(vinyl acetate), poly(ethylene[30]-co-vinyl acetate[70]) and poly(ethylene[55]-co-vinyl acetate[45]) are investigated by broadband dielectric relaxation spectroscopy and Fourier transform infrared spectroscopy. Each blend component exhibits a glassy state (beta) relaxation, and these relaxations are affected by the formation of intermolecular associations. The glassy state behavior of the blends can be modeled using the Painter-Coleman association model. All blends exhibit a single Tg and a single dielectric segmental (alpha) relaxation, indicative of strong segmental-level coupling. The fragility of the glass-formers depends on the volume fraction of intermolecularly associated segments, and the association model predicts which compositions have the highest fragilities. A relaxation related to the breaking and reforming of hydrogen bonds is observed at temperatures above the alpha process, and its temperature dependence varies systematically with ethylene content.

[1]Supported by NSF-DMR Polymers Program

11:39AM W40.00003 Partial Miscibility in Copolymer Blends[1] , ELIZABETH CLARK, JANE LIPSON, Dartmouth College — Copolymers can be used to affect the miscibility of otherwise immiscible polymer blends by acting as compatibilizers. To better understand the energetics of these types of systems, we use a simple lattice model to study phase separation in binary copolymer/homopolymer blends. We focus on a copolymer that contains both A and B type monomers and a homopolymer that contains purely A type monomer. An example of a system that we are investigating is polyethylene mixed with either random or alternating poly(ethylene-co-propylene). The sequence effect on miscibility as the copolymer microstructure is varied from random to alternating is investigated as well.

[1]The support of GAANN is gratefully acknowledged.

11:51AM W40.00004 ABSTRACT WITHDRAWN –

12:03PM W40.00005 Properties of polystyrene/poly(dimethyl siloxane) blends partially compatibilized with star polymers containing a gamma-cyclodextrin core and polystyrene arms , C. MAURICE BALIK, North Carolina State University, BRAD J. BUSCHE, Pacific Northwest National Lab, ALAN E. TONELLI, North Carolina State University — Cyclodextrins (CDs) are cyclic starch molecules having a hollow central cavity which can be threaded by a polymer to form an inclusion compound. This characteristic is exploited in a new type of compatibilizer: a star polymer with a gamma-CD (g-CD) core and polystyrene (PS) arms (CD-star). Spun-cast thin films of PS containing up 20 weight percent poly(dimethyl siloxane) (PDMS) are compatibilized by CD-star. The mechanism of compatibilization involves threading of the CD core by PDMS and solubilization of the resulting slip-ring graft copolymer via the PS star arms. Thin spun-cast films of these blends exhibit a a nanoscale level of mixing and remain well-mixed after annealing at 125 C for three days. In contrast, thicker solution-cast films of these blends exhibit larger-scale phase separation since the film solidification process occurs over a period of days rather than seconds. This allows some of the PDMS to de-thread from the CD-star and phase separate. However, DSC, DMA and PDMS leaching data show that PS and PDMS remain partially compatibilized in the solution-cast films.

12:15PM W40.00006 Crystallization in the Binary Blends of Crystalline-Amorphous Diblock Copolymers Bearing Chemically Different Crystalline Block[1] , CHE-YI CHU, HSIN-LUNG CHEN, BHANU NANDAN, Department of Chemical Engineering, National Tsing Hua University, Hsin-Chu 30013, Taiwan., MING-SIAO HSIAO, Material and Chemical Research Laboratories, Industrial Technology Research Institute, Hsin-Chu 300, Taiwan. — The crystallization behavior of a series of lamellae-forming blends of a shorter PS-b-PEO (SEO) and a longer PS-b-PLLA (SLLA) has been studied. In SLLA-rich blends, the junction point constraint coupled with the poor chain mobility at low T_c ($\leq$45 °C) hampered the formal crystallization of PLLA. In this case, a local demixing between a fraction of PEO and PLLA chains took place, yielding the PLLA crystalline domains in which the PLLA crystalline stems were intervened by the PEO chains. This crystalline species gave rise to a relatively broad peak at 2θ= 15.92° in the WAXS profile and displayed a much lower melting point of ca. 100 °C compared to that of the typical α-form crystal of PLLA. It was suggested that the inserted PEO chains served as the molecular defects which induced an expansion of the a-axis and b-axis of the α-form PLLA unit cell and lowered the crystal melting point due to introduction of defect free energy.

12:27PM W40.00007 ABSTRACT WITHDRAWN –

12:39PM W40.00008 Effect of Organoclays on Immiscible Polymer Blends , MAI HA, RAMANAN KRISHNAMOORTI, University of Houston — The effect of adding organoclays on the phase behavior, rheological properties and bulk mechanical properties of immiscible polymer blends of polystyrene (PS) and poly(methyl methacrylate) (PMMA) is investigated. Traditional organoclays, prepared using alkyl ammonium chains, display a preference to segregate to the PS phase for high PS volume fraction blends where the PS forms the continuous matrix. On the other hand, for blends with low PS volume fractions, the organoclay segregates to the interface between the PS and PMMA domains and leads to a decrease in the domain size that does not change much with organoclay concentration variations from 0.1 to 2 wt %. Linear dynamic rheological data of these samples show significant increase in the low-frequency modulus of the blends with added organoclay. A thermodynamic model for estimating the interfacial modulus is proposed and the results agree well with the interfacial modulus calculated by Palierne's emulsion model. The toughness of the blends increases at low concentrations of added organoclays with the optimal improvements observed for less than 0.5 wt % added organoclay.

12:51PM W40.00009 Characterization of the Early Stages of Phase Separation in PS/PVME Blends Using Fluorescence , ANNIKA KRIISA, SUNG PARK, CONNIE ROTH, Dept of Physics, Emory University — Controlling the early stages of phase separation in polymer blends provides a potentially easy route towards obtaining interconnected nanostructured domains. We present results of thermally induced phase separation in polystyrene (PS) / poly(vinylmethylether) (PVME) blends using different fluorophores covalently attached to the PS component. Fluorescence identifies the phase separation temperature Tc at earlier stages then the more traditional method of light scattering. At Tc, a large increase in fluorescence intensity is observed due to a strong reduction in the fluorescence quenching caused by the intimate presence of the more polar PVME component. We discuss the spectral red shifts of pyrene associated with the dissolution of the weak hydrogen bonding in this blend and the change in polarity of the local environment during phase separation.

1:03PM W40.00010 Non-Isothermal Crystallization of PET/PLA Blends[1] , HUIPENG CHEN, Texas Tech University, MAREK PYDA, Rzeszow University of Technology, PEGGY CEBE, Tufts University — Binary blends of poly(ethylene terephthalate) with poly(lactic acid), PET/PLA, were studied by differential scanning calorimetry. The solution cast blends were miscible in the melt over the entire composition range. We report the non-isothermal crystallization of: a.) PET, with and without presence of PLA crystals, and b.) PLA, with and without presence of PET crystals. PET can crystallize in all blends, regardless of whether PLA is amorphous or crystalline, and crystallinity of PET decreases as PLA content increases. PLA crystallization is strongly affected by the mobility of the PET. When PET is wholly amorphous, PLA can crystallize weakly even in 70/30 blends. When PET is crystalline, PLA cannot crystallize when its own content is below 0.90. The different behaviors may be related to the tendency of each polymer to form constrained chains, i.e., to form rigid amorphous fraction, RAF. PET is capable of forming a large amount of RAF, whereas relatively smaller amount of RAF forms in PLA. Like the crystals, rigid amorphous fraction of one component may inhibit growth of crystals of the other blend partner.

[1]Supported by the National Science Foundation, Polymers Program of the Division of Materials Research under DMR-0602473 and the MRI Program under DMR-0520655.

1:15PM W40.00011 Critical Micelle Concentrations for Different Micelle Shape in Diblock Copolymer/Homopolymer Blends , JIAJIA ZHOU, AN-CHANG SHI, McMaster University — Diblock copolymers (AB) blended with homopolymers (A) may self-assemble into lamellar, cylindrical and spherical micelles. The critical micelle concentrations for different micelle shape are determined using self-consistent field theory. The effect of varying copolymer block asymmetry, homopolymer molecular weight and monomer-monomer interaction are considered.

1:27PM W40.00012 Ordered Materials via Additive Driven Assembly and Reaction using Surfactant-Based Templates , MICHAEL R. BEAULIEU[1], VIKRAM K. DAGA[2], ALAN J. LESSER, JAMES J. WATKINS, University of Massachusetts Amherst — We recently reported (1) the ordering behavior of Pluronic surfactant melts through the addition of aromatic additives with hydrogen bond donating groups, which exhibit selective interactions with the polyethylene oxide (PEO) block. The ordered blends had domain sizes ranging from 12 to 16 nm at additive loadings up to 80%.The goal of this work is to utilize condensation chemistries based on the functionality of similar additives, to yield ordered composite materials that could be used for applications involving membranes or dielectric materials. The structure of the blends and composites are determined by small angle x-ray scattering, which indicates that the ordered structure is preserved following reaction of the additives. Differential scanning calorimetry indicates that an increase in additive loading causes a decrease in the melting temperature and enthalpy of melting of the PEO, which demonstrates that the interaction between the PEO segments and the additive is strong. 1:39PM W40.00013 Interfacial Structure and Dynamics of the liquid/liquid interface between Polydimethylsiloxane and Polystyrene[1] , MESFIN TSIGE, University of Akron — Many important phenomena in biology, chemistry and in various fields involve processes that occur at the interface between two immiscible liquids. A molecular level understanding of such interfaces is crucial for insight into the complex dynamics that are observed at such interfaces. In this study, atomistic molecular dynamics simulations were performed to study the structural and dynamical properties of the liquid/liquid interface between two immiscible polymers, polydimethylsiloxane (PDMS) and polystyrene (PS). A series of simulations is carried out to examine the temperature and molecular weight dependence of the orientation of molecules at and away from the interface, intermolecular correlation at the interface, interfacial tension and interfacial thickness. The results from these detailed simulations will be presented.

[1]This work is supported by the NSF (DMR0847580).

1:51PM W40.00014 Effect of linear contaminants on the dynamics and rheology of ring polymer melts , JONATHAN HALVERSON, Max Planck Institute for Polymer Research, GARY GREST, Sandia National Laboratories, KURT KREMER, Max Planck Institute for Polymer Research — Understanding the behavior of ring polymer melts remains a challenge. Early experimental efforts to characterize the rheological behavior of pure ring polymer melts have led to controversial results most likely because the samples were contaminated with linear chains. Recent studies found that stress relaxation follows a simple power law with no sign of a plateau. To further investigate these systems we have conducted molecular dynamics simulations for a semiflexible bead-spring model for chain lengths up to 14 entanglement lengths. The structure, dynamics and rheology of these systems are investigated for different concentrations of linear chains. We find that the viscosity of a ring melt increases dramatically when trace quantities of linear contaminants are present. The rings are found to swell slightly and diffuse more slowly with increasing linear concentration while the linear chains mostly behave as if in a pure linear melt. We use the concept of threading, analogous to thread passing through the eye of a needle, to explain the response of the ring melts to linear contaminants.

Session W41 DCP: Focus Session: Electronic Structure and Applications to Energy Conversion I A115/117

11:15AM W41.00001 Tuning the electronic structure of II-VI semiconductors and nanostructures for energy applications , SHENYUAN YANG, Molecular Foundry, Lawrence Berkeley National Laboratory — Using first-principles calculations within density functional theory (DFT), we study the impacts of quantum confinement, strain, and surface ligand passivation on the electronic structure of typical II-VI wurtzite semiconductors and nanostructures. In CdSe/CdTe core/shell nanowires, large anisotropic strains develop due to the large lattice mismatch. These strains result in significant reductions in band gap in the CdSe core with increasing CdTe shell thickness, by amounts comparable to that expected from reduced quantum confinement [1]. The response of band gaps of wurtzite compounds to anisotropic strain is further shown to be large and highly non-linear, and system-dependent [2]. In addition, we also explore the effects of chemisorbed ligand on the electronic structure of CdSe surfaces. Substantial shifts in band edge energies are predicted due to the induced dipole at the CdSe-ligand interface and the intrinsic dipole of the ligand [3]. Our studies suggest well-defined routes to control both the band gaps and band edge energies of nanomaterials for light-harvesting applications.

11:51AM W41.00002 TR-2PPE Studies of Ultrafast Charge Separation at Organic Photovoltaic Interfaces , S.W. ROBEY, G.J. DUTTON, NIST, W. JIN, J.E. REUTT-ROBEY, University of MD — Dissociation of excitons in organic photovoltaic (OPV) devices occurs exclusively at interfaces between donor and acceptor molecular materials. To help understand critical charge separation processes, we have performed time-resolved two-photon photoemission (TR-2PPE) studies of sub-picosecond exciton dynamics at well-characterized organic donor-acceptor interfaces. Interfaces between phthalocyanines and C_{60} were engineered using organic MBE and characterized using STM, STS, and UPS. Ultrafast TR-2PPE measurements were performed on CuPc\$C_{60}$ structures by pumping the lowest optical $\pi \rightarrow \pi^*$ transitions (Q-band) to generate CuPc singlet (S_1) excitons and probing this population with a time-delayed UV pulse. For thick films, CuPc S_1 decay is dominated by vibrational relaxation (several 100's femtoseconds) and singlet-to-triplet conversion ($\sim$ 1 picosecond). Directly at the interface, however, charge transfer to C_{60} dominates decay of S_1 exciton, ($\sim$ 100 femtoseconds) . We also find evidence for important recombination routes from the charge separated state back to lower-lying CuPc T_1 triplet excitons. To test the impact of intersystem crossing to triplet levels, we have performed analogous investigations for H_2Pc\$C_{60}$ interfaces. Results for this interface will be compared and contrasted with the CuPc\$C_{60}$ case.

12:03PM W41.00003 Near- and Far-Field Effects on Excited States at Organic Semiconductor and Metal Interfaces , OLIVER MONTI, MARY STEELE, NAHID ILYAS, LEAH KELLY, University of Arizona — We present an investigation of the evolution of excited states at the interface of the dipolar organic semiconductor vanadyl naphthalocyanine on highly oriented pyrolytic graphite. Using two-photon photoemission we observe several excited states at sub-monolayer to few-monolayer coverages. Excited states of this organic semiconductor are progressively stabilized with coverage, an effect that is somewhat mirrored in the image state manifold as well. These findings can be understood in the context of a simple electrostatic model that considers how molecular levels and vacuum level are influenced differentially by the the strong electrostatic fields present at the interface with dipolar molecules: While the vacuum level rises continuously with coverage, the molecular states are significantly depolarized as a function of electric fields in the near-field regime. This indicates that the interfacial excited state electronic structure is strongly sensitive to long-range intermolecular interactions mediated by the surface, with direct implications for energy level alignment and charge transfer dynamics at the interface. Interfacial electrostatic fields may therefore be used to manipulate in a concrete fashion interfacial charge transfer processes such as photoinduced interfacial electron transfer.

12:15PM W41.00004 Time-domain ab initio studies of excitation dynamics in semiconductor quantum dots , OLEG PREZHDO, University of Rochester — Solar energy applications require understanding of dynamical response of novel materials on nanometer scale. Our state-of-the-art non-adiabatic molecular dynamics techniques, implemented within time-dependent density functional theory, allow us to model such response at the atomic level and in real time. The talk will focus on single and multiple exciton generation, relaxation, annihilation and dephasing in semiconductor quantum dots.

12:51PM W41.00005 Hole Localization in Molecular Crystals From Hybrid Density Functional Theory[1] , NA SAI, PAUL F. BARBARA, University of Texas at Austin, KEVIN LEUNG, Sandia National Laboratory — Charge trapping in organic solids and interfaces plays an important role in organic photovoltaic efficiencies. Experimental confirmation of intrinsic charge trapping at the atomic scale and the tools to directly probe the trap energy landscape, however, remain lacking. We use first principles computational methods to examine hole trapping in organic molecular crystals. We present a computational scheme based on the tuning of the fraction of exact exchange in hybrid density functional theory to eliminate the many-electron self-interaction error [1]. With small organic molecules, we show that this scheme gives accurate descriptions of ionization and dimer dissociation. We demonstrate that the excess hole in perfect molecular crystals can form self-trapped hole polarons. The predicted absolute ionization potentials of both localized and delocalized holes are consistent with experimental values.

1:03PM W41.00006 Linear Dichroism and Photoluminescence Microscopy Imaging of Grain Boundaries in Crystalline Metal-Free Phthalocyanine Thin Films[1] , ZHENWEN PAN, CODY LAMARCHE, ISHVIENE COUR, NAVEEN RAWAT, LANE MANNING, RANDALL HEADRICK, MADALINA FURIS, PHYSICS DEPT. AND MATERIAL SCIENCE PROGRAM, UNIVERSITY OF VERMONT, BURLINGTON, VT 05405 TEAM — We employed a combination of linear dichroism and photoluminescence microscopy with spatial resolution of 5μm to study the excitonic properties of solution-processed metal-free phthalocyanine (H2Pc) crystalline thin films with millimeter-sized grains. We observe a highly-localized, sharp, monomer-like emission at the high angle grain boundaries, in contrast to samples with more uniform grain orientation where no such feature has been observed. The energy difference between the grain boundary luminescence and the HOMO-LUMO singlet exciton recombination of the crystalline H2Pc is measured to be 160meV. Our systematic survey of grain boundaries indicates this localized state is never present at low angle boundaries where the π-orbital overlap between adjacent grains is significant. It supports recent results which associated a decrease in carrier mobility with the presence of large angle boundaries in similar crystalline pentacene films.

1:15PM W41.00007 Theories and applications for characterizing electronic coupling factors , CHAO-PING HSU, Academia Sinica — The transport of charges and excitation energy are two processes of fundamental importance in many biological and material systems. One of the fundamental parameters in the transport rates is the electronic coupling, which is essentially an off-diagonal Hamiltonian matrix element between the initial and final diabatic states. We have developed ways to define the diabatic states and calculate the coupling factors, including those for electron transfer (ET) and excitation energy transfer (EET). The fundamental method development and applications will be discussed. For characterizing TEET, the Fragment Spin Difference (FSD) was developed and it can be to calculate the TEET coupling over a general class of systems. TEET in bacterial light-harvesting complex LH2 and the peridinin chlorophyll-a protein (PCP) of dinoflagellates were calculated and analyzed. Our results are in good agreement with experimental results and it offers limits to the photoprotection models. Therefore, with the FSD scheme, it is possible to quantify and analyze the electronic couplings in TEET processes in large systems, and to derive insights and limits of theoretical models.

1:51PM W41.00008 Ab initio calculation of optical spectra of solvated molecules: GW+BSE method for liquid environments , JEEHYE LEE, TOMAS ARIAS, Cornell University — Electronic excitations for solvated systems have drawn a great interest in the energy community because they provide a possibility to engineer photoexcitation processes. Time-dependent DFT (TDDFT) and the hybrid QM/MM approach successfully calculate the solvent shift in excitation energies (solvatochromic shift) for confined systems, but are well known to work best for small systems and Frenkel excitons. Here we present a new modification of the GW and Bethe-Salpeter equation (GW+BSE) methods which allows treatment of solvated systems beyond the TDDFT level by including the frequency-dependent polarizability of the solvent at the diagrammatic level. In this initial work, we present the solvatochromic and ionization potential shifts for a series of molecules in aqueous solution.

Session W42 DPOLY: Focus Session: Polymer Brushes A302/303

11:15AM W42.00001 Responsive Grafted Polymer Layers: the role of pH, temperature and surface geometry , IGAL SZLEIFER, Northwestern University — The competition between chemical equilibrium, e.g. protonation, and physical interactions determines the molecular organization and functionality in biological and synthetic systems. Charge regulation by displacement of acid-base equilibrium induced by changes in the local environment provides for a feedback mechanism that controls the balance between electrostatic, van der Waals, steric interactions and molecular organization. What are the mechanisms that determine the interplay between all these different factors? In this talk I will describe a molecular theory to address this question. In particular, the theory will be used to study the structural and thermodynamic properties of end-grafted polyacids with hydrophobic backbones. The molecular theory explicitly includes the size, shape, conformations, charge and charge distribution of all the molecular species in the system and incorporates excluded volume, van der Walls and electrostatic interactions coupled with acid-base equilibrium. On planar surfaces, the theory predicts the formation of surface micelles with morphologies that depend upon the bulk pH, solution ionic strength, temperature and surface coverage. The self assembled aggregates, present domains of varying local pH that is very different from that of the bulk solution. We show that a qualitatively new form of local organization arises that is only found when there is explicit coupling between charge regulation and physical interactions. The different morphologies can be manipulated by changing the bulk solution conditions and they provide for local domains with controlled charge and pH with large gradients with a characteristic size of a few nanometers. Following this we will discuss how ion conductivity in nanopores functionalized with polybases changes as a function of solution pH. The predictions of the theory are in quantitative agreement with experiments and they provide a physical explanation of the interplay between molecular organization and charge in the nanopore. The last part of the talk will be devoted to a new system in which we show how to use the theory under non-equilibrium conditions to study the flux of ions in finite nanopores with grafted polybases (or polyacids) in the presence of external potentials.

11:51AM W42.00002 Polyelectrolyte brushes in mixed ionic medium studied via intermolecular forces , ROBERT FARINA, NICOLAS LAUGEL, UC-Berkeley, PHILIP PINCUS, UC-Santa Barbara, MATTHEW TIRRELL, UC-Berkeley — The vast uses and applications of polyelectrolyte brushes make them an attractive field of research especially with the growing interest in responsive materials. Polymers which respond via changes in temperature, pH, and ionic strength are increasingly being used for applications in drug delivery, chemical gating, etc. When polyelectrolyte brushes are found in either nature (e.g., surfaces of cartilage and mammalian lung interiors) or commercially (e.g., skin care products, shampoo, and surfaces of medical devices) they are always surrounded by mixed ionic medium. This makes the study of these brushes in varying ionic environments extremely relevant for both current and future potential applications. The polyelectrolyte brushes in this work are diblock co-polymers of poly-styrene sulfonate (N=420) and poly-t-butyl styrene (N=20) which tethers to a hydrophobic surface allowing for a purely thermodynamic study of the polyelectrolyte chains. Intermolecular forces between two brushes are measured using the SFA. As multi-valent concentrations are increased, the brushes collapse internally and form strong adhesion between one another after contact (properties not seen in a purely mono-valent environment).

12:03PM W42.00003 Microsecond MD Simulations of Nano-patterned Polymer Brushes on Self-Assembled Monolayers , CREIGHTON BUIE, LIMING QIU, SOYEUN PARK, MARK VAUGHN, KWAN CHENG, Texas Tech University — Nano-patterned polymer brushes end-grafted onto a self-assembled monolayer interface have unique properties and application potential. However, the molecular-level interactions of these brushes with the substrate interface and the solvent are still not clear. Using a coarse-grained MD simulation approach we investigate the structure and dynamics of brushes of monomer length ranging from 25 to 75 units and an implant density σ of 0.2 to 1.0 nm^{-2} that were end-grafted onto a 5×5 nm^2 well in a self-assembled hexadecane monolayer. The behavior of each polymer-monolayer-water complex was simulated from 3 to 12 μs.The excess width and the extended height of the polymers, the nanosecond-resolved conformational transition kinetics from a compact helical to a random coil-like structure, and the time-averaged monomer density maps were determined. The scaling behavior of these brushes differs from that of previous thermodynamic and computational studies of homogeneous brushes and nanopatterned stripes. Here, we find a weaker dependence of brush height on implant density, $\sigma^{0.29}$ rather than $\sigma^{1/3}$ and near linear scaling of the excess width on σ rather than the $\sigma^{1/2}$. Our structural dynamics data and molecular templates are useful for future experimental and computational investigations of nano-patterned polymer brushes at the nanoscopic length and mesoscopic time scales.

12:15PM W42.00004 Nano-pillars created from the surface-grafted crosslinked polymer chains , SOYEUN PARK, DIPIKA PATEL, FERNANDO MONJARAZ, Texas Tech University, WOLFGANG FREY, The University of Texas at Austin, TEXAS TECH UNIVERSITY, DEPARTMENT OF PHYSICS TEAM, THE UNIVERSITY OF TEXAS AT AUSTIN, DEPARTMENT OF BIOMEDICAL ENGINEERING COLLABORATION — Nano-patterned polymer chains with the controlled mechanical properties are widely applicable to biological and chemical studies. We synthesized linear and crosslinked polymer chains grafted onto micro/nano-patterned substrates by developing a series of unique bottom-up fabrication steps based on the iniferter-driven quasi-living polymerization. We incorporated conventional photolithography and nanosphere lithography. The AFM study provides insight into the influence of the addition of the crosslinker on the configurative, kinetic, mechanical, and wetting properties of polymer chains grafted onto micro/nano-patterns. We found that the addition of crosslinker successfully converts the mushroom-like configuration of nanopatterned polymer chains into the well-standing brush like polymer chains, i.e, soft nano-pillars. By analyzing the AFM force-distance curves obtained in the two-dimensional array and lateral force images, we found that the shear moduli of the obtained soft nano-pillar can be adjusted by varying the concentration of crosslinkers.

12:27PM W42.00005 Polymer brushes: Tools for surface design[1] , CHRISTOPHER OBER, Cornell University — Polymers brushes are ideal materials for interfacing with biological systems as they share many of the same molecular components and properties. Polymer brushes provide remarkable screening power in shielding a substrate from the environment through both steric and charge interactions. However, the majority of biomolecular species will still non-specifically bind to polymer brush surfaces unless some care is given to molecular design. Several polymer brush systems are described to control interaction of biomacromolecules and cells by design of specific and non-specific interactions in polymer brush architectures. "Grown from" and block copolymer brushes are described, both of which provide excellent substrates for study of brush surfaces. Examples of polymer brushes used for sensor creation and for investigation of cellular interaction are given. Brushes used in non-fouling coatings tailored for marine applications and in which amphiphilic structures play an important role are also described.

[1]Support from both NSF and ONR is gratefully acknowledged.

1:03PM W42.00006 Preparation, Patterning, and Electrical Characterization of Conjugated Polymer Brushes , JOSE ALONZO, JIHUA CHEN, ONOME SWADER, NIKOLAY LAVRIK, MARK DADMUN, S. MICHAEL KILBEY II, DEPT. OF CHEMISTRY, UNI. OF TENNESSEE; CENTER FOR NANOPHASE MATERIALS SCIENCES, OAK RIDGE NATL LAB. COLLABORATION — Intimate contact at donor-acceptor interfaces and electrode-film interfaces is considered important for optoelectronic devices. This presentation will describe the formation and characterization of novel conjugated polymer brushes based on end-functionalized poly(3-hexylthiophene) and poly(para-phenylene) (PPP). In each case, end-functionalized polymers were synthesized and grafted to silicon substrates, with changes in film preparation method and polymer molecular weight used to manipulate the grafting density of the interfacial layers. Highly tunable PPP brushes having thickness ranging from 4 to 108 nm were obtained by in situ aromatization of poly(cyclohexadiene) brushes. Exceptionally smooth brush-modified interfaces were prepared, and neutron reflectometry, ellipsometry, AFM, and transmission electron microscopy were used to characterize layer structure and chain density. This presentation will also describe efforts to measure properties of these nanostructured layers using DC conductivity and AC electrical impedance measurements, as well as micro and nano-patterning of conjugated polymer brushes in the context of nanocircuit or organic solar cell applications.

1:15PM W42.00007 Quantifying Fluctuations/Correlations in Polymer Brushes , QIANG WANG, XINGHUA ZHANG, Department of Chemical and Biological Engineering, Colorado State University, PENGFEI ZHANG, BAOHUI LI, Institute of Physics, Nankai University — Fast lattice Monte Carlo (FLMC) simulations with multiple occupancy of lattice sites and Kronecker δ-function interactions give orders of magnitude faster/better sampling of the configurational space of multi-chain systems than conventional lattice MC simulations with self- and mutual- avoiding walks and nearest-neighbor interactions.[1] Using FLMC simulations with Wang-Landau – Transition-Matrix sampling, we have studied polymer brushes in both an implicit and explicit solvent. The various quantities obtained from simulations (including the internal energy, Helmholtz free energy, constant-volume heat capacity, segmental distribution, and chain sizes) are compared with predictions from the corresponding lattice self-consistent field theory and Gaussian fluctuation theory that are based on the same Hamiltonian as in FLMC simulations (thus without any parameter-fitting) to unambiguously and quantitatively reveal the effects of system fluctuations and correlations neglected or treated only approximately in the theories.

[1]Q. Wang, **Soft Matter, 5**, 4564 (2009).

1:27PM W42.00008 Structures of One and Two Polymer Mushrooms , DELIAN YANG, QIANG WANG, Department of Chemical and Biological Engineering, Colorado State University — A polymer mushroom here is referred to as a group of chains end- grafted at the same point on a flat and impenetrable substrate. Using lattice self-consistent field (LSCF) calculations with the Kronecker δ-function interactions (instead of the commonly used nearest-neighbor interactions), we have studied the structures of one and two polymer mushrooms in an explicit solvent as a function of the polymer volume fraction in the system, solvent quality characterized by the Flory-Huggins χ parameter, and distance between the two mushrooms. Since LSCF results are exact only in the limit of number of chains $n \to \infty$, we also use fast lattice Monte Carlo (FLMC) simulations[1] with the same Hamiltonian as in LSCF theory to examine how this limit is approached with increasing n. Direct comparisons between LSCF and FLMC results without any parameter-fitting quantify the fluctuation/correlation effects neglected in LSCF theory.

[1]Q. Wang, **Soft Matter, 5**, 4564 (2009).

1:39PM W42.00009 Tethered chains in good and poor solvent - effects of lateral confinement on adsorption and chain collapse , JUTTA LUETTMER-STRATHMANN, Departments of Physics and Chemistry, The University of Akron, RYAN M. VAN HORN, Department of Chemistry, Allegheny College — The grafting density of a polymer brush affects the response of the system to changes in solvent quality and surface interactions. In this work, we focus on low (mushroom) and intermediate (semi-dilute regime) grafting densities and model a polymer chain in a brush as a single tethered chain subject to an applied force field of cylindrical symmetry that pulls the chain segments toward an axis through the tethering point and normal to the surface. The polymer chain is represented by a bond-fluctuation model with extended range attractive bead-bead interactions and variable bead surface interactions. Monte Carlo simulations with a Wang-Landau type algorithm are performed to determine the density of states in the state space of monomer- monomer contacts, monomer-surface contacts, and lateral chain extension. We present results for the effect of lateral confinement on conformational transitions such as chain adsorption in good and poor solvent.

1:51PM W42.00010 Semiflexible Polymer Brushes , SHILIYANG XU, J.M. SCHWARZ, Physics Department, Syracuse University — Non-crossing flexible polymer brush configurations with N polymers correspond to N vicious random walkers, i.e. the system stalls when any two random walkers meet. We study a system of N vicious accelerating walkers with the velocity undergoing Gaussian fluctations, as opposed to the position, to model semiflexibility. We numerically compute the survival probability exponent, α, for this system, which characterizes the probability for any two semiflexible polymers in the brush not to cross. The data suggest that $\alpha = \frac{1}{8}N(N-1)$. We also numerically study N vicious Levy flights and find, for example, for $N = 3$ and a Levy index $\gamma = 1$ that $\alpha = 1.26 \pm 0.01$.

2:03PM W42.00011 Interfacial properties of statistical copolymer brushes , DAVID TROMBLY, VICTOR PRYAMITSYN, VENKAT GANESAN, University of Texas at Austin — The interfacial properties of statistical copolymers have important ramifications for the design of patterned thin films with preferred morphologies. In order to explore these properties, we study the interfacial properties of random copolymer brushes in contact with a thin film composed of a homopolymer of one of the blocks. We calculate the interfacial widths and interfacial energies between them as a function of different parameters. We find that the interfacial widths decrease (signifying expulsion of the free chains from the brush) with increasing free chain length, grafting density, and Flory interaction parameter χN as well as with decreasing grafted chain length. The interfacial energies show inverse trends to the interfacial widths, except that results for varying grafting density depend on how chemically similar the brush is to the film. We also compare the interfacial efficacies for different types of randomness and find that, except for the case of very blocky chains, blockiness has only little effect on the properties of the interface. We discuss our findings in terms of the design of neutral surfaces and show that our results are consistent with comparable experimental results.

Thursday, March 24, 2011 11:15AM - 2:15PM –

Session W43 DPOLY: Morphology and Transport in Charged Polymers, Block Copolymers, Membranes, and Films A306/307

11:15AM W43.00001 Characterization of a Model Polyelectrolyte Membrane Using a Semi-crystalline Block Copolymer , KEITH BEERS, XIN WANG, NITASH BALSARA, UC Berkeley — The microstructured block copolymer sulfonated polystyrene-block-polyethylene is studied as model system for use as a proton exchange membrane in a fuel cell. Self-assembly of this system creates proton conducting hydrophilic channels in the form of sulfonated polystyrene domains, while the polyethylene domains create a hydrophobic matrix to provide mechanical stability. This system serves as a powerful model system since the effects of domain size, morphology and crystallinity on water uptake and proton conductivity can be investigated. Similar systems have shown the ability of small hydrophilic channels to prevent drying at high temperatures in humid air, but have focused on amorphous hydrophobic blocks. The morphology, water uptake, and proton conductivity of this semi-crystalline model system will be discussed.

11:27AM W43.00002 Structure-Property Relationships in Sulfonated Pentablock Copolymers , JAE-HONG CHOI, Department of Materials Science and Engineering, University of Pennsylvania, CARL WILLIS, Kraton Polymers LLC, KAREN I. WINEY, Department of Materials Science and Engineering, University of Pennsylvania — Membranes of pentablock copolymers consisting of poly(*tert*-butyl styrene) (TBS), hydrogenated polyisoprene (HI), and partially sulfonated poly(styrene-*ran*-styrene sulfonate) (SS) were studied using small angle X-ray scattering (SAXS) and transmission electron microscopy (TEM). The TBS-HI-SS-HI-TBS pentablock copolymer in solution forms spherical micelles with a core of SS and a corona of solvated HI and TBS. The spherical micelles in solution compact as the solvent evaporates and some of SS cores merge to form interconnected SS microdomains without substantially changing their shape. The number of connections increases with the volume fraction of the SS block, which increases with sulfonation level. The structure does not have long-range order, because strong ionic interactions prevent extensive rearrangement. The morphologies of the sulfonated pentablock copolymers will be correlated with their transport properties.

11:39AM W43.00003 Interfacial Stability of Solid Block Copolymer Electrolytes for Rechargeable Lithium Metal Batteries , GREG STONE, SCOTT MULLIN, NITASH BALSARA, University of California at Berkeley — Solid electrolytes that can resist dendrite growth from the lithium surface and adhere to the electrode surface are needed for the development of rechargeable batteries with lithium metal anodes. We show that self-assembled block copolymer electrolytes are inherently more stable against lithium metal anodes than homogeneous homopolymers. This is due to an unusual combination of solid-like properties in the bulk to resist dendrite growth, arising from a randomly oriented granular structure, and the liquid-like properties of perpendicularly oriented lamellae that are formed at the lithium-electrolyte interface providing adhesion to the electrode.

11:51AM W43.00004 Local dielectric constant and its effects on the microphase separation in charged-neutral diblock copolymer melts , RAJEEV KUMAR, National Center for Computational Sciences, Oak Ridge National Lab, Oak Ridge, TN- 37831, SCOTT SIDES, Tech-X Corporation, Boulder, CO - 80303, BOBBY SUMPTER, Computer Science and Mathematics Division & Center for Nanophase Materials Sciences, Oak Ridge National Lab, Oak Ridge, TN- 37831 — Using block copolymers as mesoscale templates has potential applications for improved photovoltaic devices and fuel-cells. Charged species in these polyelectrolytic copolymers play a vital role in determining the details of the nanoscale morphologies formed when these systems phase segregate. We have carried out a quantitative analysis of the local dielectric constant for charged-neutral diblock copolymer melts using field-theoretic simulations based on the self-consistent field theory (SCFT). Quantitative expression for the local dielectric constant in terms of the local electric field will be presented along with its effects on the microphase separation in these systems. Using large-scale SCFT simulations, we will explore the effects of different experimental parameters on the morphology diagram. These parameters include the chain length, temperature, degree of ionization and length fraction of the charged block. Also, the effect of added salt on the disorder-order transition temperature and the domain spacings of the ordered morphologies along with the distribution of small ions (counterions and co-ions) will be presented.

12:03PM W43.00005 Magnetically aligned ion-transport polymer membranes[1] , PAWEL MAJEWSKI, MANESH GOPINADHAN, CHINEDUM OSUJI, Yale University — We present the use of magnetic fields to direct the self assembly and impose long-range order in amphiphilic block-copolymers which can be utilized as solid electrolytes for ion-transport membranes or nanomaterials synthesis templates. Our approach allows us to produce highly aligned hexagonally packed cylindrical or lamellar polymer microdomains over macroscopic areas. We systematically explore the influence of several parameters; the strength of magnetic field used for alignment, lithium ion content and temperature on the conductivity of such membranes. A surprising order of magnitude increase in conductivity is found in films aligned in the conduction direction relative to the non-aligned case. The conductivity of field aligned samples shows a non-monotonic dependence on temperature, with a distinct decrease on heating in the proximity of the order-disorder transition of the system before increasing again at elevated temperatures in homogenous melt state. The data suggest that domain-confined ion transport in hexagonally packed cylindrical systems differs greatly in anisotropy compared to lamellar systems.

[1]This work is funded by the NSF under DMR-0847534.

12:15PM W43.00006 The effect of salt-doping on the lamellar phase of AB diblock copolymers , ISSEI NAKAMURA, ZHEN-GANG WANG, Division of Chemistry and Chemical Engineering, California Institute of Technology — We study the effect of adding salts on the lamellar phase of AB diblock copolymers by means of the self-consistent field theory. We consider a model in which the A and B blocks have different dielectric constants. We include the Born energy to account for the preference of salt ions to be solvated by higher dielectric polymer. We first show that the effective χ parameter can be increased upon addition of salt, depending on the size of salt particles, with an accompanied increase in the domain spacing of the lamellar phase. The salt ions tend to be localized in the microphase where the higher dielectric components are dominant. The effect of the incompressibility on the distribution of salt ions is also studied. Moreover, we include a binding interaction between one of the blocks and one of the salt ions (e.g., cations), and study the effects of such strong binding on the distribution of the counterions (anions).

12:27PM W43.00007 Impact of morphology on conductivity of lamellar block copolymer electrolytes for battery applications , VENKAT GANESAN, University of Texas at Austin, VICTOR PRYAMITSYN, The University of Texas at Austin — We use bond fluctuation model based Monte Carlo simulations to study the correlations between structure and the conductivity of the lamella phase of block copolymer electrolytes. We investigate the effects of degree of segregation, polymer molecular weights and the alignment of the lamellae upon the conductivity of the block copolymer lamella. Our results indicate different influences of the preceding factors upon the conductivities parallel and perpendicular to the lamellae. These results are rationalized in terms of the distributions of the ions and the overall inhomogeneous dynamics of the polymer molecules.

12:39PM W43.00008 Dynamics of water in sulfonated poly(phenylene) membranes , NARESH OSTI, THUSITHA ETAMPAWALA, Clemson University, UMESH SHRESTHA, DVORA PERAHIA, Clemson University, CHRISTOPHER CORNELIUS, University of Connecticut — The dynamics of water in networks formed by highly rigid ionic polymers, sulfonated poly(phenylene) as observed by quasi elastic neutron scattering (QENS) is presented. These rigid ionic polymers have potential as effective ion exchange membranes with impact on a large number of applications from water purification to clean energy, where its rigidity distinguishes it from other ionic polymers. Its transport characteristics are affected by its rigidness as well as by direct interactions with the solvent. Our QENS studies as a function of sulfonation levels, temperature and solvent content have shown that on the time scale of the measurement, the polymers are rigid. While macroscopically all samples swell, and transport water, the water molecules appear locally rather confined. Water however remind non-frozen to subzero temperatures. The results will be discussed in view of theoretical models including continues diffusion and hopping of solvent molecules.

12:51PM W43.00009 Morphology and Transport Properties of Phosphonium-containing Styrenic Ionomers with Random Charge Placement , RICK BEYER, KRISTOFFER STOKES[1], JOSHUA ORLICKI, Army Research Laboratory, Aberdeen Proving Ground, MD, YUESHENG YE, YOSSEF ELABD, Drexel University, Philadelphia, PA — Alkaline fuel cell (AFC) technology is currently of interest for portable power supplies due in part to the use of less expensive non-noble metals (nickel, iron, cobalt) as the catalyst material. Wide-spread use of the AFC has been prevented by the use of aqueous KOH as the liquid electrolyte, easily poisoned by CO_2. Development of an semipermeable polymeric alkali anion exchange membrane (AEM) would significantly improve the usefulness of AFCs. We have synthesized a series of random copolymers of styrene and p-vinylbenzyl-trimethylphosphonium chloride, via RAFT polymerization. Detailed ^{1}H-NMR analysis of the polymerization conditions allowed us to refine our approach and generate materials with random monomer addition. ^{1}H-NMR was also used to quantify ion contents, which range from 15 mol% to 100 mol%. In this presentation, we will review the synthesis and characterization of these novel cationomers, and then report on their anion transport characteristics and morphological behavior as characterized via SAXS and TEM.

1:03PM W43.00010 Morphology of precise acid copolymers neutralized with monovalent cations , MICHELLE SEITZ, University of Pennsylvania, KATHLEEN OPPER, DuPont, KENNETH WAGENER, University of Florida, KAREN WINEY, University of Pennsylvania — Poly(ethylene-co-acrylic acid) copolymers with precisely spaced acid groups along the strictly linear chain backbone form the basis of a new family of ionomers with unprecedented molecular uniformity. These copolymers were neutralized with monovalent cations (Li, Na, and Cs) and their morphologies were studied using X-ray scattering. In order to more fully understand the ionic aggregation in these systems, both the low and high angle features are considered. At low angle a sharp ionomer peak arises from interaggregate interference and shifts with acid spacing. At high angle, the amorphous halo from the average backbone separation is observed. For materials with an acid group on every 9th carbon, additional high angle scattering is observed which may be related to either the internal aggregate structure or isolated ion pairs.

1:15PM W43.00011 Cubic Ordering of Aggregates in Precise Phosphonic Acid Copolymers , FRANCISCO BUITRAGO, University of Pennsylvania, KATHLEEN OPPER, KENNETH WAGENER, University of Florida, KAREN WINEY, University of Pennsylvania — Polyethylene-acid copolymers were synthesized by acyclic diene metathesis (ADMET) chemistry. The result is a series of strictly linear, high molecular weight polyethylenes with pendent acid groups separated by a precisely controlled number of methylene units. Previous studies have been focused on acrylic acid copolymers and ionomers. Here, we focus on phosphonic acid pendent groups in single and geminal architectures. The morphology of these materials has been studied by X-ray scattering at 25 and 150 $^\circ$C, along with transmission electron microscopy. For a geminal acid copolymer with low acid content, the precise molecular structure produces thermally persistent acid aggregates on a cubic lattice. This is the first report of cubic aggregate packing in polyethylene-acid copolymers.

1:27PM W43.00012 The Effect of Sulfonation and Neutralization on the Dynamics of Zn Neutralized Sulfonated Polystyrene Ionomers , ALICIA CASTAGNA, The Pennsylvania State University, WENQIN WANG, KAREN I. WINEY, University of Pennsylvania, JAMES RUNT, The Pennsylvania State University — The effect of sulfonation and neutralization levels on structure and dynamics of Zn neutralized sulfonated polystyrene (SPS) ionomers were investigated using scanning transmission electron microscopy (STEM), X-ray scattering, and dielectric relaxation spectroscopy. STEM and X-ray scattering revealed the presence of spherical aggregates 2 nm in diameter. Successful fitting of the scattering data to the Kinning-Thomas modified hard sphere model revealed that aggregate size is independent of degree of sulfonation and neutralization level, and that aggregate composition becomes increasingly ionic with increasing neutralization. Two segmental relaxations were identified in dielectric loss spectra corresponding to cooperative motion of chain segments in the unrestricted matrix and motions of chain segments restricted by aggregates. A Maxwell-Wagner-Sillars interfacial polarization process was revealed, with relaxation times that were in good agreement with predictions from a simple model of dispersed ionic spheres.

1:39PM W43.00013 Proton Transport in Nanostructured Block Copolymer/Ionic Liquid Membranes , MEGAN HOARFROST, University of California, Berkeley, MADHU TYAGI, NIST Center for Neutron Research, JEFFREY REIMER, RACHEL SEGALMAN, University of California, Berkeley — Nanostructured block copolymer/ionic liquid mixtures are of interest for creating membranes having high proton conductivity coupled with high thermal stability. In these mixtures, it is anticipated that nanoconfinement to block copolymer domains will affect ionic liquid proton transport properties. Using pulsed-field gradient NMR and quasi-elastic neutron scattering, this relationship has been investigated for mixtures of poly(styrene-b- 2-vinylpyridine) (S2VP) with ionic liquids composed of imidazole and bis(trifluoromethane)sulfonimide (HTFSI), where the ionic liquids selectively reside in the P2VP domains of the block copolymer. Proton mobility is highest in the neat ionic liquids when there is an excess of imidazole compared to HTFSI due to proton hopping between hydrogen-bonded imidazoles. As predicted, the amount of proton hopping can be tuned by nanoconfinement, as evidenced by the finding that a lamellar mixture of an imidazole- excess ionic liquid with S2VP has greater proton mobility than a corresponding disordered mixture of the ionic liquid with P2VP homopolymer.

1:51PM W43.00014 Simultaneous Electronic and Ionic Charge Transport in Poly(3-hexylthiophene)-b-Poly(ethylene oxide) , SHRAYESH PATEL, University California, Berkeley and Lawerence Berkeley National Lab, ANNA JAVIER, Lawerence Berkeley National Lab, NITASH BALSARA, University California, Berkeley and Lawerence Berkeley National Lab — Block copolymers can self-assemble to distinct channels, which allows for simultaneous transport of electronic and ionic charge carriers. A potential polymer system is Poly(3-hexylthiophene)-b-Poly(ethylene oxide) (P3HT-b-PEO). P3HT serves as the electronic conducting channel while the PEO serves as the ionic conducting channel. Both conductive blocks are doped to induce simultaneous electronic and ionic conduction. The PEO phase is doped with LiTFSI while the P3HT is doped with F_4TCNQ, which generates hole carriers. In addition, we take into account the case where no electronic dopant is added to P3HT phase. The charge transport properties of the material are analyzed via ac impedance spectroscopy and dc polarization techniques. These experiments provide decoupled electronic and ionic transport in P3HT-b-PEO.

2:03PM W43.00015 Confinement Effects on Watery Domains in Hydrated Block Copolymer Electrolyte Membranes , MOON JEONG PARK, Department of Chemistry, Pohang University of Science and Technology, SUNG YEON KIM, JOOMI YEO — The morphology of a series of diblock copolymers comprising randomly sulfonated polystyrene (PSS) and polymethylbutylene (PMB) blocks equilibrated with humid air was determined by in- situ small angle neutron scattering (SANS). In-situ SANS data were collected over a wide angular range permitting the determination of the superstructure of the hydrophilic PSS-rich and hydrophobic PMB-rich domains and the substructure within the hydrophilic PSS-rich domains. When the characteristic length of the superstructure is larger than 10 nm, the hydrophilic PSS domains are heterogeneous with periodically arranged watery domains. The scattering signature of the watery domains is very similar to the well-established "ionomer peak." This peak vanishes when the neutron scattering length density of the water (H2O/D2O mixture) is matched to that of the PSS block. The spacing between watery domains depends only on sulfonation level of the PSS block. When the characteristic length of the superstructure is less than 10 nm, the watery substructure disappears and homogeneous hydrated PSS-rich domains are obtained.

Session W44 DPOLY: Focus Session: Dynamics of Polymers-Phenomena due to Confinement - Diffusion, Particles, & Pores A309

11:15AM W44.00001 Single-molecule measurements of adsorbed polymer , CHANGQIAN YU, JUAN GUAN, SUNG CHUL BAE, STEVE GRANICK, Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign — Single-molecule tracking is used to study the surface mobility of PEG (polyethylene glycol) chains adsorbed to the solid-liquid interface from dilute aqueous solution. The end-labeled chains are visualized by objective-based total internal reflection fluorescence microscopy (TIRFM) and their trajectories are analyzed after cleaning the images with denoising algorithms. Surface mobility, which in this system depends on pH, is decomposed into one family of chains which remains adsorbed over the observation time window, and another family that appears to translate from point to point by hopping. This we quantify with nm-level resolution.

11:27AM W44.00002 Segmental motion in polystyrene thin film: a single molecule fluorescence study[1] , ZHONGLI ZHENG, JIANG ZHAO, Institute of Chemistry, Chinese Academy of Sciences — Single molecule fluorescence de-focus microscopy is used to study the segmental motion by observing the rotational motion of single fluorophores chemically attached to polystyrene chain ends. The collective nature of the rotational motion was noticed: a sudden change of the fraction of rotating fluorophores was discovered at a temperature 60 degree below the glass transition temperature of polystyrene. The dependence of the critical temperature on film thickness and surface chemistry was investigated and the results show that the effect of confinement, surface interaction and free surface.

[1]Project supported by National Natural Science Foundation of China (NSFC).

11:39AM W44.00003 Order of Magnitude Decrease in Dye Diffusion in Nanoconfined Polymer Films: Fluorescence Nonradiative Energy Transfer Technique , HUI DENG, MANISH MUNDRA, JOHN TORKELSON, Northwestern University — A fluorescence nonradiative energy transfer/multilayer film technique was used to determine the diffusion coefficient of the dyes decacyclene and Disperse Red 1 in supported polystyrene (PS) films as a function of film thickness. Previous studies on the glass transition temperature (Tg) of PS show a decrease in Tg as films are nanoconfined. This Tg-reduction is due to the enhanced role of the polymer/air interface which results in a region of increased polymer mobility as thickness is reduced. However, dye diffusion coefficients decrease upon film nanoconfinement, with the onset of diffusion coefficient reduction appearing at film thicknesses much thicker than the onset of Tg-confinement effects. These results can be explained by the fact that Tg reflects the longer time side of the polymer relaxation time distribution while dye diffusion reflects the shorter time side of the relaxation distribution. We hypothesize that confinement suppresses the shorter time side of the relaxation distribution which results in the observed decrease in diffusion coefficients.

11:51AM W44.00004 Non-classical diffusion of PDMS confined in a surface forces apparatus , SUBHALAKSHMI KUMAR, CHANGQIAN YU, University of Illinois, Urbana-Champaign, SUNG CHUL BAE, STEVE GRANICK, University of Illinois, Urbana Champaign — We present FRAP measurements inside a surface forces apparatus. Polydimethylsiloxane (PDMS), well above its glass transition, was confined into molecularly-thin films between atomically smooth mica sheets. Translational diffusion was measured using fluorescence recovery after photobleaching (FRAP) as the polymer film thickness was changed from tens of Rg to 3 Rg . The FRAP recovery curves of confined films are distinctly non-classical. Huge heterogeneity is suggested by stretched exponential behavior in which the power of time varies smoothly from β=1 (thick films) to β=0.3 (confined films) with a sharp transition between these limits.

12:03PM W44.00005 Probing In-Plane Diffusion of Nano-Confined Polymers in Ultrathin Films , JOSHUA KATZENSTEIN, University of Texas at Austin - Department of Chemical Engineering, JUSTIN CHANDLER, University of Texas at Austin, HALEY HOCKER, CHRISTOPHER ELLISON, University of Texas at Austin - Department of Chemical Engineering — In-plane (parallel to the substrate) polymer diffusion at and near interfaces has significant implications for polymeric surfactants used in tertiary oil recovery, exfoliation of clay sheets in polymer nano-composites, and several other high technology applications. Here, we report a study on the in-plane diffusion of whole polymer chains confined between interfaces using fluorescence recovery after photobleaching. Adapted from quantitative biology, FRAP provides a platform to independently study the effect of temperature, molecular weight, and film thickness on in-plane diffusion of polymers confined between interfaces. Fluorescently labeled polymers were synthesized, spin coated onto quartz substrates and the self-diffusion coefficient was measured by irreversibly photobleaching fluorophores in a pre-defined pattern and monitoring recovery of fluorescence over time. Preliminary results indicate that for thick films the diffusion coefficient is consistent with bulk values.

12:15PM W44.00006 Screening Effect of Supercritical Carbon Dioxide on Polymer/Substrate Interactions[1] , PETER GIN, NAISHENG JIANG, MAYA ENDOH, Materials Science and Engineering, Stony Brook University, BULENT AKGUN, SUSHIL SATIJA, NCNR, NIST, TAD KOGA, Materials Science and Engineering, Stony Brook University — The kinetics and thermodynamic properties of polymer melts near interfaces and in confined geometries can vary significantly from their bulk counterparts. This behavior can be attributed to the presence of an immobile layer at the polymer/substrate interface, which has been reported to hinder the mobility of polymer chains in thin films even at a large length scale. Here, we investigate the use of supercritical carbon dioxide ($scCO_2$) as a medium to screen the polymer/substrate interactions and enhance chain mobility in polymer thin films. In-situ neutron reflectivity was utilized to measure the interdiffusion of deuterated polystyrene (d-PS) into various matrices of hydrogenated PS (h-PS) with thicknesses ranging from 0.5 Rg to 5 Rg. We found that at the unique T (36°C) and P (8.2 MPa) conditions, where the anomalous adsorption of CO_2 molecules in polymer thin films occurs, the diffusion constants remained unchanged regardless of bottom layer thickness, while no diffusion occurred below 1Rg at high temperature (170°C).

12:27PM W44.00007 The Glass Transition at Silica/PMMA Nanocomposite Interfaces[1] , RAHMI OZISIK, KATELYN PARKER, RYAN T. SCHNEIDER, RICHARD W. SIEGEL, Rensselaer Polytechnic Institute, JUAN CARLOS CABANELAS, BERNA SERRANO, CLAIRE ANTONELLI, JUAN BASELGA, Universidad Carlos III de Madrid — Local glass transition temperatures (Tg) have been measured in the interfaces of solution blended silica/poly(methyl methacrylate) (PMMA) nanocomposites using florescence spectroscopy and compared with Tg measured by differential scanning calorimetry (DSC). It was found that the two types of measurements yielded significantly different information. Combinations of silanes and poly(propylene glycol)- based molecular spacers bound to fluorophores were covalently linked to the surface of the nanoparticles, allowing for variation of the fluorophore response with respect to the distance from the nanofiller surface. Increases in the bulk Tg from the neat PMMA value were found upon the addition of nanofillers, but were independent of the nanofiller concentration when the filler concentration was above 2% by weight. Furthermore, as the size of the grafted molecular spacer was increased, Tg values were found to decrease and approach Tg of the neat PMMA. Owing to variable conformations of the spacers, an effective distribution of fluorophore-silica distances exists, which influences the fluorophores' response to the transition.

12:39PM W44.00008 Structural Relaxation of 3-Dimensionally Confined Polymer Glasses: Isobaric versus Isochoric Glass Formation , YUNLONG GUO, CHUAN ZHANG, RODNEY PRIESTLEY, Department of Chemical and Biological Engineering, Princeton University — We have measured the glassy-state structural relaxation of aqueous suspended polystyrene (PS) nanoparticles and the corresponding silica-capped PS nanoparticles via modulated differential scanning calorimetry. Suspended and capped-PS nanoparticles undergo glass formation and subsequent physical aging under isobaric and isochoric conditions, respectively. To account for glass transition temperature (Tg) changes with confinement, physical aging measurements were performed at a constant value of Tg minus Ta, where Ta is the aging temperature. With deceasing diameter, aqueous suspended PS nanoparticles exhibited enhanced physical aging rates in comparison to bulk PS. At all values of Tg minus Ta investigated, capped-PS nanoparticles aged at reduced rates compared to the corresponding aqueous suspended PS nanoparticles. Due to differences in paths to glass formation, suspended and capped-PS nanoparticles aged to different apparent equilibrium states. We captured the physical aging behavior of all nanoparticles via the Tool, Narayanaswamy, and Moynihan (TNM) model of structural relaxation.

12:51PM W44.00009 Molecular Dynamics Study of Single Conjugated Polymers Confined to Nanoparticles , SABINA MASKEY, FLINT PIERCE, DVORA PERAHIA, Clemson University, GARY GREST, Sandia National Lab — Optically active polymers confined into nanoparticles are highly fluorescent and have potential applications in intracellular fluorescence imaging, bio-sensors and other optoelectronic devices. Internal conformation and dynamics of the polymers determines their optical properties. Using molecular dynamics (MD) simulations, we have explored the structure and dynamics of nanoparticles formed by conjugated polymers in a collapsed conformation, which is not the most stable conformation of the polymer. Nanoparticles were formed in a collapsed conformation and followed as the function of time in both poor and good solvents. We found that these nanoparticles are stable and remain collapsed in a poor solvent but rapidly expands and unraveled in a good solvent. The lengths of the side chains affect the internal packing of the side chains which in turn affect the size of the nanoparticles. S(q,t) was measured to characterize the internal dynamics of the collapsed nanoparticles.

1:03PM W44.00010 The Glass Transition Temperature of Polymer Nanoparticles under Soft and Hard Confinement , CHUAN ZHANG, YUNLONG GUO, RODNEY PRIESTLEY, Department of Chemical and Biological Engineering, Princeton University — When confined to the nanoscale, the glass transition temperature (Tg) of polymers can deviate substantially from the bulk, i.e., the Tg-confinement effect. Due to ease of processing, most studies have focused on the size-dependent Tg of thin films, while few have extended investigations to other geometries. As polymers confined in higher geometrical dimensions become the enabling material in technologies ranging from drug delivery to plastic electronics, a greater understanding of size effects on Tg is warranted. Here, we investigate the effect of soft and hard three-dimensional confinement on the Tg of polymer nanoparticles. Via modulated differential scanning calorimetry, we show that Tg decreases with size for bare polymer nanoparticles, i.e., the case of soft confinement while Tg is invariant with size for silica-capped polymer nanoparticles, i.e., the case of hard confinement. These results suggest that the free surface is a key factor in Tg reductions of three-dimensionally confined polymer.

1:15PM W44.00011 Statics and dynamics of confined DNA in a nanopit array , ALEXANDER KLOTZ, WALTER REISNER, McGill University, NANOBIOPHYSICS GROUP TEAM — Polymers have been proposed as tools for self-assembly in nanotechnology. There is interest in controlling the movement and conformation of the polymers by modifying the free energy landscape of their environment. It is necessary to understand the free energy and equilibrium behavior of a polymer in a nanoscale environment in order to control its dynamics. In these experiments, DNA molecules are placed in slits on the order of 100 nanometers. The slits are embedded with a lattice of square pits that act as entropic traps for which it is energetically favorable for the DNA to occupy. Based on the geometric properties of the lattice, the molecule in equilibrium will occupy a discrete number of pits. The dynamics of the system can be understood in terms the number of occupied pits. A partition function based on these states can be used to make testable predictions. Measurement of the static conformations of DNA in these pits, as well as the diffusion of the molecule throughout the lattice, as a function of geometric parameters can be used to test models of polymer free energy. Measurements show that the mean occupancy state scales as expected with various pit parameters. Early diffusion results indicate that the diffusion of DNA can be fine tuned by modifying the topography.

1:27PM W44.00012 Modeling of Free Radical Polymerization of Methyl Methacrylate (MMA) in Nanoporous Confinement , FATEMA BEGUM, SINDEE SIMON — Nanoconfinement of methyl methacrylate free radical polymerization is known to impact the molecular weight and molecular weight distribution of the polymer produced, and the results in the literature generally indicate an increase in molecular weight and a concommitant decrease in polydispersity index. In the present work, the mathematical model described by Verros et al. (2005) for free radical bulk polymerization of methyl methacrylate is extended to account for polymerization in nanopores. The model of Verros et al. (2005) incorporates diffusion effects and is capable of describing the conversion and the number- and weight-average molecular weights of the resulting poly(methyl methacrylate) as a function of polymerization time and process conditions. The model is extended by incorporating the effect of nanoconfinement on diffusivity using the scaling reported in the literature. The results indicate that nanoconfinement will lead to higher molecular weights, lower polydispersity, and the gel effect occurs earlier. The results are compared to experimental work and implications discussed.

1:39PM W44.00013 Effect of Nanopore Confinement on the Polymerization Rate of Linear Polymers , PO-HAN LIN, RAJESH KHARE, Texas Tech University — Confinement to a nanopore has a significant impact on the thermal properties as well as the rate of chemical reactions such as polymerization as compared to these processes in the bulk. In this work, we have studied the effect of nanopore confinement on the rate of free radical polymerization by using molecular simulations. In order to capture the physics of this process, we have implemented a coarse-grained model to carry out reactive molecular dynamics simulations. Our simulation method considers the three stages of polymerization process: initiation, propagation and termination. Our simulation results will be used to compare the polymerization rate in the confinement with that in the bulk. The results will be explained by focusing on the dynamics of the reacting species in the confinement.

1:51PM W44.00014 Theoretical Study of Tethered Polymers inside a Cylindrical Tube , TONGCHUAN SUO, MARK WHITMORE, Department of Physics and Astronomy, University of Manitoba, Winnipeg, Manitoba R3T 2N2, Canada — We present a numerical self-consistent mean-field theoretical (SCMFT) study of polymer chains tethered to the inside walls of cylindrical tubes. We consider cases ranging from relatively thin to relatively thick tubes, from low to high tethering densities, and in various solvents. Our focus is on the polymer concentration profiles and the chain end distributions, in particular the concentrations and chain overlap at the tube centers. We show that these quantities depend primarily on only two parameters, and that this dependence becomes exact in the limit of low polymer concentration. We find that there can be significant polymer interpenetration at the tube centers even in cases where the tube radius is greater than the polymer R_{g}, and this can be tuned by changing the solvent quality and/or tethering density.

Thursday, March 24, 2011 11:15AM - 2:15PM –

Session W45 DAMOP: Atom-Light Interactions: Experiment and Theory A310

11:15AM W45.00001 Lattice-induced nonadiabatic frequency shifts in optical lattice clocks , KYLE BELOY, New Zealand Institute for Advanced Study, Massey Univ. — We consider the frequency shift in optical lattice clocks which arises from the coupling of the electronic motion to the atomic motion within the lattice. For the simplest of three-dimensional lattice geometries this coupling is shown to affect only clocks based on blue-detuned lattices. We have estimated the size of this shift for the prospective strontium lattice clock operating at the 390-nm blue-detuned magic wavelength. The resulting fractional frequency shift is found to be on the order of 10^{-18} and is largely overshadowed by the electric quadrupole shift. For lattice clocks based on more complex geometries or other atomic systems, this shift could potentially be a limiting factor in clock accuracy.

11:27AM W45.00002 Magic wavelengths for optically trapped atoms , BINDIYA ARORA, IISER Mohali, India, MARIANNA SAFRONOVA, University of Delaware, CHARLES CLARK, JQI, NIST and the University of Maryland — The ability to trap neutral atoms inside high-Q cavities in the strong coupling regime is of particular importance for quantum computation and communication schemes, where it is essential to precisely localize and control neutral atoms with minimum decoherence. In a far-detuned optical dipole trap, the potentials experienced by an atom in its ground and excited states may be of opposite sign affecting the fidelity of experiments in which excited states are temporarily occupied. "Magic wavelengths" are those for which such potentials are equal. Single-laser schemes offer few cases in which magic wavelengths exist for Rb [Arora et al. PRA 76, 052509 (2007).] Here we explore bichromatic schemes for state-insensitive optical trapping of the Rb. We describe the use of trapping and control lasers to minimize the variance of the potential experienced by a trapped Rb atom in ground and excited states. We have also identified wavelengths $\lambda_{\rm zero}$ where the ground state frequency-dependent polarizabilities in alkali-metal atoms are zero. These are relevant for cooling and trapping experiments involving mixtures such as Rb/Yb, where the vanishing lattice potential for Rb facilitates interesting applications.

11:39AM W45.00003 Laser frequency stabilization for narrow linewidth cooling of ^{6}Li atoms[1] , ADAM REED, The Ohio State University, Department of Physics, KEVIN JOURDE, ESPCI ParisTech, PEDRO DUARTE, RANDALL HULET, Rice University, Department of Physics and Astronomy — Laser cooling to micro-Kelvin temperatures requires a laser with active frequency stabilization. The linewidth Γ of an atomic transition sets a lower bound on the Doppler cooling temperature $k_B T_D = \hbar\Gamma/2$. The $2s-2p$ transition in ^{6}Li has a lower bound temperature of $T_D \approx 140\,\mu$K. In contrast, the $2s-3p$ transition has a narrower linewidth and thus provides a lower temperature limit of $T_D \approx 20\,\mu$K. We present a method for stabilizing a laser to an atomic line in a vapor cell using modulation transfer spectroscopy and a home-built lock-in amplifier. Our results demonstrate successful locking of a 323 nm laser to the $2s-3p$ transition. The stabilized laser provides a second stage of magneto-optical trapping that results in an order of magnitude increase in the phase space density before evaporating to degeneracy in an optical dipole trap.

[1]This work was supported under ARO Award W911NF-07-1-0464 with funds from the DARPA OLE program, and by the NSF, the ONR, the Welch Foundation (grant C-1133) and the Keck Foundation.

11:51AM W45.00004 Demonstration of a ^{6}Li magneto-optical trap using the $2S_{1/2} \rightarrow 3P_{3/2}$ transition , R. HART, P.M. DUARTE, T.L. YANG, J.M. HITCHCOCK, T.A. CORCOVILOS, R.G. HULET, Department of Physics and Astronomy and Rice Quantum Institute, Rice University — We demonstrate narrow linewidth laser cooling on the $2S_{1/2} \rightarrow 3P_{3/2}$ transition of ^{6}Li at 323 nm. Typically, magneto-optical traps (MOTs) of alkali atoms cool on the D2 transition. The linewidth of this transition determines the Doppler limit of cooling which in the case of ^{6}Li is 140 μK, given a 5.9 MHz transition linewidth. Due to a lack of resolved hyperfine structure that prohibits polarization gradient cooling, typical Li MOTs reach minimum temperatures near 300 μK. Cooling on the $2S_{1/2} \rightarrow 3P_{3/2}$ transition, however, allows for a Doppler limit of 20 μK since the transition linewidth is only 790 kHz. We have implemented this cooling scheme and demonstrate ^{6}Li MOT temperatures of 65 μK. With the increased phase space density from this MOT, initial loading of the gas to an optical trap is substantially enhanced. We present our results on the characteristics of the narrow linewidth MOT and our results on the benefits of using this cooling scheme in the preparation of a degenerate gas of fermions.
