3:54PM D28.00006 Low Temperature Graphene Growth by Down-Stream Chemical Vapor Deposition[1] , LOLA BROWN, MARK LEVENDORF, CHAD HUNTER, JIWOONG PARK, Cornell University — Integration of high quality graphene directly onto the surface of metal provides a novel way of controlling the functionality of metal surfaces. This can be used to control the chemical and physical surface interactions and enhance energy transfer through the surfaces, thus allowing for new sensors, flexible electronic devices and better electrodes for organic photovoltaics. However, the implementation of a pristine graphene layer in patterned devices is currently limited, due to the high temperature growth ($\sim$1000 C) and contamination of the graphene surfaces during transfer. This work presents graphene grown at low temperatures (below 750 C) using down-stream chemical vapor deposition (DS-CVD), where a metallic growth substrate is positioned down-stream from the CVD furnace "hot zone". High quality graphene is produced using long growth times ($\sim$ 60 minutes) and low gas flow rates. We study graphene quality and grain structure using Raman spectroscopy and dark-field transmission electron microscopy (DF-TEM). We demonstrate the strength of this technique by growing graphene on thin and micro patterned copper films, and three dimensional structures.

4:06PM D28.00007 Evolution of graphene islands growing on Cu foils[1] , JOSEPH WOFFORD, University of California at Berkeley and Lawrence Berkeley National Laboratory, SHU NIE, NORMAN BARTELT, KEVIN MCCARTY, Sandia National Laboratories, OSCAR DUBON, University of California at Berkeley and Lawrence Berkeley National Laboratory — Using low-energy electron microscopy we investigate, in real time, the growth of graphene monolayers on Cu foils. Graphene islands evolve from an initially compact form into an increasingly ramified, four-lobed shape, reflecting the symmetry of the (100)-textured Cu surface. Diffraction analysis reveals that each lobe is an individual graphene domain, differentiated by a rotation about the film normal, making the islands polycrystalline. An inspection of the morphological evolution of the graphene lobes shows the growth fronts posses an angularly dependent velocity, which is consistent with a growth mode dominated by edge kinetics. The fast growth direction of each lobe tends to align with the <001> in-plane directions of the Cu surface but not with a high symmetry direction of the graphene lattice. Finally, the implications of this unexpected growth mechanism on the formation of high-quality graphene films on Cu foils are evaluated.

4:18PM D28.00008 Characterization of Graphene Films Grown on Cu-Ni Foil by XPS[1]

, P. TYAGI, R.L. MOORE, Z.R. ROBINSON, C.A. VENTRICE, JR., Univ. at Albany, D.D. MOODY, W. PRIYANTHA, R. DROOPAD, Texas State Univ., C. MAGNUSON, D. MUNSON, S. CHEN, R.S. RUOFF, Univ. of Texas — Monolayer graphene films can be grown on Cu substrates by the catalytic decomposition of methane molecules. The solubility of carbon in Cu is negligible at the growth temperatures typically used for graphene growth, which results in the formation of films that self-terminate at a monolayer. In an attempt to enhance the catalytic activity of the surface, use of Cu-Ni alloy foils has been investigated. Growth is performed in a CVD system at a temperature of 1000 $^\circ$C with pure CH_4. To determine the graphene coverage and the surface alloy composition during the different phases of growth, XPS measurements have been performed on the Cu-Ni foils before anneal, after anneal in H_2, and after growth of graphene. Analysis of the C-1s core emission for graphene/Cu is used as reference for monolayer growth. Before anneal, the measurements indicate that the surface is Ni-rich and heavily oxidized. After annealing in H_2, only a small amount of oxide remained and the Cu:Ni alloy fraction was similar to the bulk. After growth of the graphene overlayers, only trace amounts of oxygen are present, indicating uniform graphene growth.

4:30PM D28.00009 Effects of heat-treatment and hydrogen adsorption on Graphene grown on Cu foil

, JONGWEON CHO, LI GAO, Center for Nanoscale Materials, Argonne National Laboratory, JIFA TIAN, HELIN CAO, Department of Physics, Purdue University, QINGKAI YU, Center for Advanced Materials, University of Houston, JEFFREY GUEST, Center for Nanoscale Materials, Argonne National Laboratory, YONG CHEN, Department of Physics, Purdue University, NATHAN GUISINGER, Center for Nanoscale Materials, Argonne National Laboratory — Graphene has recently been a subject of intense research efforts due to its remarkable physical properties as an ideal two-dimensional material. While numerous different methods for graphene synthesis are being explored, CVD-grown graphene on Cu foil presents the possibility of a large-scale and high-quality synthesis of graphene. [1] To improve the quality of graphene films on Cu foil prepared by CVD and better understand its microscopic growth, atomic-scale characterization becomes of great importance. We have investigated the effects of thermal annealing and hydrogen adsorption/desorption on *ex-situ* CVD-grown monolayer graphene on polycrystalline Cu foil at the atomic-scale using ultrahigh vacuum scanning tunneling microscopy, and we will report on these studies.

[1] Li et al, Science **324**, 1312 (2009).

4:42PM D28.00010 Imaging Grains and Grain Boundaries in Single-Layer CVD Graphene

, P.Y. HUANG, A.M. VAN DER ZANDE, C.S. RUIZ-VARGAS, W.S. WHITNEY, M.P. LEVENDORF, Y. ZHU, J. PARK, P.L. MCEUEN, D.A. MULLER, Cornell University — Single-layer graphene can be produced by chemical vapor deposition (CVD) on copper substrates on up to meter scales [1, 2], making their polycrystallinity [3,4] almost unavoidable. By combining aberration-corrected scanning transmission electron microscopy and dark-field transmission electron microscopy, we image graphene grains and grain boundaries across five orders of magnitude. Atomic-resolution images of graphene grain boundaries reveal that different grains stitch together predominantly via pentagon-heptagon pairs. We use diffraction-filtered imaging to map the shape and orientation of several hundred grains and boundaries. These images reveal an intricate patchwork of grains with structural details depending strongly on growth conditions. These imaging techniques will enable studies on the structure, properties, and control of graphene grains and grain boundaries.

4:54PM D28.00011 Analysis of Substrate Grain Size and Orientation on the Growth of Graphene Films[1]

, Z.R. ROBINSON, P. TYAGI, T.M. MURRAY, C.A. VENTRICE, JR., CNSE, Univ. at Albany, C. MAGNUSON, D. MUNSON, S. CHEN, R.S. RUOFF, Dept. of Mech. Engr., Univ. of Texas — Graphene growth on Cu foils by catalytic decomposition of methane forms predominately single layer graphene films due to the low solubility of C in Cu. One of the key issues for the use of CVD graphene in device applications is the influence of defects on the transport properties of the graphene. For instance, growth on foil substrates is expected to result in multi-domain graphene growth because of the presence of randomly oriented grains within the foil. Therefore, the size and orientation of the grains within the metal foil should strongly influence the defect density of the graphene. To study this effect, we have initiated a study of the influence of pre-growth anneal time and H_2 pressure on the grain size and structure of Cu and Cu-Ni foil substrates. Preliminary measurements of the grain size have been performed with SEM and AFM. These results show a typical lateral dimension of $\sim$100 μm for an anneal time of 30 min in 40 mTorr of H_2 at 1000 $^\circ$C. Measurements are currently being performed with electron backscatter diffraction to determine the crystallographic orientation within each grain.

[1]Support from the NSF (1006350 and 1006411) is appreciated.

5:06PM D28.00012 Alloy substrates: towards precise control of thickness and quality of multilayer graphene growth

, SHANSHAN CHEN, Univ. of Texas at Austin, WEIWEI CAI, Xiamen University, RICHARD D. PINER, Univ. of Texas at Austin, XUESONG LI, IBM, YANWU ZHU, RODNEY S. RUOFF, Univ. of Texas at Austin — Graphene has gained a lot of attention due to its remarkable properties, such as high electron hole mobility, high current carrying capability and high mechanical robustness. It has been further demonstrated that the properties of graphene materials depend on the number of graphene layers present. As a result, it is highly desirable to develop reliable synthesis techniques to synthesize few- or multi-layered high quality large area graphene materials. Here we report a facile method to grow few-layer graphene films using an alloy substrate by chemical vapor deposition. The thickness and quality of the graphene and graphite films can be controlled using CVD with methane and hydrogen gas as precursors, by varying the deposition temperature and cooling rate. The optical and electrical properties of the graphene/graphite films were studied as a function of their thickness.

5:18PM D28.00013 Improving Polycrystalline Copper Surface by Hydrogen Etching for Graphene Growth[1]

, MERVE ARSEVEN, Advanced Materials Research Group, Nanotechnology and Nanomedicine Department, TAYFUN VURAL, Biopolymeric Systems Research Group, Chemistry Department, ENGIN OZDAS, Advanced Materials Research Group, Physics Department, Hacettepe University, Turkey — Growth of high quality, large scale pattern of graphene is the main important phenomenon to use this material in novel technological applications. CVD methods can provide an effective way to produce graphene, however, require a rigid stable substrate at high temperature processes [1]. Besides, the substrate that can be used in these processes must have low solubility of carbon to obtain mono or few layers of graphene, and be able to provide bigger grains for a large-scale growth [2]. Polycrystalline copper foil is an appropriate candidate to achieve these attributions in case of reducing the pinhole and defect density, and increase the grain size. In this study, we investigate the effect of hydrogen partial pressure, heating rate, annealing temperature and duration on the etching process to optimize the surface. Surface roughness analyses are performed by AFM, and grain size distributions are determined by the analyses of optical microscope images. Session D29 GQI: Quantum Computing and Simulation I C148

2:30PM D29.00001 Scalable Quantum Computing Over the Rainbow , OLIVIER PFISTER, University of Virginia, NICOLAS C. MENICUCCI, Perimeter Institute, Waterloo, Canada, STEVEN T. FLAMMIA, IQI, Caltech — The physical implementation of nontrivial quantum computing is an experimental challenge due to decoherence and the need for scalability. Recently we proved a novel theoretical scheme for realizing a scalable quantum register of very large size, entangled in a cluster state, in the optical frequency comb (OFC) defined by the eigenmodes of a single optical parametric oscillator (OPO). The classical OFC is well known as implemented by the femtosecond, carrier-envelope-phase- and mode-locked lasers which have redefined frequency metrology in recent years. The quantum OFC is a set of harmonic oscillators, or Qmodes, whose amplitude and phase quadratures are continuous variables, the manipulation of which is a mature field for one or two Qmodes. We have shown that the nonlinear optical medium of a single OPO can be engineered, in a sophisticated but already demonstrated manner, so as to entangle in constant time the OPO's OFC into a finitely squeezed, Gaussian cluster state suitable for universal quantum computing over continuous variables. Here we summarize our theoretical result and survey the ongoing experimental efforts in this direction.

2:42PM D29.00002 Implementing quantum gates through scattering between a static and a flying qubit , GUILLERMO CORDOURIER-MARURI, Cinvestav, Department of Applied Physics, Cordemex 97310, Merida, Mexico, FRANCESCO CICCARELLO, Universit'a degli Studi di Palermo, CNISM, I-90128 Palermo, Italy, YASSER OMAR, Universidade Tecnica de Lisboa, P-1200-781 Lisbon, Portugal, MICHELANGELO Z, Universit'a degli Studi di Palermo, Palermo, Italy, ROMEO DE COSS, Cinvestav, Department of Applied Physics, Cordemex 97310, Mérida, Mexico, SOUGATO BOSE, UCL, Department of Physics and Astronomy, London WC1E 6BT, UK — We investigate whether a two-qubit quantum gate can be implemented in a scattering process involving a flying and a static qubit. We focus on a paradigmatic setup made out of a mobile particle and a quantum impurity, whose respective spin degrees of freedom couple to each other during a one-dimensional scattering process. A condition for the occurrence of quantum gates is derived in terms of spin-dependent transmission coefficients. This can be fulfilled through the insertion of an additional narrow potential barrier. Under resonance conditions this procedure enables a gate only for Heisenberg interactions and fails for an XY interaction. We show the existence of parameter regimes for which gates able to establish a maximum amount of entanglement can be implemented. The gates are found to be robust to variations of the optimal parameters.

2:54PM D29.00003 The 2D AKLT state is a universal quantum computational resource , TZU-CHIEH WEI, University of British Columbia, IAN AFFLECK, ROBERT RAUSSENDORF, University of British Columbia — We demonstrate that the two-dimensional AKLT state on a honeycomb lattice is a universal resource for measurement-based quantum computation. Our argument proceeds by reduction of the AKLT state to a 2D cluster state, which is already known to be universal, and consists of two steps. First, we devise a local POVM by which the AKLT state is mapped to a random 2D graph state. Second, we show by Monte Carlo simulations that the connectivity properties of these random graphs are governed by percolation, and that typical graphs are in the connected phase. The corresponding graph states can then be transformed to 2D cluster states.

3:06PM D29.00004 Robust benchmarking of quantum processes , EASWAR MAGESAN, JAY GAMBETTA, JOSEPH EMERSON, Institute for Quantum Computing, University of Waterloo — Fault-tolerant threshold theorems show that as long as the noise affecting a quantum system is below some threshold, reliable quantum computation can take place. As a result, methods for noise characterization are of great interest in quantum information theory. Unfortunately, methods for complete noise characterization scale exponentially in the number of qubits comprising the system. This non-scalability highlights the importance of developing mathematical methods for scalable partial characterization of the noise affecting a quantum system. We discuss a randomized benchmarking protocol that provides fitting models for the fidelity decay of the noisy gates used in quantum information processing. We show that when the average variation of the noise is not too large the first order model gives a robust estimate of both the average error affecting the gate set and the gate-dependence of the noise. We also show that the protocol is scalable in the number of qubits comprising the system. The protocol allows the noise to be both time and gate-dependent, and takes into account state preparation and measurement errors.

3:18PM D29.00005 Universal Quantum Computation within the Bose-Hubbard Model[1] , MICHAEL S. UNDERWOOD, DAVID L. FEDER, Institute for Quantum Information Science at the University of Calgary — We present a novel scheme for universal quantum computation based on spinless bosons hopping on a two-dimensional lattice with on-site interactions. Our setup is comprised of a $2 \times n$ lattice for an n-qubit system; the two rows correspond to the computational basis states, and a boson in each column encodes a qubit. The system is initialized with n bosons occupying the n sites of the $|0\rangle$ row, and the lattice deep enough to prevent tunneling. Arbitrary single-qubit X rotations are implemented by tuning the tunneling strength between the $|0\rangle$ and $|1\rangle$ sites of the appropriate column, and Z rotations by applying a local potential to the $|1\rangle$ site. Entanglement is generated by hopping between the $|1\rangle$ sites of adjacent qubits; by tuning the on-site interaction strength of the bosons, a non-trivial controlled phase is acquired if these two qubits are in the state $|11\rangle$. Because the quantum information is encoded entirely in the lattice positions of the bosons, the encoded qubits are inherently robust against decoherence. An implementation in terms of ultracold atoms in optical lattices is suggested.

3:30PM D29.00006 Optimal Trajectories for Quantum Adiabatic Factoring , JORDAN KYRIAKIDIS, ROBERT ARCHIBALD, Dalhousie Univeristy, WILLIAM MACREADY, D-Wave Systems, Inc. — We show how a classical multiplication circuit can be expressed as an optimization problem. The circuit can then be effectively run backwards by fixing the output states in the optimization problem and determining the corresponding input states, thereby factoring the output state. This can in turn be expressed as a problem in adiabatic quantum computing. We show by solving a coupled set of Euler-Lagrange equations how (locally) optimal trajectories from initial to final Hamiltonians can be found whose efficacy vastly exceeds that of the usual linear scaling trajectory. Explicit examples will be given for factoring 6-bit integers.

3:42PM D29.00007 Deterministic Random-Length Computation with Weakly Entangled Cluster States , ADAM G. D'SOUZA, DAVID L. FEDER, Institute for Quantum Information Science, University of Calgary — Universal quantum computation can be accomplished via single-qubit measurements on a highly entangled resource state, together with classical feedforward of the measurement results. The best-known example of such a resource state is the cluster state, on which judiciously chosen single-qubit measurements can be used to simulate an arbitrary quantum circuit with a number of measurements that is linear in the number of gates. We examine the power of the orbit of the cluster states under GL(2,C), also known as the SLOCC equivalence class of the cluster state, as a resource for deterministic universal computation. We find that, under certain circumstances, these states do indeed constitute resources for such computations, but of random length.

3:54PM D29.00008 Logical operator tradeoff for local quantum codes[1] , JEONGWAN HAAH, JOHN PRESKILL, IQI, Caltech — We study the structure of logical operators in local D-dimensional quantum codes, considering both subsystem codes with geometrically local gauge generators and codes defined by geometrically local commuting projectors. We show that if the code distance is d, then any logical operator can be supported on a set of specified geometry containing $\tilde{d}$ qubits, where $\tilde{d}d^{1/(D-1)} = O(n)$ and n is the code length. Our results place limitations on partially self-correcting quantum memories, in which at least some logical operators are protected by energy barriers that grow with system size. We also show that two-dimensional codes defined by local commuting projectors admit logical "string" operators and are not self correcting.

4:06PM D29.00009 ABSTRACT WITHDRAWN –

4:18PM D29.00010 Simulating Concordant Computations , BRYAN EASTIN, Northrop Grumman — A quantum state is called concordant if it has zero quantum discord with respect to any part. By extension, a concordant computation is one such that the state of the computer, at each time step, is concordant. In this talk, I describe a classical algorithm that, given a product state as input, permits the efficient simulation of any concordant quantum computation having a conventional form and composed of gates acting on two or fewer qubits. This shows that such a quantum computation must generate quantum discord if it is to efficiently solve a problem that requires super-polynomial time classically. While I employ the restriction to two-qubit gates sparingly, a crucial component of the simulation algorithm appears not to be extensible to gates acting on higher-dimensional systems.

4:30PM D29.00011 Photonic Phase Gate via an Exchange of Fermionic Spin Waves in a Spin Chain , ALEXEY GORSHKOV, California Institute of Technology, USA, JOHANNES OTTERBACH, Universitat Kaiserslautern, Germany, EUGENE DEMLER, Harvard University, USA, MICHAEL FLEISCHHAUER, Universitat Kaiserslautern, Germany, MIKHAIL LUKIN, Harvard University, USA — We propose a new protocol for implementing the two-qubit photonic phase gate. In our approach, the π phase is acquired by mapping two single photons into atomic excitations with fermionic character and exchanging their positions. The fermionic excitations are realized as spin waves in a spin chain, while photon storage techniques provide the interface between the photons and the spin waves. Possible imperfections and experimental systems suitable for implementing the gate are discussed. [Reference: Phys. Rev. Lett. 105, 060502 (2010)]

4:42PM D29.00012 Scalable Neutral Atom Quantum Computer with Interaction on Demand[1] , MIKIO NAKAHARA, ELHAM HOSSEINI LAPASAR, KENICHI KASAMATSU, TETSUO OHMI, YASUSHI KONDO, Department of Physics, Kinki University — We propose a scalable neutral atom quantum computer with an on- demand interaction. Artificial lattice of near field optical traps is employed to trap atom qubits. Interactions between atoms can be turned off if the atoms are separated by a high enough potential barrier so that the size of the atomic wave function is much less than the interatomic distance. One-qubit gate operation is implemented by a gate control laser beam which is attached to an individual atom. Two-qubit gate operation between a particular pair of atoms is introduced by leaving these atoms in an optical lattice and making them collide so that a particular two-qubit state acquires a dynamical phase. Our proposal is feasible within existing technology developed in cold atom gas, MEMS, nanolithography, and various areas in optics.

[1]Work partially supported by "Open Research Center" Project for Private Universities: matching fund subsidy from MEXT, Japan.

4:54PM D29.00013 General-Purpose Quantum Simulation with Prethreshold Superconducting Qubits , EMILY PRITCHETT, IQC Waterloo, COLIN BENJAMIN, University of Georgia, ANDREI GALIAUTDINOV, UC Riverside, MICHAEL GELLER, ANDREW SORNBORGER, PHILLIP STANCIL, University of Georgia, JOHN MARTINIS, UC Santa Barbara — We introduce a protocol for the fast simulation of n-dimensional quantum systems on n-qubit quantum computers with tunable couplings. A mapping is given between the control parameters of the quantum computer and the matrix elements of an n- dimensional real (but otherwise arbitrary) Hamiltonian that is simulated in the n- dimensional *single-excitation subspace* of the quantum simulator. A time- dependent energy/time rescaling minimizes the simulation time on hardware having a fixed coherence time. We demonstrate how three tunably coupled superconducting phase qubits can simulate a three-channel molecular collision using this protocol. The method makes a class of general-purpose time-dependent quantum simulation practical with today's sub-thershold-fidelity qubits.

5:06PM D29.00014 Currently Realizable Quantum Error Detection/Correction Algorithms for Superconducting Qubits[1] , KYLE KEANE, Department of Physics and Astronomy, University of California, Riverside, ALEXANDER N. KOROTKOV, Department of Electrical Engineering, University of California, Riverside — We investigate the efficiency of simple quantum error correction/detection codes for zero-temperature energy relaxation. We show that standard repetitive codes are not effective for error correction of energy relaxation, but can be efficiently used for quantum error detection. Moreover, only two qubits are necessary for this purpose, in contrast to the minimum of three qubits needed for conventional error correction. We propose and analyze specific two-qubit algorithms for superconducting phase qubits, which are currently realizable and can demonstrate quantum error detection; each algorithm can also be used for quantum error correction of a specific known error. In particular, we analyze needed requirements on experimental parameters and calculate the expected fidelities for these experimental protocols.

[1]This work was supported by NSA and IARPA under ARO grant No. W911NF-10-1-0334.

5:18PM D29.00015 Interface between Topological and Superconducting Qubits[1] , LIANG JIANG, California Institute of Technology, CHARLES KANE, University of Pennsylvania, JOHN PRESKILL, California Institute of Technology — We propose and analyze an interface between a topological qubit and a superconducting flux qubit. In our scheme, the interaction between Majorana fermions in a topological insulator is coherently controlled by a superconducting phase that depends on the quantum state of the flux qubit. A controlled phase gate, achieved by pulsing this interaction on and off, can transfer quantum information between the topological qubit and the superconducting qubit.

Session D30 DCMP: Graphene: Hydrogenation and Defects C147/154

2:30PM D30.00001 Thermal conductivity of partially hydrogenated graphene , JEONG YUN KIM, JEFFREY GROSSMAN, Massachusetts Institute of Technology — Graphene superlattices made with partial hydrogenation are of great interest and have been explored recently due to the enhanced tunability of electronic properties as a function of the hydrogenation pattern. However, the thermal transport properties of such materials have received little attention. In this work, we investigate the effects of 2D periodic patterns of hydrogen atoms on the thermal conductivity of partially hydrogenated graphene using classical molecular dynamics simulations and an Einstein relation. Our calculations show that the thermal conductivity of partially hydrogenated graphene varies substantially as a function of hydrogen coverage, periodicity, edge shape, and width of hydrogenated region compared to the bare graphene region. In addition, we show that the use of patterned 2D shapes of hydrogenation on graphene could lead substantially lower thermal conductivities that may be of interest for thermoelectric applications.

2:42PM D30.00002 Thermoelectric Properties of Hydrogenated Graphene , RUWANTHA JAYASINGHA, KASUN FERNANDO, CHRISTOF KEEBAUGH, ROBERT STALLARD, GAMINI SUMANASEKERA, University of Louisville, Louisville, KY 40292 — We have studied the temperature dependence of thermopower (S) and 4-probe resistance (R) of large area Graphene subjected to various degree of hydrogenation. Graphene samples with electrical contacts mounted within a quartz reactor was placed inside a custom made inductively coupled plasma coil and hydrogen gas was introduced to a pressure of $\sim$ 10 Torr. Samples were placed well away from the plasma and both S and R were monitored *in –situ* during the hydrogenation. At desired level of hydrogenation the plasma was turned off and the sample was cooled down to $\sim$140 K by lowering the reactor into a liquid nitrogen dewar and both R(T) and S(T) were measured. Both S(T) and R(T) show metal to insulator transition characteristics during the progressive hydrogenation. Both epitaxially grown Graphene on Si-terminated face of SiC and Graphene grown by chemical vapor deposition and transferred on to quartz substrate were studied. The CVD grown sample was found to be p-type under ambient condition but could be tuned to n-type after high temperature annealing at 550 K in a vacuum of 2x10^{-7}Torr. In contrast, epitaxial sample was n-type under ambient conditions. However, the hydrogenation was performed on both samples under degassed conditions.

2:54PM D30.00003 The Influence of Hydrogenation on the Hall Effect in Exfoliated Mono- and Multi-layer Graphene , Y. MO, J.D. JONES, P.E. ECTON, M. MANESHIAN, W.D. HOFFMAN, A.V. JESSEPH, N. SHEPHERD, G.F. VERBECK, J.M. PEREZ, University of North Texas, Z. YE, G. ZHAO, Southern University and A&M College — Graphene samples exfoliated from highly ordered pyrolytic graphite are deposited using the standard scotch-tape method on 300nm thick SiO_2 covered and slightly conductive Si substrates. Devices with 4 silver electrode pads on the graphene samples for Hall effect measurements are made with simple evaporation procedures by using transmission electron microscopy grids as masks. At room temperature, we measure the Hall effect of mono- and multi-layer graphene before and after plasma hydrogenation. During plasma hydrogenation, the sample substrates are biased at +150 V to attract electrons in the plasma for hydrogenation and push away ions in the plasma avoiding possible damage to the graphene. We also measure the Hall effect after annealing the samples at 200 $^\circ$C and vacuum of 10^{-6} torr for an hour. Micro-Raman is employed to monitor the quality and change of the graphene at each process step. We compare the Hall effect results for pristine, hydrogenated, and annealed mono- and multi- layer graphene samples.

3:06PM D30.00004 Density of states of a graphene in the presence of strong point defects , BOR-LUEN HUANG, MING-CHE CHANG, Department of Physics, National Taiwan Normal University, CHUNG-YU MOU, Department of Physics, National Tsing Hua University — The density of states near zero energy in a graphene due to strong point defects with random positions are computed. Instead of focusing on density of states directly, we analyze eigenfunctions of inverse T-matrix in the unitary limit. Based on numerical simulations, we find that the squared magnitudes of eigenfunctions for the inverse T-matrix show random-walk behavior on defect positions. As a result, squared magnitudes of eigenfunctions have equal a priori probabilities, which further implies that the density of states is characterized by the well-known Thomas-Porter type distribution. The numerical findings of Thomas-Porter type distribution is further derived in the saddle-point limit of the corresponding replica field theory of inverse T-matrix. Furthermore, the influences of the Thomas-Porter distribution on magnetic and transport properties of a graphene, due to its divergence near zero energy, are also examined.

3:18PM D30.00005 Tuning graphene's electronic structure via unbalanced disordered sublattices and defect superlattices , FRANCOIS VARCHON, AURÉLIEN LHERBIER, JEAN-CHRISTOPHE CHARLIER, UCL IMCN/NAPS — Graphene, a single carbon plane arranged on a honeycomb lattice, has received a lot of attention in the last few years due to its very appealing physical properties as the room temperature quantum hall effect, a large coherence length or a high electronic mobility. These basic properties hold a high application potential for graphene in nanoelectronics. Nevertheless the future of this field strongly depends on the possibility to control the electronic properties of this material. On the basis of extensive tight-binding and ab initio calculations, we demonstrate the possibility to tune graphene's electronic structure via realistic atomic defects (epoxide and hydroxyl groups chemisorbed on graphene). For example we report on the bandgap opening in graphene monolayer induced by unbalanced disordered sublattices. Our findings show that the bandgap width depends on the nature, the concentration and the distribution (random, semi-random, periodic) of the impurities. We also perform an indepth study about the special case of periodic distribution of atomic defects. We demonstrate the existence of three different families of defect superlattices which conduct to specific band structures and therefore could lead to different electronic and transport properties [1].

[1] A. Lherbier, F. Varchon, J.-C. Charlier (in preparation)

3:30PM D30.00006 Numerical study of impurity effects in Graphene[1] , ZHOU LI, FRANK MARSIGLIO, Dept. of Physics, University of Alberta, STEPAN GRINEK, JIE CHEN, Dept. of ECE, University of Alberta — It is known that long-range Coulomb impurities could induce a novel supercritical regime in gapped graphene [1]. For short range impurities, the electron wave function is less localized near the band edge and thus numerical results may depend on the size and boundary conditions of the simulated graphene. For six attractive impurities forming a quantum well with radius=a(a is the distance between two nearest neighbor atoms in graphene), we found that the bound states will not merge into the continuum. The results from a finite size exact diagonalization with open boundary conditions agree well with that from an infinite size study based on Green's functions. Also an efficient numerical approach based on kernel polynomial methods [2] will be adopted to evaluate the Green's function accurately in the regime with strong interference effects and compared to T-matrix results.

3:42PM D30.00007 Plasma Hydrogenation of n-Layer Graphene , J.D. JONES, W.D. HOFFMAN, A.V. JESSEPH, C.J. MORRIS, G.F. VERBECK, J.M. PEREZ, University of North Texas — We propose a new mechanism for the hydrogenation of mono-, bi-, and tri-layer graphene samples using an H_2 plasma. We find that hydrogenation occurs as a result of electron irradiation of H_2O adsorbates on the sample rather than H species from within the plasma. We propose that the mechanism is electron-impact fragmentation of the H_2O adsorbates occurring naturally above and below the sample. The stability of the hydrogenation increases with the incident electron energy, allowing for hydrogenated samples that are stable at temperatures $>$ 200 $^\circ$C. We also observe fully hydrogenated bi- and tri-layer graphene, which may be evidence for new materials, diamane and *triamane*. Diamane, a two atom thick layer of hydrogenated diamond, is predicted to have a band gap of 3.12 eV and be stronger than graphane, hydrogenated graphene.

3:54PM D30.00008 ABSTRACT WITHDRAWN –

4:06PM D30.00009 Oxygen reduction activity of BN decorated bulk defects in graphene , SHYAM KATTEL, BORIS KIEFER, Physics Department, New Mexico State University, PLAMEN ATANASSOV, Chemical and Nuclearing Department, University of New Mexico — We use Density-Functional-Theory to investigate the interaction between O_2 and H_2O_2 with co-doped bulk BN defects in graphene. The results show that the mixed defects are thermodynamically stable in contrast to the nitrogen only defects that need a transition metal for stabilization. The interaction between O_2 and H_2O_2 and the BN defects are found to be very different: O_2 is adsorbed as a molecule on boron with a bond length increase of $\sim$20%. H_2O_2, on the other hand, is predicted to adsorb dissociatively to form $B(OH)_2$. The predicted binding energy (BE) of O_2 is similar to the N only defects. This observation suggests that BN defects promote the reduction of O_2 to H_2O_2. However, we also found that the binding energy per OH is $\sim$75% higher than the corresponding BE for the N only defect. Thus, restoring the catalytic site through OH removal is more difficult as compared to the N only defect. This implies that bulk BN defects are most likely less active than N only defects and edge BN defects which enhance ORR.

4:18PM D30.00010 Effect of Laser Irradiation on Structural and Electronic Properties of Single-layer and Bi-layer Graphene , PUBUDU GALWADUGE, JOSEPH LAMBERT, ROBERTO RAMOS, Drexel University — Graphene is a two-dimensional crystal with remarkable electronic properties which have made it a component of interest in fabricating chemical sensors, superconducting devices and room-temperature transistors. Fabrication and metrology techniques typically use energetic beams such as lasers which are likely to induce unintentional changes in graphene. We report results of Time-Resolved Raman Spectroscopy experiments that investigate the effect of low,medium, and high power laser irradiation on the structural and electronic properties of single-layer and bi-layer graphene. We have irradiated graphene using a 514.5nm laser at power levels of 1.8mW, 9mW and 18mW. Changes in electronic and structural properties were observed by observing the time evolution of the Raman D and G bands. Under irradiation at 1.8mW and 9mW, single layer graphene flakes show changes in charge carrier concentration. Under irradiation at 18mW,single layer graphene shows signs of defect formation and breakdown into nano-crystalline graphene. Bi-layer graphene shows no measurable changes in the Raman D and G bands under irradiation at 9mW.

4:30PM D30.00011 Effect of irradiation by electron-beam and oxygen plasma on graphene studied with Raman spectroscopy and electronic transport , ROMANEH JALILIAN, NaugaNeedles, ISAAC CHILDRES, LUIS A. JAUREGUI, Purdue University, MICHAEL FOXE, Penn State, JIFA TIAN, Purdue University, IGOR JOVANOVIC, Penn State, YONG P. CHEN, Purdue University — We report a study of the effects of electron-beam irradiation and oxygen plasma etching on graphene and graphene field-effect transistors (GFET). For both types of exposure, Raman spectra show a characteristic evolution with increasing irradiation-induced disorder. Electron-beam exposure causes a down-shifting in the charge-neutral point (CNP), interpreted as due to a hole-doping in the substrate. Oxygen plasma etching causes an up-shifting of the CNP, interpreted as due to hole-doping molecules adsorbed on the plasma-induced defects. Both types of exposure decrease the carrier mobilities and minimum conductivity of graphene. Additionally, weak localization and the quantum Hall effect are characterized in exposed devices. Our findings are valuable for understanding the effects of irradiation damage on graphene and the physics of disordered graphene through artificially generated defects.

4:42PM D30.00012 Stability and Mobility of Vacancy Defects in Monolayer Graphene[1] , WEI CHEN, U of Tennessee-Knoxville, HAIPING LAN, PING CUI, JINLONG YANG, U of Sci. and Tech. of China, ZHENYU ZHANG, Oak Ridge National Lab, U of Tennessee-Knoxville, U of Sci. and Tech. of China — Using DFTB and first-principle calculations, we study the stability and mobility of vacancy defects in graphene. First, we calculate the formation energy of vacancy defects of varying sizes in different supercells, including its dependence on the Brillouin zone sampling. We find a large difference, of 1eV, in the formation energy between the value with only Gamma-point sampling and that with more symmetrical k-point sampling in the 3N*3N (N=2,3,4) supercells. This variance is attributed to significant contributions of the electronic states around the Dirac points. We then explore the mobility of the vacancy defects, including single atom vacancy, trivacancy, and tetravacancy. We find that both trivacancy and tetravacancy have relatively small activation energies for migration via a Stone-Wales transformation of the edge atoms. These results will be compared with recent experimental observations.

4:54PM D30.00013 Controllable defect healing and N-doping of graphene by CO and NO molecules[1] , BIN WANG, Department of Physics and Astronomy, Vanderbilt University, SOKRATES PANTELIDES, Department of Physics and Astronomy, Vanderbilt University and Oak Ridge National Laboratory — Controllable defect healing and N-doping in graphene would be very valuable for potential device applications. Here we report first-principles molecular dynamic simulations that suggest a procedure with fast dynamics and low thermal budget. Vacancies can be healed by sequential exposure to CO and NO molecules. A CO molecule gets adsorbed at a vacancy site and a NO molecule subsequently removes the extra O by forming NO_2. Controllable N-doping can be achieved by sequential vacancy creation (e.g. by electron beam) and subsequent exposure to NO molecules at room temperature. A combination of CO and NO molecules can potentially provide simultaneous healing and doping at a desirable ratio. The proposed strategy introduces no extra defects and is promising for graphene-based materials in radiation environments.

Session D31 DMP: Focus Session: van der Waals Bonding in Advanced Materials: Applications to Advanced and Functional Materials C145

2:30PM D31.00001 Rotational and vibrational excitations of van der Waals bonded hydrogen in nanoporous materials: calibrating first-principle calculations with experiments[1] , LINGZHU KONG, Princeton University — The adsorption of H_2 within a metal-organic framework is studied via van der Waals density-functional calculations and maximally-localized-Wannier- function analysis. The calculated low-lying vibrational and rotational energy states as well as the adsorption sites are consistent with experiments. The induced dipole due to H_2 bond stretching and its quantum mechanic matrix element is found to be accurately given by a first-principles driven approximation. The resulting calculations of IR intensity explain the experimentally mysteriously missing primary line for para hydrogen. The strengths and positions of lines in the complex spectra of rotational-vibrational transitions are in reasonable agreement with experiment, and a selection rule is obtained.

3:06PM D31.00002 CO2 Binding in Zeolitic Imidazolate Frameworks from First Principles Calculations , KEITH RAY, DAVID OLMSTED, NING HE, YAO HOUNDONOUGBO, BRIAN LAIRD, MARK ASTA — Zeolitic Imidazolate Frameworks (ZIFs) are excellent candidate carbon capture materials owing to their high surface area, selectivity, and stability. In this work we use electronic-structure based methods to investigate the binding of CO2 in a set of ZIFs that share the same topology but feature different functionalized linkers [1]. Since a large portion of the CO2 binding comes from van der Waals (vdW) forces, we explore several different schemes for incorporating these contributions into ab-initio density-functional-theory (DFT) including vdW-DFT [2]. The results are combined with those of classical simulation studies to allow comparisons between calculations and experimentally measured values of the heat of adsorption and adsorption isotherms [1]. This research is supported by the Energy Frontier Research Center "Molecularly Engineered Energy Materials," funded by the US Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number DE-SC0001342.

3:18PM D31.00003 The Importance of van der Waals Interactions in the Stability of the Phases of $Mg(BH_4)_2$, BRIAN KOLB, Wake Forest University, ANDRZEJ BIL, ALEKSEY KOLMOGOROV, University of Oxford, TIMO THONHAUSER, Wake Forest University — As hydrogen gains attention as a potential replacement for fossil fuels, materials to store hydrogen safely and efficiently are becoming increasingly important. Metal borohydrides are attracting much attention for this role and, in particular, $Mg(BH_4)_2$ is a promising candidate for hydrogen storage because of its relatively high hydrogen content (over 12 wt%) and the abundance of its constituent elements. This system has been investigated previously, both experimentally and via density functional theory (DFT) studies. These two approaches give conflicting results, however, regarding the identity of the low-temperature ground-state. In this work, we investigate the impact of van der Waals (vdW) interactions on the stability of various phases of $Mg(BH_4)_2$. vdW interactions are included both through the fully self-consistent vdW-DF approach as well as the semi-empical PBE-D/PBE-D* approach. Our results settle the longstanding discrepancy between theory and experiment, as we find inclusion of vdW interactions stabilizes the experimentally determined ground-state structure at low temperature, relative to those predicted by previous DFT studies.

3:30PM D31.00004 Influence of van der Waals contact forces on the deformation mechanics of thin flexible membranes assembled from metallic or semiconducting single-wall carbon nanotubes[1] , ERIK K. HOBBIE, JOHN HARRIS, SWATHI IYER, NDSU, JI YEON HUH, JEFFREY A. FAGAN, STEVEN D. HUDSON, CHRISTOPHER M. STAFFORD, NIST — Thin membranes of single-wall carbon nanotubes (SWCNTs) assembled from either metallic or semiconducting SWCNTs are subjected to the compressive strains imposed by a stretched elastic substrate, and the mechanical characteristics of the membranes are inferred from the topography of the wrinkling instability that emerges. By depositing comparable films on quartz, we also use optical (UV-Vis-NIR) absorption spectroscopy to compute the effective London dispersion spectra of the purified materials, and from these we compute the attractive part of the van der Waals potential between nanotubes of identical electronic type as a function of separation and relative orientation. We find significant differences in the strength and shape of the contact potential depending on electronic type, which in turn are evident in the modulus and yield strain measured from the deformation of the films.

3:42PM D31.00005 Electrostatic Origin of Meandering C60 Chain Formation at ZnPc Interfaces[1] , JANICE REUTT-ROBEY, QIANG LIU, LEVAN TSKIPURI, WEI JIN, JOHN WEEKS, University of Maryland, DANIEL DOUGHERTY, NC State University, STEVE ROBEY, NIST — We present STM investigations of interface-formation and nanophase separation in binary films of zinc phthalocyanine (ZnPc) and C_{60} on Ag(111) and Au(111) supports. We report ZnPc:C_{60} 1-D and 2-D interfaces with distinctive molecular orientations and unusually low C_{60} packing densities. Meandering C_{60} chains of single-molecular width arise without registration to the underlying ZnPc template, islanding into a disordered chain phase. These structures are reminiscent of dipole fluids (albeit of single molecular widths!) We present detailed measurements and analysis of C_{60} wandering chain formation on ZnPc/Ag (111) and ZnPc/Au (111) substrates. We explore the physical origin of these structures through simulations with a model potential that incorporates short-range C_{60} – C_{60} attraction and a long-range dipolar repulsion. From simulations of realized structures, we estimate the effective dipole needed for chain formation. DFT calculations on the C60/ZnPc/Ag(111) structure support these conclusions and provide more detailed insight on the electrostatic interactions that drive chain formation.

3:54PM D31.00006 How van der Waals interactions affect alanine-based polypeptides , M. ROSSI, V. BLUM, X. REN, A. TKATCHENKO, M. SCHEFFLER, Fritz-Haber-Institut, Berlin — van der Waals interactions play a critical role among the intramolecular interactions that stabilize secondary structure folding motifs in polypeptides. In this work, we quantify its influence *ab initio* for the series of helix-forming alanine based polypeptides Ac-Ala_n-LysH^+ (n = 4-15). We show that: (i) applying a van der Waals (vdW) correction based on the self-consistent electron density [2] to the PBE functional, a clear α-helical conformational preference emerges at n=8, in agreement with experiment [1], while a mostly 3_{10} helical structure is preferred at plain PBE; (ii) a numeric atom-centered orbital basis enhanced specifically to converge conformational energy differences from explicitly correlated methods (MP2, EX+cRPA and beyond [3]) gives us benchmark capabilities for treatments that include long-range correlations outrightly; (iii) exploring the free energy surface through *ab initio* dynamics for longer helices (n=15) we see a dramatic influence of vdW interactions for high temperature stability and surface explored by these molecules. Our results demonstrate that we are now in a position to quantify vdW contributions accurately, and thus unravel their critical qualitative role in comparison to other contributions (strain, H-bonds) in medium-sized biomolecules. 4:06PM D31.00007 Dispersion Forces and Self-assembly of Styrene Nanowires on H-Si(100) 2×1 Surface[1] , GUO LI, Institute of Physics, CAS, P. R. China; U of Tennessee at Knoxville, VALENTINO COOPER, Oak Ridge National Laboratory, JUN-HYUNG CHO, Hanyang University, Korea, SHIXUAN DU, HONGJUN GAO, Institute of Physics, CAS, P. R. China, ZHENYU ZHANG, Oak Ridge National Laboratory; U of Tennessee at Knoxville — We present our first-principles investigation of the influence of dispersion forces (or van der Waals interactions) on the self-assembly of styrene nanowires on the hydrogenated Si(100) 2×1 surface. Using density functional theory (DFT) calculations and kinetic Monte Carlo (KMC) simulations we demonstrate that the dispersion forces enhance the binding between styrene molecules thus allowing us to tune the preferential growth of long wires for the fabrication of desired nanopatterns. Furthermore, this approach is a step towards accurate fully first-principles studies of the effects of dispersion forces on the dynamics at interfaces, and therefore will be invaluable to our understanding of chemical processes such as self-assembly and the catalysis of organic chemical reactions.

4:18PM D31.00008 Morphological Control in the Synthesis of Silver Nanostructures: Role of Polyvinylpyrrolidone[1] , KRISTEN FICHTHORN, HAIJUN FENG, RAJESH SATHIYANARAYANAN, Penn State University — Solution-phase syntheses are useful for assembling metallic nanostructures with desired morphologies. For example, a wide variety of silver nanostructures have been synthesized in the polyol process [1], including nanowires, nanoplates, cubes, etc. Polyvinylpyrrolidone (PVP) plays a key role in controlling nanostructure morphologies in these fabrication processes. Based on experimental observations, the interaction strength between PVP chains and Ag atoms in different crystallographic facets is expected to vary significantly and this shape selectivity is expected to play a key role in directing the formation of various nanostructures. Using first-principles calculations based on density-functional theory including van der Waals interactions, we compute the interactions of the basic elements of a repeat unit in PVP (2-pyrollidone and ethane) with various crystal faces of Ag. Our results indicate that PVP does exhibit the expected structure sensitivity and that this arises from an interesting balance between van der Waals interactions and direct chemical bonding. We discuss the ramifications of our calculations for the assembly of Ag nanostructures.

4:30PM D31.00009 Structure and Formation of Synthetic Hemozoin: Insights from First Principles Calculations , NOA MAROM, University of Texas at Austin, ALEXANDRE TKATCHENKO, Fritz-Haber-Institut, Berlin, SERGEY KAPISHNIKOV, LEEOR KRONIK, LESLIE LEISEROWITZ, Weizmann Institute of Science, Israel — Malaria has reemerged due to parasite resistance to synthetic drugs that act by inhibiting crystallization of the malaria pigment, hemozoin (HZ). Understanding the process of HZ nucleation is therefore vital. The crystal structure of synthetic HZ, β-hematin (βH), has recently been determined via x-ray diffraction. We employ van der Waals (vdW) corrected density functional theory to study the βH crystal and its repeat unit, a heme dimer. We find that vdW interactions play a major role in the binding of the heme dimer and the βH crystal. Accounting for the βH periodicity is a must for obtaining the correct geometry of the heme dimer, due to vdW interactions with adjacent dimers. The different isomers of the heme dimer are close in energy, consistent with the observed pseudo-polymorphism. We use these findings to comment on βH crystallization mechanisms.

4:42PM D31.00010 Adsorption of methane on Zn(bdc)(ted)0.5 microporous metal-organic framework , VAIVA KRUNGLEVICIUTE, Southern Illinois University Carbondale, SANHITA PRAMANIK, Rutgers, The State University of New Jersey, ALDO MIGONE, Southern Illinois University Carbondale, JING LI, Rutgers, The State University of New Jersey — Zn(bdc)(ted)0.5 is metal-organic framework crystallized in a tetragonal space group with a 3D porous structure containing intersecting channels of two different sizes. The larger channels are parallel to the c axis and have a cross section 7.5 $\times$ 7.5Å. The smaller channels are along both the a- and b-axes and have a cross section of 4.8 $\times$ 3.2Å. We measured methane adsorption isotherms at several different temperatures between 82 and 102 K. We calculated the effective specific surface area, isosteric heat and binding energy values. Two distinct substeps were observed in the isotherms corresponding to two different adsorption sites. The origin of the substeps will be discussed.

4:54PM D31.00011 Understanding H_2-H_2 interactions in Metal Organic Frameworks (MOFs) with unsaturated metal centers[1] , NOUR NIJEM, JEAN F. VEYAN, Univeristy of Texas at Dallas, LINGZHU KONG, YONGGANG ZHAO, JING LI, DAVID LANGRETH, Rutgers University, YVES J. CHABAL, Univeristy of Texas at Dallas — Unsaturated Metal Organic Frameworks (MOFs) are particularly interesting due to their high H_2 uptakes with relatively large isosteric heats of adsorption (Q_{st} >8 kJ/mol). This work explores H_2-H_2 interactions between adsorbed H_2 at the different sites in MOF-74 (M_2(dhtp),dhtp=2,5-dihydroxyterephthalate) and combines IR spectroscopy with vdW-DFT calculations. The adsorption sites in MOF-74 are from highest to lowest binding energies the metal, oxygen, benzene and pore-center sites. The frequency of adsorbed H_2 at the metal site suffers an additional $\sim$-30 cm^{-1} red shift (for Mg and Zn) and $\sim$-84 cm^{-1} (for Co) when the neighboring oxygen site is occupied. The dipole moment of adsorbed H_2 is also affected. These interactions extend to the benzene sites for MOF-74-Co. A decrease in dipole moment of H_2 adsorbed at the metal site is observed with the partial occupation of the benzene sites. However, the complete occupation of the benzene sites induces an additional $\sim$-10 cm^{-1} red shift.

5:06PM D31.00012 First-Principles Calculations of the Role of Dispersive Interactions in CO_2 binding in metal-organic frameworks , ROBERTA POLONI, University of California, Berkeley; Molecular Foundry, LBNL; University of California, Davis, JOSHUA HOWE, University of California, Berkeley, JEFFREY B. NEATON, Molecular Foundry, LBNL, GIULIA GALLI, University of California, Davis, BEREND SMIT, University of California, Berkeley and LBNL — Metal-organic frameworks (MOFs) have attracted much attention over the past 20 years for their possible applications in gas storage. In this study, we provide computational insight into what makes a MOF structure optimum for CO_2 capture. We present a density functional theory-based study of the electronic and structural properties of recently synthesized frameworks M'$_3$[(M$_4$Cl)$_3$(BTT)$_8$]$_2$, with M'=extraframework cation and M=Ca [1]. We study the interactions between CO_2 and different binding sites, and predict an unexpected favored binding site at the organic linker. We explore how binding energies are affected by the ordering and type of the extraframework cations. Finally, we address the role of dispersion forces by employing a recent non-local van der Waals functional [2], and compare with a DFT+D approach [3].

Session D32 DMP: Focus Session: Optical Properties of Nanostructures and Metamaterials III

C144

2:30PM D32.00001 Spatial gradient tuning in metamaterials , TOM DRISCOLL, Duke, UCSD, MICHAEL GOLDFLAM, UCSD, NAN JOKERST, Duke, DIMITRI BASOV, UCSD, DAVID SMITH, Duke — Gradient Index (GRIN) metamaterials have been used to create devices inspired by, but often surpassing the potential of, conventional GRIN optics. The unit-cell nature of metamaterials presents the opportunity to exert much greater control over spatial gradients than is possible in natural materials. This is true not only during the design phase but also offers the potential for real-time reconfiguration of the metamaterial gradient. This ability fits nicely into the picture of transformation-optics, in which spatial gradients can enable an impressive suite of innovative devices. We discuss methods to exert control over metamaterial response, focusing on our recent demonstrations using Vanadium Dioxide. We give special attention to role of memristance and mem-capacitance observed in Vanadium Dioxide, which simplify the demands of stimuli and addressing, as well as intersecting metamaterials with the field of memory-materials.

2:42PM D32.00002 Carrier concentration dependence of the tunability of the dipole resonance peak in optically excited metamaterials , IOANNIS CHATZAKIS, LIANG LUO, JIGANG WANG, NIAN HAI SHEN, THOMAS KOSCHNY, COSTAS SOUKOULIS, Department of Physics and Astronomy and Ames Laboratory, Iowa State University, Ames, Iowa 50011, USA — Currently, there is strong interest to explore the dynamic control of the electromagnetic properties of metamaterials, which have important implications on their optoelectronic applications. While the design, fabrication and photo-doping of metamaterial/semiconductor structures have been actively pursued, some fundamental issues related to highly photo-excited states, their dynamic tuning and temporal evolution remain open. Using optical-pump terahertz probe spectroscopy, we report on the pump fluence dependence of the electric dipole resonance tunability in metamaterials. We find a previously undiscovered large non-monotonic variation on the strength of the dipole resonance peak with the photo-injected carrier concentration.

2:54PM D32.00003 Optically-Nonactive Assorted Helices Array with Interchangeable Magnetic/Electric Resonance[1] , MU WANG, XIANG XIONG, RU-WEN PENG, XIAO-CHUN CHEN, DAJUN SHU, Department of Physics, Nanjing University, CHENG SUN, Department of Mechanical Engineering, Northwestern University — We report here the designing of optically-nonactive metamaterial by assembling metallic helices with different chirality. With linearly polarized incident light, pure electric or magnetic resonance can be selectively realized, which leads to negative permittivity or negative permeability accordingly. Further, we show that pure electric or magnetic resonance can be interchanged at the same frequency band by merely changing the polarization of incident light for 90 degrees. This design demonstrates a unique approach to construct metamaterial.

[1]Project supported by NSF of China and MOST of China under Grant Nos. 50972057, 10874068, 11034005, 61077023 and 2010CB630705

3:06PM D32.00004 Three-dimensional optical metamaterials and nanoantennas: Chirality, Coupling, and Sensing , HARALD GIESSEN, University of Stuttgart — This abstract not available.

3:42PM D32.00005 Temperature-Tunable Transparency Window in Metamaterials Utilizing Superconducting Dark Resonators , C. KURTER, University of Maryland, A.P. ZHURAVEL, National Academy of Sciences of Ukraine, P. TASSIN, T. KOSCHNY, L. ZHANG, Ames Laboratory, J. ABRAHAMS, C.L. BENNETT, University of Maryland, A.V. USTINOV, Karlsruhe Institute of Technology, C.M. SOUKOULIS, Ames Laboratory, S.M. ANLAGE, University of Maryland — We have developed a high quality-factor microwave frequency metamaterial to demonstrate a coherent optical phenomena analogous to electrically induced transparency (EIT). The two-dimensional design employs double planar Nb split rings acting as dark resonators symmetrically placed around a thick Au strip which is a bright resonator [1]. When Nb is in the superconducting state, the significant loss gradient between Nb and Au opens a transparency window along with a strongly enhanced group delay. The data show a systematic evolution with increasing temperature in the superconducting state of Nb, and the features disappear in the resistive state when the loss gradient between the two types of resonators closes. We have observed no RF power dependence of the magnetic response coming out of the EIT configuration, which indicates the process is linear. Laser scanning microscopy images of the RF current distributions in the dark resonators and the other microwave measurements are in good agreement with the simulations run on the same structure.
[1] L. Zhang, *et al.* arXiv:1010.2976

3:54PM D32.00006 Light propagation and Anderson localization in superlattices containing metamaterials: effects of correlated disorder , RAIMUNDO ROCHA DOS SANTOS, Universidade Federal do Rio de Janeiro, DMITRI MOGILEVTSEV, Institute of Physics, NASB, FELIPE PINHEIRO, Universidade Federal do Rio de Janeiro, SOLANGE CAVALCANTI, Universidade Federal de Alagoas, LUIZ OLIVEIRA, UNICAMP — We discuss the effect of correlated disorder on light propagation and Anderson localization in a one-dimensional superlattice made up of air (A) and a dispersive metamaterial (M). Disorder is incorporated by assuming the layer widths to be random variables; however, here we consider the cases of correlated (i.e., the A and M layers with the same width) and completely anti-correlated (the total width of the A and M layers is fixed). We use transfer matrix techniques to obtain the localization length, and compare with the uncorrelated case. We have found that the photonic gaps of the corresponding periodic structure are not completely destroyed in the presence of disorder, giving rise to minima in the localization length. Near a gap, the behavior the localization length depends crucially on the physical origin of the gap (Bragg or non-Bragg gaps). We have found that the asymptotic behavior for the localization length $\xi \propto \lambda^6$ for disordered metamaterials is not affected by correlations, and the Brewster anomalies, at which light is delocalized, are also present.

4:06PM D32.00007 Active Terahertz Metamaterials[1] , ANTOINETTE TAYLOR, Los Alamos National Laboratory — In recent years terahertz technology has become an optimistic candidate for numerous sensing, imaging, and diagnostic applications. Nevertheless, THz technology still suffers from a deficiency in high-power sources, efficient detectors, and other functional devices ubiquitous in neighboring microwave and infrared frequency bands, such as amplifiers, modulators, and switches. One of the greatest obstacles in this progress is the lack of materials that naturally respond well to THz radiation. The potential of metamaterials for THz applications originates from their resonant electromagnetic response, which significantly enhances their interaction with THz radiation. Thus, metamaterials offer a route towards helping to fill the so-called "THz gap". Here, we present a series of novel THz metamaterials. Importantly, the critical dependence of the resonant response on the supporting substrate and/or the fabricated structure enables the creation of active THz metamaterial devices. We show that the resonant response can be controlled using optical or electrical excitation and thermal tuning, enabling efficient THz devices which will be of importance for advancing numerous real world THz applications.

4:42PM D32.00008 Optical properties of chiral metal nanoparticle complexes: Plasmonic chirality and circular dichroism[1] , ZHIYUAN FAN, ALEXANDER GOVOROV, Department of Physics and Astronomy, Ohio University, Athens, Ohio 45701, DEPARTMENT OF PHYSICS AND ASTRONOMY, OHIO UNIVERSITY TEAM — Plasmonic nanocrystals with chiral geometries are able to create strong circular dichroism (CD) signals in the visible wavelength range. This offers an interesting possibility to design colloidal and other nanostructures with strong optical chirality for applications in biosensors and optoelectronic devices. We present a theoretical study of circular dichroism from chiral metal nanoparticle (NP) complexes. Dipolar Coulomb interactions between NPs are involved as the main mechanism of interaction between spherical NPs in a chiral complex. In our analysis, the CD signal shows strong dependence on geometry and composition of chiral pyramids, tetramers, and helices. The CD spectra have both positive and negative bands. Strongest CD signals were found in helical chains of metal NPs, which resemble helical structures of many biomolecules.

4:54PM D32.00009 Plasmonic Behavior of Deep Sub-Wavelength Superconducting RF Metamaterials[1] , STEVEN ANLAGE, CIHAN KURTER, LIZA SARYTCHEV, JOHN ABRAHAMS, C. BENNETT, TIAN LAN, University of Maryland, A. P. ZHURAVEL, Verkin Inst. Low Temp. Phys., NAS Ukraine, A. V. USTINOV, Karlsruhe Inst. Tech. — We have designed and built ultra-small RF metamaterials with magnetically active spiral elements made of superconducting Nb films [1]. RF transmission measurements on single, 1-D and 2-D arrays of spirals show robust magnetic response when Nb is in the superconducting state [2] at frequencies as low as 14 MHz (corresponding to wavelength $\sim$ 3000 * 'atom' size). Numerical simulations capture the main features of the experimental spectra. The resonant features are tunable via variations in temperature and RF magnetic field [3]. As temperature approaches T_c, the superconducting kinetic inductance contribution to the total inductance increases, placing this RF metamaterial in the plasmonic limit. We study this approach to the plasmonic limit and compare to the analogous situation of frequency approaching the plasma edge in normal metal metamaterials.

5:06PM D32.00010 Invisibility Using Perfect Absorption CNT Carpet at Visible Frequency and Beyond , L. JAY GUO, HAOFEI SHI, JONG OK, HYOUNGWON BAAC, Center for Nanophotonics and Spintronics, University of Michigan — The concept of invisibility cloak based on transformation optics and metamaterials has tantalized the scientific community. Cloaking of wavelength-size objects were realized at microwave and NIR frequencies. However, the complexity of metamaterials based on the previous principles limits the object to several wavelengths in size. Moreover, cloaking of 3-D objects at visible band demands challenging inhomogeneous 3D nanostructured metamaterials and still unattainable. We propose a perfect absorption ground plane cloak that works at visible range and for large area arbitrarily shaped 3D objects. Such homogeneous perfect absorption carpet is demonstrated by low density carbon nanotube (CNT) forest, which can visually compress arbitrary 3D objects to appear as a 2D perfect absorption sheet. Invisibility was observed by naked eyes for unpolarized light at entire visible band with cloaking area of 10^5 larger than a wavelength. Such a cloaking approach based on perfect absorption is not restricted to CNT carpet, and can be applied to a broader frequency range from UV to THz and acts as a universal cloak for arbitrarily large objects. In this scheme the deep space is a natural and perfect "ground plane". It would only take a "cloak" consisting of low density and broadband absorbing particles to render matters and objects totally "dark" to our current instruments.

5:18PM D32.00011 Collective dynamics in optomechanical arrays , FLORIAN MARQUARDT, University of Erlangen-Nuremberg and Max-Planck Institute for the Science of Light, GEORG HEINRICH, MAX LUDWIG, University of Erlangen-Nuremberg, JIANG QIAN, University of Munich, BJÖRN KUBALA, University of Erlangen-Nuremberg — Photonic crystals can support both localized optical and vibrational modes that couple to each other, leading to a very strong optomechanical interaction. These so-called "optomechanical crystals" have been demonstrated experimentally recently. Here we explore the dynamics that results in an array of many coupled optomechanical cells, when these are driven into a regime of self-sustained oscillations. We find synchronization of these oscillations beyond a certain coupling strength. We show that the slow phase dynamics can be efficiently described by an effective Kuramoto model. Other dynamical regimes like chaos will also be accessible in these novel systems.

Session D33 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides: Multiferroics C143/149

2:30PM D33.00001 Oxygen rotation driven ferroelectricity enables controllable magnetization-polarization coupling in $Ca_3Mn_2O_7$, CRAIG FENNIE, NICOLE BENEDEK, School of Applied and Engineering Physics, Cornell University — We show how to achieve the electric field switching of magnetism in a multiferroic with a large polarization by having the ferroelectric state arise from the same lattice instability that modulates the spin system. Oxygen octahedron rotations, ubiquitous in perovskites and related materials, are natural candidates for this lattice instability. First-principles calculations are presented for the layered perovskite $Ca_3Mn_2O_7$, in which rotations induce both ferroelectricity and weak ferromagnetism. The key point is that this rotation pattern is a combination of two non-polar structural modes with different symmetries. We introduce the term "hybrid" improper ferroelectricity to describe this phenomenon. Our results suggest a new strategy in magnetoelectronics, whereby control over magnetism is achieved through functional antiferrodistortive oxygen octahedron rotations.

2:42PM D33.00002 The search for multifunctional polar materials , JOSEPH BENNETT, KARIN RABE, Department of Physics and Astronomy, Rutgers University — One strategy in the search for new polar semiconducting (and possibly magnetic) materials is to check systems already synthesized and reported as polar in the literature to determine the intrinsic magnitude and switchability of the polarization, the band gap and magnetic properties. In many examples where a polar space group was found, neither polarization or band gap measurements were made because the sample as grown was too conductive. Using a combination of ICSD searching and symmetry analysis, we first identify potentially interesting polar materials and screen out those that are reported to definitely be metallic. We then use first-principles density functional theory (DFT) calculations to investigate the ground state structures of these experimentally synthesized materials for which limited data is available. These calculations will help us to develop criteria for screening candidate systems for polar, magnetic and semiconductive behavior, and broaden the search for new examples of these important functional materials.

2:54PM D33.00003 ABSTRACT WITHDRAWN –

3:06PM D33.00004 Higher-order Ginzburg-Landau Model for Multiferroic Hexagonal Manganites , KRIS DELANEY, UC Santa Barbara, SERGEY ARTYUKHIN, U Groningen, MANFRED FIEBIG, University of Bonn, NICOLA SPALDIN, UC Santa Barbara, MAXIM MOSTOVOY, U Groningen — Hexagonal manganites have been studied intensely as some of the few multiferroic materials with relatively high ordering temperatures. The recent experimental discovery of topological defects in the domain structure of YMnO3 has led to renewed interest in these materials [1, 2, 3]. Though a Landau free-energy model has already been parameterized at low order[4], we show the form of the parameterization with higher-order terms, including for the first time an angular dependence to the structural trimerization mode. Analysis of the resulting model explains clearly the origin of the topological defects in the domain structure, provides further theoretical insight into the contentious issue of the nature of the ferroelectric phase transition, and gives theoretical input into understanding the thickness of ferrelectric domain walls.

3:18PM D33.00005 Local and Long-Range High Pressure Structure of Orthorhombic $REMnO_3$[1] , H. CHEN, T. WU, T. TYSON, New Jersey Institute of Technology, R. TAPPERO, Brookhaven National Laboratory, L. HUANG, Stony Brook University, S. KIM, S.-W. CHEONG, Rutgers University — Orthorhombic perovskite $REMnO_3$ multiferroic systems were prepared by high pressure synthesis and solid state reaction. High pressure synchrotron x-ray diffraction and x-ray absorption measurements were performed to explore the structural changes. The influence of the pressure on the electrical polarization is discussed. Theoretical simulations are utilized to predict the stable magnetic phases based on the experimental parameters. This work is supported by DOE Grant DE-FG02-07ER46402.

3:30PM D33.00006 On the Nature of the Ferroelectric Transition in Multiferroic Hexagonal $REMnO_3$, TREVOR TYSON, TAO WU, HAIYAN CHEN, NJIT, JAINMING BAI, University of Tennessee, SANG-WOOK CHEONG, Rutgers University — Combined local and long range structural measurements were conducted on $REMnO_3$ for temperatures extending significantly above the ferroelectric transition temperature (T_{FE}). We find in hexagonal REMnO3 no large atomic (bond distance or thermal factors) or electronic structure changes on crossing T_{FE}. The born effective charge tensor is found to be highly anisotropic at the O sites indicating very strong hybridization of the charge. The tensor does not change significantly above T_{FE} revealing no charge redistribution and suggests an unusual transition. This work is supported by DOE Grants DE-FG02-07ER46402 (NJIT) and DE-FG02-07ER46382 (Rutgers University).

3:42PM D33.00007 Anomalous Phonon Behavior in Orthorhombic LuMnO3 at Low Temperature , PENG GAO, HAIYAN CHEN, TREVOR A. TYSON, Department of Physics, New Jersey Institute of Technology, Newark, NJ 07102, ZHENXIAN LIU, Geophysical Laboratory, Carnegie Institution of Washington DC 20015, JIANMING BAI, Oak RidgOak Ridge National Laboratory Oak Ridge, TN 37831, LIPING WANG, Mineral Physics Institute, Stony Brook University, Stony Brook, NY 11794, YOUNGJAI CHOI, SANG-WOOK CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, Piscataway, NJ 08854 — We present the pressure dependent phonon spectra of orthorhombic-LuMnO3 which are conducted in the low temperature region (below T_N and T_L). A temperature dependent anomalous phonon coincides with the ferroelectric behavior at low pressure condition. At ∼10 GPa, this anomalous phonon exhibits an unusual softening trend which will be suppressed at higher pressure. This work is supported by DOE Grant DE-FG02-07ER46402 (NJIT), by DE-FG02-07ER46402 (Rutgers), by COMPRES (U2A beam line at NSLS), the Consortium for Materials Properties Research in Earth Sciences under NSF Cooperative Agreement EAR01-35554, U.S. Department of Energy (DOE-BES and NNSA/CDAC) and by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-98CH10886 (use of NSLS at Brookhaven National Laboratory).

3:54PM D33.00008 Induction of novel macroscopic properties by local symmetry violations in spin-spiral multiferroics[1] , D. MEIER, UC Berkeley, N. LEO, University Bonn, P. BECKER, L. BOHATY, University of Cologne, R. RAMESH, UC Berkeley, M. FIEBIG, University Bonn — Incommensurate (IC) structures are omnipresent in strongly correlated electron systems as high-T_C superconductors, CMR manganites, as well as multiferroics. In each case they are origin of a pronounced symmetry reduction reflecting the complexity of the underlying microscopic interactions. Macroscopically, this can lead to new phases and possibilities to gain control of the host material. Here we report how the IC nature of a spin-spiral multiferroic induces new physical properties by renormalizing the relevant length scales of the system. Local symmetry violations directly manifest in the macroscopic response of the material and co-determine the multiferroic order giving rise to additional domain states. These usually hidden degrees of freedom become visible when non-homogenous fields are applied and condition for instance the second harmonic generation. Our study shows that incommensurabilities play a vital role in the discussion of the physical properties of multiferroics – they represent a key ingredient for further enhancing the functionality of this class of materials.

[1]This work was supported by the DFG through the SFB 608. D.M. thanks the AvH for financial support.

4:06PM D33.00009 Origin of the magnetic-field controlled polarization reversal in multiferroic $TbMn_2O_5$[1] , N. LEO, University Bonn, Germany, D. MEIER, UC Berkeley, USA, R.V. PISAREV, Ioffe Institute, St. Petersburg, Russia, S. PARK, S.-W. CHEONG, Rutgers University, USA, M. FIEBIG, University Bonn, Germany — The interplay of multi-dimensional complex magnetic order parameters leads to interesting effects like magnetically induced ferroelectricity. A particular interesting example is $TbMn_2O_5$ because of the associated magnetic-field controllable electric polarization. By optical second harmonic generation we show that the gigantic magnetoelectric effect originates in three independent ferroelectric contributions. Two of these are manganese-generated. The third contribution is related to the magnetism of the Tb^{3+} sublattice and has not been identified so far. It mediates the remarkable magnetic-field induced polarization reversal. This model is verified by experiments on the isostructural YMn_2O_5 where Y^{3+} ions are nonmagnetic and only two polarization contributions are present and no magnetoelectric coupling is observed. These results underline the importance of the $3d-4f$-interaction for the intricate magnetoelectric coupling in the class of isostructural RMn_2O_5 compounds.

4:18PM D33.00010 Electronic mechanism for ferroelectricity and strong magneto-electric coupling in charge-ordered multiferroics , GERARDO ORTIZ, LEONID ISAEV, Indiana University Bloomington, CRISTIAN BATISTA, T-4, LANL — We study magneto-electric phenomena in multiferroic materials, which exhibit ferroelectricity due to the charge ordering. Using rare-earth iron oxides as an example, we derive an effective model, which takes into account the Coulomb interaction, magnetic superexchange and spin-orbit effects, and is consistent with the recent X-ray absorption spectroscopy measurements in multiferroic $LuFe_2O_4$. Then we demonstrate, how the interplay between quantum fluctuations and geometric frustration stabilizes the charge and ferrimagnetic spin orderings. The strong coupling, due to the double-exchange mechanism, between these orders, leads to a large magneto-electric response. Our results provide a complete physical description of the magneto-electric properties of charge-ordered multiferroics.

4:30PM D33.00011 Colossal Magnetoelectric Effect with Competing Multiferroic and Weak-Ferromagnetic Phases , YOUNG JAI CHOI, Rutgers University, CHENGLIN ZHANG, University of Tennessee, NARA LEE, SANG-WOOK CHEONG, Rutgers University — From our investigation of magnetoelectric properties of $Eu_{0.75}Y_{0.25}MnO_3$, where a multiferroic phase competes with a weak ferromagnetic phase in magnetic fields, we found intriguing hysteretic behaviors of physical properties with variation of temperature and magnetic field. These hysteretic behaviors arise from the kinetic arrest/de-arrest processes of the first order magnetic transition, resulting in freezing or melting of a magnetoelectric glass state with the coexistence of two competing phases. We note that most of large magnetoelectric coupling effects in multiferroics are associated with the large change of polarization with magnetic fields, but the control of ferromagnetic-type magnetization by applying electric fields is most relevant to technological applications, which is scarcely observed. This important issue of mutual controllability is achieved in $Eu_{0.75}Y_{0.25}MnO_3$ utilizing dynamical modulations of the coexistence of two contraindicative phases, highly susceptible to the external perturbations such as electric and magnetic fields.

4:42PM D33.00012 Pairing and Self-Organization of Vortices and Antivortices in h-$YMnO_3$, S.C. CHAE, Y. HORIBE, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA, D.Y. JEONG, Department of Mathematics, Soongsil University, Seoul 156-743, Korea, S. RODAN, N. LEE, S.-W. CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA — Fascinating vortices and antivortices with ferroelectric domains were discovered in multiferroic hexagonal $YMnO_3$ [1]. Interlocking of ferroelectric and structural antiphase domain walls of h-$YMnO_3$ is one of the important ingredients for the topologically-nontrivial domain pattern formation. We have recently investigated the large-scale configuration of vortices and antivortices in h-$YMnO_3$ using selective chemical etching. Our results indicate the importance of pairing of vortices and antivortices, and provide valuable insights into understanding the self-organization mechanism of a zoo of vortices and antivortices. Furthermore, we have studied the response of the vortices and antivortices configuration to external stimuli such as external electric fields.

4:54PM D33.00013 Ferroelectricity driven by symmetric exchange striction in orthorhombic $HoMnO_3$, NARA LEE, YOUNG JAI CHOI, SANG-WOOK CHEONG, Rutgers University — Orthorhombic $HoMnO_3$ crystallizes in a distorted perovskite structure (space group *Pbnm*). It has been predicted that the spin configuration below the Néel temperature corresponds to a collinear E-type antiferromagnetic phase, which accompanies a large ferroelectric polarization originated from local oxygen distortions driven by exchange striction. In order to understand the exact nature of the E-type magnetism-driven ferroelectricity as well as the influence of Ho magnetism on ferroelectricity, we have performed comprehensive measurements of physical properties of the system, including magnetic susceptibility, dielectric constant, ferroelectric polarization and heat capacity with the variation of temperature and magnetic fields.

5:06PM D33.00014 Landau theory of composite domain walls and vortices in multiferroic hexagonal manganites , SERGEY ARTYUKHIN, U Groningen, KRIS DELANEY, NICOLA SPALDIN, UC Santa Barbara, MAXIM MOSTOVOY, U Groningen — Multiferroic materials with their coexisting magnetic and ferroelectric orders may find applications in memory devices. In hexagonal manganites, where electric polarization is induced by a periodic lattice distortion, ferroelectric and magnetic domain walls are firmly locked[1] even though electric polarization and spin ordering are decoupled in the bulk. Recent measurements showed that electric polarization changes sign at the boundaries of structural domains and revealed the existence of unusual vortices where six structural domains merge and the electric polarization changes sign six times around the defect.[2,3] We present a phenomenological theory of coupled lattice, charge and spin degrees of freedom in hexagonal manganites, which we use to calculate how electric polarization, structural distortions and magnetic ordering vary at the domain walls and vortices, and how the shape of these defects changes in an applied electric field.

5:18PM D33.00015 Analysis of the magnetic structure and spin exchange interactions of multiferroic $YBaCuFeO_5$ by first principles DFT calculations , JERRY BETTIS, YUEMEI ZHANG, C. LEE, MIKE WHANGBO — In the layered perovskites $RBaCuFeO_5$ (R = Y, Lu, Tm), the $CuFeO_9$ dumbbells made up of apex-sharing CuO_5 and FeO_5 square pyramids share their basal corners to form perovskite layers, and the resulting $CuFeO_5$ slabs are stacked along the c-direction. Recently, these compounds were found to exhibit ferroelectric polarization when a modulated magnetic component is superposed on their antiferromagnetic structure. To help understand this finding, we examined the spin exchange interactions between the Fe^{3+} (d^5) ions, between the Cu^{2+} (d^9) ions, and between the Fe^{3+} and Cu^{2+} ions on the basis of DFT+U and DFT+U+SOC calculations for $YBaCuFeO_5$. The ferroelectric polarization of $YBaCuFeO_5$ was also calculated for several modulated magnetic structures that were constructed based on the cone-model.

Session D34 DMP: Focus Session: Interfaces in Complex Oxides - Photo and Electric Field Induced Devices C141

2:30PM D34.00001 Band profiles of Mott-insulator/band-insulator heterointerfaces revealed by photocurrent and electromodulation spectroscopies[1] , MASAO NAKAMURA, Cross-Correlated Materials Research Group (CMRG), ASI, RIKEN, Wako, 351-0198, Japan — Heterointerfaces of Mott insulators provide a good laboratory to explore unprecedented electronic states induced by the strong electron correlation. Although a number of intriguing phenomena have been reported so far, their fundamental origins have not been fully addressed yet. This is partly because the interface band profile, which is one of the most basic knowledge to understand the interface electronic states, is still left to be unveiled. In this study, we have investigated in detail the interface band profiles of Mott insulators employing photocurrent and electromodulation spectroscopies as well as the conventional current-voltage and capacitance-voltage characterizations. We chose p-type ($LaMnO_3$ and La_2CuO_4) and n-type ($SrMnO_3$ and Sm_2CuO_4) as the Mott insulators and these are epitaxially connected to Nb doped $SrTiO_3$ (electron-doped band insulator). The photocurrent action spectra for these heterojunctions showed negligibly-small band reconstruction as well as the existence of band bending and discontinuity in the Mott insulators, which are of no salient discrepancy with the rigid-band picture valid in the interface of conventional semiconductors [1]. However, the electromodulation spectra clearly indicate the band reconstruction in the Mott insulators [2]. The results mean that the rigid-band picture is valid in the low carrier-density regime even in Mott-insulator/band-insulator interfaces, but the intentional charge modulation leads the electron correlation effect in the Mott insulators. This work was done in collaboration with A. Sawa, J. Fujioka, M. Kawasaki and Y. Tokura.

3:06PM D34.00002 Mechanisms for the enhancement of the lateral photovoltage in perovskite heterostructures

, KUI-JUAN JIN, CHEN GE, HUIBIN LU, GUOZHEN YANG, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — The mechanisms for greatly enhanced lateral photovoltaic effect in the perovskite oxide heterostructures are studied by solving *time-dependent* two-dimensional drift-diffusion equations self-consistently. By our calculations, we find that the lateral photovoltage of p type material is larger than that of n type material owing to the larger drift electric field induced in the p type material than that in the n type material. Moreover, the built-in electric field at the interface between the thin film and substrate can also enhance the lateral photovoltage. The above two mechanisms can well explain one-order-of-magnitude enhancement of the LPV in the perovskite heterostructures. In addition, we find that the materials with larger mobility ratio have stronger Dember effect. Such an understanding of the mechanisms for the enhancement of lateral photovoltage in oxide heterostructures should be useful in further designing of the structures of position-sensitive detectors and new THz sources.

3:18PM D34.00003 Electronic Transport in Ion Gel-Gated Strontium Titanate[1]

, MEN YOUNG LEE, JAMES R. WILLIAMS, DAVID GOLDHABER-GORDON, Stanford University, SIPEI ZHANG, C. DANIEL FRISBIE, University of Minnesota, BHARAT JALAN, JUNWOO SON, SUSANNE STEMMER, UC Santa Barbara — In recent years much attention has been focused on the structure and properties of two-dimensional electron liquids (2DEL) in complex oxide heterostrucutres and delta- doped layers. We report on the fabrication and measurements of mesoscopic devices of metal oxides, with focus given to an electric field-induced 2DEL at the surface of undoped strontium titanate (STO). We describe the design and fabrication of field- effect structures, gated with an ionic gel, and show the measurements of induced swings of charge carrier density in STO. Other transport properties of the 2DEL are studied by magneto-transport measurements at low temperature.

[1]Studies of 2DELs in oxides were supported by MURI program of the ARO (W911-NF-09-1-0398). Development of electrolytic gating was supported by the DOE, Office of Basic Energy Sciences as part of an Energy Frontier Research Center (DE-SC0001060).

3:30PM D34.00004 Origin of Electrical Conduction in Domain Walls of $BiFeO_3$ Thin Films[1]

, JAMES LEE, ANOOP DAMODARAN, LANE MARTIN, PETER ABBAMONTE, University of Illinois at Urbana-Champaign, HELEN HE, RAMAMOORTHY RAMESH, University of California at Berkeley — $BiFeO_3$ thin films grown on $DyScO_3$ substrates unexpectedly exhibit metallic electrical conduction at ferroelectric (FE) domain walls (DWs). Resonant x-ray scattering near Fe L and O K absorption edges was used to probe the electronic structure of these films. In-plane wavevectors of resonant Fe edge magnetic scattering, and non-resonant Cu K α diffraction peaks near the (0, 0, 1) $BiFeO_3$ Bragg peak, match the domain period observed by PFM. Fe edge scattering intensifies as the beam energy is tuned to Fe 2p $\rightarrow$ ligand-3d transitions. No O K charge scattering is observed. These results suggest that metallic conduction does not arise from charge build- up at the DWs from FE polarization discontinuities, but from the bandgap closing near DWs as the crystal symmetry changes from rhombohedral-like in the domain bulk to higher-symmetries.

3:42PM D34.00005 Sketched ferroelectric single-electron transistor[1]

, GUANGLEI CHENG, U. of Pittsburgh, PABLO SILES, Laboratório Nacional de Luz Síncrotron, Brazil, FENG BI, CHENG CEN, DANIELA BOGORIN, U. of Pittsburgh, CHUNG WUNG BARK, CHAD FOLKMAN, JAE-WAN PARK, CHANG-BEOM EOM, U. of Wisconsin-madison, GILBERTO MEDEIROS-RIBEIRO, HP labs, JEREMY LEVY, U. of Pittsburgh — Oxide heterostructures formed from ultrathin layers of $LaAlO_3$ grown on TiO_2-terminated $SrTiO_3$, combined with a reversible nanoscale patterning technique, provide a versatile platform for nanoscale control at the single-electron limit. Here we demonstrate the creation and characterization of "sketched" single-electron transistors made from ultrasmall (1-2 nm) quantum dots. Shell filling from N=0 up to N=2 electrons by single-electron tunneling is observed. Resonant tunneling can be controlled in a deterministic and non-volatile fashion by altering the ferroelectric polarization within the $SrTiO_3$ tunnel barrier. These single-electron devices may find use as nanoscale hybrid piezoelectric/charge sensors, and as elemental building blocks for solid-state quantum computation and quantum simulation platforms.

3:54PM D34.00006 Characterizing Interfacial Bipolar Resistive Switches at Low Temperatures

, STEPHEN TSUI, Department of Physics, California State University San Marcos — Bipolar resistive switching has continued to be a topic of interest for many years because of the phenomenon's potential for memory device applications. Typically, a voltage pulse is applied to a metal-oxide sandwich structure, which drives the sample into a nonvolatile high or low resistance state depending upon the pulse polarity. A great deal of research has already been performed on a diverse array of materials with several different characteristics. However, few systematic investigations have been carried out at low temperature, which may have application to "cryo-memory." In this work, we compare the room temperature and low temperature behaviors of switches formed at the interfaces between a silver electrode and CeO_2, Al_2O_3, and $Pr_{0.7}Ca_{0.3}MnO_3$, respectively. We investigate the performance of the switching in response to temperature change and characterize the electronic transport at the interfaces in order to identify the dominant physical processes at these various temperatures.

4:06PM D34.00007 Role of the surface in writing, erasing and maintaining nanostructures at the $LaAlO_3/SrTiO_3$ interface[1]

, FENG BI, DANIELA F. BOGORIN, CHENG CEN, JEREMY LEVY, University of Pittsburgh, CHUNG WUNG BARK, JAE-WAN PARK, CHANG-BEOM EOM, University of Wisconsin-Madison — Nanoscale control of the metal-insulator transition in $LaAlO_3/SrTiO_3$ heterostructures can be achieved using local voltages applied by a conducting AFM probe. The mechanism is believed to be governed by a "water cycle" in which the surface is locally charged via hydrogen passivation, resulting in high-resolution modulation doping of the $LaAlO_3/SrTiO_3$ interface.[2] A Kelvin probe image method is applied to study how water content in the gas environment influences such charge writing. Persistence tests are performed, in which the long-term behavior is studied by keeping the AFM-written nanostructures (nanowire and sketch FET[3]) in different ambient environments. The self-erasure process is particularly obvious in moisture environments, but is slowed greatly in dry inert gas and can be even halted under modest vacuum conditions ($\sim 10^{-3}$ Torr).

4:18PM D34.00008 Electric field-tuning of the magneto-transport of superconducting $LaAlO_3/SrTiO_3$ interfaces , STEFANO GARIGLIO, NICOLAS REYREN, ANDREA D. CAVIGLIA, CLAUDIA CANCELLIERI, DPMC, University of Geneva, TONI SCHNEIDER, Physikinstitut, University of Zurich, JEAN-MARC TRISCONE, DPMC, University of Geneva, DPMC, UNIVERSITY OF GENEVA TEAM, PHYSIKINSTITUT, UNIVERSITY OF ZURICH TEAM — $LaAlO_3/SrTiO_3$ interfaces display a complex phase diagram that can be explored by an electric field [1,2]. Using transport measurements in magnetic fields for different doping levels, we have characterized the superconducting phase diagram in three dimensions (temperature, electric and magnetic fields). Analyses of the anisotropy for parallel and perpendicular magnetic fields [3] reveal a two-dimensional superconducting state for all doping levels. Magneto-resistances in perpendicular fields present hallmarks of superconductor-insulator and superconductor-metal transitions depending on the doping level. We will discuss scaling analyses of the magnetic field-tuned transitions and the role of fluctuations and disorder in this two-dimensional superconductor.

4:30PM D34.00009 Cooper Pair Writing at the $LaAlO_3/SrTiO_3$ Interface[1] , CHENG CEN, DANIELA F. BOGORIN, University of Pittsburgh, CHUNG WUNG BARK, CHAD M. FOLKMAN, CHANG-BEOM EOM, University of Wisconsin-Madison, JEREMY LEVY, University of Pittsburgh — Superconducting semiconductors offer unique ways to exert electrostatic control over macroscopic quantum phases. The recently demonstrated nanoscale control over conductivity at the $LaAlO_3/SrTiO_3$ interface raises the question of whether nanoscale control over superconducting phases can be realized. Here we report low-temperature magnetotransport experiments on structures defined with nanoscale precision at the $LaAlO_3/SrTiO_3$ interface. A quantum phase transition is observed that is associated with the formation of Cooper pairs, but a finite resistance is observed at the lowest temperatures. Higher mobility interfaces exhibit larger Ginsburg-Landau coherence lengths, a stronger suppression of pairing by magnetic field as well as Shubnikov-de Haas oscillations. Cooper pair localization, spin-orbit coupling, and finite-size effects may factor into an explanation for some of the unusual properties observed.

[1]The work is supported by Department of Energy and State of Florida, NSF (DMR-0906443 and DMR-0704022), DOE (DE-FG02-06ER46327) and the Fine Foundation

4:42PM D34.00010 Electric and magnetic field control of superconducting transition at the $LaAlO_3/SrTiO_3$ heterointerface[1] , DMITRIY DIKIN, MANAN MEHTA, VENKAT CHANDRASEKHAR, Northwestern University, CHUNG WUNG BARK, CHAD FOLKMAN, CHANG-BEOM EOM, University of Wisconsin-Madison — We report on detailed measurements of the normal state-superconducting phase transition of the two-dimensional electron gas that develops at the LAO/STO interface as a function of gate voltage and magnetic field. We will discuss the specifics of the R versus T and the T-H phase diagrams for this superconductor and the potential origin of observed dissipation and hysteretic behavior. These data are analyzed in connection with magnetoresistance and Hall measurements.

[1]Funded by DOE through grant number DE-FG02-06ER46346.

4:54PM D34.00011 Metal-insulator transition at the interface of $LaAlO_3$ /$SrTiO_3$ induced by H_2O adsorption , YUN LI, School of Advanced Materials Science & Engineering, Sungkyunkwan University, Suwon, 440-746, Korea, JAEJUN YU, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea — We investigated the adsorption configurations at various H_2O coverages on the AlO_2 surface of n-type interface of 3 unit cell layers of $LaAlO_3$ (LAO) overlayer on $SrTiO_3$ (001) (STO) and the effects on the electronic properties at the interface by carrying out density-functional-theory calculations. For 0.25 monolayer (ML) and 0.5 ML coverages of H_2O the dissociation processes are barrierless. While for 1 ML coverage the mixing adsorption configuration comprising 0.5 ML molecular and 0.5 ML dissociated H_2O is most stable and the dissociation from fully molecular adsorption has to overcome 1 eV barrier. Insulator-metal transition at the n-type interface of (LAO)3/STO occurs as the coverage of dissociated H_2O reaches to 0.5ML. Insulator-metal transition at the interface can be realized by two ways: (1) changing H_2O coverage of from less than 0.5ML to equal to 0.5ML; (2) fixing H_2O coverage at 1ML and converting the adsorption configuration form fully molecular adsorption to mixing (0.5:0.5) adsorption. The second scheme can be utilized to realizing single-electron controlled nanoscale memory and switch.

5:06PM D34.00012 GHz operation of $LaAlO_3$/ $SrTiO_3$-based transistor[1] , PATRICK IRVIN, MENGCHEN HUANG, JEREMY LEVY, U. Pittsburgh, CHUNG WUNG BARK, CHAD M. FOLKMAN, CHANG-BEOM EOM, U. Wisconsin-Madison — Local modification of the metal-insulator transition of the $LaAlO_3$ /$SrTiO_3$ interface with a conducting-atomic force microscope (c-AFM) has resulted in a variety of electrical[2] and photonic[3] devices. Using a heterodyne measurement technique, we show that a sketch-based, nanoscale transistor ("SketchFET") can operate at frequencies in excess of 1 GHz. This demonstration of GHz functionality opens the door for new applications for oxide-based, rewritable nanoscale devices.

5:18PM D34.00013 Nanoscale control at the $LaAlO_3/SrTiO_3$ Interface grown on LSAT[1] , DANIELA BOGORIN[2], CHENG CEN, Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, PA 15260, CHUNG WUNG BARK, CHANG BEOM EOM, Department of Materials Science, University of Wisconsin-Madison, Madison, WI 53706, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, PA 15260 — The two-dimensional electron gas (2DEG) that forms at the interface between two semiconductors or between a semiconductor and oxide is currently the basis for some of the most useful electronic devices. We are able to control the 2DEG interface between $LaAlO_3/SrTiO_3$ with nanoscale precision and create transistors, nanodiodes and other nanostructures. Future scaling of oxide nanoelectronics requires scaling to wafer sizes larger than what can be provided from $SrTiO_3$. $(LaAlO_3)_{0.3}$–$(Sr_2AlTaO_3)_{0.7}$ (LSAT) substrates can allow for coherently strained $LaAlO_3/SrTiO_3$ heterostructures to be created. A sharp insulator to metal transition occurs at 8 uc $LaAlO_3$ thicknesses, in contrast to what is observed for unstrained $SrTiO_3$ substrates. We describe the properties of nanoscale structures created at the 2DEG interface of $LaAlO_3/SrTiO_3$ grown on LSAT wafers and compare them with structures grown on bulk $SrTiO_3$ substrates.

Monday, March 21, 2011 2:30PM - 5:30PM –
Session D35 DCMP: Topological Insulators: Theory II C140

2:30PM D35.00001 Antiferromagnetic topological insulators , ROGER S.K. MONG, ANDREW M. ESSIN, JOEL E. MOORE, University of California, Berkeley — We consider antiferromagnets breaking both time-reversal (Θ) and a primitive lattice translational symmetry ($T_{1/2}$) of a crystal but preserving the combination $S = \Theta T_{1/2}$. The S symmetry leads to a Z_2 topological classification of insulators, separating the ordinary insulator phase from the "antiferromagnetic topological insulator" (AFTI) phase. This state is similar to the "strong" topological insulator with time-reversal symmetry, and shares with it such properties as a quantized magnetoelectric effect. However, for certain surfaces the surface states are intrinsically gapped with a half-quantum Hall effect [$\sigma_{xy} = e^2/(2h)$], which may aid experimental confirmation of $\theta = \pi$ quantized magnetoelectric coupling. Step edges on such a surface support gapless, chiral quantum wires. In closing we discuss GdBiPt as a possible example of this topological class.

2:42PM D35.00002 Strong topological insulator phase in cold-atom systems , PETER P. ORTH, STEPHAN RACHEL, KARYN LE HUR, Yale University — With the recent technological advance of creating (electromagnetic) gauge fields for ultracold atoms, the fascinating prospect of realizing novel topological phases in these systems arises. Specifically, we consider spin-1/2 fermions on a square lattice under the influence of various experimentally feasible gauge fields. In two dimensions and if particles with different spin are exposed to magnetic fields in time-reversed directions, the system displays a quantum spin Hall ground state. We then study the influence of hopping into the third direction (2D-3D crossover), and in the three-dimensional system, we are able to identify a strong topological insulator phase. We further elaborate on the influence of the external trapping potential as well as the unambiguous detection of the topological phases.

2:54PM D35.00003 Quantum Hall Viscosity and the Torsional Response of Topological Insulators , ROBERT LEIGH, TAYLOR HUGHES, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — In this talk I will discuss a dissipationless viscosity that has recently appeared in connection with the quantum Hall effect. I will show that this can be connected to the response of time-reversal breaking 2+1-d topological insulators under a mechanical torque. The torque is represented by a coupling of the electronic degrees of freedom to external torsion fields and gives rise to a Chern-Simons-like term commonly seen in gravitational theories in the presence of spacetime torsion. I will discuss possible thought experiments which illustrate the effects and will briefly cover the extension to 3+1-d topological insulators.

3:06PM D35.00004 Topological BF field theory description of topological insulators , JOEL E. MOORE, University of California, Berkeley and Lawrence Berkeley National Laboratory, GIL YOUNG CHO, University of California, Berkeley — Topological phases of matter are described universally by topological field theories in the same way that symmetry-breaking phases of matter are described by Landau-Ginzburg field theories. We propose that topological insulators in two and three dimensions are described by a version of abelian BF theory. For the two-dimensional topological insulator or quantum spin Hall state, this description is essentially equivalent to a pair of Chern-Simons theories, consistent with the realization of this phase as paired integer quantum Hall effect states. The BF description can be motivated from the local excitations produced when a π flux is threaded through this state. For the three-dimensional topological insulator, the BF description is less obvious but quite versatile: it contains a gapless surface Dirac fermion when time-reversal-symmetry is preserved and yields "axion electrodynamics", i.e., an electromagnetic $E \cdot B$ term, when time-reversal symmetry is broken and the surfaces are gapped. Just as changing the coefficients and charges of 2D Chern-Simons theory allows one to obtain fractional quantum Hall states starting from integer states, BF theory could also describe (at a macroscopic level) fractional 3D topological insulators with fractional statistics of point-like and line-like objects. Preprint available at http://arxiv.org/abs/1011.3485.

3:18PM D35.00005 Detecting 3d Non-Abelian Anyons via Adiabatic Cooling , SEIJI YAMAMOTO, National High Magnetic Field Lab and FSU Dept of Physics, MICHAEL FREEDMAN, Microsoft Research, Station Q, KUN YANG, National High Magnetic Field Lab and FSU Dept of Physics — Majorana fermions lie at the heart of a number of recent developments in condensed matter physics. One important application is the realization of non-abelian statistics and consequently a foundation for topological quantum computation. Theoretical propositions for Majorana systems abound, but experimental detection has proven challenging. Most attempts involve interferometry, but the degeneracy of the anyon state can be leveraged to produce a cooling effect, as previously shown in 2d. We apply this method of anyon detection to the 3d anyon model of Teo and Kane. Like the Fu-Kane model, this involves a hybrid system of topological insulator (TI) and superconductor (SC). The Majorana modes are localized to anisotropic hedgehogs in the order parameter which appear at the TI-SC interface. The effective model bears some resemblance to the non-Abelian Higgs model with scalar coupling as studied, for example, by Jackiw and Rebbi. In order to make concrete estimates relevant to experiments, we use parameters appropriate to Ca doped Bi_2Se_3 as the topological insulator and Cu doped Bi_2Se_3 as the superconductor. We find a temperature window in the milli-Kelvin regime where the presence of 3d non-abelian anyons will lead to an observable cooling effect.

3:30PM D35.00006 Topological invariants of adiabatic cycles of Bloch Hamiltonians[1] , RAHUL ROY, Oxford University — Invariants are constructed for various adiabatic cycles of Bloch Hamiltonians and discuss their physical implications. Many of these cycles lead to a pumping of fermions, but in other cases, the physical implications are more subtle. I also discuss the construction of these invariants for insulators in the various symmetry classes and periodicities in the table of these invariants.

[1]EPSRC

3:42PM D35.00007 On the stability of surface states in topological insulators , YOUNG HOON MOON, LEONID ISAEV, GERARDO ORTIZ, Indiana University Bloomington — The existence of robust surface/edge states is arguably a fingerprint of topological insulators. These states are protected against scattering by time-reversal invariant perturbations, and lead to dissipationless transport even at high temperatures. This characteristic behavior is believed to be quite insensitive to the properties of the surface of a particular sample. We investigate the above conjecture by considering the stability of edge states with respect to the *time-reversal invariant* surface perturbations in several models of topological insulators. We demonstrate that in certain regimes the surface spectrum is modified quite dramatically. In particular, the number of edge states, which cross the Fermi level inside the bulk band gap, is very sensitive to the properties of the surface. Our results can be of great importance for future transport measurements in topological insulators.

3:54PM D35.00008 Topological quantization in units of the fine structure constant , JOSEPH MACIEJKO, Stanford University, XIAO-LIANG QI, Stanford University and Microsoft Research, Station Q, H. DENNIS DREW, University of Maryland, SHOU-CHENG ZHANG, Stanford University — Fundamental topological phenomena in condensed matter physics are associated with a quantized electromagnetic response in units of fundamental constants. Recently, it has been predicted theoretically that the time-reversal invariant topological insulator in three dimensions exhibits a topological magnetoelectric effect quantized in units of the fine structure constant $\alpha = e^2/\hbar c$. In this Letter, we propose an optical experiment to directly measure this topological quantization phenomenon, independent of material details. Our proposal also provides a way to measure the half-quantized Hall conductances on the two surfaces of the topological insulator independently of each other.

4:06PM D35.00009 Refraction and interference of electrons on the topological insulator surface , RYUJI TAKAHASHI, Tokyo Institute of Technology, SHUICHI MURAKAMI, Tokyo Institute of Technology, and PRESTO, JST — We theoretically study electron transport on the topological insulator surface, in analogy with optics. The surface states are represented by spinors, unlike optics, and therefore different behaviors from those in optics are expected. First, we consider the refraction phenomena at the boundary between the surfaces of two different topological insulators, where the velocities of the surface states are different. We compare its transmission and refraction coefficients with optics. Furthermore, we discuss the case when the velocities of the surface states of the two topological insulators have opposite signs. Second, we study interference phenomena on the surface states. The result shows that if the detector is very far from the scatterer or the slit, the interference is asymptotically similar to ordinary two-dimensional scattering problems. We also study the spin directions of scattered wave due to the surface interference phenomena.

4:18PM D35.00010 Gauge field fluctuations in three-dimensional topological Mott insulators[1] , WILLIAM WITCZAK-KREMPA, TING PONG CHOY[2], University of Toronto, Canada, YONG BAEK KIM, University of Toronto, Canada & Korea Institute for Advanced Study, Korea — We discuss the low-energy properties of 3D topological Mott insulators that can be viewed as strong topological insulators of spinons interacting with a 3D gauge field. The low-energy behavior of such systems is dominated by gapless surface spinons (Dirac fermions) coupled to bulk gauge bosons. We find that a dimensional crossover from 3D to 2D in the gauge field fluctuations may occur as the system's thickness and/or temperature is varied. In the thin sample limit, the gauge field fluctuations effectively become 2D and the problem becomes analogous to the standard 2D spinon-gauge field theory. In the 3D limit, the bulk gauge field fluctuations lead to a novel low-energy theory for the coupled system that is more controlled than in the 2D regime. We discuss various experimental signatures such as the heat capacity scaling as T ln(1/T) as well as modified RKKY interactions on the surface.

4:30PM D35.00011 Symmetry aspects of localized Dirac fermions within topological defects[1] , CHI-KEN LU, Department of Physics, Simon Fraser University, IGOR HERBUT, Department of Physics, SFU — We study the conditions for the existence of zero-energy bound states within topological defects in various insulating and superconducting order parameters for Dirac fermions in graphene and topological insulators. In particular, we discuss several physically relevant realizations of the "Dirac vortex" which include the finite chemical potential and Zeeman terms, and the orbital magnetic fields, and present some explicit solutions for the zero-modes. The crucial role in our discussion is assumed by the antilinear symmetry between the positive and negative parts of the energy spectrum. The effects of the orbital symmetry of the defect's underlying order on the zero-modes are also considered.

4:42PM D35.00012 Massive Dirac Fermion on the Surface of a Magnetically Doped Topological Insulator , YULIN CHEN, SLAC National Accelerator Laboratory, JIUN-HAW CHU, JAMES ANALYTIS, ZHONGKAI LIU, KYUSHIRO IGARASHI, HSUEH-HUI KUO, XIAOLIANG QI, SUNG-KWAN MO, ROBERT MOORE, DONGHUI LU, MAKOTO HASHIMOTO, TAKAO SASAGAWA, SHOUCHENG ZHANG, IAN FISHER, ZAHID HUSSAIN, ZHI-XUN SHEN — Insulating massive Dirac fermion state is a novel state of topological insulators in which the massless surface Dirac fermion becomes massive due to the braking of time reversal symmetry. In this state a gap develops at the Dirac point, with the Fermi energy resides inside both the surface and bulk gaps. By introducing magnetic dopants into three dimensional topological insulator Bi_2Se_3 to break the time reversal symmetry, we successfully observed the formation of massive Dirac fermion on the surface, with the Dirac gap magnitude tunable by magnetic dopant concentration. Furthermore, by precise control of simultaneous magnetic and charge doping, we successfully position the Fermi level inside the Dirac gap, thus realizing the much sought after insulating massive Dirac fermion state. This discovery paves the way for realizing striking topological phenomena and testing profound theoretical predictions.

4:54PM D35.00013 Exotic Effects of Spin-Flip Scattering on Massive Dirac Fermions[1] , SHENGYUAN YANG, ZHENHUA QIAO, The University of Texas at Austin, YUGUI YAO, JUNREN SHI, Institute of Physics, Chinese Academy of Sciences, QIAN NIU, The University of Texas at Austin — We investigate the effects of spin-flip scattering on the Hall transport and spectral properties of massive Dirac fermions. We find that in the weak scattering regime, the Berry curvature distribution is dramatically compressed in the electronic energy spectrum, becoming singular at band edges. As a result the Hall conductivity suffers a sudden jump (or drop) of $e^2/2h$ when the Fermi energy sweeps across the band edges, and otherwise is a constant quantized in units of $e^2/2h$. In parallel, spectral properties such as the density of states and spin polarization are also greatly enhanced at band edges. Possible experimental methods to detect these effects are discussed.

[1]This work is supported by NSFC (10974231) (Y.Y.), DOE (DE-FG02-02ER45958) and Texas Advanced Research Program (Q.N.).

5:06PM D35.00014 Weak indices and dislocations in general topological band structures , YING RAN, Boston College — It has recently been shown that crystalline defects - dislocation lines - in three dimensional topological insulators, can host protected one dimensional modes propagating along their length. We generalize this observation to the case of topological superconductors and other insulators of the Altland Zirnbauer classification, in d=2,3 dimensions. In general, protected dislocation modes are controlled by the topological indices in (d-1) dimensions. This is shown by relating this feature to characteristic properties of surface states of these topological phases. This observation also allows us to constrain these surface states properties, which is illustrated by an addition formula for (d-1) and (d-2) indices of a topological superconductor.

5:18PM D35.00015 Topological insulator in a non-Abelian lattice model and anyonic fermions in two-body color code model[1] , MEHDI KARGARIAN, GREGORY A. FIETE, Department of Physics,The University of Texas at Austin — We investigated topological phases in several decorated lattices such as the square- octagon and spin ruby lattices. The underlying models can be potentially simulated in optical lattices or in multi-orbital transition metal oxides. In the square-octagon lattice we apply a set of non-Abelian gauge fields to modulate the hopping between sites. Inversion symmetric fields open a gap and the model realizes topological band insulating phase. If the inversion symmetry is broken, a quantum phase transition between phases with different quantum orders takes place. These phases are characterized by number of Dirac nodes and the associated winding numbers. We also probe the topological phases in the spin ruby lattice with emerging anyonic fermions coupled to nontrivial gauge fields associated with the local symmetry of the model. And we further characterize our results by topological entanglement entropy and entanglement spectrum. M. Kargarian and G. A. Fiete, Phys. Rev. B 82, 085106 (2010).

Session D36 GERA: Photovoltaics: Nanostructured Materials C142

2:30PM D36.00001 ABSTRACT WITHDRAWN –

2:42PM D36.00002 Study of photo induced optical transparency of I/I3 redox couple in Dye Sensitized Solar Cells

, JOSEF VELTEN, JULIA BYKOVA, JAVIER CARRETERO-GONZALEZ, ELIZABETH CASTILLO MARTINEZ, ANVAR ZAKHIDOV — Dye sensitized solar cells (DSCs) are an alternative to the standard silicon solar cell, consisting of a photoelectrochemical cell that has a light absorbing working electrode, a I-/I3- charge mediator and a counter electrode for reduction of I3- back to I-. Tradtionally, this counter electrode is composed of a few nanometer layer of platinum deposited onto transparent conductive oxide glass. Our work has focused on using structured carbon materials as a counter electrode. Earlier work focused on the use of carbon nanotubes, both single and multiwalled as a replacement for this platinum counter electrode material. Recent work has moved into using 2 dimensional carbon materials, such as graphene flakes and graphene ribbons. With the use of graphene ribbons we have discovered a unique effect that has not been reported for DSCs: under operating condition of AM 1.5 light, the charge mediating electrolyte undergoes a change in its absorption profile. We conclude that this phenomenon must arise from the structure of the graphene ribbons. This process has been demonstrated to be completely reversible, and shows no degradation to the DSC's operation. This presentation will also discuss the application of this phenomenon in the use of inverted DSCs and hybrid tandem cells.

2:54PM D36.00003 Dye Sensitized Solar Cells with bilayer Multi/Single Carbon Nanotubes

, ZHARKYNAY KUANYSHBEKOVA, ANVAR ZHAKHIDOV, Nano Tech Institute UTD — In this presentation, we demonstrate the fabrication of dye sensitized solar cells using bilayers of MWCNT coated by SWCNT on top. Each DSC cell uses a typical titania photoelectrode deposited onto a transparent window electrode with photosensitive dye absorbed on the surface of the TiO_2.Adding SWCNT layer to MWCNT increased short circuit current from 10 to 14 mA/cm^2. Conventional DSC uses couterelectrode with Pt coated FTO, the Pt layers play role of catalyst for better charge transfer rate from electrolyte. In our bilayer electrode MWCNT sheet play a role a good conductor (similar to FTO), while SWCNT provide better catalytic properties for charge transfer (similar to Pt). The relatively high obtained efficiency of DSS ($\sim$7-8%) cell is determined by the high generated photocurrent, which is comparable to the reference DSS made by same method using the standard PT catalyst. However, the fill-factor of the device is still low ($\sim$0.4-0.5). Therefore further improvement of electrical conductivity of these carbon based electrodes is under investrigation with CNT sheets to achieve high performance device. We acknowledge the help with transparent SWCNTs made in A.Nasibullin of Aolto University (Finland).

3:06PM D36.00004 Equivalent Circuit Description of Non-compensated n-p Codoped TiO2 as Intermediate Band Solar Cells(IBSCs)1[1]

, TIAN-LI FENG, YI XIA, GUANG-WEI DENG, FENG-CHENG WU, PING CUI, HAIPING LAN, U of Sci. and Tech. of China, ZHENYU ZHANG, Oak Ridge Nat.Lab, U of Tennessee, U of Sci. and Tech. of China — The novel concept of non-compensated n-p codoping has made it possible to create tunable intermediate bands in the intrinsic band gap of TiO2 [1] as a promising materials for developing IBSCs [2]. Here we investigate the quantum efficiency of such IBSCs with or without current extracted from the intermediate bands (IBs). Using the ideal equivalent circuit model, we find that the maximum efficiency of 57% in the first case and 53% in the second are both much higher than the Shockley-Queisser limit. We also obtain various key quantities of the circuits, allowing us to simplify the IBSCs into an ordinary cell with an intrinsic resistance, a useful step in realistic development of TiO2 based solar cells invoking device integration. These equivalent circuit results are also compared with the efficiencies obtained directly from consideration of electron transition between the energy bands, and both approaches reveal the intriguing existence of double peaks in the maximum efficiency as a function of the location of IBs.

3:18PM D36.00005 Fluctuation-Induced Tunneling Conductivity in TiO_2 Nanoparticle Thin Films[1]

, STEVEN J. KONEZNY, CHRISTIAAN RICHTER, ROBERT C. SNOEBERGER III, ALEXANDER R. PARENT, GARY W. BRUDVIG, CHARLES A. SCHMUTTENMAER, VICTOR S. BATISTA, Yale University — We integrate temperature-dependent dark DC conductivity measurements and theoretical modeling to elucidate the mechanism of electron transport in nanoporous TiO_2, a common photoanode material for dye-sensitized solar cells (DSSCs) and solar photocatalysis. We show that fluctuation-induced tunneling conduction through contact junctions between sintered TiO_2 nanoparticles can account for the temperature dependence over the entire temperature range studied. We find quantitative agreement between experimental and calculated conductivities, which span over four orders of magnitude and change with decreasing temperature from thermally activated to temperature-independent. The reported results suggest that efforts to optimize charge transport in nanoporous TiO_2 thin films as a means of improving the overall efficiency of DSSCs and solar photocatalysis should focus on fabrication conditions that optimize the properties of the contact junctions between sintered TiO_2 nanoparticles.

[1]The authors acknowledge support from DOE (NERSC supercomputer time; DE-FG02-07ER15909; DE-PS02-08ER15944) and NSF (Graduate Research Fellowship to ARP; ECCS-0404191; CHE 0911520).

3:30PM D36.00006 ZnO Nanoparticles and Nanowire Arrays with Liquid Crystals for Photovoltaic Apprications[1]

, LOURDES SALAMANCA-RIBA, NICHOLAS WEADOCK, LUZ MARTINEZ-MIRANDA, University of Maryland — Liquid crystals are small monodisperse molecules with high mobilities and are easy and cheap to process. In addition, some of their phases exhibit molecular orientation that can provide a path for the electrons, or holes, to move from one electrode to the other. We have mixed a smectic A liquid crystal (8CB) with varying concentrations of ZnO nanoparticles of $\sim$5 nm in diameter and have observed a photovoltaic effect as a function of the concentration of ZnO. The liquid crystal is believed to enhance the alignment of the nanoparticles and aid in the diffusion of electrons through the particles to the collection electrode. We have also made PV cells of ZnO nanowire arrays grown on Au layers on Si substrates. The nanowire arrays are covered with 8CB liquid crystal for hole conduction. We compare the light absorption of the PV cells as a function of wavelength of the light for the ZnO nanoparticle and the ZnO nanowire cells. We present a detailed study of the structure of the two systems.

3:42PM D36.00007 Intermediate Band Gap Solar Cells: The Effect of Resonant Tunneling on Delocalization , REID WILLIAM, DOTY MATHEW, U. Delaware, SHILPA SANWLI, U.Delaware, DAN GAMMON, ALLAN BRACKER, NRL — Quantum dots (QD's) have many unique properties, including tunable discrete energy levels, that make them suitable for a variety of next generation photovoltaic applications. One application is an intermediate band solar cell (IBSC); in which QD's are incorporated into the bulk material. The QD's are tuned to absorb low energy photons that would otherwise be wasted because their energy is less than the solar cell's bulk band gap. Current theory concludes that identical QD's should be arranged in a superlattice to form a completely delocalized intermediate band maximizing absorption of low energy photons while minimizing the decrease in the efficiency of the bulk material. We use a T-matrix model to assess the feasibility of forming a delocalized band given that real QD ensembles have an inhomogeneous distribution of energy levels. Our results suggest that formation of a band delocalized through a large QD superlattice is challenging; suggesting that the assumptions underlying present IBSC theory require reexamination. We use time-resolved photoluminescence of coupled QD's to probe the effect of delocalized states on the dynamics of absorption, energy transport, and nonradiative relaxation. These results will allow us to reexamine the theoretical assumptions and determine the degree of delocalization necessary to create an efficient quantum dot-based IBSC.

3:54PM D36.00008 Development of High Efficient Flexible Dye-Sensitized Solar Cells[1] , XIAOJUAN FAN, Marshall University — We are developing a low cost and easy process to fabricate double-layer porous metal oxide thin films on flexible substrates for high performance dye-sensitized solar cells (DSSCs**).** The research addresses on the formulation of TiO_2 precursor to create smooth and continuous porous thin films on large size plastic or metal foil substrates enabling excellent adhesion, robust mechanics, and chemical stability. A second layer built on the underline porous nanocrystalline TiO_2 thin films are primarily used as bedding to receive more organic sensitizers. A variety of blending of polymer and Ti alkoxide precursors at different concentrations has been studied. After depositing the mixture on the substrates such as Al foils, samples are annealed to remove polymer residues leading to a porous nanocrystalline structure. Photo-electricity conversion efficiency of the fabricated solar cells will be tested under one sun illumination.

4:06PM D36.00009 A novel nano-structured GaAs solar cell , DONG LIANG, ANJIA GU, YIJIE HUO, Stanford University, JINGZHOU YAN, OEpic Semiconductors Inc., SHUANG LI, ERIK GARNETT, EVAN PICKETT, YANGSEN KANG, MEIYUEH TAN, ANTONIO XAVIER CERRUTO, JIA ZHU, CHING-MEI HSU, YAN YAO, Stanford University, MAJID RIAZIAT, OEpic Semiconductors Inc., YI CUI, JAMES S. HARRIS, Stanford University — In this presentation, we will demonstrate a novel solar cell with nano-structured dense arrays of single crystal GaAs conformally grown on nanopillar templates with wafer-scale uniformity. The template is prepared via plasma enhanced etching with a monolayer of SiO_2 nanospheres as a mask followed by wet chemical etching. The GaAs p-n junction with an AlGaAs passivation window layer is grown via metal-organic chemical vapor deposition (MOCVD). The rectangular shape of the nano single crystal GaAs reveals anisotropic lateral growth rates of GaAs along (011) and (01$\underline{1}$) directions, which can be engineered by tuning the AsH_3 flow and temperature during growth. Optical absorption measurements show the outstanding light trapping properties of the nano-structured cell, which agree with the simulation results. I-V characteristics show an efficiency of 1.67% for the nano GaAs solar cell, which is 15% higher than its planar control cell with the same thickness of 200nm. The efficiency is the highest among all the large area GaAs nanowire core-shell solar cells reported in literature by 2010.

4:18PM D36.00010 Highly Efficient Dye Sensitized Solar Cells based on Free-Standing Titania Nanotube[1] , CHAEHYUN KIM, SUNGJIN KIM, ALEXANDER CARTWRIGHT, HAO ZENG, SUNY at Buffalo — Dye sensitized solar cells (DSSC) attract great attention due to their respectable efficiency with very low fabrication cost, good performance under diffuse light conditions and ability to be fabricated on flexible substrates. Its main efficiency limiting factor is the random hopping of electrons within the titania nanoparticle network, which causes carrier trapping and recombination. The charge transport and collection can be enhanced by employing ordered nanostructures such as nanowire or nanotube arrays. However, nanowire/nanotube based DSSCs with efficiencies higher than those of conventional DSSCs have yet to be demonstrated. In this work, we report the fabrication of DSSCs using highly crystalline free-standing titania nanotube arrays. The high crystallinity leads to high electron mobility and diffusion length, allowing thick nanotube films to be used for improving the long wavelength light absorption. This greatly enhances the photocurrent and power conversion efficiency as compared to that of nanotube DSSCs in earlier studies.

[1]Work supported by NSF DMR-0547036.

4:30PM D36.00011 Nanowire electrodeposition for advanced photovoltaics , ERIK MENKE, JUSTIN HUJDIC, SOMNATH GHOSH, University of California, Merced — According to the Department of Energy's "Basic Research Needs for Solar Energy Utilization" report, there are a number of fundamental scientific issues that need to be addressed for nanostructure based solar cells, including: a. Control of nanoarchitecture b. Light harvesting c. Control of charge separation and recombination d. Control of charge carrier transport to the contacts Here, I will describe how lithographically patterned nanowire electrodeposition (LPNE) can address these issues by discussing the synthesis of high-density semiconductor nanowire arrays, as well as their optical and electronic properties. This talk consists of three parts. Part 1 presents a brief overview of how LPNE, essentially the combination of photolithography and electrodeposition, can be used as a general method to prepare high-density nanowire arrays. Part 2 demonstrates this method specifically for CIS/CdS core-shell nanowire arrays by discussing the electrodeposition of the nanowire arrays as well as the physical and chemical properties of the resulting nanowires. Finally, part 3 presents the optoelectronic properties of the resulting nanowire arrays and their potential application as solar cells.

4:42PM D36.00012 Shedding Light on Solar Cells with Synchrotron Radiation , FRANZ HIMPSEL, PETER COOK, PHILLIP JOHNSON, UW Madison, XIAOSONG LIU, WANLI YANG, ALS, ANGEL RUBIO, JUAN-MARIA GARCÍA-LASTRA, ENRIQUE ORTEGA, CELIA ROGERO, RUBEN GONZALEZ-MORENO, Univ. San Sebastian, ENEKO AZACETA, RAMON TENA-ZAERA, CIDETEC, San Sebastian, ELENA GUILLEN, JUAN ANTA, Univ. Sevilla — X-ray absorption and photoelectron spectroscopy with synchrotron radiation are used to systematically determine the energy levels of molecules for dye-sensitized solar cells (including porphyrins and phthalocyanines [1-3]). N 1s absorption spectra combined with theoretical modeling provide the unoccupied molecular orbitals and the charge transfer between the central metal atom and the surrounding N atoms. Metal 2p-to-3d spectra provide the oxidation state of the metal. Fe and Mn, which occur frequently in biological analogs, easily change their oxidation between $+3$ and $+2$. Some dyes interact with the electronic states of nano-structured ZnO acceptor electrodes, causing a change in the electronic states of the ZnO or the dye.

4:54PM D36.00013 Dye Sensitized Solar Cells Using Freestanding TiO2 Nanotube Arrays , XUKAI XIN, JUN WANG, Iowa State University, LEI ZHAO, Iowa State Univeristy, ZHIQUN LIN, Iowa State University — A TiO2 photoanode was prepared by depositing TiO_2 nanoparticle on the FTO glass followed by placing TiO_2 nanotube arrays on the top of TiO_2 nanoparticle film. The resulting TiO_2 nanotube/nanoparticle photoanode was sensitized with N719 dye after $TiCl_4$ treatment and exposure to O_2 plasma. The resulting dye sensitized solar cell (DSSC) showed that the highest DSSC power conversion efficiency of 8.02% and 7.00% were yielded when a 20 μm thick TiO_2 nanoparticle and a 13/7 μm TiO_2 nanoparticle/nanotube were used as photoanode, respectively. The I$\sim$V curve analysis suggested that the nanotubes had better electron transport pathway but lower electron generation. Future work will be focused on increasing the dye loading of nanotubes to improve the power conversion efficiency.

5:06PM D36.00014 Dye-sensitized solar cells employing TiO2 nanotube arrays modified by hydrothermal process , MEIDAN YE, 5152940804, CHANGJIAN LIN, ZHIQUN LIN — Dye sensitized solar cells (DSSCs) based on TiO2 nanotube photoanode prepared by a facile combination of electrochemical anodization and hydrothermal process exhibited a remarkable performance. Well-ordered and smooth TiO2 nanotube arrays fabricated by a two-step anodic oxidation were subjected to hydrothermal process, thereby creating roughness on the surface of nanotubes and leading to increased dye loading. Subsequently, the resulting nanotubes were used to fabricate DSSC in backside illumination mode, yielding a significantly high power conversion efficiency of 7.12% that was further increased to 7.75% upon oxygen plasma treatment.

5:18PM D36.00015 Nanostructured Thin Film Solar Cells: A Heterojunction of PbS Colloidal Quantum Dots and TiO2 Nanopillars , HO-CHEOL KIM, IBM Almaden Research Center, ILLAN KRAMER, University of Toronto, JOHN BASS, TEYA TOPURIA, LESLIE KRUPP, PHILIP RICE, IBM Almaden Research Center, RATAN DEBNATH, LUKASZ BRZOZOWSKI, LARISSA LEVINA, EDWARD SARGENT, University of Toronto — Colloidal quantum dot (CQD) has been recognized as a promising solar cell material that offers tunable band gap and inexpensive solution process. Recent report demonstrated the power conversion efficiency (PCE) of above 5% (AM 1.5) using thin films of PbS CQDs and TiO_2 nanoparticles. This so-called depleted-heterojunction-CQD solar cells have overcome limitations of CQD Schottky devices and promised potential for further improvement of solar cell performance. In this paper, we report the effect of nanostructures of TiO_2 on the performance of heterojunction CQD solar cells. Well-defined nanopillars of TiO_2 were prepared on top of F:SnO_2 substrate using micro-transfer molding technique. TiO_2 nanopillars of 70 nm in diameter (half-width), 340 nm in height and 275 nm in center-to-center distance were used for subsequent layer-by-layer spin coating of PbS CQD. PCE of $>$5% was measured for the nanopillar solar cells without extensive optimization. Detailed studies on the microstructure of materials, surface properties, optical and electrical properties and optimization will be discussed along with performance of flat TiO_2-PbS CQD solar cells.

Monday, March 21, 2011 2:30PM - 5:30PM –

Session D37 DMP: Focus Session: Graphene Structure, Dopants, and Defects: Strain Engineering I C146

2:30PM D37.00001 Strain Engineering in Graphene[1] , ANTONIO CASTRO NETO[2], Department of Physics, Boston University — Graphene is a unique example of a one atom thick metallic membrane. Hence, graphene brings together properties of soft and hard condensed matter systems. The elementary electronic excitations in graphene, the Dirac quasiparticles, couple in a singular way to structural distortions in the form of scalar and vector potentials. Therefore, graphene has an effective electrodynamics where structural deformations couple to the Dirac particles at equal footing to electric and magnetic fields. This so-called strain engineering of the electronic properties of graphene opens doors for a new paradigm in terms of electronic devices, where electronic properties can be manipulated at will using its membrane-like properties.

3:06PM D37.00002 Optical absorption and giant Faraday rotation in strained graphene , VITOR PEREIRA, National University of Singapore, NUNO M.R. PERES, RICARDO M. RIBEIRO, Universidade do Minho, Portugal, ANTONIO CASTRO NETO, Boston University — Slightly doped or undoped graphene is characterized by an universal optical absorption coefficient of $\pi\alpha$ (nearly 2%), which is constant in a frequency band spanning the near UV, down to the far IR. Strain-induced anisotropy breaks this universality, while keeping the optical response constant up to energies close to the van-Hove singularity of the spectrum. This allows for the possibility of exploring the photoelasticity of graphene towards the development of atomically thin, broadband optical elements. We show, and analytically quantify, the amount of polarization rotation and dichroism expected for uniaxially strained graphene. The effect can be used to tailor the optical response of graphene or, conversely, to use light to measure the amount and direction of uniaxial strain in graphene for sensing applications. Exposure to an external magnetic field brings about the Faraday effect, which is shown to be extremely large in comparison with conventional materials. Moreover, the sharp enhancement of Faraday rotation and absorption at the field and stain tunable cyclotron frequency opens the possibility of tunable broadband optics in atomically thin transparent membranes.

3:18PM D37.00003 Electron-electron interactions in strained graphene , ANAND SHARMA, VALERI KOTOV, University of Vermont — We present a theoretical study on the effects of electron-electron interactions under an applied weak uni-axial strain in graphene, described as anisotropic Dirac liquid. We calculate the electron self-energy using perturbation theory in both the Coulomb interactions and strain, and find that near the Dirac point the self-energy exhibits logarithmic singularity structure, similarly to an un-deformed graphene. We present results for the renormalization of the electronic anisotropy by using first the bare Coulomb interaction, as well as the random-phase approximation, which takes into account the anisotropic nature of the vacuum polarization. The mutual interplay of interactions and strain can provide a route towards understanding the role of correlations in graphene, which so far have been quite elusive in the un-deformed case.

3:30PM D37.00004 Scattering from localized strain profiles in graphene: effects on conductance , MATTHEW BARR, Harvard University, ERIC HELLER, HELLER GROUP TEAM — Graphene has attracted significant attention for, amongst other properties, its Dirac-like quasiparticles and long coherence length. In the ballistic regime, we theoretically investigate the scattering properties of localized strain profiles. Manipulating strain in graphene has been proposed as a novel method of shaping graphene devices; modulated hopping parameters effectively introduce vector potentials equivalent to pseudomagnetic fields up to 300T [1]. We determine the localized potential and scattering parameters of several such "bubbles"; with this information we calculate the effects on conductance in both valleys of introducing one or many such impurities.

[1] N. Levy, S. A. Burke, K. L. Meaker, M. Panlasigui, A. Zettl, F. Guinea, A. H. Castro Neto and M. F. Crommie, Science 30, July 2010

3:42PM D37.00005 Ab-initio study of the Kohn anomalies in strained graphene[1] , M.E. CIFUENTES-QUINTAL, R. DE COSS, Department of Applied Physics, Cinvestav-Merida, Mexico, O. DE LA PEÑA-SEAMAN, R. HEID, K.-P. BOHNEN, Institute for Solid State Physics, Karlsruhe Institute of Technology, Germany — Recent experimental studies have show that the electronic and vibrational properties of graphene can be modulated by means of strain. However, there are not studies on strain effects on the Kohn anomalies, which is a principal key to understand the electron phonon coupling in graphene. In this work we have studied the phonon band structure of graphene under biaxial and uniaxial strain using the mixed basis pseudopotential method, within the framework of the density functional perturbation theory. For tensile/compressive biaxial strain, we found an increasing/decreasing behavior on the slop of the phonon frequencies close to Kohn anomalies. Under uniaxial strain, the two highest optical branches show a discontinuity in the frequency derivative at gamma point, instead of only one branch like in the biaxial and unstrained case. The present results suggest that the electron-phonon coupling in graphene can be modulated via strain.

3:54PM D37.00006 Graphene rubber band: suspended graphene sheets with controlled uniaxial strain , ZENGHUI WANG, DAVID HUTCHISON, CARLOS RUIZ-VARGAS, PINSHANE HUANG, SUNIL BHAVE, DAVID MULLER, JIWOONG PARK, Cornell University — The recent advances in growth and transfer techniques of CVD graphene have made it an excellent candidate for making electrical and mechanical devices, especially at larger scale than with exfoliated graphene flakes. Nevertheless, the electrical, electromechanical and optomechanical properties of CVD graphene need to be further characterized before one can make full use of this 2D material. Here, we study the properties of CVD graphene under well controlled uniaxial strain. We fabricate devices with adjustable-width gaps actuated by comb drives, and transfer CVD graphene sheets onto these gaps. We study the slipping, straining, and breaking of CVD graphene in real time under TEM, with identification of individual single crystal domains and domain boundaries.

4:06PM D37.00007 Suspension of Graphene and Bi2Se3 Atomic Membrane , ZENG ZHAO, JAIRO VELASCO, HANG ZHANG, FENGLIN WANG, ZHIYONG WANG, PHILIP KRATZ, LEI JING, WENZHONG BAO, JING SHI, JEANIE LAU, Department of Physics and Astronomy, UCR, SHI JING'S GROUP COLLABORATION — Coupling high quality, suspended atomic membranes to specialized electrodes enables investigation of many novel phenomena, such as spin or Cooper pair transport in these two dimensional systems. However, many electrode materials are not stable in acids that are used to dissolve underlying substrates. Here we present a versatile and powerful multi-level lithographical technique to suspend atomic membranes, which can be applied to the vast majority of substrate, membrane and electrode materials. We also demonstrate, for the first time, fabrication and measurement of a free-standing thin Bi_2Se_3 membrane, which has low contact resistance to electrodes and a mobility of $\gtrsim$500 cm^2/Vs.

4:18PM D37.00008 In-situ Investigation of Electrical-Mechanical Coupling in graphene-based devices , MINGYUAN HUANG, California Institute of Technology, TOD PASCAL, HYUNGJUN KIM, WILLIAM GODDARD III, JULIA GREER, California Institute of Technology — Graphene, a truly two-dimensional gapless semiconducting material, recently deemed strongest ever measured, can sustain very high (up to 25%) in-plane tensile elastic strains. Several recent theoretical-only studies on strained graphene predict that strain can shift the Dirac cones, reduce the Fermi velocity, introduce a pseudo-magnetic field, and be used to engineer the electronic structure. However, no direct experiments on electrical measurements of highly strained graphene have yet been reported. Here, we present the results of *in-situ* investigation of electrical-mechanical coupling in graphene-based devices. In our experiment, *in-situ* nanoindentation was performed on suspended graphene transistors to introduce homogeneous tensile strain up to 3%, while electrical measurements were carried out simultaneously. We find that the electrical resistance shows only a marginal change under strain, and the electronic transport measurement confirms that there is no opening of the band gap for graphene under moderate uniform strain. We also report first-principles informed molecular dynamics simulation that lead to Young modulus consistent with our experiments and show no opening of a band gap.

4:30PM D37.00009 Radio Frequency Electrical Transduction of Graphene Mechanical Resonators , CHANGYAO CHEN, VIKRAM DESHPANDE, YUEHANG XU, FRANK DIRENNO, ALEXANDER GONDARENKO, DAVID HEINZ, SHUAIMIN LIU, PHILIP KIM, JAMES HONE, Columbia University — We report radio frequency (RF) electrical readout of graphene mechanical resonators. The mechanical motion is actuated and detected directly by using a vector network analyzer (VNA), employing a local gate to minimize parasitic capacitance. Resist-free doubly-clamped samples with resonant frequency in MHz range, Q factor ~10,000 at 77 K and signal-to-background ratio of over 20 dB, are demonstrated. In addition to being over two orders of magnitude faster than the electrical RF mixing method, this technique paves the way for use of graphene in RF devices such as filters and oscillators.

4:42PM D37.00010 Measurement of the shear modulus of single-layer graphene[1] , THOMAS METCALF, Naval Research Laboratory, XIAO LIU, JEREMY ROBINSON, KEITH PERKINS, BRIAN HOUSTON — We have measured the shear modulus of large area (2mm $\times$ 5mm), single-layer (90–95%) polycrystalline graphene sheets and found values consistent with theoretical predictions of G=200 GPa. The graphene was grown by chemical vapor deposition onto a copper foil and subsequently transferred onto a mechanical resonator known as a double-paddle oscillator (DPO). DPOs are fabricated from single-crystal, 0.3mm thick silicon wafers, and have a torsional vibratory mode at 5500 Hz which has a very large quality factor, $Q = 5 \times 10^7$, at low (< 10 K) temperatures, giving the DPO a high sensitivity to a film deposited on its torsional element. Such a film increases the (lumped-element) spring constant of the resonator, and the film's shear modulus can be deduced from the subsequent resonant frequency shift.

[1]Work supported by the Office of Naval Research

4:54PM D37.00011 Tearing of Graphene[1] , MARIA MOURA, MICHAEL MARDER, Department of Physics - University of Texas at Austin — Experiments on free standing graphene can expose the graphene sheets to out-of-plane forces. An example of that is the back-gate voltage experimental setup. Here we show that out-of-plane forces can cause free standing graphene to fracture. This fracture mode is known as tearing mode and is common in materials like paper. We present a numerical study of the propagation of cracks in clamped, free standing graphene as a function of the out-of-plane force. We report a threshold for the graphene fracture energy.

[1]We thank Fulbright and CAPES for scholarship funding and the National Science Foundation for funding through DMR 0701373.

5:06PM D37.00012 Variable strain in graphene sealed microchambers studied with Raman spectroscopy[1] , A.L. KITT, Boston University, J.W. SUK, University of Texas, Austin, S. REMI, S. AHMED, Boston University, R. PINER, K.M. LIECHTI, R.S. RUOFF, University of Texas, Austin, A.K. SWAN, B.B. GOLDBERG, Boston University — Raman measurements are a sensitive tool for evaluating strain in graphene. Graphene sealed cylindrical microchambers provide a unique way of generating strain. Suspended graphene avoids substrate interactions which make it difficult to evaluate the graphene response, e.g., combined graphene-substrate Poisson ratio, or slippage. Additionally, the system provides a wide range of strain states with different lattice symmetries. At a fixed external pressure, the strain state varies radially. The strain is biaxial in the center and changes gradually to only radial strain at the edges. The continuum model is evaluated to find the radial strain states. Combined with Raman Spectroscopy, several fundamental parameters can be measured. We will discuss the strain and polarization dependent splitting of the G and 2D bands and compare to previous works [1,2]. Furthermore, preliminary measurements of the strain dependence of thermal properties will be discussed.

5:18PM D37.00013 An Effective Tensional Strain View on the Bandgap Tunability of Helical Graphene Nanoribbons with Open and Closed Edges , DONG-BO ZHANG, TRAIAN DUMITRICA, University of Minnesota — Despite the scientific importance of graphene nanoribbons, little is known about their electronic structure other than in the flat-form presupposition. To quantify the strain stored in helical graphene nanoribbons and fractional carbon nanotubes, we supplement the standard elasticity concepts with an effective tensional strain. Using π-orbital tight binding and objective molecular dynamics coupled with density functional theory, we develop a unified theory for the electromechanical response in which the consequences of the torsional deformation are taken into account via the effective tensional strain. In spite of the open and closed edges as well as the inverse Poynting effect exhibited by these nanostructures, from the effective strain perspective the twist-induced bandgap modulations appear strikingly similar with those exhibited by carbon nanotubes in tension. Our theory may be useful for designing new electromechanical devices and experiments using carbon nanocomponents, and for establishing edge-chemistry driven nanofabrication principles for helical graphene nanoribbons with tunable bandgaps.

Monday, March 21, 2011 2:30PM - 5:06PM –

Session D38 DCP: Earle K. Plyler Prize Session II: Spectroscopy A130/131

2:30PM D38.00001 Ultrafast Nonlinear Optical Spectroscopy or where would we be without Shaul Mukamel? , GRAHAM FLEMING, University of California Berkeley — The development of ultrafast nonlinear optical spectroscopy owes much to the pioneering work of Shaul Mukamel in developing a unifying framework and language with which to understand and relate the content of different types of experiment. The culmination of this work, to date, is in the development of multidimensional optical spectroscopies. In this talk, I will describe recent work in my group on two dimensional electronic spectroscopy of photosynthetic light-harvesting complexes and, if time permits, single walled carbon nanotubes and molecular systems relaxing via conical intersections.

3:06PM D38.00002 2D IR Spectroscopy of Protein Conformation, Folding, and Binding , KEVIN JONES, ANDREI TOKMAKOFF, ZIAD GANIM, JOSHUA LESSING, C. SAM PENG, MIT Department of Chemistry — 2D IR spectroscopy is an increasingly powerful tool for investigation of protein structure and dynamics. As an ultrafast spectroscopy, it provides information on protein structure and conformational variation with high time resolution, providing a tool to study the dynamics of folding and binding. Some of the unique characteristics of 2D IR result from the powerful structure based modeling that is available for amide vibrations. This talk will cover recent examples from our group in which different forms of protein 2D IR and computational spectroscopy are used to reveal conformational heterogeneity in peptides, the folding and binding of proteins, and protein-water interactions. When combined with temperature-jump experiments, the formation and interchange of these structures is probed.

3:18PM D38.00003 Three-dimensional Fourier-transform spectroscopy of potassium vapor , HEBIN LI, ALAN BRISTOW, MARK SIEMENS, GALAN MOODY, STEVEN CUNDIFF, JILA, University of Colorado and National Institute of Standards and Technology, Boulder, CO 80309 — We have implemented three-dimensional (3D) Fourier-transform spectroscopy to study potassium vapor contained in a $\sim$20 μm transmission cell with argon buffer gas. The four-wave mixing signal is measured in three time dimensions corresponding to the delays between three $\sim$100 fs, phase-stabilized excitation pulses that are arranged in the box geometry. The emission is detected using a phase-stabilized reference pulse by spectral interferometry, and other time axes are Fourier transformed to construct the 3D spectra. The 3D spectra contain the full information of third-order coherent response of the vapor, yet the contribution from each of the single-quantum excitation pathways is unambiguously isolated. Projecting a 3D spectrum onto a specific two-dimensional (2D) plane retrieves rephasing, non-rephasing, and T-scan 2D spectra, as well as the spectra that are not accessible by conventional 2D scans. The spectral features which overlap in congested 2D spectra can be isolated for studying unique processes represented by a single pathway.

3:30PM D38.00004 Reflection Geometry Electronic Two-dimensional Fourier Transform Spectroscopy[1] , THOMAS W. JARVIS, ZHENG SUN, XIAOQIN LI, Department of Physics, University of Texas at Austin, Austin, Texas 78712, MIKHAIL EREMENTCHOUK, MICHAEL N. LEUENBERGER, NanoScience Technology Center & Department of Physics, University of Central Florida, Orlando, Florida 32826 — Studying dynamics in nanostructures is vital to develop new opto-electronic devices and to understand fundamental processes in the solid state. Electronic Two-dimensional Fourier Transform Spectroscopy (2DFTS) is a powerful technique that coherently probes the nonlinear optical polarization, establishing correlations between absorption and subsequent emission or dispersion. We perform 2DFTS in reflection, a novel experimental geometry that allows us to probe structured materials. The coupling features and dimensionally extended lineshapes revealed by 2DFTS provide a description of decoherence and dephasing processes, coherent and incoherent energy transfer, and relaxation.

3:42PM D38.00005 Ultrafast two dimensional infrared chemical exchange spectroscopy[1] , MICHAEL FAYER, Stanford University — The method of ultrafast two dimensional infrared (2D IR) vibrational echo spectroscopy is described. Three ultrashort IR pulses tuned to the frequencies of the vibrational transitions of interest are directed into the sample. The interaction of these pulses with the molecular vibrational oscillators produces a polarization that gives rise to a fourth pulse, the vibrational echo. The vibrational echo pulse is combined with another pulse, the local oscillator, for heterodyne detection of the signal. For fixed time between the second and third pulses, the waiting time, the first pulse is scanned. Two Fourier transforms of the data yield a 2D IR spectrum. The waiting time is increased, and another spectrum is obtained. The change in the 2D IR spectra with increased waiting time provides information on the time evolution of the structure of the molecular system under observation. In a 2D IR chemical exchange experiment, two species A and B, are undergoing chemical exchange. A's are turning into B's, and B's are turning into A's, but the overall concentrations of the species are not changing. The kinetics of the chemical exchange on the ground electronic state under thermal equilibrium conditions can be obtained 2D IR spectroscopy. A vibration that has a different frequency for the two species is monitored. At very short time, there will be two peaks on the diagonal of the 2D IR spectrum, one for A and one for B. As the waiting time is increased, chemical exchange causes off-diagonal peaks to grow in. The time dependence of the growth of these off-diagonal peaks gives the chemical exchange rate. The method is applied to organic solute-solvent complex formation, orientational isomerization about a carbon-carbon single bond, migration of a hydrogen bond from one position on a molecule to another, protein structural substate interconversion, and water hydrogen bond switching between ions and water molecules.

4:18PM D38.00006 Can the Isomerization of Retinal in Bacteriorhodopsin be Coherently Controlled in Strong Fields? , VALENTYN PROKHORENKO[1], University of Toronto, Chemistry Department, ALEXEI HALPIN, University of Toronto, Physics Department, PHILIP JOHNSON, University of Toronto, Chemistry Department, LEONID BROWN, University of Guelph, Physics Department, DWAYNE MILLER, University of Toronto, Chemistry and Physics Departments — Conflicting results have been obtained between weak field experiments (one-photon absorption) [1] and strong field recent studies [2] (multi-photon effects). Here we present our strong field experiments performed using linearly-chirped excitation pulses. Contrary to [2], we clearly observe phase-dependent control of photoproduct yield over a wide range of excitation energies. Above the excitation limit of $\sim$200 GW/cm^2 our results do however come into agreement with [2], but only for a single observation wavelength (650 nm) whereas the transient spectra unambiguously show drastic changes in the protein due to its ionization. At these excitation levels, this deleterious side channel precludes correct determination of the amount of 13-cis isomer. As such, we argue that it is impossible to make assignments of mechanistic details of control at a high field that in effect "kills" the protein. [1] V. I. Prokhorenko, A. M. Nagy, S. A. Waschuk, L. S. Brown, R. R. Birge, and R. J. D. Miller, Science 313, 1257-1261 (2006). [2] A. C. Florean et al., PNAS 106, 10896-10900 (2009).

4:30PM D38.00007 Toward Investigating Protein Folding Using the Combination of Computer Simulation and Spectroscopy , WEI ZHUANG — Protein folding is an important problem that is attracting scientists from a wide range of disciplines. One of the major challenges comes from the gap between the experimental and the theoretical studies. We proposed a computational protocol of simulating the T-jump peptide unfolding experiments and the related transient IR and 2DIR spectra based on the Markov State Model (MSM) and Nonlinear Exciton Propagation (NEP) methods. MSMs partition the conformation space into a set of non-overlapping metastable states, and we can calculate spectra signal for each of these states using NEP method. Thus the overall spectroscopic observable for a given system is simply the sum of spectra of different metastable states weighted by their populations. Simulated spectra based on MSM have a much better agreement with the equilibrium experimental 2DIR spectra compared to MD simulations starting from the folded state. MSMs are also capable of simulating the unfolding relaxation dynamics upon the temperature jump. The agreement of the simulation using MSMs and NEP with the experiment provides a justification for our protocol as well as a physical insight underlying the spectroscopic observables.

4:42PM D38.00008 Supersymmetry and fluctuation relations for currents in closed networks , VLADIMIR CHERNYAK, Wayne State University, NIKOLAI SINITSYN, Los Alamos National Laboratory — The discovery of fluctuation theorems and nonequilibrium work relations has stimulated considerable interest in nonequilibrium statistical mechanics and theory of counting statistics. It is important to obtain exact relations that do not directly rely on the thermodynamic concepts, such as work or entropy, but rather describe unambiguous microscopic characteristics, such as statistics of particle currents in systems driven by time-dependent fields. We identify hidden supersymmetry in evolution, governed by the master equation, that survives on the level of the counting statistics of stochastic particle currents. Supersymmetry connects the evolutions in the spaces of populations (boson component) and empirical currents (fermion component). We present exact relations for statistics of currents in strongly driven mesoscopic stochastic systems. Being reminiscent of known fluctuation theorems, a part of our exact result is not directly related to the condition of microscopic reversibility but rather follows from *supersymmetry* of the counting statistics of currents.

4:54PM D38.00009 Understanding Metal-Adsorbate Binding with Surface-Enhanced Raman Spectroscopy: Theory and Experiment[1] , ALEXEY ZAYAK, Molecular Foundry, LBNL, HYUCK CHOO, EECS, UC Berkeley, YING HU, Bioengineering Dpt., Rice University, JEFFREY BOKOR, EECS, UC Berkeley, STEFANO CABRINI, JAMES SCHUCK, JEFFREY NEATON, Molecular Foundry, LBNL — Building on recent work [1], we use a combination of density functional theory (DFT) calculations and surface-enhanced Raman spectroscopy (SERS) measurements to explain experimentally observed variations in SERS data of an organic molecule, trans-1,2-two (4-pyridyl) ethylene (BPE). For the BPE on Au surfaces, our DFT calculations provide a quantitative description of chemical enhancement (CE), and elucidate that variations reported in experiments arise from a convolution of two factors: a nonuniform frequency dependent electromagnetic enhancement, and dependence of CE on the sample incubation time. The later reveals aspects of the binding kinetics of BPE to Au surfaces.

Session D39 DBP: Physics of Physiological Systems A124/127

2:30PM D39.00001 Axonal Transport and Morphology: How Myelination gets Nerves into Shape[1] , PETER JUNG, PENG ZHAO, Ohio University, PAULA MONSMA, TONY BROWN, Ohio State University — The local caliber of mature axons is largely determined by neurofilament (NF) content. The axoskeleton, mainly consisting of NFs, however, is dynamic. NFs are assembled in the cell body and are transported by molecular motors on microtubule tracks along the axon at a slow rate of fractions of mm per day. We combine live cell fluorescent imaging techniques to access NF transport in myelinated and non-myelinated segments of axons with computational modeling of the active NF flow to show that a), myelination locally slows NF transport rates by regulating duty ratios and b), that the predicted increase in axon caliber agrees well with experiments. This study, for the first time, links NF kinetics directly to axonal morphology, providing a novel conceptual framework for the physical understanding of processes leading to the formation of axonal structures such as the "Nodes of Ranvier" as well as abnormal axonal swellings associated with neurodegenerative diseases like Amyotrophic lateral sclerosis (ALS).

2:42PM D39.00002 Experimental evaluation of biophysical neurite growth models , ZACHARY WISSNER-GROSS, Harvard University, MARK SCOTT, DAVID KU, PRIYA RAMASWAMY, MEHMET YANIK, Massachusetts Institute of Technology — During nervous system development, neurons exhibit complex growth dynamics, as several neurites compete to become each neuron's axon. Numerous mathematical and biophysical models have been proposed to explain this competition, but these models remain experimentally unverified. Large-scale and repeatable measurements of neurite dynamics are difficult to perform, since neurons have varying numbers of neurites, which themselves have complex morphologies. To overcome these challenges using a minimal number of primary neurons, we generated repeatable neuronal morphologies by laser-patterning micron-wide stripes of adhesive proteins on an otherwise highly non-adherent substrate. Upon analyzing thousands of time-lapse measurements, we observed three key neuronal behaviors: total neurite growth accelerated until neurons polarized, immature neurites competed even at very short lengths, and neuronal polarity underwent an apparent phase transition as the neurites grew beyond a critical length. Proposed biophysical neurite growth models agreed only partially with our experimental observations, and simple yet specific modifications significantly improved these models. The protein patterning and high-content analyses presented here could also be employed for studying other structural or biomechanical cellular phenomena.

2:54PM D39.00003 Deep Brain Stimulation using Magnetic Fields , DAVID JILES, Iowa State University, Ames, Iowa 50011, PAUL WILLIAMS, LAWRENCE CROWTHER, Wolfson Centre for Magnetics, Cardiff University, United Kingdom, IOWA STATE UNIVERSITY TEAM, WOLFSON CENTRE FOR MAGNETICS TEAM — New applications for transcranial magnetic stimulation are developing rapidly for both diagnostic and therapeutic purposes. Therefore so is the demand for improved performance, particularly in terms of their ability to stimulate deeper regions of the brain and to do so selectively. The coil designs that are used presently are limited in their ability to stimulate the brain at depth and with high spatial focality. Consequently, any improvement in coil performance would have a significant impact in extending the usefulness of TMS in both clinical applications and academic research studies. New and improved coil designs have then been developed, modeled and tested as a result of this work. A large magnetizing coil, 300mm in diameter and compatible with a commercial TMS system has been constructed to determine its feasibility for use as a deep brain stimulator. The results of this work have suggested directions that could be pursued in order to further improve the coil designs.

3:06PM D39.00004 Growth of Necrotic Cores in Vulnerable Plaque , PAK-WING FOK, Mathematical Sciences — Plaques are fatty deposits that grow mainly in arteries and develop as a result of a chronic inflammatory response. Plaques are called *vulnerable* when they are prone to mechanical rupture. Vulnerable Plaques (VPs) are characterized by lipid-rich, necrotic cores that are heavily infiltrated with macrophages. The rupture of VPs releases thrombogenic agents into the bloodstream, usually resulting in myocardial infarctions. We propose a quantitative model to predict the development of a plaque's necrotic core. By solving coupled reaction-diffusion equations for macrophages and dead cells, we explore the joint effects of hypoxic cell death and chemo-attraction to Ox-LDL, a molecule that is strongly linked to atherosclerosis. Our model predicts cores that have approximately the right size and shape. Normal mode analysis and subsequent calculation of the smallest eigenvalues allow us to compute the times required for the system to reach its steady state. This study allows us to make quantitative predictions for how quickly vulnerable plaques develop and how their growth depends on system parameters such as chemotactic coefficients and cell death rates.

3:18PM D39.00005 Understanding cellular architecture in cancer cells , SIMONE BIANCO, CHAO TANG, Department of Bioengineering and Therapeutic Science, University of California San Francisco — Understanding the development of cancer is an important goal for today's science. The morphology of cellular organelles, such as the nucleus, the nucleoli and the mitochondria, which is referred to as cellular architecture or cytoarchitecture, is an important indicator of the state of the cell. In particular, there are striking difference between the cellular architecture of a healthy cell versus a cancer cell. In this work we present a dynamical model for the evolution of organelles morphology in cancer cells. Using a dynamical systems approach, we describe the evolution of a cell on its way to cancer as a trajectory in a multidimensional morphology state. The results provided by this work may increase our insight on the mechanism of tumorigenesis and help build new therapeutic strategies.

3:30PM D39.00006 A two-scale model for correlation between B cell VDJ usage in zebrafish , KEYAO PAN, MICHAEL DEEM, Rice University — The zebrafish (Danio rerio) is one of the model animals for study of immunology. The dynamics of the adaptive immune system in zebrafish is similar to that in higher animals. In this work, we built a two-scale model to simulate the dynamics of B cells in primary and secondary immune reactions in zebrafish and to explain the reported correlation between VDJ usage of B cell repertoires in distinct zebrafish. The first scale of the model consists of a generalized NK model to simulate the B cell maturation process in the 10-day primary immune response. The second scale uses a delay ordinary differential equation system to model the immune responses in the 6-month lifespan of zebrafish. The generalized NK model shows that mature B cells specific to one antigen mostly possess a single VDJ recombination. The probability that mature B cells in two zebrafish have the same VDJ recombination increases with the B cell population size or the B cell selection intensity and decreases with the B cell hypermutation rate. The ODE model shows a distribution of correlation in the VDJ usage of the B cell repertoires in two six-month-old zebrafish that is highly similar to that from experiment. This work presents a simple theory to explain the experimentally observed correlation in VDJ usage of distinct zebrafish B cell repertoires after an immune response.

3:42PM D39.00007 Modelling Nanoparticle Diffusion into Cancer Tumors , VISHWA PRIYA PODDUTURI, Louisiana Tech University, Institute for Micromanufacturing, PEDRO DEROSA, Louisiana Tech University,Institure for Micromanufacturing. Grambling State University, Physics Department — Cancer is one of the major, potentially deadly diseases and has been for years. Non-specific delivery of the drug can damage healthy tissue seriously affecting in many cases the patient's living condition. Nanoparticles are being used for a targeted drug delivery thereby reducing the dose. In addition, metallic nanoparticles are being used in thermal treatment of cancer cells where nanoparticles help concentrate heat in the tumor and away from living tissue. We proposed a model that combines random walk with diffusion principles. The particle drift velocity is taken from the Hagen-Poiseuille equation and the velocity profile of the particle at the pores in the capillary wall is obtained using the Coventorware software. Pressure gradient and concentration gradient through the capillary wall are considered. Simulations are performed in Matlab using the Monte Carlo technique. Number of particles leaving the blood vessel through a pore is obtained as a function of blood pressure, the osmotic pressure, temperature, particle concentration, blood vessel radius, and pore size, and the relative effect of each of the parameters is discussed.

3:54PM D39.00008 ABSTRACT WITHDRAWN –

4:06PM D39.00009 Hearing and Infinite-Period Bifurcations , SEUNG JI, UCLA, DOLORES BOZOVIC, ROBIJN BRUINSMA, UCLA — Auditory and vestibular systems present us with biological sensors that can achieve sub-nanometer sensitivity orders of magnitude in the dynamic range, while operating in a fluid-immersed, room-temperature environment. While the mechanisms behind this extreme sensitivity and robustness of the inner ear have not been fully explained, nonlinear response has been shown to be crucial to its proper function. Recent experiments have recorded innate motility of hair cells of the bullfrog sacculus, under varying degrees of steady-state offset. The bundle deflection was shown to suppress or enhance spontaneous oscillations, and affect the sensitivity of the mechanical response. We will present a theoretical model based on cubic nonlinearity and show that in different parameter regimes, the system can be induced to cross a supercritical Hopf bifurcation, an infinite-period bifurcation, or a multi-critical point. Comparing the numerical simulation to the experiment, we will present evidence that the multi-critical point corresponds most closely to the dynamic state of saccular hair cells. Further, we will discuss the crossing of the bifurcation, and the sensitivity of the phase-locked response in various frequency regimes.

4:18PM D39.00010 Axonal Transport and Morphogenesis near Retinal Excavation of the eye[1] , YINYUN LI, Department of Physics and Astronomy, Ohio University, ANTHONY BROWN, Center for Molecular Neurobiology and Department of Neuroscience, Ohio State University, PETER JUNG, Department of Physics and Astronomy, Ohio University — Neurofilaments(NFs) represent the main space-filling elements of mature axons. NFs are transported on microtubule (MT) tracks along the axon at a slow rate of mm/day and thus form a dynamic cytoskeleton. During development, the optic nerve forms a sharp increase of caliber at about $150\mu m$ from the retinal excavation of the eye. Our key hypothesis is a relation between NF kinetics and nerve morphology based on the continuity of the active flow of NFs. We use computational modeling of axonal transport to infer modulation of NF kinetics consistent with the observed increase of nerve caliber. We show that the inferred kinetics is also consistent with reported spatial distribution of NFs and MTs near the retinal excavation. We further show that the predicted time course of development of the observed nerve swelling is consistent with the time course of animal development.

[1]This work has been sponsored by NSF under grants IOS-0818412(PJ) and IOS-0818653(AB)

4:30PM D39.00011 Hydroxyapatite in Physiological Environment , ALEXANDER SLEPKO, ALEXANDER A. DEMKOV, The University of Texas at Austin — A carbonated form of hydroxyapatite (HA) [$Ca_{10}(PO_4)_6(OH)_2$] is one of the most abundant materials in mammal bone. It crystallizes within the spaces between tropocollagen protein chains in an aqueous solution and strengthens the bone tissue. An emerging application of synthetic HA is bone repair and replacement. Bulk electronic and chemical properties of HA were studied theoretically recently. However, the absorption of H_2O molecules and amino acids of the tropocollagen chains at HA surfaces remains an area of active research. Using density functional theory we analyze the electronic properties and surface energetics of HA for different orientations and terminations and generate a theoretical surface phase diagram of HA. The reactivity of these surface models is analyzed using the frontier orbital approach. We find two dominant surfaces which are most stable over the widest chemical range. However, we expect them to show little surface reactivity. Using a HA slab with a highly reactive surface we build atomistic models of HA covered with up to one monolayer of water and analyze interactions between this surface and the water molecules.

4:42PM D39.00012 Excitable signal relay in Dictyostelium discoideum , TROY MESTLER, DAVID SCHWAB, PANKAJ MEHTA, THOMAS GREGOR, Department of Physics, Princeton University — The social amoeba D. discoideum transitions when starved from a collection of individual cells into a multicellular spore-complex. During this process, amoebae display several interesting phenomena including intercellular signaling, pattern formation, and cell differentiation. At the heart of these phenomena is the exchange of the signaling molecule cyclic-AMP, which has previously been extensively studied using a variety of indirect methods. Here we employ a sensor that uses a compound fluorescent protein whose emission spectrum changes in the presence of bound cyclic AMP to directly monitor, in real time and in vivo, intracellular cAMP concentrations. We use cells expressing this sensor in microchemostats to study intracellular cAMP concentrations at the single-cell level in response to precise, dynamically-controlled external cAMP stimulation. Specifically, we show that these cells display excitability much like that found in neurons and agree experimentally quite well with a modified FitzHugh-Nagumo dynamical systems model. This single-cell model sets groundwork for a comprehensive multicellular model that promises to explain emergent behavior in D. discoideum.

4:54PM D39.00013 Modeling Intracellular Oscillations and Polarity Transition in Fission Yeast , TYLER DRAKE, Lehigh University, MAITREYI DAS, FULVIA VERDE, Miami University, DIMITRIOS VAVYLONIS, Lehigh University — Fission yeast, a pill-shaped model organism, restricts growth to its tips. These cells maintain an asymmetric growth state, growing at only one tip, until they meet length and cell-cycle requirements. With these met, they grow at both. The mechanism of this transition, new-end take-off (NETO), remains unclear. We find that NETO occurs due to long-range competition for fast-diffusing signaling protein Cdc42 between the old and new tips. From experimental results, we suppose that symmetric tips compete for Cdc42, which triggers growth. We describe a symmetric growth model based on competition between tips. This model restricts short cells to monopolar states while allowing longer cells to be bipolar. Autocatalytic Cdc42 recruiting at both cells tips leads to broken symmetry, and the recruiting cuts off as tip Cdc42 levels saturate. Non-linear differential equations describe the model, with stable attractors indicating valid distributions. Linear stability analysis and numerical methods identify stable fixed points over a twofold increase in cell length. The model reproduces qualitative behavior of the organism. We show that observed pole-to-pole Cdc42 oscillations may facilitate the polarity transition and discuss their relationship to the Min system in E. Coli.

5:06PM D39.00014 Biomineral Structure and Strength of Barnacle Exoskeletons , NATHAN SWIFT, Colgate University — Studying the construction of organic-inorganic compound structures through biomineralization is potentially very useful. During biomineral formation, organisms restructure naturally occurring minerals in conjunction with their own organically produced minerals to create new structures. While there is extensive knowledge about material properties and structure of the raw minerals themselves, insight into how specific biomineral structures and compounds contribute to an object's mechanical properties is lacking. In this study, the exoskeletons of barnacles from the genus *Balanus* were examined, both for their physical structure (how they're put together) and for their mechanical properties (strength, hardness, and elasticity). Scanning electron microscopy produced close-up, detailed images of the inner shell structure to determine what type of structure barnacles build during exoskeleton formation. Energy dispersive x-ray spectroscopy was used to map the elemental components of the shells. Nanoindentation tested the mechanical properties of these mapped structures to determine how certain characteristics of the exoskeleton contribute to its mechanical properties.

5:18PM D39.00015 Enhancing mechanical properties of calcite by Mg substitutions: An ab initio study , PAVLINA ELSTNEROVA, MARTIN FRIAK, TILMANN HICKEL, HELGE OTTO FABRITIUS, LIVERIOS LYMPERAKIS, MICHAL PETROV, DIERK RAABE, JOERG NEUGEBAUER, Max Planck Institute for Iron Research, Duesseldorf, Germany, SVETOSLAV NIKOLOV, Institute of Mechanics, Bulgarian Academy of Sciences, Sofia, Bulgaria, ANDREAS ZIGLER, Central Facility for Electron Microscopy, University of Ulm, Ulm, Germany, SABINE HILD, Department of Polymer Science, Johannes Kepler University Linz, Linz, Austria — Arthropoda representing a majority of all known animal species are protected by an exoskeleton formed by their cuticle. The cuticle represents a hierarchically structured multifunctional bio-composite based on chitin and proteins. Some groups like Crustacea reinforce the load-bearing parts of their cuticle with calcite. As the calcite sometimes contains Mg it was speculated that Mg may have a stiffening impact on the mechanical properties of the cuticle. We present a theoretical parameter-free quantum-mechanical study of thermodynamic, structural and elastic properties of Mg-substituted calcite. Our results show that substituting Ca by Mg causes an almost linear decrease in the crystal volume with Mg concentration and of substituted crystals. As a consequence the calcite crystals become stiffer giving rise e.g. to substantially increased bulk moduli.

Session D40 DBP: Lipid Bilayers and Biological Membranes: Peptide Interactions A122/123

2:30PM D40.00001 Molecular Simulations of Sequence-Specific Association of Transmembrane Proteins in Lipid Bilayers , MANOLIS DOXASTAKIS, ANUPAM PRAKASH, LORANT JANOSI, University of Houston — Association of membrane proteins is central in material and information flow across the cellular membranes. Amino-acid sequence and the membrane environment are two critical factors controlling association, however, quantitative knowledge on such contributions is limited. In this work, we study the dimerization of helices in lipid bilayers using extensive parallel Monte Carlo simulations with recently developed algorithms. The dimerization of Glycophorin A is examined employing a coarse-grain model that retains a level of amino-acid specificity, in three different phospholipid bilayers. Association is driven by a balance of protein-protein and lipid-induced interactions with the latter playing a major role at short separations. Following a different approach, the effect of amino-acid sequence is studied using the four transmembrane domains of the epidermal growth factor receptor family in identical lipid environments. Detailed characterization of dimer formation and estimates of the free energy of association reveal that these helices present significant affinity to self-associate with certain dimers forming non-specific interfaces.

2:42PM D40.00002 An amino acid composition criterion for membrane active antimicrobials , NATHAN SCHMIDT, GHEE HWEE LAI, Physics, UIUC, ABHIJIT MISHRA, Bioengineering, UCLA, DENNIS BONG, Chemistry, Ohio State U, PAUL MCCRAY, JR., Pediatrics, U. Iowa, MICHAEL SELSTED, ANDRE OUELLETTE, Pathology, USC, GERARD WONG, Bioengineering, UCLA — Membrane active antimicrobials (AMPs) are short amphipathic peptides with broad spectrum anti microbial activity. While it is believed that their hydrophobic and cationic moieties are responsible for membrane-based mechanisms of action, membrane disruption by AMPs is manifested in a diversity of outcomes, such as pore formation, blebbing, and budding. This complication, along with others, have made a detailed, molecular understanding of AMPs difficult. We use synchrotron small angle xray scattering to investigate the interaction of model bacterial and eukaryotic cell membranes with archetypes from beta-sheet AMPs (e.g. defensins) and alpha-helical AMPs (e.g. magainins). The relationship between membrane composition and peptide induced changes in membrane curvature and topology is examined. By comparing the membrane rearrangement and phase behavior induced by these different peptides we will discuss the importance of amino acid composition on AMP design.

2:54PM D40.00003 Interaction between Cell Penetrating pVEC and cell membranes , ABHIJIT MISHRA, Bioengineering Dept., University of California Los Angeles, GHEE HWEE LAI, NATHAN SCHMIDT, GERARD WONG, Bioengineering Dept., University of California Los Angeles, Dept. of Physics University of Illinois Urbana Champaign — Vascular Endothelial Cadherin (VEC) is a transmembrane-spanning glycoprotein that belongs to the family of cell adhesion molecules and plays an active role in control of vascular permeability and angiogenesis. PVEC, an 18 amino acid domain, has been shown to be able to traverse cell membranes with attached macromolecules. pVEC is an amphiphilic molecule with a high content of basic amino acids resulting in a net positive charge. Electrostatic and hydrophobic interactions can perturb membrane self-assembly and stability and are likely to be responsible for peptide uptake. We use synchrotron x-ray scattering and confocal microscopy to examine the phase behavior of the pVEC lipid system, and its relation to membrane permeation mechanisms.

3:06PM D40.00004 Interactions between cyclic cell penetrating peptides and lipid membranes , KUN ZHAO, Bioengineering Department, University of California, Los Angeles, TAO LIU, Chemistry Department, the Ohio State University, MIKE CHOE, DANIEL KAMEI, Bioengineering Department, University of California, Los Angeles, DEHUA PEI, Chemistry Department, the Ohio State University, GERARD WONG, Bioengineering Department, University of California, Los Angeles — Cyclic peptides exhibit strong enhancement in receptor-binding affinity, specificity, and stability relative to their linear counterparts, partially due to their reduced conformational freedom. In this work, we examine cyclic versions of cell penetrating peptides. Using small-angle x-ray scattering (SAXS) measurements, we show that cyclic polyarginine peptides generate saddle-splay curvature more efficiently than their linear counterparts, We show how this increase in induced saddle splay curvature impinges on the efficiency of cell penetration in a series of giant vesicle and intracellular trafficking experiments.

3:18PM D40.00005 Interaction of a P. aeruginosa Quorum Sensing Signal with Lipid Membranes , REBECCA MORRISON, AMELIA HALL, ELLEN HUTCHISON, THUC NGUYEN, BENJAMIN COOLEY, VERNITA GORDON, University of Texas at Austin — Bacteria use a signaling and regulatory system called "quorum sensing" to alter their gene expressions in response to the concentration of neighboring bacteria and to environmental conditions that make collective activity favorable for bacteria. P. aeruginosa is an opportunistic human pathogen that uses quorum sensing to govern processes such as virulence and biofilm formation. This organism's two main quorum sensing circuits use two different signaling molecules that are amphiphilic and differ primarily in the length of their hydrocarbon side chain and thus in their hydrophobic physical chemistry. How these physical chemistries govern the propagation and spatial localization of signals and thus of quorum sensing is not known. We present preliminary results showing that signals preferentially sequester to amphiphilic lipid membranes, which can act as reservoirs for signal. This is promising for future characterization of how the quorum sensing signals of many bacteria and yeast partition to spatially-differentiated amphiphilic environments, in a host or biofilm.

3:30PM D40.00006 Criticality in Plasma Membranes , BENJAMIN MACHTA, STEFANOS PAPANIKOLAOU, JAMES SETHNA, Cornell University, SARAH VEATCH, University of Michigan — We are motivated by recent observations of micron-sized critical fluctuations in the 2d Ising Universality class in plasma membrane vesicles that are isolated from cortical cytoskeleton. We construct a minimal model of the plasma membrane's interaction with intact cytoskeleton which explains why large scale phase separation has not been observed in Vivo. In addition, we use analytical techniques from conformal field theory and numerical simulations to investigate the form of effective forces mediated by the membrane's proximity to criticality. We show that the range of this force is maximized near a critical point and we quantify its usefulness in mediating communication using techniques from information theory. Finally we use theoretical techniques from statistical physics in conjunction with Monte-Carlo simulations to understand how criticality can be used to increase the efficiency of membrane bound receptor mediated signaling. We expect that this sort of analysis will be broadly useful in understanding and quantifying the role of lipid "rafts" in a wide variety of membrane bound processes. Generally, we demonstrate that critical fluctuations provide a physical mechanism to organize and spatially segregate membrane components by providing channels for interaction over relatively large distances.

3:42PM D40.00007 Fluctuation-induced forces between inclusions in a fluid membrane under tension , HSIANG-KU LIN, ROYA ZANDI, LEONID P. PRYADKO, Department of Physics and Astronomy, University of California at Riverside — We discuss the fluctuation-induced force, a finite-temperature analog of the Casimir force, between two inclusions embedded in a fluid membrane under tension. We suggest a method to calculate this Casimir interaction in the most general case, where membrane fluctuations are governed by the combined action of surface tension, bending modulus, and Gaussian rigidity. We find that the surface tension strongly modifies the power law in the separation dependence of the Casimir interaction. Furthermore, the method allows us to calculate the Casimir force both at short and large separations.

3:54PM D40.00008 Nanoparticles Induced Microscaled Pore Formation on Supported Lipid Bilayer , BENXIN JING, Y. ELAINE ZHU — Most of recent researches on the cytotoxicity of nanomaterials focused on hydrophilic nanomaterials because of their good dispersion in water, but much less on hydrophobic ones. In this work, we have investigated the effect of semi-hydrophobic nanoparticles (NPs) on the dynamics and morphology of model cell membrane. We have found carboxyl functionalized polystyrene nanoparticles can induce the formation of microscaled pores on neutral supported Egg PC lipid bilayer at the ionic strength range similar to that in the human body with a strong dependence on nanoparticle size and concentration. The hydrophobic interaction between the NP surface and lipid bilayer is accounted for the induced line tension in lipid bilayer; when the tension exceeds a critical value, pores are formed and grow rapidly with dependence on nanoparticle size and ionic strength.

4:06PM D40.00009 Modeling the Elastic Properties of Lipid Bilayer Membranes , EDWARD BARRY[1], MRSEC at Brandeis University, THOMAS GIBAUD, MRSEC at Brandeis Universiy, MARK ZAKHARY, ZVONIMIR DOGIC, MRSEC at Brandeis University — Model membranes such as lipid bilayers have been indispensable tools for our understanding of the elastic properties of biological membranes. In this talk, I will introduce a colloidal model for membranes and demonstrate that the physical properties of these colloidal membranes are identical to lipid bilayers. The model system is unique in that the constituent molecules are homogenous and non-amphiphilic, yet their self-assembly into membranes and other hierarchical assemblages, such as a lamellar type phases and chiral ribbons, proceeds spontaneously in solution. Owing to the large size of the constituent molecules, individual molecules can be directly visualized and simultaneous observations at the continuum and molecular lengthscales are used to characterize the behavior of model membranes with unprecedented detail. Moreover, once assembled in solution, molecular interactions can be controlled in situ. In particular, the strength of chiral interactions can be varied, leading to fascinating transitions in behavior that resembles the formation of starfish vesicles. These observations point towards the important role of line tension, and have potential implications for phase separated lipid mixtures or lipid rafts.

4:18PM D40.00010 Dielectric sensors for measuring membrane potential[1] , KIMAL RAJAPAKSHE, ASANGA WIJESINGHE, JIE FANG, WILLIAM WIDGER, JOHN MILLER — Membrane potential in a biological cell depends on the ionic concentration difference between the extracellular and the intracellular medium. Ions close to the membrane show high polarizations under an electric field. Recent theoretical studies have related these polarizations to the alpha (α) dispersions in the impedance spectroscopy of a cell suspension. Therefore these dispersions can be used to measure the membrane potential of a single cell. Here we report the dielectric properties of phosphatidylcholine liposomes and its changes with the membrane potential. Liposomes have been prepared to have a higher concentration of potassium ions (K^+) inside the membrane compared to external medium. Under valinomycin (K^+ ionophores) these liposomes generate a negative membrane potential, as verified by fluorescent voltage sensitive dye measurements. Both dielectric and conductivity spectra display low frequency dispersions that are dependent on membrane potential. Possible future applications include noninvasive sensors for in vitro testing of new drugs and other applications.

4:30PM D40.00011 Laser Transmission Spectroscopy and applications to liposome studies , FRANK LI, JAMES MARR, CHING-TING HWANG, ROBERT SCHAFER, ZACHARY SCHULTZ, STEVEN RUGGIERO, CAROL TANNER, University of Notre Dame — We describe the implementation of precision laser transmission spectroscopy (LTS) for sizing nanoparticles in suspension. Our apparatus incorporates a tunable laser and balanced optical system which measures light transmission over a wide (210 – 2300 nm) wavelength range with high precision and sensitivity. Spectral inversion was employed to determine both the particle size distribution and absolute density of particles with diameters over a total range of 5 to 3000 nm. LTS has a dynamic range of $\sim 10^3$ particles/mL to $\sim 10^{10}$ particles/mL ($5x10^{-8}$ vol.% to 0.5 vol.%). Currently, LTS is being applied as a tool to investigate the behavior of liposomes, dipalmitoylphosphatidycholine (DPPC) and dipalmitoylphosphatidylserine (DPPS), under the presence of fusing and de-aggregating agents. Our measurements indicate a maximum diameter of 400 nm for liposomes suspended in solution after fusion.

Monday, March 21, 2011 2:30PM - 5:30PM –

Session D41 DCP: LeRoy Apker Prize Session: Clusters and Nanoscale Systems A115/117

2:30PM D41.00001 LeRoy Apker Award Talk: Self-Assembly of DNA-Functionalized Nanoparticles , CHIA WEI HSU, Wesleyan University / Harvard University — Nanoparticles tethered with DNA strands can self-assemble into highly organized structures through the bonding of complementary nucleobases. These are promising building blocks for the bottom-up nanotechnology, and computational tools are useful to probe the behaviors of such complex materials. In this talk I will summarize my work on the phase behavior of nanoparticles tethered with a small number of DNA strands, and on the development of theories for the clustering and self-assembly kinetics of a specific case. Due to a separation of repulsion and attraction length scales, these nanoparticles exhibit an interesting hierarchy of phases made up of multiple interpenetrating structures.

3:06PM D41.00002 DNA-driven assembly of phospholipid bilayer nanodiscs , NIENKE GEERTS, Department of Chemical Engineering, Yale University, New Haven, CT 06511, PAUL A. BEALES, Centre for Molecular Nanoscience, School of Chemistry, University of Leeds, Leeds LS2 9JT, UK, T. KYLE VANDERLICK, Department of Chemical Engineering, Yale University, New Haven, CT 06511 — Phospholipid nanodiscs are a rare form of stable lipid self-assembly. The discs are formed by allowing lipids to self-assemble in the presence of membrane scaffold proteins (MSP). Each disc contains two MSP, wrapping around the edge of a leaflet of the bilayer. Although nanodiscs have become an important and versatile tool among model membrane systems to functionally reconstitute membrane proteins, they are yet to be utilized as building blocks in material science. However their highly monodisperse nanoscale structure make them ideal for this purpose. Here we report the first superstructures of nanodiscs self-assembled via membrane anchored single stranded DNA. The discs assemble into columnar stacks with high aspect ratio. The MSPs provide another powerful feature, as the His-tags of the protein can be used to attach the discs to colloids or other molecules of interest. This has strong potential for assembly of nanomaterials with greater degrees of complexity.

3:18PM D41.00003 Orthogonal DNA-colloid Clusters[1] , JESSE W. COLLINS, Harvard SEAS, VINOTHAN N. MANOHARAN, Harvard Physics and SEAS — We experimentally investigate the self-assembly of colloids labelled with different DNA strands into small clusters. We coat 1 micron diameter spheres with 65 base DNA strands having highly specific "sticky ends." Particles with different surface-bound DNA sequences represent different particle "types." We tune the short-ranged, pairwise interactions between some types to be attractive and interactions between other types to be purely repulsive; in this sense, the interactions are orthogonal. The magnitude of attraction (and repulsion) is constant across various types. We control the number and types of colloids at the single particle level, and distinguish the type of each particle from the types of their binding partners within each cluster. In an example experiment, 2 particles of each of 3 different types explore a volume less than 100 picoliters and assemble into equilibrium configurations. We characterize the structures with a microscope and compare observed averages with statistical mechanical predictions.

3:30PM D41.00004 Size Characterization of Surfactant and Polymer Coated Gold Nanorods[1] , CHRISTOPHER GRABOWSKI, PAUL LUCHETTE, PETER PALFFY-MUHORAY, Liquid Crystal Institute - KSU — Polarization-dependent dynamic light scattering was conducted on gold nanorods (Au NRs) coated with CTAB (hexadecyltrimethylammonium bromide) in water and coated with 50k MW PS (polystyrene) in toluene. The autocorrelation function of the scattered light intensity was determined for a series of scattering angles under VH and VV scattering geometries. The data were fit to a model of rotational and translational diffusivities. From this fit, we estimate the effective length (L) and diameter of the coated nanorods in solution. Au NRs coated with 50k PS show greatly reduced rotational diffusion compared to CTAB-coated NRs. Since the rotational diffusion coefficient scales as $1/L^3$, this implies significant extension of the grafted PS chains in toluene. We investigate this phenomenon for PS grafted onto Au nanoparticles and nanorods of varying aspect ratio to determine the impact of surface curvature on polymer layer thickness.

3:42PM D41.00005 A ligand phase transition on nanorods and its effect on their surface forces[1] , ASAPH WIDMER-COOPER, University of Sydney, PHILLIP GEISSLER, U.C. Berkeley — Synthesizing nanometer-scale objects with controlled optical and electronic properties is now a relatively straightforward task, however organizing such objects into extended structures that could revolutionize technology remains a challenge, especially for anisotropic particles. Nanorods behave like liquid crystals in solution and can assemble into structures with the rods oriented perpendicular with respect to a substrate upon drying, assemblies that could potentially be used to print nanostructured solar cells and photoelectrochemical devices. Achieving complete control of this process, however, requires detailed understanding of the rod-rod and rod-surface interactions. Like most nanoparticles, CdS nanorods are passivated with ligands to stabilize them from random aggregation in solution. Using molecular dynamics simulations with explicit ligands and solvent we investigate the structure of phosphonic acid ligands on CdS nanorods as a function of temperature and show that they can undergo an ordering transition close to room temperature. We calculate the potential of mean force between the rods and show that this changes the rod-rod interaction from purely repulsive to attractive. This should have a significant effect on their self-assembly behavior.

3:54PM D41.00006 Chemical Preparation and Characterization of Elemental Cu, Ni, and Cu/Ni Core/Shell Nanoparticles , LAURA HIGGINS, MICHAEL LATTANZI, BRIAN KELLY, University of Delaware, GERALD POIRIER, Princeton University, KARL UNRUH, University of Delaware — Elemental Ni, Cu, and Cu core/Ni shell nanoparticles have been prepared in a polyol-type process. The elemental nanoparticles were prepared by dissolving $NiCl_2{\cdot}6H_2O$ and/or $CuCl_2{\cdot}2H_2O$ in ethylene glycol (EG) and heating the solution to reflux prior to the addition of NaOH. The resulting precipitate was then extracted, dried, and characterized by scanning electron microscopy (SEM) with elemental analysis, x-ray diffraction (XRD), and in the case of the elemental Ni nanoparticles, vibrating sample magnetometry (VSM) measurements. The best fit lattice parameters obtained from the elemental Ni and Cu nanoparticles were 0.35289(28) and 0.36171(23) nm, respectively, in good agreement with the corresponding bulk values. On the other hand, the measured saturation magnetization of about 49 emu/g was somewhat smaller than the bulk Ni value. In the case of the Cu/Ni nanoparticles, the best fit lattice parameters for the Ni and Cu components of the core/shell structure were 0.35299(26) and 0.36101(10) nm, indicating the formation of an essentially pure Ni shell and a slight amount of Ni incorporation in the Cu core.

4:06PM D41.00007 Solid-State Homogenization Reactions in Cu Core/Ni shell Nanoparticles , MICHAEL LATTANZI, LAURA HIGGINS, BRIAN KELLY, University of Delaware, GERALD POIRIER, Princeton University, KARL UNRUH, University of Delaware — Air stable Cu core/Ni shell nanoparticles have been prepared in a polyol-type process by heating an ethylene glycol (EG) solution containing $CuCl_2{\cdot}2H_2O$ and $NiCl_2{\cdot}6H_2O$ to its boiling temperature, adding an appropriate amount of NaOH, and allowing the reaction to proceed at reflux for 30 minutes prior to cooling. The as-prepared nanoparticles were characterized by scanning electron microscopy (SEM) with elemental mapping, x-ray diffraction (XRD), and vibrating sample magnetometry (VSM) measurements. Chemical composition maps of the particles revealed a well-defined core/shell structure consisting of a Cu core about 100-150 nm in diameter surrounded by a Ni shell about 30-40 nm in thickness. XRD measurements indicated that while the Cu core contained a small amount of incorporated Ni, the shell was essentially pure Ni. The solid-state transformation from the as-prepared core/shell structure to an essentially homogeneous Cu-Ni alloy was studied by high temperature VSM and XRD measurements as a function of annealing temperature and time. These measurements reveal that the core/shell structure remains largely intact to temperatures above 400 $^\circ$C and that complete homogenization occurs at temperatures above about 600 $^\circ$C.

4:18PM D41.00008 The Discovery of a New Class of Magnetic Superhalogens , P. JENA, M.M. WU, H. WANG, Y. KO, Q. WANG, Q. SUN, B. KIRAN, A. KANDALAM, K. BOWEN, VIRGINIA COMMONWEALTH UNIVERSITY TEAM, PEKING UNIVERSITY COLLABORATION, JOHNS HOPKINS UNIVERSITY COLLABORATION, MCNEESE STATE UNIVERSITY COLLABORATION — We report the discovery of a new class of magnetic superhalogens and their unusually stable molecular anions. These are formed when a hot plume of manganese atoms is cooled through collisions with an inert gas in the presence of chlorine atoms. The anions, with a composition of $(Mn_xCl_{2x+1})^-$ (x = 1, 2, 3. . .), appear as prominent (magic) peaks in mass spectra. Using calculations based on density functional theory and experiments utilizing anion photoelectron spectroscopy, we traced the origin of their unusual stability to the half-filled d-shell of the Mn atoms in anionic clusters and the large electron affinities of their neutral counterparts. The calculated and measured electron affinities are almost twice as high as that of the chlorine atom. However, unlike conventional superhalogens which are non-magnetic and consist of a single metal atom at the core surrounded by halogen atoms, the superhalogens discovered here are magnetic and have $(MnCl_2)_x$ moiety as a core to which a chlorine atom is attached. In addition, our calculations show that Mn atoms carry large magnetic moments and Mn_xCl_{2x+1} superhalogen moieties can serve as building blocks of a new category of salts with magnetic properties.

4:30PM D41.00009 Dielectron Attachment and Hydrogen Evolution Reaction in Water Clusters[1] , ROBERT BARNETT, Georgia Institute of Technology, RINA GINIGER, ORI CHESHNOVSKY, Tel-Aviv University, UZI LANDMAN, Georgia Institute of Technology — Binding of excess electrons to nano-size water droplets, with a focus on the hitherto largely unexplored properties of doubly-charged clusters, were investigated experimentally using mass spectrometry and theoretically with large-scale first-principles quantum simulations. Doubly-charged clusters were measured in the range of $83 \leq n \leq 123$, with $(H_2O)_n^{-2}$ clusters found for $83 \leq n < 105$, and mass-shifted peaks corresponding to $(H_2O)_{n-2}(OH^-)_2$ detected for $n \geq 105$. Simulations revealed surface and internal dielectron, e_2^-, localization modes and elucidated the mechanism of the reaction $(H_2O)_n^{-2} \rightarrow (H_2O)_{n-2}(OH^-)_2 + H_2$ (for $n \geq 105$), which was found to occur via concerted approach of a pair of protons belonging to two water molecules located in the first shell of the dielectron internal hydration cavity, culminating in hydrogen formation $2H^+ + e_2^- \rightarrow H_2$. Instability of the dielectron internal localization impedes the reaction for smaller ($n < 105$) clusters.

4:42PM D41.00010 Investigations into aggregate growth dynamics *via in situ* structural quantification of flame synthesized silica nanoparticle aggregates , DURGESH RAI, GREGORY BEAUCAGE, University of Cincinnati, JAN ILAVSKY, Argonne National Laboratory, HENDRIK KAMMLER, Clariant Corporation, SOTIRIS PRATSINIS, ETH Zurich — Ramified aggregates are formed in many dynamic processes such as in flames. The structures are disordered and present a challenge to quantification. The topological quantification of such nanostructured materials is important to understand their growth processes. Small-angle X-ray scattering (SAXS) is widely used to characterize such nanoparticle aggregates. Recently, we have developed a method for the quantification of topology in aggregated material using SAXS. This methodology will be used to describe topologies from *in-situ* SAXS studies on flame synthesized silica aggregates on millisecond time scales. This is an important step to facilitate understanding of the growth dynamics and the structural rearrangements that occur during flame synthesis.

4:54PM D41.00011 Influence of Nanoparticles on Fragility and Collective Particle Motion in Polymer Glass-Formation , JACK DOUGLAS, Polymers Division, NIST, FRANCIS STARR, Department of Physics, Wesleyan University — We investigate the impact of nanoparticles (NP) on glass-formation in polymer melts by molecular dynamics simulation. The NP cause significant changes in both fragility and the average length of string-like cooperative motion, where the extent of the effect depends on the NP-polymer interaction and NP concentration. These dynamical changes can be interpreted via the Adam-Gibbs (AG) theory if we assume the strings represent the abstract cooperatively rearranging regions (CRR) of the AG model, whose basic assumptions are reviewed. Molecular additives are also effective at altering the fragility of glass-formation and extent of string-like collective motion so the modulation of fragility and cooperative motion with additives seems to be a general effect. We find that the fragility of glass formation is mainly controlled mainly by the differential change of L with respect to T near the glass transition rather than the actual size L of the collective motion. We also find a near proportionality between m and the glass transition temperature in our nanocomposite system, which greatly simplifies the T dependence of structural. The classical entropy theory of glass-formation is considered as a complementary tool to gain analytic insights into these additive effects on polymer glass formation.

5:06PM D41.00012 Anion Photoelectron Spectroscopy and First-Principles Study of PbxIny Clusters[1] , S. VINCENT ONG, Virginia Commonwealth University, JOSHUA MELKO, UJJWAL GUPTA, The Pennsylvania State University, J. ULISES REVELES, Virginia Commonwealth University, JONATHAN D'EMIDIO, The Pennsylvania State University, SHIV KHANNA, Virginia Commonwealth University, A.W. CASTLEMAN, The Pennsylvania State University, DEPARTMENT OF PHYSICS, VIRGINIA COMMONWEALTH UNIVERSITY COLLABORATION, DEPARTMENTS OF CHEMISTRY AND PHYSICS, THE PENNSYLVANIA STATE UNIVERSITY COLLABORATION — Anionic and neutral Pb_xIn_y clusters containing up to 5 Pb and up to 7 In atoms have been investigated using negative ion photodetachment spectroscopy along with first-principles electronic structure studies within a gradient corrected density functional approach. The stability and electronic properties of these clusters have been characterized through studies of the detachment energies, gaps in the electronic spectrum, variations in binding energy, and nature of the electronic states. Particularly stable clusters have been grouped into two families of stable species. $PbIn_3^-$, Pb_2In_2, and Pb_3In_2 exhibit enhanced stability compared to their neighbors and the stability is linked to the aromatic character identified in their molecular orbitals. On the other hand, $PbIn_5^-$ and Pb_2In_4 exhibit enhanced stability associated with filled electronic shells within a confined nearly free electron gas.

[1]We acknowledge support from the U.S. Department of the Army through a MURI Grant W911NF-06-1-0280.

5:18PM D41.00013 Structural Analysis of Bonding in Au-Ge Clusters , DANIELLE MCDERMOTT, KATHIE NEWMAN, University of Notre Dame — The study of Gold-Germanium clusters is important in understanding systems such as gold catalyzed nanowire growth. Of particular concern is the bonding behavior between the two chemical elements, one tending to form metallic bonds, the other covalent. DFT calculations and Conjugate Gradient relaxations were performed on clusters ranging in size from 50 to 150 atoms using the SIESTA code to find the geometries of metastable states. Emphasis has been placed on developing accurate and dependable bases to be used to study nano-sized systems. The binding energy, coordination number, bond lengths and bond angles are studied as a function of the size and composition of Ge-Au clusters. We will discuss a nanoscale "phase diagram" for gold and germanium and will also discuss the topology of the bonding network.

Monday, March 21, 2011 2:30PM - 5:30PM –

Session D42 DFD: Colloids Theory & Computation, Emulsions, and Foams A302/303

2:30PM D42.00001 Liquid loss from foams with low water content , MICHAEL CONROY, JUSTIN TAYLOR, JOHN FARLEY, JAMES FLEMING, RAMAGOPAL ANANTH, Naval Research Laboratory — The liquid content of a foam can be significantly affected by liquid loss (drainage), a process that occurs both during and after the foam fills a space. We develop a theoretical model to describe liquid loss and evolution of average liquid volume fraction over time for advancing and static foams. We also perform bench-scale drainage experiments on foams with low water content. The theoretical model shows a constant drainage rate during the filling process which decays exponentially after a static column is formed. The measured loss of liquid is found to be in good agreement with the theoretical predictions. We find that drainage is greatly affected by the time scale for filling a space with foam. Significant effects on drainage are also found by varying bubble size, foam column height, and initial liquid content. The study indicates that drainage behavior can substantially deviate from that described by free-drainage theories, which assume that drainage initiates from a foam of static height.

2:42PM D42.00002 Molecular Dynamics Study of the Foam Stability of a Mixed Surfactant System with and without Calcium Ions , XIAOZHEN YANG, WENHONG YANG, Institute of Chemistry, CAS, INSTITUTE OF CHEMISTRY, CAS TEAM — Foam stability performance of a mixture surfactant system with and without calcium ions, including linear alkylbenzene sulfonate (LAS) and sodium dodecyl sulfate (SDS), has been studied by molecular dynamics. Microscopic interaction analysis reveals that the fraction of free calcium ions, X_f, in film system indicates the extent of the foam stabilities when X_f is in different calcium ion zones. In the system without ions, we found the variable of the surfactant tail mass out of water film, W, is indicator of foam stability. Performance of the mixture system predicted here was supported by experiments.

2:54PM D42.00003 Structural Properties of a Sheared Dense Emulsion[1] , S.K. DUTTA, E.D. KNOWLTON, D.L. BLAIR, Department of Physics, Georgetown University — The flow of a compressed emulsion above its yield point can be described by a velocity profile in addition to a rearrangement of individual droplets on top of this time averaged motion. Using a confocal microscope, we have tracked the droplets of an oil-in-water emulsion as they are sheared in a rheometer. When the applied stress is large, the velocity profile shows a nearly affine deformation, while there is strong strain localization close to yield. The crossover between these two behaviors occurs at higher shear rates as the volume fraction of the droplets is increased. At shorter length scales, rearrangement events are heterogeneously distributed, reflecting the disordered packing of the emulsion droplets. This characterization is a step towards linking bulk viscoelastic properties to local structural relaxation as the system leaves the jammed state.

[1]This work is funded by the NSF through Grant DMR 0847490.

3:06PM D42.00004 Janus and Gemini Nanoplates , ZHENGDONG CHENG, ANDRES MEJIA, YA-WEN CHANG, PENG HE, Artie McFerrin Department of Chemical Engineering, Texas A&M University, College Station, TX 77840, AGUSTIN DIAZ, ABRAHAM CLEARFIELD, Department of Chemistry, Texas A&M University, College Station, TX 77842 — Janus particles were used to make stable Pickering emulsions (emulsions stabilized by particles). Here we demonstrated a novel method to produce high aspect ratio Janus plates with atomic thickness. Gemini plates with only the edges functionalized are also fabricated. These novel nanoplates are observed to have super surface activity. Most importantly, these particles overcome the two *opposite* effects in the stabilization of Pickering emulsions using spherical particles: stabilization requires particles as small as possible; but smaller particles are easy to escape the interface due to Brownian motion since the adsorption energy to the oil-water interface is proportional to the diameter of the spheres. Our nanoplates have a *large* aspect ratio due to the extremely thin thickness, which offers extraordinary stability to the liquid film between two emulsions to prevent coalescence. In the meantime, their large lateral surface area offers strong adsorption energy at the oil-water interface.

3:18PM D42.00005 Control over the number, size, and type of inner drops inside a double emulsion , LAURA ADAMS, YUANJIN ZHAO, ANDERSON SHUM, DAVID WEITZ, Harvard University — The formation of monodisperse double emulsions, drops inside of drops, has revealed a rich range of configurations not possible without the precise control of microfluidics. Yet-to-date, development of double emulsions with a controlled number of two different inner drops has not emerged. Here we demonstrate exquisite control over the number, size and type of inner drops encapsulated inside a double emulsion. These are fabricated using glass capillary devices implemented with a dual bore injection tube. We will show our latest results and discuss the scientific and technological opportunities made possible by these stable binary configurations.

3:30PM D42.00006 Yielding and Shear Induced Structure Formation in Emulsions with Attractive Interactions , ZHEN SHAO, AJAY NEGI, CHINEDUM OSUJI, Yale University, OSUJI LAB TEAM — The yielding behavior of colloidal suspensions is a strong function of inter-particle interactions. Recent results [Pham et al. 2006, 2008] indicate that attractive colloidal glasses display a two-step yielding due to inter-particle bond rupture followed by particle cage escape. From this perspective, we examine the yielding behavior of an oil-in-water emulsion system with attractive interactions using dynamic bulk rheology. In strain sweep experiments, after a limited linear regime, the system yields with a pronounced bump in the viscous modulus, a sharp decrease in the elastic modulus and a crossover between the two. The yielding response is marked by bond-breaking at low volume fractions and bond-breaking accompanied by cage escape above a critical concentration. An increase in the complex modulus is observed at yet higher strains (>100%), with both the elastic and viscous components showing small frequency dependent peaks. The onset, peak strains and peak stress display different dependences on volume fraction. We speculate that this display is due to the formation of shear induced structures at high strains and advance a simple model for this behavior.

3:42PM D42.00007 Force Network in a 2D Frictionless Emulsion Model System , KENNETH W. DESMOND, PEARL YOUNG, DANDAN CHEN, ERIC R. WEEKS, Emory University — We confine oil-in-water emulsion droplets between two parallel plates to create a quasi-two-dimensional model system to study the jamming transition. This model system is analogous to granular photoelastic disks with the exception that there is no static friction between our droplets. To study the jamming transition we compress the droplets in small increments and investigate how the force network evolves with increasing area fraction, where the forces are measured using a calibration technique we have developed. The forces in our system are spatial heterogeneous with a probability distribution that is similar to that found for photoelastic disks. We also find that the probability distribution of the forces narrows with area fraction, and that the correlation length of the largest forces is only few particle diameters.

3:54PM D42.00008 New activated dynamical regimes in dense suspensions of attractive uniaxial colloids , RUI ZHANG, KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — Our microscopic theory of cooperative translational-rotational activated glassy dynamics of hard uniaxial particles [PRE,80,011502(2009); JCP,133,104902(2010)] is extended to treat short range attractions. For small aspect ratio dicolloids, a plastic glass (PG) state exists for weak attractions, but is destroyed beyond a critical attraction strength resulting in a new dynamic triple point (fluid, PG, gel), and two novel re-entrant behaviors: PG-fluid-gel, and repulsive glass(RG)-PG-gel. A new mixed "glass-gel" state also emerges characterized by center-of-mass and rotational angle localization parameters of intermediate magnitude. At high volume fractions, increasing attraction transforms the RG to an attractive glass (AG) characterized by a dynamic free energy surface with a gel-like localization state but a glass-like saddle point, and a non-monotonic variation of relaxation time and diffusion constant. AG dynamics is of a 2-step nature where physical bonds first break followed by hopping over a glass-like barrier. At high attractions a sharp crossover from a gel to AG with increasing volume fraction is predicted. As the particle aspect ratio grows, the PG state is destroyed, and translational motion becomes increasingly more important for escaping dynamical traps.

4:06PM D42.00009 A new analysis methodology for the motion of self-propelled particles and its application , YOUNG-MOO BYUN, PAUL LAMMERT, VINCENT CRESPI, Penn State University — The self-propelled particle (SPP) on the microscale in the solution is a growing field of study, which has a potential to be used for nanomedicine and nanorobots. However, little detailed quantitative analysis on the motion of the SPP has been performed so far because its self-propelled motion is strongly coupled to Brownian motion, which makes the extraction of intrinsic propulsion mechanisms problematic, leading to inconsistent conclusions. Here, we present a novel way to decompose the motion of the SPP into self-propelled and Brownian components; accurate values for self-propulsion speed and diffusion coefficients of the SPP are obtained for the first time. Then, we apply our analysis methodology to ostensible chemotaxis of SPP, and reveal the actual (non-chemotactic) mechanism of the phenomenon, demonstrating that our analysis methodology is a powerful and reliable tool.

4:18PM D42.00010 Diffraction effects on optical trapping of small particles , RACHAEL HARPER, ALEX LEVINE, University of California, Los Angeles — Geometric ray optics is an elegant and computationally efficient means of numerically calculating the forces on particles of arbitrary shape due to their interaction with a beam of light. This method is limited to the regime in which the particle is much larger than the wavelength of light. Ashkin's pioneering work [1] on force exerted by a laser trap on a spherical dielectric particle relies on this geometric optics limit. In current experiments, however, the size of the trapped particles can be comparable to the wavelength of the trapping radiation field. In this talk, we discuss the corrections to ray-tracing-based calculations of the laser trapping forces due to diffraction effects. Specifically, we compare the momentum transfer from a uniform beam of light to hollow dielectric cylindrical shells obtained from two different calculations using: (i) ray-tracing and (ii) the full physical optics formulation. By changing the radii of the inner and outer edges of the hollow cylinder with respect to the wavelength of light we determine the limits of validity of the ray-tracing solution. In the limit in which the radius of the inner cylinder is comparable to the wavelength radiation we show that the corrected momentum transfer is smaller than that predicted by geometric optics. We attribute this result to the reduction in the scattering force on the cylinder due to diffraction effects not accounted for in the geometric optics formalism. [1] A Ashkin, Biophys. J., 61, 569 (1992).

4:30PM D42.00011 Capillary Interactions among Spherical Particles at a Curved Liquid Interface , CHUAN ZENG, University of Massachusetts Amherst, FABIAN BRAU, Physique Theorique, Universite de Mons, BENNY DAVIDOVITCH, ANTHONY D. DINSMORE, University of Massachusetts Amherst — Colloidal particles tend to adsorb on liquid interfaces, where in- plane interactions can arise from a variety of mechanisms. We focus on capillary interactions induced by the curvature of the liquid interface, where particles were assumed to have a constant Young-Laplace contact angle at the three-phase contact line. Whereas spherical particles can adsorb on flat or spherical interfaces without deforming the interface, adsorption on a cylindrical interface deforms the interface because of the lack of azimuthal symmetry around the contact line. We present an analytical model of the interfacial shape and energy upon adsorption of a single particle as well as the interaction between two particles. Based on our result on a cylindrical interface, we propose a general formula for the force on a particle on a curved interface. This study provides an important step toward understanding the interactions among interfacial particles when the interface is distorted by an external field. We acknowledge support from the NSF-supported MRSEC on Polymers at UMass (DMR- 0820506) and NSF CBET-0967620.

4:42PM D42.00012 Slow relaxations of individual colloidal spheres following the breach of a fluid interface , MADHAV MANI, KITP & UCSB Physics, DAVID M. KAZ, RYAN MCGORTY, VINOTHAN N. MANOHARAN, Harvard University — Although the equilibrium state of a micron sized spherical particle at an interface is well understood, the dynamics associated with the approach to equilibrium is not. Recent high-resolution experiments from the Manoharan Lab (Ref: David M. Kaz's Talk) have shown that the dynamics are richer than expected. Subsequent to the initiation of a contact-line at a fluid interface the dynamics towards equilibrium are much slower than predicted by a hydrodynamic theory and the center of mass of the particle appears to follow a logarithmic law in time. We propose the importance of thermally agitated interactions between the contact-line and physical/chemical defects that pin the contact-line locally, thereby leading to an enhancement of the overall dissipation. We deduce that the interface must remain flat during this dynamic process and derive a force-velocity relation, which agrees with both the slow velocities and the logarithmic law. This surprisingly slow approach to equilibrium has significant consequences for processes where interactions between colloids and interfaces are present.

4:54PM D42.00013 Using Micron-Sized Ellipsoids as a New Tool for Microrheology , DAVID KILGORE, KENNETH W. DESMOND, ERIC R. WEEKS, Emory University — It is a well-established principle that the viscosity of a fluid can be calculated by observing the diffusion of microspheres, provided the diameter of the microspheres is known. We are developing a microrheology technique using ellipsoids, where the rheology can be measured without prior knowledge of the length and width of the ellipsoid. The advantage of using ellipsoids is that their asymmetry allows for the diffusion to be decomposed into two translational motions and one rotational motion. For each of these diffusive motions, we can measure a diffusion constant and relate the constant to the three unknowns: the length and width of the ellipsoid, and the viscosity. By measuring the three diffusion constants, we can determine the three unknowns. To verify this technique, we produce ellipsoids in the lab and suspend them in a viscous solution for three-dimensional imaging of the diffusion with a confocal microscope. We are able to get good agreement between the microrheological measurements and macroscopic viscosity measurements.

5:06PM D42.00014 Inferring elastic properties in colloidal solids: artifacts of a restricted observation window , ASAD HASAN, CRAIG MALONEY, Carnegie Mellon University — Recently, it has been shown how to extract information about the effective elasticity in colloidal solids, granular packings, *etc.*, using two point displacement correlations as obtained in, *e.g.*, optical microscopy experiments or computer simulations. At its core, this technique relies on the observation that, within the harmonic approximation, the Hamiltonian, H, is the inverse of the elastic response function, G, *defined over the whole domain of the elastic body*. However, most experiments (and even most simulations) have access to G only over some restricted sub-domain of the experimental system. Here, we study restricted observation domains of various size and dimensionality in face centered cubic (fcc) crystals of various size using a pseudo-analytic approach in which G is obtained analytically and is inverted numerically *on a compact sub-domain* to obtain the projected Hamiltonian, $\tilde{H}$. We show that the effective plane-wave energy, $E_k = \langle\psi_k|\tilde{H}|\psi_k\rangle$, for either a [111] or [100] planar subdomain has an unusual dispersion, $E \sim k$, rather than the familiar $E \sim k^2$ and motivate this observation from continuum considerations. We also show how this leads to an anomaly in the density of states of $\tilde{H}$.

5:18PM D42.00015 Enhancing tracer diffusivity by tuning interparticle interactions and solvation shell structure , JAMES CARMER, GAURAV GOEL, TOM TRUSKETT, University of Texas at Austin Chemical Engineering — Using computer simulations, we explore how tuning the tracer-solvent interactions affects the dynamics of a tracer particle. Optimizing the tracer particle contribution to excess entropy results in significant increases in tracer particle diffusivity. We also observe increases in dynamics while increasing the effective particle size. These changes are investigated at various densities and particle size ratios.

Monday, March 21, 2011 2:30PM - 5:30PM –
Session D45 DAMOP: Many Body Physics of Quantum Gases in Reduced Dimension A310

2:30PM D45.00001 Moving Impurities and Spin-Boson Systems in One-Dimensional BECs , THOMAS SCHMIDT, PETER ORTH, KARYN LE HUR, Yale University — We theoretically investigate the dynamics of two moving impurities immersed in a one-dimensional interacting Bose liquid. Interactions between the two impurities are mediated via excitations in the quantum liquid, and lead to correlations between them. For certain parameter regimes, the system can be mapped onto a spin-boson model, in which the relative momentum of the impurities plays the role of a spin-1/2 or spin-1. We will discuss the implications of the spin-impurity model onto observables of the liquid and impurities.

2:42PM D45.00002 Exact result for the three-body local correlator in the 1D Bose gas at finite temperature , MARTON KORMOS, ADILET IMAMBEKOV, Rice University — The 1D Bose gas with Dirac-delta interaction (Lieb–Liniger model) gives a very good description of cold atomic gases confined in quasi one-dimensional waveguides. While the model is integrable by means of the Bethe Ansatz it can also be regarded as a particular non-relativistic limit of an integrable relativistic quantum field theory, the sinh-Gordon model. This fact can be exploited to calculate form factors and correlation functions for the Bose gas. We derive an exact expression for the finite temperature expectation value of the third power of the density operator $:\rho^3:$, a quantity which is closely related to the three-body losses in cold atom experiments. We achieve this by summing up an infinite integral series obtained using the connection with the sinh-Gordon model. Our method can be generalized to other local correlators.

2:54PM D45.00003 The density profile of interacting Fermions in a one-dimensional optical trap[1] , SEBASTIAN EGGERT, Univ. of Kaiserslautern, Germany, STEFAN SOEFFING, Univ of Kaiserslautern, Germany — The density distribution of the Hubbard model in a one-dimensional external harmonic potential is investigated in order to study the effect of the confining trap. The broadening of the Fermion cloud with increasing interaction is analyzed in detailed, which can be described by a surprisingly simple scaling form. Strong superimposed "Friedel" oscillations are always present despite the absence of any hard wall boundaries. The wavelength of the dominant oscillation changes with interaction, which indicates the crossover to a spin-incoherent regime. We present an analytical formula, which describes the behavior of the oscillations very well for all interactions strengths and in return gives some insight for the use of bosonization in a trapping potential.

[1]Financial support has been received from the DFG funded TRANSREGIO 49, the research center OPTMAS, and the graduate school of excellence MAINZ/MATCOR

3:06PM D45.00004 Pairing correlations in one-dimensional Bose-Fermi mixtures with molecular boundstates , SHIMUL AKHANJEE, RIKEN - Condensed Matter Theory Laboratory, MASAHISA TSUCHIIZU, Nagoya University, AKIRA FURUSAKI, RIKEN - Condensed Matter Theory Laboratory — We study the ground-state properties of one-dimensional (1D) 3-component mixtures of Tonks bosons having infinite repulsion and nearly free fermionic atoms that can combine to form molecular fermions. Using a bosonization scheme, the form of the interaction is equivalent to the hopping term between weakly coupled spinless Tomonaga Luttinger liquids (TLL). Upon reduction of the energy scale, the 3-component TLL system scales down into a phase with coupled massive modes accompanied by pairing correlations.

3:18PM D45.00005 Scaling of noise correlations in one-dimensional lattice hard-core boson systems , KAI HE, MARCOS RIGOL, Department of Physics, Georgetown University — Noise correlations are studied for systems of hard-core bosons in one-dimensional lattices. We use an exact numerical approach based on the Bose-Fermi mapping and properties of Slater determinants. We focus on the scaling of the noise correlations with system size in superfluid and insulating phases, which are generated in the homogeneous lattice, with period-two superlattices, and with uniformly distributed random diagonal disorder. For the superfluid phases, the leading contribution is shown to exhibit a density independent scaling proportional to the system size, while the first subleading term exhibits a density dependent power-law exponent.

3:30PM D45.00006 Double occupancy as a probe of the Mott transition for fermions in one-dimensional optical lattices[1] , JORGE QUINTANILLA, SEPnet, University of Kent and Rutherford Appleton Laboratory, VIVALDO L. CAMPO, JR, UFScar, Brazil, VITO SCAROLA, Virginia Tech, USA, CHRIS HOOLEY, SUPA and University of St Andrews, UK, KLAUS CAPELLE, UFABC, Brazil — We study theoretically double occupancy D as a probe of the Mott transition for trapped fermions in one-dimensional optical lattices and compare our results to the three-dimensional case. The ground state is described using the Bethe Ansatz in a local density approximation and the behavior at finite temperatures is modelled using a high-temperature series expansion. In addition, we solve analytically the model in the limit in which the interaction energy is the dominant energy scale. We find that enhanced quantum fluctuations in one dimension lead to increased double occupancy in the ground state, even deep in the Mott insulator region of the phase diagram. Similarly, thermal fluctuations lead to high double occupancies at high temperatures. Nevertheless, D is found to be a good indicator of the Mott transition just as in three dimensions. We discuss possible experiments to verify these results and argue that the one-dimensional Hubbard model could be used as a benchmark for quantitative quantum analogue simulations.

3:42PM D45.00007 ABSTRACT WITHDRAWN –

3:54PM D45.00008 Analysis of the single-particle excitation spectrum of ultracold fermions in 1D optical lattices , ATSUSHI YAMAMOTO, SUSUMU YAMADA, MASAHIKO MACHIDA, CCSE, Japan Atomic Energy Agency — We present single-particle excitation spectra of ultracold fermions in one-dimensional(1D) optical lattices by using dynamical density-matrix renormalization group (DDMRG) method. Our model is described by a Hubbard model with the harmonic trap potential. We find that the spectra show many kinds of intriguing structures owing to the harmonic trap potential and on-site interaction. In an analysis of weakly-interaction regimes, we find that the spectrum structure changes from a typical Hubbard band as obtained from periodical 1D lattice to band branching as increasing the trap potential, and finally, we observe clear discrete bound-state levels. On the other hand, in case of strongly-interacting regimes, we confirm the multiple flat bound-state levels lying above 1D Tomonaga-Luttinger (TL) liquid spectrum on a central Mott-plateau phase surrounded by metallic regions. Furthermore, we also investigate spectral changes as a metallic state partially emerges at the center region and find one-dimensional TL spectrum breakdown with an emergence of a new dispersive band due to the central metal portion. The observed features are closely related with the spectral changes when doping into Mott insulator. We will show the more details of spectra in 1D fermionic optical lattices by comparing non-trapped uniform 1D spectra.

4:06PM D45.00009 A quantum Monte Carlo study of the two-component mixture of hard-core bosons in one dimension , MIN-CHUL CHA, JONG-GEUN SHIN, INHO JEON, Hanyang University — The two-component mixture of hard-core bosons in one dimension is studied by quantum Monte Carlo simulations. A rich variety of phases exists in the parameter space of the inter-species interaction strengths, the ratio of the hopping amplitudes between two species, and the filling fractions. Physical properties of different phases are investigated by measuring the superfluid stiffness, the counter-flow stiffness, the compressibility, and the structure factor. We examine the nature of some phase transitions between a superfluid and an insulator and the 1st-order transition in the occurrence of phase separations.

4:18PM D45.00010 Fermionic Cold Atom Systems in Mixed Dimensions , KYLE IRWIN, SHAN-WEN TSAI, Dept. of Physics and Astronomy University of California, Riverside — Cold atom experiments can now realize mixtures of components that move in different dimensions [1]. We investigate such a system with two species of fermions. One species, f-fermions, moves on a two-dimensional square lattice. Another species, c-fermions, is constrained to move on a one-dimensional lattice embedded in the square lattice of f-fermions. We investigate the effective one-dimensional system who's interactions are mediated by the two-dimensional system, and explore effective theories, quantum phases, correlations, and relevant energy scales for various fillings of the mixed dimensional system using a functional renormalization group approach.

4:30PM D45.00011 Long range bosonic correlations in 2D optical lattice traps , K.W. MAHMUD, University of California, Davis, E.N. DUCHON, Ohio State University, Y. KATO, Los Alamos National Laboratory, N. KAWASHIMA, University of Tokyo, R.T. SCALETTAR, University of California, Davis, N. TRIVEDI, Ohio State University — We use quantum Monte Carlo (QMC) simulations to study the combined effects of harmonic confinement and temperature for bosons in a two dimensional optical lattice. We present the scale invariant, finite temperature, state diagram for the Bose- Hubbard model in terms of experimental parameters - the particle number, confining potential and interaction strength. We examine the correlation decay of the superfluid trapped in annular rings, and find that the width of the superfluid ring determines a distance after which the correlation decays faster than in an equivalent 2D superfluid. At zero temperature, the correlation decay is intermediate between 1D and 2D decay, while at finite temperature, the decay is similar to a 1D decay at a much lower temperature. These provide the strongest evidence for the breakdown of the local density approximation (LDA) in trapped superfluid bosons.

4:42PM D45.00012 Interference signatures of thermal and quantum phase fluctuations in the two dimensional Bose-Hubbard Model[1] , MASON SWANSON, YEN LEE LOH, NANDINI TRIVEDI, The Ohio State University — Superfluidity in the Bose-Hubbard model is destroyed by the interplay of thermal and quantum phase fluctuations. In two dimensions, Berezinskii-Kosterlitz-Thouless theory predicts that deep in the superfluid phase quasi-long-range order is destroyed by the proliferation of thermally induced free vortices. As the Mott insulator regime is approached, the effect of quantum phase fluctuations must also be taken into account. By using a $(2+1)$-dimensional XY phase model, we investigate the signatures of thermal and quantum vortices in interference patterns. The possibility of extracting spatial and temporal correlation lengths from such interference images provides a new experimental probe for characterizing the state of ultracold atomic gases in 2D optical lattices.

4:54PM D45.00013 The Fluctuation-Dissipation Theorem at Low Temperatures in a 2D Optical Lattice[1] , ERIC DUCHON, Department of Physics, The Ohio State University, YASUYUKI KATO, Theoretical Division, Los Alamos National Laboratory, NAOKI KAWASHIMA, Institute for Solid State Physics, University of Tokyo, NANDINI TRIVEDI, Department of Physics, The Ohio State University — We calculate local density fluctuations and the local compressibility[2] of bosons in a two dimensional optical lattice as a function of temperature T and the tuning parameter U/t, the on-site boson repulsion strength in units of hopping, using worldline Quantum Monte Carlo. Our numerical results, coupled with the quantum fluctuation-dissipation theorem applied locally, make significantly different predictions for direct simulations of lattice bosons in a harmonic trap versus simulations that treat the trap within a local density approximation, especially at low temperatures. We discuss implications of our results for local thermometry, equilibration and characterization of the quantum critical regime.

5:06PM D45.00014 The Effects of Disorder on a Quasi-2D System of Ultracold Atoms , MATTHEW BEELER, MATTHEW REED, TAO HONG, STEVEN ROLSTON, UMD/JQI — An ultra-cold gas of atoms can be used to create many different model Hamiltonians. When tightly confined in one spatial dimension, the gas can become effectively two-dimensional. At low temperature, a quasi-2D Bose gas undergoes a Berezinskii-Kosterlitz-Thouless phase transition to a superfluid, mediated by the binding and unbinding of vortex pairs. As disorder affects vortex transport properties, a slight amount of fine-grain disorder in the potential energy may alter the properties of this phase transition. We will present experimental observations of a 2D Bose gas of rubidium atoms in the presence of disorder created by a laser speckle field.

5:18PM D45.00015 Atomic Fermi superfluids in a honeycomb optical lattice: Supercurrents and dynamical instabilities , SHUNJI TSUCHIYA, Department of Physics, Tokyo University of Science, RAMACHANDRAN GANESH, ARUN PARAMEKANTI, Department of Physics, University of Toronto — Cold Fermi and Bose atoms on a honeycomb lattice have been of great recent interest given the possibility to simulate graphene physics and to realize interesting topological phases of matter.[1,2,3] We study the attractive Hubbard model of fermions on the honeycomb lattice in order to explore the strongly correlated superfluid state in this lattice geometry. We calculate the superfluid order parameter and collective modes in the presence of a superfluid flow in order to investigate the superflow stability. We find that the superfluid order parameter and density fluctuations exhibit nontrivial dependence on the flow, and these collective modes lead to novel dynamical instabilities.

Session H1 DCMP: Spin-Triplet Supercurrents in Superconductor/Ferromagnet/Superconductor Josephson Junctions Ballroom A1

8:00AM H1.00001 Odd Triplet superconductivity in Superconductor-Ferromagnet hybrid structures

, SEBASTIAN BERGERET, Centro de Fisica de Materiales CSIC/UPV and DIPC, San Sebastian — Since the prediction of a long-range triplet component of the superconducting condensate in ferromagnetic-superconductor (S/F) proximity structures in 2001 [1], the activity in the field has increased considerably, both theoretically and experimentally The coexistence of conventional singlet superconductivity and ferromagnetism in S/F structures is closely related with the appearence of a triplet component of the condensate, which is odd in frequency and even in momentum and therefore insensitive to nonmagnetic impurities. The presence of the triplet component leads to new effects as for example, long-range Josephson coupling in SFS junctions [1], flow of a supercurrent through a half-metallic link [2] and screening of the magnetic moment of ferromagnetic particles embbeded in a superconductor [3]. In this talk I will review the main issues of the odd-triplet superconductivity, its manifestation in physical properties, and briefly discuss the relevant experiments in the field [4].

8:36AM H1.00002 Proximity effect-induced superconductivity in crystalline metallic and ferromagnetic nanowires[1]

, JIAN WANG, The Pennsylvania State University — In a single crystal gold nanowire of 1.2 microns contacted by superconducting contacts, the proximity effect induced superconductivity was found to appear in two distinct steps. The superconducting and normal regions are separated by a mini-gap state of low critical field. We suggest that a superposition of two distinct magnetic-flux states, which correspond to quantum flux 0 and 1 trapped in the nanowire, can explain the mini-gap state. Furthermore, we observed clear periodic differential magnetoresistance oscillations in the superconducting to normal transition region, which corresponds to the generation or annihilation of one vortex. In crystalline ferromagnetic Co and Ni nanowires, unexpected long-range proximity effect was observed. Josephson current associated with weakly damped singlet superconducting correlations or triplet correlations produced by the contact regions may lead to the observed long ranged proximity effect. In addition, a large and sharp resistance peak around the transition temperature was observed in the wires exhibiting incomplete superconductivity. Further theoretical model needs to be developed to reveal the physics behind the "peak effect."

[1]This work was supported by the Penn State MRSEC under NSF grant DMR-0820404.

9:12AM H1.00003 Observation of spin-triplet supercurrent in Co-based Josephson junctions[1]

, NORMAN BIRGE, Michigan State University — When a superconductor (S) and a ferromagnet (F) are put into contact with each other, the combined S/F system may exhibit altogether new properties. There is a proximity effect where pair correlations from S penetrate into F, but these correlations decay over a very short distance due to the large exchange splitting between the spin-up and spin-down electron bands in F. Theory predicts that, under certain conditions, electron pair correlations can be generated with spin-triplet rather than spin-singlet symmetry [1]. The two electrons in such a spin-triplet pair have parallel spins and are not subject to the exchange splitting in F; hence they propagate long distances. We have measured a long-range supercurrent in Josephson junctions of the form S/X/N/SAF/N/X/S, where S is a superconductor (Nb), N is a normal metal (Cu), SAF is a synthetic antiferromagnet of the form Co/Ru/Co, and X is a thin ferromagnetic layer necessary to induce spin-triplet correlations in the structure [2]. Spin-triplet correlations are generated due to non-collinearity of the magnetizations in each X layer and the nearest Co layer. Using X = PdNi, CuNi, and Ni, we observe enhancements of the critical current of up to 300 times relative to similar samples lacking the X layers. We also observe a large additional enhancement of the spin-triplet supercurrent after the samples are magnetized in a large field. This result is counter-intuitive, since one would expect magnetizing the samples to suppress the occurrence of non-collinear magnetization. We will present a model of the SAF magnetization structure that explains these intriguing results.

9:48AM H1.00004 Triplet supercurrents in ferromagnets[1]

, MARK BLAMIRE, University of Cambridge — In almost all superconductors the pairs of electrons which carry the charge are in the so-called singlet state in which the quantum spin of the two electrons is antiparallel. During the past five years there has been increasing evidence that proximity coupling between singlet superconductors and ferromagnets can sometimes generate triplet pairs within the ferromagnet in which the spins of the electrons are parallel rather than antiparallel – the evidence being that supercurrents can be passed through thicknesses of ferromagnetic material which are simply too large for singlet pairs to survive. The superconductor-ferromagnet proximity effect describes the fast decay of a spin-singlet supercurrent originating from the superconductor upon entering the neighboring ferromagnet. For strong ferromagnets such as Co, a thickness of only a few nanometres is sufficient to almost completely suppress the critical current of a Nb/Co/Nb Josephson junction. Here we report experiments in which a conical magnet (holmium) is placed at the interface between the superconductor and ferromagnet. The results showed that a long-ranged supercurrent can occur through the ferromagnetic Co layer but only for certain critical thicknesses of the Ho [1]. These thicknesses correspond to maximum magnetic inhomogeneity on the Ho and are therefore consistent with models which predict that a spin-mixing interface between the superconductor and ferromagnet can generate triplet pairs which are long-ranged in the ferromagnet. This paper reports recent experiments which aim to understand further the behaviour of triplet pairs in superconductor / ferromagnet heterostructures.

10:24AM H1.00005 Long-ranged supercurrents through half-metallic ferromagnetic CrO_2[1]

, JAN AARTS, Leiden University — In the last few years, the scenery in the physics of superconductor/ ferromagnet hybrids has changed considerably with the realization that spin triplets may be induced in the ferromagnet through the mechanism of odd-frequency pairing. Since the equal-spin component of the triplet is not susceptible to pair breaking by the exchange field, such correlations can sustain supercurrents over long lengths, in particular in fully spin polarized materials where only one spin band is available. In halfmetallic ferromagnetic CrO_2 for instance, where superconducting contacts were deposited on top of the ferromagnetic films, we observed the current to flow over 700 nm at 4.2 K [1]. Still, we also have fabricated devices where the supercurrent is absent, which indicates that the mechanism of triplet generation is not yet well in hand. The presence of non-homogeneous magnetization is important, and here the grain structure of the film appears to play a key role, as can be illustrated with data for films grown on different substrates (TiO_2 and Al_2O_3). Moreover, recent data will be presented which suggest that triplet generation can be improved by using an additional ferromagnetic layer in the contact area.

Session H2 DCMP: New Materials for Spin Quantum Hall Effect and Topological Insulators

Ballroom A2

8:00AM H2.00001 Bulk Topological Insulators and Superconductors: Discovery and the new Frontiers , M. ZAHID HASAN, Princeton University, Department of Physics — While most known phases of matter are characterized by broken symmetries, the discovery of quantum Hall effects (1980s) revealed that there exists an organizational principle based on topology rather than broken symmetry. In the past few years, theory and experiments have suggested that new types of topological states of matter exist in certain bulk insulators without any applied magnetic field. These topological insulators are characterized by a full band gap in their bulk and gap-less conducting edge or surface states protected by time-reversal symmetry. Unlike the quantum Hall systems, the bulk 3D topological insulators can be doped into superconductors and magnets revealing the interplay between topological-order and broken-symmetry-order [Rev. Mod. Phys 82, 3045 (2010)]. In this talk, I will highlight the experimental observations and focus on recent experimental developments on bulk topological insulators. I will then draw connections between the topological physics and their potential applications in electronics and the emergent new frontiers in fundamental physics. Work in collaboration with D. Hsieh, Y. Xia, L. Wray, D. Qian, C.L. Kane, H. Lin, A. Bansil, D. Grauer, R.J. Cava, Y.S. Hor, J. H. Dil, F. Meier, L. Patthey, J. Osterwalder, A.V. Fedorov.

8:36AM H2.00002 Tunable multifunctional topological insulators in ternary Heusler and related compounds , CLAUDIA FELSER, University of Mainz — Recently the quantum spin Hall effect was theoretically predicted and experimentally realized in quantum wells based on the binary semiconductor HgTe. The quantum spin Hall state and topological insulators are new states of quantum matter interesting for both fundamental condensed-matter physics and material science. Many Heusler compounds with C1b structure are ternary semiconductors that are structurally and electronically related to the binary semiconductors. The diversity of Heusler materials opens wide possibilities for tuning the bandgap and setting the desired band inversion by choosing compounds with appropriate hybridization strength (by the lattice parameter) and magnitude of spin–orbit coupling (by the atomic charge). Based on first-principle calculations we demonstrate that around 50 Heusler compounds show band inversion similar to that of HgTe. The topological state in these zero-gap semiconductors can be created by applying strain or by designing an appropriate quantumwell structure, similar to the case of HgTe. Many of these ternary zero-gap semiconductors (LnAuPb, LnPdBi, LnPtSb and LnPtBi) contain the rare-earth element Ln, which can realize additional properties ranging from superconductivity (for example LaPtBi) to magnetism (for example GdPtBi) and heavy fermion behaviour (for example YbPtBi). These properties can open new research directions in realizing the quantized anomalous Hall effect and topological superconductors. Heusler compounds are similar to a stuffed diamond, correspondingly, it should be possible to find the "high Z" equivalent of graphene in a graphite-like structure with 18 valence electrons and with inverted bands. Indeed the ternary compounds, such as LiAuSe and KHgSb with a honeycomb structure of their Au-Se and Hg-Sb layers feature band inversion very similar to HgTe which is a strong precondition for existence of the topological surface states. These materials have a gap at the Fermi energy and are therefore candidates for 3D-topological insulators. Additionally they are centro-symmetric, therefore, it is possible to determine the parity of their wave functions, and hence, their topological character. Surprisingly, the compound KHgSb with the strong SOC is topologically trivial, whereas LiAuSe is found to be a topological non-trivial insulator.

9:12AM H2.00003 Quantized Anomalous Hall Effect in Magnetic Topological Insulators , ZHONG FANG, Institute of Physics, Chinese Academy of Sciences — The anomalous Hall effect is a fundamental transport process in solids arising from the spin-orbit coupling. In a quantum anomalous Hall insulator, spontaneous magnetic moments and spin-orbit coupling combine to give rise to a topologically nontrivial electronic structure, leading to the quantized Hall effect without an external magnetic field. Based on first-principles calculations, we predict that the tetradymite semiconductors Bi_2Te_3, Bi_2Se_3, and Sb_2Te_3 form magnetically ordered insulators when doped with transition metal elements (Cr or Fe), in contrast to conventional dilute magnetic semiconductors where free carriers are necessary to mediate the magnetic coupling. In two-dimensional thin films, this magnetic order gives rise to a topological electronic structure characterized by a finite Chern number, with the Hall conductance quantized in units of e^2/h. 9:48AM H2.00004 Search for Topological Insulators in Ternary Chalcogenides[1] , CHAOXING LIU, Physikalisches Institut(EP3), Institut fuer Theoretische Physik und Astrophysik, Universitaet Wuerzburg — A topological insulator (TI) is a novel quantum state, which is a bulk insulator but has gapless surface states. Recently, binary chalcogenides, Bi2Te3, Bi2Se3 and Sb2Te3 have been theoretically predicted and experimentally observed to be a family of TIs [1]. In this talk, we extend our search of TIs to ternary chalcogenides by replacing some of Bi or Sb atoms by other atoms, such as thallium and rare earth atoms. It is found that for thallium-based materials [2], only TlSbS2 is trivial and all the others are TIs, while for rare earth-based materials[3], LaBiTe3 is a TI and the others are trivial. The search in ternary chalcogenides not only bring new members of TIs in the family of chalcogenides but also may provide candidates for other new topological states such as topological superconductor, quantum anomalous Hall insulator, axionic insulator and topological Kondo insulator.

10:24AM H2.00005 Magnetotransport studies of new topological insulators: Bi_2Te_2Se and others[1]

, ALEXEY TASKIN, Institute of Scientific and Industrial Research, Osaka University — A topological insulator (TI) is a material that has a gapped insulating bulk and a gapless metallic surface. However, presently available TI materials are not truly insulating, making surface transport measurements to be a challenge. The second generation of TIs, Bi_2Se_3 and related compounds, turned out to be more suitable for the experimental studies of the topological 2D states than the first discovered Bi-Sb alloys, due to a much larger bulk gap and a simpler surface state consisting of a single Dirac cone. Unfortunately, near-stoichiometric Bi_2Se_3 is always a metallic n-type material owing to a finite amount of Se vacancies. We searched for new TI materials that are better suited for achieving a bulk insulating state and found that Bi_2Te_2Se, which has an ordered tetradymite structure with the Te-Bi-Se-Bi-Te layer sequence, is a very promising material. It was found that high-quality single crystals of Bi_2Te_2Se show a high resistivity exceeding 1 Ωcm, together with a variable-range hopping behavior which is a hallmark of an insulator; yet, they present Shubnikov-de Haas oscillations which signify the 2D surface state consistent with the topological one observed by photoemission spectroscopy. Moreover, we are able to clarify both the bulk and surface transport channels, establishing a comprehensive understanding of the transport in this material. Our results demonstrate that Bi_2Te_2Se is the best material to date for studying the surface quantum transport in a topological insulator. Transport properties of other new TI materials are also presented.

Tuesday, March 22, 2011 8:00AM - 11:00AM –
Session H3 GMAG: Collective Effects in Molecular Magnets Ballroom A3

8:00AM H3.00001 Experimental realization of random-field Ising ferromagnetism in a molecular magnet[1]

, MYRIAM P. SARACHIK, Physics Department, City College of New York, CUNY, New York, New York 10031 — The longitudinal magnetic susceptibility of single crystals of the molecular magnet Mn_{12}-acetate obeys a Curie-Weiss law, indicating a transition to a ferromagnetic phase at $\sim$ 0.9 K [1,2]. With increasing magnetic field applied transverse to the easy axis, a marked change is observed in the temperature dependence of the susceptibility, with a considerably more rapid suppression of the Curie-Weiss temperature than predicted by mean-field theory for an ordered single crystal. Our results can instead be fit by a Hamiltonian for a random-field Ising ferromagnet in a transverse magnetic field, where the randomness derives from the intrinsic distribution of locally tilted magnetic easy axes known to exist in Mn_{12}-acetate crystals. Mn_{12}-ac and other single molecule magnets may thus serve as clean model systems for the study of random field ferromagnetism where the random fields are controllable and considerably larger than typical hyperfine fields. This discovery promises to enable widespread and convenient experimental study of magnetism in a random field in a broad class of new materials.

8:36AM H3.00002 Pure and Random–field quantum criticality in dipolar Ising magnets[1]

, ANDREW MILLIS, Columbia University — A theoretical model for Mn_{12} acetates and related materials is derived. Isomer effects present in some families of host acetate materials are argued to lead to a random field of a strength which may be tuned by a magnetic field applied in a direction perpendicular to the easy axis of the Mn_{12} unit. A mean field phase diagram is presented and consequences of beyond-mean-field physics are outlined. Measureable consequences in the experimentally accessible high temperature regime are presented and in this regime the importance of a complete treatment of the molecular level structure is emphasized. Open theoretical problems are described. Work reported in Phys. Rev. B 82, 014406 (2010) and Phys. Rev. B 82, 174405 (2010)). and performed in collaboration with: M. 9:12AM H3.00003 Deflagration, fronts of tunneling, and dipolar ordering in molecular magnets

, DMITRY GARANIN, CUNY — Although there is no exchange interaction in crystals of molecular magnets characterized by a giant effective spin S (S =10 for Mn_{12}, and Fe_8), magnetic field $B^{(D)}$ generated by magnetic moments $g\mu_B S$ of magnetic molecules creates energy bias $W^{(D)}$=2$Sg\mu_B B^{(D)}$ on a molecule that largely exceeds the tunnelling splitting Δ of matching quantum states on different sides of the anisotropy barrier. Thus the dipolar field has a profound influence on the processes of tunnelling and relaxation in molecular magnets. Both theoretical and experimental works showed a slow non-exponential relaxation of the magnetization in both initially ordered and completely disordered states since most of the spins are off tunneling resonance at any time. Recently a new mode of relaxation via tunneling has been found, the so-called fronts of tunneling, in which (within a 1d theoretical model) dipolar field adjusts so that spins are on resonance within the broad front core. In this "laminar" regime fronts of tunnelling are moving fast at speeds that can exceed that of the temperature-driven magnetic deflagration, if a sufficiently strong transverse field is applied. However, a "non-laminar" regime has also been found in which instability causes spins to go off resonance and the front speed drops. In a combination with magnetic deflagration, the laminar regime becomes more stable and exists in the whole dipolar window 0$\leq W \leq W^{(D)}$ on the external bias W, where the deflagration speed strongly increases. Another dipolar effect in molecular magnets is dipolar ordering below 1 K that has recently been shown to be non-uniform because of formation of magnetic domains. An object of current research is possible non-uniformity of magnetic deflagration and tunneling fronts via domain instability that could influence their speed.

9:48AM H3.00004 Experiments on Magnetic Deflagration , JAVIER TEJADA, University Barcelona — Magnetic deflagration was first observed in molecular magnets [1,2] and then in glassy magnetic materials like manganites [3,4] and intermetallic systems like Gd_5Ge_4 [5]. The role of the chemical energy is played by the magnetic energy of the material. In the case of a molecular magnet, this is Zeeman energy, while in manganites and Gd_5Ge_4 the free energy is a combination of the Zeeman energy and the energy of the metastable magnetic phase. In molecular magnets both the ignition process and the speed of the flame are assisted by quantum spin reversal [2]. There also exists some evidence of the transition from deflagration to detonation [6]. Various experimental techniques have been used to detect the speed of the magnetic flame. They include SQUID magnetometry, Hall bars and coils. Magnetic deflagration has been ignited by local heating, application of external fields, by surface acoustic waves and microwaves. High frequency EPR measurements of the population of spin levels permitted observation of magnetic deflagration in real time. The talk will review these experiments and their interpretation.

10:24AM H3.00005 Electronic Structure and Transport Through Single Molecule Magnets[1] , KYUNGWHA PARK, Dept. of Physics, Virginia Tech — Over the past decade, single-molecule magnets have drawn considerable attention due to observed magnetic quantum tunneling and interference and a possibility of using them for information storage or devices. There have been so far significant experimental efforts to build and characterize monolayers of single-molecule magnets on various surfaces or single-molecule magnets connected to electrodes. There is need to understand changes of electronic and magnetic properties of single-molecule magnets in those environments using quantum mechanical simulations. We simulate, within density-functional theory, a nanostructure in which prototype single-molecule magnets Mn12 are adsorbed onto a gold surface. We investigate coupling between the Mn12 and the surface and discuss electronic structure and magnetic anisotropy of the Mn12 on a gold surface in comparison to an isolated Mn12. In addition, we present electron transport properties through a Mn12 bridged between gold electrodes, using the nonequilibrium Green's function method in conjunction with density-functional theory. We discuss a possibility of using a Mn12 molecule as a spin filter and an effect of interface geometry and bonding type on transport across a Mn12.

Session H4 DPOLY: Polymer Physics Prize Ballroom A4

8:00AM H4.00001 Polymer Physics Prize Talk: Polymer Brushes: Why do we still care?[1] , GARY S. GREST, Sandia National Laboratories — Polymer molecules have been widely used to modify the properties of surfaces including its adhesion. Among the most studied have been polymer brushes, in which polymer chains are grafted at one end to a surface and immersed in a small molecule solvents. Experiments and simulations have shown that the conformation of the chains grafted onto a flat surface depends on the grafting density and the interaction of the polymer with the solvent. As the molecular weight of the solvent increases, the structure of the brush changes. Consequently the brush chains are expelled from the solvent due to entropic loss that originate from the fact that the melt chains penetrating the brush cannot overcome the translational, or mixing, entropy. This crossover from wetted to non-wetted brushes, has important implications for polymer adhesion, where the phase separation of melt and brush chains reduces entanglements at the interface. As polymers are grafted to nanoparticles, the curvature of the surface offers the polymer brush chains a significantly larger space to explore compared to a flat surface, reducing the tendency for autophobic dewetting. Using large scale molecular dynamics simulations we have studied the interface between brush coated nanoparticles and a polymer melt. Effects of chain length of the brush, and that of the polymer melt, the coverage of the nanoparticle and its curvature on the brush/melt interface will be discussed. The role of individual entanglements, between the brush chains and the melt, as identified by primitive path analysis will be introduced. These simulations provide insight into the structure of the brush/polymer interface which is not accessible through other theoretical or experimental means.

[1]Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy under Contract No. DE-AC04-94AL85000.

8:36AM H4.00002 Polymer Physics Prize Talk: Topological Constraints Matter – or Back to the Origin[1] , KURT KREMER, Max Planck Institute for Polymer Research, Mainz, Germany — Topological constraints, being permanent or temporal, influence many properties of soft matter, especially polymers. While at a first glance the simple Rouse models describes the motion of short chains surprisingly well, the fact that chains cannot cut through each other dominates the dynamics of long chain melts, ring polymers and the relaxation in networks and gels. Furthermore new phenomena in special melts and mixtures even make this more obvious. The talk will review some developments and will also address new problems linked to material science as well as biology. To illustrate the importance of topological constraints, numerical simulations for a melt on non concatenated ring polymers with and without linear contaminants will be presented. While the static properties of long rings can be rationalized by the concept of a crumpled globule, dynamic properties are much less understood. Our simulations clearly show that diffusion and stress relaxation in such a system of globules decouple. In addition the first results for non concatenated rings added to a melt of linear polymers and for a few linear polymers added to a melt of rings will be discussed.

[1]The work over the years benefited from intense and fruitful collaborations with many colleagues. For the topics discussed above I especially want to thank K. Binder, G. S. Grest. B. Duenweg, R. Everaers, M. Pütz, A. Yu Grosberg and J. Halverson.

9:12AM H4.00003 Bottle-brush polymers versus worm-like chains: Do we understand the stiffness of macromolecules? , KURT BINDER, Johannes Gutenberg Universitaet Mainz — Bottle-brush polymers contain a long flexible macromolecule as a backbone to which flexible side-chains are grafted. Through the choice of the grafting density of the length of the side chains to the local stiffness of this cylindrical molecular brush can be controlled. However, understanding mesoscopic length scales (cross-sectional radius, persistence length, contour length) of these semiflexible cylindrical brushes poses a challenging problem. While self-avoiding walks of variable stiffness show a crossover to the Kratky-Porod worm-like chain model, and hence a (pre-asymptotic) regime of Gaussian behavior, bottle-brushes under good solvent conditions are not compatible with this model. Consequences for the description of chain stiffness in terms of the concept of the persistence length are discussed, as welll as pertinent experiments.

9:48AM H4.00004 Entanglements and the Mechanical Properties of Glassy Polymers[1] , MARK ROBBINS, Johns Hopkins University — The response of glassy polymers to shear or tensile strain is strongly influenced by the entanglement network that is inherited from the melt. Molecular dynamics simulations are used to probe the microscopic origins of stress-strain curves and their connection to entanglements. The latter are identified in real space by examining topological constraints along the primitive path. The first part of the talk will consider the process of craze formation, where the entanglement density is correlated to the volume increase during crazing. Simulations show that entanglements are preserved during crazing, but the craze density does not correspond to pulling chains taut between entanglements. The second part of the talk will examine the effect of entanglements on strain hardening under uniaxial strain. The stress is directly associated with the degree of orientational order along the strain axis, and nearly independent of order along perpendicular directions [1]. Studies with mixtures of short and long chains show that the degree of order is independent of the surrounding chains [2]. The final part of the talk will examine the strength of welds formed by diffusion across polymer interfaces. The shear stress follows the bulk response until chains are pulled taut on the scale of the length of segments that have diffused across the interface. When this length is several times the entanglement length, the maximum shear stress saturates at the bulk value and chains fail through scission. Similar trends are found for the fracture energy in tensile loading.

10:24AM H4.00005 Conjugated Polymer Nanoparticle Hybrids: Structure, Dynamics and Forces[1] , DVORA PERAHIA, Clemson University — While nanoparticles (NPs) have unique tunable elctro-optical properties and exceptional mechanical strength, it remains a challenge to integrate them into devices while retaining the advantages of the nanoscale. Tethering polymeric materials to the NPs surfaces has the potential to stabilize single NPs and direct their assembly. The polymers may serve in several capacities from a simple tether to a matrix to directed assembly tool taking advantage of the inherent structure of the polymers and as an active component in a complex material. However confining a large molecule to a highly curved surface affects the inherent configuration of the polymer. These effects are of particular interests in conjugated polymer-nanoparticle hybrids, where the conformation of the polymers affects not only the assembly of the nanoparticles but also the optical and electronic communication between the NPs. Using molecular dynamic simulations we have studied the structure of a single hybrid of *para* dialkyl phenylene ethynelyne (PPE) grafted nanoparticles. PPEs are polymers whose conformation determines their degree of conjugation and therefore their electro-optical response. Using simulations coupled with neutron scattering studies we have shown that PPE is a rigid polymer that is fully extended in dilute solutions in good and theta solvents but can be forced into a collapsed configuration in a poor a solvent. When confined to a nanoparticle surface, the PPE chains are fully extended but cluster as the solvent quality is reduced. Results for the conformation of grafted PPE molecules on a single nanoparticle and the forces between two nanoparticles as a function of chain length and solvent quality will be presented. These simulations provide insight to the interactions that result in formation of tunable hybrids.

Session H5 FIAP GERA DNP: Drowning in Carbon: The Imperative of Nuclear Power Ballroom C1

8:00AM H5.00001 A Strategy for Expanded Nuclear Power: The Role of the U.S. Department of Energy , VICTOR REIS, U.S. Department of Energy — This abstract not available.

8:36AM H5.00002 What happened to the US nuclear renaissance? , ROBERT ROSNER , The University of Chicago — While nuclear power generation is seeing a distinct revival internationally, especially in Asia, a corresponding revival within the United States has not yet occurred. I will discuss the various reasons for this difference, as well as the consequences - some distinctly unintended - for the future U.S. role in the spread of nuclear power generation as well as in non-proliferation internationally.

9:12AM H5.00003 Used Nuclear Fuel: From Liability to Benefit , RAYMOND L. ORBACH, The University of Texas at Austin — Nuclear power has proven safe and reliable, with operating efficiencies in the U.S. exceeding 90%. It provides a carbon-free source of electricity (with about a 10% penalty arising from CO_2 released from construction and the fuel cycle). However, used fuel from nuclear reactors is highly toxic and presents a challenge for permanent disposal – both from technical and policy perspectives. The half-life of the "bad actors" is relatively short (of the order of decades) while the very long lived isotopes are relatively benign. At present, spent fuel is stored on-site in cooling ponds. Once the used fuel pools are full, the fuel is moved to dry cask storage on-site. Though the local storage is capable of handling used fuel safely and securely for many decades, the law requires DOE to assume responsibility for the used fuel and remove it from reactor sites. The nuclear industry pays a tithe to support sequestration of used fuel (but not research). However, there is currently no national policy in place to deal with the permanent disposal of nuclear fuel. This administration is opposed to underground storage at Yucca Mountain. There is no national policy for interim storage—removal of spent fuel from reactor sites and storage at a central location. And there is no national policy for liberating the energy contained in used fuel through recycling (separating out the fissionable components for subsequent use as nuclear fuel). A "Blue Ribbon Commission" has been formed to consider alternatives, but will not report until 2012. This paper will examine alternatives for used fuel disposition, their drawbacks (e.g. proliferation issues arising from recycling), and their benefits. For recycle options to emerge as a viable technology, research is required to develop cost effective methods for treating used nuclear fuel, with attention to policy as well as technical issues.

9:48AM H5.00004 Fuel Cycle R&D Requirements for Future Nuclear Power , LEE SCHROEDER, Lawrence Berkeley National Lab and TechSource — Recently, DOE Nuclear Energy completed its Road Map for a science-based approach to future nuclear energy development. Fuel cycle R&D is a central element of the Road Map, which covers nuclear energy through the period 2040-2050 and perhaps beyond. Examples of fuel cycle R&D activities will be presented, along with an outline of the types of research facilities needed to support this effort. Experimental facilities within several areas of the DOE, including DOE's Office of Nuclear Energy and its Office of Science, will be required for this task. In addition, advanced modeling and simulation will play a growing major role in these activities.

10:24AM H5.00005 Roundtable Discussion and Q&A –

Tuesday, March 22, 2011 8:00AM - 11:00AM –

Session H6 DAMOP: Ultracold Molecules and Quantum Many Body Physics Ballroom C2

8:00AM H6.00001 Control of dipolar collisions of polar molecules in the quantum regime[1] , AMODSEN CHOTIA, JILA, University of Colorado, Boulder and National Institute of Standards and Technology — Ultracold polar molecular quantum gases promise to open new research directions ranging from the study of ultra-cold chemistry, precision measurements to novel quantum phase transitions. Based on the preparation of high-phase space density gases of polar KRb molecules, I will discuss the control of dipolar collisions and chemical reactions of polar molecules in a regime where quantum statistics, single scattering partial waves, and quantum threshold laws play a dominant role. In particular, I will discuss the crucial role of electric dipole-dipole interactions and external confinement in determining the chemical reaction rate. Finally, I will discuss prospects of reaching quantum degeneracy in bi-alkali samples of polar molecules and prospects for these systems as novel dipolar quantum many-body systems.

8:36AM H6.00002 Ultracold high-density samples of rovibronic ground-state molecules in an optical lattice , JOHANN GEORG DANZL, Institute of Experimental Physics, University of Innsbruck — Ultracold molecules controlled at the level of single quantum states with respect to all internal and external degrees of freedom will enable a series of fundamental studies in physics and chemistry, ranging from novel quantum gas experiments and cold controlled chemistry to quantum information and quantum simulation. Ultracold molecules trapped in an optical lattice at high density and prepared in their lowest internal quantum state are an ideal starting point for these studies. We create ultracold and dense samples of molecules in a single hyperfine sublevel of the rovibronic ground state while each molecule is individually trapped in the motional ground state of an optical lattice well [1,2]. Starting from an atomic Mott-insulator state with optimized double-site occupancy, weakly bound Cs dimer molecules are efficiently formed on a Feshbach resonance and subsequently transferred to the rovibronic ground state by a stimulated 4-photon process with the Stimulated Raman Adiabatic Passage (STIRAP) technique. The molecules are trapped in the lattice with a lifetime of 8 s. We aim at producing Bose-Einstein condensates of ground-state molecules by adiabatically removing the lattice. Our results, when suitably generalized to heteronuclear molecules, present an important step towards the realization of dipolar quantum-gas phases in optical lattices. I will report on recent progress in Innsbruck on the formation of RbCs ground state molecules.

9:12AM H6.00003 Theory of ultracold heteronuclear polar molecules , JOHN BOHN, Univ of Colorado - Boulder — This abstract not available.

9:48AM H6.00004 Laser Cooling of a Diatomic Molecule , EDWARD SHUMAN, Yale University — Laser cooling techniques to produce ultracold (T<1μK) atoms have lead to rapid advances in a wide array of fields. However, extending laser cooling to molecules has remained elusive. The primary problem is that laser cooling requires a large number (>104) of photon absorption/emission cycles. Molecules, however, have vibrational and rotational degrees of freedom, which typically lead to high branching probabilities into a large number of unwanted sublevels. Here we report on experiments demonstrating the laser cooling of a diatomic molecule which have overcome this problem. We use the molecule strontium monofluoride (SrF) where only three lasers and a magnetic field are necessary to scatter >105 photons. We have demonstrated 1-D transverse cooling of a beam of SrF, dominated by Doppler or Sisyphus-type cooling forces depending on experimental parameters. We observe a reduction in the velocity distribution by a factor of 3 or more, corresponding to final 1-D temperature T $<$ 1 mK. This transverse cooling may be useful for a variety of experiments; in addition, our results open a path to trapping and 3D cooling of SrF to the ultracold regime.

10:24AM H6.00005 Meta-stable 1-D gases of polar molecules with attractive dipole forces[1] , ROBIN CÔTÉ, University of Connecticut — The recent achievements in the formation and manipulation of ultracold polar molecules have opened the gate to exciting new studies in several fields of physical sciences. Polar molecules could find uses in quantum information science and in precision measurements, while dense samples could provide a fertile ground for novel quantum gases because of their long-range and anisotropic interactions. Until now, stable dipolar gases were thought to require a repulsive dipole-dipole interaction, such as provided by parallel dipoles aligned perpendicularly to a two-dimensional (2-D) trap. However, to observe interesting new correlations and condensed matter phases, attractive interactions are needed. Here, we explore how meta-stable one-dimensional (1-D) samples of ultracold polar molecules could be created with attractive long-range dipole-dipole interaction. We show that a repulsive barrier due to a strong quadrupole interaction can stabilize a gas of ultracold KRb molecules and even lead to long-range wells supporting bound states. The properties of these wells can be controlled by external electric fields, allowing the formation of long chains of KRb polymers, and the further study of Luttinger liquid transition. We also discuss the general molecular properties necessary for the existence of a repulsive barrier.

Tuesday, March 22, 2011 8:00AM - 11:00AM –
Session H7 DBP DPOLY: Physics of Proteins II: Dynamics and Functions Ballroom C3

8:00AM H7.00001 Energy Landscapes Encoding Function in Enzymes Investigated Over Broad Time Scales[1] , ROBERT CALLENDER, Albert Einstein College of Medicine — The operating hypothesis of much of our current work is that atomic motion, over broad time scales (femtoseconds to milliseconds, the latter being the time scale of most enzyme catalyzed reactions), contributes to enzymic catalysis in proteins. It is clear from our work that specific types of motions are important in binding of ligands to proteins and transition state formation in enzymatic catalysis. Since new experimental and theoretical approaches are needed to understand the dynamical nature of proteins broadly and enzymatic catalysis specifically, we have employed time-resolved "pump-probe" spectroscopic techniques because of the sensitivity of these type of approaches to all relevant time scales. And we have also developed and applied new theoretical methods. The talk will focus on how lactate dehydrogenase brings about catalysis based on current experimental and theoretical studies.

[1]Work supported by NIH Grant P01GM068036.

8:36AM H7.00002 NMR investigations of molecular dynamics , ARTHUR PALMER, Columbia University — NMR spectroscopy is a powerful experimental approach for characterizing protein conformational dynamics on multiple time scales. The insights obtained from NMR studies are complemented and by molecular dynamics (MD) simulations, which provide full atomistic details of protein dynamics. Homologous mesophilic (*E. coli*) and thermophilic (*T. thermophilus*) ribonuclease H (RNase H) enzymes serve to illustrate how changes in protein sequence and structure that affect conformational dynamic processes can be monitored and characterized by joint analysis of NMR spectroscopy and MD simulations. A Gly residue inserted within a putative hinge between helices B and C is conserved among thermophilic RNases H, but absent in mesophilic RNases H. Experimental spin relaxation measurements show that the dynamic properties of *T. thermophilus* RNase H are recapitulated in *E. coli* RNase H by insertion of a Gly residue between helices B and C. Additional specific intramolecular interactions that modulate backbone and sidechain dynamical properties of the Gly-rich loop and of the conserved Trp residue flanking the Gly insertion site have been identified using MD simulations and subsequently confirmed by NMR spin relaxation measurements. These results emphasize the importance of hydrogen bonds and local steric interactions in restricting conformational fluctuations, and the absence of such interactions in allowing conformational adaptation to substrate binding.

9:12AM H7.00003 Kinetic vs. Thermodynamic Control of Bacteriorhodopsin Pumping[1] , MARILYN GUNNER, City College of New York — Bacteriorhodopsin is a transmembrane proton pump that converts light energy to a transmembrane electrochemical gradient. Retinal, bound in the center of the protein, absorbs light and isomerizes from the all-trans to 13-cis configuration. A series of conformational changes and proton transfers then restores the structure to the all-trans ground state while pumping one proton from the high pH cell interior to the low pH exterior, saving energy in an electrochemical gradient. Poorly understood gating elements control key steps where incorrect proton transfer would return the protein to the ground state without pumping. The gate's barrier height determines how much the pump leaks. Analysis of high-resolution structures trapped in different intermediates has produced ideas for how bacteriorhodopsin ensures pumping. There are two contrasting strategies, one primarily thermodynamic and the other relying on kinetic control to ensure that protons are moved uphill. With thermodynamic control, residue protonation states always remain in quasi-equilibrium. Relatively slow conformational changes shift the energy landscape modifying site pKas. Residues then change ionization remaining in equilibrium in each metastable intermediate. The sequence of intermediates imparts the directionality to the transfers. Alternatively, the direction of transfer is determined by the accessibility of low energy pathways so is thus is under kinetic control. We will discuss which steps in the bacteriorhodopsin photocycle are under thermodynamic or under kinetic control. The role of three specific conformational changes (retinal isomerization, Arg82 reorientation and Glu194 and 204 separations) on the degree of proton transfer will be described. Supported by NFS MCB 1022208.

[1]Carried out with Yifan Song now at the University of Washington Department of Biochemistry

9:48AM H7.00004 Beller Lectureship Talk: Ultrafast Excitation Energy Transfer and the Mechanism of Non-Photochemical Quenching in Plant Photosynthesis , RIENK VAN GRONDELLE, VU University Amsterdam — The success of photosynthesis relies on two ultrafast processes: excitation energy transfer in the light-harvesting antenna followed by charge separation in the reaction center. LHCII, the peripheral light-harvesting complex of Photosystem II, plays a major role. At the same time, the same light-harvesting system can be 'switched' into a quenching state, which effectively protects the reaction center of Photosystem II from over-excitation and photodamage. In this talk I will demonstrate how LHCII collects and transfers excitation energy. Using single molecule spectroscopy we have discovered how LHCII can switch between this light-harvesting state, a quenched state and a red-shifted state. We show that the switching properties between the light-harvesting state and the quenched state depend strongly on the environmental conditions, where the quenched state is favoured under 'NPQ-like' conditions. It is argued that this is the mechanism of non-photochemical quenching in plants.

10:24AM H7.00005 Protein Dynamics, Ligand Binding, and Biological Function , HUAN-XIANG ZHOU, Florida State University — Dynamics is essential for protein function. To demonstrate this point, this talk presents three studies. (1) For a ligand-gated ion channel, ligand binding leads to channel activation by modulating the dynamics of the channel protein. A common theme that emerges from different families of ligand-gated ion channels is that agonist binding closes the ligand-bidning domain (LBD), leading to pore opening in the transmembrane domain (TMD); in contrast, antagonist binding opens the LBD, leading to pore closing in the TMD [1]. (2) When the structure [2] and gating dynamics [3] of the influenza M2 proton channel are accounted for, the calculated rate of ion transport is in quantitative agreement with experimental data [4]. (3) In enzymes, gating dynamics afford substrate selectivity [5].

Session H9 DFD: Colloids: Experimental D220

8:00AM H9.00001 Universality in the delayed failure of colloidal gels , JORIS SPRAKEL, DAVID WEITZ, Harvard University — The mechanical failure of heterogeneous solids is not always instantaneous with the application of a load, but can be significantly delayed. We use colloidal gels, a prototypic heterogeneous material, to unravel the microscopic mechanisms behind this delayed failure. A universal behavior is revealed; the delay time depends only on the magnitude of the applied stress not on its origin. Whether the gel succumbs to internal tension, gravitational compression or shear stresses, the behavior can be quantitatively explained using a generalized bond-rupture model that describes the microscopic events triggering macroscopic failure.

8:12AM H9.00002 Glassy dynamics of 2D colloid crystals in a random pinning potential[1] , SUNGCHEOL KIM, ALEXANDROS PERTSINIDIS[2], XINSHENG LING, Brown University — Recently, we have demonstrated that a monolayer charged colloidal crystal confined to a rough charged surface provides a realization of the Larkin-Ovchinnikov random-pinning model in two dimensions [1]. The statics of the system is found to agree with Larkin's prediction of balkanization into small ordered domains. However, the dynamics are in disagreement with the collective creep model. Detailed analysis of the particle trajectories suggest that collective creep is preempted by channel flow. We also find that the velocity response to a step-like driving force shows a stretched exponential behavior similar to that found in structural glasses. Here, we provide a detailed analysis of this process.

8:24AM H9.00003 Field-driven pattern formation of charged particles in nonpolar solvent , TINA LIN, SHMUEL RUBINSTEIN, DAVID WEITZ, Harvard University — We combine microfluidics and high-speed imaging to investigate transport dynamics of charged colloidal particles in a nonpolar solvent as the polarity of an external electric field is switched periodically. Immediately following a switch, particles which were initially all packed against one electrode move towards the opposite electrode in an unstable manner; instead of remaining uniform, the particle front develops undulations. This results in a heterogeneous deposition of particles on the electrode wall. For a range of wait times between switches, we find that the particles localize at exceptionally well-defined periodic modes and we offer a simple physical model to account for this pattern formation.

8:36AM H9.00004 Colloids with magnetic patches: synthesis and self-assembly , STEFANO SACANNA, NYU, LAURA ROSSI, Utrecht University, WILLIAM IRVINE, DAVID PINE, NYU — We developed a new class of colloidal particles that programmably and reversibly self-assemble into well-defined clusters by virtue of "magnetic patches" carrying a permanent magnetic dipole moment. The resulting clusters form spontaneously in a zero external field, and their geometry is entirely determined by the interplay between magnetic, steric, and electrostatic interactions. Imposing an external magnetic field enables the clusters to unbind or change their geometry allowing, in principle, to create materials with tunable structural arrangements.

8:48AM H9.00005 Melting Dynamics of Colloidal Thin Films on Patterned Substrates , JOHN MERGO, School of Applied and Engineering Physics, Cornell University, JOHN SAVAGE, Department of Physics, Cornell University, ITAI COHEN, Deparment of Physics, Cornell University — We present results of experiments on the melting dynamics of colloidal crystals formed on patterned substrates. Our system consists of micron-sized colloidal particles and a tunable short- range attractive depletion interaction that can be controlled by small temperature changes. We investigate the melting rates of crystalline islands that form on substrates with square and hexagonal symmetry. We find that crystals with square symmetry melt significantly slower than those with hexagonal symmetry despite the fact that particles at the edge of the hexagonal crystal are on average bound more strongly than those at the edge of a square crystal. We find that the symmetry of the substrate affects the ability of particles to diffuse away from a melting crystal, and these differences in single-particle diffusion rates account for the difference in melting rates.

9:00AM H9.00006 Dynamics of Transient Vorticity Aligned Structures in Attractive Colloidal Suspensions , AJAY NEGI, Yale University, MICHELLE BEBRIN, McGill University, CHINEDUM OSUJI, Yale University — Shear rate jumps from high to low flow rates in an attractive colloidal suspension of carbon black particles in a non-polar solvent result in the formation of transient log-like structures aligned in the vorticity direction. Optical microscopy in situ with bulk rheology shows that the appearance of these aggregates is attended by an increase in the suspension viscosity. The viscosity shows a peak and then gradually recedes with passage of time under flow in concordance with the disappearance of the log-like structures. The time at which the viscosity reaches its maximum scales inversely with the shear rate applied to the system. This emergence of the peak in viscosity appears to be controlled by a critical strain and rescaling in these terms produces a common response across several different shear rates. Alteration of the attraction strength between particles by the addition of surfactant severely inhibits the structure formation. We present a simple model to account for these observations.

9:12AM H9.00007 Two-dimensional Fibonacci spiral optical thermal ratchets , KE XIAO, DAVID GRIER, Center for Soft Matter Research at New York University — A novel two-dimensional optical thermal ratchet has been implemented with holographic optical trapping arrays structured as the "Fibonacci spiral" for diffusing colloidal particles. Periodically rotating the optical trapping array by an angle in a three-step cycle yields a two-dimensional time-varying optical landscape that acts either as (1) a deterministic pump when traps are closely dispersed in space, whose induced radial and azimuthal fluxes can be quantitatively mapped out according to the geometry of Fibonacci spiral, or else as (2) an optical thermal ratchet when traps are widely dispersed, whose transport property depends on the competition between the temporal evolution in optical landscapes and Brownian particles' diffusivity. The Fibonacci ratchet displays independent flux reversals in both the radial and azimuthal directions as a function of the cycle frequency and the inter-trap separation.

9:24AM H9.00008 Using shear to assemble colloidal strings , ITAI COHEN, XIANG CHENG, Dept. of Physics, Cornell University — Sheared colloidal suspensions exhibit various fascinating phases under the influence of hydrodynamic, interparticle and thermal interactions. These shear-induced phases have been intensively studied for suspensions well above the crystalline threshold, but remain relatively unexplored for amorphous suspensions. Here, we report a novel string phase in less concentrated colloidal suspensions under shear, where particles assemble into long strings normal to the plane of shear. This finding contradicts previous numerical results that predict the formation of particle strings along the shear velocity direction. We systematically investigate how the phase depends on the shear rates, the confinement of shear plates, and the volume fractions of samples. We demonstrate the relation between the string phase of low volume fraction samples and the shear-induced crystallization of high volume fraction samples. A simple mechanism for the formation of this novel phase is suggested.

9:36AM H9.00009 Biomembrane-mediated control of like-charge colloidal attraction , MAUNTA MANANDHAR, YUPENG KONG, RAGHUVEER PARTHASARATHY, Department of Physics and Material Science Institute, The University of Oregon — The nature of attractions observed between like-charged colloidal particles near a confining wall is still mysterious, due in part to the lack of experimental systems with tunable inter-particle interactions. Biomembranes are appealing candidates for colloidal functionalization, enabling access to electrostatic and chemical properties that influence inter-particle relations. Previous optical-trap based examinations of lipid membrane functionalized particles revealed a surprising linear relationship between the magnitude of the attractive pair potential and the particle charge in presence of a wall of constant charge density. Here, using lipid membranes to also functionalize the confining wall, thereby controlling its charge density, we find a non-linear relationship between inter-particle attraction and charge. Our results highlight the role of substrate-induced fields in controlling pair interactions between colloidal microparticles.

9:48AM H9.00010 Colloidal Gas-Liquid Condensation induced by the Critical Casimir Effect , DUC NGUYEN, SUZANNE FABER, GERARD H. WEGDAM, PETER SCHALL, University of Amsterdam — We explore a new temperature control over colloidal phase formation by using the Critical Casimir effect. This effect allows direct control over particle interactions via temperature-dependent solvent fluctuations: In analogy to the confinement of fluctuations of the electromagnetic field between two dielectrics (quantum mechanical Casimir effect), the confinement of fluctuations of a critical solvent leads to an attraction between surfaces that are immersed in this solvent. This allows exquisite temperature control over the interactions of colloidal particles that are suspended in this critical solvent. We show that this temperature control allows us to "freeze" a dilute colloidal gas into a dense colloidal liquid, and a crystalline solid. By using confocal microscopy, we follow these phase transitions directly in real space, and we measure the particle pair potential. We show that we can quantitatively account for the gas-liquid condensation by using Van der Waals theory. We study the growth of colloidal liquid droplets by following the mean droplet radius <R> with dynamic light scattering. We find <R> $\sim$ t1/2 and <R> $\sim$ t1/3 indicating that the droplets form by nucleation, followed by diffusion limited growth.

10:00AM H9.00011 Comparison of different analysis techniques in inline holographic video microscopy , FOOK CHIONG CHEONG, New York University — Holographic video microscope can be analyzed on a frame-by-frame basis to track individual colloidal particles' three-dimensional motions with nanometer resolution. In this work, we compare the performance of two complementary analysis techniques, one based on fitting to the exact Lorenz-Mie theory and the other based on phenomenological interpretation of the scattered light field reconstructed with Rayleigh-Sommerfeld back-propagation. Although Lorenz-Mie tracking provides more information and is inherently more precise, Rayleigh-Sommerfeld reconstruction is faster and more general.

10:12AM H9.00012 Dynamics of colloidal particles in ice , MELISSA SPANNUTH, S.G.J. MOCHRIE, Yale University, S.S.L. PEPPIN, Oxford University, J.S. WETTLAUFER, Yale University — Solidification of the solvent phase of a colloidal suspension occurs in many natural and technological settings and is becoming a popular technique for creating microporous structures and composite materials. During freezing, regions of high particle density can form as particles are rejected from the growing solid and guided into a variety of macroscopic morphologies. The particles in the high density regions form an amorphous colloidal solid that deforms in response to internal and external stresses. Using X-ray Photon Correlation Spectroscopy, we studied this deformation for silica particles in polycrystalline ice. We found that the particles in the high density regions underwent ballistic motion coupled with a non-exponential decay of the intensity autocorrelation function (ACF) that transitions from a stretched to a compressed exponential with increasing scattering vector q. While ballistic motion and a compressed exponential decay of the ACF is common, the coupling with a stretched exponential decay is very rare and a transition with increasing q has not previously been reported. We explain this behavior in terms of ice grain boundary migration.

10:24AM H9.00013 Imaging the microscopic structure of shear thinning and thickening colloidal suspensions , XIANG CHENG, Dept of Physics, Cornell University, JONATHAN MCCOY, Department of Physics and Astronomy, Colby College, JACOB ISRAELACHVILI, Dept. of Chemical Engineering, University of California, Santa Barbara, ITAI COHEN, Dept. of Physics, Cornell University — The viscosity of colloidal suspensions varies by orders of magnitude depending on how quickly they are sheared. Such non- Newtonian behavior arises from the arrangement of suspended particles and their mutual interactions. Although numerical simulations and various scattering experiments have revealed much about the local and average suspension structures, particle dynamics at mesoscopic length scales, where non- Newtonian behaviors are believed to originate, are still poorly understood. Here, by combining fast confocal microscopy with simultaneous rheological measurements, we systematically investigate changes in suspension structure over a range of length scales, as the suspension transitions through regimes with different rheological signatures. Our measurements bridge previous simulation and scattering results, and unambiguously show that shear thinning is coupled to particle layering, that shear thickening is decoupled from suspension order-to-disorder transitions, and that there exists a novel phase where particles self-assemble into strings oriented normal to the plane of shear.

10:36AM H9.00014 Cubic crystals from cubic colloids , LAURA ROSSI, Van't Hoff Laboratory, Utrecht University, STEFANO SACANNA, WILLIAM IRVINE, PAUL CHAIKIN, DAVID PINE, Center for Soft Matter Research, New York University, ALBERT PHILIPSE, Van't Hoff Laboratory, Utrecht University — We have studied the crystallization behavior of colloidal cubes by means of tunable depletion interactions. The colloidal system consists of novel micron-sized cubic particles prepared by silica deposition on hematite templates and various non-adsorbing water-soluble polymers as depletion agents. We show that under certain conditions the cubes can self-organize into crystals with a simple cubic symmetry, which is set by the size of the depletant. The dynamic of crystal nucleation and growth is investigated monitoring the samples in time by optical microscopy. Furthermore, by using temperature sensitive microgel particles as depletant it is possible to fine tune depletion interactions as to induce crystal melting. Assisting crystallization with an alternating electric field improves the uniformity of the cubic pattern allowing the preparation of macroscopic (almost defect-free) crystals that show visible Bragg colors.

10:48AM H9.00015 Spin-coating of rapidly dried colloidal suspensions: model and experiments[1] , MAXIMILIANO GIULIANI, University of Guelph, WENCESLAO GONZÁLEZ-VIÑAS, University of Navarra, ANAND YETHIRAJ, Memorial University of Newfoundland — The study of the formation of colloidal crystals has been a very active field in recent years. The spin-coating technique has proven to be a highly reproducible process to form large area colloidal crystals. Here, we present recent results on spin- coating of rapidly dried colloidal suspension. We show that the dynamics observed can be represented by an extension of classical Emslie model to highly volatile fluids. We obtained this extension while maintaining the explicit solution for the temporal evolution of the fluid thickness. We observed that the dynamics can be separated in two regimes: one dominated by non-evaporative effects and a second dominated by evaporative effects. The transition between these two dynamical regimes corresponds well with the transition between two symmetries observed during the fluid phase (six and four-fold). Similarly, the quality of the deposited structure is also well correlated to the relative strength of the capillary forces with respect to the viscous ones.

Tuesday, March 22, 2011 8:00AM - 11:00AM –
Session H10 DCMP: Semiconductor Surfaces and Interfaces D221

8:00AM H10.00001 Reversible vertical manipulation of Ag atoms on Si(111)-(74×7) at room temperature , FANGFEI MING, KEDONG WANG, SHUAN PAN, JIEPENG LIU, XIEQIU ZHANG, JINLONG YANG, XUDONG XIAO, DEPARTMENT OF PHYSICS, THE CHINESE UNIVERSITY OF HONG KONG, SHATIN, NEW TERRITORY, HONG KONG, CHINA TEAM, HEFEI NATIONAL LABORATORY FOR PHYSICAL SCIENCES AT MICROSCALES, UNIVERSITY OF SCIENCE AND TECHNOLOG TEAM — We have demonstrated a technique to conduct reproducible and reversible vertical manipulation of Ag atoms on the Si(111)-(7×7) surface at room temperature using a scanning tunneling microscope tip. The direction of the transfer of Ag atoms between the sample surface and the tip is simply controlled by the polarity of the bias voltage. Using the 7×7 unit cell as a nanometer size template, complex Ag nano-clusters could be assembled or disassembled by adding or removing Ag atoms in an atom-by-atom manner. With controlled number of Ag atoms filled in a half unit cell, we can construct Ag clusters with up to 25 Ag atoms. The precise control of the number of Ag atoms in the Ag clusters can provide critical information for understanding their physical and chemical properties, and form a fundamental base for the relevant studies of the Ag/Si(111)-(7×7) system and for fabricating nano-devices.

8:12AM H10.00002 Probing surface electronic structure with conductance measurements on Si nanomembranes , WEINA PENG, JAMES ENDRES, SHELLEY SCOTT, DONALD SAVAGE, IRENA KNEZEVIC, MARK ERIKSSON, MAX LAGALLY, University of Wisconsin Madison, MRSEC OF UNIVERSITY OF WISCONSIN MADISON TEAM — The surface electronic structure of nanostructures has a strong, sometimes dominant, influence on their transport properties, because of their large surface to volume ratios. Different surface terminations result in different transport behavior, and therefore conductance measurements on nanostructures can be used to study surface and interface electronic spectra. In our experiments, the conductance of the thin (200nm or less in thickness) top Si layer in silicon-on-insulator is measured as the back gate voltage is varied, for both hydrogen terminations and clean reconstructed surfaces in UHV. Experimental results on samples of different thicknesses are compared systematically with simulations to understand the role of the Si/SiO_2 interface and the electronic structure of the front surface. We explain why the transport behavior of NMs with a clean Si(001) surface is distinct from that with hydrogen termination. Donor type surface states are present in the majority on the hydrogenated surface, and their concentration is on the order of 10^{12} cm^{-2}. On the reconstructed Si surface, instead, pseudo-pinning of the Fermi level occurs because of the high density of states of the clean-surface band (2x1 reconstruction) and the presence of surface defect states.

8:24AM H10.00003 Experimental evidence for trapped volumes in thin Ag films on Si(111)-7x7 , S.T. HAYDEN, YIYAO CHEN, M.W. GRAMLICH, R.S. GARI, G.M. KING, P.F. MICELI, University of Missouri Department of Physics and Astronomy — Thin films of Ag on Si(111)-7x7 were prepared in UHV at room temperature by vapor depositing Ag at a glancing angle with respect to the surface normal. Comparing x-ray reflectivity and atomic force microscopy (AFM) measurements, it is found that both techniques give the same height distribution at the surface. However, for a given deposition angle, x-ray reflectivity measurements reveal that there is a significant portion of trapped volume that goes undetected by the AFM. Also, by increasing the deposition angle from normal to glancing incidence angles, both the roughness and the maximum height distribution profile increase. Experimental evidence for trapped volumes in Ag/Si(111)-7x7 will be discussed. Research funding is supported by NSF DMR-0706278. The Advanced Photon Source Sector 6 beam-line at Argonne National Laboratory is supported by the US-DOE through Ames Lab under Contract No. W-7405-Eng-82.

8:36AM H10.00004 Growth of Iridium and Silver on Ge(111) Studied by STM[1] , MARSHALL VAN ZIJLL, CORY MULLET, EMILIE HUFFMAN, SHIRLEY CHIANG, UC Davis — We have used scanning tunneling microscopy (STM) to characterize the growth of iridium and silver onto Ge(111) as a function of coverage and annealing temperature. Ir was deposited onto the Ge(111) c(2x8) surface at different coverages less than 1ML. The Ir forms islands with a $(\sqrt{3}x\sqrt{3})R30^\circ$ phase and island size increasing with increasing annealing temperature. Stranski-Krastanov growth was observed at most coverages. Ag deposited onto the Ge(111) c(2x8) surface and annealed at 450K forms both a (4x4) phase and a (3x1) phase. The Ge(111) surface reorganizes to a (2x2) phase after deposition of both Ir and Ag. High resolution images have been obtained allowing direct observation of the different phases.

8:48AM H10.00005 One-dimensional Mn atom chains templated on a Si(001) surface[1] , SIGRUN A. KÖSTER, JAMES H.G. OWEN, FRANÇOIS BIANCO, University of Geneva, Switzerland, ALEX M.P. SENA, DAVID R. BOWLER, University College London/London Centre for Nanotechnology, UK, CHRISTOPH RENNER, University of Geneva, Switzerland — Single-atom chains on a wide gap substrate are a very attractive embodiment of a truly one-dimensional system to explore the remarkable physical properties emerging in such low dimensions. We present self-assembled single-atom Mn chains on a Si(001) surface with Bi nanolines, which serve to increase greatly the average length of the Mn chains. They grow perpendicular to the Si(001) dimer rows, at densities which can be adjusted by means of the growth parameter. High resolution scanning tunneling microscopy (STM) micrographs are in perfect agreement with density functional theory (DFT), providing detailed insight into the chain structure. We further discuss low temperature STM spectroscopy and spin dependent DFT modeling suggesting Mn-chains are indeed a suitable candidate to observe electronic and magnetic properties in one-dimension experimentally.

9:00AM H10.00006 Low energy alkali ion-surface charge exchange for Si(111) as a function of doping , REUBEN D. GANN, JORY A. YARMOFF, University of California, Riverside — Alkali ion-surface charge exchange, which can be used to probe surface electronic states, is well understood within the context of the resonant charge transfer (RCT) model. Recent studies have extended the use of alkali ion scattering and the RCT model from metal surfaces to semiconductors and insulators. In the present work, we measure the effect of doping type and concentration on the neutralization probability of alkali ions scattered from semiconductors. Si(111) surfaces were prepared in UHV, and the neutralization probability of scattered Li^+ ions was measured for projectiles that were singly scattered from Si atomic sites. For the clean Si(111)-7×7 surface, the neutralization is determined by the surface electronic states [1] and is independent of doping. Samples were then dosed with atomic hydrogen in order to passivate the surface states and unpin the Fermi level. This affects the neutralization probabilities and reveals differences between n and p-type materials.

9:12AM H10.00007 Binding sites and diffusion barriers of a Ga adatom on the GaAs(001)-$c(4\times 4)$ surface from first-principles computations[1] , J. ROEHL, A. KOLAGATLA, V.K.K. GANGURI, S. KHARE, University of Toledo, R.J. PHANEUF, University of Maryland — The Ga adatom adsorption and diffusion processes on the $\mathrm{GaAs}(001)$-$c(4 \times 4)$ surface were studied using *ab initio* density-functional-theory computations in the local density approximation. Two distinct sets of minima and transition sites were discovered for a Ga adatom relaxing from heights of 3 and 0.5 Å from the surface. These two sets show significant differences in the interaction of the Ga adatom with surface As dimers. An electronic signature of the differences in this interaction was identified. We computed the energetic barriers to diffusion for various adsorption sites. From these, we propose three pathways for diffusion of a Ga adatom on this surface which indicate anisotropic diffusion along different directions.[2]

9:24AM H10.00008 Surface Structure of Bi-terminated GaAs Grown with Molecular Beam Epitaxy , ADAM DUZIK, JOANNA MILLUNCHICK, University of Michigan — Control of III-V semiconductor surfaces is crucial for high-quality device production. A means of interface control involves the use of Bi as a surfactant, which both smooths the surface and alters the surface reconstruction. We examined the effects of Bi deposition via molecular beam epitaxy on the GaAs(001) surface structure using reflective high energy electron diffraction and scanning tunneling microscopy. After ∼0.2 ML of Bi deposition, scanning tunneling microscopy revealed a disruption in the initial c(4×4) reconstruction. Coverages of ∼0.4 ML and ∼0.6 ML produced a (1×3) and a (2x3) diffraction pattern, respectively, and an atomic surface structure consisting of a disordered row reconstruction, β2(2×4) reconstruction rows, and surface clusters, with 1 ML deep pits at a coverage of ∼0.6 ML. Calculations show these changes in surface structure and morphology are likely not the result of As desorption, but due to the presence of Bi on the surface. These observations may help explain the origin of Bi clusters that give GaAsBi most of its unique properties.

9:36AM H10.00009 Design of carbide thin film coatings from first principles , MIKAEL RÅSANDER, University of California Davis, BIPLAB SANYAL, ULF JANSSON, OLLE ERIKSSON, Uppsala University — Transition metal carbides have many interesting physical properties and have therefore been used in many technological applications, e.g. as thin film metal coatings. A commonly studied thin film coating material is nc-TiC/a-C, where nanocomposites (nc-) of TiC are dispersed in an amorphous (a-) C matrix. An interesting feature of these types of materials is the possibility to design the material to obtain new functionality, e.g. by tuning the C to Ti content. In this talk we will present results obtained by first principles density functional theory calculations of a different approach, where various metals have been alloyed into TiC. Depending on the alloying metals ability to form carbides this will yield different effects. One of these effects is the creation of a driving force for the release of C from the carbide. This C release has been shown to yield favorable lubricating properties of nc-(Ti,Al)C/a-C thin films. We will show that the C release can be tuned by a careful selection of the alloying metal in order to optimize the properties of these types of thin film carbide coatings.

9:48AM H10.00010 THz optical Hall-effect and MIR-VUV ellipsometry characterization of 2DEG properties in HfO_2 passivated AlGaN/GaN HEMT structures[1] , S. SCHÖCHE, A. BOOSALIS, University of Nebraska-Lincoln, C.M. HERZINGER, J.A. WOOLLAM, J.A. Woollam Co. Inc., J. SHI, W.J. SCHAFF, L.F. EASTMAN, Cornell University, M. SCHUBERT, T. HOFMANN, University of Nebraska-Lincoln — We present non-contact, optical measurements of free-charge carrier mobility, sheet density, and effective mass parameters of the 2DEG for different HfO_2 passivated AlGaN/GaN high electron mobility transistor structures at room temperature. Spectroscopic ellipsometry (SE) in the spectral range from THz and Mid-IR to the VUV and THz optical Hall-effect (generalized ellipsometry in magnetic fields) (OHE) are employed. Changes in the HfO_2 layer growth conditions are found to drastically influence the electron density of the channel. The sheet density and the carrier mobility obtained by the optical investigations are in excellent agreement with results from electrical Hall-effect measurements. The electron effective mass parameters determined here using the OHE corroborate previous SdH and cyclotron resonance studies. The surface sensitivity of VUV-SE in combination with OHE allows for correlation of surface passivation and changes in the 2DEG properties.

10:00AM H10.00011 Low Temperature Epitaxial Growth of Ge Quantum Dots on Si(100) , ALI ER, HANI ELSAYED-ALI, Old Dominion University — The effect of laser-induced electronic excitations on the self-assembly of Ge quantum dots (QD) on Si(100)-(2x1) grown by pulsed laser deposition is studied. The experiment was conducted in ultrahigh vacuum. A chirped pulse amplified Ti:sapphire laser with ∼60 femtosecond pulse width, center wavelength ∼800 nm, and operating at 1 kHz repletion rate was split into two beams; one used to ablate a Ge target while the other to electronically excite the substrate. *In situ* reflection high-energy electron diffraction (RHEED), scanning tunneling microscopy (STM), and *ex situ* atomic force microscopy (AFM) were used to study the morphology of the grown QDs. For Ge coverage of 12 monolayer, it was observed that the excitation laser reduces the epitaxial growth temperature to 70 $^\circ$C, at which no epitaxy is possible without excitation. By using nanosecond Nd:YAG laser for ablation and excitation, it was shown that applying the excitation laser to the substrate during the growth changes the QD morphology and island density and improves the size uniformity of the QDs at 390 $^\circ$C. RHEED recovery curves show that the excitation laser increases the surface diffusion of the Ge atoms. A purely electronic mechanism of enhanced surface diffusion of the Ge adatoms is involved.

10:12AM H10.00012 Large scale atomic engineering of silicon (100) surfaces , KAI LI, University of Maryland, PRADEEP NAMBOODIRI, SUMANTH CHIKKAMARANAHALLI, JOSEPH FU, RICHARD SILVER, National Institute of Standards and Technology, NATIONAL INSTITUTE OF STANDARDS AND TECHNOLOGY COLLABORATION, UNIVERSITY OF MARYLAND, COLLEGE PARK COLLABORATION — Control of atomic morphology at the micrometer scale has been a long term challenge to enable atomically precise manufacturing. In this presentation we describe our method to pattern micrometer scale, ordered features on a Si surface with subsequent etch and high temperature processing. Following high temperature UHV processing, high quality atomically-ordered surfaces are imaged using atomic-resolution STM. A significant attribute of these surfaces is that the micrometer scale features evolve, but persist, allowing external location of nanometer scale features as well as comprehensive control of atomic terrace sizes and step bunching. A multi step thermal process is used, resulting in surface with symmetric, reproducible step-terrace patterns and very wide atomically flat regions. A kinetic Monte Carlo (KMC) model is used to simulate the current induced electromigration process which is primarily responsible for the long range evolution of surfaces.

10:24AM H10.00013 Theory of Scanning Tunneling Microscopy of Dangling Bonds on Silicon Surfaces , LUCIAN LIVADARU, University of Alberta, JASON PITTERS, NINT, ROBERT WOLKOW, University of Alberta/NINT — Silicon surface dangling bonds (DBs) are electronic gap states with eigenenergy close to the middle of the bandgap of bulk silicon and can be explored as quantum dots. During exploratory fabrication and characterization of DB-structures on H-Si(100) surfaces, scanning tunneling microscopy (STM) imaging showed sharp halo-like features around single DBs that cannot be explained by the standard STM theory. Halo appearance varies with sample doping level and imaging conditions (sample bias and current). Here we investigate the nature of such features in the STM imaging of DBs. We propose a theory of image formation based on non-equilibrium charge transfer balance (via elastic and inelastic channels), from the STM tip to DB on one hand, and from DB to bulk Si on the other. For empty-state imaging mode, in the immediate proximity of a DB (<1nm) tip-induced band bending shifts the DB-level to a value between the Fermi levels of the STM tip and of the sample. Consequently, a steady-state of charge flow is established through the DB state, which dictates the time-average amount of charge on the DB. This in turn affects the total STM current in that proximity leading to the appearance of a halo.

10:36AM H10.00014 The Electronic and Transport Properties of Si(111)-7×7 and Related Reconstructions[1] , MANUEL SMEU, McGill University, WEI JI, Renmin University of China, ROBERT WOLKOW, National Institute for Nanotechnology, HONG GUO, McGill University — The 7×7 reconstruction of Si(111) has the interesting property of being metallic despite bulk Si being a semiconductor. This surface has a complex reconstruction that takes on a dimer-adatom stacking fault (DAS) structure composed of adatoms, rest atoms, and several other key features. It is believed that the conductivity occurs through the dangling bonds of the adatoms, and that it is entirely a surface effect. To elucidate the details of this mechanism, we have investigated a set of related Si(111) reconstructions of increasing complexity in order to resolve the effect of the different DAS features on the electronic and transport properties of the Si(111)-7×7 surface. Density functional theory (DFT) calculations have been carried out on the $\sqrt{3}\times\sqrt{3}$-$R30^\circ$, 2×2, 5×5, and 7×7 reconstructions of Si(111). Additionally, our work is extended to electron transport simulations employing the non-equilibrium Green's function technique coupled with DFT (NEGF-DFT) to calculate the conductance for these systems. Finally, the effect of atomic steps and adsorbates on the conductive properties will also be discussed.

[1]Supported by NSERC, CIFAR, FQRNT and RQCHP.

10:48AM H10.00015 Size dependent superconductivity of Pb islands grown on Si (111) , JIEPENG LIU, XUEFENG WU, FANGFEI MING, XIEQIU ZHANG, KEDONG WANG, BING WANG, XUDONG XIAO, DEPARTMENT OF PHYSICS, THE CHINESE UNIVERSITY OF HONG KONG TEAM, HEFEI NATIONAL LABORATORY FOR PHYSICAL SCIENCES AT MICROSCALES,UNIV. OF SCIENCE AND TECHNOLOGY CHINA TEAM — The superconductivity of nano-sized Pb islands grown on Si (111) with different size at 9 monolayer thickness was studied by low temperature scanning tunneling spectroscopy. By measuring the zero bias conductance as a function of temperature, for larger islands we observed a transition from pseudogap state at high temperature to superconductivity state at low temperature through two distinct slopes, where the superconductivity transition temperature (Tc) of the island can be determined. For island size of $\sim$58 nm^2, a large drop in Tc is found; when the size is further reduced to about 30 nm^2, no superconducting state was observed down to the measured temperature of 3.2 K. By properly subtracting the background and pseudogap effect, information on the temperature dependent superconductivity gap can be obtained. The ratio of $\frac{2\Delta_0}{k_B T_c}$ decreased from 4.5 to 3.3 with the reduction of island size, showing that the electron-phonon coupling becomes weaker as the size decreases.

Tuesday, March 22, 2011 8:00AM - 11:00AM –
Session H11 SPS: SPS Undergraduate Research III D222

8:00AM H11.00001 Nanodynamics of Ferroelectric Ultrathin Films[1] , RYAN HERCHIG, QINGTENG ZHANG, INNA PONOMAREVA, University of South Florida — An active area of research in nanoscale science is the study of ferroelectric ultrathin films. We will report a first-principles-based study of the nanodynamics in ferroelectric $Pb(Zr_{0.4}Ti_{0.6})O_3$ films with thickness 20-192 nm. In our computational experiment we first anneal such films under realistic conditions of partial screening of the surface charge to obtain the ground state nanodomain pattern. After that the films are subjected to ac electric fields with frequencies varying from 0.1 THz to 4.0 THz and close to nanodomain resonance frequency. The domain evolution is then studied as a function of time, electric field frequency, and film thickness in order to quantitatively characterize the laws and parameters associated with it. This allows us to reveal for the first time ever intrinsic high-frequency dynamics of ferroelectric nanostripe domains.

[1]This work is supported by DOE grant DE-SC0005245. The authors would like to acknowledge the use of the services provided by Research Computing, University of South Florida. I. P. acknowledges support from the USF under Grant No. R070699.

8:12AM H11.00002 Thermal Conductivity of Random Multilayer Thin Films , ANTHONY FRACHIONI, B.E. WHITE JR., Binghamton University — Thermoelectric based energy scavenging has tremendous potential for the recovery of waste heat and temperature regulation. Manufactured thermoelectric devices today are limited in efficiency, and therefore widespread use, by high lattice thermal conductivity. In an effort to minimize lattice conductivity with respect to electrical conductivity, opportunities for utilizing the Anderson localization of phonons have been explored. In particular, the thermal conductivity of a model random multilayer thin film with Lennard-Jones bonding has been determined using classical reverse non-equilibrium molecular dynamics as a function of mass induced disorder. Results indicate that the inclusion of random planes in which the atomic mass has been increased by a factor of ten can produce reductions in lattice thermal conductivity by over a factor of one hundred. The dependence of thermal conductivity on the magnitude and nature of this disorder has been measured. Finite size effects have been quantified and a length scale has been determined on which they can be neglected. These results indicate that the pursuit of nanostructured thermoelectric materials in the form of random multilayers may provide a path to efficient and sustainable thermoelectric materials.

8:24AM H11.00003 Controlling the microstructure of binary carbide films with elemental substitutions[1] , K. FELLER, M. HAIDER, A. HODGES, R. SPRENG, E. POSBERGH, H. WOODWARD, S.E. LOFLAND, J.D. HETTINGER, Physics and Astronomy, Rowan University, M. HEON, Y. GOGOTSI, Materials Science and Engineering, Drexel University — We report on experiments to control the microstructure of textured binary carbide thin films deposited by reactive magnetron sputter deposition. Controlling the microstructure in these materials is important as the microstructure of these films provides a template for the resulting carbide-derived carbon (CDC) film and impacts their performance. Specifically, a combinatorial approach is used to add chromium to TiC films creating a compositional gradient as a function of position. We present a measurement of surface roughness as a function of material composition. The resulting materials, $(Ti_{1-x}Cr_x)C$ films, are significantly smoother than their pure TiC counterparts and the resulting CDC's have correlated defects which will improve the performance of the CDC in supercapacitor applications.

8:36AM H11.00004 Polypeptide Chirality Influences Multilayer Thin Film Growth and Structure , ZEPHRA BELL, DHAN KHADKA, DONALD HAYNIE — Polypeptide multilayer thin films are being developed for a variety of applications.These include coatings for implant devices and systems for drug delivery in thebiomedical sciences, and optical coatings. Subsequent polymer adsorption steps involve polymers of opposite polarity. Here, the polymers were polypeptides. This project compared the consequences of changing polypeptide chirality on film growth and structure. The peptides were poly(L-glutamic acid), its right-handed counterpart, poly(D-glutamic acid), and poly(lysine-tyrosine). The first two are negatively charged at neutral pH, the third one is positively charged. Poly(lysine-tyrosine)/poly(L-glutamic acid) films and poly(lysine-tyrosine)/poly(D-glutamic acid) films werefabricated on 1 mm-thick quartz plates. In one experiment, films were grown to 34layers. The UV absorption spectrum was taken after each layer deposited to determinethe rate of polymer self-assembly. Separately, UV or visible wavelength spectra wereobtained for films stained with a dye cooled/heated in the range 4-65 $^\circ$C. In anotherexperiment, a mixture of poly-L-glutamic acid and poly-D-glutamic acid was used as thepolyanion for film buildup. The data show that poly(lysine-tyrosine)/poly(L-glutamicacid) films built up at a higher rate than the corresponding right-handed films.

8:48AM H11.00005 Thermoelectric Properties and Microstructure of $Ca_3Co_4O_9$ thin films on $SrTiO_3$ and Al_2O_3 Substrates[1] , T. PAULAUSKAS, Q. QIAO, A. GULEC, R.F. KLIE, UIC, M. OZDEMIR, C. BOYRAZ, D. MAZUMDAR, A. GUPTA, UA — $Ca_3Co_4O_9$ (CCO), a misfit layered structure exhibiting large Seebeck coefficient at temperatures up to 1000K has attracted increasing attention as a novel high-temperature thermoelectric material. In this work, we investigate CCO thin films grown on $SrTiO_3$ (001) and Al_2O_3 (0001) using pulsed laser deposition. Quality of the thin films was examined using high-resolution transmission electron microscopy and thermoelectric transport measurements. HRTEM images show incommensurate stacks of CdI_2-type CoO_2 layer alternating with rock-salt-type Ca_2CoO_3 layer along the c-axis. Perovskite buffer layer about 10nm thick was found present between CCO and $SrTiO_3$ accompanied by higher density of stacking faults. The CCO grown on Al_2O_3 exhibited numerous misoriented grains and presence of Ca_xCoO_2 phase. Seebeck coefficient measurements yield an improvement for both samples compared to the bulk value. We suggest that thermoelectric properties of CCO increase due to additional phonon scattering at the stacking faults as well as at the film surfaces/interfaces.

9:00AM H11.00006 Antireflective Coatings using Layer-by-Layer Self Assembly of Silica and Titania Nanoparticles[1] , RAISA VELASCO CASTEDO, ANITESH ANAND LAL, DAN MAZILU[2], Washington and Lee University — It is known that glass substrates (borosilicate glass) reflect about 4% of light at each air/glass interface and thus, they transmit only 92% of light. For some devices like camera lenses, it is important to maximize the amount of transmitted light. Previous research has demonstrated that it is possible to do so by adding antireflective coatings to the substrates. Our research aimed to deposit thin films on glass substrates that would minimize the reflectance of light and thus, maximize its transmittance. The thin films consisted of multiple alternating layers of silica and titania nanoparticles following the theory behind double-quarter periodic systems and were deposited on the substrates via the ISAM (ionically self-assembled monolayers) technique. Several experiments were conducted in order to investigate the factors that affected the quality of the coatings and some of the significant factors observed were the pH and the molarity of the silica, titania and PDDA solutions. A number of factor-level combinations yielded transmittances in excess of 96%, well above the value for uncoated substrates.

9:12AM H11.00007 Compositional dependence of the narrow band emission from zinc oxide nanowires[1] , BRADLEY GOLDER, ERIC DRISCOLL, MARIAN TZOLOV, Lock Haven University of PA — Zinc oxide is a versatile platform thanks to the unique combination of optical, semiconducting, and piezoelectric properties of ZnO. The properties can be further diversified by creating microstructures and by varying the Zn/O ratio in the crystallites. We are illustrating this concept for the case of narrow band emission for ZnO nanostrutures grown through chemical vapor transport. The samples were characterized by photoluminescence spectroscopy (pulsed and continuous wave), scanning electron microscopy, and energy dispersive x-ray spectroscopy. Narrow band emission has been observed in the pulsed excitation mode. The narrowing is intensity dependent suggesting a mechanism of stimulated emission. The emission properties were correlated with the degree of oxidation of the ZnO nanocrystallites and with the presence of optically active defects. The influence of different oxidizing agents on the emission properties of the ZnO nanocrystals will be shown.

[1]This work was partly supported by the NSF grant # 0923047.

9:24AM H11.00008 Dependence of the band gap of highly confined CdSe and PbSe nanocrystals on temperature , AARON ZAUBI, Cornell College, J. BYLSMA, P. DEY, J. REJMAN, S. WITANACHCHI, P. MUKHERJEE, D. KARAISKAJ, University of South Florida, M. BEARD, NREL — We have recorded fluorescence spectra from PbSe and CdSe quantum dots in hexane/toluene respectively between 5K and 300K in order to investigate the temperature dependence of the electronic band gap of these highly confined nanostructures. The band gap for CdSe follows the known blue shift with decreasing temperature. We have measured the temperature dependence of the band gap of PbSe quantum dots for two different diameters below 4 nm and indeed observe a red shift of the band gap with decreasing temperature, which is stronger for the smaller size quantum dots. Such behavior would contradict the expected blue shift of the band gap with decreasing temperature. The origin of this peculiar behavior is not well understood and we are pursuing further theoretical and experimental studies in order to elucidate the mechanism behind it. Using the method of single-nanostructure laser spectroscopy will allow us to observe individual nanostructures while simultaneously removing ensemble averaging effects due to quantum interactions between multiple structures.

9:36AM H11.00009 Synthesis and characterization of ZnO nanocrystals co-doped with Ce^{3+} and Tb^{3+}[1] , KELLY MCCUTCHEON, CHRISTIE LAROCHELLE, Franklin and Marshall College — Rare earth doped zinc oxide nanocrystals produce visible emissions under ultraviolet excitation. Using a sol-gel process, we synthesized a series of ZnO nanocrystals doped with Tb^{3+} and Ce^{3+} in silica glass, keeping the ZnO/SiO_2 ratio constant at 10/90 and doping with 1% rare earth by weight, with varying relative concentrations of Tb^{3+} and Ce^{3+}. The nanocrystals were characterized using photoexitation and emission spectroscopy, time-resolved photoluminescence, UV/VIS spectroscopy, and transmission electron microscopy. We determined that co-doping with cerium enhanced the visible terbium emissions to a point, with the most effective enhancement occurring at mid-range Ce^{3+} concentrations.

9:48AM H11.00010 Growth and Morphology of High Mobility Organic Semiconductors[1] , CORTNEY BOUGHER, Appalachian State University, KATELYN GOETZ, Wake Forest University, ZHONG LI, JOHN ANTHONY, University of Kentucky, OANA JURCHESCU, Wake Forest University, BRAD CONRAD, Appalachian State University — We utilize atomic force microscopy (AFM) to image the growth and morphology of chemically modified, solution-deposited anthradithiophene transistors. We discuss the effects of backbone modifications on crystal structure, film properties, and electrical device performance. These devices display a mobility of 0.001 cm^2/Vs to 1 cm^2/Vs. Crystal orientation and film structures, such as film thickness, grain size, and growth modes will be discussed. In addition, AFM images are related to diffraction data and conduction channel crystallographic information is extracted.

10:00AM H11.00011 Effect of the polymer concentration on the ON/OFF states of a TN-LCD: polyvinyl alcohol vs. soy lecithin , ROMEO DE COSS MARTINEZ, JOSE LUIS GONZALEZ MURGUIA, Facultad de Ingenieria - UADY — In this work we study the response of a Twisted Nematic Liquid Crystal Display (TN-LCD) by varying both the concentration and the polymer used for the microgroove. We compare the performance of two polymers: polyvinyl alcohol and soy lecithin. In particular, the light transmission for the ON/OFF states is evaluated. The polyvinyl alcohol is a polymer widely used in LCDs while lecithin soy is a natural polymer.

10:12AM H11.00012 Tunable Schottky diodes fabricated from electrospun crossed SnO_2/PEDOT-PSSA nanoribbons[1] , KATHERINE CARRASQUILLO, NICHOLAS PINTO, University of Puerto Rico-Humacao — Hardware in most solid state devices contains at least one interface between a p-type and an n-type semiconductor. Such hetero-junctions are typically fabricated from all inorganic Si based materials. In the past two decades however, devices fabricated from organic-inorganic semiconductors that are not Si based, or from all organic semiconductors have been the focus of much research. Semiconducting n-doped metal oxides are also attractive for use in devices and of particular interest is tin oxide (SnO_2) as it is stable in air and is optically transparent with a band gap of $\sim$3.4 eV. The p-doped conducting polymer PEDOT-PSSA is also stable in air and is widely used in flexible devices. We shall report on the electrospinning technique to fabricate in air Schottky diodes, by simply crossing n-doped SnO_2 and p-doped PEDOT-PSSA nanoribbons. The device parameters could be tuned by a back gate bias and by shining UV light. The diode parameters were calculated using the standard thermionic emission model of a Schottky and was tested as a half wave rectifier.

10:24AM H11.00013 UV-vis and Transport Characterization of Degradation in Polymer Blend Photovoltaics[1] , EMILEE SENA, JUSTIN PEEL, SHREYA NATHAN, DEVIN WESENBERG, MARIANNE WALLIS, THORSTEINN ADALSTEINSSON, BRIAN MCNELIS, RICHARD BARBER, Santa Clara University — Organic photovoltaic cells are prepared using an active layer containing a functionalized C60 molecule, [6-6]-phenyl C61 butyric acid octadecyl ester (PCBOD); and a conjugated polymer, poly(3-hexylthiophene) (P3HT). PCBOD functions as an electron acceptor in conjunction with P3HT, the electron donor. Both current-voltage (IV) transport data of solar cells and spectroscopic absorption data of the corresponding active layer are collected at regular time intervals for periods up to several days. IV data show changes in power conversion efficiency which are strongly dependent on device preparation (stoichiometry, annealing, etc.). Ultraviolet and visible light absorption exhibits similar time dependence. Recent results show that annealing the active layer up to 200 $^\circ$C substantially improves device performance. Further spectroscopic studies, such as Carbon-13 NMR spectroscopy, are ongoing.

10:36AM H11.00014 Modeling of Quantum Cascade lasers with different waveguide profiles[1] , CHARLES ZHANG, RICHARD CENDEJAS, CLAIRE GMACHL, Princeton University — Quantum Cascade (QC) laser-based sensor systems help us monitor the environment through the detection of trace chemicals that have optical spectra in the mid-infrared. For the laser to become more efficient and usable, the thermal management and the optical and electrical properties of the laser waveguides need to be more closely examined. The performances of QC lasers with different waveguide profiles have so far not been systematically compared and the device optimization for the three design components has not yet been coupled together. Here, we use a finite element solver to calculate the active region peak core temperature, the optical confinement factor and waveguide loss, and the local current density, and compare these for QC lasers with dry- and wet-chemical etch profiles, i.e. with vertical or sloped sidewalls, respectively. Initial results show a preference for wet-etched profiles under thermal conductivity considerations.

10:48AM H11.00015 Photoluminescence studies of WO_3 and WO_{3-x} single crystals , J. EASLEY, Department of Physics, MIT, P. DEY, D. KARAISKAJ, Department of Physics, University of South Florida, S. DEB, NREL, T. CISZEK, Geolite/Siliconsultant, D. DESSAU, University of Colorado, Boulder — WO_3 is an important material to study, not only due to its interesting electronic properties, but also because it has other applications in both electrochromics and energy storage. The mechanism behind the electrochromic effect has been debated for several decades [1]. We have studied two WO_3 single crystals, a transparent and doped WO_{3-x}, in an attempt to understand this effect. A photoluminescence center around 865 nm is observed after sub-band gap excitation at 405 nm with relatively higher intensity in the crystal containing oxygen vacancies. The center appears as a broad transition of 35 nm FWHM and does not appear to be correlated with temperature. However, polarization studies reveal at least two polarization dependent components of the center.

Session H12 DMP: Focus Session: Dopants and Defects in Semiconductors: Silicon D223/224

8:00AM H12.00001 Isotopic Fingerprints in the Luminescence of Deep Defects in Silicon , MICHAEL L.W. THEWALT, Simon Fraser University — In a series of recent papers [1, 2] we have shown that the dramatic improvements in spectral resolution made possible in highly enriched ^{28}Si can provide surprising new information on the detailed constituents of deep luminescence centers. The 'isotopic fingerprints' reveal the presence, and number, of different chemical species involved in the deep centers. While many of these luminescence centers have been studied for decades, this new technique revealed that *none* of these was what it was thought to be. Armed with this new information, many new centers have been discovered, containing either four or five atoms chosen from among: Cu, Ag, Au, Pt and Li. There is at present no theoretical explanation for the stability and ubiquity of these centers in rapidly thermally quenched silicon.

8:36AM H12.00002 Theoretical study of the Cu_{PL} defect in Si , ALEXANDRA CARVALHO, University of Aveiro, STEFAN K. ESTREICHER, Texas Tech University — Copper is a common contaminant in Si processing. When in supersaturation, a fraction of 1% of the Cu in the sample forms an electrically-active defect easily seen by photoluminescence. This Cu_{PL} defect in Si has a no-phonon line at 1014 meV. It has long been believed to consist of an interstitial copper (Cu_i) weakly bound to a substitutional copper (Cu_s) : The $\{Cu_sCu_i\}$ pair. However, PL studies in isotopically pure ^{28}Si crystals have shown that the defect contains not two but four copper atoms [1]. We examine the possibility that the core of the defect consists of not one but two adjacent substitutional Cu atoms. This core traps two Cu_i atoms, resulting in defect with D_{3d} symmetry. We will discuss its formation mechanism and stability, and show that they are consistent with the conditions at which Cu_{PL} is observed. If this model is correct, then then DLTS lines associated with Cu_s should be re-assigned to $\{Cu_sCu_s\}$.

8:48AM H12.00003 EPR parameters of the dangling bond defect in crystalline and amorphous silicon: A DFT-study , GERNOT PFANNER, CHRISTOPH FREYSOLDT, JÖRG NEUGEBAUER, Max-Planck-Institut fuer Eisenforschung, Duesseldorf, Germany — Thin-film a-Si:H solar cells are considered as low-cost alternatives to bulk crystalline silicon (c-Si) solar cells. A disadvantage of these devices is that their efficiency is severely limited by light-induced defects (Staebler-Wronski effect). In this context, electron-paramagnetic resonance (EPR) is a key technique to probe for the local atomic structure of defects with unpaired spins such as the silicon dangling bond. However, the assignment of the EPR signal to a specific defect structure requires comparison to theoretical models. Using density-functional theory, we address structure-property relationships by combining systematic studies for idealized dangling-bond models in c-Si with a statistical analysis of a variety of dangling bonds in a-Si:H supercells. Our studies reveal the influence of the local geometry on sp-hybridization and delocalization. Yet, the structural variability of a-Si:H cannot be captured by these idealized defect models alone. Rather, our calculations indicate that a relatively broad distribution of dangling-bond like structures gives rise to the experimental signal supporting a recent re-evaluation of EPR parameters from multifrequency EPR.

9:00AM H12.00004 Electrically Detected Pulsed ENDOR in Phosphorus-Doped Silicon[1] , FELIX HOEHNE, LUKAS DREHER, Walter Schottky Institut, Technische Universitaet Muenchen, Am Coulombwall 3, 85748 Garching, Germany, HANS HUEBL, Walther-Meissner-Institut, Bayerische Akademie der Wissenschaften, Walther-Meissner-Strasse 8, 85748 Garching, Germany, MARTIN STUTZMANN, MARTIN S. BRANDT, Walter Schottky Institut, Technische Universitaet Muenchen, Am Coulombwall 3, 85748 Garching, Germany — We demonstrate the electrical detection of X-band electron nuclear double resonance (ENDOR) in phosphorus-doped silicon at 4 K. A pulse sequence analogous to Davies ENDOR in conventional electron spin resonance is used to measure the nuclear spin transition frequencies of the ^{31}P nuclear spins, where the ^{31}P electron spins are detected electrically via spin-dependent transitions through Si/SiO_2 interface states. In addition, electrical detection of coherent nuclear spin oscillations is shown, demonstrating the feasibility to electrically read out the spin states of possible nuclear spin qubits. Combining the enhanced sensitivity of electrically-detected magnetic resonance and the wide range of applications of pulsed ENDOR, this techniques could be a versatile tool to study paramagnetic defects in semiconductor nanostructures.

9:12AM H12.00005 Electroelastic Hyperfine Tuning of Phosphorus Donors in Silicon[1] , LUKAS DREHER, TIMON A. HILKER, Walter Schottky Institut, Technische Universitaet Muenchen, Am Coulombwall 3, 85748 Garching, Germany, ANDREAS BRANDLMAIER, SEBASTIAN T.B. GOENNENWEIN, HANS HUEBL, Walther-Meissner-Institut, Bayerische Akademie der Wissenschaften, Walther-Meissner-Strasse 8, 85748 Garching, Germany, MARTIN STUTZMANN, MARTIN S. BRANDT, Walter Schottky Institut, Technische Universitaet Muenchen, Am Coulombwall 3, 85748 Garching, Germany — We demonstrate an electroelastic control of the hyperfine interaction between nuclear and electronic spins opening an alternative way to address and couple spin-based qubits. The hyperfine interaction is measured by electrically detected magnetic resonance in phosphorus-doped silicon epitaxial layers employing a hybrid structure consisting of a silicon-germanium virtual substrate, a piezoelectric actuator, and a loop-terminated coplanar strip line for on-chip microwave magnetic-field generation. By applying a voltage to the actuator, the hyperfine interaction is changed by up to 0.9 MHz, which would be enough to address spin-qubits in isotopically purified ^{28}Si with a sufficient fidelity under optimized conditions.

[1]This work was supported by the DFG (Grant No. SFB 631, C3).

9:24AM H12.00006 Characterizing Individual Group V donors in Silicon , CYRUS F. HIRJIBEHEDIN, PHILIPP STUDER, STEVEN R. SCHOFIELD, VERONIKA BRAZDOVA, DAVID R. BOWLER, NEIL J. CURSON, UCL, UK — The study of dopants in silicon has been rapidly growing in importance because the dimensions of semiconductor devices have now decreased to the point where their functionality relies upon only a few atoms. Group V donors are especially interesting due to their potential application in spintronics and quantum computing. Whereas P dopants have been extensively studied, comparatively little is known about the characteristics of other group V donors. Using a combination of ion implantation and cross-sectional scanning tunneling microscopy (XSTM) and, we study individual Bi and Sb atoms in the cleaved Si(111)2x1 surface. High-resolution STM topography images and scanning tunneling spectroscopy (STS) data allow us to probe the structural and electronic properties of these individual dopants in silicon. Density functional theory (DFT) calculations further support our structural assignments.

9:36AM H12.00007 Ab initio shallow impurity level calculations in semiconductors , GAIGONG ZHANG, UC Davis, ANDREW CANNING, NIELS JENSEN, UC Davis/ LBNL, STEPHEN DERENZO, LIN-WANG WANG, LBNL — Binding energies of B, Al, Ga, In and Tl shallow acceptors in bulk Si were calculated using a GW + Semi-empirical procedure. Within the procedure, both density functional theory calculation within local density approximation (LDA) and GW calculation were performed. In the LDA calculation, a large supercell containing tens of thousands of Si atoms and the center impurity atom was constructed from a potential patching procedure. The central potential of this system was further corrected by 64 atom GW calculations. The folded spectrum method was used to calculate the eigen energies of this large supercell containing the center impurity. The calculated binding energies show good agreement with experimental impurity binding energies. This procedure represents an efficient approach to study shallow impurity levels which are important for semiconductor devices.

9:48AM H12.00008 First principles study of phosphorus and boron defects in Si-XII[1] , BRAD D. MALONE, MARVIN L. COHEN, Department of Physics, University of California, Berkeley, and Materials Science Division, Lawrence Berkeley National Laboratory — We present a first-principles study of phosphorus and boron substitutional defects in Si-XII, a polytype of silicon in the R8 structure. Recent results from nanoindentation experiments reveal that this phase is semiconducting and has the interesting property that it can be doped n- and p-type at room temperature without an annealing step. We examine the formation energies of the B and P defects at the two distinct atomic sites in the R8 structure. We also calculate the thermodynamic transition levels of each defect in its relevant charge states.

[1]This work was supported by National Science Foundation Grant No. DMR10-1006184, the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. Computational resources have been provided by the Lawrencium cluster at LBNL.

10:00AM H12.00009 Stability of donor-pair defects in $Si_{1-x}Ge_x$ alloy nanowires , JI-SANG PARK, BYUNGKI RYU, K.J. CHANG, Department of Physics, Korea Advanced Institute of Science and Technology — Semiconductor nanowires (NWs) have attracted much attention because of the quantum confinement effect, large surface-to- volume ratio, and compatibility with the existing Si technology. Although impurity doping is important for applications to optoelectronic devices, it is generally difficult to dope nanostructures due to segregation of dopants to the surface, high activation energies induced by the surrounding low dielectric medium, and compensation by defects such as surface dangling bonds. Furthermore, compared with bulk Si, electrically deactivating donor-pair defects are energetically more favorable than isolated shallow donors in NWs. In this work, we perform first-principles density functional calculations to study the stability of donor-pair defects and the doping efficiency in $Si_{1-x}Ge_x$ alloy NWs doped with P impurities. The stability of donor-pair defects is enhanced as the Ge concentration increases. Consequently, the doping efficiency in $Si_{1-x}Ge_x$ alloy NWs is expected to be suppressed by the formation of donor-pair defects, similar to previous calculations for Si NWs with small diameters. The effects of reduced dimensionality, Ge chemical bonding, and strain on the stability of donor-pair defects in alloy NWs are discussed.

10:12AM H12.00010 New electronic effects observed on n-type Si(111)2x1 using cross-sectional STM , NEIL J. CURSON, PHILIPP STUDER, STEVEN R. SCHOFIELD, GREG LEVER, DAVID R. BOWLER, CYRUS HIRJIBEHEDIN, UCL, UK — Cross-sectional scanning tunneling microscopy (XSTM) of in-situ cleaved semiconductor surfaces has two distinct advantages over STM experiments where studies are performed on the surface of the annealed and/or sputtered semiconductor wafers. Firstly, the cleaving process exposes a clean surface without the usual need for high temperature annealing, thus revealing a surface that has not been driven to its thermodynamic minimum energy state. Secondly, the surface being imaged is perpendicular to the surface of the original wafer, which is of particular value for the study of implanted or epitaxially overgrown wafers. We use XSTM measurements, spatially resolved scanning tunneling spectroscopy (STS) and density functional theory (DFT) to study the electronic properties of the cleaved (111)2x1 surface of silicon. We examine bulk-doped, and ion-implanted samples. Our studies reveal new, long range, electronic effects that have implications for future nanoscale devices in silicon.

10:24AM H12.00011 Charged Defects in the Si(001) Surface , STEVEN SCHOFIELD, London Ctr. Nanotech. and Dept. Phys. & Astron., UCL, London, UK, PHILIPP STUDER, London Ctr. Nanotech. and Dept. Electron. & Elec., UCL, London, UK, CYRUS HIRJIBEHEDIN, London Ctr. Nanotech., Dept. Phys. & Astron. and Dept. Chem., UCL, London, UK, NEIL CURSON, London Ctr. Nanotech. and Dept. Electron. & Elec., UCL, London, UK, GABRIEL AEPPLI, DAVID BOWLER, London Ctr. Nanotech. and Dept. Phys. & Astron., UCL, London, UK — The Si(001) surface has been the subject of intense research for decades due to its ubiquitous use in the semiconductor industry, its applicability as a model semiconductor surface, and proposals for its use in novel quantum devices. Surprisingly, atomic-scale investigations using scanning tunneling microscopy and spectroscopy (STM/STS) continue to produce new insights into the structural and electronic properties of this deceptively simple semiconductor surface. Tip- and charge-induced band bending are generally considered to play only minor roles in measurements of silicon surfaces due to Fermi level pinning by surface states and defects. However, such effects become important when investigating charged defects and/or surfaces that have had their surface states removed through chemical passivation. We present high resolution STM images and spectroscopy data of defects in the Si(001) surface. We include band bending and charge state in the discussion of the results.

10:36AM H12.00012 Near surface dopant depletion in UHV prepared H-Si(100): spectroscopic and imaging effects , JASON PITTERS, NINT-NRC, ROBERT WOLKOW, University of Alberta — Dangling bonds (DBs) have been shown to be useful in directing chemical reactions on silicon and for atom scale electronics such as quantum cellular automata. One enabling aspect of DBs is that they can assume various charge states depending on the type and level of crystal doping. We have found that for degenerately doped n-type silicon, the scanning tunneling spectroscopy (STS) and imaging characteristics H-Si(100) surfaces and DBs varies depending on the preparation method. Samples heated to 1050°C were found to have a consistent level of doping throughout the bulk and near surface regions. Samples heated to 1250°C showed a reduced dopant concentration in the near surface region. STS showed shifted I/V spectra. The loss of degeneracy was indicated by the loss of tunneling through dopant states in the band gap. These results show that UHV prepared silicon does not have a consistent dopant profile and that the bulk dopant density should not be assumed in the near surface region. This has important ramifications for DB imaging and modeling.

10:48AM H12.00013 Ab initio study of water molecule dissociation on the hydrogenated Si(100) surface[1] , MARILIA J. CALDAS, REGINA LELIS-SOUSA, Institute of Physics, University of Sao Paulo — The reaction mechanisms for the H_2O molecule dissociation at the Si surface, and the resulting oxidation sites, are still object of debate. Here, we present a detailed theoretical investigation of the reaction pathways for the dissociation of water on the Si(100)(2x1):H surface, starting from different initial "attack" sites and leading to different final, oxidized configurations. We use extended-surface (slab) models, working within DFT, with pseudo-potentials and plane wave basis set in the quantum-espresso code. The pathways were mapped using the CI-NEB method with both local and gradient corrected exchange-correlation functionals in order to obtain a fair estimate of energy barriers. Our results indicate that the oxidation routes suggested by earlier experimental works are not favored. We propose two new oxidation routes, with simultaneous release of one H2 molecule: one related to chemisorption of the oxygen atom on the Si-Si dimer bond, and another related to the absorption on the back-bond. Analysis of energy barriers showed that these two new possibilities are both kinetically and energetically viable. We also present analyses of the profiles obtainable through STM for the investigated structures, which should help experimental identification.

Tuesday, March 22, 2011 8:00AM - 11:00AM –
Session H13 GSNP: Focus Session: Jamming Theory and Experiment I D225/226

8:00AM H13.00001 Jamming in Disordered and Ordered States: From RLP to FCC[1] , LEONARDO SILBERT, Southern Illinois University — The concept of jamming was originally introduced in the context of zero-temperature, frictionless sphere packings through which the jamming transition was identified with the more familiar idea of random close packing. More recently, the jamming behaviour for particles with friction has led to a practical definition of the less well-defined random loose packed limit. However, there are a number of subtleties associated with jamming that extend these concepts further. Here we implement a range of protocols to generate jammed packings both with and without friction, and find that the jamming transition actually consists of a finite region in packing fraction depending on the protocol used to create the jammed state. Furthermore, we examine how it is possible to tune the structural properties of jammed packings from the disordered regime through to the ordered face centred cubic lattice, and the subsequent changes in the jamming properties as the structure is manipulated.

8:36AM H13.00002 Long wavelength behavior of the static structure factor in jammed packings , JAIME BOHORQUEZ-BALLEN, LEONARDO SILBERT, Southern Illinois University Carbondale — There are several features associated with the jamming transition in monodisperse sphere packings. One recently reported property is the anomalous long wavelength behavior of the static structure factor, $S(k)$. An unusual linear dependence with the wavenumber k, becomes increasingly pronounced on approach to the jamming transition. However, it remains unclear how polydispersity and force model affect this behavior. Here, we study the structure factor of jammed disordered bidisperse sphere packings using computer simulations, especially its behavior in the long wavelength regime ($k \to 0$). We evaluated the structure factor using an appropiate formalism for polydisperse systems and extract information on the susceptibility in the low-k limit.

8:48AM H13.00003 Topology of the force field in a jammed granular systems exposed to an intruder[1] , LOU KONDIC, XIAONI FANG, NJIT, MIROSLAV KRAMAR, KONSTANTIN MISCHAIKOW, Rutgers, COREY O'HERN, Yale, JIE ZHANG, ROBERT BEHRINGER, Duke — It is well known that the structure of forces and stresses in granular systems goes through significant changes close to jamming. In this talk, we will present precise and objective measures of these changes based on topological properties of the force field in granular systems exposed to compression and shear. Then, we will discuss how these measures evolve in granular systems during an impact of a large intruder. We will particularly concentrate on the role of packing, polydispersity, and friction on structure of the force field.

9:00AM H13.00004 Critical Scaling of Shearing Rheology at the Jamming Transition of Soft Core Frictionless Disks[1]

, STEPHEN TEITEL, University of Rochester, PETER OLSSON, Umeå University — We perform numerical simulations to determine the shear stress and pressure of steady-state shear flow in a soft-disk model in two dimensions at zero temperature in the vicinity of the jamming transition ϕ_J. We use critical point scaling analyses to determine the critical behavior at jamming, and we find that it is crucial to include *corrections to scaling* for a reliable analysis. We find that the relative size of these corrections are much smaller for pressure than for shear stress. We furthermore find a superlinear behavior for pressure and shear stress above ϕ_J, both from the scaling analysis and from a direct analysis of pressure data extrapolated to the limit of vanishing shear rate.

[1]Supported by DOE Grant No. DE-FG02-06ER46298, Swedish Research Council Grant No. 2007-5234, and a grant from the Swedish National Infrastructure for Computing (SNIC) for computations at HPC2N.

9:12AM H13.00005 Glassiness, Rigidity and Jamming of Frictionless Soft Core Disks[1]

, STEPHEN TEITEL, University of Rochester, DANIEL VÅGBERG, PETER OLSSON, Umeå University — The jamming of frictionless bi-disperse soft core disks is considered, using a variety of different protocols to produce the jammed state. We find, consistent with earlier works, that cooling and compression can lead to a broad range of jamming packing fractions ϕ_J, depending on cooling or compression rate and on initial configuration. Such ϕ_J show no clear upper bound as the cooling or compression rate decreases. In contrast, we show that shearing leads to a jamming transition to a disordered solid, with a well-defined, non-trivial, value of ϕ_J as the shearing rate vanishes. We show that shearing breaks up the particle clustering (the precursor to phase separation) that can lead to increasing values of ϕ_J under slow cooling or compression, and argue that the process of shearing creates a well-defined ensemble that is independent of the starting configuration.

[1]Supported by DOE Grant No. DE-FG02-06ER46298, Swedish Research Council Grant No. 2007-5234, a grant from the Swedish National Infrastructure for Computing (SNIC) for computations at HPC2N and the Univer. of Rochester Center for Research.

9:24AM H13.00006 Exact tools for 2D granular packings

, ERIC DEGIULI, NEIL BALMFORTH, Dept. of Mathematics, University of British Columbia — Building on the loop force formulation of Ball and Blumenfeld[1], a new, exact potential formulation is given for two dimensional, static packings of frictional, monodisperse disks. Using degree-of-freedom counting and explicit constructions, it is shown that the natural graph for analysis of stress distribution in such packings is the Delaunay triangulation. Edges of this graph which do not correspond to contacts yield "virtual contact" vectors, which are shown to be of great physical importance. In particular, the new potential satisfies force and torque balance identically and is subject only to the Coulomb constraint and a new set of physically transparent constraints on the "virtual contacts." Using the new coordinates, previous results on the contact force distribution are rationalized, and a unified framework is presented for understanding the sources of correlation between contact forces. A new maximum-entropy argument is presented to derive the contact force distribution, and the dependence on shear, friction, and coordination number is discussed.

9:36AM H13.00007 Particle-to-Particle Dynamics in a Granular Pile Subject to Cyclic Shear

, STEVEN SLOTTERBACK, WILLIAM UPDEGRAFF, University of Maryland, MARTIN VAN HECKE, Universiteit Leiden, WOLFGANG LOSERT, University of Maryland — We report a study of the particulate motions of a granular pile under cyclic shear and how they relate to the bulk rheological properties of the pile. Using a laser sheet scanning technique, we track the trajectories of all of the particles within a section of a split-bottom shear cell. We shear the pile quasistatically to ensure rate independence of shear stress. Immediately after reversal of the shear direction, we observe a transient drop in shear stress of the pile over a characteristic strain. We construct a network of nearest neighbors that roll or slide past one another between frames. We find that, for strain amplitudes less than the aforementioned characteristic strain, rolling/sliding links are extinguished with higher frequency than for larger amplitudes. We also report other particle level measures, such as mean squared displacements, for various amplitudes of oscillatory shear.

9:48AM H13.00008 Ratio of effective temperature to pressure controls the dynamics of sheared hard spheres

, THOMAS HAXTON, Molecular Foundry, Lawrence Berkeley National Laboratory, ANDREA LIU, Department of Physics and Astronomy, University of Pennsylvania — Using molecular dynamics simulations, we calculate the effective temperature, $T_{\rm eff}$, and the pressure, p, of steadily sheared mixtures of hard spheres of mass m and diameters σ and 1.4σ in contact with a thermal reservoir at temperature T. We vary the packing fraction, ϕ, and the shear stress, Σ. We define $T_{\rm eff}$ from the ratio of correlations to response and show that different correlation-response relations yield a consistent numerical value $T_{\rm eff} \geq T$ that reduces to $T_{\rm eff} = T$ when $\Sigma = 0$. We show that the effective temperature represents the limiting value of the effective temperature for soft spheres in the limit $p\sigma^3/\epsilon \to 0$, where ϵ is the repulsive energy scale. We find that the dimensionless ratio $T_{\rm eff}/p\sigma^3$ controls the dynamic jamming transition that occurs with decreasing shear stress and increasing packing fraction. In particular, we find that the dependence of the dimensionless relaxation time, $\tau\sqrt{p\sigma/m}$, on $T_{\rm eff}/p\sigma^3$ as shear stress is varied is quantitatively similar to the dependence of $\tau\sqrt{p\sigma/m}$ on $T/p\sigma^3$ in equilibrium.

10:00AM H13.00009 Shear-jammed states in granular materials[1]

, DAPENG BI, Brandeis University, JIE ZHANG, Indiana University - Purdue University Fort Wayne, R.P. BEHRINGER, Duke University, BULBUL CHAKRABORTY, Brandeis University — For frictionless particles with purely repulsive interactions, there is a critical packing fraction ϕ_J below which no jammed states exist. Experiments by Zhang & Behringer on physical granular systems show jammed states in the regime of $\phi < \phi_J$ can be created by the application of shear stress. Compared to the states above ϕ_J, the shear-jammed states are mechanically more fragile, but they resist shear. These shear-jammed states cannot exist under isotropic stress. Rather, their formation require the anisotropic contact network as a backbone which is created by an applied shear stress. The anisotropic components of the stress tensor and contact network fabric tensor form a classic hysteresis loop suggesting an analogy to ferromagnetic behavior and critical phenomena. These new states must be incorporated into a more general jamming picture. We also carry out extensive analysis on shear-jammed states and find local stress fluctuations are controlled by their respective global pressures. To explain the scaling of local stress fluctuations, we construct a mean-field model based on the entropy of stress configurations.

10:12AM H13.00010 Quasistatic flows near jamming: The role of inertia and dissipation

, CRAIG MALONEY, Carnegie Mellon University, Department of Civil and Environmental Engineering, PETER TROCHA, Carnegie Mellon Univeristy, Department of Civil and Environmental Engineering — We perform massively parallel computer simulations of granular particles at fixed shearing rate and density near the onset of jamming. The microscopic dynamical model contains two types of damping; one which damps the *absolute* motion of a particle with respect to a homogeneously shearing background (as in SLLOD type approaches) and another which damps the *relative* motion of a particle with respect to its near-neighbors (as in discrete element approaches). We study how the damping mechanism and its strength affects the collective particle dynamics through the statistics of local particle displacements and local strains. In particular, we show that for strong, *absolute* damping, the single particle displacement statistics can be similar for systems at different distances from jamming while the short-time plastic activity can vary dramatically.

10:24AM H13.00011 Viscoelastic response near the jamming transition[1] , BRIAN TIGHE, Lorentz Institute, Leiden University — We use numerical and theoretical methods to investigate oscillatory rheology in soft sphere packings, which serve as a minimal model for foams, emulsions, and other complex fluids that undergo a jamming transition. Although the zero frequency (elastic) properties of jammed media are well documented, far less is known about their viscoelastic response. We demonstrate that the frequency-dependent storage and loss moduli display critical scaling with distance to the jamming point. This behavior is governed by a diverging time scale that separates quasistatic response from a critical regime in which viscous and elastic forces contribute equally to the stress. We provide scaling arguments for all of the relevant critical exponents.

10:36AM H13.00012 Phase transition kinetics in the site dilute Ising model[1] , KANG LIU, CHRISTOPHER SERINO, Boston University, RANJIT CHACKO, Clark University, WILLIAM KLEIN, Boston University — We consider the phase transition kinetics of a quenched site dilute Ising model. To date, most studies of this model have focused on dilution-averaged quantities, such as the critical temperature and the associated critical exponents. In this talk we study how the spatial distribution of the dilution affects the local growth of the stable phase after an instantaneous quench. For an off critical quench, we find growth occurs most rapidly in areas of increased dilution for both unstable state decay and nucleation. Conversely, growth after a critical quench is accelerated in environments with relatively few vacant sites. Additionally, we consider the role of the range of interaction in these processes.

[1]The authors wish to thank the DOE for support through grant DE-FG02-95ER14498.

10:48AM H13.00013 A first-order phase transition defines the random close packing of hard spheres , YULIANG JIN, HERNAN MAKSE, The City College of New York — Randomly packing spheres of equal size into a container consistently results in a static configuration with a density of ∼64%. The ubiquity of random close packing (RCP) rather than the optimal crystalline array at 74% begs the question of the physical law behind this empirically deduced state. Indeed, there is no signature of any macroscopic quantity with a discontinuity associated with the observed packing limit. Here we show that RCP can be interpreted as a manifestation of a thermodynamic singularity, which defines it as the "freezing point" in a first-order phase transition between ordered and disordered packing phases. Despite the athermal nature of granular matter, we show the thermodynamic character of the transition in that it is accompanied by sharp discontinuities in volume and entropy. This occurs at a critical compactivity, which is the intensive variable that plays the role of temperature in granular matter. This approach is useful since it maps out-of-equilibrium problems in complex systems onto simpler established frameworks in statistical mechanics.

Tuesday, March 22, 2011 8:00AM - 11:00AM –

Session H14 DMP GSNP DCOMP: Focus Session: Friction, Fracture and Deformation Across Length Scales I: Sliding Friction and Asperities D227

8:00AM H14.00001 Nanoscale friction anisotropy controlled by interface inhomogeneous slip and lattice defects[1] , SHUNFANG LI, Zhengzhou U., U. of Tennessee, ZHENYU ZHANG, Oak Ridge Nat. Lab, U. of Tennessee, YANFEI GAO, U. of Tennessee, Oak Ridge Nat. Lab — Stick-slip behavior observed from nanoscale asperity friction experiments is often simulated by the one-degree-of-freedom Tomlinson model, which is unable to explain well the effects of lattice structure and interface defects, particularly the friction anisotropy. Using our recently developed Rice-Peierls framework, we study the relative sliding of two elastic half-spaces with a circular contact for two types of interplanar potential: i) triangular lattice potential (3-fold); ii) rectangle potential (2-fold). Our major findings are as follows: first, one can construct friction anisotropy from the interface interaction potential; second, one can modulate the friction anisotropy by controlling the sliding direction and the ratio of contact radius to lattice spacing. We identify that for both cases, when a/b is small, the frictional behavior approaches the Tomlinson limit, while, when a/b is large, the frictional behavior is governed by interface defects. The latter case and its resulting friction anisotropy are very sensitive to the degree of interface incommensurability.

8:12AM H14.00002 Frictional Sliding of Amorphous Contacts over Six Decades of Velocity[1] , MICHAEL FALK, Johns Hopkins University, WOO KYUN KIM, University of Minnesota — Our understanding of the nanoscale origins of sliding friction primarily arises from theories of idealized crystalline surfaces in contact. However, many if not most tribological interactions involve one or more surfaces that are disordered in structure. The role that the amorphous nature of these surfaces plays in mediating friction is poorly understood. We apply an emerging simulation methodology, hyperdynamics, for the first time to friction, examining sliding between an oxidized silicon tip and surface over a previously inaccessibly wide range of sliding velocities. The simulations replicate interesting temperature dependent change in the velocity dependence of the friction force observed in this system experimentally, and reveal the nature of the intermediate state-switching transitions responsible for this behavior. A theory based on these transitions is developed and used to describe the experimental and simulated data. We conclude that this type of transition must be quite common in frictional sliding when one or more of the involved surfaces are not perfectly crystalline.

8:24AM H14.00003 Sliding Over a Phase Transition[1] , ERIO TOSATTI, SISSA, ICTP, CNR-IOM-Democritos, Trieste, Italy, ANDREA BENASSI, CNR-IOM-Democritos, Trieste, Italy, ANDREA VANOSSI, SISSA and CNR-IOM-Democritos, Trieste, Italy, GIUSEPPE E. SANTORO, SISSA, ICTP, CNR-IOM-Democritos, Trieste, Italy — The frictional response experienced by a stick-slip slider when a phase transition occurs in the underlying solid substrate is a potentially exciting, poorly explored problem. We show, based on 2-dimensional simulations modeling the sliding of a nanotip, that indeed friction may be heavily affected by a continuous structural transition. First, friction turns nonmonotonic as temperature crosses the transition, peaking at the critical temperature T_c where fluctuations are strongest. Second, below Tc friction depends upon order parameter directions, and is much larger for those where the frictional slip can cause a local flip. This may open a route towards control of atomic scale friction by switching the order parameter direction by an external field or strain, with possible application to e.g., displacive ferroelectrics such as $BaTiO_3$, as well as ferro- and antiferro-distortive materials.

8:36AM H14.00004 Onset of Sliding in Single Asperity Contacts[1] , VINCENT LIGNERES, MARK ROBBINS, Johns Hopkins University — Continuum models of friction often assume that sliding initiates at the edge of a contact, and gradually spreads across the contact. However these partial slip models make simple assumptions about friction laws and must break down at atomic scales. Molecular dynamics simulations are used to analyze the nature of atomistic effects and the variation of partial slip with length scale. In continuum theory there are singularities in tangential force at the edge of the contact that initiate slip. The discrete spacing between atoms and interfacial elasticity reduce these singularities in small contacts. Elastic coupling within the contact also limits partial slip and favors coherent slip across the interface. The variation of these effects with length scale, atomic geometry and the presence of adsorbed monolayers is described.

8:48AM H14.00005 Finite size effects at high speed frictional interfaces[1] , J.E. HAMMERBERG, R. RAVELO, T.C. GERMANN, B.L. HOLIAN, Los Alamos National Laboratory — Non-Equilibrium Molecular Dynamics simulations have exhibited characteristic velocity weakening for the tangential frictional force at smooth single crystal interfaces for velocities greater than a critical velocity, v_c. This behavior has been seen in a number of material pairs including Cu-Ag, Ta-Al and Al-Al. Expressions for v_c that characterize this behavior depend on system size. We discuss the size dependence for Al-Al single crystal interfaces for two cases: an Al(111)/Al(001) interface sliding along [1-10],N=1.5M, and an Al(110)[001]/Al(110)[1-10] interface sliding along [001], N=$7.5\text{x}10^6$ corresponding to a three-fold increase in system size normal to the sliding direction. We find agreement with an inverse size scaling for v_c. We discuss the similarities in behavior for a highly defective plastically deformed sample with Al(110)[001]/Al(110)[1-10] orientation having the same normal dimension and N= $16.0\text{x}10^6$.

9:00AM H14.00006 The Tribological Properties of Nanocrystalline Metals , MICHAEL CHANDROSS, SHENGFENG CHENG, Sandia National Laboratories — Materials that perform well in electrical contacts usually exhibit high adhesion during frictional contacts. An excellent example of this phenomenon is pure gold, which has extremely low electrical contact resistance, but generally has a high friction coefficient. The exception to this, however, is nanocrystalline gold alloyed with minute amounts of Ni or Co, which in addition to its low contact resistance can also show low friction. The mechanism for this remains poorly understood. We carried out large scale molecular dynamics (MD) simulations to study the tribological response of both single crystal and nanocrystalline gold or silver films in contact with curved probe tips or flat slabs under a variety of sliding conditions. Results show that grain reorientation and coalescence across the contact interface under compressive load or during shearing are responsible for the observed high friction in these contacts. In metallic alloys of silver, the addition of other elements such as copper introduces lattice mismatch and hinders the grain coalescence, which reduces friction during sliding.

9:12AM H14.00007 Tribo-induced melting transitions at sliding tungsten/gold-nickel asperity contacts , LIMING PAN, Department of physics, North Carolina State University, DANIEL LICHTENWALNER, Department of Materials Science and Engineering, North Carolina State University, ANGUS KINGON, Brown University, JACQUELINE KRIM, Department of Physics, North Carolina State University — Tribo-induced nanoscale surface melting mechanisms have been investigated by means of a combined QCM-STM technique [1] for a range of Au and Au-Ni alloys with varying compositional percentages and phases. A transition from solid- solid to solid-"liquid like" contact[1] was observed for each sample at sufficiently high asperity sliding speeds. Pure gold, solid-solution and two-phase Au-Ni (20 at.% Ni) alloys were compared, which are materials of great relevance to MEMS RF switch technology [2]. The transition points agree favorably with theoretical predictions for their surface melting characteristics. We acknowledge NSF and AFOSR support for this research.

9:24AM H14.00008 *In-situ* study of AFM tip wear by contact resonance force microscopy , JASON KILLGORE, ROY GEISS, DONNA HURLEY, National Institute of Standards & Technology — The size and shape of an atomic force microscope (AFM) tip strongly influence the resolution and accuracy of the instrument. Here we present a new means to directly measure tip wear *in situ* during contact-mode AFM scanning. Tip wear is observed from changes in contact radius determined by contact resonance force microscopy (CR-FM). In CR-FM, a flexural eigenmode of the cantilever is excited and tracked while the tip is in contact with a sample. As the tip wears, the resonant frequency increases, corresponding to increased contact radius. We demonstrate excellent agreement between quantitative tip wear results from CR-FM and from established *ex-situ* techniques such as scanning electron microscope imaging. Even for compliant cantilevers scanned at very low forces, we are able to resolve subnanometer changes in contact radius. Overall, benefits of our wear-monitoring approach are that CR-FM provides quantitative values of contact radius, allows continuous measurements, affords high spatial resolution, and does not adversely influence the wear rate.

9:36AM H14.00009 A physical basis for frictional ageing using single-asperity measurements , QUNYANG LI, University of Pennsylvania, DAVID GOLDSBY, TERRY TULLIS, Brown University, ROBERT CARPICK, University of Pennsylvania — Rate and state friction laws are widely used to model laboratory data and reproduce a variety of phenomena in earthquake modeling, and in other multi-asperity contacts. However, these laws lack a physical basis. To identify mechanisms underlying the time dependence of friction, especially the ageing effect, atomic force microscopy (AFM) was employed to probe friction for nanometer-scale single asperity contacts between oxidized silicon AFM tips and a set of substrates. Similar to macroscopic rock friction experiments, 'slide-hold-slide' (SHS) experiments on silica revealed a linear increase in friction with the log of the hold time. However, SHS experiments on chemically inert substrates showed little to no ageing. This indicates that the ageing mechanism is related to interfacial chemical reactions, and not plastic deformation of asperities. Ageing in silica-silica contacts is more than an order of magnitude higher than for macroscopic interfaces. However, modeling of slip in multi-asperity contacts suggests that the single- and multi-asperity results agree, since the magnitude of the ageing effect in multi-asperity contacts is reduced by asperity interactions. These results provide the first asperity-level insights into possible mechanisms behind rate and state friction laws.

9:48AM H14.00010 Friction at the nanoscale:theory and experiment , MICHAEL MARDER, The University of Texas at Austin — Bowden and Tabor established more than 50 years ago that friction is due to populations of asperities. In recent years, increasingly detailed experiments have begun to document the dynamics of these asperities during sliding, and to show that several different modes of motion are possible. I will discuss experiments that probe slipping motion of macroscopic samples down to the nanoscale, and show that the small slow slipping motions are described by the rate and state theory of friction that was developed for very different length and time scales.

10:24AM H14.00011 Stiffness of Contacts of Self-Affine Surfaces[1] , TRISTAN A. SHARP, MARK O. ROBBINS, SREEKANTH AKARAPU, Johns Hopkins University — The presence of roughness on a wide range of scales has a profound effect on the contact area and interfacial stiffness between contacting surfaces. In turn, the interfacial stiffness dominates the response of many macroscopic systems. Molecular dynamics simulations are used to characterize contacts between self-affine fractal surfaces with different roughness exponents. A unified framework describes the relation between roughness, system size, surface separation, stiffness, and contact area for a wide variety of systems. The contact area and normal stiffness rapidly approach Persson's continuum theory with increasing system size [1]. The lateral stiffness and friction are much more sensitive to atomic-scale effects. Atomic scale displacements at the interface can greatly reduce lateral stiffness and may explain the low lateral stiffness observed in some experiments.

10:36AM H14.00012 Stick-Slip and the Transition to Sliding in a 2D Granular Medium and a Fixed Particle Lattice[1] , ROBERT BEHRINGER, Duke University, JACKIE KRIM, NC State University — We report an experimental study of stick-slip to steady sliding for a solid object pulled via a spring across 2D granular substrates of photoelastic disks that are either fixed in a solid lattice or unconstrained, i.e. a disordered granular bed. We observe a progression of friction regimes with increasing sliding speed: single, mixed, and double slip-stick regimes, steady sliding, and inertial oscillations. For the granular bed, we characterize frictional behavior for the low speed stick-slip regime, including spring and elastic energy dependencies. For the granular solid, we explore friction with/without externally applied vibrations, and compare to sliding on a granular bed. We find that external vibration reduces transition values for both the single to double slip transition and the stick-slip to steady sliding transition. Moreover, we observe that the effect of packing disorder on granular friction appears similar to the effect of vibration induced disorder, a result that to our knowledge has not been reported previously in the experimental literature.

[1]Support from US ARO grant W911NF-07-1-1031 and NSF grant DMR0906908

10:48AM H14.00013 A simple model fault system[1] , CHRISTOPHER SERINO, WILLIAM KLEIN, Boston University — The Gutenberg-Richter distribution, which characterizes the frequency-magnitude statistics collected over earthquake fault systems, has lead seismologists as well as physicists and geophysicists to propose various simple models to explain this empirical scaling relation. To date, these models have been limited to the description of a single fault. We discuss a model of an earthquake fault system made up of non-interacting faults that are represented as damaged, Olami-Feder-Christensen models. The frequency-magnitude statistics do not, in general, scale on a single fault with some realization of damage; however, these statistics follow a simple distribution that can also be used to describe the data collected from actual earthquake faults. What is more, by varying the amount of damage on each fault in the system, as well as the relative frequency with which a fault with a given amount of damage occurs within the system, we obtain a one-parameter family of models, all of which produce Gutenberg-Richter-like statistics. This parameter is a measure of the stress dissipation within the fault system, a quantity known to vary with various geological properties, and offers an explanation for the range of b-values observed by seismologists.

Tuesday, March 22, 2011 8:00AM - 10:48AM –

Session H15 DMP GMAG FIAP: Focus Session: Spins in Semiconductors - Ferromagnetic Semiconductors D171

8:00AM H15.00001 Interplay of confinement and spin-orbit interaction in ferromagnetic semiconductors , TOMASZ DIETL, Institute of Physics, PAS; University of Warsaw, Poland — We review experimental and theoretical works which show a surprising influence of confinement on properties of III-V ferromagnetic semiconductors related to the spin-orbit interaction. In particular, according to SQUID studies, magnetization of (Ga,Mn)As thin films show two distinct components of orthogonal in-plane easy axes, whose relative strength can be controlled by the gate voltage [M. Sawicki et al. Nature Phys. 6, 22 (2010)]. Furthermore, in high T_C structures a confinement leads to an unanticipated collapse of the anomalous Hall effect [D. Chiba et al. Phys. Rev. Lett. 104, 106601 (2010)]. A possibility of a non-trivial interplay of confinement and spin orbit interaction is further highlighted by the theoretical prediction of a non-collinear spin arrangement in thin films of (Ga,Mn)As [A. Werpachowska and T. Dietl, Phys. Rev. B 82, 085204 (2010)]. Finally, we show how a large energy separation between the heavy and light hole subbands in compressively strained gated InAs:Mn quantum wells leads to hysteretic behavior even in the single Mn impurity limit [U. Wurstbauer et al. Nature Phys. (2010) doi:10.1038/nphys1782].

8:36AM H15.00002 Room Temperature Ferromagnetism in GaN-AlN Quantum Confined Heterostructures[1] , T.F. KENT, J. YANG, L. YANG, S.D. CARNEVALE, B. NILES, Department of Materials Science and Engineering, The Ohio State University, D.R. HOY, Y.-H. CHIU, E. JOHNSTON-HALPERIN, Department of Physics, The Ohio State University, M.J. MILLS, R.C. MYERS, Department of Materials Science and Engineering, The Ohio State University — GaN and AlN two dimensional electron gas heterostructures were grown by plasma assisted molecular beam epitaxy. During growth, a δ-doped layer of Gd was introduced at a controlled distance from the interface of the GaN and AlN layers. Resulting magnetic and structural properties were characterized by a variety of complementary methods including X-ray diffractometry, atomic force microscopy, transmission electron microscopy, superconducting quantum interference device magnetometry, photoluminescence spectroscopy and measurement of the anomalous Hall effect. Doping with Gd was observed to give rise to a colossal magnetic moment of 200$\mu_{\rm B}$/Gd with a Curie point in excess of 300K. To elucidate the mechanism by which introduction of Gd results in such a large moment, a wide variety of heterostructure geometries and growth conditions have been explored.

[1]Work supported by the Institute for Materials Research at The Ohio State University.

8:48AM H15.00003 Digital magnetic heterostructures based on GaN , LUIZ G. FERREIRA, Universidade de São Paulo, Brazil, MARCELO MARQUES, JOÃO P. T. SANTOS, LARA K. TELES, Instituto Tecnologico de Aeronautica, Brazil — Delta doped heterostructures based on GaN are possible wide band gap spintronic material with high temperature ferromagnetic transition [Hory et al, Physica B 324, 142 (2002); Reed et al, Appl. Phys. Lett. 79, 3473 (2001)]. They are formed by a thin magnetic layer or submonolayer, embedded into thick semiconductor layers [Marques et al, Phys. Rev. B 73, 224409 (2006)]. In this work we studied digital magnetic heterostructures with isolated magnetic monolayers of V, Cr, Mn, Fe, Co, Ni, or Cu embedded in GaN. We performed first-principles calculations within the density functional theory with self-energy, to account for excitation energies [Ferreira et al, Phys. Rev. B 78, 125116 (2008)]. The technique allowed us to calculate the GaN band gap as $E_{gap}^{calculated} = 3.53eV$ with no adjustable parameters. GaN:V and GaN:Cr do have ferromagnetic ground states with high Curie temperatures, as predicted by a mean-field approximation. GaN:Cr presents a 2D half-metallic ground state with 100% spin polarization. GaN:V has an unusual ground state, with a 2.0μ_B magnetic moment, no states at the Fermi energy, a minority spin gap of 3.0eV, and a majority spin gap of only 0.3eV.

9:00AM H15.00004 Intrinsic ferromagnetism at AlN-MgB_2 interfaces , YOSHIHIRO GOHDA, SHINJI TSUNEYUKI, Univ. of Tokyo — Spin polarization without magnetic elements is possible utilizing dangling bonds. In particular, nitrogen-dangling bonds of cation vacancies are responsible for spin polarization in nitride semiconductors. Enhancement of ferromagnetism due to cation vacancies by Gd dopants has also been found [1], which is consistent with colossal magnetic moments per Gd observed in experiments. However, randomness of point-defect distribution is not feasible to control magnetisation. In this situation, ordered structures of spin sites are highly desirable for the control of magnetization. In this study, we demonstrate by means of first-principles calculations that nitride-boride interfaces could be a candidate for such ordered spin sites. Partially occupied N p states at AlN-MgB_2(0001) interfaces exhibits two-dimensional spin polarization, which cannot be anticipated from the atomic structure because the N dangling bonds are apparently saturated by Mg. Hund's coupling of the two N $p_{||}$ orbitals as well as high density of spin-unpolarized states at the Fermi energy contribute to strong itinerant ferromagnetism. Roles of metal-induced gap states [2] will also be discussed.

9:12AM H15.00005 Room temperature ferromagnetism in cluster free, Co doped Y_2O_3 dilute magnetic oxide , C.N. WU, S.Y. HUANG, W.C. LIN, T.S. WU, Y.L. SOO, Dept. of Physics, National Tsing Hua Univ., Taiwan, W.C. LEE, Y.J. LEE, Y.H. CHANG, M. HONG, Dept. of Materials science and Engineering, National Tsing Hua Univ., Taiwan, J. KWO, Dept. of Physics, National Tsing Hua Univ., Taiwan; Center for Condensed Matter Sciences, National Taiwan Univ, Taiwan — Diluted magnetic oxides (DMO) displaying the ferromagnetic behavior far above room temperature has attracted much attention for potential spintronic applications. Our study using low temperature co-deposition has produced uniformly doping of transitional metal (TM) Co (2-10 at.%) in Y_2O_3 films without formation of clusters or second phases, stable up to 450°C anneals under most ambient. This was confirmed by EXAFS local structural analysis, XANES, and XMCD measurement. Ferromagnetic behavior of magnetic moment was observed at 300K, and the Co saturation magnetization was modulated by the concentration of oxygen vacancies under various post treatments. The observation is consistent with the impurity band exchange model to account for apparent ferromagnetism in these nearly insulating DMO films. One surprising implication from this model is the occurrence of ferromagnetic insulator behavior in TM doped HfO_2 is more likely than the widely studied TM doped ZnO, TiO_2, and SnO_2 systems of smaller band gaps for doping concentrations kept under cation percolation threshold.

9:24AM H15.00006 No role of magnetic impurities in observed ferromagnetism in $Ti_{1-x}Ta_xO_2$ thin film[1] , MALLIKARJUNA RAO MOTAPOTHULA, Graduate Student, A. ROY BARMAN, N.L. YAKOVLEV, S. DHAR, M.B.H. BREESE, T. VENKATESAN, NANOCORE, NATIONAL UNIVERSITY OF SINGAPORE TEAM, CIBA, DEPARTMENT OF PHYSICS, NATIONAL UNIVERSITY OF SINGAPORE COLLABORATION, ELECTRICAL AND COMPUTER ENGINEERING, NATIONAL UNIVERSITY OF SINGAPORE COLLABORATION — Recently, the idea of cationic-vacancy-induced FM in wide band-gap semiconducting oxides was proposed on theoretical grounds. Experimentally, we observed ferromagnetism in thin films of anatase $Ti_{1-x}Ta_xO_2$ grown by PLD. Ta incorporation gives rise to cationic defects, acting as magnetic centers and free charge carriers as detected by various spectroscopic and transport measurements. To confirm that the ferromagnetism is an intrinsic property of $Ti_{1-x}Ta_xO_2$ and to rule out any impurity issues such as presence of magnetic elements and clustering, we carried out in-depth analysis based on Rutherford backscattering spectroscopy (RBS), Proton induced X-Ray Emission spectroscopy (PIXE) and Secondary Ion Mass Spectroscopy (SIMS). Form these results we concluded that the observed FM was not due to magnetic impurities. Rather it is an intrinsic property of $Ti_{1-x}Ta_xO_2$ thin film.

9:36AM H15.00007 Magnetism of DMS SnO_2:Co Thin Films Grown by RF Sputtering[1] , GRATIELA STOIAN, Florida State University, PATRICIA STAMPE, ROBIN KENNEDY, Florida A&M University, STEPHAN VON MOLNAR, Florida State University — SnO_2:Co thin films with dopant concentrations ranging from 2-15at% were deposited on r-cut sapphire substrates via RF sputtering, to examine the origin of the room temperature ferromagnetism (RTFM) observed in such materials. Films deposited with 9:1 Ar/O_2 partial pressure ratio have a saturation moment of $\sim 0.34 \mu_B$/Co. Utilizing Coey's generalized grain boundary model [1], this implies that only $\sim(2 \pm 0.5)$% of the sample is FM. Furthermore, XPS studies reveal that the cobalt valance is 2+, suggesting it exists in the form of an oxide, either Co substitutional or as CoO clusters. Furthermore, angle dependent measurements indicate no sign of phase segregation. We speculate that the FM is due to the spontaneous magnetization of uncompensated spins at the surface of the CoO antiferromagnetic nanocrystals [2] in the host SnO_2. This model may also explain the large anisotropy observed in some of our films.

9:48AM H15.00008 Observation of room-temperature ferromagnetism in Cu:ZnO films part I; soft X-ray Magnetic Circular Dichroism , C. SANCHEZ-HANKE, Brookhaven National Laboratory, T.S. HERNG, D.-C. QI, National University of Singapore, T. BERLIJN, Brookhaven National Laboratory, J.B. YI, K.S. YANG, National University of Singapore, Y. DAI, Shandong University, Y.P. FENG, I. SANTOSO, X.Y. GAO, A.T.S. WEE, National University of Singapore, W. KU, Brookhaven National Laboratory, J. DING, A. RUSYDI, National University of Singapore — We report direct evidence of room-temperature ferromagnetic ordering in O-deficient Cu:ZnO films by using soft x-ray magnetic circular dichroism and x-ray absorption [1]. Our measurements have revealed unambiguously two distinct features of Cu atoms associated with (i) magnetically ordered Cu ions present only in the oxygen-deficient samples and (ii) magnetically disordered regular Cu^{2+} ions present in all the samples. We find that a sufficient amount of both oxygen vacancies and Cu impurities is essential to the observed ferromagnetism, and a non-negligible portion of Cu impurities is uninvolved in the magnetic order.

[1] T.S. Herng et al, Phys. Rev. Lett. **105**, 207201 (2010)

10:00AM H15.00009 Observation of room-temperature ferromagnetism in Cu:ZnO films part II; a theoretical study , T. BERLIJN, W. KU, Brookhaven National Laboratory, T.S. HERNG, D.-C. QI, J.B. YI, K.S. YANG, National University of Singapore, Y. DAI, Shangdong University, Y.P. FENG, I. SANTOSO, National University of Singapore, C. SANCHEZ-HANKE, Brookhaven National Laboratory, X.Y. GAO, A.T.S. WEE, J. DING, A. RUSYDI, National University of Singapore — To better understand the observation of room-temperature ferromagnetic ordering in O-deficient Cu:ZnO films [1], we calculated the configuration-averaged spectral function $\langle A(k,\omega)\rangle$ of ZnO with 2% Cu impurities and 1% O vacancies within the "LDA+U" approximation, solving the Hamiltonian only within the low energy Hilbert space, defined via the first-principles Wannier functions [2]. Based on these first principles results we proposed a microscopic "indirect double-exchange" model for the FM in Cu:ZnO that explains our main experimental findings.

[1] T.S. Herng et al, Phys. Rev. Lett. **105**, 207201 (2010)
[2] T. Berlijn et al, arXiv:1004.1156 (2010)

10:12AM H15.00010 Electrodeposition of Co-doped Cu_2O layers with high Curie temperature[1] , ANDRE A. PASA, IURI S. BRANDT, ALEXANDRE D.C. VIEGAS, MILTON A. TUMELERO, JOSE J. S. ACUNA, Departamento de Fisica, Universidade Federal de Santa Catarina, Florianopolis, Brazil, ENIO LIMA JR., ROBERTO D. ZYSLER, Centro Atomico Bariloche and Instituto Balseiro, Argentina — In this work, we have studied the magnetic properties of room temperature electrodeposited Cu_2O layers doped with Co. These layers were growth from electrolytes containing lactic acid and copper sulfate, with the addition of cobalt sulfate for the doping process. The layers are considered as a diluted magnetic semiconductor, showing ferromagnetic behavior above room temperature and saturation magnetization proportional to the concentration of cobalt sulfate. The decrease of lattice parameter and resistivity with the increase of the band gap for doped samples were results that pointed out to the Co incorporation to the growing layers as individual atoms. In addition, no evidences for the existence of superparamagnetic particles were observed from ZFC and FC curves, hysteresis loops and HRTEM images. The magnetic behavior is associated to Co atoms diluted in the Cu_2O lattice and a promising Curie temperature for spintronic application of 550 K was determined.

[1]CNPQ, CAPES, FAPESC, FINEP, ANPCyT (PICT2007-832), CONICET (PIP2008-1333) and UNCuyo

10:24AM H15.00011 The spin polarized electronic structures and magnetic properties of Co doped and Ga codoped ZnO , M.-H. TSAI, T.-Y. JIANG, C.-Y. HUANG, National Sun Yat-Sen University — The understanding of the magnetic property of Co doped ZnO (ZnO:Co) has been inconclusive with confusing experimental observations. Here, spin-polarized first-principles calculations have been performed for ZnO:Co to better understand its magnetic property. Without O and Zn vacancies, the total energy per Co ion in ZnO:Co in the ferromagnetic (FM) state was found to be only 6meV lower than that in the antiferromagnetic (AFM) state, which suggests that at room or higher temperature ZnO:Co is in the spin glass state. O vacancies and co-doping with Ga ions were found to enhance Co-Co FM coupling by induced delocalized states in the vicinity of Co 3d bands. The O vacancy was found to have a greater effect of FM enhancement than the co-doped Ga ion. While Zn vacancies were found to lower the Fermi level and enhance hybridization between Co 3d and valence-band O 2p states, which enhances super-exchange coupling and renders ZnO:Co to be in the AFM state. The opposite effects of O and Zn vacancies imply that the magnetic property of ZnO:Co depends strongly on the relative concentrations of O and Zn vacancies.

10:36AM H15.00012 Magnetotransport in the amorphous Ge(1-x)Mn(x) with self-assembled nanostructures[1] , WENJING YIN, University of Virginia, JAN JAROSZYNSKI, National High Magnetic Field Lab, JIWEI LU, University of Virginia, COPELAND KELL, LI HE, Rensselaer Polytechnic Institute, MELISSA DOLPH, JERROLD FLORO, STUART WOLF, University of Virginia — Mn ions have been reported to segregate into intermetallic precipitates or form coherent clusters in crystalline Ge(1-x)Mn(x) thin films. In this study, we investigated the microstructure of amorphous Ge(1-x)Mn(x) synthesized using low temperature molecular beam epitaxy, and observed the self-assembly of Mn rich nanostructures in Ge matrix with both cluster and column shapes by varying the Mn concentration. The magnetotransport properties were found to closely correlate with the magnetism. Negative magnetoresistance (MR) showed a dominant effect in as-grown materials, and required a very high magnetic field to saturate, whereas only positive MR was observed in post-annealed Ge(1-x)Mn(x). The anisotropic behavior in magnetism and magnetoresistance will also be discussed.

Session H16 GMAG DMP: Focus Session: Spins in Carbon-Based Materials– Spin Valves and Interfaces D173

8:00AM H16.00001 Spin filtering effect of ferromagnetic metal-organic interfaces , MIRKO CINCHETTI, Department of Physics and Research Center OPTIMAS, University of Kaiserslautern — The study of the spin properties of organic semiconductors (OSC) is recently receiving great attention. Being characterized by moderate spin-relaxation lengths, one of the most promising routes to employ OSC for spintronics applications is probably to exploit the high spin injection achievable across ferromagnetic metal-organic interfaces [1,2]. Combined with the extreme flexibility and tunability of OSC, it is expected that such hybrid interfaces will constitute a fundamental building block for advanced spintronics devices, where spin-injection is controlled by fine-tuning of the interface physical ad chemical properties. An example has been recently presented in [3], where doping of the OSC copper phthalocyanine (CuPc) has been successfully used to tune the spin functionality of a cobalt-CuPc interface. In particular, the presence of a spin-polarized hybrid interface state, acting as a spin-filter at the interface, has been used to enhance the efficiency of spin injection to values above 100%. In order to exploit such great potential of hybrid organic-inorganic interfaces, fundamental knowledge about their spin-dependent properties is essential. Besides the cobalt-CuPc interface, we have studied the iron-CuPc, cobalt- tris[8-hydroxyquinoline]aluminium (Alq3) and iron-Alq3 interfaces. We applied several complementary experimental techniques, namely spin polarized scanning tunnelling microscopy and spectroscopy together with spin polarized ultraviolet photoemission spectroscopy and spin- and time-resolved two-photon photoemission. We found evidence for spin-polarized interface states and show that they act as a spin-filter for electrons crossing the interface between the ferromagnetic metal and the OSC. Correspondingly, we observed a pronounced spin-dependency of the lifetime of electrons injected in the above mentioned hybrid spin-polarized interface states.

8:36AM H16.00002 Spin valve effect and high field magnetoresistance in hybrid magnetic tunnel junction of V(TCNE)$_{x\ 2}$/rubrene/ $La_{2/3}Sr_{1/3}MnO_3$[1] , JUNG-WOO YOO, BIN LI, C.Y. CHEN, V.N. PRIGODIN, A.J. EPSTEIN, The Ohio State University, H.W. JANG, C.W. BARK, C.B. EOM, University of Wisconsin — Molecule/organic-based magnets, that allow chemical tuning of electronic and magnetic properties, are a promising new class of magnetic materials for future spintronics [1]. V (TCNE:tetracyanoethylene)$_x$ ($x \sim 2$) is the room temperature organic-based magnetic semiconductor ($T_c \sim 400$ K). It has ferrimagnetic coupling between the spins in the $TCNE^-$ anions and spins in V^{II} leading highly spin- polarized valence and conduction bands. In this talk, we present realization of an organic-based magnetic as an electron spin polarizer in the standard spin valve device geometry [2]. The room temperature organic-based magnet, V(TCNE)$_x$ was successfully incorporated into the standard magnetic tunnel junction devices in tandem with LSMO ($La_{2/3}Sr_{1/3}MnO_3$) film. Beside spin valve effect, the device exhibits large negative high-field magnetoresistance, which may be associated with anomalous field dependent Fermi level shift in LSMO.

8:48AM H16.00003 Organic Spin Valves with Characteristics of Inelastic Tunneling and Hopping Transport , MINN-TSONG LIN, KAI-SHIN LI, YIN-MING CHANG, SANTHANAM AGILAN, JHEN-YONG HONG, JUNG-CHI TAI, Dept. of Physics, National Taiwan University, WEN-CHUNG CHIANG, Dept. of Physics, Chinese Culture University, KEISUKE FUKUTANI, P.A. DOWBEN, Dept. of Physics and Astronomy, University of Nebraska — We report on the inelastic scattering characteristics of an organic-based spin valve with a thin organic barrier of 3,4,9,10-perylene-teracarboxylic dianhydride (PTCDA) dusted with alumina at organic/ferromagnetic interfaces. Spin injection with magnetoresistance up to 12% at room temperature was achieved. In the inelastic tunneling spectrum, the observation of characteristic vibrational loss peak of organic spacer provides direct evidence of the interplay between the spin-polarized electrons and the organic molecules. The spin-dependent transport mechanism can be further described with a model of combined tunneling and hopping processes as verified by experiments as a function of organic layer thickness.

9:00AM H16.00004 Coulomb blockade magnetoresistance in organic spin transport device[1] , DALI SUN, X.-G ZHANG, PAUL C. SNIJDERS, Oak Ridge National Laboratory, HANGWEN GUO, The University of Tennessee / Oak Ridge National Laboratory, ZHENG GAI, T. ZAC WARD, Oak Ridge National Laboratory, JIAN SHEN, The University of Tennessee / Fudan University — Using buffer-layer-assisted growth, we successfully fabricated organic spin transport devices with a discontinuous granular magnetic layer centered in an organic spacer film. The Coulomb blockade magnetoresistance (MR) effects were observed, as predicted by X.-G. Zhang *et al* (Phys. Rev. B. 81, 155122, 2010). The spin-dependent Coulomb blockade voltage arises from the coupled magnetic dots inside the organic material and correlate with the observed MR effect.

9:12AM H16.00005 Spin-polarized tunnel injection and extraction effects on magneto-resistance in organic semiconductor spin valves[1] , MOHAMMAD YUNUS, P. PAUL RUDEN, University of Minnesota, DARRYL L. SMITH, Los Alamos National Lab. — Experimental evidence of large magneto-resistance has been reported for organic spin valves. An organic spin valve consists of a conjugated hydrocarbon semiconductor sandwiched between two ferromagnetic contacts. Tunnel injection of charge carriers from a ferromagnetic contact can be strongly spin-polarized. The process is modeled as tunneling through a thin interfacial layer into localized molecular states of the organic semiconductor near the equilibrium Fermi level, and subsequent thermally activated hopping of the charge carriers out of these localized states into the bulk of the semiconductor, where the transport can be described by macroscopic device equations. The extraction of charge carriers follows an analogues process at the collecting contact. We explore the consequences of parallel or anti-parallel alignment of contact magnetizations on the spin-polarization and the magneto-resistance associated with the spin-polarized current in the device.

9:24AM H16.00006 Spin-orbit coupling, spin relaxation, and spin diffusion in organic solids: applications to Alq_3 and CuPc[1] , ZHI-GANG YU, SRI International — We develop a systematic approach of quantifying spin-orbit coupling (SOC) and a rigorous theory of carrier spin relaxation caused by the SOC in disordered organic solids. The SOC mixes up- and down-spin in the polaron states and can be characterized by an admixture parameter γ^2. The spin mixing effects spin flips as polaron hops from one molecule to another even through the interaction that facilitate hopping is spin-indepdent. The spin relaxation time is $\tau_{sf} = \bar{R}^2/(16\gamma^2 D)$ and the spin diffusion length is $L_s = \bar{R}/4|\gamma|$, where $\bar{R}$ is the mean polaron hopping distance and D the carrier diffusion constant. We show that the SOCs in tris-(8-hydroxyquinoline) aluminum (Alq_3) and in copper phthalocyanine (CuPc) are particularly strong, due to the orthogonal arrangement of the three ligands in the former and Cu $3d$ orbitals in the latter. The theory quantitatively explains the recent observed spin diffusion lengths in Alq_3 from muon measurements and in CuPc from two-photon photoemission.

9:36AM H16.00007 Triplet exciton controlled current in an organic semiconductor , WILLIAM BAKER, University of Utah, DANE MCCAMEY, University of Sydney, KIPP VAN SCHOOTEN, University of Utah, JOHN LUPTON, Universität Regensburg, CHRISTOPH BOEHME, University of Utah, BOEHME GROUP COLLABORATION, LUPTON GROUP COLLABORATION — Organic materials like MEH-PPV have relatively low spin-orbital coupling leading to long spin lifetimes and good spin-selection rules. As a result, the rates of recombination of an ensemble of polaron pairs can be changed by resonant manipulation of either the P^+ or the P^- spins, leading to a flopping between the singlet to triplet manifolds - this can be observed as a small change in the device current [1]. In this study we have used pulsed electrically detected magnetic resonance with electron-rich OLED devices to investigate the possibility of other spin-dependent processes like an exciton-polaron interaction. We expect that devices with excess electrons will show signals from free electrons interacting with long lived triplet excitons. Coherent Rabi nutation experiments were carried out from room temperature down to 5K. At room temperature only a single polaron-pair resonance is observed at g$\sim$2.003. However, as the temperature is decreased a signal at g$\sim$4(triplet exciton resonance) is observed along with a second signal at g$\sim$2.003 corresponding to the rotation of a single polaron.

9:48AM H16.00008 STM studies of Lanthanide Phthalocyanine molecules on metallic and thin-insulating surfaces , FADI EL HALLAK, BEN WARNER, UCL, UK, MICHAEL WATERS, U. Nottingham, UK, JORIS VAN SLAGEREN, U. Nottingham, UK; U. Stuttgart, Germany, CYRUS F. HIRJIBEHEDIN, UCL, UK — Molecules deposited onto surfaces are of interest because of their potential use as nano-scale electronic components. More recently, the magnetic properties of these systems have also become accessible. Using scanning tunneling microscopy (STM), it is possible to study both sets of properties, and to examine the local environment of the molecules. For example, large magnetic anisotropies have been observed for transition metal Phthalocyanine (Pc) molecules on thin insulators, which decouple the spin from the underlying metal. We present STM imaging and spectroscopy data on lanthanide double-decker Pcs. We explore the different binding configurations and study how these can influence the properties of these molecules on surfaces.

10:00AM H16.00009 STM Studies of Iron Phthalocyanine on Fe(110) Films[1] , ANDREAS SANDIN, DAN DOUGHERTY, J. E. (JACK) ROWE, NC State University — We have observed molecular-scale-resolution arrays of Iron Phthalocyanine (FePc) molecules which we adsorbed at room temperature on thin ($\sim$5-10 ML) films of Fe(110). These molecular layers were grown in a UHV Omicron/AFM/STM/ multi-probe system at NC State in the Physics Department at pressures of $\sim 10^{-10}$ torr. Our results indicate a strong inter-molecular interaction that produces well-ordered films at monolayer coverage. For lower coverage ($\sim$0.2 – 0.6 ML) the FePc-Fe substrate interaction strongly dominates and the STM image morphology has only small clusters of 2-6 molecules. Our data clearly shown that the FePc molecules are lying flat on the surface in the ordered $\sim$1 ML samples since we see evidence of the carbon-ring ligands in some images. We discuss the possibility of spin-dependent effects between the molecular Fe and the substrate Fe as an example of potential molecular-modified spin-based devices. Initial STM-spectroscopy including both I vs. V and Z vs. V results are consistent with our structural observations.

10:12AM H16.00010 Scanning Tunneling Microscopy and Spectroscopy Studies of a Model Organic Spintronic Interface: Alq3 on Cr(001) , ZHENGANG WANG, ALEX PRONSCHINSKE, DANIEL DOUGHERTY, NC State University, SURFACE SCIENCE TEAM — Scanning tunneling microscopy was used to observe coverage-dependent structure during growth of the first monolayer of Alq3 on a Cr(001) surface. No long range molecular ordering is observed, though molecules tend to form randomly oriented chain-like aggregates even at the lowest coverages. This illustrates that the well-known amorphous nature of Alq3 films begins even in the first layer, but that the disorder in films have subtle local correlations relevant to electronic and spintronic device modeling. Scanning tunneling spectroscopy was used to locate the LUMO-derived transport state above the Fermi level and correlate its position with local film structure.

10:24AM H16.00011 STM studies of a novel organic/inorganic interface: TCNE/GaAs(110)[1] , N.M. SANTAGATA, J.A. GUPTA, The Ohio State University — Recent efforts in the field of spintronics have focused on the integration of organic molecular magnets with inorganic semiconductors. Little is known, however, about the interfacial chemistry and physics that occurs between the organic spin injector and the inorganic device structure. We are therefore studying tetracyanoethylene/GaAs(110) as a model system to gain a basic understanding of the properties that emerge upon integration of these materials. Utilizing low temperature (7 K) ultrahigh vacuum scanning tunneling microscopy we are able to identify both bonding geometries and bonding sites for isolated TCNE molecules on the unreconstructed GaAs(110) surface. Scanning tunneling spectroscopy can provide a detailed look at the interfacial electronic structure, including alignment of individual molecular orbitals with respect to the band structure of the underlying substrate. Single transition metal–TCNE complexes can be realized and investigated via atomic/molecular manipulation.

10:36AM H16.00012 Magnetic Field Effects Generated by Inter-molecular Excited States in Organic Semiconductors , LIANG YAN, MING SHAO, BIN HU, University of Tennessee — It has experimentally found that an external magnetic field can change electroluminescence, electric current, and photocurrent, generating magnetic field effects (MFEs) in non-magnetic organic semiconductors. Our photoluminescence studies have found that the intermolecular excited states are accountable for the MFEs while the intra-molecular excited states exhibit negligible MFEs. Our experimental studies further indicated that inter-molecular excited states can exhibit tunable spin-orbital coupling and exchange interaction based on materials mixing. We observed that tuning inter-molecular spin-orbital coupling and exchange interaction can largely modify the MFEs through spin-dependent formation and intersystem crossing in inter-molecular excited states. Therefore, the use of inter-molecular excited states presents a new mechanism to generate magnetic responses in non-magnetic organic semiconductors.

10:48AM H16.00013 Charge transport through single alkanedithiol molecules on an ultrathin insulating film: Influence on an atomic Kondo resonance , TAEYOUNG CHOI, JAY GUPTA, ohio state university — Studies of charge/spin transport through single molecules are important for understanding organic-based electronic and memory devices. We have realized a single molecule wire comprising an alkanedithiol molecule and a single Co atom contact using a low temperature scanning tunneling microscope. This wire is formed on an ultrathin insulating layer (Cu2N on Cu(100)). A Kondo resonance observed on isolated Co atoms on Cu2N indicates minimal contact to the Cu substrate. However, increased contact to Cu is achieved by connecting the Co atom via the alkanedithiol molecule. A change in the Kondo lineshape on the Co atom indicates an open conduction channel through the molecule. This result provides an opportunity to study charge/spin transport through single molecules with atomically precise contacts. We acknowledge financial support from NSF CAREER Award No. DMR-0645451 and NSF MRSEC-0820414. http://www.physics.ohio-state.edu/∼jgupta.

Tuesday, March 22, 2011 8:00AM - 10:48AM –

Session H17 DMP GMAG: Focus Session: Bulk Properties of Complex Oxides - Ferrites D174

8:00AM H17.00001 Inelastic neutron scattering measurements on the triangular lattice antiferromagnet CuFe1-xGaxO2 in the paraelectric and multiferroic phases , FENG YE, Oak Ridge National Laboratory — The intensive efforts to study multiferroic materials in recent years have led to a better understanding of the fundamental physical processes and interactions leading to the complex behavior in those compounds. In this talk, I will focus on the recent neutron scattering measurements and calculations of the spin dynamics of the triangular lattice antiferromagnet $CuFe_{1-x}Ga_xO_2$. In pure $CuFeO_2$ a low-temperature collinear spin structure is stabilized by long range magnetic interactions. The spin wave spectra show dynamics precursory to the multiferroic phase. When this system is doped with a few percent of nonmagnetic gallium, its low-temperature phase has a complex noncollinear (CNC) spin order and becomes multiferroic. The CNC phase appears to have distorted screw-type magnetic configuration that is stabilized by the displacement of the oxygen atoms. The spin dynamics and the spin order in this material, as well as their implications to the origin of the ferroelectricity will be discussed [1,2].

8:36AM H17.00002 Investigating the spin dynamics of the non-collinear magnetic phase of 3.5% Ga-doped $CuFeO_2$[1] , T. KIMURA, Division of Materials Physics, Osaka University, J.T. HARALDSEN, Theoretical Division, Los Alamos National Laboratory, F. YE, Neutron Scattering Science Division, Oak Ridge National Laboratory, R.S. FISHMAN, Materials Science and Technology Division, Oak Ridge National Laboratory, J.A. FERNANDEZ-BACA, Neutron Scattering Science Division, Oak Ridge National Laboratory and Department of Physics and Astronomy, The University of Tennessee, Y. YAMAGUCHI, K. KIMURA, Division of Materials Physics, Osaka University — We examine the evolution of the non-collinear phase of a hexagonal lattice antiferromagnet to help understand the inelastic neutron scattering measurements for the multiferroic ground state of 3.5% Ga-doped $CuFeO_2$. With the complex ground state stabilized by the displacement of the oxygen atoms, the multiferroic coupling is explained by the predicted "spin-driven" model. By comparing the observed and calculated spectrum of spin excitations for multiple spin configurations, we conclude that the magnetic ground state is a distorted screw-type spin configuration with a distribution of turn angles produced by lattice distortions.

8:48AM H17.00003 Long-period solitonic lattice in the rare earth orthoferrite TbFeO3 , NIELS JENSEN, Riso National Laboratory, Roskilde, Denmark, SERGEY ARTYUKHIN, University of Groningen, ANDREY MALJUK, Helmholtz-Zentrum Berlin, KIM LEFMAN, University of Copenhagen, MAXIM MOSTOVOY, University of Groningen, DIMITRI ARGYRIOU, European Spallation Source ESS AB — Rare earth orthoferrites show a variety of magnetic transitions and spectacular magneto-electric effects originating from the coupling between the iron and rare earth magnetic sublattices. Our recent single-crystal neutron diffraction measurements revealed the presence of an unusual incommensurate phase in TbFeO3, which is induced by the magnetic field along the c axis and has a period of about 100 unit cells. We also present the results of model calculations, which explain the origin of this novel phase and reproduce the magnetic phase diagram of TbFeO3.

9:00AM H17.00004 Magnetic and Raman spectroscopic studies of yttrium substituted $BiFeO_3$, R. NAIK, S. TALEBI, AMBESH DIXIT, Wayne State University, V. NAIK, University of Michigan, Dearborn, G. LAWES, Wayne State University — As a room temperature multiferroic $BiFeO_3$is attractive for a number of applications. However the relatively weak magnetism limits its suitability for applications. $Bi_{1-x}Y_xFeO_3$ (x=0, 0.05, 0.10, 0.15 and 0.20) ceramic samples have been prepared by sol-gel technique and thin films by metalorganic decomposition. X-ray diffraction, X-ray photoelectron and Raman spectroscopy measurements confirm that these ceramic and thin film samples are of single phase. More remarkably these Y modified $BiFeO_3$ samples exhibit enhanced room temperature magnetic and magnetodielectric properties, with the saturation magnetization approaching 25 emu cm^{-3} for x=0.20. We discuss the correlation between the enhanced room temperature magnetization and two-phonon Raman modes in the context of investigating the origin of the magnetic properties in $Bi_{1-x}Y_xFeO_3$.

9:12AM H17.00005 ABSTRACT WITHDRAWN –

9:24AM H17.00006 Relation between electric phase and magnetic ordering of Y-type Hexaferrite , WOO-SUK NOH, H. JANG, K.-T. KO, J.-H PARK, c-CCMR & Dept. of Physics, POSTECH, S.H. CHUN, K.H KIM, XMPL, Seoul National University, B.-G PARK, J.-Y KIM, PAL, POSTECH — Y-type hexaferrite $Ba_{0.5}Sr_{1.5}Zn_2Fe_{12}O_{22}$(BSZFO), one of multiferroic materials, we could acquire magnetic field-induced commensurate phase, changing of magnetic phase of BSZFO and $Ba_{0.5}Sr_{1.5}Zn_2(Fe_{1-x}Al_x)_{12}O_{22}$ (x = 0.08)(BSZFAO) using resonant soft X-ray scattering(RSXS) experiment. Also we could confirm that magnetic ordering changing has some relation with electric phase transition, q=1.5 at ferroelectric phase not only BSZFO but also BSZFAO. This research results were acquired by using 2A EPU beamline at PAL.

9:36AM H17.00007 Magnetic Spectra on Charge Ordering in $R_{1/3}Sr_{2/3}FeO_{3-\sigma}$ (R = La, Pr, and Nd) , JIE MA, JIAQIANG YAN, SOULEYMANE OMAR DIALLO, REBECCA STEVENS, ANNA LLOBET, FRANS TROUW, DOUGLAS ABERNATHY, MATTHEW STONE, ROBERT MCQUEENEY, AMES LABORATORY, AMES, IA 50011 COLLABORATION, DEPARTMENT OF PHYSICS AND ASTRONOMY, IOWA STATE UNIVERSITY, AMES, IA 50011 COLLABORATION, OAK RIDGE NATIONAL LABORATORY, PO BOX 2008, OAK RIDGE, TN 37831, USA COLLABORATION, LOS ALAMOS NATIONAL LABORATORY, LOS ALAMOS, NM 87545 COLLABORATION — $R_{1/3}Sr_{2/3}FeO_{3-\sigma}$ (R = La, Pr, and Nd) compounds are reported to have the same charge ordering (CO) and Neel temperatures. Inelastic neutron scattering is applied to study the magnetic energy effect on the CO state in this system. Based on the ratio of the ferromagnetic exchange energy (J_F) and antiferromagnetic exchange energy ($|J_{AF}|$), the magnetic exchange energy can stabilize the CO state in $La_{1/3}Sr_{2/3}FeO_{3-\sigma}$ and $Pr_{1/3}Sr_{2/3}FeO_{3-\sigma}$ alone; with the smaller R^{3+} substitution, $|J_{AF}|$ increases a lot from $La_{1/3}Sr_{2/3}FeO_{3-\sigma}$ to $Nd_{1/3}Sr_{2/3}FeO_{3-\sigma}$, but the CO of Fe ions could still be driven by magnetic energy itself with the correction on magnetic energy ratio.

9:48AM H17.00008 First-principles calculations for XAS of infinite-layer iron oxides , MITSURU KODERA, ISIR, Osaka University, TATSUYA SHISHIDOU, ADSM, Hiroshima University, TAMIO OGUCHI, ISIR, Osaka University — The oxygen defect perovskite $SrFeO_{3-x}$ shows various properties such as the giant magnetoresistance effect and the thermoelectric effect. It had been believed that the oxygen content in $SrFeO_{3-x}$ changes up to $x = 0.5$. Recently, Tsujimoto *et al.* have succeeded in synthesizing the infinite-layer iron oxide $SrFeO_2$. $SrFeO_2$ has a square-planar oxygen coordination, while the iron oxides usually have the tetrahedral and octahedral coordination. $CaFeO_2$ has also infinite layer structure and the same magnetic ordering as $SrFeO_2$. However, it is suggested that the oxygen coordination of $CaFeO_2$ is different from that of $SrFeO_2$. In order to investigate the electronic structure of iron in (Ca, Sr)FeO_2, the x-ray absorption spectroscopy (XAS) spectrum has been measured. In this work, we perform the calculation for XAS spectrum near the Fe-K edge of (Ca, Sr)FeO_2 using the first-principles calculations. We compare the results with the experiment and discuss the electronic structure of iron in (Ca, Sr)FeO_2.

10:00AM H17.00009 Canted-spin-caused electric dipoles: a local symmetry theory , THOMAS A. KAPLAN, SUBHENDRA D. MAHANTI, Michigan State University — A pair of magnetic atoms with canted spins $\mathbf{S}_a$ and $\mathbf{S}_b$can give rise to an electric dipole moment **P.** Several forms for the dependence of **P** on the spins have been derived from various microscopic models, some of which have been invoked to explain experimental results found in some multiferroic materials. The forms are $\mathbf{P}_1 \propto \mathbf{R} \times (\mathbf{S_a} \times \mathbf{S}_b)$, $\mathbf{P}_2 \propto \mathbf{S_a} \times \mathbf{S}_b$, $\mathbf{P}_3 \propto \mathbf{S_a}(\mathbf{S_a} \cdot \mathbf{R}) - \mathbf{S}_b(\mathbf{S}_b \cdot \mathbf{R})$, where **R** is the relative position of the atoms. To unify and generalize these various forms we consider **P** as the most general quadratic function of the spin components that vanishes whenever $\mathbf{S_a}$ and $\mathbf{S}_b$are collinear. The study reveals new forms. We generalize to the vector **P**, Moriya's symmetry considerations on the (scalar) DM energy $\mathbf{D} \cdot \mathbf{S_a} \times \mathbf{S}_b$(which led to restrictions on **D**). This provides a rigorous proof that $\mathbf{P}_1$ is allowed no matter how high the symmetry of the atoms plus environment, and gives restrictions for all other contributions. The analysis leads to the suggestion of new terms omitted in the existing microscopic models, and predicts an unusual antiferroelectric ordering in the antiferromagnetically and ferroelectrically ordered phase of $RbFe(MoO_4)_2$.

10:12AM H17.00010 Structural and magnetic ordering in bulk Sr2FeMoO6 synthesized by planetary ball mill: The effects of grinding.[1] , J.M. LUCY, A.J. HAUSER, B. PETERS, F.Y. YANG, The Ohio State University — The standard solid-state synthesis procedure has been widely used to make bulk complex oxides, including half-metallic double perovskite Sr2FeMoO6. However, although it is generally recognized that multi-step grinding and heating are crucial for synthesis of high quality materials, little has been done to quantitatively characterize the effect of grinding on the quality of the final products. We systematically varied the level of grinding, ranging from poor grinding by hand for a short period of time (∼10 min) to very fine grinding and mixing by a planetary ball mill for many hours which produces uniform sub-micron particles. XRD, SEM and VSM were used to characterize the structural and magnetic properties. The Sr2FeMoO6 samples made by different grinding methods exhibit drastically different structural and magnetic ordering. The highest quality Sr2FeMoO6 is from the most thorough grinding and gives a close to ideal Fe/Mo ordering and magnetic moment close to 4 Bohr magneton per formula unit.

[1]This work is supported by the Center for Emergent Materials, a NSF MRSEC at OSU (DMR-0820414).

10:24AM H17.00011 Theory of ferromagnetic double perovskites[1] , OINAM NGANBA MEETEI, ONUR ERTEN, ANAMITRA MUKHERJEE, MOHIT RANDERIA, NANDINI TRIVEDI, PATRICK WOODWARD, The Ohio State University — We derive and validate an effective classical spin model which describes the magnetic properties of double perovskites (DP) like Sr_2FeMoO_6, including the effects of disorder and carrier concentration. This model generalizes the Anderson-Hasegawa model for manganites to DP's. We validate our effective spin model by making detailed comparisons with the results obtained from a quantum Hamiltonian of itinerant electrons interacting with spins on the Fe-sites. We show that the conduction electron polarization at the chemical potential $P(T)$ tracks the temperature-dependence of the total magnetization $M(T)$. We point out the importance of Coulomb correlation U on Mo-sites and of direct Mo-Mo hopping t' on stabilizing the ferromagnetic phase as a function of electron doping (by La substitution of Sr). We show how the small parameters U and t' are crucial in understanding the experimental results for T_c as a function of carrier concentration. We predict how the ferromagnetic T_c can be raised substantially (up to 40%), without sacrificing the polarization P, by a combination of excess Fe and La-doping.

[1]Supported by the NSF-MRSEC grant DMR-0820414

10:36AM H17.00012 Role of disorder and doping in ferromagnetic double perovskites[1] , ANAMITRA MUKHERJEE, OINAM NGANBA MEETEI, ONUR ERTEN, MOHIT RANDERIA, NANDINI TRIVEDI, PATRICK WOODWARD[2], The Ohio State University — We use an effective classical spin model, which we have recently derived and validated, to examine the effect of disorder on the magnetic properties of double perovskites like Sr_2FeMoO_6 (SFMO). We compute the effects of excess Fe, excess Mo, and anti-site disorder on the magnetization $M(T)$ and the ferromagnetic transition temperature T_c, and show that our results are quantitatively consistent with available experiments. We then use these results to propose routes to increase the ferromagnetic T_c above that of pure SFMO (420K). We predict that, by adding excess Fe on Mo sites and compensating for the change in conduction electron density by La substitution on the Sr sites, we can raise T_c by as much as 40%, without substantially sacrificing the conduction electron polarization P at the chemical potential.

Session H18 DCOMP: Electronic Structure II D172

8:00AM H18.00001 Spectral element solution of the Kohn-Sham atom , KRISTOPHER ANDERSEN, High Performance Technologies, Inc / Naval Research Laboratory, NOAM BERNSTEIN, Naval Research Laboratory, JOHN PASK, Lawrence Livermore National Laboratory — Electronic structure calculations of atoms are important in nuclear physics, and are necessary input for most methods to construct first-principles effective potentials (i.e., pseudopotentials and projector augmented wave potentials). The standard method to solve the atomic problem within Kohn-Sham density functional theory is the shooting method. In this work, the more robust spectral element method is applied to the 1D atomic radial equation. The spectral element method provides a strict, upper-bound on the absolute error in the Kohn-Sham eigenvalues and wavefunctions enabling the solution to be converged to a well controlled accuracy. The results of this method are compared to the extensive "NIST Atomic Reference Data for Electronic Structure Calculations" database for elements H to U, providing a more rigourous assessment of this dataset than previously available.

8:12AM H18.00002 Ab initio calculations of optical absorption spectra: Solution of the Bethe-Salpeter equation within density matrix perturbation theory[1] , DARIO ROCCA, UC Davis, DEYU LU, Brookhaven National Laboratory, HUY-VIET NGUYEN, GIULIA GALLI, UC Davis — We present an approach to compute optical absorption spectra from first principles, which is suitable for the study of large systems and gives access to spectra within a wide energy range. In this approach, the quantum Liouville equation is solved iteratively within first order perturbation theory, with a Hamiltonian containing a static self-energy operator [1]. This is equivalent to solving the Bethe-Salpeter equation. Explicit calculations of single particle excited states and inversion of dielectric matrices are avoided using techniques based on Density Functional Perturbation Theory [1,2]. The calculation and inclusion of GW quasi-particle corrections within this framework are discussed. The efficiency and accuracy of our approach are demonstrated by computing optical spectra of solids, nanostructures and dipeptide molecules exhibiting charge transfer excitations.

8:24AM H18.00003 Ab-initio calculations of absorption spectra of nanowires by solving the Bethe-Salpeter Equation[1] , YUAN PING, DARIO ROCCA, Department of Chemistry, University of California, Davis, DEYU LU, Brookhaven National Laboratory, GIULIA GALLI, Department of Chemistry and Department of Physics, University of California, Davis — A first principle approach to the solution of the Bethe Salpeter equation without empty electronic states has been recently developed [1], which makes possible the calculations of absorption spectra of relatively large systems (with several hundreds of electrons). We present applications of this approach to quasi-one dimensional systems, including chains of hydrogen molecules and Si nanowires. We discuss techniques to further improve the performance of absorption spectra calculations, and present a general scheme to accurately integrate the divergence in the screened exchange integrals. Finally, in the case of Si nanowires, we discuss the effect of surface reconstruction in shaping optical absorption spectra.

8:36AM H18.00004 Efficient GW calculations using eigenvalue-eigenvector decomposition of the dielectric matrix[1] , HUY-VIET NGUYEN, T. ANH PHAM, DARIO ROCCA, GIULIA GALLI, University of California-Davis — During the past 25 years, the GW method [1] has been successfully used to compute electronic quasi-particle excitation spectra of a variety of materials. It is however a computationally intensive technique, as it involves summations over occupied and empty electronic states, to evaluate both the Green function (G) and the dielectric matrix (DM) entering the expression of the screened Coulomb interaction (W). Recent developments have shown that eigenpotentials of DMs can be efficiently calculated without any explicit evaluation of empty states [2]. In this work, we will present a computationally efficient approach to the calculations of GW spectra by combining a representation of DMs in terms of its eigenpotentials [3] and a recently developed iterative algorithm [4]. As a demonstration of the efficiency of the method, we will present calculations of the vertical ionization potentials of several systems. [1] L. Hedin, Phys. Rev. 139, A796 (1965). [2] H.-V. 8:48AM H18.00005 A TDLDA+U approach on strongly hybridized Frenkel excitons in Mott insulators and implications to TDDFT and GW+BSE[1] , CHI-CHENG LEE, Academia Sinica, Taiwan, H.C. HSUEH, Tamkang University, Taiwan, WEI KU, Brookhaven National Laboratory — The applicability of nowadays first-principles approach on local excitations of strongly correlated systems is unknown. We therefore derived the dynamical linear response of LDA+U functional within the framework of TDDFT.[2] The strength and weakness of LDA+U functional in describing charge excitations of strongly interacting Mott insulators is examined via this TDLDA+U method. Formulated using real-space Wannier functions, a computationally inexpensive framework gives detailed insights into the formation of tightly bound Frenkel excitons with reasonable accuracy. Specifically, a strong hybridization of multiple excitons is found to significantly modify the exciton properties. Furthermore, our study exposes a significant generic limitation of adiabatic approximation in TDDFT with hybrid functionals and in existing Bethe-Salpeter-equation approaches, advocating the necessity of strongly energy-dependent kernels in future development. Finally, a superatom approach beyond TDLDA+U will also be discussed.

9:00AM H18.00006 Level alignment at covalently bonded metal-organic interfaces within the GW approximation , JEFFREY NEATON, ISAAC TAMBLYN, Molecular Foundry, LBNL, SU YING QUEK, Institute of High Performance Computing (IHPC) and Physics and Applied Physics in Nanyang Technological University, STANIMIR BONEV, LLNL and Dalhousie University, PIERRE DARANCET, Molecular Foundry, LBNL — Accurate calculations of orbital energies for molecules chemisorbed on metal surfaces are important for understanding energy conversion, molecular scale transport, and charge transfer events at metal electrodes. Here, using density functional theory (DFT) and many-body perturbation theory within the GW approximation (GWA), we report the orbital energies of a well-studied molecule, benzene diamine (and derivatives), covalently bonded to aluminum and gold surfaces. For chemisorbed derivatives on Al surfaces, we predict a shift in the highest occupied molecular orbital resonance energy greater than 1 eV relative to the DFT result. We discuss our GWA results in the context of a model self-energy approach based on prior work [1], which can be applied to larger systems at greatly reduced computational cost.

9:12AM H18.00007 GW approach to degenerate systems[1] , JOHANNES LISCHNER, JACK DESLIPPE, STEVEN G. LOUIE, UC Berkeley — Many-body perturbation theory based on the GW approximation to the electron self energy describes accurately in first-principles calculations the electronic (quasiparticle) excited states of solids, clusters and molecules. However, despite the multitude of important systems with degenerate ground states, ranging from open-shell atoms and molecules to magnetic defects in solids, the GW approach has been applied almost exclusively to closed-shell systems. In this talk, we discuss some of the problems with existing GW calculations for degenerate systems, such as spin contamination, the multiplet problem, and the proper definition of the Green function in open-shell systems. Different formulations to overcome these problems are explored.

[1]This work was supported by National Science Foundation Grant No. DMR10-1006184, the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. Computational resources have been provided by DOE at Lawrence Berkeley National Laboratory's NERSC facility

9:24AM H18.00008 Ab-initio theory of spin fluctuations in magnets , VLADIMIR ANTROPOV, LIQIN KE, Ames Laboratory, MARK VAN SCHILFGAARDE, Arizona State University, MIKHAEL KATSNELSON, Radboud University of Nijmegen — We propose a framework for a true ab initio theory of magnetism, based on many-body perturbation theory (MPBT). It fits in naturally with methods based MPBT such as the GW approximation; but the approach can be implemented as an extension to any existing static method for electronic structure such as the local spin density approximation to density functional theory, to include spin fluctuations. Initially we calculated the spin fluctuation contributions using random phase approximation. The self consistency procedure similar to the one used in Moryia-Kawabata theory can be naturally implemented. The fluctuation dissipation theorem is used to calculate the reduction of the mean field magnetic moment in itinerant magnets. The applications of the technique includes traditional 3d ferromagnetic metals, their alloys and compounds and 5f systems.

9:36AM H18.00009 A GW-based many-body perturbation theory approach for investigating materials with strong spin-orbit coupling , BRADFORD BARKER, JACK DESLIPPE, OLEG YAZYEV, STEVEN LOUIE — Spin-orbit coupling is an essential ingredient in understanding the electronic properties of materials of recent interest. We have developed a means of incorporating spin-orbit coupling to the quasiparticle excitations in solids within the GW approach. We apply our method to the properties of materials with heavy ion cores. This work was supported by National Science Foundation Grant No. DMR10-1006184, the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. Computational resources have been provided by NERSC.

9:48AM H18.00010 Self-consistent band-structure calculations at GW quality and DFT expense[1] , STEPHAN LANY, P. GRAF, M. D'AVEZAC, A. ZUNGER, Natl. Renewable Energy Lab., CO — GW provides rather accurate quasi particle energies where approximate DFT methods tend to fail, yet are too computer intensive for complex inorganic materials (large systems or dense Brillouin zone sampling) that are currently of interest, e.g. for energy conversion. We explore the possibility that the trends of the GW quasi-particle energy corrections due to the non-local and energy dependent self-energy Σ(r,r',E) can be captured by atomic potentials that do not significantly increase the computational effort of a standard DFT calculation. We proceed in 4 steps: (i) Perform GW reference calculations for II-VI and III-V semiconductors (ii) Define atomic potentials that are added to the DFT Hamiltonian. Here we extend the concept of the non-local external potentials (NLEP) of Ref. [1], now allowing for two parameters per atom type and angular momentum. (iii) Fit the NLEP parameters to the GW test set. (iv) Finally, we test transferability by applying the potentials to the III_2-VI_3 and II_3-V_2 compounds that were not included in the fitting set.

10:00AM H18.00011 The sc-COHSEX+GW and the static off-diagonal GW approaches to quasiparticle wavefunctions and energies , JACK DESLIPPE, MANISH JAIN, GEORGY SAMSONIDZE, MARVIN COHEN, STEVEN LOUIE, University of California at Berkeley and Lawrence Berkeley National Lab — Within the conventional GW approach, density functional theory (DFT) is typically used as a mean-field starting point; the self-energy operator is evaluated to 1st order in the DFT Green's function G_0 and screened Coulomb interaction W_0. The quasiparticle energies are calculated from diagonal elements of Σ in the DFT orbital basis. This approach works extraordinarily well for many materials but has limitations when the DFT states are far from the quasiparticle wavefunctions. In such cases, off-diagonal elements of Σ in the mean-field basis are large and the full Σ matrix is needed. The slow convergence of the off-diagonal elements make approaches requiring the explicit construction of this matrix prohibitively expensive. We present two alternative approaches based on the static (COHSEX) approximation that efficiently include the mean-field off-diagonal matrix element effects: a sc-COHSEX+GW approach where a renormalized basis is obtained from a self-consistent evaluation of quasiparticle wavefunctions in the static approximation and a less intensive treatment of just the off-diagonal elements within the COHSEX approximation. We show examples of the approaches for molecules and crystalline systems. Support by NSF DMR10-1006184, DOE DE-AC02-05CH11231.

10:12AM H18.00012 Constructing unoccupied states for G_0W_0 quasiparticle calculations from plane-waves , GEORGY SAMSONIDZE, MANISH JAIN, JACK DESLIPPE, MARVIN L. COHEN, STEVEN G. LOUIE, Department of Physics, University of California, Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720 — Standard methods of first-principles calculations of the quasiparticle energies within the G_0W_0 scheme require summing over large numbers of unoccupied states. The generation of these states within the ab initio pseudopotential plane-wave density functional theory (DFT) quickly becomes a bottleneck of the calculation with increasing system size, especially in low-dimensional systems. In this work, we propose a method for approximating the high-energy continuum and resonant states in low-dimensional systems. The continuum and resonant states above a chosen energy are replaced with symmetrized plane-waves and localized DFT states computed with short-range localized basis functions (such as in the SIESTA code), respectively. The Gram-Schmidt process is used to orthogonalize these constructed high-energy unoccupied states. The method opens a route towards precise G_0W_0 quasiparticle calculations in large low-dimensional systems using a small number of unoccupied DFT states. This work was supported by NSF Grant No. DMR10-1006184, the U.S. DOE under Contract No. DE-AC02-05CH11231. Computational resources have been provided by NSF through TeraGrid at NICS and DOE at LBNL's NERSC.

10:24AM H18.00013 On-site screened Coulomb interactions for localized electrons in transition metal oxides and defect systems , BI-CHING SHIH, Department of Physics, University at Buffalo, State University of New York, PEIHONG ZHANG, Department of Physics, University at Buffalo, State University of New Your, DEPARTMENT OF PHYSICS TEAM — Electronic and structural properties of strongly correlated material systems are largely determined by the strength of the on-site Coulomb interaction. Theoretical models devised to capture the physics of strongly correlated materials usually involve screened Coulomb interactions as adjustable parameters. We present first-principles results for the screened on-site Coulomb and exchange energy for transition metal oxides. The dielectric screening is calculated within the random phase approximation and the localized electrons are represented by maximally localized Wannier functions. We further extend our study to calculate on-site Coulomb interactions for localized defect states in semiconductors. We acknowledge the computational support provided by the Center for Computational Research at the University at Buffalo, SUNY. This work is supported by the National Science Foundation under Grant No. DMR-0946404 and by the Department of Energy under Grant No. DE-SC0002623.

10:36AM H18.00014 Optimizing Generalized Norm-Conserving Pseudopotentials , D.R. HAMANN, Dept. of Physics & Astronomy, Rutgers University — The "generalized" method permits the construction of norm-conserving pseudopotentials at energies that do not correspond to bound atomic states, giving added flexibility in the treatment of angular-momentum channels for which no bound states exist.[1] An effective method for optimizing the convergence of pseudopotential calculations with plane-wave-basis cutoff energy requires atomic wave functions with decaying tails, and has not been applicable to such "generalized" states.[2] By introducing a potential well outside the core radius for selected angular-momenta, an artificial decaying tail can be produced for positive-energy states. This permits the application of the optimization method, and we find convergence behavior comparable to that for ordinary bound states. In practice, we terminate the positive-energy all-electron wave function smoothly with an exponential or Gaussian tail, and never need to treat the implied well potential explicitly. The projectors to form fully-nonlocal operators[3] can be terminated at the core radii as usual, despite differences of the semi-local potentials outside the well radii.

10:48AM H18.00015 Development of a Semi-empirical Hamiltonian for Phosphorus for Quantum Mechanics Based Simulations of Phosphorous-based Nanostructures , PAUL TANDY, CHRISTOPHER LEAHY, MING YU, C.S. JAYANTHI, S.Y. WU, University of Louisville — We have developed a parameterized semi-empirical Hamiltonian for phosphorous for simulation studies of phosphorous-based nanostructures including phosphorous-doped silicon nanowires.This Hamiltonian models the environment-dependent electron-ion and ion-ion interactions and electron-electron correlations, by capturing the salient features of *ab initio* Hamiltonians/*ab initio* methods, (*e.g.*, electron screening and charge self-consistency).Such a semi-empirical Hamiltonian has been shown to be successful in predicting the properties of intermediate-sized silicon, boron, and carbon clusters and extended structures of boron and silicon [1-4]. We optimized the parameters of our Hamiltonian for phosphorous by fitting the properties of bulk (black phosphorous) and small clusters (P_2 to P_{10}) as obtained by our method to *ab initio* calculations. It is expected that such a Hamiltonian will have the predictive power to enable the study of larger phosphorous based nanostructures that are not possible via *ab initio* studies.

Tuesday, March 22, 2011 8:00AM - 11:00AM –

Session H19 GMAG DMP: Focus Session: Spin Transport & Magnetization Dynamics in Metals III D170

8:00AM H19.00001 Large and inverted spin signals in nonlocal spin valves , YI JI, HAN ZOU, SIU-TAT CHUI, XIAOJUN WANG, University of Delaware — For a metallic nonlocal spin valve (NLSV), usually the nonlocal resistance value is high for the parallel (P) state of spin injector and detector and the value is low for the antiparallel (AP) state. The difference between two states is known as the spin signal. We show that a 6 miliohms spin signal was observed in a typical NLSV device. However, in another NLSV device with apparently similar structure and dimensions as the previous one, we found a very large spin signal of 90 milliohms with an inverted sign, meaning that the P state yields a low value and the AP state yields a high value. The resistance between the spin detector and the Cu channel is extremely large, exceeding mega-ohms. We conclude that a break-junction is formed at the detector/Cu interface due to static discharge. The large magnitude of the spin signal is due to the spin-charge coupling at the low-conductance break-junction interface. The inverted sign is due to a very different spin-dependent density of states near the break-junction. Work supported by DOE grant No. DE-FG02-07ER46374.

8:12AM H19.00002 Spin transfer effects in non-local spin valves with sustained d.c. currents , HAN ZOU, YI JI, University of Delaware — We utilized pure spin current in a nonlocal spin valve (NLSV) for spin-transfer. The submicron lateral device consists of a Py spin injector (80 nm wide), a Py spin detector (60 nm wide), and a Cu nonmagnetic channel (100 nm wide). The thickness of the spin detector is 3.5 nm, and a nanoscale magnetic domain (60 nm by 100 nm) in the detector underneath the Cu channel can be switched by spin-transfer. We explore reversible spin-transfer switching over a wide temperature range and using both d.c. current pulses and sustained dc currents. Since a d.c. current changes the baseline of the nonlocal resistance, spin-transfer in NLSV has only been explored by d.c. current pulses. In this work, we achieved NLSV spin-transfer with sustained d.c. currents. The hysteresis of nonlocal resistance as a function of the sustained current is clearly observed, despite the baseline variations. High field and polarity-dependent features in the nonlocal MR curves indicate evidence of spin-transfer induced magnetization dynamics. Work supported by US DOE grant No. DE-FG02-07ER46374.

8:24AM H19.00003 Spin injection into ferromagnetic insulators , SABURO TAKAHASHI, Institute for Materials Research, Tohoku University, Sendai 980-8577, Japan, JUN-ICHIRO OHE, HIROTO ADACHI, SADAMICHI MAEKAWA, Advanced Science Research Center, Japan Atomic Energy Agency, Tokai 319-1195, Japan — Spin current in a junction of a normal metal and a ferromagnetic insulator is theoretically studied. At the interface, spins of conduction electrons in a normal metal interact with localized spins in ferromagnetic insulator through the exchange interaction. When a spin accumulation is present in the normal metal, accumulated spins decay into magnons via spin-flip scattering of conduction electrons at the interface, thereby creating a magnon spin current in the ferromagnet. Using the linear response theory, we calculate the spin current across the interface and find that spin accumulation plays a role of spin voltage for generating the spin current thorough the junction. Using the spin Hall effect, the spin current injection from a normal metal into a ferromagnetic insulator is demonstrated. We also discuss the spin current in the presence of temperature difference between the normal metal and the ferromagnetic insulator.

8:36AM H19.00004 Quantifying Spin Hall Effects in Nonmagnetic Metals[1] , AXEL HOFFMANN[2], Materials Science Division, Argonne National Laboratory — Spin Hall effects intermix spin and charge currents even in nonmagnetic materials and, therefore, offer the possibility to generate and detect spin currents without the need for using ferromagnetic materials. In order to gain insight into the underlying physical mechanism and to identify technologically relevant materials, it is important to quantify the spin Hall angle γ, which is a direct measure of the charge-to-spin (and vice versa) conversion efficiency. Towards this end we utilized non-local transport measurements with double Hall bars fabricated from gold and copper.[3] In principle, this geometry permits the study of spin currents both generated and detected via spin Hall effects. We observe an unusual non-local resistivity that changes sign as a function of temperature. However, this results is quantitatively similar in gold and cooper, indicating that the non-local signals are not due to spin transport. An analysis of the data based on a combination of diffusive and quasi-ballistic transport leads to an upper limit of $\gamma < 0.027$ for gold at room temperature. Therefore we developed an approach based on spin pumping, which enables us to quantify even small spin Hall angles with high accuracy. Spin pumping utilizes microwave excitation of a ferromagnetic layer adjacent to a normal metal to generate over a macroscopic area a homogeneous *dc* spin current, which can be quantified from the line-width of the ferromagnetic resonance. In this geometry voltages from spin Hall effects scale with the device dimension and therefore good signal-to-noise can be obtained even for materials with small spin Hall angles. We integrated ferromagnet/normal metal bilayers into a co-planar waveguide and determined the spin Hall angle for a variety of non-magnetic materials (Pt, Pd, Au, and Mo) at room temperature. Of these materials Pt shows the largest spin Hall angle with $\gamma = 0.013 \pm 0.002$.[4]

9:12AM H19.00005 Giant spin Hall effect of Au films with Pt impurities: Surface-assisted skew scattering , BO GU, Japan Atomic Energy Agency, TIMOTHY ZIMAN, Institut Laue Langevin, GUANG-YU GUO, National Taiwan University, NAOTO NAGAOSA, University of Tokyo, SADAMICHI MAEKAWA, Japan Atomic Energy Agency — We show theoretically a novel route to obtain giant room temperature spin Hall effect (SHE) using surface-assisted skew scattering. By a combined approach of density functional theory and the quantum Monte Carlo (QMC) method, we have studied the SHE due to a Pt impurity in different Au hosts. We show that the spin Hall angle (SHA) could become larger than 0.1 on the Au (111) surface, and decreases by about a half on the Au (001) surface, while it is small in bulk Au. The QMC results show that the spin-orbit interaction (SOI) of the Pt impurity on the Au (001) and Au (111) surfaces is enhanced, because the Pt 5 levels are lifted to the Fermi level due to the valence fluctuations. In addition, there are two SOI channels on the Au (111) surface, while only one for Pt either on the Au (001) surface or in bulk Au.

9:24AM H19.00006 Spin Hall angle in Pd below the spin diffusion length[1] , V. VLAMINCK, H. SCHULTHEISS, J. PEARSON, F. FRADIN, S. BADER, A. HOFFMANN, Argonne National Laboratory, O. MOSENDZ, Hitachi San Jose Research Center — The spin-orbit coupling gives rise to an inter-conversion of spin and charge currents. A pure spin current is accompanied by a charge accumulation perpendicular to both the spin polarization and spin current, so-called inverse spin Hall effect (ISHE). We report measurements of the ISHE in a permalloy/palladium (Py/Pd) bilayer integrated with a coplanar wave-guide by pumping a pure spin current via ferromagnetic resonance (FMR) [1]. The magnetization precession creates a spin accumulation at the Py/Pd interface that diffuses into the normal metal and partially scatters back into the permalloy when the Pd thickness is smaller than the spin diffusion length. We observe an increasing broadening of the FMR linewidth with increasing thickness of Pd from which we extract the spin diffusion length in Pd and an average spin mixing conductance. The resultant pure spin current induces, in turn, a spin Hall voltage that is measured across the metallic layer. The spin Hall angle obtained from fitting the dc voltage [1] remains fairly constant even for thickness smaller than the spin diffusion length.

9:36AM H19.00007 Spin Torque Ferromagnetic Resonance Induced by the Spin Hall Effect , LUQIAO LIU, TAKAHIRO MORIYAMA, DAN RALPH, ROBERT BUHRMAN, CORNELL UNIVERSITY TEAM — We demonstrate that the spin Hall effect in a thin film with strong spin-orbit scattering can excite magnetic precession in an adjacent ferromagnetic film. The flow of alternating current through a Pt/NiFe bilayer generates an oscillating transverse spin current in the Pt, and the resultant transfer of spin angular momentum to the NiFe induces ferromagnetic resonance (FMR) dynamics. The Oersted field from the current also generates an FMR signal but with a different symmetry. The ratio of these two signals allows a quantitative determination of the spin current. As an independent check, we also apply a DC charge current to the Pt/NiFe bilayer while measuring the FMR signal. The effective damping of the NiFe layer can be increased or decreased depending on the relative angle between the magnetic moment and the injected spin. The amplitude of spin current extracted from this measurement agrees quite well with that obtained from the FMR lineshape. The self-calibration nature of this new technique makes it an excellent solution for a quantitative measurement of the SHE in a ferromagnetic/non-magnetic metal bilayer.

9:48AM H19.00008 Spin-orbit dichroism in SX-ARPES of Pt(111)[1] , JUN MIYAWAKI, ASHISH CHAINANI, YASUTAKA TAKATA, MASAKI OURA, RIKEN SPring-8 Center, YASUNORI SENBA, HARUHIKO OHASHI, JASRI/SPring-8, SHIK SHIN, RIKEN SPring-8 Center, ISSP Univ. Tokyo — We study the bulk electronic structure of Pt(111) using polarization dependent soft x-ray (SX)-ARPES ($h\nu$=450–610 eV). Pt is known to exhibit the largest spin Hall conductivity of all metals, which is derived from its large spin orbit coupling [1,2]. We have measured band dispersions along Γ-K-X ($h\nu$=466 eV) with clockwise and counterclockwise circularly polarized x-rays and obtained circular dichroism (CD) in the valence band of Pt. A comparison with calculated band dispersions including spin-orbit coupling gives a very good match with the experimental results [3,4], thus establishing the role of spin-orbit coupling in the electronic structure of Pt. Our results also identify (i) a hybridization gap with symmetry switching dichroism and (ii) strong CD of bands at the Fermi level, which provide the carriers responsible for SHE.

10:00AM H19.00009 Anisotropic Spin Hall Effect from First Principles[1] , FRANK FREIMUTH, STEFAN BLÜGEL, YURIY MOKROUSOV, Institut fuer Festkoerperforschung & Institute for Advanced Simulation, Forschungszentrum Juelich and JARA, 52425 Juelich, Germany — We present first principles calculations [1] of the intrinsic non-dissipative spin Hall conductivity (SHC) for $3d$, $4d$ and $5d$ transition metals focusing in particular on the anisotropy of the SHC in nonmagnetic hcp metals and in antiferromagnetic Cr. For the metals of this study we generally find large anisotropies. We derive the general relation between the SHC vector and the direction of spin-polarization and discuss its consequences for hcp metals. Especially, it is predicted that for systems where the SHC changes sign due to the anisotropy the spin Hall effect may be tuned such that the spin polarization is parallel either to the electric field or to the spin current. Additionally, we describe our computational method [2,3] emphasizing the Wannier interpolation technique and the definition of the conserved spin current.

10:12AM H19.00010 Detection of the transverse voltage associated with the spin Seebeck effect in ferromagnetic thin films , AZURE D. AVERY, RUBINA SULTAN, DAIN BASSETT, University of Denver, MATTHEW R. PUFALL, National Institute of Standards and Technology, Boulder, CO, BARRY L. ZINK, University of Denver — The spin Seebeck effect, the generation of spin current in response to an applied thermal bias across a sample, is a novel effect involving spin current that is being researched in nanostructures for advances in spin caloritronics. Understanding the fundamental physics governing heat transport at the nanoscale is challenging because thermal properties of nanostructures are often difficult measurements to make. We present a novel technique for detecting the presence of a thermally generated spin current based on a micromachined thermal isolation platform. Our technique offers advantages including the ability to measure this effect in a reduced dimension sample, to reverse the thermal gradient, and to generate a large $\triangle T$ across the sample. We present results for a range of thin films and compare to previously reported similar larger scale structures. We discuss future experiments to probe the local nature of the spin Seebeck effect, additional thermal properties including the traditional Seebeck effect and thermal conductivity, and the application of our technique to an array of nanowires.

10:24AM H19.00011 Gigantic enhancement of spin Seebeck effect by phonon drag , HIROTO ADACHI, Japan Atomic Energy Agency, KEN-ICHI UCHIDA, EIJI SAITOH, Tohoku University, JUN-ICHIRO OHE, Japan Atomic Energy Agency, SABURO TAKAHASHI, Tohoku University, SADAMICHI MAEKAWA, Japan Atomic Energy Agency — We investigate both theoretically and experimentally a gigantic enhancement of the spin Seebeck effect [K. Uchida et al., Nature 455, 778 (2008); C. M. Jaworski et al., Nature Mater. 9, 898 (2010); K. Uchida et al., Nature Mater. 9, 894 (2010)] in a prototypical magnet $LaY_2Fe_5O_{12}$ at low temperatures. Our theoretical analysis sheds light on the important role of phonons; the spin Seebeck effect is enormously enhanced by nonequilibrium phonons that drag the low-lying spin excitations. We further argue that this scenario gives a clue to understand the observation of the spin Seebeck effect that is unaccompanied by a global spin current, and predict that the substrate condition affects the observed signal.

10:36AM H19.00012 Two Exponentials Associated with Temperature in Spin-Seebeck Effect Geometry[1] , WAYNE SASLOW, MATTHEW SEARS, Texas A&M University — Recent experiments report the observation of a Spin-Seebeck effect, where an applied thermal gradient along (x) a very thin (z), narrow (y) ferromagnetic sample F is associated with a spin current.[2] In present geometries this spin current is measured indirectly via a Pt bar above (z) the sample; a voltage difference V along y is measured and interpreted as being due to a spin current j_s into (z) the Pt, which then causes an inverse Spin Hall effect (j_s causes transverse V). Measured voltages often show a $\sinh(x/s)$ dependence, where s is long compared to any relevant spin-diffusion length.[3] The spin current has been interpreted as accompanying a temperature disequilibrium between the phonons and magnons in F.[4] The present work uses irreversible thermodynamics to include magnon-phonon equilibration in F and the thermal properties of the (non-magnetic) substrate S. We find two exponentials describing the overall thermal response along x, the second one associated with equilibration between F and S. If the thermal coupling between F and S is poor, then the second length can be rather long.

10:48AM H19.00013 Dissipationless mechanism of skyrmion Hall effect in two-dimensional double-exchange ferromagnets , SHIGEKI ONODA, Condensed Matter Theory Laboratory, RIKEN, KI-SEOK KIM, Asia Pacific Center for Theoretical Physics and Department of Physics, Pohang University of Science and Technology — We revisit a theory of nonequilibrium single-skyrmion transport in two-dimensional double-exchange ferromagnets with the Rashba spin-orbit interaction. Combining the collective-coordinate approach with the Keldysh formalism and an effective U(1) gauge theory, the velocity of a skyrmion core is calculated under the electric field. Then, it is found that the emergent Chern-Simons term and the associated intrinsic anomalous Hall can produce a dissipationless skyrmion Hall current through the coupling between electrons and localized spins, which takes the form of the spin transfer torque. In metals, this is additive to the conventional dissipative motion of magnetic vortices, which relies on phenomenological damping terms in the Landau-Lifshitz-Gilbert equation.

Session H20 FIAP/DMP GERA/DCOMP: Focus Session: Physics of Energy Storage Materials III – Hydrogen Storage Adsorbents D168

8:00AM H20.00001 Strategies for Hydrogen Storage in Nanoporous Metal-Organic Framework Materials , RANDALL SNURR, Northwestern University — Storing hydrogen by physisorption in porous materials is a challenging problem of great interest for future vehicle technology. Metal-organic frameworks (MOFs) are a new class of nanoporous materials that have demonstrated exciting potential for solving this problem. MOFs are synthesized by the self-assembly of metal nodes and connecting organic linker molecules to create stable, porous frameworks. The synthetic chemistry opens the possibility to create an almost unlimited number of MOFs and to tailor them for particular applications, such as hydrogen storage. The diversity of MOFs also creates an opportunity to learn more about the fundamentals of hydrogen adsorption in porous materials. We have used a combination of classical Monte Carlo simulations and quantum mechanical approaches to investigate fundamental questions about hydrogen storage in MOFs and to design new materials with improved storage capabilities. Relationships have been elucidated between hydrogen uptake and properties such as the MOF surface area, void volume, degree of catenation, enthalpy of adsorption, and cation content. Introduction of cations is a promising strategy to improve hydrogen uptake at room temperature, and different metal cations and different strategies for introducing them into MOFs have been screened computationally.

8:36AM H20.00002 Increased hydrogen uptake of MOF-5 by powder densification , DONALD SIEGEL, JUSTIN PUREWAL, Mechanical Engineering Department, University of Michigan, DONG'AN LIU, ANDREA SUDIK, JUN YANG, Ford Motor Company, STEFAN MAURER, ULRICH MULLER, BASF SE — The metal-organic framework MOF-5 has attracted significant attention due to its ability to store large quantities of H_2 by mass, up to 10 wt.% absolute at 70 bar at 77K. On the other hand, since MOF-5 is typically obtained as a bulk powder, it exhibits a low volumetric density and poor thermal conductivity—both of which are undesirable characteristics for a hydrogen storage material. Here we explore the extent to which powder densification can overcome these deficiencies, as well as to characterize the impact of densification on crystallinity, pore volume, surface area, and crush strength. MOF-5 powder was processed into cylindrical tablets with densities up to 1.6 g/cm^3 by mechanical compaction. We find that optimal hydrogen storage properties are achieved for $\rho \sim 0.5$ g/cm^3, yielding a 350% increase in volumetric H_2 density with only a modest 15% reduction in gravimetric H^2 excess in comparison to the powder. Higher densities result in larger reductions in gravimetric excess. Total pore volume and surface area decrease commensurately with the gravimetric capacity, and are linked to an incipient amorphization transformation. Nevertheless, a large fraction of MOF-5 crystallinity remains intact in densities up to 0.75 g/cm^3, as confirmed from powder XRD.

8:48AM H20.00003 First-principles study of hydrogen adsorption in metal-doped COF-10 , M.M. WU, Q. WANG, Q. SUN, P. JENA, Y. KAWAZOE, DEPARTMENT OF ADVANCED MATERIALS AND NANOTECHNOLOGY, PEKING UNIVERSITY TEAM, DEPARTMENT OF PHYSICS, VIRGINIA COMMONWEALTH UNIVERSITY COLLABORATION, INSTITUTE FOR MATERIALS RESEARCH, TOHOKU UNIVERSITY COLLABORATION — Covalent organic frameworks (COFs), due to their low-density, high-porosity, and high-stability, have promising applications in gas storage. In this study we have explored the potential of COFs doped with Li and Ca metal atoms for storing hydrogen under ambient thermodynamic conditions. Using density functional theory we have performed detailed calculations of the sites Li and Ca atoms occupy in COF-10 and their interaction with hydrogen molecules. The binding energy of Li atom on COF-10 substrate is found to be about 1.0 eV and each Li atom can adsorb up to three H2 molecules. However, at high concentration, Li atoms cluster and, consequently, their hydrogen storage capacity is reduced due to steric hindrance between H2 molecules. On the other hand, due to charge transfer from Li to the substrate, O sites provide additional enhancement for hydrogen adsorption. With increasing concentration of doped metal atoms, the COF-10 substrate provides an additional platform for storing hydrogen. Similar conclusions are reached for Ca doped COF-10.

9:00AM H20.00004 Enhanced Dihydrogen-Metal Interaction in Transition Metal Exposed Paddle-Wheel Frameworks , YONG-HYUN KIM, KAIST, JOONGOO KANG, SU-HUAI WEI, National Renewable Energy Laboratory, JI HYUN BAK, KAIST — The experimentally observed enhancement of hydrogen adsorption in Cu_2-tetracarboxylate paddle-wheel frameworks is investigated by first-principles density-functional theory calculations [1]. We reveal that the puzzling enhancement is due to the effective orbital coupling between the occupied H_2 σ and the unoccupied Cu 4s-derived states. The nontrivial dihydrogen-metal σs interaction is enabled by a strong localization of the Cu 4s orbital after hybridizing with the neighboring oxygen 2p orbitals. Based on this understanding, we predict that the dihydrogen-metal interaction can be further increased by alloying Cu with s-orbital element Zn or Mg. We will also discuss on the enhanced dihydrogen adsorption on other 3d-transition-metal paddle wheel frameworks.

[1] Y.-H. Kim, J. Kang, and S.-H. Wei, Phys. Rev. Lett., in press (2010).

9:12AM H20.00005 Iron decorated - functionalized MOF for high-capacity hydrogen storage: First-principles calculations , MOON-HYUN CHA, JISOON IHM, Department of Physics and Astronomy, Seoul National University — We perform electronic structure calculations for the Fe-decorated, OH-functionalized isoreticular metal organic framework 16 (IRMOF16) to investigate the hydrogen storage capacity. Because of the relatively strong Kubas interaction between Fe and H_2, hydrogen molecule can be adsorbed on the proposed MOF even at room temperature. The reversibly usable storage capacity under ambient conditions reaches 6.0 wt%. Fe has a much lower oxidation tendency than other metals (e.g., Ti, Ca, or Li) used for decorating backbone structures and therefore far more convenient in practical implementation. We also find that the spin flip, which comes from the competition between exchange field splitting and ligand field splitting, plays a significant role in the interaction between Fe and H_2.

9:24AM H20.00006 Study on Ca32C60 Cluster for Hydrogen Storage[1] , PING CUI, ZHILING DUN, MENG YE, RAN TAO, HAIPING LAN, U of Science and Technology of China, ZHENYU ZHANG, Oak Ridge National Laboratory, U of Tennessee-Knoxville, U of Science and Technology of China — Using first-principles calculations within density functional theory (DFT), we study the assembly of Ca32C60, the most desirable metal-coating fullerene as hydrogen storage medium. We first explore possible structures of Ca32C60 dimer with different initial configurations, and find a surprisingly large binding energy up to 2.8 eV. Our further analysis on electronic structures indicates that such a large binding strength stems from the enhanced chemical reactivity of Ca due to the Ca-3s valence electrons partially transferred to the fullerene. We then systematically investigate the alkali and alkali earth elements coated on fullerene, and find that the chemical reactivity of these metal elements can be tuned due to the large electron affinity of C60. Based on this finding, we then extend our studies to the bulk form and two-dimensional structures of Ca32C60, and propose an optimum assemble structure for hydrogen storage. These results shall facilitate designing and optimizing carbon-based materials for hydrogen storage.

[1]Supported by NNSF of China, DMSE/BES of USDOE, and USNSF.

9:36AM H20.00007 Interaction potential and IR absorption of endohedral H_2 in C_{60}[1] , TOOMAS ROOM, MIN GE, D. HUVONEN, U. NAGEL, Nat. Inst. of Chem. Phys. Biophys., Estonia, S. MAMONE, M.H. LEVITT, M. CARRAVETTA, Southampton Uni., UK, Y. MURATA, K. KOMATSU, Kyoto Uni., Japan, J.Y.-C. CHEN, N.J. TURRO, Columbia Uni. — We measured the IR spectra of a H_2 molecule trapped inside a C_{60} cage at temperatures from 6 to 300 K and analyzed the spectra by using a model of a vibrating rotor in a spherical potential. The electric dipole moment of IR transitions is induced by the translational motion of H_2. The rotation of H_2 is unhindered but coupled to the translational motion. The isotropic and translation-rotation coupling part of the potential are anharmonic and different in the ground and excited vibrational states of H_2. The vibrational frequency and the rotational constant of endohedral H_2 are smaller than in the gas phase. The assignment of IR lines to ortho- and para-H_2 is confirmed by measuring spectra of a para enriched $H_2@C_{60}$ and is consistent with the earlier interpretation of the low temperature IR spectra [S. Mamone *et al.*, J. Chem. Phys. **130**, 081103 (2009)].

9:48AM H20.00008 Metallacarboranes: Towards promising hydrogen storage metal organic framework , ABHISHEK SINGH, Materials Research Centre, Indian Institute of Science, Bangalore 560012, India, ARTA SADRZADEH, BORIS YAKOBSON, Department of Mechanical Engineering and Materials Science, Rice University, Houston, Texas 77005, USA — Using first principles calculations we show the high hydrogen storage capacity of metallacarboranes,[1] where the transition metal (TM) atoms bind hydrogen via Kubas interaction. The average binding energy of ∼0.3 eV/H favorably lies within the reversible adsorption range The Sc and Ti are found to be the optimum metal atoms maximizing the number of stored H_2 molecules. Depending upon the structure, metallacarboranes can adsorb up to 8 wt% of hydrogen, which exceeds DOE goal for 2015. Being integral part of the cage, TMs do not suffer from the aggregation problem. Furthermore, the presence of carbon atom in the cages permits linking the metallacarboranes to form metal organic frameworks (MOF), thus able to adsorb hydrogen via Kubas interaction, in addition to van der Waals physisorption.

10:00AM H20.00009 Anomalous Characteristics of a PVDC Carbon Adsorbant[1] , CARLOS WEXLER, MATTHEW BECKNER, JIMMY ROMANOS, TYLER RASH, PETER PFEIFER, RAINA OLSEN, University of Missouri Columbia — Nanoporous carbon produced by the pyrolisis of poly(vinylidene chloride-co-vinyl chloride) shows remarkably high adsorption of molecular hydrogen despite its relatively low surface area. In particular, its room temperature volumetric storage is significantly higher than other carbons with surface areas four times higher. In this talk we will present experimental hydrogen adsorption isotherms (and low-temperature isosteric heats of adsorption), subcritical nitrogen adsorption, real space images (TEM), and inelastic neutron scattering. In all cases, the sample characteristics are quite unusual. Whereas the sample under consideration is quite unusual in its high hydrogen sorption capacity, other samples in the literature also show similar unusual characteristics, suggesting the presence of phenomena not fully understood by standard adsorption theory.

[1]This material is based upon work supported in part by the Department of Energy under Award Nos. DE-FG02-07ER46411, DE-FG36-08GO18142, and DE-AC02-06CH11357.

10:12AM H20.00010 ABSTRACT WITHDRAWN –

10:24AM H20.00011 Inelastic Neutron Scattering from Hydrogen Adsorbed in Carbon[1] , RAINA OLSEN, MATTHEW BECKNER, HASKELL TAUB, PETER PFEIFER, CARLOS WEXLER, University of Missouri — Inelastic neutron scattering (INS) from adsorbed hydrogen offers a powerful tool to probe the local adsorption environment of storage material. We will show recently measured INS spectra of hydrogen adsorbed on four different carbon samples and discuss the interpretation of their spectral features, using previous theoretical calculations [1]. Both rotational and vibrational transitions can be observed, along with free recoil scattering parallel to the adsorption plane. The spectra from carbon nanotubes and activated carbon are well explained by theory. However, the spectra from PVDC carbon is quite unusual.

[1]This material is based upon work supported in part by the Department of Energy under Award Nos. DE-FG02-07ER46411, DE-FG36-08GO18142, and DE-AC02-06CH11357.

10:36AM H20.00012 Analysis of hydrogen sorption characteristics of boron-doped activated carbons[1] , M. BECKNER, J. ROMANOS, D. STALLA, E. DOHNKE, A. SINGH, M. LEE, G. SUPPES, M.F. HAWTHORNE, P. YU, C. WEXLER, P. PFEIFER, U of Missouri — There is significant interest in the properties of boron-doped activated carbons for their potential to improve hydrogen storage.[2] Boron-doped activated carbons have been produced using a novel process involving the pyrolysis of a boron containing compound and subsequent high-temperature annealing. In this talk we will present a systematic study of the effect of different boron doping processes on the samples' surface area, micropore structure, and hydrogen sorption. Experimental results include boron content from prompt gamma neutron activation analysis, boron-carbon chemistry from Fourier transform infrared spectroscopy (FTIR), nitrogen subcritical adsorption, and 80K and 90K hydrogen adsorption isotherms which allow us to evaluate the hydrogen binding energy for each sorptive material.

10:48AM H20.00013 The effect of KOH:C and activation temperature on hydrogen storage capacities of activated carbons[1] , TYLER RASH, MATT BECKNER, JIMMY ROMANOS, ERIC LEIMKUEHLER, ALI TAKEEI, GALEN SUPPES, CARLOS WEXLER, PETER PFEIFER, University of Missouri — The Alliance for Collaborative Research in Alternative Fuel Technologies (ALL-CRAFT[2]) has been producing high surface area activated carbons. Here we will investigate the effect of the ratio of activating agent to carbon and activation temperature on hydrogen sorption characteristics and sample structure. Results show that a ratio of 3:1 KOH:C and an activation temperature of 790 C are the ideal activation conditions for hydrogen storage applications. Hydrogen sorption measurements are completed using a volumetric instrument that operates at pressures up to 100 bar and at temperatures of 80 K, the sublimation temperature of dry ice (-78.5 C), and room temperature. Specific surface area and pore size distributions are measured using subcritical nitrogen isotherms.

Session H21 GIMS: Focus Session: Advances in Scanned Probe Microscopy II – High Frequencies and Optical Techniques D161

8:00AM H21.00001 Rapid Serial Prototyping and Analysis of Nanomagnet-Tipped Attonewton-Sensitivity Cantilevers for Magnetic Resonance Force Microscopy[1] , JOHN MAROHN, ERIC MOORE, JONILYN LONGENECKER, Cornell Univ., Ithaca, NY 14853 — Magnetic resonance force microscopy offers exciting possibilities for imaging protons and electrons in native and spin-labeled biomolecules. The central component of a magnetic resonance force microscope experiment is a custom-fabricated attonewton-sensitivity cantilever with an overhanging magnetic-nanorod tip. We have recently developed a method for making precision tips which involves 1) fabricating overhanging magnetic tips on shortened mock cantilevers, 2) using focused ion beam milling and deposition (FIB/FID) to cut the mock cantilever (and attached tip) free from the substrate, and then 3) attaching the released structure to a full-length high-sensitivity cantilever. The resulting magnets have been characterized by cantilever magnetometry, high-resolution transmission electron microscopy (HR-TEM), and nanometer-resolution electron energy loss spectroscopy (EELS). This approach to fabrication and analysis is allowing us to optimize tips for proposed single-electron-spin imaging experiments in a very short time. Rapid access to such high-quality tips will significantly advance our ability to image individual biomolecules and macromolecular complexes.

8:12AM H21.00002 Development of Magnet-on-Oscillator Low Temperature NMR Force Microscopy[1] , J.W. PASTER, J.T. MARKERT, Department of Physics, The University of Texas at Austin — We report recent advances for our nuclear magnetic resonance force microscopy (NMRFM) experiment. Force detection of nuclear spins is made possible by coupling NMR spin flip sequences to a mechanical oscillator. Periodic inversion of the spins in a magnetic field gradient provides the ac coupling force. The force sensitivity for NMRFM improves with decreasing distance between a small gradient magnet and the spins in a sample. Adapting a perpendicular oscillator orientation allows us to decrease the magnet-to-sample distance, providing increased sensitivity. We've also adapted a magnet-on-oscillator design. With this approach, we can perform experiments using oscillating cantilever-driven adiabatic reversal, a technique which has been used to detect single electron spins below the surface of a solid [1]. We've integrated an optical fiber interferometer to measure an oscillator's motion with sub nanometer precision. We can routinely measure the resonance frequencies, quality factors, and spring constants of various oscillators.

8:24AM H21.00003 Correlation of Noise in Multiple Cantilever Modes , DORAN SMITH, DIMITRI ALEXSON, US Army Research Lab — The ultrasensitive cantilevers utilized in frequency detection MRFM schemes are susceptible to noncontact interactions between the cantilever tip and the sample. Large efforts have been undertaken to comprehensibly understand the surface related dissipation mechanisms. We propose that sample dielectric fluctuations near DC frequencies should effect all the driven cantilever's oscillatory modes similarly. Utilizing the fundamental and second harmonic mode of the cantilever we have demonstrated this. The correlation between the frequency deviations of the two modes of a driven cantilever increases as the tip-to-sample distance decreases and the measured 1/f noise due to dielectric fluctuations becomes manifest. This result provides additional support for the theory developed by Yazdanian, Marohn and Loring, J. Chem. Phy. 128, 224706 (2008) explaining the origins of noncontact friction and frequency jitter.

8:36AM H21.00004 Nanoscale scanning probe ferromagnetic resonance imaging using localized modes[1] , P. CHRIS HAMMEL, Ohio State University — We report the demonstration of scanned probe ferromagnetic resonance imaging (FMRI), a new technique based on Magnetic Resonance Force Microscopy that offers a window into nanoscale properties of buried ferromagnets. Images have been obtained with a current resolution of 200 nm, and significant improvements are straightforwardly possible. Ferromagnetic Resonance (FMR) is a powerful spectroscopic tool for studying internal magnetic fields, interactions and dynamic magnetic properties of ferromagnetic systems, but conventional FMR measures global properties of an entire sample. In FMRI the "magnetic field well" created by the probe tip field confines the spin wave modes; these can then be scanned to obtain FMR images. This new microscope is unique in its ability to map internal magnetic fields in buried ferromagnets with spectroscopic precision and nanoscale resolution. First images in permalloy films reveal the ability to image inhomogeneities in magnetic properties with field resolution of approximately 1 Gauss/$\sqrt{\mathrm{Hz}}$. We report a first application to imaging the internal exchange bias field in exchange-biased films.

9:12AM H21.00005 MRFM based spectroscopy of GaAs , DIMITRI ALEXSON, DORAN SMITH, US Army Research Lab — The apparent contradiction of how to perform NMR spectroscopy given the large magnetic field gradients present in MRFM is resolved by removing the magnetic field gradient while RF based NMR spectroscopic pulses are applied to the sample. This is accomplished by 1) shuttling (move) the sample away from the magnetic particle mounted on the cantilever, 2) apply RF spectroscopic pulse sequences to the sample, 3) store a component of the free induction decay along the z-axis, 4) shuttle the sample back to the cantilever, and 5) read out the magnetization stored on the z-axis with MRFM using an adiabatic rapid passage protocol (ARP). We will describe our progress on performing shuttle based spectroscopy of GaAs using MRFM. We will describe our measurements of T1 of Ga69 in GaAs with an inversion-recovery experiment. Using a single ARP sweep, the polarization is inverted and its recovery is monitored with a driven cantilever using the CERMIT protocol.

9:24AM H21.00006 Development of Variable Temperature NMR Force Microscopy[1] , ISAAC V. MANZANERA ESTEVE, JOHN T. MARKERT, University of Texas. Physics Department — We report our progress on the construction of a variable temperature NMR force microscopy probe and the development of its control system for three dimensional nanoscale scanning. The probe contains two 3-axis piezo-driven slip-stick motion stages for fiber interferometer and for gradient magnet positioning. The control station is a LabView software based control system capable to perform signal generation and data acquisition. Preliminary scan position dependent NMR Force measurements on ammonium sulfate $(NH_4)_2SO_4$ were performed at room temperature in a sample-on-oscillator configuration. Both piezo-driven and thermal noise cantilever motion have been analyzed to determine resonant frequencies ω_c, quality factor Q, and spring constants k; a typical cantilever yielded $\omega_c = 1494.40 \pm 0.10$Hz, $k = 0.039 \pm 0.004 N/m$, $Q = 93$. RF frequency-modulation-driven artifact effects have been observed and measured during analysis.

9:36AM H21.00007 Nitrogen Impurities in Diamond Studied using Magnetic Resonance Force Microscopy , MICHAEL HERMAN, PALASH BANERJEE, DENIS PELEKHOV, P. CHRIS HAMMEL, The Ohio State University — Spin-bearing defects and impurities in diamond have attracted much attention in recent years, with the N-V center defect being a good example. A related defect in the diamond lattice is comprised of a substitutional nitrogen alone and is known as the P1 center with an electron spin S = 1/2 localized on a N-C bond with a strong hyperfine coupling to the ^{14}N nuclear spin I = 1. We have used Magnetic Resonance Force Microscopy (MRFM) to study the properties of a small collection of P1 centers in diamond. By operating with large field gradients approaching a few Gauss per nanometer, we are able to couple fewer than 100 spins and probe their relaxation properties with a sensitivity approaching a few spins. We have seen that spin lifetimes in the rotating frame are dependent on impurity concentration. We'll show long spin lifetimes (>2 s) while undergoing tens of thousands adiabatic spin flips. We also show that spin lifetimes are shorter in diamond implanted with nitrogen ions to create P1 centers. This work was supported by The Army Research Office under W911NF-07-1-0305 and the National Science Foundation under DMR-0807093.

9:48AM H21.00008 Parametric Amplification Protocol for Frequency-Modulated Magnetic Resonance Force Microscopy Signals , LEE HARRELL, Department of Physics and Nuclear Engineering, U.S. Military Academy, West Point, NY, ERIC MOORE, SANGGAP LEE, STEVEN HICKMAN, JOHN MAROHN, Department of Chemistry and Chemical Biology, Cornell University, Ithaca, NY — We present data and theoretical signal and noise calculations for a protocol using parametric amplification to evade the inherent tradeoff between signal and detector frequency noise in force-gradient magnetic resonance force microscopy signals, which are manifested as a modulated frequency shift of a high- Q microcantilever. Substrate-induced frequency noise has a $1/f$ frequency dependence, while detector noise exhibits an f^2 dependence on modulation frequency f. Modulation of sample spins at a frequency that minimizes these two contributions typically results in a surface frequency noise power an order of magnitude or more above the thermal limit and may prove incompatible with sample spin relaxation times as well. We show that the frequency modulated force-gradient signal can be used to excite the fundamental resonant mode of the cantilever, resulting in an audio frequency amplitude signal that is readily detected with a low-noise fiber optic interferometer. This technique allows us to modulate the force-gradient signal at a sufficiently high frequency so that substrate-induced frequency noise is evaded without subjecting the signal to the normal f^2 detector noise of conventional demodulation.

10:00AM H21.00009 Nonlinear Near-Field Microwave Microscopy for RF Defect Localization in Nb-Based Superconducting Radio Frequency Cavities[1] , TAMIN TAI, University of Maryland — Niobium Superconducting Radio Frequency (SRF) cavities are very sensitive to localized defects that give rise to quenches at high accelerating gradients. In order to identify these defects via scanning microscopy, and to further understand the origins of the quench under high radio frequency excitation (1-3 GHz), a scanning probe with localized and up to ∼200 mT RF magnetic field is required for low temperature microscopy to achieve sub-micron resolution. For this purpose, we developed a micro loop probe on silicon substrate with outer diameter 20 μm and inner diameter 17 μm and successfully fabricated it by lithography. The probe has been used to identify a signal arising from the nonlinear Meissner effect in a Nb thin film. In addition, a magnetic write head is another promising candidate to achieve this goal of understanding localized defect behavior under high RF magnetic field at low temperatures [1]. We will discuss and compare both types of probe for nonlinear scanning microscopy and RF defect localization in superconductors.

10:12AM H21.00010 Super-rolloff electron tunneling transduction of nanomechanical motion using frequency downmixing , MENG KAN, MARK FREEMAN, WAYNE HIEBERT, National Institute for Nanotechnology, National Research Council of Canada and Department of Physics, University of Alberta, Edmontonton, Canada — Electron tunneling transduction has high sensitivity for detecting the motion of nanomechanical devices, but the relatively low detection bandwidth of a few 10's of kHz has limited its development. Here we demonstrate a novel downmixing transduction scheme which eliminates the detection bandwidth problem of electron tunneling transduction. With this technique, the high frequency vibration modes (∼ 1 MHz) of a MEMS doubly clamped beam are measured. This measurement is 2 orders of magnitude above the electronic bandwidth of our readout circuitry with no fundamental limitation anticipated up to microwave frequencies. The displacement sensitivity is 40 fm/Hz$^{1/2}$ comparable to state-of-the-art low finesse free-space optical interferometry. The back-action force induced by the STM tip on the MEMS device is also explored and is shown to have a small effect on the measurement resonance frequency, causing slight resonance frequency shifts of order 1%.

10:24AM H21.00011 ABSTRACT WITHDRAWN –

10:36AM H21.00012 Toward Atomic-Scale Optical Probes with UHV STM[1] , ÖZGÜN SÜZER, LI GAO, JOSEPH A. SMERDON, JONGWEON CHO, NATHAN P. GUISINGER, JEFFREY R. GUEST, Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL 60439, USA — We present the details of a variable temperature ultra-high vacuum (UHV) scanning tunneling microscopy (STM) apparatus with optical access for the investigation of optically active materials at the atomic scale. Local field enhancement in close proximity to the ultra-sharp STM tip enables the observation of optical signals from a very small number of surface adsorbates and even single molecules, which, combined with the electronic sensitivity and high spatial resolution of STM, allows the simultaneous optical, electronic, and topographic analysis of nanoscale systems. A high-numerical-aperture (NA) optic is integrated into the STM to achieve sharp and stable focusing of the laser excitation while maintaining polarization integrity and high collection efficiency. The initial findings of investigations carried out on epitaxial graphene grown on SiC and operational characteristics of the apparatus are discussed. A next-generation optically accessible 4K UHV STM apparatus under development is also introduced.

[1]This work was supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Contract No. DE-AC02-06CH11357 and "SISGR" Contract No. DE-FG02-09ER16109.

10:48AM H21.00013 Protecting TERS Probes While Keeping Extreme Enhancement , REBECCA AGAPOV, ANDREY MALKOVSKIY, The University of Akron, Dept. of Polymer Science, Akron, OH, ALEXEI SOKOLOV, Chemical Sciences Division, ORNL and Dept. of Chemistry, University of Tennessee, Knoxville, TN, MARK FOSTER, The University of Akron, Dept. of Polymer Science, Akron, OH — Protecting the probes used for tip enhanced Raman spectroscopy (TERS) with alumina coatings reduces chemical, mechanical and thermal degradation that otherwise limit the applicability of this emerging technique. Protected plasmonic structures are of interest for surface enhanced Raman spectroscopy (SERS) generally, especially for SERS-based sensors, but we focus particularly on the special case of TERS. Most recently we have focused on the detailed effect of the protective coating for cases in which the enhancement is particularly strong. "Blinking," which is characteristic of extreme enhancement, has been observed with TERS on polymer films for the first time. An Al_2O_3 coating prolongs the duration of blinking from 20 minutes to 2 days without significant detriment to the extreme enhancement. The fact that blinking has been observed in the presence of the alumina coating allows us to eliminate chemical enhancement as a major mechanism of the extreme enhancement evidenced by blinking.

Tuesday, March 22, 2011 8:00AM - 11:00AM –
Session H22 DCMP: Heavy Fermions D163

8:00AM H22.00001 Field-induced Spin Fluctuations in Intermetallic CeX_2Ge_2(X= Cu, Ag, Au) , DEEPAK SINGH, National Institute of Standard and Technology, A. THAMIZHAVEL, Tata Institute of Fundamental Research, SUNG CHANG, JEFFREY LYNN, National Institute of Standard and Technology — Intermetallic rare-earth compounds containing a lattice of 4 f or 5 f- electrons are prototypical systems to study the magnetic quantum phase transition which mainly results from the fluctuation of the antiferromagnetic moment at T= 0 K. Therefore, understanding the mechanism behind spin fluctuations is important towards a meaningful universal formulation of the QPT phenomena. We have performed magnetic, thermodynamic and neutron scattering measurements on CeX_2Ge2 (X = Cu, Ag, Au) compounds in single crystal form to further understand the mechanism behind spin fluctuations. CeX_2Ge_2 crystallize in a $ThCr_2Si_2$-type tetragonal crystal structure and undergo antiferromagnetic transitions at T_N = 4.2 K (Cu), 4.6 K (Ag) and 13.5 K (Au). Detail measurements of Q-vectors associated with the long-range order and the numerical modeling of the data revealed the propagation of amplitude modulated spin density wave in $CeCu_2Ge_2$ and $CeAg_2Ge_2$ with the propagation vectors of (0.29,0.29,0.52) and (0,0.705,0.11) respectively. Dynamic measurements of CeX_2Ge_2 compounds in applied magnetic field, exhibiting the varying nature of spin fluctuations as X changes, will be discussed and compared with other Ce-based intermetallic compounds.

8:12AM H22.00002 Growth and properties of heavy fermion thin films and superlattices[1] , YIZE LI, MAO ZHENG, BRIAN MULCAHY, L.H. GREENE, JAMES N. ECKSTEIN, University of Illinois at Urbana-Champaign — We have grown thin films of the heavy fermion phases $CeCu_2Ge_2$ (CCG) and $CeFe_2Ge_2$ (CFG) on MgO and DySrO3 substrates using molecular beam epitaxy. We find that the growth begins via island nucleation leading to a granular morphology, since there are two equivalent registrations of the film with the substrate. After nucleating, the grains grow flat with c-axis orientation. These single phase films show similar temperature(T) dependent transport behavior as seen in single crystals of the materials, including for CCG Kondo scattering and the emergence of coherent coupling of the heavy fermion transport channel at low T and for CFG a monotonic decrease in resistivity as the temperature is lowered. Superlattices combining CCG and CFG in different supercell architectures were also grown. In transport, they show a systematic evolution with composition between the distinct R(T) behavior of the two parent phases. A correlation between spectroscopic measurements and resistivity was found and details will be presented.

[1]This work is supported by DOE under Award No.DE-AC02-98CH10886.

8:24AM H22.00003 Neutron Scattering Study of the Field Induced Non-Fermi-Liquid Behavior in $CeAuSb_2$, SUNG CHANG, DEEPAK SINGH, NIST Center for Neutron Research, ARUMUGAM THAMIZHAVEL, Tata Institute of Fundamental Research — The modestly heavy Fermion compound $CeAuSb_2$ ($\gamma = 90$ mJ/K^2 mol) was reported to exhibit highly anisotropic magnetic properties with an antiferromagnetic transition temperature $T_N \approx 5$ K [1]. In addition, the unconventional temperature dependence of the resistivity and specific heat, observed when an external magnetic field suppresses T_N to 0 K, has lead to the identification of $CeAuSb_2$ as a system showing possible magnetic field-induced quantum critical behavior [2]. Here we report on neutron scattering measurements of $CeAuSb_2$ in magnetic fields up to 9 T applied along the $\langle h, h, 0\rangle$ direction. Both elastic and inelastic measurements were carried out to track the evolution of the magnetic structure and spin fluctuations as a function of applied field.

8:36AM H22.00004 Shubnikov-de Haas Effect measured on single crystals of $CeOs_4Sb_{12}$ and $NdOs_4Sb_{12}$ along the high symmetry directions , P.-C. HO, Physics/CSU-Fresno, J. SINGLETON, NHMFL/LANL, New Mexico, M.B. MAPLE, D.B. SHREKENHAMER, X. LEE, A. THALE, Physics/UCSD, T. YANAGISAWA, Hokkaido U, Japan — The filled skutterudite compounds $CeOs_4Sb_{12}$, $PrOs_4Sb_{12}$, and $NdOs_4Sb_{12}$ are respectively a 1 K antiferromagnetic (AFM) Kondo insulator, a 1.85 K unconventional superconductor, and a 1 K mean-field type ferromagnet (FM), suggesting that superconductivity in $PrOs_4Sb_{12}$ may result from proximity to AFM and FM quantum-critical points. Fermi-surface measurements of $NdOs_4Sb_{12}$ and $CeOs_4Sb_{12}$ could therefore give insights into the pairing mechanism. We have used a MHz skin-depth technique to observe Shubnikov-de Haas oscillations (SdHos) in single crystals of these materials at fields of up to 60 T. In $CeOs_4Sb_{12}$ for $\mathbf{H}$ // [001], a previously-unobserved semimetal-to-metal transition was detected at ≈ 25 T; above this, a series of SdHos with a frequency of 1700 T and $m_{\rm CR} \approx 3.6m_{\rm e}$ emerge. For $\mathbf{H}$ // [011] in $NdOs_4Sb_{12}$, a single series of SdHos, frequency ≈ 874 T, was found. These may correspond to the β band in $PrOs_4Sb_{12}$, but with a much smaller $m_{\rm CR} \approx 1.5m_{\rm e}$. Research at CSU-Fresno is supported by RC CCSA #7669 and the start-up fund; at NHMFL by DOE, NSF, and FL.; at UCSD by NSF#0802478 and US DOE DE FG02-04ER46105; at Hokkaido U by MEXT, Japan.

8:48AM H22.00005 The non-centrosymmetric heavy fermion ferromagnet $Sm_2Fe_{12}P_7$[1] , MARC JANOSCHEK, RYAN E. BAUMBACH, JAMES J. HAMLIN, IVY K. LUM, M. BRIAN MAPLE, University of California, San Diego — The investigation of quantum critical points (QCPs) in heavy fermion compounds (HF) has proven to be a useful tool in gaining insight into strongly correlated electron physics. However, the body of work on HF systems mainly focuses on antiferromagnetic QCPs. We report measurements of the electrical resistivity, magnetization and specific heat on single crystals of the non- centrosymmetric compound $Sm_2Fe_{12}P_7$, that exhibits ferromagnetic (FM) order below $T_{M,1}$ = 6.3 K. The ratio of the effective magnetic moment in the paramagnetic state, to the saturation magnetic moment in the ordered state indicates that the ordered state is associated with itinerant electrons. An enhanced value for the coefficient of the electronic speci?c heat $\gamma \sim 450$ mJ mol^{-1}K^{-1} is observed, that is accompanied by a large coefficient A of the T^2 term in the electrical resistivity, suggesting a HF ground state. Three consecutive magnetic phase transitions, indicative of competing magnetic energy scales, and the observation of a metamagnetic transition additionally suggest proximity to a QCP. Thus, we propose that $Sm_2Fe_{12}P_7$ is a possible candidate to study a FM QCP in a HF compound.

[1]Financial support was provided by AFOSR-MURI (FA9550-09-1-0603), US DOE (DE FG02-04ER46105), and NSF (0802478).

9:00AM H22.00006 Multiple regions of quantum criticality in YbAgGe , G.M. SCHMIEDESHOFF, Occidental College, S.L. BUD'KO, P.C. CANFIELD, Ames Laboratory, Iowa State University — YbAgGe is a stoichiometric heavy fermion antiferromagnet that exhibits field-induced quantum criticality. We present and discuss thermal expansion and magnetostriction measurements that reveal a new field-induced state. On the low-field side of this state we find evidence for a first-order phase transition and suggest that YbAgGe may be close to a quantum critical end point at 4.5 T. On the high-field side we find evidence for a second-order phase transition suppressed to a quantum critical point near 7.2 T. We will discuss these results in light of global phase diagrams proposed for Kondo lattice systems. Work at Occidental College was supported by the National Science Foundation under DMR-1006118. Work at Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

9:12AM H22.00007 Quasiparticle duality in the Kondo-screened state of YbInCu4 , MARCO GUARISE, EPFL, Lausanne, JASON HANCOCK, JOHN SARRAO, Los Alamos, THORSTEN SCHMITT, PSI, Switzerland, MARCO GRIONI, EPFL, Lausanne — We present a study of the excitation spectra of YbInCu4. This system exhibits a first- order isoelectronic phase transition which separates regimes with very different T/T_K. Using infrared optics, we were first able to demonstrate the existence of a hybridization gap feature which is ubiquitous in heavy fermion systems. More recently, using the burgeoning technique of resonant inelastic X-ray scattering (RIXS) at the Yb M5 edge, we identify a feature at the same energy, strongly suggesting that components of this excitation have mixed itinerant and localized character. Prospects for the future studies using the RIXS technique in the context of heavy fermion materials will be discussed.

9:24AM H22.00008 High-resolution angle-resolved photoemission studies of $YbRh_2Si_2$ using 7 eV laser , S.-K. MO, Advanced Light Source, LBNL, W.S. LEE, F. SCHMITT, Y.L. CHEN, Stanford University and SLAC National Lab, D.H. LU, SLAC National Lab, C. CAPAN, D.J. KIM, Z. FISK, UC Irvine, C.-Q. ZHANG, Shandong University, China, Z. HUSSAIN, Advanced Light Source, LBNL, Z.-X. SHEN, Stanford University and SLAC National Lab — We present angle-resolved photoemission spectra of prototypical heavy fermion compound $YbRh_2Si_2$ measured with 7 eV ultraviolet laser. Much improved energy and momentum resolutions enable us to resolve the sharp weakly dispersing peaks at the lowest energy of single-electron spectra. This coherent state grows in intensity and weight as temperature decreases below a characteristic temperature. The characteristic temperature is not only different from the single-ion Kondo temperature of $YbRh_2Si_2$ derived from thermodynamic measurements, it is of the same scale as the energy and the lifetime of the coherent state.

9:36AM H22.00009 Zeeman-driven Lifshitz transition: A scenario for the Fermi-surface reconstruction in YbRh2Si2 , MATTHIAS VOJTA, Technische Universitaet Dresden, ANDREAS HACKL, California Institute of Technology — The heavy-fermion metal $YbRh_2Si_2$ displays a field-driven quantum phase transition where signatures of a Fermi-surface reconstruction have been identified, often interpreted as breakdown of the Kondo effect. We argue that instead many properties of the material can be consistently described assuming a Zeeman-driven Lifshitz transition of heavy-fermion bands. Using a suitable quasiparticle model, we find a smeared jump in the Hall constant and maxima in susceptibility and specific heat, very similar to experimental data. An intermediate non-Fermi liquid regime emerges due to the small effective Fermi energy near the transition. Further experiments to discriminate the different scenarios are proposed.

9:48AM H22.00010 Neutron magnetic form factor in strongly correlated materials , MARIA PEZZOLI, KRISTJAN HAULE, GABRIEL KOTLIAR, Serin Physics Laboratory, Rutgers University,Piscataway, NJ 08854, USA. — We introduce a formalism to compute the neutron magnetic form factor F(q) within a first-principles Density Functional Theory (DFT) + Dynamical Mean Field Theory (DMFT). We use our method to compute the form factor of PuCoGa5. We find that the local physics of this material is described by a mixed valence mechanism of the type observed in elemental Plutonium. This picture explains nicely the experimental neutron form factor of PuCoGa5 and it is consistent with the photo-emission spectra shape and the value of the specific heat linear coefficient.

10:00AM H22.00011 Formation of heavy electron bands by ordering in two-channel Kondo lattice , SHINTARO HOSHINO, Tohoku university, JUNYA OTSUKI, YOSHIO KURAMOTO — Itinerant and localized characters of electrons are one of the most fundamental problems in condensed matter physics. In typical Kondo lattice systems, the f electrons are localized in the high temperature region, and acquire the itinerancy by the interaction between f and conduction electrons with decreasing temperature. In the present work, however, we show that the localized character of f electrons changes into itinerant one at the transition point in two-channel Kondo lattice systems. We have analyzed the system using the dynamical mean-field theory combined with the continuous-time quantum Monte Carlo method. With one conduction electron per site, which corresponds to the quarter filling of each band, a channel order emerges in wide parameter region with metal-insulator transition. At the same time, the heavy electron bands are formed, which indicates the itinerant f-electron states. Since f electrons acquire the itinerancy only below the transition temperature, this behavior can be regarded as itinerant-localized transition of electronic states. We will discuss these behaviors through temperature dependence of the single-particle spectrum.

10:12AM H22.00012 Hard X-Ray Photoelectron Spectroscopic Analysis of single crystal UPd_3, UGe_2, and USb_2 , M. BEAUX, T. DURAKIEWICZ, J. JOYCE, E. BAUER, LANL, Los Alamos, NM 87545, L. MORESCHINI, Lawrence Berkeley National Laboratory, Berkeley, California, F. OFFI, CNISM and Dipartimento de Fisica, Universita Roma Tre, Via della Vasca Navale 84, 1-00146 Rome, Italy, M. GRIONI, IPN, EPFL,CH-1015 Lausanne, Switzerland, G. MONACO, ESRF, B.P. 220, F-38042 Grenoble, France, G. PANNACIONE, Laboratorio Nazionale TASC-INFM-CNR, Area Science Park, Basovizza S.S. 14Km 163.5, I-34012 Trieste, Italy — Hard X-ray Photoelectron Spectroscopy (HAXPES) with 7.6 keV photons has been performed on single crystals of UPd3, UGe2, and USb2 at the European Synchrotron Radiation Facility (ESRF). A potential correlation between the localization/itinerancy of the 5f electrons and the core levels of these materials is investigated. The greatly reduced surface sensitivity of HAXPES enabled observation of the bulk core levels in spite of some surface oxidation. An 800 meV splitting of the Sb 3d and 4d core levels was observed. The splitting of the Sb core levels is attributed to manifestations of two distinct binding modes within the USb2 single crystal as supported by consideration of interatomic distances and charge transfer calculations.

10:24AM H22.00013 Small Angle Neutron Scattering and the Vortex Lattice of UPt_3[1] , W.J. GANNON, W.P. HALPERIN, J.A. SAULS, J.P. DAVIS, Northwestern University, IL, USA, K. SCHLESINGER, M.R. ESKILDSEN, University of Notre Dame, IN, USA, J. GAVILANO, ETH Zurich and Paul Scherrer Institute, Switzerland — UPt_3 is among the most well studied of the unconventional superconductors. However, there are still many unanswered questions, two of which are: understanding chirality in the superconducting B-phase and understanding the nature of the B-C transition. Central to theories describing both of these areas are predictions for unusual vortex structures. Small angle neutron scattering (SANS) provides a unique way to explore the bulk vortex lattice (VL) and thus can be used to investigate the bulk superconducting state without electronic surface scattering which complicates results from other probes. Ongoing SANS experiments on high quality single crystals in a novel geometry seek to explore the the relationship between field history and the VL in UPt_3. Preliminary results show well defined diffraction patterns and narrow rocking curves at fields well into the C-phase and interesting behavior for a variety of field histories. These results will shed new light on chirality, the B-C transition, and VL (meta)stability.

[1]Support from DOE/BES awards DE-SC0005051 and DE-FG02-05ER46248.

10:36AM H22.00014 Unconventional Anomalous Hall Effect in UCu_5[1] , B.G. UELAND, C.F. MICLEA, I. MARTIN, E.D. BAUER, R. MOVSHOVICH, F. RONNING, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA, Z. FISK, Department of Physics & Astronomy, University of California, Irvine, California 92697, USA, J.D. THOMPSON, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA — Field-dependent resistivity, magnetization, and specific heat measurements have been carried out on the heavy fermion compound UCu_5. We find an unconventional anomalous Hall resistance below the lower temperature magnetic transition at $T_2 \sim 1$ K that is proportional to neither the magnetization nor the longitudinal resistivity. We discuss the origin of this resistance in terms of the itinerant carriers' interaction with the magnetically ordered U cations. Complementary measurements on $Lu_{1-x}U_xCu_5$, x = 0 to 0.15 show how non-magnetic dilution affects the Hall resistance and magnetic phase diagram. Interestingly, light Lu substitution for U appears to stabilize the low temperature magnetic phase.

[1]Work at Los Alamos National Laboratory was performed under the auspices of the U.S. Department of Energy, Office of Science and Los Alamos Laboratory Directed Research and Development. Z.F. acknowledges funding from NSF-DMR-0801253.

10:48AM H22.00015 Temperature Dependent Hybridization Gaps[1] , PETER RISEBOROUGH, Physics Department Temple University — A number of heavy-fermion/mixed-valent materials show hybridization gaps either at the Fermi-energy or close to the Fermi-energy. In the former case, a heavy-fermion semiconducting state ensues and in the later case, the system remains metallic at low temperatures. In either case, the electronic structure is extremely temperature-dependent. It has been observed that the gap closes and the heavy quasiparticle bands disappear at high temperatures. The magnitude of the gaps scale with effective quasiparticle masses. A phenomenological model is presented that exhibits a temperature-dependence which is consistent with the above behavior. The model is based on a periodic array of Anderson impurities in which the electron correlations are represented by the coupling to bosons with an Einstein spectra. The model can be solved via systematic approximation. The solution describes the temperature- dependence of coherent and incoherent structures in the electronic excitation spectra. The predicted hybridization gaps for the metallic case are compared with data from photoemission experiments on UPd_2Al_3.

Tuesday, March 22, 2011 8:00AM - 10:48AM –
Session H23 DCMP: Superconductivity: Mainly ARPES D165

8:00AM H23.00001 Doping dependence of the electron-phonon and electron-spin fluctuation interactions in Bi-2212 , ELBERT CHIA, DANIEL SPRINGER, SARITHA NAIR, XINAQUAN ZOU, SIEW ANN CHEONG, CHRISTOS PANAGOPOULOS, Nanyang Technological University, ANTOINETTE TAYLOR, Los Alamos National Laboratory, TSUYOSHI TAMEGAI, University of Tokyo, HIROSHI EISAKI, AIST, SHIGEYUKI ISHIDA, SHIN-ICHI UCHIDA, University of Tokyo, JIAN-XIN ZHU, Los Alamos National Laboratory — In the BCS theory of conventional superconductors, electrons form (Cooper) pairs via interactions with the underlying crystal lattice. In the cuprate superconductors, it is not clear whether Cooper pairing takes place via electrons interacting with phonons, spin fluctuations, or whether a bosonic mechanism is necessary at all. Though time-integrated optical measurements on the cuprates can give information on the coupling strength between electrons and an effective boson, it is difficult to tell whether one or more bosons are involved, or the nature of these bosons. We report measurements of time-resolved quasiparticle relaxation of $Bi_2Sr_2CaCu_2O_{8+\delta}$ single crystals (hole concentration p = 0.10-0.22). Our data indicate that *two* bosonic modes are associated with superconductivity: the electron-phonon coupling constant (λ_{e-ph}) peaks at optimal doping, while the electron-spin fluctuation coupling constant (λ_{e-sf}) decreases monotonically with doping.

8:12AM H23.00002 Time-Resolved ARPES Study of Non-Equilibrium Quasiparticle Dynamics in Cuprate Superconductors , CHRISTOPHER SMALLWOOD, University of California, Berkeley; Lawrence Berkeley National Laboratory, JEFF GRAF, CHRIS JOZWIAK, Lawrence Berkeley National Lab, HIROSHI EISAKI, University of Tokyo; CREST, Japan Science and Technology Agency; RIKEN (The Institute of Physical and Chemical Research), ROBERT KAINDL, Lawrence Berkeley National Lab, DUNG-HAI LEE, ALESSANDRA LANZARA, University of California, Berkeley; Lawrence Berkeley National Laboratory — We use Time- and Angle-Resolved Photoemission (TR-ARPES) to measure the relaxation dynamics of low energy excitations in the cuprate superconductor Bi-2212. We find an as-yet unreported temperature dependence in nodal quasiparticle spectral weight which is sensitive to the critical temperature. We also find possible evidence for non-thermal transient electronic behavior.

8:24AM H23.00003 Ultra High Resolution Pump Probe Angle Resolved Photoemission Experiments on High Temperature Superconductor Bi2Sr2CaCu2O8 , WENTAO ZHANG, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA, CHRIS SMALLWOOD, Department of Physics, University of California, Berkeley, CA 94720, USA, CHRIS JOZWAIK, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA, HIROSHI EISAKI, Nanoelectronics Research Institute (NeRI), National Institute of Advanced Industrial Science and Technology, Ibaraki 305-8568, Japan, ALESSANDRA LANZARA, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA — Ultra high resolution laser-based pump probe angle-resolved photoemission measurements have been carried out on underdoped Bi2Sr2CaCu2O8 high temperature superconductor. In this talk, we will report on the observation and analysis of quasiparticle relaxation in Bi2Sr2CaCu2O8.

8:36AM H23.00004 Bands, spin fluctuations and traces of Fermi surfaces in ARPES intensities on high-T_C cuprates , THOMAS JARLBORG, DPMC, University of Geneva, CH1211 Geneva 4, Switzerland — The band structures of pure and hole doped La_2CuO_4 with anti-ferro magnetic (AFM) spin-fluctuations are calculated and compared to spectral weights of ARPES. It is shown that the observation of coexisting Fermi surface (FS) arcs and closed FS pockets are consistent with antiferromagnetic spin fluctuations of varying wave lengths. The FS signal of the underlying non-magnetic material is mixed with echos of FS-breaks from domains with AFM spin waves. Large variations of strong spin fluctuations make the outer part of the FS break diffuse at low doping. This part of the FS is suppressed at high doping when spin fluctuations becomes weak. The resulting superimposed spectral weight has features both from FS arcs and closed pockets. This makes a connection between results of ARPES and neutron scattering, and it implies that spin-phonon coupling is an important mechanism for cuprate properties.

8:48AM H23.00005 Origin of magnetic resonance spectrum in cuprate high-temperature superconductors and related issues , A. BANSIL, Northeastern U, TANMOY DAS, Northeastern U and LANL, R.S. MARKIEWICZ, Northeastern U. — A distinct low energy magnetic mode has been observed in almost all the cuprate materials in a broad range of experiments including ARPES, Raman, optical, STM, RIXS, as well as neutron scattering. This mode is enhanced in the superconducting (SC) state and its energy scales universally as $\omega_{res} \propto 2\Delta$, suggesting that these modes play an important role in the mechanism of superconducting pairing. Here we study this resonance via first-principle susceptibility calculations in a Hubbard model with $d-$wave superconductivity [1]. The resulting excitation mode produces the universal $\omega_{res} \propto 2\Delta$ relation as well as the puzzling 'hour-glass' dispersion and the 45° rotation of the spin excitations with energy in a series of cuprates in accord with experiments [2]. Work supported by US DOE.

9:00AM H23.00006 Particle-hole asymmetric components of QPI in the pseudogap phase of underdoped Bi-2212 , C.K. KIM, Cornell, BNL, JHINHWAN LEE, KAIST, Cornell, K. FUJITA, Cornell, H. EISAKI, AIST, S. UCHIDA, Tokyo U, J.C. DAVIS, Cornell, BNL, St. Andrews, JINHO LEE, BNL — QPI visualized by SI-STM became an extremely useful tool in the study of complex electronic matter. Particle-hole(p-h) symmetric QPI observed in the superconducting cuprates revealed many interesting phenomena including the disappearance of the QPI signal around the reduced zone boundary[1], and the persisting QPI signal above the T_c[2]. Recently, the most dominating band of $Sr_3Ru_2O_7$ was identified above the metamagnetic nematic phase transition temperature by analyzing p-h asymmetric QPI [3]. Also p-h asymmetric QPI in the parent compound of the ferropnictide superconductor revealed a nematic like electronic structure[4]. Within the same rationale, it is of great interest to find the QPI signature of the band before the superconducting gap opens in the cuprates. Here we explore QPI with particle-hole asymmetric dispersion in the pseudogap phase of underdoped $Bi_2Sr_2CaCu_2O_8$; it appears to disperse continuously through E_F. Our measured value of the v_F of this dispersion is 0.2×10^6m/s which compares well with the reported value 1.7eVÅ from ARPES. We will discuss the possible origin of this QPI by examining its symmetry and dispersion near the zone boundary using theoretical models and currently available experimental data from other probes. [1] Y. Kohsaka et al., Nature(2008) [2] Jhinhwan Lee et al., Science(2009) [3] Jinho Lee et al., Nature Physics(2009) [4] T.-M. Chuang et al., Science(2010)

9:12AM H23.00007 Oxygen reduction effects on the electronic structures of electron doped cuprates: investigating the mechanism of the metal insulator transition , D.J. SONG, S.R. PARK, C.S. LEEM, CHUL KIM, Y.K. KIM, S.K. CHOI, W.S. JUNG, C. KIM, Yonsei university, H. EISAKI, AIST, D.H. LU, Z.-X. SHEN, Stanford university, S. ISHIDA, S. UCHIDA, University of Tokyo — In electron doped cuprates, oxygen reduction process not only induces superconductivity but also causes changes in many physical properties. In order to understand these oxygen reduction effects, we performed ARPES studies on as-grown and de-oxygenated superconducting electron doped cuprates, PLCCO, NCCO and SCCO. We observe Fermi surface topology change and pseudo gap filling due to weakening of AFM as reported in other studies. In addition, sharp quasi-particles (QP) appear out of broad incoherent features as the as-grown samples are de-oxygenated through the oxygen reduction process. We believe that this behavior of the QP peak closely related to the insulator to metal transition in the reduction process. We attribute the suppression of the QP states in as-grown sample to the Anderson localized electron states due to strong disorder and impurity scattering.

9:24AM H23.00008 Renormalization of f-levels away from the Fermi energy in electron excitation spectroscopies: Density functional results of $Nd_{2-x}Ce_xCuO_4$, B. BARBIELLINI, Northeastern U., T. JARLBORG, DPMC, University of Geneva (Switzerland), H. LIN, R.S. MARKIEWICZ, A. BANSIL, Northeastern U. — Relaxation energies for photemission, when an occupied electronic state is excited, and for inverse photoemission, when an empty state is filled, are calculated within the density functional theory with application to $Nd_{2-x}Ce_xCuO_4$ (NCCO). The associated relaxation energies are obtained by computing differences in total energies between the ground state and an excited state in which one hole or electron is added into the system. The relaxation energies of f-electrons are found to be of the order of several eV's, indicating that f-bands will appear substantially away from the Fermi energy (E_F) in their spectroscopic images, even if these bands lie close to the E_F in the ground state of NCCO. Our analysis explains why it would be difficult to observe f electrons at the E_F even in the absence of strong electronic correlations. Work supported by the US DOE.

9:36AM H23.00009 Differential heat capacity studies of $Nd_{2-x}Ce_xCuO_4$[1] , JOHN COOPER, JAMES STOREY, EDWARD CAVANNA, JOHN LORAM, Cavendish Laboratory, University of Cambridge, CB3 0HE, U.K — The electronic heat capacity of several *hole*-doped cuprate systems has been determined accurately over a wide temperature range using a unique differential calorimeter. It gives important thermodynamic information about the electronic excitations and the pseudogap [1] that is difficult to obtain in other ways, so it is clearly of interest to extend these studies to some *electron*-doped materials. Here we report progress in measuring the specific heat capacity of a series of polycrystalline $Nd_{2-x}Ce_xCuO_4$ samples with x varying from 0.14 to 0.18 in steps of 0.01, between 2K and 100K, in magnetic fields from 0 – 13T and complementary magnetic and transport data. The aims of this work are to look for possible signatures of the pseudogap and to compare our results with recent quantum oscillation studies [2].

9:48AM H23.00010 Consequences of two-dimensionality for the quantum oscillations in underdoped YBCO , NEIL HARRISON, Los Alamos National Labs, SUCHITRA SEBASTIAN, Cavendish Lab, Cambridge, MOAZ ALTARAWNEH, LANL, RX. LIANG, D.A. BONN, W.N. HARDY, UBC, Canada, GIL LONZARICH, Cavendish Lab, Cambridge — We report new high resolution measurements on underdoped YBCO over an unprecedented magnetic field range with a high signal- to-noise ratio. The reduced-dimensionality of the Fermi surface is found to strongly influence the quantum oscillations and result in unusual properties. Careful analysis of these unconventional properties is found to severely constrain the Fermi surface topology.

10:00AM H23.00011 Lifshitz transitions in the underdoped cuprates with spin-density wave order[1] , JIE LIN, Materials Science Division, Argonne National Laboratory — It has recently been proposed that a neck-disrupting Lifshitz transition can explain the disappearance of quantum oscillations and diverging cyclotron mass observed in underdoped YBCO. We found that both pocket-disappearing and neck-disrupting types of Lifshitz transitions can be realized in two-dimensional spin-density wave models for underdoped cuprates. Close to Lifshitz transitions, the impurity relaxation rate acquires strong energy-dependence. The thermoelectric power is strongly enhanced, and behaves differently for the two types of transitions.

[1]Work supported by the U.S. DOE, Office of Science, under Contract No. DE-AC02-06CH11357

10:12AM H23.00012 ABSTRACT WITHDRAWN –

10:24AM H23.00013 Observation of Electronic Structures on Alkali-earth Metal Intercalated Superconducting GICs , WONSHIK KYUNG, C.S. LEEM, CHUL KIM, Y.K. KIM, G.R. HAN, C. KIM, Yonsei University, J.S. KIM, Y.W. KIM, Pohang University of Science and Technology, YONSEI UNIVERSITY TEAM, POHANG UNIVERSITY OF SCIENCE AND TECHNOLOGY COLLABORATION — We synthesized alkali-metal intercalated GICs(Ca, Ba, Sr). To compare electronic structure of these GICs, we performed high resolution angle-resolved photoemission spectroscopy (ARPES) on it. Through quantitative analysis of band structure, we can see alkali metal dependent band structure.

10:36AM H23.00014 Evidence of nodes in the non-centrosymmetric superconductor Y_2C_3 , J. CHEN, Dept. Physics, Zhejiang Univ., H.Q. YUAN, Dept. Physics, Zhejiang Univ., M.B. SALAMON, Dept. Physics, U. Texas at Dallas, S. AKUTAGAWA, J. AKIMITSU, Dept. Physics, Aoyama Gakuin U. — In a non-centrosymmetric superconductor, antisymmetric spin-orbit coupling (ASOC) can admix spin-singlet and spin-triplet pairing states, leading to accidental nodes in the energy gap [1]. Y_2C_3 is such a superconductor with a T_c of 18K. Early NMR and μSR results [2] indicated a gap structure incompatible with either BCS s-wave or typical d-wave behavior. To further elucidate its superconducting properties, we have measured the temperature dependence of the magnetic penetration depth using a tunneling-diode oscillator technique. While the high temperature penetration depth, and therefore its corresponding superfluid density, can be well described by a two-gap BCS model, as discussed in Ref. [2], the low temperature penetration depth follows a linear temperature dependence, indicating possible existence of nodes in the energy gap. Together with the large upper critical field observed in Y_2C_3 [3], the existence of nodes, we argue, might be attributed to the ASOC as a result of absent inversion symmetry even though other possibilities cannot be excluded. Yuan et al, J. Phys. Chem. Solids (in press).

Tuesday, March 22, 2011 8:00AM - 10:36AM –

Session H24 DCOMP: Focus Session: What is Computational Physics? I D167

8:00AM H24.00001 Computational Physics' Greatest Hits , AMY BUG, Swarthmore College — The digital computer, has worked its way so effectively into our profession that now, roughly 65 years after its invention, it is virtually impossible to find a field of experimental or theoretical physics unaided by computational innovation. It is tough to think of another device about which one can make that claim. In the session "What is computational physics?" speakers will distinguish computation within the field of computational physics from this ubiquitous importance across all subfields of physics. This talk will recap the invited session "Great Advances...Past, Present and Future" in which five dramatic areas of discovery (five of our "greatest hits") are chronicled: The physics of many-boson systems via Path Integral Monte Carlo, the thermodynamic behavior of a huge number of diverse systems via Monte Carlo Methods, the discovery of new pharmaceutical agents via molecular dynamics, predictive simulations of global climate change via detailed, cross-disciplinary earth system models, and an understanding of the formation of the first structures in our universe via galaxy formation simulations. The talk will also identify "greatest hits" in our field from the teaching and research perspectives of other members of DCOMP, including its Executive Committee.

8:36AM H24.00002 Nicholas Metropolis Award Talk for Outstanding Doctoral Thesis Work in Computational Physics: Computational biophysics and multiscale modeling of blood cells and blood flow in health and disease , DMITRY FEDOSOV, Forschungszentrum Juelich GmbH — Computational biophysics is a large and rapidly growing area of computational physics. In this talk, we will focus on a number of biophysical problems related to blood cells and blood flow in health and disease. Blood flow plays a fundamental role in a wide range of physiological processes and pathologies in the organism. To understand and, if necessary, manipulate the course of these processes it is essential to investigate blood flow under realistic conditions including deformability of blood cells, their interactions, and behavior in the complex microvascular network. Using a multiscale cell model we are able to accurately capture red blood cell mechanics, rheology, and dynamics in agreement with a number of single cell experiments. Further, this validated model yields accurate predictions of the blood rheological properties, cell migration, cell-free layer, and hemodynamic resistance in microvessels. In addition, we investigate blood related changes in malaria, which include a considerable stiffening of red blood cells and their cytoadherence to endothelium. For these biophysical problems computational modeling is able to provide new physical insights and capabilities for quantitative predictions of blood flow in health and disease.

9:12AM H24.00003 Computational Physics Across the Disciplines , VINCENT CRESPI, PAUL LAMMERT, TYLER ENGSTROM, BEN OWEN, Penn State University — In this informal talk, I will present two case studies of the unexpected convergence of computational techniques across disciplines. First, the marriage of neutron star astrophysics and the materials theory of the mechanical and thermal response of crystalline solids. Although the lower reaches of a neutron star host exotic nuclear physics, the upper few meters of the crust exist in a regime that is surprisingly amenable to standard molecular dynamics simulation, albeit in a physical regime of density order of magnitude of orders of magnitude different from those familiar to most condensed matter folk. Computational results on shear strength, thermal conductivity, and other properties here are very relevant to possible gravitational wave signals from these sources. The second example connects not two disciplines of computational physics, but experimental and computational physics, and *not* from the traditional direction of computational progressively approaching experiment. Instead, experiment is approaching computation: regular lattices of single-domain magnetic islands whose magnetic microstates can be exhaustively enumerated by magnetic force microscopy. There resulting images of island magnetization patterns look essentially like the results of Monte Carlo simulations of Ising systems... statistical physics with the microstate revealed.

9:24AM H24.00004 Role of Electronic Structure Calculations in Understanding Superconductors[1] , DAVID SINGH, Oak Ridge National Lab — Superconductivity remains one of the most challenging and exciting areas in condensed matter physics. It is a field that often sees surprises. These come in the form of new superconducting materials with unprecedented properties that need explanation. Here we briefly discuss the role that computational electronic structure studies have played in understanding some of these new systems over the years. The materials discussed are high temperature cuprates, borocarbides, Sr_2RuO_4, MgB_2, and the iron-based superconductors. Computation has played a key role in understanding properties of these materials and in some but not all cases pointing directly to the mechanism of superconductivity.

[1]This work was supported by the Department of Energy, Office of Basic Energy Sciences, Materials Sciences and Technology Division

9:36AM H24.00005 What is computational physics? An embarrassment of riches for teaching computational physics , LARRY ENGELHARDT, Francis Marion University — The first decade of the 21^{st} century has provided a wealth of exceptional resources for teaching computational physics, including numerous textbooks, libraries of computer codes (visual as well as numerical), and high-level interfaces for accessing these libraries. We are now faced with the very real challenge of choosing which of these resources to incorporate into the finite number of courses available in a given curriculum. This choice depends on several factors: How much time can be allocated to teaching computational methods and at what stage in the curriculum? What are the goals? (Learning physics better? Learning to individually implement numerical solutions for small-scale problems? Being prepared to work in research labs studying large-scale problems?) Are commercial packages an appropriate option for your student population? There are no right and wrong answers to these questions, and I will present more questions than answers! However, in recent years I have taught three undergraduate computational physics courses per year, and I will discuss some of the decisions that have been made regarding those courses.

9:48AM H24.00006 Computational Physics? Some perspectives and responses of the undergraduate physics community[1] , NORMAN CHONACKY, Yale University — Any of the many answers possible to the evocative question "What is ..." will likely be heavily shaded by the experience of the respondent. This is partly due to absence of a canon of practice in this still immature, hence dynamic and exciting, method of physics. The diversity of responses is even more apparent in the area of physics education, and more disruptive because an undergraduate educational canon uniformly accepted across institutions for decades already exists. I will present evidence of this educational community's lagging response to the challenge of the current dynamic and diverse practice of computational physics in research. I will also summarize current measures that attempt respond to this lag, discuss a researched-based approach for moving beyond these early measures, and suggest how DCOMP might help. I hope this will generate criticisms and concurrences from the floor.

[1]Research support for material in this talk was from: IEEE-Computer Society; Shodor Foundation; Teragrid Project.

10:00AM H24.00007 High-performance scientific computing in the cloud[1] , KEVIN JORISSEN, FERNANDO VILA, JOHN REHR, University of Washington — Cloud computing has the potential to open up high-performance computational science to a much broader class of researchers, owing to its ability to provide on-demand, virtualized computational resources. However, before such approaches can become commonplace, user-friendly tools must be developed that hide the unfamiliar cloud environment and streamline the management of cloud resources for many scientific applications. We have recently shown that high-performance cloud computing is feasible for parallelized x-ray spectroscopy calculations.[2] We now present benchmark results for a wider selection of scientific applications focusing on electronic structure and spectroscopic simulation software in condensed matter physics. These applications are driven by an improved portable interface that can manage virtual clusters and run various applications in the cloud. We also describe a next generation of cluster tools, aimed at improved performance and a more robust cluster deployment.

[1]Supported by NSF grant OCI-1048052.
[2]J.J. Rehr et al., CiSE, **12**, 34 (2010)

10:12AM H24.00008 Characterizing Large-Scale Computational Physics , TIMOTHY WILLIAMS, Argonne National Laboratory — Large-scale computational physics calculations typically share some of a number of basic characteristics:

- Brute-force approaches: Atomistic molecular dynamics, particle-in-cell plasma physics, particle-mesh cosmological simulations, DNS of turbulence, lattice QCD, Monte Carlo, ...
- Wide range of relevant scales: Angstroms to millimeters in molecular dynamics, ion/electron cyclotron period to seconds or minutes in plasmas, galaxy to observable universe in cosmology, high Reynolds number turbulence, ...
- Obvious need for yet larger scale: higher resolution, larger simulation domain, more particles, ...
- Code is named, parallel, community, long-lived (but evolving).

This talk views the computational physics landscape from the perspective a physicist who has worked at three DOE large-scale computing centers: the Argonne Leadership Computing Facility, the (former) Advanced Computing Laboratory, and NERSC. The "usual suspects" at the large-scale end of computational physics are remarkably persistent, even in the face of an ever-increasing definition of large-scale.

10:24AM H24.00009 Discussion of DCOMP Activities[1] , RICHARD SCALETTAR, University of California, Davis — The APS Division of Computational Physics, founded in 1986, explores the use of computers in physics research and education as well as the role of physics in the development of computer technology. Its goals are to promote research and development in computational physics, enhance the prestige and professional standing of its members, encourage scholarly publication, and promote international cooperation in these activities. This talk will mainly invite an open discussion of these objectives and how best to achieve them.

Tuesday, March 22, 2011 8:00AM - 10:48AM –
Session H25 DCMP: Superconductivity: Tunneling Spectroscopy D166

8:00AM H25.00001 Pairing Glue in High Tc Cuprates from Tunneling Spectroscopy , JOHN ZASADZINSKI, OMID AHMADI, LIAM COFFEY, Illinois Institute of Technology, LUTFI OZYUZER, Izmir Institute of Technolgy, NOBUAKI MIYAKAWA, Tokyo University of Science — Break junction tunneling spectroscopy data in Bi2212 over a wide range of doping are fit using a d-wave Eliashberg model. Self consistency is achieved as the electron-boson spectral function, α^2F(ω), that fits the tunneling conductance dip feature also leads to the correct superconducting gap. The anomalous negative dI/dV observed in break junctions on optimal doped Bi2212 is also reproduced in the analysis. The diagonal and off-diagonal self energies, $\Sigma(\omega)$ and $\phi(\omega)$, respectively are generated in the analysis and they show trends with doping which are in agreement with numerical simulations of the Hubbard model. The peak in α^2F(ω) is consistent with the resonance mode in the spin fluctuation spectrum. Tunneling data of other cuprates are also discussed.

8:12AM H25.00002 How Topological Defects Couple the Smectic and Nematic Electronic Structure of the Cuprate Pseudogap States , K. FUJITA, Cornell Univ., A. MESAROS, Universiteit Leiden, H. EISAKI, AIST, Japan, S. UCHIDA, Univ. of Tokyo, J. C. DAVIS, Cornell Univ., S. SACHDEV, Harvard Univ., J. ZAANEN, Universiteit Leiden, M. LAWLER, Binghamton Univ., EUN-AH KIM, Cornell Univ. — We study the recently discovered coexisting smectic and nematic broken symmetries in the pseudogap-energy electronic structure of underdoped $Bi_2Sr_2CaCu_2O_{8+\delta}$. By visualizing their spatial components separately, we discover 2π topological defects throughout the phase-fluctuating smectic states. Imaging the locations of large numbers of these topological defects simultaneously with the fluctuations of the electronic nematicity about its average, reveals strong empirical evidence for a coupling between them. We also found the same phenomenology in a single layer compound of $Bi_2Sr_{1.6}La_{0.4}CuO_{6+\delta}$. From these observations, we propose a Ginzburg-Landau free energy describing the quantum nematic/smectic coupling and demonstrate how it can explain the coexistence of these states and correctly predict their interplay at the atomic scale. This theoretical understanding of the coupling between the quantum nematic and smectic broken symmetries can lead to unraveling the complexities of the phase diagram of cuprate high-T_c superconductors[1]. [1]A. Mesaros, K. Fujita, H. Eisaki, S. Uchida, J. C. Davis, S. Sachdev, J. Zaanen, M. J. Lawler, and Eun-Ah Kim, *Submitted* (2010).

8:24AM H25.00003 Universal properties of disordered electron nematics from surface probes , BENJAMIN PHILLABAUM, ERICA CARLSON, Purdue University, KARIN DAHMEN — When the electronic degrees of freedom break the rotational symmetry of the host crystal, i.e. from C_4 to C_2, the resulting state is an electronic Ising nematic. However the combination of reduced dimensionality and material disorder can forbid the formation of a long- range-ordered electron nematic, especially in strongly layered materials. Nevertheless, large domains are still possible. In this talk we will present results from a new kind of analysis for Scanning Tunneling Microscopy (STM) experiments as well as other surface probes. We map the locally broken C_4 to C_2 rotational symmetry of the electronic degrees of freedom to an Ising-type order parameter,use the local order parameter configuration to shed light on the universality class controlling the local pattern formation in cuprate superconductors.

8:36AM H25.00004 Vacuum-aging effect on electronic structure of $YBa_2Cu_3O_{6+x}$ thin film: a STM/STS study , Y.H. LIU, J. XIONG, D. YAROTSKI, Q. JIA, A.J. TAYLOR, MPA-CINT, MS K771, Los Alamos National Laboratory, NM 87545 — It is well known that oxygen plays a key role in the occurrence of superconductivity in high-temperature cuprate superconductors. Variation of oxygen content changes carrier concentration and directly affects electronic structure and superconducting properties of cuprate superconductors. Majority of previous studies relied on the intake process of oxygen to change the oxygen content in samples, while the reverse process, oxygen depletion, was rarely investigated. Nevertheless, the escape of oxygen from the surface of cuprate sample that was kept at room temperature under ultrahigh vacuum for extended period of time might lead to significant degradation of its superconducting properties due to the decrease of the carrier concentration. Here, we report this so-called vacuum-aging effect in $YBa_2Cu_3O_{6+x}$ thin films grown by laser-MBE technique. In particular, we use variable-temperature scanning tunneling microscopy/spectroscopy to follow the evolution of superconductivity and pseudogap states in this material as a function of aging time and tip position on the surface.

8:48AM H25.00005 Influence of the tunneling property on the noise thermometry using a metal-insulator-metal tunnel junction , JUNG HWAN PARK, MUSHTAQ REHMAN, Korea Research Institute of Standards and Science, ZHEONG G. KHIM, Seoul National University, SANG-WAN RYU, Chonnam National University, WOON SONG, YONUK CHONG, Korea Research Institute of Standards and Science — We are developing a noise thermometry setup based on precision RF measurement, where temperature can be inferred from the noise of a tunnel junction as a function of the bias voltage. We measure the electrical noise of an Al-AlOx-Al tunnel junction around 1 GHz with a bandwidth of a few hundred MHz. In this presentation, as an analysis on the source of error in thermometry, we studied the influence of the junction quality and the inelastic process on the temperature measurement. We compared the noise of an as-fabricated tunnel junction with that of a degraded tunnel junction after thermal cycling. Except for the junction degradation, all measurement environments were kept exactly same. We observed an apparently higher noise value near the zero-bias, which leads to an overestimation of temperature. We present a simple model to describe how the inelastic process in a tunnel junction affects the temperature measurement.

9:00AM H25.00006 ABSTRACT WITHDRAWN –

9:12AM H25.00007 Mapping the Pseudogap by Fourier Transform Scanning Tunneling Spectroscopy in $Bi_2Sr_2CaCu_2O_{8+x}$[1] , E.W. HUDSON, MIT, E MAIN, A.E. PIVONKA, I. ZELJKOVIC, Harvard, G. GU, Brookhaven, J.E. HOFFMAN, Harvard — The relationship between pseudogap and superconductivity in cuprate superconductors remains an important open question. To shed light on this issue, we have used Fourier-transform scanning tunneling microscopy to map quasiparticle interference (QPI) patterns as well as the "checkerboard," a weak charge modulation associated with the pseudogap, as a function of doping and temperature in $Bi_2Sr_2CaCu_2O_{8+x}$ (Bi-2212). We can extract the doping dependence of the pseudogap transition temperature T* within the superconducting dome. Our results strongly suggest that the pseudogap is a competing order.

9:24AM H25.00008 Phenomenological model for extracting local energy scales across dopings and temperatures in cuprates[1] , KYLE MCELROY, EDUARDO CALLEJA, JIXIA DAI, University of Colorado Boulder, GENDA GU, Brookhaven National Laboratory, JACOB ALLDREDGE, National Institute of Standards and Technology Boulder — One of the key questions that remains unanswered in the cuprate high temperature superconductors is the nature of the pesudogap phase that exists above the superconducting transition temperature in underdoped materials. In order to differentiate the different proposed origins of this phase, a detailed phenomenology of the different energy scales that characterize it and the superconducting phase is required. In addition, many of these materials (BSCCO-2212 in particular) have shown striking inhomogeneity that further complicates observations of these scales. Spectroscopic imaging scanning tunneling microscopy has the unique ability to resolve density of states features with the needed spatial resolution for seeing through this inhomogeneity. We will present a new phenomenological model for extracting three different energy scales that are present with atomic resolution across several dopings. In addition, preliminary data on the temperature dependence of these scales will be shown. Lastly, how these different scales relate to the different phases present in the underdoped cuprates will be discussed.

9:36AM H25.00009 Understanding the Measurement of the K-Space Gap Using Spectroscopic Imaging Scanning Tunneling Microscopy[1] , EDUARDO CALLEJA, JIXIA DAI, University of Colorado, GENDA GU, Brookhaven National Laboratory, KYLE MCELROY, University of Colorado — Two of the many tools used to probe the High Tc cuprates are Angle Resolved Photo Emission (ARPES) and Spectroscopic Imaging Scanning Tunneling Microscopy (SI-STM). While the two probes have had many qualitative agreements recently there has been a movement in the field to strive for quantitative agreement in order to better understand the phase diagram of the cuprates. When looking for quantitative agreement we are met with striking disagreements such as, the measurement of the super conducting gap by both probes and the observation of Fermi arcs. We have generated a preliminary simulation based on a superconducting tight binding model where we can tune different parameters in order to begin exploring some of these issues. With our STM just beginning to take data our simulation is allowing us to understand the type of data we need to shed some light on these issues.

9:48AM H25.00010 a-axis NIS tunnel junctions using LaSrCuO4[1] , MAO ZHENG, Department of Physics, University of Illinois, Urbana, IL, YIZE LI, JAMES ECKSTEIN — Planar tunneling in NIS structures with crystalline order reveals the density of states largely focused in the tunneling direction. Earlier experiments with a-axis YBCO showed an unexpected strongly broken particle hole symmetry in the CuO bond direction. Here we report on work to make similar structures with a-axis LaSrCuO4.

10:00AM H25.00011 Determining the pseudogap Dirac point in the underdoped cuprate superconductors using FT-STS and AC-ARPES , E.J. NICOL, K.A.G. FISHER, University of Guelph, J.P. CARBOTTE, McMaster University — Prominent in the underdoped cuprate superconductors is the existence of a pseudogap in the excitation spectrum which opens above T_c but below a temperature T^*. Whether this gap is the same as the superconducting energy gap or is a manifestation of a competing order independent of the superconductivity remains an open and central question. If there are two distinct gaps of d-wave symmetry, they each will exhibit a Dirac point at a different energy and momentum in the band structure. We demonstrate how to find the pseudogap Dirac point by using quasiparticle interference (QPI) measurements from Fourier transform scanning tunneling spectroscopy (FT-STS) or by extrapolating information from the autocorrelation function of angle-resolved photoemission spectroscopy (AC-ARPES) to positive energies. Current examination of photoemission data supports our proposal and suggests that a Dirac point exists at positive energy relative to the Fermi level.

10:12AM H25.00012 Spatial Variations in the Fermi Surface of Bi-2212[1] , ELIZABETH MAIN, A.E. PIVONKA, I. ZELJKOVIC, Harvard, G. GU, Brookhaven, E.W. HUDSON, MIT, J.E. HOFFMAN, Harvard — In cuprate superconductors, scanning tunneling microscopy can be used to see variations in the Fermi surface on a nanometer length scale caused by doping inhomogeneity. Prior STM studies show that the local wavelength of the checkerboard, a weak charge modulation ascribed to antinodal Fermi surface nesting, varies with the size of the pseudogap in $Bi_2Sr_2CuO_{6+\delta}$ (Bi-2201) [1]. Here we report similar STM measurements in Bi-2212. We therefore confirm the local relationship between pseudogap energy and charge ordering wavevector in a second high-Tc superconductor.

10:24AM H25.00013 Vortex-core structure in d-wave superconductors with weak triplet pairing attraction , MIKAEL FOGELSTRÖM, Chalmers University of Technology, ANNICA BLACK-SCHAFFER, NORDITA — The quasiparticle states found in the vortex core of an d-wave high-T_c cuprate superconductor may be probed by STM experiments. Results of such experiments have revealed typical spectra that are quite different from what is seen in conventional low-T_c superconductors. In particular the Caroli-deGennes-Matricon state at $E \sim 0$ in the core center is not seen. Instead, in a high-T_c vortex core, quasiparticle states are found at energies that are at a sizable fraction of the gap energy. One explanation for this could be that a finite amplitude of a competing orderparameter stabilizes in the vortex-core center. We explore the possibility of nucleating a vortex-core state that locally breaks inversion symmetry. The vortex-core orderparameter is of mixed parity, in our case a (d + ip)-wave, and the quasiparticle spectra in the core center lacks the $E = 0$ states. We compare our results with available experimental data.

10:36AM H25.00014 Possible mechanism of enhanced pairing correlation near dopant oxygen in cuprate , MICHIYASU MORI, Japan Atomic Energy Agency, GINIYAT KHALIULLIN, Max-Planck-Institut fur Festkorperforschung, TAKAMI TOHYAMA, Kyoto University, SADAMICHI MAEKAWA, Japan Atomic Energy Agency — Recent experiments on Bi-based cuprate superconductors have revealed an unexpected enhancement of the pairing correlations near the interstitial dopant oxygens. We propose a mechanism by which the dopant oxygens strongly enhance the interaction J locally [1]. We notice that there is a strong covalency between the dopant oxygen and closely located apical oxygens, forming a molecular orbital complex. By considering virtual p-d and d-d charge transitions within the Cu-O-Cu bond that lead to the spin exchange J, we will show that the corresponding excitation energies are screened by the polarization of molecular orbitals hence enhancing J. The effect is greatly amplified due to cooperative response of the spatially extended oxygens complex. We will also show, by an exact diagonalization of the t-J model, that local enhancement of J leads to the spatial variations in density of electronic states observed in STM experiments. Our findings suggest an interesting possibility of quantum-chemistry control of the key interaction J in cuprates.

Session H26 DMP DCOMP: Focus Session: Iron Based Superconductors – Anisotropic Spin Dynamics D162/164

8:00AM H26.00001 Impact of the Spin Density Wave Order on the Superconducting Gap of $Ba(Fe_{1-x}Co_x)_2As_2$, LUDIVINE CHAUVIERE, YANN GALLAIS, MAXIMILIEN CAZAYOUS, MARIE-AUDE MEASSON, ALAIN SACUTO, Laboratoire Materiaux et Phenomenes Quantiques UMR 7162 CNRS Universite Paris Diderot, Paris, France, DOROTHEE COLSON, ANNE FORGET, CEA Saclay IRAMIS, SPEC CNRS URA 2464, Gif-sur-Yvette, France, SQUAP TEAM, SPEC COLLABORATION — We report a doping dependent electronic Raman scattering measurements on iron-pnictide superconductor $Ba(Fe_{1-x}Co_x)_2As_2$ single crystals. The B_{2g} Raman spectrum at optimal doping is consistent with a strongly anisotropic gap on the electron pocket. Upon entering the coexistence region between superconducting (SC) and spin-density-wave (SDW) orders, the effective pairing energy scale is strongly reduced. Our results are interpreted in terms of a competition between SC and SDW orders for electronic states at the Fermi level. Our findings advocate for a strong connection between the SC and SDW gaps anisotropies which are both linked to interband interactions.

8:12AM H26.00002 Frustrated square lattice Heisenberg model and magnetism in Iron Telluride , IGOR ZALIZNYAK, ZHIJUN XU, GENDA GU, JOHN TRANQUADA, Brookhaven National Laboratory, MATTHEW STONE, Oak Ridge National Laboratory — We have measured spin excitations in iron telluride Fe1.1Te, the parent material of (1,1) family of iron-based superconductors. It has been recognized that J1-J2-J3 frustrated Heisenberg model on a square lattice might be relevant for the unusual magnetism and, perhaps, the superconductivity in cuprates [1,2]. Recent neutron scattering measurements show that similar frustrated model might also provide reasonable account for magnetic excitations in iron pnictide materials. We find that it also describes general features of spin excitations in FeTe parent compound observed in our recent neutron measurements, as well as in those by other groups. Results imply proximity of magnetic system to the limit of extreme frustration. Selection of spin ground state under such conditions could be driven by weak extrinsic interactions, such as lattice distortion, or strain [3]. Consequently, different nonuniversal types of magnetic order could arise, both commensurate and incommensurate. These are not necessarily intrinsic to an ideal J1-J2-J3 model, but might result from lifting of its near degeneracy by weak extrinsic perturbations.

8:24AM H26.00003 Superconductivity and Magnetism in the Checkerboard Models for Iron-based Superconductors , CHEN FANG, Purdue University, XIAOLI LU, YONGJIN JIANG, Zhejiang Normal University, WEI-FENG TSAI, Tokyo University, JIANGPING HU, Purdue University — We study three different checkerboard models for iron-based superconductors and obtain their phase diagrams in the solvable limit of weakly coupled checkerboards. We demonstrate that the strongest superconducting pairing is in the A_{1g}-S wave channel and the development of the superconductivity (SC) is correlated with the emergence of the next nearest neighbor antiferromagnetism (AFM). Moreover, this study suggests that the superconductivity and magnetism are orbital-selective. In the three-band model, the AFM is more robust in the d_{xy} orbital and the superconductivity is easier to be generated in the d_{xz} and d_{yz} orbitals. Comparisons between our theoretical results and current experimental measurements are discussed.

8:36AM H26.00004 Anisotropy of the spin dynamics in hole and electron-doped 122 , PENGCHENG DAI, University of Tennessee/ORNL — This abstract not available.

9:12AM H26.00005 Magnetic properties in the Mott-insulating iron oxychalcogenides $La_2O_2Fe_2OSe_2$[1] , JIAN-XIN ZHU, Theoretical Division, Los Alamos National Laboratory, Los Alamos, NM 87545, RONG YU, QIMIAO SI, Department of Physics & Astronomy, Rice University, Houston, TX 77005 — The role of electron correlation and magnetism in high-temperature superconductivity of the iron pnictides has been a topic of discussion. It has also motivated interest to compare related compounds with the iron pnictides and chalcogenides. Recently both electronic structure calculations and experimental measurements have indicated that the iron oxychalcogenides $La_2O_2Fe_2OSe_2$, which contains an Fe square lattice with an enlarged unit cell, has a larger U/t and is a Mott insulator [1]. We focus here on the understanding of the magnetism of this system. Within the density functional theory, we consider the magnetic phase diagram. Using an effective frustrating spin-exchange model in a doubled checker-board lattice, we study the magnetic excitation spectrum. Our theoretical results are compared with the emerging elastic and inelastic neutron scattering data in this compound.

9:24AM H26.00006 Consistent model of magnetism in ferropnictides , ALEKSANDER WYSOCKI, KIRILL BELASHCHENKO, Department of Physics and Astronomy and Nebraska Center for Materials and Nanoscience, University of Nebraska-Lincoln, VLADIMIR ANTROPOV, Ames Laboratory — The character of magnetic interactions and spin fluctuations in ferropnictides has until now resisted understanding within any conventional model of magnetism. We show that the most puzzling features can be naturally reconciled within a rather simple effective spin model with biquadratic interaction, which is consistent with electronic structure calculations. While preserving the symmetry of the lattice, this model spin Hamiltonian stabilizes the collinear stripe ground state and generates an anisotropic spin wave spectrum. A natural reinterpretation of the measured spin wave spectra in ferropnictides is presented based on this model. Classical Monte Carlo simulations with experimentally motivated parameters produce reasonable Neel temperatures for 122 compounds. The model predicts that the phase transition to the paramagnetic phase changes from second to first order as the magnitude of the biquadratic term is increased. This property agrees with the observed behavior of the 122 compounds under doping. A clear signature of the separation of the nematic and antiferromagnetic phase transitions is also found. Preprint: arXiv:1011.1715.

9:36AM H26.00007 Spin-resolved electron-phonon coupling in FeSe[1] , TIMUR BAZHIROV, JESSE NOFFSINGER, MARVIN L. COHEN, University of California Berkeley — FeSe is one of the simplest iron-based superconductors. There are previous studies indicating that including the iron magnetic moment ordering has a significant effect on electron-phonon interactions and thus might be important for superconductivity. To explore the role of spin-dependent phonon induced pairing of the electrons, we apply first principle techniques based on the pseudopotential density functional approach and the local spin density approximation to calculate the electron-phonon coupling properties of FeSe. Our results indicate that introducing magnetic moments leads to a significant increase in coupling at least for certain phonon modes. At the gamma point in the Brillouin zone the increase is two-fold. Both phonon renormalization and electron-phonon matrix elements increases are present.

[1]This work was supported by National Science Foundation Grant No. DMR10-1006184, the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. Computational resources have been provided by DOE at Lawrence Berkeley National Laboratory's NERSC facility

9:48AM H26.00008 Spin-phonon coupling and superconductivity in iron pnictides , TANER YILDIRIM, UPENN & NIST, XUHUI LUO, UIC & NIST, SERDAR OGUT, UIC — Early electron-phonon (el-ph) coupling calculations for iron pnictide system based on standard non-spin-polarized perturbation theory indicate that conventional el-ph coupling cannot explain the observed high Tc in these systems. However, the experimental phonon spectrum indicates features which are not produced in the standard linear response non-magnetic phonon calculations. The magnetic phonon calculations clearly indicate that the observed phonon-DOS at room temperature is much closer to the magnetic phonon-DOS rather than non-magnetic DOS and Fe-magnetism must present in the iron-pnictide systems all the time [1-2]. Thus we need to calculate the magnetic el-phonon coupling with the Fe-spins included before we can rule out any type of phonon-mediated mechanism. In order to carry out such complex self-consistent magnetic el-ph coupling calculations we are developing a finite-displacement method in which both the phonon energies and the corresponding el-ph coupling constant are easily calculated. Implications of our results on the mechanism of superconductivity in iron pnictides will be discussed. Finally, we will compare our calculations with the available phonon energy and line-width measurements.

10:00AM H26.00009 Gap structure of the iron-pnictide superconductor LiFeAs via low-temperature thermal conductivity , J.-PH. REID, S. RENÉ DE COTRET, LOUIS TAILLEFER, University of Sherbrooke, Sherbrooke, Canada, M.A. TANATAR, H. KIM, K. CHO, R. PROZOROV, Ames Laboratory, Ames, Iowa, Y.J. SONG, Y.S. KWON, Sungkyunkwan University, Gyeonggi-Do, Korea — The thermal conductivity of the stoichiometric iron-pnictide superconductor LiFeAs was measured at temperatures down to $T \sim 50$ mK in magnetic fields up to $H = 17$ T on high-quality single crystals with $T_c \simeq 18$ K. The absence of any residual linear term at $T \to 0$ shows that there are no nodal quasiparticles. The slow increase of thermal conductivity with magnetic field shows that the gap is large everywhere on the Fermi surface. The same behaviour is observed for both in- plane and out-of-plane directions. We conclude that the superconducting gap in LiFeAs is basically isotropic. This is similar to what has been found in the iron-pnictide superconductors $Ba_{1-x}K_xFe_2As_2$ [1] and $Ba(Fe_{1-x}Co_x)_2As_2$ [2] at optimal doping (maximal T_c).

10:12AM H26.00010 NMR Study of the SDW ordering and the Spin Fluctuations on NaFeAs single crytals[1] , WEIQIANG YU, L. MA, S. ZHANG, J. ZHANG, T.-L. XIA, G.F. CHEN, Department of Physics, Renmin University of China, Beijing 100872, China, DAO-XIN YAO, School of Physics and Engineering, Sun Yat-sen University, Guangzhou 510275, China — In iron pnictides, the nature of the spin density wave (SDW) ordering is still not clear. Recently, increasing attention has been drawn to the correlation between the SDW transition and the high-temperature tetragonal to the low-temperature orthorhombic structure transition. In NaFeAs, the magnetic moment is small and both transitions are well separated, and therefore NaFeAs could be a good candidate to study the interplay of different degrees of freedom microscopically. In this talk, we report our ^{23}Na and ^{75}As NMR observations on NaFeAs single crystals. We found that 1) the spin fluctuations are largely enhanced below the structure transition; 2) the SDW transition temperature and the magnetic moment increase significantly with pressure; and 3) the NMR linewidth and the temperature/field dependence of the spin- lattice relaxation rate show signatures of an incommensurate SDW ordering in a limited temperature range just below the SDW transition. Based on these results, we discuss the coupling between the magnetism and the lattice/band structure in NaFeAs.

[1]Supported by NSFC and National Basic Research Program of China.

10:24AM H26.00011 Spin excitation in LiFeAs[1] , MENG WANG, HUIQIAN LUO, XIANCHENG WANG, Institute of Physics Chinese Academy of Sciences, YANG ZHAO, JEFFREY LYNN, NIST Center for Neutron Research, CHANGQING JIN, Institute of Physics Chinese Academy of Sciences, PENGCHENG DAI, University of Tennessee, PENGCHENG DAI TEAM, CHANGQING JIN COLLABORATION, JEFFREY LYNN COLLABORATION — We used inelastic neutron scattering to study the spin excitations in LiFeAs. Clear spin excitations were found but there was no spin resonance. Surprisingly, very big spin gap exists in this material.

[1]Institute of Physics Chinese Academy of Sciences

10:36AM H26.00012 Neutron Diffraction Studies of PrFe(1-x)Ru(x)AsO[1] , YUEN YIU, Univ of Tenn, OVIDIU GARLEA, ASHFIA HUQ, Oak Ridge Natl Lab, MICHAEL MCGUIRE, Oak Ridge National Laboratory, DAVID MANDRUS, Univ of Tenn, Oak Ridge Natl Lab, STEPHEN NAGLER, Oak Ridge Natl Lab — We report neutron powder diffraction (NPD) studies of Ru doped PrFe(1- x)Ru(x)AsO. The parent compound PrFeAsO undergoes a structural transition as well as magnetic transitions involving Fe and Pr moments upon cooling. Previous measurements (M. A. McGuire et al, Jrnl of Solid State Chem, 182- 8, 2326-2331) showed that Ru doping suppresses the above transitions. However, unlike most 1111's, this does not lead to superconductivity. To investigate the origin of this odd behavior we performed NPD measurements as a function of temperature for values of x up to 0.75. The results showed that although the structural and magnetic transitions are suppressed, the c axis displayed apparent negative thermal expansion (NTE) for all values of x. Such NTE has been seen in the parent compound (S. A. J. Kimber et al, PRB 78-140503), but to our knowledge there are no reports of NTE in superconducting samples. This suggests that the mechanism producing the NTE could also be responsible for the absence of superconductivity. We also report data on the magnetic transitions for lightly doped samples with x up to 0.1.

[1]Supported by the USDOE BES SUF and MSE Division.

10:48AM H26.00013 Interactions between rare earth and iron magnetism in *RE*FeAsO single crystals[1] , A. KREYSSIG[2,3], [2]Ames Laboratory; [3]Dep. of Physics and Astronomy, Iowa State University, Ames, M.G. KIM[2,3], W. TIAN[2], W. RATCLIFF II[4], [4]NIST, NCNR, Gaithersburg , J.-W. KIM[5], [5]APS, ANL, Argonne , S. NANDI[2,3], J.-Q. YAN[2], B. JENSEN[2], K.W. DENNIS[2], R.W. MCCALLUM[2,6], [6]Dep. of Materials Science and Engineering, Iowa State University, Ames , T.A. LOGRASSO[2], J.W. LYNN[4], J.L. ZARESTKY[2], R.J. MCQUEENEY[2,3], A.I. GOLDMAN[2,3] — In iron-based pnictides high-temperature superconductors, magnetic fluctuations and magneto-elastic effects are believed to be important for the superconducting electron pairing mechanism. To gain insight into the interplay between the different ordering phenomena and the underlying couplings we studied the tetragonal-to-orthorhombic distortion and the magnetic order by x-ray and neutron diffraction on *RE*FeAsO single crystals. The onset of rare earth (*RE* = Nd, Pr) magnetic order is coupled to changes in the iron magnetic structure without affecting the lattice distortion. High-resolution neutron and x-ray resonant magnetic scattering measurements down to 0.4 K revealed complex magnetic structures with multiple propagation vectors at low temperatures.

Tuesday, March 22, 2011 8:00AM - 11:00AM –
Session H27 GQI: Focus Session: Semiconductor Qubits- Silicon Spin Qubits C155

8:00AM H27.00001 Considerations for spin-based quantum computing in the solid-state , CHARLES TAHAN, RUSKO RUSKOV, ONEY SOYKAL, Laboratory for Physical Sciences — We give an update on recent work towards practical quantum computing using gated spins in semiconductors, especially in silicon.

8:12AM H27.00002 Fast initialization of a silicon spin qubit via an excited orbital state , C.B. SIMMONS, J.R. PRANCE, B.J. VAN BAEL, TECK SENG KOH, ZHAN SHI, D.E. SAVAGE, M.G. LAGALLY, R. JOYNT, MARK FRIESEN, S.N. COPPERSMITH, M.A. ERIKSSON, University of Wisconsin-Madison — We present data showing the initialization and measurement of individual electron spins in a silicon quantum dot. Spectroscopy of the electronic excited states of the dot reveals a relatively low-lying excited orbital state that is much more strongly coupled to the reservoir than the ground orbital state. As a function of an applied magnetic field, Zeeman splitting is observed for both the ground and the excited orbital states. By tuning a gate voltage, electron spins can be preferentially loaded into the quantum dot via any of these spin-split orbital states. Loading at either of the excited orbital states is measured to be over an order of magnitude faster than loading at directly into the orbital ground state. We use single-shot readout to measure the spin state of the loaded electrons. We observe two clear peaks in the fraction of spin-up electrons that are loaded, and these peaks correlate with loading through the spin-up ground or excited orbitals.

8:24AM H27.00003 Measurement of the electron spin relaxation time in a silicon quantum dot using single-shot readout , J.R. PRANCE, C.B. SIMMONS, B.J. VAN BAEL, TECK SENG KOH, ZHAN SHI, D.E. SAVAGE, M.G. LAGALLY, R. JOYNT, MARK FRIESEN, S.N. COPPERSMITH, M.A. ERIKSSON, University of Wisconsin-Madison — Electron spins in Si/SiGe quantum dots are promising candidates as qubits for quantum information processing, because spins in silicon couple weakly to the host material. We present a measurement of the spin lifetime for electrons in a silicon quantum dot. The spin state of individual electrons is measured using single-shot charge readout and spin-to-charge conversion: only spin-up electrons will tunnel off the quantum dot. Charge sensing is performed with an integrated quantum point contact that detects single electron tunnel events as steps in current. We determine the relaxation time by measuring the fraction of measurements that contain spin-up tunneling events as a function of the time that the electron spins are held on the quantum dot. We observe a clear decay in this spin-up fraction versus time, and an exponential fit yields $T_1 \sim 2.8$ seconds at a magnetic field of 1.85 T.

8:36AM H27.00004 Measurement of the Spin Relaxation Lifetime (T_1) in a One-Electron Strained-Si Accumulation-Mode Quantum Dot , EDWARD CROKE, MATTHEW BORSELLI, ANDREY KISELEV, PETER DEELMAN, IVAN MILOSAVLJEVIC, IVAN ALVARADO-RODRIGUEZ, RICHARD ROSS, ADELE SCHMITZ, MARK GYURE, ANDREW HUNTER, HRL Laboratories, LLC — We report measurements of the spin-relaxation lifetime (T_1) as a function of magnetic field in a strained-Si, accumulation-mode quantum dot. An integrated quantum-point contact (QPC) charge sensor was used to detect changes in dot occupancy as a function of bias applied to a single gate electrode. The addition spectra we obtained are consistent with theoretical predictions starting at N=0. The conductance of the charge sensor was measured by applying an AC voltage across the QPC and a 3 kΩ resistor. Lifetime measurements were conducted using a three-pulse technique consisting of a load, read, and flush sequence. T_1 was measured by observing the decay of the spin bump amplitude as a function of the load pulse length. We measured decay times ranging from approximately 75 msec at 2T to 12 msec at 3T, consistent with previous reports and theoretical predictions. Sponsored by United States Department of Defense. Approved for Public Release, Distribution Unlimited.

8:48AM H27.00005 Undoped Si/SiGe Depletion-Mode Few-Electron Double Quantum Dots , MATTHEW BORSELLI, HRL Laboratories LLC, BIQIN HUANG, RICHARD ROSS, EDWARD CROKE, KEVIN HOLABIRD, THOMAS HAZARD, CHRISTOPHER WATSON, ANDREY KISELEV, PETER DEELMAN, IVAN ALVARADO-RODRIGUEZ, ADELE SCHMITZ, MARKO SOKOLICH, MARK GYURE, ANDREW HUNTER — We have successfully formed a double quantum dot in the sSi/SiGe material system without need for intentional dopants. In our design, a two-dimensional electron gas is formed in a strained silicon well by forward biasing a global gate. Lateral definition of quantum dots is established with reverse-biased gates with $\sim$40 nm critical dimensions. Low-temperature capacitance and Hall measurements confirm electrons are confined in the Si-well with mobilities $>10^4$ cm^2/V-s. Further characterization identifies practical gate bias limits for this design and will be compared to simulation. Several double dot devices have been brought into the few-electron Coulomb blockade regime as measured by through-dot transport. Honeycomb diagrams and nonlinear through-dot transport measurements are used to quantify dot capacitances and addition energies of several meV. Sponsored by United States Department of Defense. Approved for Public Release, Distribution Unlimited.

9:00AM H27.00006 Transport, Charge Sensing, and Quantum Control in Si/SiGe Double Quantum Dots[1] , KE WANG, PANU KOPPINEN, YULIYA DOVZHENKO, JASON PETTA, Department of Physics, Princeton University, Princeton, NJ 08544 — Si/SiGe quantum dots hold great promise as ultra-coherent qubits [1]. In comparison with the GaAs system, Si has a weaker hyperfine interaction due to the zero nuclear spin of ^{28}Si and smaller spin-orbit coupling due to its lighter atomic weight [2]. However, the fabrication of highly controllable Si/SiGe quantum dots is complicated by valley degeneracy, the larger effective electron mass, and the difficulty of obtaining high quality samples [3]. Here we develop a robust fabrication process for depletion mode Si/SiGe quantum dots, demonstrating high quality ohmic contacts and low-leakage Pd top gates. We report DC transport measurements as well as charge sensing in single and double quantum dots. The quantum dot gate electrode pattern allows a relatively high level of control over the confinement potential, tunneling rates, and electron occupation.

9:12AM H27.00007 Double quantum dot with tunable coupling in an enhancement-mode silicon metal-oxide semiconductor device with lateral geometry , L.A. TRACY, R.W. YOUNG, G.A. TEN EYCK, K. ENG, K.D. CHILDS, J.R. WENDT, R.K. GRUBBS, J. STEVENS, M.P. LILLY, M.S. CARROLL, Sandia National Labs, E.P. NORDBERG, Sandia National Labs; University of Wisconsin-Madison, C. BORRAS PINILLA, Universidad Industrial de Santander-Colombia, H.L. STALFORD, Sandia National Laboratories; University of Oklahoma-Norman, M.A. ERIKSSON, University of Winsconsin-Madison — We present transport measurements of a tunable silicon metal- oxide-semiconductor double quantum dot device with lateral geometry. Experimentally extracted gate-to-dot capacitances show that the device is largely symmetric under the gate voltages applied. Intriguingly, these gate voltages themselves are not symmetric. Comparison with numerical simulations indicates that the applied gate voltages serve to offset an intrinsic asymmetry in the physical device. We also show a transition from a large single dot to two well isolated coupled dots, where the central gate of the device is used to controllably tune the interdot coupling.
This work was supported by the LDRD program at Sandia National Laboratories, a multi-program laboratory operated by Sandia Corporation, a wholly owned subsidiary Lockheed-Martin Company, for the U. S. DOE NNSA under Contract No. DE-AC04-94AL85000

9:24AM H27.00008 The effect of donors on lateral gated quantum-devices in Si/SiGe heterostructures[1] , XI LIN, JINGSHI HU, A. LAI, MIT, Z. ZHANG, UCLA, K. MACLEAN, MIT, Y.H. XIE, UCLA, M.A. KASTNER, MIT — Much activity has focused on the development of quantum dots in Si/SiGe because of its potentially very long decoherence times (T2). However, to fabricate well-controlled quantum dots in Si/SiGe heterostructures, one must overcome complications that do not arise in GaAs/AlGaAs heterostructures. We demonstrate that switching charge noise and donor-layer conduction can lead to instability and cross-coupling among the tunnel barriers, thus making it difficult to achieve highly stable and tunable quantum devices in a Si/SiGe heterostructure. In particular, we have used an integrated charge-sensing quantum point contact to investigate the charge motion that originates from the excess donors, and present a systematic capacitance measurement to show how the donor layer affects device function in devices with large ($\sim$100 μm^2) gates as well as nanometer-size ones.

9:36AM H27.00009 Pauli Spin Blockade and Lifetime-Enhanced Transport in a Si/SiGe double quantum dot[1] , TECK SENG KOH, C.B. SIMMONS, NAKUL SHAJI, MADHU THALAKULAM, L.J. KLEIN, HUA QIN, H. LUO, D.E. SAVAGE, M.G. LAGALLY, University of Wisconsin-Madison, A.J. RIMBERG, Dartmouth College, ROBERT JOYNT, ROBERT BLICK, MARK FRIESEN, S.N. COPPERSMITH, M.A. ERIKSSON, University of Wisconsin-Madison — We analyze electron transport data through a Si/SiGe double quantum dot in terms of spin blockade and lifetime-enhanced transport (LET), which is transport through excited states that is enabled by long spin relaxation times. We present a series of low-bias voltage measurements showing the sudden appearance of a strong tail of current that we argue is an unambiguous signature of LET appearing when the bias voltage becomes greater than the singlet-triplet splitting for the (2,0) electron state. We present eight independent data sets, in both forward and reverse bias regimes, and show that excellent fits to all data sets were obtained using one consistent set of parameters. We also obtain quantitative estimates for the tunneling rates and currents in the reverse bias regime using the Lindblad formalism. [Ref: arXiv:1008.5398v1]

9:48AM H27.00010 Fabrication of Few-Electron Carbon Nanotube Single and Double Quantum Dots , HUGH CHURCHILL, PATRICK HERRING, RUBY LAI, CHARLES MARCUS, Harvard University — We discuss fabrication methods for carbon nanotube quantum dot devices designed to satisfy the requirements of spin qubit applications. These requirements include low disorder for reliable access to the few-electron regime, detection of charge states, and rapid manipulation with multiple gates. Nanotube growth occurs at or near the end of the fabrication process, a scheme that has been shown previously to produce clean devices for transport studies. In our devices the nanotubes are grown over pre-patterned gates or the nanotubes are located and gates are placed on top. A new atomic layer deposition process was developed to coat the nanotubes in a high-k dielectric for effective gating and suppression of electron interactions. We find in these devices that disorder on the length scale of the quantum dot is made small enough for routine occupancy with few charges, but disorder with sufficiently short range to couple valleys remains an uncontrolled parameter that is important for qubit applications of nanotubes. We acknowledge support from NSF-MWN, IBM, and Harvard University.

10:00AM H27.00011 Undoped Heterostructure Materials for SiGe Quantum Devices , R.S. ROSS, M.G. BORSELLI, B. HUANG, K.S. HOLABIRD, T.M. HAZARD, A.A. KISELEV, P.W. DEELMAN, I. ALVARADO-RODRIGUEZ, A.E. SCHMITZ, M. SOKOLICH, A.T. HUNTER, M.F. GYURE, HRL Laboratories LLC, 3011 Malibu Canyon Road, Malibu CA 90265 — Quantum well heterostructures, widely used for the fabrication of quantum dots and related devices, typically make use of modulation doping. Removal of the dopants, by use of globally "field-gated" and/or back-gated heterostructure designs, eliminates the dominant sources of scattering, charge noise and instability in devices intended for low-temperature operation. In this talk we present recent progress in designing and fabricating undoped quantum well heterostructures in sSi/SiGe. A combination of simulation based modeling and experimental work has enabled us to successfully engineer materials for stable and quiet quantum dot operation. Specific topics to be presented include the important role of substrate and buffer layer background doping, concurrent MOS accumulation, leakage to front and back gates via barrier tunneling, and the expected range of electric fields that determine valley mixing in quantum dots. Sponsored by United States Department of Defense. Approved for Public Release, Distribution Unlimited.

10:12AM H27.00012 Heterostructure surface effects on Si/SiGe 2DEGs , XIAN WU, C.B. SIMMONS, J.R. PRANCE, D.E. SAVAGE, M.G. LAGALLY, M.A. ERIKSSON, University of Wisconsin-Madison — We present the results of Hall and Shubnikov-de Haas measurements of the two-dimensional electron gas (2DEG) in Si/SiGe heterostructures at 2 K. We demonstrate that the condition of the surface has significant effects on the carrier density and mobility of electrons in the quantum well. Results from multiple samples show that the carrier density and mobility decrease with the amount of time that the samples are exposed to air. Surface treatment via a forming gas anneal or by dipping the samples in HF restores the carrier density and mobility of the degraded samples, and storing the samples in vacuum slows the rate of degradation. We believe that the reduction in carrier density of the 2DEG is a result of interface traps that form in the surface native oxide. Forming gas anneal passivates the interface traps, and HF strips the oxide. Illuminating the degraded samples at 2 K also improves the carrier density and mobility, possibly by activating electrons out of trap states. Deposition of AL2O3 on the surface using ALD caused a severe reduction in carrier density, which we believe is the result of a high trap density.

10:24AM H27.00013 Density and Depth of Natural Quantum Dots in Silicon MOS Structures , R.M. JOCK, S. SHANKAR[1], A.M. TYRYSHKIN, J.-H. HE, S.A. LYON, Princeton University, K. ENG[2], K. CHILDS, L. TRACY, M. LILLY, M. CARROLL, Sandia National Laboritories — Electron spins in MOS structures have shown promise as qubits for quantum information processing. Typically, characteristics such as mobility, mid-gap interface states and oxide fixed charge are considered figures of merit for the Si/SiO_2 interface, however, other properties may be important. Recently, we have shown that, by biasing the gate above threshold and then reducing V_G to 0V, we freeze electrons into natural quantum dots, where 2D electrons are confined by interface disorder. The depth of these dots is determined by the temperature and can be extracted using a Schottky-Hall-Read model. Additionally, we measure the density of confined electron states from the magnitude of the ESR signal. These measurements offer us a means to characterize the interface disorder in these MOS structures. Experiments have been performed on devices from different labs. Preliminary results from industrial quality devices fabricated at Sandia National Laboratories indicate a shallower dot depth, though a similar mobility. The shallower confinement suggests a higher quality for single-electron quantum devices.

10:36AM H27.00014 Real time electron counting through wavelet edge detection[1] , BJORN VAN BAEL, JONATHAN PRANCE, CHRISTIE SIMMONS, TECK SENG KOH, ZHAN SHI, DON SAVAGE, MAX LAGALLY, ROBERT JOYNT, MARK FRIESEN, SUSAN COPPERSMITH, MARK ERIKSSON, University of Wisconsin-Madison — We have recently demonstrated single-shot measurements of individual electron spins in a Si/SiGe quantum dot. These experiments were analyzed using a wavelet-based technique that allows detection of charging events in real time. An alternative method, based on level thresholding, is not well suited for real time detection, due to drifting background currents in the charge sensor. In contrast, the wavelet technique relies on edge detection and is hence robust against drifting currents levels. In this talk, we describe our wavelet algorithm and its applications for charge sensing. We benchmark the performance of the algorithm under realistic signal noise conditions.

10:48AM H27.00015 Triangulating the source of tunneling resonances in a point contact with nanometer scale sensitivity , N.C. BISHOP, Sandia National Labs, C. BORAS PINILLA, Universidad Industrial de Santander-Colombia, H.L. STALFORD, University of Oklahoma, R.W. YOUNG, G.A. TEN EYCK, J.R. WENDT, K. ENG, M.P. LILLY, M.S. CARROLL, Sandia National Labs — We observe resonant tunneling in split gate point contacts defined in a double gate enhancement mode Si-MOS device structure. We determine the capacitances from the resonant feature to each of the conducting gates and the source/drain two dimensional electron gas regions. In our device, these capacitances provide information about the resonance location in three dimensions. Semi-classical electrostatic simulations of capacitance, already used to map quantum dot size and position [Stalford et al., IEEE Nanotechnology], identify a combination of location and confinement potential size that satisfy our experimental observations. The sensitivity of simulation to position and size allow us to triangulate possible locations of the resonant level with nanometer resolution. We discuss our results and how they may apply to resonant tunneling through a single donor. This work was supported by the Laboratory Directed Research and Development program at Sandia National Laboratories. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy's National Nuclear Security Administration under Contract DE-AC04-94AL85000.

Session H28 DMP: Focus Session: Carbon Nanotubes and Related Materials: Devices I C156

8:00AM H28.00001 Individual SWCNT based ionic field effect transistor[1] , PEI PANG, Department of Physics, Biodesign Institute, Arizona State University, JIN HE, Biodesign Institute, Arizona State University, JAE HYUN PARK, PREDRAG KRSTIC, Physics Division, Oak Ridge National Laboratory, STUART LINDSAY, Department of Physics, Biodesign Institute, Department of Chemistry and Biochemistry, Arizona State University — Here we report that the ionic current through a single-walled carbon nanotube (SWCNT) can be effectively gated by a perpendicular electrical field from a top gate electrode, working as ionic field effect transistor. Both our experiment and simulation confirms that the electroosmotic current (EOF) is the main component in the ionic current through the SWCNT and is responsible for the gating effect. We also studied the gating efficiency as a function of solution concentration and pH and demonstrated that the device can work effectively in the physiological relevant condition. This work opens the door to use CNT based nanofluidics for ion and molecule manipulation.

8:12AM H28.00002 Chemically-Driven Two Level Fluctuations in Single-Walled Carbon Nanotubes (SWCNTs) with Defects , DANNY WAN, STEVEN R. HUNT, BRAD L. CORSO, ISSA S. MOODY, GREGORY A. WEISS, PHILIP G. COLLINS, Departments of Physics and Astronomy, Chemistry, Molecular Biology and Biochemistry, University of California, Irvine, CA 92697 — When a SWCNT conductor contains a defect, its electronic fluctuations are sensitive indicators of the surrounding chemical environment and of the chemical state of the defect itself. We demonstrate this effect by fabricating single SWCNT devices and then engineering their defect condition through the method of electrochemical point-functionalization. By characterizing the same SWCNT before and after the introduction of a point defect, we clearly establish the defect's contribution to the overall device noise. Carboxylate defects are particularly interesting because they have a deprotonated state that is sensitive to pH, electrolyte, and electrochemical potential. Large amplitude, two level fluctuations are observed from carboxylate sites when probed under conditions near the dissociation constant pKa, and the occupation statistics can be reversibly tuned by either pH or potential. We interpret the fluctuation in terms of the controlled protonation and deprotonation of the defect site, and describe a simple electrostatic gating model that supports this conclusion.

8:24AM H28.00003 Gas detection mechanism for single-walled carbon nanotube networks[1] , ANTHONY BOYD, ISHA DUBE, Georgtown University Washington, DC 20057, GEORGY FEDOROV, RRC Kurchatov Institute, Moscow, Russia 123182, MAKARAND PARANJAPE, PAOLA BARBARA, Georgtown University Washington, DC 20057, GEORGETOWN/RRC KURCHATOV COLLABORATION[2] — We study field-effect transistors fabricated with carbon nanotube (CNT) networks to determine whether the gas sensing mechanism is due to molecules adsorbed on the nanotubes, or changes at the interface between the nanotubes and the contacts. Our previous work showed that in devices made with isolated CNT, the response to nitrogen dioxide was mainly due to the contact interfaces [1]. Here, we focus on CNT networks and use SU-8 layers patterned with e-beam lithography to passivate the contact interfaces, while leaving the network exposed. We look to investigate possible differences in sensing mechanism for devices made with isolated tubes versus networks.

8:36AM H28.00004 Effects of adsorbed gases on the conductance of individual carbon nanotubes[1] , DAVID COBDEN, HAO-CHUN LEE, ERIK FREDRICKSON, University of Washington, RICHARD ROY, University of Puget Sound, OSCAR VILCHES, University of Washington — We investigate the effects of adsorbed monolayers of Ar, Kr and other gases on individual suspended single-walled carbon nanotubes. The down-shifts of the vibrational resonances of a nanotube can be used to determine the monolayer density[2] while the electrical conductance is measured simultaneously, at temperatures as low as 4.3 K. In the case of Ar, by studying density isotherms in the range 38 to 65 K, we see behavior resembling that of the well known two-dimensional vapor, liquid and solid phases on exfoliated graphite, although the correspondence is not exact and is device dependent. In addition, we find that the conductance changes significantly and non-monotonically with the density, and there are indications that it is sensitive to ordering in the monolayer.

8:48AM H28.00005 Anomalous Current-Voltage Characteristics in Suspended Carbon Nanotubes in Various Gas Environments , MOH AMER, University of Southern California, ADAM BUSHMAKER, The Aerospace Corporation, STEVE CRONIN, University of Southern California — Electrically-heated suspended, carbon nanotubes (CNTs) exhibiting negative differential conductance in the high bias regime experience a sudden drop in current (or "kink") in various gaseous environments. We study the effect of different gas molecules on these $I-V$characteristics while simultaneously monitoring the changes in the nanotube vibrational structure under high bias voltages using Raman spectroscopy. When the nanotube is electrically biased at the kink, the G band Raman mode is observed to downshift, as is typical of electrically heated devices. However, the G band frequency at the kink (ω_G^{kink}) lies in the narrow range between 1575 and 1579cm^{-1} for all samples measured, regardless of gas environment. The voltage at which the kink occurs depends on the type of the gas environment with the following dependence: $V_{kink}^{Ar} < V_{kink}^{He} < V_{kink}^{CO_2}$. The magnitude of the kink, however, has the following ordering: $\Delta I_{kink}^{Ar} < \Delta I_{kink}^{CO_2} < \Delta I_{kink}^{He}$. This ordering was observed consistently in all samples measured. Several possible mechanisms underlying this phenomenon are discussed within the context of these findings.

9:00AM H28.00006 Heat Dissipation from Suspended Carbon Nanotubes to their Surrounding Gas Environment , I. KAI HSU, MICHAEL T. PETTES, MEHMET AYKOL, LI SHI, STEPHEN CRONIN — The assistance of gas molecules to dissipate heat in 5-μm-long, electrical heated suspended carbon nanotubes (CNTs) is observed by comparing the Gband Raman phonon temperature profiles measured in different gas environments and in vacuum. The measurement results show that 50-60% of the heat generated in the CNT is carried away by its surrounding gas molecules. By analyzing the temperature profiles investigated in different gases, the thermal boundary conductance (TBC) between the gas molecules and the CNT can also be extracted. We find the TBC to be higher in carbon dioxide than in nitrogen, argon and helium.[1] Moreover, we report another optical method to explore the heat spreading behavior on a longer suspended CNTs in air, in which one laser is used as a heat source while another laser is used as a local temperature probe. A fin-shape thermal transport model is applied to fit the exponentially decaying temperature profiles measured away from the heat source. These results yield a heat decay length and TBC for air to be around 6.5 μm and 3×10^5 W/m^2 •K, respectively.

9:12AM H28.00007 Electroluminescence from a single nanotube-molecule-nanotube junction , RALPH KRUPKE, Karlsruhe Institut für Technologie — The reliable fabrication of metallic singlewall carbon nanotube (mSWNT) electrode pairs with sub-10 nm spacing allows us to contact organic molecules (M) via dielectrophoresis and to form mSWNT-M-mSWNT junctions. For this purpose we used specific designed molecules which have an appropriate length to bridge the SWNT electrode gap, and a sufficient polarizability to allow the molecule deposition between the SWNT electrodes via DC-dielectrophoresis. The molecules comprise a fluorescent chromophore subunit. During transport measurements several mSWNT-M-mSWNT junctions showed light emission at voltages > 4 V. The electroluminescence spectrum from the junction is very similar to the photoluminescence signal of the molecules on HOPG-surfaces. This result together with control experiments indicates that light is emitted from the chromophore core of the mSWNT contacted molecule [1]. If time allows I will also report on a related work about phonon-assisted electroluminescence from biased metallic single wall carbon nanotubes (SWNT), multi wall carbon nanotube (MWNT) and few layer graphene (FLG) devices [2].

[1] C.W. Marquardt, S. Grunder, A. Blaszczyk, S. Dehm, F. Hennrich, H. v. Löhneysen, M. Mayor, R. Krupke, Nature Nanotechnology 2010; DOI: 10.1038/NNANO.2010.230

9:48AM H28.00008 Thermal Emission of Suspended Carbon Nanotube , ZUWEI LIU, ADAM BUSHMAKER, MEHMET AYKOL, STEVE CRONIN, USC TOPRAMAN TEAM — We study the thermal emission spectra of individual suspended carbon nanotube induced by electrical heating. Semiconducting and metallic devices exhibit different spectra, based on their distinctive bandstructures. These spectra are compared with the ideal blackbody emission spectrum. In the response region of our detector, i.e. visible to near infrared, the thermal emission spectra of semiconducting devices agree well with Planck's law, while the spectra of metallic devices show an additional peak around 1.65 eV. For semiconducting devices, the temperature of the nanotube was fitted to Planck's law, and was compared with the temperature fitted from the G band downshift as well as the Stokes:anti-Stokes intensity ratio. For devices showing thermal non-equilibrium, the electron temperature agrees well with G+ downshift, but deviates from G- downshift. Finally, for metallic devices, partially polarized IR emission was observed, and possible mechanisms are discussed.

10:00AM H28.00009 Electric field dependence of photoluminescence from individual single-walled carbon nanotubes[1] , S. YASUKOCHI, T. MURAI, T. SHIMADA, S. CHIASHI, S. MARUYAMA, Y.K. KATO, The University of Tokyo — Using suspended single-walled carbon nanotubes, we investigate electric field effects on photoluminescence. Trenches are fabricated on SiO_2/Si substrates, and Pt is deposited for electrical contacts. Carbon nanotubes are grown by patterned chemical vapor deposition. These devices operate as back-gate field effect transistors, allowing application of electric fields on as-grown ultraclean nanotubes. Individual suspended carbon nanotubes are identified by taking photoluminescence images using a home-built laser-scanning confocal microscope. After determining the chirality by photoluminescence excitation spectra, we measure gate voltage dependence of photoluminescence. We observe quenching of photoluminescence intensity and shifts of emission wavelength as gate voltages are applied.

10:12AM H28.00010 Simultaneous Rayleigh and Raman spectroscopy on suspended single-walled carbon nanotubes under electrostatic gating , YUHEI MIYAUCHI, ZHENGYI ZHANG, MITSUHIDE TAKEKOSHI, VIKRAM DESHPANDE, Columbia University, New York, NY 10027, STÉPHANE BERCIAUD, Université de Strasbourg, PHILIP KIM, JAMES HONE, TONY HEINZ, Columbia University, New York, NY 10027 — The optical properties of single-walled carbon nanotubes (SWNTs) under electrostatic gating are of great interest for fundamental understanding of one-dimensional physics and for their application as optoelectronics devices. Here, we report how the electronic transitions are modified by gating conditions through direct measurements of Rayleigh (elastic) light scattering from individual suspended SWNTs [1]. With increasing gate voltage, we observed both a broadening and shift of the excitonic resonances in the Rayleigh scattering spectra. The influence of carrier doping on the optical resonances and, as gauged through simultaneous Raman measurements, on vibrational transitions will be discussed.

[1] M. Y. Sfeir et al., Science 306, 1540 (2004).

10:24AM H28.00011 Photoconductivity measurements of single-walled carbon nanotube field effect transistors[1] , T. MURAI, S. YASUKOCHI, S. MORITSUBO, T. SHIMADA, S. CHIASHI, Y. MURAKAMI[2], S. MARUYAMA, Y.K. KATO, The University of Tokyo — Photoconductivity measurements are performed on carbon nanotube field effect transistors. Carbon nanotubes are grown on SiO_2/Si substrate by patterned chemical vapor deposition using ethanol as carbon source. Next, electron beam lithography, metal deposition, and liftoff processes are performed to form source and drain electrodes. The Si substrate is used as a back-gate in these devices. Wavelength tunable Ti:sapphire laser is focused onto the sample with an objective lens, and the laser spot is scanned with a steering mirror. A lock-in amplifier is used to detect the photoconductivity signal of carbon nanotube field effect transistors.

10:36AM H28.00012 Role of defects in optical phonon decay, softening and 1/f noise resonance in carbon nanotubes , MOONSUB SHIM, University of Illinois — Scattering and relaxation of optical phonons are especially important processes in carbon nanotubes. Strong phonon softening near the Dirac point in metallic nanotubes occurs by coupling of carrier excitation to optical phonon transitions. Current saturation and negative differential conductance in the high bias regime in nanotube devices are attributed optical phonon absorption and emission. Cooling of hot carriers occurs mostly via optical phonons which eventually decay anharmonically into acoustic phonons. Whether intentional or unavoidable, defects will strongly influence these fundamentally important processes. In this talk, how defects affect optical phonon scattering will be discussed. In particular, defect-dependent optical phonon lifetime and resonant 1/f noise associated with phonon softening via the Kohn anomaly will be discussed.

10:48AM H28.00013 Micro-scale "air-gap" circuitry with conducting carbon nanotube-copper composite , CHANDRAMOULI SUBRAMANIAM, Technology Research Association for Single Wall Carbon Nanotubes, Central 5, 1-1-1 Higashi, Tsukuba, Ibaraki, 305-8565, Japan, TAKEO YAMADA, DON N. FUTABA, KENJI HATA, Super-growth CNT Team, Nanotube Research Centre, National Institute of Advanced Industrial Science and Technology, Central 5, 1-1-1 Higashi, Tsukuba, — The ability of water-assisted CVD to produce aligned close-packed single wall carbon nanotubes(CNT) with superior thermal and mechanical properties make them ideal materials for use in microelectronics. However, their poor electrical conductivity has been a major obstacle in realizing this. To overcome this, we report the synthesis of conducting CNT-copper composite (conductivity σ=10^5 Scm^{-1}) through a novel organic phase electrodeposition. The conductivity enhancement (10^3 times over CNT) is due to the high, uniform filling of Cu in the aligned CNT matrix. Micro-scale, three-dimensional lithographic engineering of CNT-Cu, involving fully suspended CNT-Cu beams, is achieved for microelectronic applications. Multi-tier CNT-Cu circuits are also fabricated, with the constituent lines separated by air (replaceable with vacuum). This "vacuum-separation" exists in the horizontal and vertical directions providing unique multi-tier "air-gap" circuits. This realization of dielectric-less, air-gap circuits with CNT-Cu is thought to be a breakthrough for developing faster and efficient microelectronic devices.

Session H29 GQI: Focus Session: Quantum Information for Quantum Foundations - Axiomatics and Toy Models C148

8:00AM H29.00001 Toward a conceptual foundation of Quantum Information Processing , GIULIO CHIRIBELLA, Perimeter Institute for Theoretical Physics — Quantum Information Science has brought to light an enormous amount of new protocols showing that the structure of quantum theory dramatically impacts the way in which information can be processed. It also made clear that the rules of information processing are dictated by physics and that different physical theories entail different models of information processing. Quantum Information poses an exciting challenge to foundational research: the challenge is to reduce the multiplicity of quantum protocols to a small number of basic physical principles and to answer questions like "What are the physical roots of the power of quantum information?" A satisfactory answer to these questions calls for the solution of a long-standing problem: deriving quantum theory from physical principles, as opposed to the abstract mathematical principles of the Hilbert space formulation. In this talk I will show that quantum theory can be derived from few principles about information processing. The central principle of the derivation will be the purification principle, stating that ignorance about a part (subsystem) is always compatible with maximal knowledge of the whole (compound system). A large number of quantum information features, including e.g. teleportation and no-cloning, are direct consequences of the purification principle, which appears a strong candidate for the conceptual foundation of Quantum Information Processing. Moreover, the derivation of quantum theory from purely informational principles provides a rigorous justification of the diffuse claim that quantum theory is ultimately a theory of information.

8:36AM H29.00002 Physics as Information , GIACOMO MAURO D'ARIANO, Università di Pavia — The experience from Quantum Information has lead theorists to look at Quantum Theory and the whole Physics from a different angle. A new information-theoretic paradigm is emerging, long time ago prophesied by John Archivald Wheeler with his popular coinage "It from bit." Theoretical groups are now addressing the problem of deriving Quantum Theory from informational principles, and similar lines are investigated e.g. in new approaches to Quantum Gravity. In my talk I will review some recent advances on these lines. The general idea synthesizing the new paradigm is that there is only Quantum Theory (without quantization rules), and the whole Physics—including space-time and relativity–is emergent from the quantum-information processing. And, since Quantum Theory itself is made with purely informational principles, the whole Physics must be reformulated in information-theoretical terms. The review is divided into four parts: a) Very short review of the informational axiomatization of Quantum Theory; b) How space-time and relativistic covariance emerge from the quantum computation; c) What is the information-theoretical meaning of inertial mass and Planck constant, and how the Dirac field emerges; d) Observable consequences of the new theory. I will then conclude with some possible future research lines.

8:48AM H29.00003 A derivation of quantum theory from physical requirements , MARKUS MUELLER, Perimeter Institute for Theoretical Physics, Waterloo (ON), Canada, LLUIS MASANES, ICFO-Institut de Ciencies Fotoniques, Barcelona, Spain — Quantum theory is usually formulated by postulating the mathematical structure and representation of states, transformations, and measurements. The general physical consequences that follow (like violation of Bell-type inequalities, the possibility of performing state tomography with local measurements, or factorization of integers in polynomial time) come as theorems which use the postulates as premises. In this work, this procedure is reversed: we impose five simple physical requirements, and this suffices to single out quantum theory and derive its mathematical formalism uniquely. This is more similar to the usual formulation of special relativity, where two simple physical requirements —the principles of relativity and light speed invariance— are used to derive the mathematical structure of Minkowski space-time and its transformations.

9:00AM H29.00004 Homogeneous Self-Dual Cones and the Structure of Quantum Theory , ALEXANDER WILCE, Susquehanna University — This talk reviews recent and on-going work with Howard Barnum on the origins of the Jordan-algebraic structure of finite-dimensional quantum theory. I begin by surveying various principles — e.g., that every state of a bipartite system arise as the marginal of a "steering" bipartite state – - that force the cone of (un-normalized) states of a finite-dimensional probabilistic system to be homogenous and *weakly* self-dual, that is, isomorphic to its dual cone. Where this weak self-duality can be implemented by an inner product, the cone is *strongly* self dual. In this case, classical results of Koecher and Vinberg show that it is isomorphic to the cone of squares in a formally real Jordan algebra. If this is the case, then (using a theorem of H. Hanche-Olsen) one can show that the only locally-tomographic theory containing at least one qubit is finite-dimensional Complex QM. I conclude with a brief discussion of how one might motivate strong self-duality.

9:12AM H29.00005 Quaternions and the Quantum[1] , MATTHEW GRAYDON, University of Waterloo and Perimeter Institute for Theoretical Physics — Birkhoff and von Neumann pointed out that quantum probability calculi could be formulated over rings admitting involutory anti-automorphisms [1]. We discuss a model for generalized quantum measurements and quantum states based on quaternionic matrix algebras. We show that the usual Born rule for calculating probabilities for outcomes of quantum measurements can be carried over into quaternionic quantum theories within a Jordan-algebraic framework. We exploit a group isomorphism between Sp(1) and SU(2) to show that single-system unitary dynamics and generalized measurements in a quaternionic quantum theory can be simulated by corresponding processes in usual quantum mechanics. We resurvey the divide between quaternionic and complex quantum theories given this quadit-qudit correspondence. Reference: [1] G. Birkhoff and J. Von Neumann, "The logic of quantum mechanics", Ann. Math., 37, 823-843 (1936).

[1]This work was supported in part by the U. S. Office of Naval Research (Grant No. N00014-09-1-0247).

9:24AM H29.00006 Quantum theory cannot be extended , ROGER COLBECK, Perimeter Institute, Canada, RENATO RENNER, ETH Zurich, Switzerland — Predictions made by quantum theory are generally not deterministic: the theory tells us only how to calculate the probabilities with which measurement outcomes occur. This indeterminism is one of the key differences from classical mechanics and one can ask whether this is the best any theory can offer, or whether observable quantities could be better predicted by some higher theory. In a famous work, Bell considered extensions of quantum theory in the form of local hidden variables and showed that these cannot determine the outcomes of measurements on maximally entangled particles. Here, we go beyond the case of such classical extensions and ask whether any improved predictions can be achieved by any extension of quantum theory. We answer this question in the negative. More precisely, under the assumption that measurement settings can be chosen freely, there cannot exist any extension of quantum theory that provides us with any additional information about the outcomes of future measurements.

9:36AM H29.00007 Eliminating remnants of classical mechanics and the birth of the Schrödinger equation , WOLFGANG P. SCHLEICH, Institute of Quantum Physics, Ulm University, DANIEL GREENBERGER, City College, City University of New York, DONALD H. KOBE, Department of Physics, University of North Texas — We show that the Schrödinger equation emerges from the Hamilton-Jacobi equation for a specific choice of the amplitude R of a wave $\psi \equiv R\exp[IS/\hbar]$ where S is the classical action. This choice eliminates in the wave equation for ψ all remnants of classical mechanics associated with S but at the same time builds via the wave equation for R a bridge to classical mechanics and to the de Broglie pilot wave theory.

9:48AM H29.00008 Modal Quantum Theory , MICHAEL WESTMORELAND, Denison University, BENJAMIN SCHUMACHER, Kenyon College — We present a class of toy model theories similar in structure to ordinary quantum mechanics. Some of these models are based on finite fields instead of complex amplitudes. The interpretation of such theories involves only the "modal" concepts of possibility and necessity rather than quantitative probability measures. Despite its very simple structure, our toy model nevertheless includes many of the key phenomena of actual quantum systems: interference, complementarity, entanglement, nonlocality, and the impossibility of cloning. These results are detailed in arXiv:1010.2929 and arXiv:1010.5452.

10:00AM H29.00009 Time-asymmetry and causal structure , BOB COECKE, RAYMOND LAL, Oxford University — We consider devices with two inputs and two outputs, Alice and Bob each having access to one input and one output. To such a device we associate time-reverses by exchanging the roles of the inputs and the outputs. We find that there are devices which admit a local hidden variable representation, but for which time- reverses enable perfect signaling between Alice and Bob. That is, a "perfect channel in one time direction" becomes a "non-channel in the other direction." Also, for PR boxes time-reverses enable signaling between Alice and Bob, but never as a perfect channel. This result has several consequences. Firstly, it establishes that the arrow of time can be read from signaling structure: signaling means backward in time. It undermines the representation of causal structures as partial orders or similar 'time-symmetric structures', as is often assumed in search of a theory of quantum gravity. They also provide new insights into the structure of the polytope of generalized probabilistic correlations, hence on theories more general than quantum theory. Finally, it contributes to the growing area of research into quantum information processing in relativistic spacetimes. Ref: arXiv:1010.4572

10:12AM H29.00010 Topos formulation of History Quantum Theory , CECILIA FLORI, Perimeter Institute — In this talk I will describe a topos formulation of consistent histories obtained using the topos reformulation of standard quantum mechanics put forward by Doering and Isham. Such a reformulation leads to a novel type of logic with which to represent propositions. In the first part of the talk I will introduce the topos reformulation of quantum mechanics. I will then explain how such a reformulation can be extended so as to include temporally-ordered collection of propositions as opposed to single time propositions. Finally I will show how such an extension will lead to the possibility of assigning truth values to temporal propositions.

10:24AM H29.00011 Causal Tapestries , WILLIAM SULIS, McMaster University — Causal sets provide one of many approaches to the problem of quantum gravity. Causal tapestries generalize the concept of a causal set, extending the range of putative dynamics from sequential growth to include iterative and non deterministic methods, and the range of embedding manifolds to include those with curvature. Like causal sets, causal tapestries are manifestly Lorentz invariant in spite of possessing a form of "transient now". It is shown that the order relations of the local causal structures must possess an order theoretic (Dushnik & Miller) dimension not exceeding the topological dimension of the embedding manifold and the finite free dimension is bounded by the number of elementary processes generating the causal relations.

10:36AM H29.00012 ABSTRACT WITHDRAWN –

10:48AM H29.00013 The quantal algebra and abstract equations of motion , SAMIR LIPOVACA — Classical and quantum mechanics common characteristics reveal core physics features that are hidden by the details related to the realizations of those theories in phase and Hilbert space respectively. The quantal algebra combines classical and quantum mechanics into an abstract structurally unified structure. It is based on two observations which can be made about classical and quantum mechanics. The first observation is that classical and quantum mechanics use two products: one symmetric and one anti-symmetric. The second observation is that classical and quantum mechanics obey the so-called composability principle: any two physical systems can interact with each other. The local structure of spacetime is contained in the quantal algebra without having been postulated. We will generalize classical and quantum mechanics equations of motion to abstract equations of motion in which the anti-symmetric product of the quantal algebra plays a central role. We will express the defining identities of the quantal algebra in terms of the abstract derivation. In this form it is easy to see that the first defining identity (the Jacobi identity) captures the essence of the Bianchi identity in general relativity which is one set of gravitational field equations for the curvature tensor.

Tuesday, March 22, 2011 8:00AM - 10:00AM –

Session H30 DCMP: Graphene: Synthesis and Characterization C147/154

8:00AM H30.00001 Electrical breakdown of graphene and few-layer graphene structures , ABHISHEK SUNDARARAJAN, STEPHEN JOHNSON, D. PATRICK HUNLEY, ROEL FLORES, University of Kentucky, A.T CHARLIE JOHNSON, University of Pennsylvania, DOUGLAS STRACHAN, University of Kentucky — The electrical breakdown of graphene and few-layer graphene (FLG) structures are investigated. To better understand the dynamics of these nano-scale thermal effects, we investigate graphene and FLG nanowires of various dimensions and find that significant joule heating occurs inducing the structures to evolve. A distinct change in the behavior during electrical stressing indicates that different mechanisms occur at the various stages of evolution. The results are compared to detailed thermal modeling of our structures and could have implications on the development of high current carrying nanoscale graphene devices. Supported in part by NSF Award No. DMR-0805136, the Kentucky NSF EPSCoR program, the University of Kentucky Center for Advanced Materials, and the University of Kentucky Center for Nanoscale Science and Engineering.

8:12AM H30.00002 Designing all-graphene nano-junctions by covalent functionalization , CATERINA COCCHI, ALICE RUINI, S3 CNR-Nano & University of Modena, IT, DEBORAH PREZZI, S3 CNR-Nano, IT, MARILIA J. CALDAS, University of Sao Paulo, BR, ELISA MOLINARI, S3 CNR-Nano & University of Modena, IT — We study the effect of covalent edge functionalization, with organic functional groups, on the opto-electronic properties of graphene nano-flakes and nano-junctions. We work within the frame of Hartree-Fock-based semi-empirical methods [1,2]. Our study shows that functionalization can be designed to tune electron affinities and ionization potentials of graphene flakes. The stability of the proposed mechanism is analyzed with respect to the functional groups, the functionalization rate and the width of graphene nanostructures. We show that this effect can be exploited to realize type-II all-graphene nano-junctions. Different frontier orbital alignments can be engineered varying the functionalization, leading to specific optical properties: The conditions to obtain charge transfer excitations are investigated.

8:24AM H30.00003 Schottky diode via dielectrophoretic assembly of reduced graphene oxide sheets between dissimilar metal contacts , MUHAMMAD R. ISLAM, DAEHA JOUNG, SAIFUL KHONDAKER, Nanoscience Technology Center, Department of Physics, University of Central Florida, Orlando, Florida 32826 — Reduced graphene oxide (RGO) has attracted significant attention due to its ability to produced graphene nanostructures in large quantities. It has been also considered as a promising building block for future generation of electronic and optoelectronic devices. Here we demonstrate fabrication of RGO Schottky diodes with high yield via dielectrophoretic (DEP) assembly between two dissimilar metal contacts. Titanium (Ti) was used to make a Schottky contact, while palladium (Pd) was used to make an Ohmic contact. From the current - voltage characteristics, we obtain rectifying behavior with a rectification ratio of up to 600. The ideality factor was high (4.9) due to the presence of a large number of defects. The forward biased threshold voltage was 1 V while the reverse bias breakdown voltage was - 3.1 V which improved further upon mild annealing at 200° C and can be attributed to an increase of work function of RGO due to annealing.

8:36AM H30.00004 Graphitic carbon molecular beam epitaxy on dielectric substrates[1] , ULRICH WURSTBAUER, RUI HE, ALBERT RIGOSI, Dept. of Physics, Columbia University, THEANNE SCHIROS, Energy Frontier Research Center, Columbia University, ANNETTE PLAUT, School of Physics, Exeter University, LOREN N. PFEIFFER, Princeton University, PHILIP KIM, ABHAY PASUPATHY, ARON PINCZUK, Dept. of Physics, Columbia University, JORGE M. GARCIA, Dept. of Physics, Columbia University, Instituto de Microelectrónica de Madrid, IMM-CNM, CSIC — We report on growth of thin large area graphitic layers on dielectric substrate materials by means of molecular beam epitaxy (MBE) under UHV conditions. This solid source MBE technique offers highly controllable conditions without the need of gas precursors or metal surfaces. Our initial experiments on dielectric substrates such as mica, SiO_2 and BN clearly demonstrates the potential of this new growth technique. NEXAFS studies show that the binding mechanism in our sheets is dominated by sp^2 bonds and the Raman spectra confirm their graphitic nature. We will also describe STM measurements of the topography and local electronic structure of these films.

[1]Work supported by ONR (N000140610138 and Graphene Muri), NSF (CHE-0117752 and CHE-0641523), NYSTAR, CSIC-PIF (200950I154), Spanish CAM (Q&C Light (S2009ESP-1503), Numancia 2 (S2009/ENE-1477)), Spanish MICINN (NANINPHO-QD, TEC2008-06756-C03-01).

8:48AM H30.00005 Stability of epitaxial graphene on pristine Si(111) , BRANDEN KAPPES, TERESA DAVIES, Colorado School of Mines, SUKKY JUN, University of Wyoming, ADRI VAN DUIN, Penn State University, CRISTIAN CIOBANU, Colorado School of Mines — Incorporation of carbon nanostructures with silicon-based nanoelectronics will involve the direct integration of graphene with silicon chips, but so far graphene has not been grown on pristine silicon surfaces. Because usual synthesis routes would likely lead to the formation of silicon carbide, we calculate the binding energy of graphene transferred onto the Si(111) surface and also analyze its stability at various temperatures. Our calculations based on (commensurate) moiré superstructures with periodic boundary conditions show a strong graphene–substrate binding, about 1.5 eV/carbon atom, over a wide range of in-plane orientations of the graphene layer. Molecular dynamics simulations based on bond-order and reactive force field interatomic potentials suggest that the graphene binds to the substrate where carbon is rehybridized sp^3, and that this rehybridized graphene structure does not lead to the decomposition of graphene into silicon carbide even at temperatures as high as 80% of the substrate melting temperature.

9:00AM H30.00006 Synthesis and characterization of graphene patterned with Fe_3O_4 nanoparticles , SAYAN CHANDRA, K. STOJAK, D. FERIZOVIC, M. MUNOZ, M.H. PHAN, H. SRIKANTH, University of South Florida — Graphene has emerged as a very exciting material with its outstanding physical, chemical, and mechanical properties. Due to the presence of excess free electrons on a graphene surface, the possibility of graphene-mediated long-range interactions between magnetic nanoparticles would open up new avenues of research and device development. Our studies aimed to deposit $\sim$9 nm Fe_3O_4 NPs on graphene layers to understand the role of the metallic interface in mediating the magnetic interactions between the particles. We successfully grew the high-quality graphene on Ni films using CVD and used the Langmuir-Blodgett technique to pattern different layers of the Fe_3O_4 nanoparticles on the graphene sheets. The samples were well structurally characterized by XRD, TEM, AFM, and Raman spectroscopy. Interestingly we have observed strong variation in the magnetic properties such as magnetic anisotropy of the NPs pattered graphene samples when compared to just the NPs. These results point to the important role of the metallic interface in mediating the magnetic interactions between the Fe_3O_4 nanoparticles.

9:12AM H30.00007 Scaled-Up Synthesis and Characterization of High-Purity Graphene , PATRICIA JOHNSON, MARK GRIEP, KRISTOPHER BEHLER, ROSE PESCE-RODREQUEZ, SHASHI KARNA, WENDY SARNEY, Army Research Laboratory, KATE DUNCAN, CERDEC — Graphene, a two-dimensional, single-atom sheet of carbon atoms, discovered in 2004, has emerged as a new class of novel nano-scale material due to its unique chemical and physical properties, and potential applications in a wide range of civilian and military technologies. However, a major challenge in its technological application is a lack of chemical/physical method(s) to produce/synthesize high-purity graphene in viable quantity. Another challenge in the technological application of graphene is a lack of detailed understanding of its structure-property relationship. In order to address these issues, we have developed a chemical exfoliation method that yields high-purity graphene in bulk quantity. The method is scalable to produce large quantities of high purity graphene. In this paper, we present the results of our synthetic approach and structure-property characterization of graphene.

9:24AM H30.00008 Two-Dimensional Molecular Crystals of Phosphonic Acids on Graphene , MARIANA PRADO, BERNARDO NEVES, REGIANE NASCIMENTO, LUCIANO MOURA, MATHEUS MATOS, MARIO MAZZONI, LUIZ CANCADO, HELIO CHACHAM, Universidade Federal de Minas Gerais — The synthesis and characterization of two-dimensional (2D) molecular crystals comprised of long and linear phosphonic acids atop graphene is reported. Using scanning probe microscopy in combination with first-principles calculations, we show that these true 2D crystals are oriented along graphene armchair direction only, thereby enabling an easy determination of graphene flake orientation. We have also compared the doping level of graphene flakes via Raman spectroscopy. The presence of the molecular crystal atop graphene induces a well-defined shift in the Fermi level, corresponding to hole doping, which is in agreement with our ab initio calculations.

9:36AM H30.00009 Carbon chains grown perpendicularly on graphene: Nanobrush , CAN ATACA, Department of Physics, Bilkent University, Ankara, Turkey, 06800, SALIM CIRACI, Department of Physics, Bilkent University, Ankara, Turkey, 06800; UNAM-Material Science and Nanotechnology, Bilkent University, Ankara, Turkey, 06800. — We predict a peculiar growth process, where carbon adatoms adsorbed to graphene readily diffuse above room temperature and form linear chains. These chains grow longer on graphene through insertion of carbon atoms one at a time from the bottom end. Through this growth process two allotropic forms of carbon, namely graphene and polyyne are combined to make several novel nanostructures. Brush like graphene sheets with protruding polyynes can achieve chemical activity and attain new functionalities.

9:48AM H30.00010 Size Control of Nanographene Directly Grown On Glass , JAEWU CHOI, Kyung Hee University — We directly deposited very thin carbon film was on glass by thermal chemical deposition at 750 °C without using any catalyst. The directly deposited carbon film consists of nanographene with an in-plane crystal size of $\sim$ 15 nm. The in-plane crystal size of nanographene increased up to 23 nm by annealing of the post-deposited nickel film on the nanographene film at 300 °C to 500 °C. This study suggests that nanographene can be directly deposited on glass at low temperature and that the crystalline size can be controlled.

Tuesday, March 22, 2011 8:00AM - 10:48AM –

Session H31 DMP GSCCM DCOMP: Focus Session: Materials at High Pressure I: Molecular and Simple Materials C145

8:00AM H31.00001 Structural investigation and shock Hugoniot calculations of methane under high temperatures and pressures , BENJAMIN SHERMAN, California State University, Northridge, BURKHARD MILITZER, HUGH WILSON, University of California, Berkeley, DAYANTHIE WEERARATNE, California State University, Northridge — The behavior of methane under pressures and temperatures spanning 0.02-7.75 Mbar and 300-30,000 K was studied using density functional molecular dynamics. The structural properties of fluid and crystalline methane were analyzed with simulations at various (P,T) conditions. These simulations were also used to calculate the shock Hugoniot curves of methane for a range of initial densities between 0.4-0.57 g/cc. These curves allow us to make predictions of state and phase that correspond to future methane shock experiments.

8:12AM H31.00002 Proton Exchange Reactions in Deuterium Water Mixtures[1] , GUSTAV BORSTAD, Institute for Shock Physics, Dept. of Physics, Washington State University, Pullman, WA 99164, CHOONG-SHIK YOO, Institute for Shock Physics, Dept. of Chemistry, Washington State University, Pullman, WA 99164 — Binary mixtures of water and hydrogen under pressure are of interest both as fundamental systems in physics and chemistry and due to their applicability to fuel cells. Their behaviors at extreme pressures and temperatures are also of significance to understanding the interaction of chemical species in the interiors of giant gas planets and other planetary objects. In this talk, we will present high-pressure Raman data of deuterium water mixtures, which provides both kinetic information regarding the proton exchange reactions and the structure of deuterium in the mixtures.

[1]The work has been supported by NSF (DMR-0854618) and DOE-NNSA (# DE-F603-97SF21388).

8:24AM H31.00003 Zero-Temperature Structures of Atomic Metallic Hydrogen , JEFFREY MCMAHON, DAVID CEPERLEY, Department of Physics, University of Illinois, Urbana-Champaign, IL 61801 — Since the first prediction of an atomic metallic phase of hydrogen by Wigner and Huntington over 75 years ago, there have been many theoretical efforts aimed at determining the crystal structures of the zero-temperature phases. We present results from ab initio random structure searching with density functional theory performed to determine the ground state structures from 500 GPa to 5 TPa. We estimate that molecular hydrogen dissociates into a monatomic body-centered tetragonal structure near 500 GPa ($r_s = 1.225$), which then remains stable to 2.5 TPa ($r_s = 0.969$). At higher pressures, hydrogen stabilizes in an $...ABCABC...$ planar structure that is remarkably similar to the ground state of lithium, which compresses to the face-centered cubic lattice beyond 5 TPa ($r_s < 0.86$). Our results provide a complete ab initio description of the atomic metallic crystal structures of hydrogen, resolving one of the most fundamental and long outstanding issues concerning the structures of the elements.

8:36AM H31.00004 Phase Diagram of Carbon Dioxide at High Pressure and Temperatures: Implications to the Deep Carbon Cycle[1] , CHOONG-SHIK YOO, Dept of Chemistry and Institute for Shock Physics, Washington State University, Pullman, WA 99164, AMARTYA SENGUPTA, Institute for Shock Physics, Washington State University, Pullman, WA 99164 — Carbon dioxide is an important terrestrial volatile often considered to exist in the deep interior of the Earth. The phase diagram of carbon dioxide is critical to validate such hypothesis. In this study, we will present the phase diagram of carbon dioxide including the most recent finding of coesite-like carbon dioxide, a missing analog to SiO_2, address several controversies in terms of phase metastabilities and thermal path dependent transitions, and discuss about the implication to the deep carbon cycle.

[1]The work has been supported by NSF (DMR-0854618) and DARPA (W911NF-10-1-0081).

8:48AM H31.00005 Structural and optical properties of liquid CO_2 up to 1 terapascal[1] , BRIAN BOATES, Lawrence Livermore National Laboratory & Dalhousie University, SEBASTIEN HAMEL, ERIC SCHWEGLER, Lawrence Livermore National Laboratory, STANIMIR BONEV, Lawrence Livermore National Laboratory & Dalhousie University — The properties of liquid CO_2 have been studied through first-principles molecular dynamics simulations in the pressure-temperature range of 0-1 TPa and 200-100,000 K. The resulting equation of state data is used to predict shock Hugoniots for several initial conditions. Comparison with available experimental data up to 70 GPa is excellent. We find a gradual phase transition characterized by the destabilization of CO_2 molecules and the formation of other molecular compounds. The liquid phase diagram is divided into several regimes based on a thorough analysis on changes in bonding, structural properties, and chemical composition. Calculations of optical properties such as conductivity and reflectivity will also be discussed.

[1]Work supported by NSERC, LLNL, the Killam Trusts, and Acenet. Prepared by LLNL under Contract DE-AC52-07NA27344.

9:00AM H31.00006 Density Functional Theory (DFT) simulations of CO2 under shock compression and design of liquid CO2 experiments on Z[1] , T. R. MATTSSON, L. SHULENBURGER, S. ROOT, Sandia National Laboratories, Albuquerque, NM., K. R. COCHRANE, Ktech Corporation, Albuquerque, NM. — Quantitative knowledge of the thermo-physical properties of CO2 at high pressure is required to confidently model the structure of gas-giants like Neptune and Uranus and the deep carbon cycle of the earth. DFT based molecular dynamics has been established as a method capable of yielding high fidelity results for many materials, including shocked gases, at high pressure and temperature. We predict the principal Hugoniot for liquid CO2 up to 500GPa. Our simulations also show that the plateau in shock pressure identified by Nellis and co-workers [1] is the result of dissociation. At low temperatures we validate the DFT results by comparing with diffusion Monte Carlo calculations. This allows for a more accurate determination of the initial conditions for the shock experiments. We also describe the design of upcoming flyer-plate experiments on the Z-machine aimed at providing high-precision shock compression data for CO2 between 150 and 600 GPa. [1] W. Nellis, et. al. , J. Chem. Phys. **95**, 5268 (1991).

[1]Sandia National Laboratories is a multiprogram laboratory managed and operated by Sandia Corp. for the US Dept. of Energy's National Nuclear Security Administration under Contract DE-AC04-94AL85000.

9:12AM H31.00007 Novel phases of simple substances at megabar pressures , MIKHAIL EREMETS, Max Planck Institute for Chemistry — Under megabar pressures solids can be strongly compressed: volume of solid hydrogen decreases in $\sim$20 times, even diamond is 1.5 fold compressed at achievable pressures of $>$300 GPa. This dramatically changes interatomic distances in materials eventually leading to metallization in a number of presenting substances. Metals under compression supposedly remain in metallic state. But at high densities the core electrons come in to play and the electronic structure significantly departs from the simple metal as it was demonstrated for lithium. We present an ultimate case: sodium - simple metal - becomes transparent at pressures of $\approx$200 GPa transforming into ionic- electride-like state. We will present also our recent studies on nitrogen and nitrogen-rich materials: ammonia, azides and others, and progress on studies at pressures $\sim$400 GPa.

9:48AM H31.00008 Diamond as a high pressure gauge up to 2.7 MBar , NATALIA DUBROVINSKAIA, LEONID DUBROVINSKY, RAZVAN CARACAS, MICHAEL HANFLAND — Diamond anvil cell (DAC) technique has become a very important method of probing materials behaviour under pressure in various fields of research ranging from physics to biology and geoscienses. Optical methods of pressure determining in DAC experiments are based on fluorescent markers or calibrated pressure dependence of the Raman shift of suitable materials. Diamond has been since long recognised as a good pressure marker in experiments conducted in a diamond anvil cell. It is stable at ultra-high pressures that allows one to use the pressure dependence of the Raman frequency of the LTO optical phonon of diamond as a pressure gauge. A pressure gauge is a key issue of any high pressure experiment in a diamond anvil cell. Here we present a method of *in situ* synthesis of microcrystals of diamond that can be further used as a pressure standard in course of the same DAC experiment. Calibration curve of the Raman shift *vs* pressure is extended up to 270 GPa and experimental results are compared with those of *ab initio* calculations.

10:00AM H31.00009 High-pressure and high temperature deformation studies of polycrystalline diamond , XIAOHUI YU — With Vicker's hardness 120 GPa, shear modulus 535 GPa, diamond is the hardest material known to mankind. However, because diamond is difficult to deform, little is known with regard to its constitutive properties such as yield strength. In this work, we present results obtained at NSLS using deformation-DIA on polycrystalline diamond at different P-T conditions. As expected, even at total strains up to 20%, we did not observe the yield point of diamond at room temperature and a confining pressure of 4 GPa. However, for deformation at 1000 and 1200 °C, we observed an plastic flow of diamond at total strains of 10% and 5%, respectively, indicating that diamond weakens rapidly when temperature is over 1000 °C. We further derived the micro stress of diamond from peak width analysis, and found that the micro and macro stresses show similar variations with total strain at both room temperature and 1000 °C. However, at 1200 °C, the micro stress remains constant in entire deformation, indicating that stress is uniformly distributed within diamond particles at 1200 °C. We also carried out SEM studies on the recovered samples to investigate the miscrostructures, and find that the grain size of diamond decreases substantially during the deformation, from the initial microns to sub-microns for the room temperature deformation, however, almost doesn't change for the 1200 °C.

10:12AM H31.00010 New primary pressure calibrants for high pressure and temperature scale: SiC-3C and cBN are possible candidates , KIRILL ZHURAVLEV, ALEXANDER GONCHAROV, Carnegie Institution of Washington, VITALI PRAKAPENKA, University of Chicago — Since the invention of a diamond-anvil cell, various high-pressure scales for in situ pressure measurements have been realized. Ruby-based pressure scale (Mao et al., 1986) is the best known and high-pressure scientific community has been using it for over two decades. However, it has limited use at elevated temperatures, due to the weakening and broadening of the ruby fluorescence line. The recent developments in the field of high temperature, high pressure physics and geophysics require some alternative pressure scale, capable of measuring pressures at temperatures up to 3000 K. Cubic boron nitride (cBN) was recently proposed as the possible pressure calibrant. It has been suggested that the simultaneous use of x-ray diffraction to measure density and Brillouin spectroscopy to obtain elastic properties of the crystal can be used to construct the pressure scale independent of any other pressure standards. However, the acoustic velocities of cBN are very close to those of diamond and, therefore, are hard to resolve in experiment in diamond-anvil cell. Another possible primary pressure calibrant is cubic silicon carbide (SiC-3C). We performed single crystal x-ray diffraction and Brillouin spectroscopy up to 1 Mbar in pressure at room temperature in the diamond-anvil cell and show that cBN and SiC-3C, indeed, can be used in constructing reliable and accurate high-pressure, high-temperature scale.

10:24AM H31.00011 Formation and superconductivity of hydrides under pressure[1] , DUCK YOUNG KIM, TCM group, Cavendish laboratory, University of Cambridge, UK, RALPH H. SCHEICHER, Uppsala University, Sweden, CHRIS J. PICKARD, University College London, UK, RICHARD J. NEEDS, TCM group, Cavendish laboratory, University of Cambridge, UK, RAJEEV AHUJA, Uppsala University, Sweden — Hydrogen is the lightest and smallest element in the periodic table. Despite its simplest electronic structure, enormous complexity can arise when hydrogen participates in the formation of solids. Pressure as a controllable parameter can provide an excellent platform to investigate novel physics of hydrides because it can induce structural transformation and even changes in stoichiometry accompanied with phenomena such as metallization and superconductivity. In this presentation, we will briefly overview contemporary high-pressure research on hydrides and show our most recent results on predicting crystal structures of metal hydrides under pressure using ab initio random structure searching. Our findings allow for a better understanding of pressure-induced metallization/superconductivity in hydrides which can help to shed light on recent observations of pressure-induced metallization and superconductivity in hydrogen-rich materials.

10:36AM H31.00012 Mechanical properties of icosahedral boron carbide explained from first principles , ROMAN RAUCOULES[1], NATHALIE VAST, EMMANUEL BETRANHANDY, JELENA SJAKSTE, LSI - Ecole Polytechnique — An exhaustive DFT study of the structural defects of icosahedral B_4C and of their behavior under high pressure has been performed. Among the possible atomic structures, the lowest value of the formation energy has been found for the *polar* model B_4C^P, which consists of one distorted icosahedron and of one CBC chain. This result, together with the inspection of the vibrational and NMR spectra, has proved that B_4C^P is the proper structural model for B_4C.[1,2] Consequently, B_4C^P has been used as a matrix to isolate the defects. The native defects have been identified and shown to be energetically stable at high pressure. Most vacancy locations in B_4C^P are found to be energetically unstable and only a boron vacancy in the CBC chain is stable. A cluster of this vacancy is shown to induce a dynamical instability of the icosahedra when the pressure is increased. The dynamical failure of shocked B_4C [3] is attributed to the increase in the concentration of these unstable vacancies under plastic deformation. 1. R. Lazzari, N.Vast, J.M. Besson, S. Session H32 DMP: Focus Session: Photonic Crystals, Metamaterials and Other Optical Systems C144

8:00AM H32.00001 Disordered Hyperuniform Photonic Band Gap Materials , MARIAN FLORESCU, Department of Physics, Princeton University, WEINING MAN, Department of Physics and Astronomy, San Francisco State University, PAUL CHAIKIN, Department of Physics, New York University, SALVATORE TORQUATO, Department of Chemistry, Princeton University, PAUL J. STEINHARDT, Department of Physics, Princeton University — Until recently, the only materials known to have complete photonic band gaps were photonic crystals, periodic structures, and it was generally assumed that long-range periodic order was instrumental in the band gap formation. We have shown that there exists a more general class of systems, called hyperuniform photonic structures, which exhibit large and complete photonic band gaps. This classification includes not only crystalline structures, but also non-crystalline materials, ranging from quasicrystals with crystallographically-forbidden rotational symmetries to isotropic, translationally-disordered structures. Remarkably, we find that the photonic band gaps in hyperuniform disordered structures are not only comparable to those found in photonic crystals, but also display a high degree of isotropy. These new materials possess unique photonic and physical properties that provide important advantages for applications. Our results show that hyperuniform disordered structures enable the realization of optical cavities with ultimate isotropic confinement of the electromagnetic radiation, lossless waveguides with arbitrary bending angles and flexible optical insulator platforms.

8:12AM H32.00002 Experimental observation of photonic bandgaps in two dimensional hyperuniform disordered materials , SEYED HASHEMIZAD, WEINING MAN, San Francisco State University, MARIAN FLORESCU, Princeton University, POLIN YADAK, KAZUE MATSUYAMA, San Francisco State University, SALVATORE TORQUATO, PAUL STEINHARDT, Princeton University, PAUL CHAIKIN, New York University — We report the first experimental demonstration of photonic bandgaps (PBGs) in 2D hyperuniform disordered materials and show that is possible to obtain isotropic, disordered, photonic materials of arbitrary size with complete PBGs. There are only limited numbers of allowed rotational symmetries in periodic or quasiperiodic structures. Periodicity and Bragg scattering lead to different stop gap center frequencies in different directions, since periodicities change in different directions. Hyperuniformity together with short range geometric order and uniform local topology are enough to give raise to an isotropic PBG. Hyperuniform systems have a variance in mass or particle number which varies with distance, r, from an arbitrary point less rapidly than the d dimensional volume. We present a new class of photonic materials posessing PBGs that have a number of advantages, including: isotropy, robustness against disorder (they are already disordered), flexibility (can fit arbitrary regions of space in which one may have trouble putting a periodic system), and possibly lower minimum dielectric contrast.

8:24AM H32.00003 Photonic density of states of 2D quasicrystals from level set equations and decorated quasiperiodic tiling patterns , LIN JIA, ION BITA, EDWIN THOMAS, DMSE Massachusetts Institute of Technology — The TE and TM photonic band gaps (PBG) of 8mm, 10mm, and 12mm rotationally symmetric 2D quasicrystals (QCs) were numerically investigated for families of morphologies generated from level set equations and from quasiperiodic tiling patterns decorated with cylindrical rods, respectively. We discovered a 12mm QC with 56.5% TE PBG, which is the largest reported TE PBG for aperiodic crystals to date. Further, we find that the TM PBG of 2D QC is highly related to the shape of the structural features comprised by the QC morphology. Two physical models are presented to explain the decrease of the center frequency of PBG as dielectric filling ratio increases.

8:36AM H32.00004 Measurement of photonic band diagram in non-crystalline photonic band gap (PBG) materials , WEINING MAN, ERIC WILLIAMSON, SEYED HASHEMIZAD, POLIN YADAK, San Francisco State Univ., Dept. of Physics & Astronomy, MARIAN FLORESCU, Princeton University, Physics Dept. — Non-crystalline PBG materials have received increasing attention recently and sizeable PBGs have been reported in quasi-crystalline structures or even in disordered structures. Band calculations for periodic structures produce accurate dispersion relations in them and refraction properties at their surfaces. However, band calculations for non-periodic structures employ large super-cells of N $>$100 building blocks, and provide little useful information other than the PBG frequency and width. Since band is folded into N bands, within the first Brillouin zone of the supper-cell. Using stereolithography, we construct various quasi-crystalline or disordered PBG materials and perform transmission measurements. The dispersion relations of EM wave (band diagrams) are reconstructed from the measured phase data. Our experiments not only verify the existence of sizeable PBGs in these structures, but also provide detailed information of the effective band diagrams, dispersion relation, group velocity vector, and their angular dependence. Slow light phenomena are also observed in these structures near gap frequencies. This study presents a powerful tool to investigate photonic properties of non-crystalline structures and provides important dispersion information, which is otherwise impossible to obtain.

8:48AM H32.00005 MWIR tunable polarmetric scatterometery applied to a fishnet structure , STEPHEN NAUYOKS, MICHAEL MARCINIAK, Air Force Institute of Technology — Understanding how light is scattered by a material, such as a metamaterial, which is engineered to have specific optical properties is necessary for a better understanding of the design parameters and for refining designs. Because of their high irradiance and small spot size, lasers are an ideal light source for these scatter measurements. However, lasers are highly monochromatic and it can be very difficult to manufacture metamaterials to resonate at such specific wavelengths. By modifying a Schmitt Measurement System's Complete Angle Scatter Instrument (CASI) with the addition of 6 external cavity Quantum Cascade Lasers by Daylight Solutions we were able to have a tunable laser light source from 4.35 to 9.71 μm with a small exclusion from 6.54 to 7.40 μm. The CASI system was further modified with the addition of a dual rotating retarder which allows the full Mueller matrix to be calculated for both specular scatter and off specular scatter. This makes the system unique to commercially available systems like Woollam's IR-VASE which can only measure the Mueller matrix elements for the specular reflection. This unique system was used to measure a fishnet structure at both resonate and off resonate frequencies. The fishnet sample was also measured using an IR-VASE system to compare specular results.

9:00AM H32.00006 Electromagnetism in multicoaxial negative-index metamaterial cables , BAHRAM DJAFARI-ROUHANI, University of Science & Technology of Lille1, France, MANVIR KUSHWAHA, Rice University — By using an elegant Green [or response] function theory, which does not require matching of the messy boundary conditions, we investigate the surface plasmon excitations in the multicoaxial cylindrical cables made up of negative-index metamaterials. The multicoaxial cables with *dispersive* metamaterial components exhibit rather richer (and complex) plasmon spectrum with each interface supporting two modes: one TM and the other TE for (the integer order of the Bessel function) $m \neq 0$. The cables with *nondispersive* metamaterial components bear a different tale: they do not support simultaneously both TM and TE modes over the whole range of propagation vector. The computed local and total density of states enable us to substantiate spatial positions of the modes in the spectrum. Such quasi-one dimensional systems as studied here should prove to be the milestones of the emerging optoelectronics and telecommunications systems.

9:12AM H32.00007 Universal shift of the Brewster angle in stratified random media , KWAGN JIN LEE, KIHONG KIM, Division of Energy Systems Research, Ajou University, Suwon, 443-749, Korea — We study theoretically the propagation and the Anderson localization of p-polarized electromagnetic waves incident obliquely on randomly stratified dielectric media with weak uncorrelated Gaussian disorder. Using the invariant imbedding method, we calculate the localization length and the disorder-averaged transmittance in a numerically precise manner. We find that the localization length takes an extremely large maximum value at some critical incident angle, which we call the generalized Brewster angle. The disorder-averaged transmittance also takes a maximum very close to one at the same incident angle. Even in the presence of an arbitrarily weak disorder, the generalized Brewster angle is found to be substantially larger than the ordinary Brewster angle in uniform media. It is a rapidly increasing function of the average dielectric permittivity and approaches 90 degrees when the average relative dielectric permittivity is slightly larger than two. We find that the dependence of the generalized Brewster angle on the average dielectric permittivity is universal in the sense that it is independent of the strength of disorder and the wave frequency. We also make a surprising observation that when the p wave is incident from an optically denser region, the localization length and the average transmittance become larger for stronger disorder in a wide range of incident angle.

9:24AM H32.00008 Unidirectional suppresion of Bragg reflection in grated PT-symmetric media , ZIN LIN, Wesleyan University, HAMIDREZA RAMEZANI, TSAMPIKOS KOTTOS, TONI EICHELKRAUT, DEMETRIS CHRISTODOULIDES, University of Central Florida, COMPLEX QUANTUM DYNAMICS AND MESOSCOPIC PHENOMENA GROUP, WESLEYAN UNIVERSITY TEAM, COLLEGE OF OPTICS AND PHOTONICS-CREOL,UNIVERSITY OF CENTRAL FLORIDA TEAM — We study the scattering properties of light through optical fibers with grating that involves gain/loss modulation that respect Parity-Time (PT) symmetry. We derive analytical expressions for transmission and reflection coefficients both in the presence and absence of Kerr non-linearity. At the spontaneous PT-symmetric point we have found that Bragg reflection is suppressed once the light is injected from the left, while it is amplified (with respect to the passive medium) if the fiber is illuminated from the right. Our results are robust for a large interval of the detuning parameter away from the Bragg wavelength.

9:36AM H32.00009 Application of Iterative Time-Reversal for Electromagnetic Wave Focusing in a Wave Chaotic System[1] , BINIYAM TADDESE, THOMAS ANTONSEN, EDWARD OTT, STEVEN ANLAGE, University of Maryland — Time-reversal mirrors exploit the time-reversal invariance of the wave equation to achieve spatial and temporal focusing, and they have been shown to be very effective sensors of perturbations to wave chaotic systems. The sensing technique is based on a classical analogue of the Loschmidt echo [1]. However, dissipation results in an imperfect focusing, hence we created a sensing technique employing exponential amplification to overcome this limitation [1,2]. We now apply the technique of iterative time-reversal, which had been demonstrated in a dissipative acoustic system, to an electromagnetic time-reversal mirror, and experimentally demonstrate improved temporal focusing. We also use a numerical model of a network of transmission lines to demonstrate improved focusing by the iterative technique for various degrees and statistical distributions of loss in the system. The application of the iterative technique to improve the performance and practicality of our sensor is explored.

9:48AM H32.00010 Optimizing energy transfer efficiency in highly branched nanoplasmonic waveguides , DMITRI VORONINE, ANDREW TRAVERSO, KAI WANG, ZHENHUAN YI, ALEXEI SOKOLOV, Institute for Quantum Science and Engineering, Texas A&M University, College Station TX — Energy transfer in highly branched nanoplasmonic particle waveguides is simulated and optimized by varying the waveguide branching geometry and composition. The periodically branched nanostructures provide a new route towards efficient nanoscale light concentration and local field enhancement. On the one hand, they mimick the analogous randomly branched plasmonic nanostructures which have been previously used for surface-enhanced optical spectroscopy such as SERS. On the other hand, the design is inspired by branched molecular aggregates used for energy funneling. The proposed nanostructures may find applications in sensing, light harvesting and nanophotonics.

10:00AM H32.00011 A Novel Nanoscale Coaxial Optical Microscope by Converging Array of Subwavelength Waveguides , FAN YE, GREGORY MCMAHON, KYLE MARRA, KRZYSZTOF KEMPA, MICHAEL J. NAUGHTON, Boston College — A novel nanoscale coaxial optical microscope (NCOM) is proposed by constructing a converging array of coaxial subwavelength optical waveguides (nanocoax). This new design has potential for deep subdiffraction limit resolution, essentially independent of wavelength of the light source. The coaxial structure also has the capability of modal confinement, which can be utilized to extract phase information in the imaging plane. The transmittance and energy dissipation properties of a single nanocoax are obtained, in the visible light range, by numerical simulation. Optical properties of a converging nanocoax array are also investigated numerically. Finally, progress toward an experimental realization of this novel NCOM is discussed.

10:12AM H32.00012 Trap rainbow in a self-similar coaxial optical waveguide[1] , RU-WEN PENG, QING HU, FENG GAO, RUI-LI ZHANG, MU WANG, National Laboratory of Solid State Microstructures — We report in this work that the light waves with different frequencies can be selectively guided and spatially separated in a self-similar dielectric waveguide, where a hollow core is surrounded by a coaxial Thue-Morse multilayer. Due to the self-similar furcation feature in the photonic band structure, the transmission multibands are achieved. More interestingly, this dielectric waveguide supports cladding modes, which are spatially separated and confined along the waveguide. Consequently, a rainbow can be trapped (spatial confined but not stopped) in the Thue-Morse waveguide. The finding can be applied to designing miniaturized compact photonic devices, such as spectroscopy on a chip. 10:24AM H32.00013 Optical Transmission through Archimedeam Spiral Nanotrenches in Ti Film , FENG WANG, Kent State University, XUEJIN WEN, Ohio State University, KAI SUN, University of Michigan, WU LU, Ohio State University, QIHUO WEI, Kent State University — We study the optical transmission of circularly polarized light through nanoscale Archimedean spiral trenches in Ti film through experiments and numerical simulations; the focus of these studies is on the effect of radial repetition of the spiral nanotrenches. Experimental measurements show that the left and right circularly polarized light exhibit different transmission through the spiral nanotrenches, and the transmission difference decays when the number of the radial periods of the spiral trenches is increased. Numerical simulations reproduce this interesting phenomenon. The underlying physical mechanism of the radial period dependence is attributed to the absorption difference at the center of the spirals.

10:36AM H32.00014 Bio inspired replication and mimicry of optical structure from nature , BEOM-JIN YOON, MATIJA CRNE[1], JUNG OK PARK, MOHAN SRINIVASARAO, CHRISTOPER J. SUMMERS, School of Materials Science and Engineering, Georgia Institute of Technology, Atlanta, GA, 30332 — The optical response from some insects and animals is not from dye or pigment but from their complex structure. The so-called structural color involves interference, diffraction, scattering and photonic crystal effect in various combinations. Structures associated with the structural color have been invasively attended because they have been considered as essentials of optical and photonic devices. The diffraction grating was replicated from beetles by the atomic layer deposition (ALD), and the optical response of resulting structures was characterized. We also present our result on mimicry of the structure of Papilio butterfly. To mimic the structure in the butterfly, we created the basic cup-like structure from polymer films having ordered array of holes, and coated it with an alternating multilayer of the materials. The optical properties of the mimicked structures are also investigated.

10:48AM H32.00015 Carrier recombination lifetime in InGaN/GaN multiquantum well LED , ANTARYAMI MOHANTA, DER-JUN JANG, Department of Physics, National Sun Yat-sen University, Kaohsiung 80424, Taiwan, R.O.C., TAI-FA YOUNG, Department of Mechanical and Electromechanical Engineering, National Sun Yat-sen University, Kaohsiung 80424, Taiwan, R. O. C. — Carrier dynamics in InGaN/GaN multiquantum well LED with 5% In content in InGaN wells is studied by time-resolved photoluminescence (TRPL) using time-correlated single photon counting detection system. The excitation energy is 3.06 eV, frequency-doubled output of a Ti: sapphire laser operating at 808 nm (1.53 eV) with 100 fs pulse width and a repetition rate of 80 MHz. TRPL spectra are fitted biexponentially to obtain decay times. The fast decay process is carrier relaxation and slow decay is the carrier recombination process. The fast relaxation decay time shows insignificant variation with the photon energies and pump fluences. On the other hand carrier recombination time increases with increase of photon energies attaining maximum near photoluminescence peak energy and then decreases again on further increase of photon energies. The carrier recombination life time shows increasing behavior with increase of pump fluences and is obtained as long as $\sim$ 7 ns at pump fluence of 0.21 μJ/cm^2 at room temperature. As the temperature decreases, the carrier recombination life time increases indicating the dominating nature of radiative decay process at low temperatures.

Session H33 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides: Multiferroics & Magnetoelectrics I C143/149

8:00AM H33.00001 Changing Dielectrics into Multiferroics—Alchemy Enabled by Strain , DARRELL SCHLOM, Cornell University — Ferroelectric ferromagnets are exceedingly rare, fundamentally interesting multiferroic materials. The properties of what few compounds simultaneously exhibit these phenomena pale in comparison to useful ferroelectrics or ferromagnets: their spontaneous polarizations (P_s) or magnetizations (M_s) are smaller by a factor of 1000 or more. The same holds for (magnetic or electric) field-induced multiferroics. Recently, however, Fennie and Rabe proposed a new route to ferroelectric ferromagnets[1]—transforming magnetically ordered insulators that are neither ferroelectric nor ferromagnetic, of which there are many, into ferroelectric ferromagnets using a single control parameter: strain. The system targeted, $EuTiO_3$, was predicted to simultaneously exhibit strong ferromagnetism ($M_s \sim 7\ \mu_B$/Eu) and strong ferroelectricity ($P_s \sim 10\ \mu$C/cm^2) under large biaxial compressive strain. These values are orders of magnitude higher than any known ferroelectric ferromagnet and rival the best materials that are solely ferroelectric or ferromagnetic. Hindered by the absence of an appropriate substrate to provide the desired compression, we show[3] both experimentally and theoretically the emergence of a multiferroic state under biaxial *tension* with the unexpected benefit that even lower misfits are required, thereby enabling higher quality crystalline films. The resulting genesis of a strong ferromagnetic ferroelectric points the way to high temperature manifestations of this spin-phonon coupling mechanism.[2] Our work[3] demonstrates that a single experimental parameter, strain, simultaneously controls multiple order parameters and is a viable alternative tuning parameter to composition for creating multiferroics.

Schubert, J.W. Freeland, D.A. Muller, C.J. Fennie, P. Schiffer, V. Gopalan, E. Johnston-Halperin, and D.G. Schlom, *Nature* **466** (2010) 954-958.

8:36AM H33.00002 Magnetoelectric coupling in the strain-induced multiferroic $BiMnO_3$, PATRICK MICKEL, HYOUNGJEEN JEEN, AMLAN BISWAS, ARTHUR HEBARD, University of Florida — $BiMnO_3$ is a rare single phase, multiferroic compound which displays both ferromagnetic and ferroelectric properties. We have grown thin films of $BiMnO_3$on $SrTiO_3$ (100) substrates using pulsed laser deposition that display the presence of both order parameters. The ferroelectricity is found to be highly tunable, modulated by both magnetic fields (decreasing by more than 10%) and external strain (increasing by more than 50%). Time dependent ferroelectric measurements in addition to dielectric characterizations reveal $BiMnO_3$ is a relaxor ferroelectric. The polar-nano-regions (PNRs) responsible for relaxor ferroelectricity are shown to reside at the island edges where strain is inherently high. Understanding the PNR properties is shown to be essential for understanding the magnetoelectric and strain couplings.

8:48AM H33.00003 Magnetoelectric coupling in layered perovskites from first principles , TURAN BIROL, CRAIG J. FENNIE, School of Applied and Engineering Physics, Cornell University — The rational design of a multiferroic with a large polarization and a strong coupling between the polarization and the magnetization remains a challenge. Recognizing the limitations of bulk materials, we attempt to design a strongly coupled multiferroic by focusing on artificial layered materials. In particular, strained Sr-Ti-O layered perovskites have recently been shown to have ferroelectric lattice instabilities that can be controlled by altering the effective dimensionality of the layered system. We use a combination of density-functional theory and group theoretical methods to investigate the interplay of magnetization with ferroelectricity when a layer of magnetic transition metal ions are introduced into this highly tunable dielectric superlattice.

9:00AM H33.00004 Electrical field control of interface magnetic anisotropy[1] , LEI XU, SHUFENG ZHANG, University of Arizona — The interface magnetic anisotropy of ferromagnetic metals comes from the spin-orbit interaction. By explicitly taking into account the interaction between the symmetry-broken interface potential and the spin-dependent electric dipoles of the Bloch states, we find that the interface spin-orbit coupling can be modeled by the Rashba spin-orbit Hamiltonian (RSOH). Due to the presence of the RSOH, the spin up and down states of the ferromagnet are spin mixed at the interface. Among other consequences, the RSOH induces a perpendicular surface magnetic anisotropy whose magnitude is comparable to the observed values in transition metals. When an external electric field is applied across the interface, the induced screening potential modifies the RSOH and thus the perpendicular anisotropy can be manipulated. Our calculated results are in agreement with the experiments [1].

9:12AM H33.00005 First Principles Studies of Electronic structure and Lattice Dynamics of Multiferroic $GaFeO_3$, AMRITENDU ROY, Indian Institute of Technology, Kanpur, RAJENDRA PRASAD, SUSHIL AULUCK, ASHISH GARG, ndian Institute of Technology, Kanpur — $GaFeO_3$ (GFO) is a room temperature piezoelectric material with antiferromagnetic ordering in the ground state. However, experimental observation reports ferrimagetic behavior below the magnetic transition temperature, attributed to the site disorder of Fe and Ga sites. This transition occurs at temperatures close to room temperature, depending upon the Fe content of the material. Previous structural characterization studies indicate that the room temperature crystal structure ($Pc2_1n$) is retained at least until 4 K. While there are a few experimental studies on this compound, there is no well established understanding of its electronic structure and lattice dynamics which can give insight into the piezoelectric and magnetic properties of the material. From this perspective, we started our calculations with the experimental lattice parameters of stoichiometric GFO assuming no partial occupancies of the constituent ions. The calculations are carried out using local spin density approximation (LSDA+U). Electronic structure and Born effective charges were calculated based on the ground state structure. First principles density functional theory based calculations using small displacement method was adopted to calculate the phonon dispersion relations for the material. On the basis of the dispersion relations modes were assigned.

9:24AM H33.00006 Ferroelectricity-ferromagnetism coexistence and electromagnons in multi-band electron systems , TAKAHIRO MIKAMI, TAKASHI OKA, HIDEO AOKI, Department of Physics, University of Tokyo — While it has been established that noncoliner spin textures can realize multiferroics through magnetoelectric effect, here we look into another senario. Namely, in multi-band systems that comprise odd- and even-parity orbits, homogeneous ferromagnetism and ferroelectricity can coexist as proposed by Batista. In multi-orbital systems Hund's exchange coupling is obviously expected to play an important role, but this has yet to be studied in the above scenario. We have here determined the finite-temperature phase diagram for the quarter-filled two-band Hubbard model in the strong coupling limit. A ferroelectric-ferromagnetic phase appears in multi-band insulator phases, where Hund's coupling, neglected in previous researches, is indeed found to be important for the multiferroic phase. We have further explored low-lying excitation spectrum in the multiferroic phase, since collective excitations should be an interesting experimental probe in the multiferroics. Similar to previous studies for the SU(4) Kugel-Khomskii model, magnon-pseudomagnon bound states appear as electromagnetic excitations due to a cross correlation in the homogeneous multiferroic phase.

9:36AM H33.00007 Electromagnon in $TbMnO_3$ under magnetic field by Raman scattering , PAULINE ROVILLAIN, MAXIMILIEN CAZAYOUS, YANN GALLAIS, ALAIN SACUTO, MARIE-AUDE MEASSON, Laboratoire Materiaux et Phenomenes Quantiques - Paris 7, HIDEAKI SAKATA, Department of physics University of Science Tokyo, LABORATOIRE MATERIAUX ET PHENOMENES QUANTIQUES - PARIS 7 TEAM, DEPARTMENT OF PHYSICS UNIVERSITY OF SCIENCE TOKYO COLLABORATION — Magnetoelectric excitations in the multiferroic $TbMnO_3$ have been investigated by Raman spectroscopy. Our observations reveal electromagnons excitations at 30 cm^{-1} and at 60 cm^{-1} with electric polarization of light parallel to the a axis [1]. When a magnetic field is applied along the c axis, no flop of the spiral plane or polarization is observed but $TbMnO_3$ becomes paraelectric and a simple antiferromagnetic phase is developed. We show that the dipole character of the electromagnons disappears whereas their magnon compound appears immediately when the spins spiral is destabilized with a magnetic field along the c axis. The magnon dispersion curve associated with the electromagnons is preserved before the construction of the magnon dispersion of the simple antiferromagnetic phase at higher magnetic field. The effect of the phase transition on the phonon modes shows that the Mn-O distance is the key that controls the polar character of the electromagnons.

9:48AM H33.00008 Dielectric and Resistive Response in Multiferroic Superlattices , SANDRA DUSSAN, ASHOK KUMAR, RAM S. KATIYAR, University of Puerto Rico — Building superlattices (SLs) with alternate layers of ultra thin films of ferroelectric and ferromagnetic materials is one of the ways to engineer magnetoelectric multiferroic materials. Alternate thin layers of ferroelectric $PbZr_{0.52}Ti_{0.48}O_3$ (PZT) and ferromagnetic $La_{0.67}Sr_{0.33}MnO_3$ (LSMO) materials were grown on $LaAlO_3$ (001) substrates using Pulsed laser deposition technique. X-ray diffraction patterns displayed the typical satellite peaks confirming SLs formation. The surface topography indicates homogeneous films with average surface roughness of $\sim$ 1.5 nm. Well saturated polarization and high dielectric tunability were observed at room temperature. Piezo-force microscopy (PFM) measurements revealed switching of polarization under the external DC bias field. The zero field cooled (ZFC) and field cooled (FC) magnetic measurements revealed the ferromagnetic behavior of SLs, and it undergoes phase transition at lower temperature compared to the bulk and thin films of pure LSMO. To gain further understanding of the electrical properties of the SLs, impedance spectroscopy, dielectric permittivity and ac conductivity were investigated. We observed dynamic magneto-resistive and magneto-dielectric effects around the LSMO metal-insulator and ferromagnetic phase transition temperature

10:00AM H33.00009 Enhanced resonant magnetoelectric coupling in frequency-tunable composite multiferroic bimorph structures , PETER FINKEL, NUWC, SAM LOFLAND, Rowan Unoversity, ED GARRITY, ACR Scientific Inc, DWIGHT VIEHLAND, Virginia Tech — We report on a giant tunable enhanced resonant magnetoelectric (ME) coupling in multiferroic magnetostrictive/piezoelectric composite based on Fe-Ni/PVDF and Metglas/PZT-fiber bimorph structures. The approach was shown to provide more than a tenfold gain in the ME coefficient, and a magnetic/electric field assisted stress-reconfigurable resonance frequency tuning, up to 100%. The studies were performed by laser Doppler spectroscopy. We also show that this principle of a continuously tuned resonance that might be used to enhance sensitivity and to reject noise for ME magnetic sensors.

10:12AM H33.00010 Interface magnetoelectric effect in ferroelectric/antiperovskite heterostructures , PAVEL LUKASHEV, KIRILL BELASHCHENKO, EVGENY TSYMBAL, University of Nebraska - Lincoln, RENAT F. SABIRIANOV, University of Nebraska at Omaha — We present results of the first principles calculations of the magnetoelectric effect in thin film layered heterostructures of typical ferroelectric (FE), such as PbTiO3, with Mn-based antiperovskite (AP), such as Mn3GaN. Mn-based antiperovskite materials are interesting due to a non-trivial magnetic order and a linear magnetic response to applied strain that makes them piezomagnetic. The symmetry breaking produces a net magnetization at the FE/AP heterostructure interfaces. This magnetization can be controlled by reversing the polarization of the FE layer. Our calculations show that for the positive FE polarization the induced net magnetization is 3.8 μ_B at the PbO/GaMn and 0.6 μ_B at the TiO2/Mn2N interface, while the corresponding values are 1.6 μ_B and 1.2 μ_B for the negative FE polarization and 2.2 μ_B and 0.4 μ_B for the zero FE polarization. Thus, the FE/AP interface magnetization exhibits a strong dependence on the direction of the FE polarization, with difference as large as by a factor of 2. The presented novel approach to electrically control the magnetic properties of thin-film layered ferroelectric/piezomagnetic heterostructures may be interesting for practical applications. Therefore, we hope that our results will stimulate experimental work on the FM/AP thin-film layered heterostructures.

10:24AM H33.00011 Electric field tuning of magnetic domains in permalloy thin films using elastic coupling with ferroelectric PZT bilayers[1] , ANBUSATHAIAH VARATHARAJAN, ARUN LUYKX, LUZ SANCHEZ, University of Maryland, R. POLCAWICH, Army Research Lab, ICHIRO TAKEUCHI, University of Maryland — We are investigating electric field controlled magnetic domain motion in permalloy films deposited on $Pb(Zr_xTi_{(1-x)})$ O_3 (PZT) bilayers. Previously, we have shown that bilayered heterostructures consisting of a tetragonal $PbZr_{0.3}Ti_{0.7}O_3$ film (70 nm) deposited on a rhombohedral $PbZr_{0.7}Ti_{0.3}O_3$ (70 nm) display large ferroelastic domains in the top tetragonal PZT layer (Adv. Mat. 21, 3497, 2009). The reversible non-volatile twin boundary motion in this layer can serve as a basis for inducing controlled strain on magnetic thin films deposited on top. We find that permalloy films (50 nm) sputtered on top of the ferroelastic layer exhibit out-of-plane magnetization whose domains can be imaged by magnetic force microscopy (MFM). Voltage pulses are applied between patterned pads of the permalloy film and the bottom electrode underneath the PZT bilayer. This results in different twin configurations in the tetragonal PZT layer, which in turn leads to changes in magnetic domains in the permalloy film as monitored by MFM.

[1]Work at Maryland was supported by UMD-NSF-MRSEC.

10:36AM H33.00012 Magnetism of Fe nanostructure on ultrathin $BaTiO_3$ film , X. CHEN, University of Nebraska-Lincoln, J. KIM, S. YANG, J.S KIM, G. ROJAS, R. SKOMSKI, M. BODE, A. BHATTACHARYA, T. SANTOS, N. GUISINGER, H. LU, A. GRUVERMAN, C. BINEK, V. SESSI, J. HONOLKA, A. ENDERS — A study of Fe nanostructure on $BaTiO_3$ (BTO) thin films with variable temperature scanning tunneling microscopy (STM) and X-Ray Magnetic Circular Dichroism (XMCD) under ultrahigh vacuum is presented. Fe/BTO is a prototype system for the study of magneto-electric effects but it is experimentally challenging to achieve high quality metal-oxide interfaces. Our approach is to use atomically flat, unreconstructed and stoichiometric BTO films of 13 unit cell thickness on $SrTO_3$, and to deposit Fe impurity atoms and small clusters with molecular beam epitaxy at T = 8 K and compact nanometer clusters by buffer layer assisted growth for comparison. The magnetism of both systems was studied by XMCD at the Fe L3/2 absorption edges. The key observation is that even isolated Fe atoms on the BTO have a sizeable magnetic moment, which quickly increases with increasing coverage. This, together with a detailed analysis of the L 3/2 line shape, is evidence that intermixing and oxidation at the Fe/BTO interface is strongly suppressed. The interface quality achieved can thus potentially be exploited to experimentally observe a magneto-electric interface effect predicted by Tsymbal et al. [Phys. Rev. Lett. 97, 047201 (2006)].

10:48AM H33.00013 Voltage Manipulation of Magnetic Anisotropy in MgO/Ferromagnet/Ag system , JARED WONG, ADRIAN SWARTZ, WEI HAN, ROLAND KAWAKAMI, University of California, Riverside — Recently, the development of new types of memory storage and processing devices has led to great interest in voltage-induced manipulation of magnetic properties in ferromagnetic metals (FM). We investigate the voltage-induced changes in the magnetic properties of a FM in an Indium Tin Oxide (ITO)/Poly(methyl methacrylate) (PMMA)/MgO/FM/Ag system. Samples are fabricated through molecular beam epitaxy (MBE) synthesis and PMMA resist is used as a dielectric layer. ITO is used for the top transparent conductive electrode and magnetic properties are examined through magneto-optic Kerr effect (MOKE) measurements. We report our results and observations of voltage-induced manipulation of the magnetic anisotropy in ITO/PMMA/MgO/FM/Ag system.

Tuesday, March 22, 2011 8:00AM - 11:00AM –

Session H34 DMP: Focus Session: Atomic, Molecular, and Memristive Junctions C141

8:00AM H34.00001 Memory effects in nanoscale systems , MASSIMILIANO DI VENTRA, University of California, San Diego — Memory emerges quite naturally in systems of nanoscale dimensions: the change of state of electrons and ions is not instantaneous if probed at specific time scales, and it generally depends on the past dynamics. This means that the resistive, capacitive and/or inductive properties of these systems generally show interesting time-dependent (memory) features when subject to time-dependent perturbations. In other words, nanoscale systems behave as a combination of (or simply as) memristors, memcapacitors or meminductors, namely circuit elements whose resistance, capacitance and inductance, respectively, depend on the past states through which the system has evolved. After an introduction to the theory and properties of memristors, memcapacitors and meminductors, I will discuss several memory phenomena in nanostructures associated to charge, ion and spin dynamics and their far-reaching applications ranging from information storage to computation to biologically-inspired systems. Work supported in part by NSF, NIH, and DOE.

8:36AM H34.00002 Multiple switching modes and multiple level states in memristive devices , FENG MIAO, J. JOSHUA YANG, JULIEN BORGHETTI, JOHN PAUL STRACHAN, M.-X. ZHANG, ILAN GOLDFARB, GILBERTO MEDEIROS-RIBEIRO, R. STANLEY WILLIAMS, Hewlett-Packard Laboratories, Palo Alto, California — As one of the most promising technologies for next generation non-volatile memory, metal oxide based memristive devices have demonstrated great advantages on scalability, operating speed and power consumption. Here we report the observation of multiple switching modes and multiple level states in different memristive systems. The multiple switching modes can be obtained by limiting the current during electroforming, and related transport behaviors, including ionic and electronic motions, are characterized. Such observation can be rationalized by a model of two effective switching layers adjacent to the bottom and top electrodes. Multiple level states, corresponding to different composition of the conducting channel, will also be discussed in the context of multiple-level storage for high density, non-volatile memory applications.

8:48AM H34.00003 Stochastic memory: getting memory out of noise[1] , ALEXANDER STOTLAND, MASSIMILIANO DI VENTRA, Department of Physics, University of California–San Diego, La Jolla, California 92093-0319 — Memory circuit elements, namely memristors, memcapacitors and meminductors [1], can store information without the need of a power source. These systems are generally defined in terms of deterministic equations of motion for the state variables that are responsible for memory. However, in real systems noise sources can never be eliminated completely. One would then expect noise to be detrimental for memory. Here, we show that under specific conditions on the noise intensity memory can actually be enhanced. We illustrate this phenomenon using a physical model of a memristor in which the addition of white noise into the state variable equation improves the memory and helps the operation of the system. We discuss under which conditions this effect can be realized experimentally, discuss its implications on existing memory systems discussed in the literature, and also analyze the effects of colored noise.

9:00AM H34.00004 Nano-Ionic in Molecular Nanojunctions[1] , LAM YU, MATTHEW ROBERSON, University of Memphis — Metal filament growth can be induced on the surfaces of electrochemically active metals such as silver and copper by an external electric potential. We study the voltage-driven formation and dissolution of nanoscale silver filaments in silver/molecular-layer/gold junctions. In this system, an applied electric voltage causes oxidation at the silver surface and the resulting silver cations from the reaction are transported away from the silver surface toward the gold surface. The silver cations are reduced at the gold surface and from the accumulation of the transported silver particles, filaments are formed from the gold surface. We found that the energy required for silver nanofilament formation depends critically on the thickness and electrostatic property of the molecular layer, while the energy required for the dissolution of silver nanofilaments is virtually molecule-independent. I will discuss what our results tell us about chemical reactions in the nanoscale, and the practical application of our results in the area of electronic memory and chemical sensors.

[1]This work was supported by a grant provided by the FedEx Institute of Technology

9:12AM H34.00005 Bias dependent shot noise measurement in STM style Au junction at room temperature , RUOYU CHEN, PATRICK WHEELER, AMANDA WHALEY, DOUGLAS NATELSON, Rice University — Shot noise in nanoscale junctions is suppressed strongly near certain conductance values because of nearly fully transmitted modes. Using a gold tip in a STM style motion as the source, combining with high-frequency techniques, we simultaneously measured the conductance and the mean square current noise in nanoscale junctions at a series of voltage biases at room temperature. We have observed peaks in the conductance histogram and related shot noise suppression at different biases near integer multiples of the conductance quantum G0, especially the first three. It demonstrates that quantized electronic transport through quantum channels takes place. We will discuss the relevant noise processes and their evolution with bias across the junctions.

9:24AM H34.00006 Large bandwidth measurements of break junctions for molecular electronics at microwave frequencies , GABRIEL PUEBLA-HELLMANN, ANDREAS WALLRAFF, Quantum Device Lab, ETH Zurich — The controlled breaking of a thin gold wire, by mechanical stress or by electromigration, has not only been successfully employed to produce the nm-spaced electrodes necessary for creating single molecule devices, but has also attracted attention as the means to produce optical field enhancement for surface enhanced Raman scattering on the few to single molecule level. Although frequently employed, such break junctions usually have a low bandwidth when performing electrical transport measurements of single molecule devices. We investigate such junctions and single molecule devices by using microwave reflectrometry, where a break junction is integrated into a superconducting impedance matching circuit. This allows the impedance and thus the state of the junction to be deduced from the measured reflection coefficient with a bandwidth of 10-100 MHz. We electrically characterize such impedance matching circuits at microwave frequencies as well as gold break junctions at DC. We also show measurement results of the combined system, where the break junction is formed either by electromigration or by mechanical means. This setup will be used to study the transport properties of single molecule devices with a bandwidth larger than that of standard low frequency techniques.

9:36AM H34.00007 Shot Noise Measurements in Individual Electromigrated Nanoscale Jsunctions , PATRICK WHEELER, DOUGLAS NATELSON, Department of Physics and Astronomy Rice University — Shot noise provides insight into the correlated motion of electrons in nanostructures. Previous measurements have examined shot noise in mechanically controlled break junctions (MCBJs), looking at a large ensemble of junction configurations. Electromigrated, lithographically created Au structures at liquid nitrogen and helium temperatures allow for the shot noise measurement of individual junction configurations. High frequency excess noise is amplified by a rf amplifier chain and measured in combination with lock-in techniques simultaneously with the dc conductance. Preliminary noise measurements across bias and temperature are compared to previous experiments preformed with MCBJs at room temperature, with an emphasis on the dependence of the noise on bias conditions.

9:48AM H34.00008 Entanglement dynamics within the micro-canonical approach to transport , MASSIMILIANO DI VENTRA, UCSD, CHIH-CHUN CHIEN, MICHAEL ZWOLAK, Los Alamos National Lab — When a central barrier is located between two biased electrodes, the tunneling of electrons may build a quasi steady-state current and the entanglement entropy between the two sides increases. We study these quantities using the micro-canonical picture of transport [1]. The quasi steady-state current from our simulations agree with that obtained from single-particle scattering theory. In addition, we find that the entanglement entropy increases linearly in time and with bias, so long as the barrier is only partially transmitting, which agrees qualitatively with previous results derived under restrictive assumptions. The micro-canonical approach also allows us to investigate this system highly out-of-equilibrium and under a range of conditions. We present further results on barriers with different tunneling probabilities, biases, and time-dependent fields.

10:00AM H34.00009 The number of transmission channels through a single-molecule junction , STAFFORD CHARLES, JUSTIN BERGFIELD, JOSHUA BARR, University of Arizona — We calculate transmission eigenvalue distributions for Pt-benzene-Pt and Pt-butadiene-Pt junctions using realistic state-of-the-art many-body techniques. An effective field theory of interacting pi-electrons is used to include screening and van der Waals interactions with the metal electrodes. We find that the number of dominant transmission channels in a molecular junction is equal to the degeneracy of the molecular orbital closest to the metal Fermi level. Thus for Pt-benzene-Pt junctions we predict two dominant transmission channels, and for Pt-butadiene-Pt junctions only one. Pt-buckyball-Pt junctions are predicted to exhibit up to five dominant transmission channels.

10:12AM H34.00010 Vibrational heating in molecular junctions , DANIEL WARD, DAVID CORLEY, JAMES TOUR, DOUGLAS NATELSON, Rice University — Energy injection, distribution and dissipation are of great important in understanding molecular electronics. One method of characterizing the distribution of energy in a system is to measure the effective temperature. Using surface-enhanced Raman spectroscopy (SERS) of molecular nanojunctions, we measure the effective vibrational temperatures of a molecular nanojunction as a function of bias. We observe significant mode-specific vibrational pumping by both optical excitation and DC current, with effective temperature changes exceeding several hundred Kelvin. These measurements provide direct information about heat generation and dissipation in molecular-scale junctions and allow direct comparisons with theories of nanoscale heating.

10:24AM H34.00011 Effective field theory of interacting pi electrons in molecular junctions , JOSHUA BARR, JUSTIN BERGFIELD, CHARLES STAFFORD, University of Arizona — We present an effective field theory that allows the two-body Hamiltonian for a π electron system to be expressed in terms of three effective parameters: the π orbital quadrupole moment, the on-site repulsion, and a dielectric constant. As an application of this theory, we present a model of screening in single-molecule junctions based on the image charge method, and use this technique to calculate the van der Waals interaction between a neutral molecule and a metallic conductor.

10:36AM H34.00012 Temperature dependence of charge transport in conjugated single molecule junctions[1] , EEK HUISMAN, MASHA KAMENETSKA, LATHA VENKATARAMAN, Columbia University — Over the last decade, the break junction technique using a scanning tunneling microscope geometry has proven to be an important tool to understand electron transport through single molecule junctions. Here, we use this technique to probe transport through junctions at temperatures ranging from 5K to 300K. We study three amine-terminated (-NH_2) conjugated molecules: a benzene, a biphenyl and a terphenyl derivative. We find that amine groups bind selectively to undercoordinate gold atoms gold all the way down to 5K, yielding single molecule junctions with well-defined conductances. Furthermore, we find that the conductance of a single molecule junction increases with temperature and we present a mechanism for this temperature dependent transport result.

[1]Funded by a Rubicon Grant from The Netherlands Organisation for Scientific Research (NWO) and the NSEC program of NSF under grant # CHE-0641523.

10:48AM H34.00013 Charge transport in mechanically controlled single-molecule break-junctions , YOUNGSANG KIM, FLORIAN STRIGL, HANS-FRIDTJOF PERNAU, ELKE SCHEER, University of Konstanz, Germany, HYUNWOOK SONG, TAKHEE LEE, Gwangju Institute of Science and Technology, Korea, THOMAS HELLMUTH, FABIAN PAULY, Karlsruhe Institute of Technology, Germany, LINDA A. ZOTTI, JUAN CARLOS CUEVAS, Universidad Autónoma de Madrid, Spain — We present inelastic electron tunneling spectroscopy (IETS) measurements carried out on single molecules incorporated into a mechanically controllable break-junction (MCBJ) at low temperature. The single molecules contacted with a MCBJ or with a STM show various conductance values under stretching depending on the contact geometry and the molecular conformation (*e.g.*, *trans* or *gauche*). In such single-molecule devices, the metal of electrodes (*e.g.*, gold or platinum) and anchoring groups (*e.g.*, thiol (-SH) or amine (-NH_2)) can also significantly influence the charge transport through the single molecules. Here we demonstrate how these individual aspects influence the conductance properties of single-molecule junctions.

Tuesday, March 22, 2011 8:00AM - 11:00AM –
Session H35 DCMP: Topological Insulators: General C140

8:00AM H35.00001 ABSTRACT WITHDRAWN –

8:12AM H35.00002 Topological Insulators as Substrates for CO Oxidation Catalysis by Ultrathin Au Films[1] , HUA CHEN, U of Tennessee-Knoxville, WENGUANG ZHU, U of Tennessee-Knoxville; Oak Ridge National Laboratory, DI XIAO, Oak Ridge National Laboratory, ZHENYU ZHANG, Oak Ridge National Laboratory; U of Tennessee-Knoxville; ICQD/HFNL, USTC — We propose a novel application of three dimensional topological insulators (3DTIs) in heterogeneous catalysis based on first- principles calculations within density functional theory. We use a Bi_2Se_3 substrate as the support of an ultrathin Au film, and show that the Au adatoms are strongly bound to and able to wet the surface of Bi_2Se_3. More importantly, we find the topological surface states of Bi_2Se_3 are robust against Au deposition, and it can enhance the interaction between Au and CO, O_2 molecules by acting as an "electron bath". The present study may broaden the potential technological applications of 3DTIs, and shine some new light on the understanding of the role of surface states in heterogeneous catalysis.

[1]Supported by DMSE/BES of USDOE, USNSF, and NNSFC

8:24AM H35.00003 Topological insulators on the ruby lattice[1] , XIANG HU, MEHDI KARGARIAN, GREGORY FIETE, The University of Texas at Austin — We study a tight-binding model on the two-dimensional ruby lattice. This lattice supports two types of second neighbor spin-dependent hopping parameters in an s-band model that preserves time-reversal symmetry. We discuss the phase diagram of this model for various values of the hopping parameters, and note an interesting interplay between the two spin-orbit terms that individually would drive the system to a Z2 topological insulating phase. The fidelity of each phase is also calculated.

[1]We gratefully acknowledge funding from ARO grant W911NF-09-1-0527

8:36AM H35.00004 Extension of the Kitaev model on the square lattice , RYOTA NAKAI, Department of Physics, The University of Tokyo, AKIRA FURUSAKI, Condensed Matter Theory Laboratory, RIKEN, SHINSEI RYU, Department of Physics, University of California at Berkeley — We study an extension of the Kitaev model [1] on the square lattice, where two types of Gamma matrices on neighboring sites have interaction that respects time reversal symmetry. A family of Kitaev models can be classified as the topological insulator/superconductor when described by Majorana fermions [2]. Our model is in class DIII in Altland-Zirnbauer classification, and thus a Z_2 invariant characterizes two distinct phases. There appear helical Majorana edge modes in the topological phase. The same model on the one-dimensional ladder is also studied.

8:48AM H35.00005 Electrical manipulation and measurement of spin properties of quantum spin Hall edge states , TEEMU OJANEN[1], JUKKA VAYRYNEN, Low Temperature Laboratory, Aalto University, Finland — The existence of the quantum spin Hall state has been confirmed in a series of experiments performed in HgTe quantum wells but a quantitative observation of the helical edge structure is still lacking. We study an electrical manipulation and measurement of helicity properties of the edge states by employing the Rashba spin-orbit interaction (SOI). Specifically, we show that a spatially uniform Rashba SOI, controllable by the gate voltage, can be utilized in tuning the spin orientation of the edge modes (J. I. Väyrynen and T. Ojanen, arXiv:1010.1353). We introduce a point-contact geometry where helicity of the edge modes can be accessed by two- terminal conductance measurements.

[1]Aalto University was previously known as Helsinki University of Technology.

9:00AM H35.00006 Electronic Transport in Exfoliated Bismuth Selenide[1] , ANDREW BESTWICK, JAMES WILLIAMS, PATRICK GALLAGHER, DAVID GOLDHABER-GORDON, JAMES ANALYTIS, IAN FISHER, Stanford University — Recent theoretical and experimental work has identified bismuth selenide as a promising candidate for studies of three-dimensional topological insulators due to its large bulk semiconducting gap crossed by topological Dirac surface states. We report on the fabrication and measurement of mesoscale exfoliated bismuth selenide devices, including the effects of electric-field-effect gating and magnetic field on transport and possible signatures of topological states. We will also discuss fabrication strategies to mitigate surface disorder and doping

[1]The authors acknowledge support from the Keck Foundation.

9:12AM H35.00007 Approaching the insulating state in Ca-doped Bi_2Se_3 nanodevices[1] , PENG WEI, ZHIYONG WANG, JING SHI, Department of Physics and Astronomy, University of California at Riverside — We report a systematic tuning of the carrier density in Ca-doped Bi_2Se_3 nanodevices. A clear transition from the metallic to insulating state is observed as both the Ca-concentration and the gate voltage are tuned. At high temperatures, the devices behave metallic as indicated by the linear temperature dependence of the electrical resistivity as the devices are initially cooled. As the temperature is lowered, the resistivity shows a minimum then increases. This insulating behavior can be modeled by a thermal activated conductivity, which is taken over by saturation at the lowest temperatures. At 1.5 K, the resistivity undergoes a $\sim$5-fold increase as a gate voltage is swept from -60 V to 60 V. The field-effect mobility is found to be about $\sim$ 5000 cm2/Vs. We have also observed a systematic evolution of the magnetoresistance as the chemical potential is tuned via the gate voltage. The combination of the chemical and electronic dopings provides an effective way to access the low carrier density gap states in Bi2Se3 topological insulator nanodevices. This work was supported in part by DOE and NSF.

[1]This work was supported in part by DOE and NSF

9:24AM H35.00008 Topological Response Theory of Doped Topological Insulators , MAISSAM BARKESHLI, Stanford University, XIAOLIANG QI — We generalize the topological response theory of three-dimensional topological insulators (TI) to metallic systems – specifically, doped TI with finite bulk carrier density and a time-reversal symmetry breaking field near the surface. We show that there is an inhomogeneity-induced Berry phase contribution to the surface Hall conductivity that is completely determined by the occupied states and is independent of other details such as band dispersion and impurities. In the limit of zero bulk carrier density, this intrinsic surface Hall conductivity reduces to the half-integer quantized surface Hall conductivity of TI. Our theory is directly related to the TI materials currently under experimental investigation, which have finite residual bulk carrier densities.

9:36AM H35.00009 Topological states in one dimensional solids and photonic crystals , TIMOTHY ATHERTON, HARSH MATHUR, Case Western Reserve University — We show that the band structure of a one-dimensional solid with particle-hole symmetry may be characterized by a topological index that owes its existence to the non-trivial homotopy of the space of non-degenerate real symmetric matrices. Moreover we explicitly demonstrate a theorem linking the topological index to the existence of bound states on the surface of a semi-infinite one dimensional solid. Our analysis is a one-dimensional analogue of the analysis of topological insulators in two and three dimensions by Balents and Moore; our results may be relevant to long molecules that are the one dimensional analogue of topological insulators. We propose the realization of this physics in a one-dimensional photonic crystal. In this case the topology of the bandstructure reveals itself not as a bound surface state but as a Lorentzian feature in the time delay of light that is otherwise perfectly reflected by the photonic crystal.

9:48AM H35.00010 Robustness of topologically protected surface states in layering of Bi_2Te_3 thin films[1] , KYUNGWHA PARK, JEAN HEREMANS, VITO SCAROLA, DJORDJE MINIC, Virginia Tech — Recently, topological insulators with time-reversal symmetry have drawn great attention due to their topologically protected states. Topological insulators differ from band insulators in that a bulk energy gap opens up due to strong spin-orbit coupling and that metallic surface states reside in the energy gap. The surface states of topological insulators are topologically protected in that impurities preserving time-reversal symmetry neither destroy the surface states nor impact the topological nature of the surface states. Recently, bulk bismuth-based alloys were shown to be topological insulators. Thin films offer valuable probes of topological insulators as well as device applications. Additionally, bismuth-based thin films of a thickness of a few nanometers were fabricated on substrates or suspended across trenches. We investigate surface states of Bi_2Te_3(111) thin films of one to six quintuple layers using density-functional theory including spin-orbit coupling. We construct a method to identify topologically protected surface states of thin film topological insulators. Applying this method to Bi_2Te_3 thin films, we examine the topological nature of the surface states as a function of the film thickness and compare our results with experimental data and other theoretical reports.

10:00AM H35.00011 Spin and Charge Transport on the Surface of a Topological Insulator , ANTON BURKOV, DAVID HAWTHORN, University of Waterloo — We derive diffusion equations, which describe spin-charge coupled transport on the helical metal surface of a three-dimensional topological insulator. The main feature of these equations is a large magnitude of the spin-charge coupling, which leads to interesting and observable effects. In particular, we predict a new magnetoresistance effect, which manifests in a nonohmic correction to a voltage drop between a ferromagnetic spin-polarized electrode and a nonmagnetic electrode, placed on top of the helical metal. This correction is proportional to the cross-product of the spin polarization of the ferromagnetic electrode and the charge current between the two electrodes. We also demonstrate tunability of this effect by applying a gate voltage, which makes it possible to operate the proposed device as a transistor.

10:12AM H35.00012 Spin and Charge Transport in Thin Films of Topological Insulators , ALEXANDER ZYUZIN, ANTON BURKOV, University of Waterloo — We develop a theory of spin-charge coupled transport in thin films of topological insulator materials, when the top and bottom surfaces of the sample hybridize. We find significant differences from the case of transport on unhybridized surfaces. In particular, we find significant reduction of the spin relaxation rates, which enhances all the spin-related transport effects, compared to the case of a single surface. We also find that the out-of-plane component of the spin, which is absent from the hydrodynamic transport equations in the single surface case, reappears when the surfaces are hybridized.

10:24AM H35.00013 Conductance of a helical edge liquid coupled to a magnetic impurity , YOICHI TANAKA, AKIRA FURUSAKI, Condensed Matter Theory Laboratory, RIKEN, K.A. MATVEEV, Argonne National Laboratory — In a quantum spin Hall system, which can be realized in HeTe/(Hg,Cd)Te semiconductor quantum wells [1], helical edge states carry a current and the conductance takes the universal value of $2e^2/h$. This is because an impurity without internal degrees of freedom cannot backscatter an electron at the edge in the presence of time-reversal symmetry [2]. On the other hand, backscattering by a magnetic impurity is allowed. We study the effect of backscattering from a magnetic impurity on the conductance of a quantum spin Hall system [3], and obtain the correction $\delta G(\omega)$ to the electrical conductance as a function of frequency ω. We find that the correction $\delta G(\omega)$ vanishes in the dc limit ($\omega \to 0$), when our model conserves the total spin S_z. Another interesting transport property is the thermal conductance, which is affected by the coupling to the magnetic impurity even at $\omega \to 0$. We find that the temperature dependence of the thermal conductance shows a non-monotonic behavior with a minimum occurring at the Kondo temperature.

10:36AM H35.00014 Design Principles and Coupling Mechanisms in the 2D Quantum-Well Topological Insulator HgTe/CdTe[1] , JUN-WEI LUO, ALEX ZUNGER, National Renewable Energy Lab, SOLID STATE THEORY TEAM — We present atomistic band structure calculations revealing a different mechanism than recently surmised via $\mathbf{k} \cdot \mathbf{p}$ calculations about the evolution of the topological state (TS) in HgTe/CdTe. We show that *2D interface* (not *1D edge*) TS are possible. We find that the transitions from a topological insulator at critical HgTe thickness of $n = 23$ ML (62.5 Å) to a normal insulator at smaller n is due to the crossing between two interface localized states: one derived from the S-like Γ_{6c} and one derived from the P-like Γ_{8v} light-hole, not because of the crossing of an interface state and an extended QW state. These atomistic calculations suggest that a 2D TS can exist in a 2D system, even without truncating its symmetry to 1D, thus explaining the otherwise surprising similarity between the 2D dispersion curves of the TS in HgTe/CdTe with those of the TS in 3D bulk materials such as Bi_2Se_3. Ref: J.W. Luo and A. Zunger, Phys. Rev. Lett. **105**, 176805 (2010).

10:48AM H35.00015 Towards Quantum Spin Hall Effect in InAs/GaSb Quantum Wells , IVAN KNEZ, RUI-RUI DU, Rice University, GERRARD SULLIVAN, Teledyne Scientific Co. — Recently, it has been proposed that inverted InAs/GaSb composite quantum wells (CQWs) should exhibit the Quantum Spin Hall Effect (QSHE), characterized by the energy gap in the bulk and gapless edge modes which are protected from backscattering by time reversal symmetry. We have successfully fabricated a double-gated device on high-quality MBE-grown InAs/GaAs CQWs in the inverted regime, in which we were able to vary the band structure via an electrical field, and tune the Fermi level into mini-gap regime. We observed clear evidence for an energy gap in the inverted regime, with values of the gap consistent with those theoretically predicted; however, the mini-gap exhibits residual conductivity of non-trivial origin, which complicates transport investigation of proposed edge channels. We note that the InAs surface states around the sample edges may play a role in the observed resistivity features. In ongoing work, we pursue Cooper pair injection experiments by proximity to an s-wave superconductor, which should provide a novel probe of the proposed helical edge modes. We will discuss our progress towards observing QSHE in this unique material system. The work at Rice was supported by grants from NSF, Keck Foundation, and Hackerman Advanced Research Program.

Tuesday, March 22, 2011 8:00AM - 11:00AM –
Session H36 GERA: Photovoltaics: Compound Semiconductors and Organics C142

8:00AM H36.00001 Effects of doping on the band gap of iron pyrite[1] , JUN HU, YANNING ZHANG, MATT LAW, RUQIAN WU, University of California, Irvine — Iron pyrite (FeS_2), a highly abundant materials in Earth's upper continental crust, is of great interests in photovoltaic and photo-electrochemical applications, due to its wide band gap of 0.9 - 0.95 eV and large absorption coefficient of $\alpha > 10^5$ cm-1 for $\lambda < 10^3$ nm. However, its electron/hole mobility is typically very low, caused by the presence of sulfur deficiency in crystalline FeS_2 bulks or nanostructures. In principle, doping electrons or holes by exotic elements may not only compensate sulfur deficiency but also create mobile carriers. In this work, we systematically studied the dopabilities of N, P, F and Cl in bulk FeS_2, by using the first-principles calculations. First of all, we found that these elements substitute S under sulfur poor condition in the FeS_2 bulk and nanostructures. While N, P and F dopants merely induce deep localized defect levels, doping 1.6% Cl not only generates a 0.996 μ_B local magnetic moment per Cl and but also increases the carrier density by $3x10^{18}/cm^{-3}$. The defect states are delocalized and hence doping of Cl also improve the carrier mobility in FeS_2. We found that incorporation of Cl also leads to significant structural distortions around Cl atom.

[1]We thank the NSF SOLAR Program (Award CHE-1035218).

8:12AM H36.00002 The reason FeS_2 is not a good PV absorber[1] , LIPING YU, S. LANY, A. ZUNGER, NREL, H.A.S. PLATT, R. KYKYNESHI, B. PELATT, R. RAVICHANDARIN, D.A. KESZLER, J.F. WAGER, Oregon State University — FeS_2 is representative of an ideal earth-abundant candidate absorber for thin film PV, because of its appropriate band gap, high absorption coefficient and good electron/hole mobility. Yet, despite ∼15 years of research, the promise of FeS_2 as an absorber layer has been unrealized, manifesting as a low open circuit voltage which has been attributed to E_f pinning arising from bulk sulfur vacancies. Our first-principles calculations and experimental thermogravimetirc analyses, however, show that S vacancies and other point defects have rather high formation energies. Hence, they are unlikely to form and pin E_f. We find that the widely observed S deficiency in FeS_2 is accommodated by phase-coexistence of a few $Fe_{1-x}S$ compounds, rather than S vacancies. These minority phases are metallic and detrimental for PV. We find select ternary Fe sulfides do not have thermodynamically-mandated phase-coexistence like FeS_2, yet they retain optimal band gaps and high absorption strengths comparable to FeS_2. These properties and associated surface-defect calculations will be discussed.

8:24AM H36.00003 Direct measurement of the built-in potential in a nanoscale heterostructure

, ANNA ZANIEWSKI, MATTHIAS LOSTER, Department of Physics, University of California at Berkeley, Berkeley, CA 94720 U.S.A, BRYCE SADTLER[1], A. PAUL ALIVISATOS, Department of Chemistry, University of California at Berkeley, Berkeley, CA 94720 U.S.A, A. ZETTL, Department of Physics, University of California at Berkeley, Berkeley, CA 94720 U.S.A — Recently synthesized heterostructured nanorods are a promising material for applications such as photovoltaics. Understanding the electronic structure of these materials is both an interesting scientific question and vitally important for applications. We present the measurement of the built-in potential across individual Cu2S-CdS heterostructured nanorods by combining transmission electron microscopy with electrostatic force microscopy. This represents the first experimental determination of the electrostatic potential across an isolated nanostructure. We observe a variation of built-in potentials, ranging from 100 to 920 mV, with an average of 250 mV. Nanorods of a uniform composition with no heterojunction do not show built-in potential, as expected.

8:36AM H36.00004 First Principles Calculation of Optical Properties of Ternary Semiconductors Cu_3PSe_4 and Cu_3PS_4

, DAVID FOSTER, GUENTER SCHNEIDER, Oregon State University — The ternary semiconducting compounds Cu_3PSe_4 and Cu_3PS_4 are of interest as potential optoelectronic materials. Of particular interest for solar photovoltaic devices is Cu_3PSe_4, as its band gap lies in the desired 1.0 to 1.6 eV range for an absorber. We have theoretically calculated the optical properties of these materials using density functional theory with GGA and hybrid exchange-correlation functionals, as well as with the GW_0 approximation from many-particle theory. We find that Cu_3PSe_4 has a direct band gap with relatively strong optical absorption above 2 eV, indicating that this compound is a candidate photovoltaic absorber. Cu_3PS_4 has a larger band gap of approximately 2.4 eV, placing it outside consideration as a solar absorber.

8:48AM H36.00005 Crystalline ordered states and local surface potential variations of photovoltaic $Cu(In,Ga)Se_2$ thin-films[1]

, A.R. JEONG, R.H. SHIN, WILLIAM JO, Ewha Womans University — Structural and electrical properties of $CuInSe_2$(CIS), $Cu(In,Ga)Se_2$ (CIGS) and $CuGaSe_2$ (CGS) grown by co-evaporation were studied. Intriguing morphology and grain growth behaviors were found in the surface of the films. X-ray diffraction of the films exhibited phase formation of the stoichiometric chalcopyrite while Cu_2Se and $CuSe_2$ were observed. Using Raman scattering spectroscopy, shift of A_1 mode was observed from 177 cm^{-1} for CIS to 189 cm^{-1} for CGS as Ga content increased. It is very interesting that two different crystalline ordered states with chalcopyrite (CH) and CuAu structure (CA) were found. Effects of the grain boundaries on local electrical properties of the films with different chemical contents were examined. Local current mapping and surface potential distribution were obtained in the film by conductive atomic force microscopy and Kelvin probe microscopy. Minority carrier transport behaviors and local variations of potential values on and near the grain boundaries were characterized. These results suggested that a local built-in potential is possibly formed on positively charged grain boundaries.

9:00AM H36.00006 Minority-Carrier Lifetimes in GaInP

, LINDA FRITZ, NREL and Franklin & Marshall College, JERRY OLSON, National Renewable Energy Laboroatory, DARIUS KUCIAUSKAS, National Renewable Energy Laboratory — Minority-carrier lifetimes are very important to the performance of photovoltaic materials and are quite sensitive to the structure of the material. The impact of lifetimes can be readily illustrated using computer modeling of cell performance, and a brief discussion of the results of our modeling will be given. AlInP/GaInP double heterojunctions of varying thickness and doping concentration were grown on GaAs substrates by metallorganic chemical vapor deposition (MOCVD). Lifetimes were measured using time-resolved photo-luminescence. Carrier concentrations were determined using capacitance-voltage measurements. Here we report on the minority carrier lifetime as a function of active layer thickness and doping concentration for n-type and p-type GaInP that is lattice-matched to the substrate.

9:12AM H36.00007 Photvoltaic effects in ferroelectrics due to nonlinear optical processes

, STEVE YOUNG, ANDREW RAPPE, Makineni Theoretical Laboratories, Department of Chemistry, University of Pennsylvania — The physical mechanism for the bulk photovoltaic effect that appears in noncentrosymmetric materials, especially in ferroelectric devices, is not well understood. A promising candidate for a truly bulk photovoltaic effect is non-linear optical processes – most notably "shift current," which describes the net motion of coherently excited electrons in the absence of inversion symmetry, and has been described analytically several times in the literature. Shift current is also of interest due to the appearance of a gauge invariant phase describing the carrier mobility. We have developed an expression for shift current suitable for efficient computation and analysis utilizing wavefunctions of arbitrary origin, and calculated the response for several prominent ferroelectrics – including $LiNbO_3$, $BaTiO_3$, and $PbTiO_3$ – using KS eigenstates. The calculated short-circuit currents appear to be in rough agreement with available experimental results where they exist. Furthermore, they indicate a more subtle relationship between polarization and band gap than has heretofore been presumed, with strong implications for the materials design process, as well as shift current's overall viability as a mechanism for efficiently harvesting solar energy.

9:24AM H36.00008 Nanostructured multiferroic materials for optoelectronics and energy-related nanodevices

, RIAD NECHACHE, NAST Center & Department of Chemical Science and Technology, U. of Rome Tor Vergata, ENRICO TRAVERSA, International Research Center for Materials Nanoarchitectonics (MANA), National Institute for Materials Science (NIMS), SILVIA LICOCCIA, NAST Center & Department of Chemical Science and Technology, U. of Rome Tor Vergata, FEDERICO ROSEI, Centre Énergie, Matériaux et Télécommunications, INRS — Combining properties into multifunctional materials is one of innovative ways explored by the modern technology to achieve high miniaturization of integrated devices. In this context, besides their exciting physics, multiferroic materials hich combine two or more ferroic order offer opportunities for potential applications in emerging fields of spintronics, optoelectronics and data storage. For such applications, successful integration of these multifunctional materials needs to develop adequate fabrication processes and to the coexistence in singe phase of robust properties at room temperature (RT). Furthermore, a synergistic interaction between magnetic and electric orders leads to additional freedom for designing related devices. Here we review recent progress of our group in growth and nanopatterning of multiferroic thin films developed to overcome those drawbacks. We will present the fabrication of RT-multiferroic Bi_2FeCrO_6thin films. Successful nanopatterning of these complex oxides by a versatile and generic approach and their photovoltaic properties will be also discussed.

9:36AM H36.00009 Energy Transfer in Organic Photovoltaic Cells and its Impact on Measurements of the Exciton Diffusion Length

, RUSSELL HOLMES, University of Minnesota — In order to generate photocurrent from an organic photovoltaic cell (OPV), the optically generated exciton must be dissociated into its constituent charge carriers. This process is carried out at the interface between electron donating and accepting materials. Consequently, photocurrent is generated only at the donor-acceptor (D-A) interface, and exciton diffusion to the interface is a critical step in the photoconversion process. The focus of this work is on the development of methods that permit the accurate measurement of the exciton diffusion length, and realizing architectures that demonstrate enhanced exciton harvesting. In measuring the exciton diffusion length, emphasis is placed on quantifying the role of excitonic energy transfer in the dissociation process by explicitly measuring the Förster radius between donor and acceptor materials. Many of the techniques currently used to estimate the exciton diffusion length incorrectly ignore these effects, potentially leading to overestimates. Efforts to overcome the short diffusion length are focused on small molecule OPVs that contain a continuously graded D-A film composition as a means to simultaneously optimize both exciton diffusion and charge collection. In a properly optimized graded heterojunction OPV, power conversion efficiencies >4% can be realized, exceeding the performance of conventional planar and uniformly mixed structures.

9:48AM H36.00010 Effect of Thin Polymer Layers on the Performance of ZnO/Cu_2O Solar Cells[1]

TALIA GERSHON, KEVIN MUSSELMAN, ANDREW MARIN, JUDITH MACMANUS-DRISCOLL, University of Cambridge — Transition metal oxides are a class of stable, non-toxic, and inexpensive semiconductors with great potential in low-cost photovoltaics (PV) applications. Cu_2O is a versatile p-type oxide that absorbs visible light and can be solution-processed at low temperatures. ZnO is a wide-E_g n-type material with good electronic properties and has already been widely incorporated into other low-cost PV technologies such as organic and dye-sensitized solar cells. While ZnO/Cu_2O devices have large theoretical efficiencies (as high as 20%) [1], practical devices do not reach their full potential due to poor charge collection and recombination. ZnO/Cu_2O PV's can be improved by optimizing deposition conditions, such as solution pH and temperature, and device geometry, such as layer thickness [2]. This talk, however, will discuss how semiconducting polymer layers can further enhance performance for scalable device fabrication. In particular, polymer type and the Cu_2O/polymer interface will be discussed as routes to better performance.

10:00AM H36.00011 Nanoscale Morphology and Charge Transport in Hybrid Solar Cells by Conducting Probe Atomic Force Microscopy

, JIEBING SUN, SEAN R. WAGNER, DANIEL ENDERICH, PHILLIP DUXBURY, PENGPENG ZHANG, Physics and Astronomy Department and Center of Research Excellence in Complex Materials, Michigan State University — Measurements of the dependence of photoactive response on nanoscale morphology provide essential insights to further improve processing and achieve morphologies with enhanced device performance. To study the correlation between local morphology and photoactive response, we have fabricated hybrid polymer/zinc oxide thin films and have characterized their electrical properties at nanoscale resolution with conducting probe atomic force microscopy (c-AFM). The charge carrier mobilities were extracted based on local IV characteristics. The surface morphology and current mapping were recorded simultaneously under various illumination and biasing conditions, enabling direct study of morphology dependent transport processes in these photoactive devices.

10:12AM H36.00012 Development of Phase Stable Organic Photon Upconverters[1]

, YOICHI MURAKAMI, Tokyo Institute of Technology — Recently, high efficiency photon upconversions (UCs) utilizing triplet-triplet annihilation (TTA) in aromatic hydrocarbon molecules, applicable to sunlight intensity, have been actively studied for the purpose of improving external quantum efficiencies of photovoltaics. These studies have been using volatile organic solvents as media in order for TTA to occur, which are currently hindering its applications. I have discovered that those aromatic molecules can be stably dispersed by a simple method within certain class of ionic liquids (ILs), which are non-volatile and thermally stable up to several hundred degree C, to form unprecedented organic photon upconverters with improved phase stability [1,2]. The proposed mechanism for the molecular stabilization in ILs as well as the UC quantum efficiencies is presented.

10:24AM H36.00013 Charge transport and absorption study of metal nanoparticle plasmonics for organic photovoltaics[1]

, MEI XUE, JINFENG ZHU, HUAJUN SHEN, SEONGKU KIM, JACK J. HO, UCLA, HUSSAM ALDEEN S. QASEM, ZAID S. AL OTAIBI, KANG L. WANG, DEVICE RESEARCH LABORATORY, UCLA TEAM, KACST/CALIFORNIA INSTITUTE OF EXCELLENCE ON GREEN NANOTECHNOLOGY TEAM — A hybrid plasmonic nanostructure of an optically sensitive heterojunction organic film incorporating metal nanoparticles is fabricated. From the Charge Extraction in Linearly Increasing Voltage (CELIV) measurements, the mobility of this hybrid plasmonic nanostructure has been experimentally extracted to be at least one order of the magnitude higher than that of the organic film without metal nanoparticles. The measured absorption spectrum also shows the increasing of the intensity by around 28% as well as the broadening of the spectrum. The theoretical calculation confirms this broadband optical absorption enhancement results from localized surface plasmon resonance. The optimization of the density of the metal nanoparticles has been done to achieve the best performance for the photovoltaic devices.

10:36AM H36.00014 The Effect of a Self Assembled Monolayer in Small Molecule Organic Solar Cells

, ALEXANDER COOK, KAMIL MIELCZAREK, ANVAR ZAKHIDOV, The University of Texas at Dallas Physics Department — We have previously found that a Self Assembled Monolayer (SAM) of Flouroalkyl TrichloroSilane (FTS) molecules on Single-Walled and Multi-Walled Carbon Nanotubes (SWCNT & MWCNT) can greatly improve the conductivity [1]. In present work we have studied the effect of SAM modified carbon nanotubes in Small molecule organic photovoltaic cells. (OPV) We have fabricated and characterized OPV of the general structure: CNT(FTS)/CuPC/C60/BCP/Al. We observed improvement of the performance of the OPV with CNT anodes with FTS SAM both for SW and MW CNT. The major effect is an improvement of the open circuit voltage and also small improvements in both short circuit current and filling factor. The increase in open circuit voltage is likely due to modifications of the carbon nanotube work function by the strong dipole moments of the FTS molecules. The improvements in short circuit current and filling factor is probably due to improved active layer morphology and removal of absorbed water from the substrate.

10:48AM H36.00015 Inverted Polymeric Photovoltaic Cells and Parallel Tandems with Transparent Single Wall Carbon Nanotubes Interlayer[1]

, KAMIL MIELCZAREK, ALEX COOK, ANVAR ZAKHIDOV, University of Texas at Dallas, ANTTI KASKELA, ALBERT NASIBULIN, ESKO KAUPPINEN, Aalto University, Finland — We demonstrate an organic photovoltaic (OPV) monolithic multi junction cell in a parallel electrical configuration utilizing polymers with complementary absorption spectra and transparent single wall CNT (SWCNT) as an interlayer electrode (IE). Parallel tandem cells are of importance because they can append to the limited spectral coverage of available polymers and because there is no need balance current as is the case with in-series configurations. Devices comprise of polymeric sub cells where one is inverted using ZnO nanoparticles and a MoO_3 buffer layers, this inverted structure allows for the SWCNT IE to function as a cathode. Each sub cell is characterized independently and the short circuit current of the tandem device is shown to increase. Overall increase in efficiency is observed and attributed to enhanced spectral coverage by spectrally complimentary polymers and the effective use of parallel tandem architecture. We also demonstrate a semi transparent inverted OPV structure with a SWCNT electrode and a efficiency of over 3%.

Session H37 DMP: Focus Session: Graphene Structure, Dopants, and Defects: Transport I

C146

8:00AM H37.00001 Probing the nature of impurity scattering in graphene , HELENE BOUCHIAT, LPS CNRS Univ. Paris Sud — Since the very first investigations of the electronic properties of graphene the nature of defects has been shown to play an essential role in determining the carrier density dependence of the conductance. Impurity scattering is characterized by two different times the transport and elastic scattering times which are sensitive to the mass less energy dispersion of graphene. The analysis of the ratio between these two times gives insight on the nature (neutral or charged) and range of the scatterers. We will discuss how to extract these two times from magneto-transport measurements in macroscopic samples and analyze their differences in monolayer and bilayer Graphene in relation with the different symmetry properties of their band structure and wave functions.

"Transport and Elastic Scattering Times as Probes of the Nature of Impurity Scattering in Single-Layer and Bilayer Graphene" M. Monteverde, C. Ojeda-Aristizabal, R. Weil, K. Bennaceur, M. Ferrier, S. Guéron, C. Glattli, H. Bouchiat, J. N. Fuchs, and D. L. Maslov Phys. Rev. Lett. **104**, 126801 (2010).

8:36AM H37.00002 ABSTRACT WITHDRAWN –

8:48AM H37.00003 Transport and optical measurements on Graphene - hBN heterostructures , LEI WANG, CORY DEAN, ANDREA YOUNG, ZHEYUAN CHEN, INANC MERIC, KEN SHEPARD, LOUIS BRUS, PHILIP KIM, JAMES HONE — Placing graphene on hexagonal BN (hBN) substrates has recently been shown to lead to improved device quality. In addition, the planar nature of the h-BN allows for the realization of novel device architectures with high mobility graphene, including dual-gated devices. I will discuss recent transport and optical measurements on such graphene-hBN heterostructures, focusing on high mobility dual gated bilayer graphene, in which the carrier density and the band-gap can be tuned independently.

9:00AM H37.00004 Fabrication and transport characterization of Graphene/Hexagonal Boron Nitride sandwich structures , JIAN-HAO CHEN, KWANPYO KIM, WILL REGAN, WILLIAM GANNETT, KRIS ERICKSON, MICHAEL ROUSSEAS, ALEX ZETTL, Department of Physics, University of California at Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory — High quality, large size hexagonal Boron Nitride (h-BN) thin films and single layer graphene were grown on metal substrates via the chemical vapor deposition method (CVD) and transferred to form Graphene/h-BN sandwich structures. High resolution transmission microscopy (TEM) was performed on Graphene and h-BN, confirming highly-ordered crystalline structures of both. The electronic transport properties of various sandwich configurations were investigated at low temperature and high magnetic field.

9:12AM H37.00005 Tunable band gaps in bilayer graphene-BN heterostructures , ASHWIN RAMASUBRAMANIAM, University of Massachusetts Amherst, DORON NAVEH, ELIAS TOWE, Carnegie-Mellon University — We investigate band-gap tuning of bilayer graphene between hexagonal boron nitride sheets, by external electric fields. Using density functional theory, we show that the gap is continuously tunable from 0 to 0.2 eV, and is robust to stacking disorder. Moreover, boron nitride sheets do not alter the fundamental response from that of free-standing bilayer graphene, apart from additional screening. Our calculations suggest that graphene-boron nitride heterostructures could provide a viable route to graphene-based electronic devices.

9:24AM H37.00006 Dielectric thickness dependence of carrier mobility in graphene with Al_2O_3 and HfO_2 top dielectrics , BABAK FALLAHAZAD, SEYOUNG KIM, University of Texas at Austin, LUIGI COLOMBO, Texas Instrument, EMANUEL TUTUC, University of Texas at Austin — We study the carrier mobility in graphene with high-k top dielectrics, as a function of the dielectric thickness and temperature. Metal-oxide high-k films, Al_2O_3 (k ~8.4) and HfO_2 (k ~16), are deposited on graphene by atomic layer deposition (ALD), at deposition temperatures of 200-250 $^\circ$C. A considerable (~50%) mobility drop is observed after the deposition of the first 2-4 nm of dielectric. For thicker dielectrics the mobility is relatively insensitive to thickness. The carrier mobility has a weak temperature dependence, which indicates that phonon scattering is not the primary mobility limiting factor in these devices. Our results suggest that Coulomb scattering caused by fixed charged impurities located in the high-k dielectric, and in proximity to the graphene layer plays a significant role in mobility degredation. The ALD grown high-k films are inherently oxygen deficient, and oxygen vacancies form donor levels which become positively charged in the proximity of the graphene layer. We speculate that Coulomb scattering due to charged point defects is the mobility limiting mechanism in graphene devices with Al_2O_3 or HfO_2 high-k dielectrics.

9:36AM H37.00007 Coulomb Drag in Independently Contacted Graphene Bilayers[1] , SEYOUNG KIM, INSUN JO, JUNGHYO NAH, YAO ZHEN, SANJAY BANERJEE, EMANUEL TUTUC, The University of Texas at Austin — Two graphene layers placed in close proximity, and electrically isolated, offer a unique system to investigate interacting electron physics. In such graphene bilayer, the interlayer spacing can be reduced to values much smaller than otherwise achievable in semiconductor heterostructures. Moreover, the zero energy band-gap allows the realization of coupled hole-hole, electron-hole, and electron-electron two-dimensional systems in the same sample. Here we demonstrate the realization of independently contacted graphene bilayers. We probe the resistance and density of each layer, and quantitatively explain their dependence on the back-gate bias. We experimentally measure the Coulomb drag between the two graphene layers, by flowing current in one layer and measuring the voltage drop in the opposite layer. The drag resistivity gauges the momentum transfer between the two layers, which in turn probes the interlayer coupling. The temperature dependence of the Coulomb drag above temperatures of 77K reveals that the ground state in each layer is a Fermi liquid. Below 77K we observe mesoscopic fluctuations of the drag resistivity, as a result of the interplay between coherent transport in the graphene layer and interlayer interaction.

[1]We thank NRI and NSF for support.

9:48AM H37.00008 Probing charge scattering mechanisms in suspended and supported graphene by varying dielectric environment , A.K.M. NEWAZ, KIRILL I. BOLOTIN, Vanderbilt University — The electronic properties of graphene are drastically affected by its environment, such as the substrate underneath it and the impurities near it. To elucidate the effect of scattering due to the environment, we used the Hall probe technique to study the electronic transport properties and the quantum capacitance of single layer graphene devices in environments with different dielectric susceptibility κ. We have varied the susceptibility by i) using solvents of different dielectric constants, ii) mixing two miscible solvents of different dielectric strengths and iii) varying the temperature of the solvent. To eliminate the effects due to a substrate, we have also studied suspended graphene devices. We have observed enhancement in the Hall mobility and reduction in the minimal conductivity in both supported and suspended devices as the static dielectric constant is increased from $\kappa \sim 2$ to $\kappa \sim 30$. This suggests stronger screening of charge scattering in higher κ dielectric environment. Our results support the conjecture that the dominant scattering mechanism in graphene is the long range Coulomb interaction due to the charge impurities.

10:00AM H37.00009 Charge transport studies in graphene devices: a focus on mobility behavior[1] , ARCHANA VENUGOPAL, WILEY KIRK, LUIGI COLOMBO, ERIC VOGEL, University of Texas at Dallas — Graphene has been the subject of extensive electrical characterization since 2004. As in semiconductor based FETs, mobility (μ) is used as the parameter to gauge and compare the device performance. Typically reported is the effective mobility, μ_{eff}, extracted from $I_d - V_g$ characteristics or the channel mobility (μ_H) extracted from Hall measurements, which can be especially illuminating when more than one carrier type is participating in the charge transport process. The dependence of the mobility on parameters such as applied field, dielectric type, underlying oxide thickness, channel dimensions and temperature is not well understood. A study of μ_H and the accompanying magnetoresistance as a function of the above mentioned parameters in low to moderate magnetic fields was performed, as well as μ_{eff} on the same devices, the results of which will be compared and presented. The dependence on graphene type (grown vs. exfoliated) will also be discussed.

[1]SRC-NRI Southwest Academy for Nanoelectronics

10:12AM H37.00010 Graphene nanoelectronics from ab initio theory[1] , JESSE MAASSEN, McGill University, WEI JI, HONG GUO — We employ atomic first principles theory to study the properties of realistic graphene nanoelectronic systems. We focus on the role of different contact materials and their effect on the transport properties at the graphene/metal junction. The current-voltage characteristics were calculated using density functional theory (DFT) combined with non-equilibrium Green's functions (NEGF).

[1]NSERC, FQRNT and CIFAR

10:24AM H37.00011 Charge transport in two-terminal graphene junctions with bonding metal contacts , BARRAZA-LOPEZ SALVADOR, M. Y. CHOU, School of Physics. Georgia Institute of Technology — One has to attach graphene to metal leads to measure charge transport characteristics. In a number of experiments a thin Ti film is grown on top of graphene and additional metal leads (e.g., Au or Al) are created on top of this film. Ti forms covalent bonds with graphene, destroying the linear dispersion at the Ti/graphene contact. For practical reasons (i.e., the use of Hamiltonians with a linear dispersion) most theoretical approaches either consider only the effects of the inhomogeneities caused by the insulating substrate, or, when two-terminal calculations exist, use assumptions that preclude quantitative modeling. These assumptions include: (i) extremely large bias steps separating the leads and the central region of the device, or (ii) unusually large imaginary contributions to the self-energies representing metal leads. We depart from these models and follow an atomistic approach to compute transmission characteristics of Ti/graphene/Ti junctions. From these calculations we identify the key physical ingredients determining the transport features, and extract parameters to be used in a quantitative effective model that describes accurately the electronic structure and the transmission probabilities of charge carriers. This work complements our previous results in metal/graphene/metal junctions where the metal does not bond covalently to graphene (PRL **104**, 076807 (2010)).

10:36AM H37.00012 Transport in Metal/Graphene Tunnel Junctions , CHRIS MALEC, DRAGOMIR DAVIDOVIC, Georgia Tech — We present a technique to fabricate thin oxide barriers between graphene and Al and Cu to create tunnel junctions and directly probe graphene in close proximity to a metal. We map the differential conductance of our junctions versus probe and back gate voltage, and observe fluctuations in the conductance that are directly related to the graphene density of states. We develop a simple theory of tunneling into graphene to extract experimental numbers, and take into account the electrostatic gating of graphene by the tunneling probe. Results of measurements in magnetic fields will also be discussed, including evidence for incompressible states in the Quantum Hall regime.

10:48AM H37.00013 Quantum transport in high-quality Bilayer Graphene pnp Junctions , YONGJIN LEE, LEI JING, JAIRO VELASCO JR., PHILIP KRATZ, GANG LIU, WENZHONG BAO, MARC BOCKRATH, CHUN NING LAU, Department of Physics, University of California, Riverside, California 92521 — Using high-quality bilayer grapheme pnp junctions with suspended top gates, we perform transport measurements. At a magnetic field B=0, by an applied perpendicular electric field, band gap opens at 260mK. Within the band gap, we demonstrate the conductance decreases exponentially by 3 orders of magnitude with increasing electric field and this can be explained by variable range hopping with a gate-tunable density of states, effective mass, and localization length.

Tuesday, March 22, 2011 8:00AM - 10:48AM –
Session H38 DCP DBP: Focus Session: Quantum Coherence in Biology I A130/131

8:00AM H38.00001 Indicators of quantum coherence in light-harvesting dynamics , ALEXANDRA OLAYA-CASTRO, Department of Physics and Astronomy, University College London — Characterizing quantum dynamics of electronic excitations in a variety of light-harvesting systems is currently of much interest [1]. In particular, it is important to identify measures that appropriately quantify the strength of coherent dynamics and its impact on different time scales of the light-harvesting process. In this talk I will discuss quantum transport performance measures that are defined based on the probability for the dynamics to successfully distinguish different initial photo-excitation conditions. I will also discuss how initial state distinguisability can provide information on spatially correlated phonon fluctuations as well as on the non-markovian character of the quantum dynamics. The prototype systems considered here are cryptophyte light-harvesting antennae isolated from marine algae [2, 3]. Experimental quantification of state distinguishability can be realized by monitoring the evolution of selected off-diagonal density matrix elements and therefore it could be achieved with current two-dimensional spectroscopy techniques.

8:36AM H38.00002 Phonon-mediated path-interference in electronic energy transfer , HODA HOSSEIN-NEJAD, University of Toronto, ALEXANDRA OLAYA-CASTRO, University College London, GREGORY D. SCHOLES, University of Toronto — Motivated by the recent observations of quantum coherence in light-harvesting antennae, we present a formalism to quantify the contribution of path-interference in phonon-mediated electronic energy transfer. The transfer rate between two molecules is computed by considering the quantum mechanical amplitudes associated with pathways connecting the initial and final sites. This includes contributions from classical pathways, but also terms arising from their interference. By treating the vibrational modes of the molecules as a non-Markovian harmonic oscillator bath, we compute the first-order path-interference correction to the classical transfer rate. We show that the correction due to path-interference may have either a vibrational or an electronic character, and may exceed the contribution of the indirect classical pathways.

8:48AM H38.00003 Efficiency of the energy transfer in the FMO complex using hierarchical equations on Graphics Processing Units , TOBIAS KRAMER, CHRISTOPH KREISBECK, University of Regensburg, Germany, MIRTA RODRIGUEZ, IEM CSIC, Madrid, Spain, BIRGIT HEIN, University of Regensburg, Germany — We study the efficiency of the energy transfer in the Fenna-Matthews-Olson complex solving the non-Markovian hierarchical equations (HE) proposed by Ishizaki and Fleming in 2009, which include properly the reorganization process. We compare it to the Markovian approach and find that the Markovian dynamics overestimates the thermalization rate, yielding higher efficiencies than the HE. Using the high-performance of graphics processing units (GPU) we cover a large range of reorganization energies and temperatures and find that initial quantum beatings are important for the energy distribution, but of limited influence to the efficiency. Our efficient GPU implementation of the HE allows us to calculate nonlinear spectra of the FMO complex. References see www.quantumdynamics.de

9:00AM H38.00004 Efficient GPU calculation of 2D-echo spectra of excitonic energy-transfer in systems with large reorganization energy , BIRGIT HEIN, CHRISTOPH KREISBECK, TOBIAS KRAMER, University of Regensburg, Germany, MIRTA RODRIGUEZ, IEM, CSIC, Madrid, Spain — Using the Fenna-Matthews-Olson light harvesting complex as example, we calculate the two dimensional echo spectra (2D echo) of a multi-site system coupled to phonon baths using the propagation scheme suggested by Ishizaki and Fleming in 2009 which works for large system-bath couplings. We study the anti-correlations in the shapes of the 2D spectrum peaks which are seen as evidence for exciton energy transfer. This computationally demanding calculation uses 2.6 h GPU (graphics processing unit) time compared to 2.8 weeks time on a high performance conventional CPU cluster. The efficient implementation of the exact hierarchical equations obliterates the need for approximative methods and facilitates the interpretation and comparison of theory and experiment for systems with large reorganization energies. References see www.quantumdynamics.de

9:12AM H38.00005 Simulation of dissipative quantum dynamics in the presence of strongly-interacting and structured environments: a many-body approach to memory effects , ALEX CHIN, Ulm University, JAVIER PRIOR, Universidad Politécnica de Cartagena, SUSANA F. HUELGA, MARTIN B. PLENIO, Ulm University — Quantum systems which interact strongly with complex and structured environments are receiving increasing attention due to their importance in contexts such as solid-state quantum information processing and bio-molecular quantum dynamics. Unfortunately, these systems are difficult to simulate as the system-bath interactions cannot be treated perturbatively, and standard approaches are invalid or inefficient. Here we combine time-dependent density matrix renormalization group methods with techniques from the theory of orthogonal polynomials to provide an efficient method for simulating open quantum systems at zero and finite temperatures. Using this technique we demonstrate a number of novel dynamical effects which result from long bath memories induced by either sharp spectral structures or strong coupling, and comment on how these can be exploited to drive efficient transport in small networks. We also show how our technique can be used to find the equilibrium properties of excitations in strongly renormalizing environments, and present some results on the quantum phase transition in the sub-Ohmic spin-boson model.

9:24AM H38.00006 Optimal Excitation energy transfer dynamics in light-harvesting systems[1] , JIANLAN WU[2], JIANSHU CAO, ROBERT SILBEY, Chemistry Department, MIT — With the facilitation of surrounding protein environments, excitation energy transfer (EET) in photosynthetic systems can be highly efficient and robust. This talk compares different descriptions of dissipative exciton dynamics, discusses the generic mechanism of optimal energy transfer, and explores its implications for light-harvesting systems. (i) The generalized Bloch-Redfield equation provides a reliable description of exciton dynamics over a broad range of parameter space. (ii) The generic mechanism of optimal efficiency allows us to examine the interplay of quantum coherence, dynamics noise, and static disorder in a unified conceptual framework. (iii) The topological symmetry and network structures in photosynthetic systems reveal useful insights for the optimal design of artificial energy transfer systems.

9:36AM H38.00007 A quantum landscape study of energy transfer efficiency in light-harvesting complexes , ALIREZA SHABANI, Princeton, MASOUD MOHSENI, MIT, HERSCHEL RABITZ, Princeton, SETH LLOYD, MIT — Over billion years of evolution some photosynthetic complexes have turned into highly efficient light energy harvesting systems. In this work, we demonstrate optimality and robustness of energy transfer in the Fenna-Matthews-Olson (FMO) protein complex with respect to all the relevant parameters of system and environmental interactions. To this end we developed an efficient technique for studying the dynamics of energy transfer in a non-Markovian and non-perturbative regime. For the FMO protein of green sulfur bacteria we find that all the relevant natural parameters to lay within the optimal and robust regimes of energy transfer process. This suggests a peculiar interplay of internal and external forces in order to have a system that functions optimally while being robust under physiological conditions.

9:48AM H38.00008 Fast and efficient excitation transfer across disordered molecular networks , ANDREAS BUCHLEITNER, TORSTEN SCHOLAK, Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, Hermann-Herder-Str. 3, D-79104 Freiburg, Germany, FERNANDO DE MELO, Instituut voor Theoretische Fysica, Katholieke Universiteit Leuven, Celestijnenlaan 200D, B-3001 Heverlee, Belgium, THOMAS WELLENS, Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, Hermann-Herder-Str. 3, D-79104 Freiburg, Germany, FLORIAN MINTERT, Freiburg Institute of Advanced Studies, Albertstr. 18, 79014 Freiburg, Germany — In this talk, we will present our statistical investigations on coherent excitation transfer through finite-size disordered molecular networks. As we have found, there exist certain molecular conformations that exhibit fast and highly efficient transport – mediated by constructive quantum interference. We will discuss the properties of these optimal conformations which go along with the enhancement of efficiency. These insights may be relevant for explaining efficient energy transfer in the photosynthetic FMO complex.

10:00AM H38.00009 Regenerative quantum coherence in photosynthesis under natural conditions[1] , STEPHAN HOYER, K. BIRGITTA WHALEY, University of California, Berkeley — Recent experiments provide compelling evidence for the feasibility of quantum coherent beating in photosynthetic light harvesting complexes, even at room temperature. However, whether this coherence arises *in vivo* and its biological function (if any) have remained unclear. Here we present theoretical evidence for the creation and regeneration of electronic coherence under natural conditions. We show how such regenerated coherence may contribute to energy transfer efficiency in the Fenna-Matthews-Olson (FMO) complex of green sulfur bacteria.

10:12AM H38.00010 Enhanced exciton diffusion length via cooperative quantum transport , MASOUD MOHSENI, MIT, DAMIAN ABASTO, USC, SETH LLOYD, MIT, PAOLO ZANARDI, USC — The energy transfer rate in biomolecular systems is typically calculated from the transition probability of an excitation hopping from one molecule to another using Förster energy transfer based on dipole-dipole interaction of individual molecules in the perturbative regime. However, due to strong interactions of among a group of molecules the excitation can become highly delocalized leading to an effective large dipole moment with an enhanced oscillator strength. Under certain symmetries, this could lead to an enhancement in exicton transfer rate via cooperative donation or acceptance of an excitation. Here, we explore this phenomenon in various multichromophoric geometries, under different symmetries, initial conditions, and dynamics. We study the behavior of the exciton diffusion length under the effects of disorders and environmental fluctuations and quantify the crossover from ballistic to diffusive regimes. Specifically, for a quasi-1 D array of rings containing N chromophores interacting with a bosonic bath, an interplay of time scales dictates the exciton dynamics. In the "far-field" regime, environmental interactions are dominating and the system properties are approaching those of the incoherent equilibrium Gibbs state. However, in the "near-field" the coherent interactions among dipole aggregates dominate other time scales and exciton diffusion length is enhanced by a factor of $\sqrt{N}$.

10:24AM H38.00011 Concatenated quantum codes in biological systems[1] , SETH LLOYD, Massachusetts Institute of Technology — This talk investigates how biological systems such as photosynthetic bacteria use quantum coding techniques such as decoherent subspaces, noiseless subsystems, and concatenated quantum codes to engineer long exitonic lifetimes and rapid energy transport. The existence of hierarchical structures in photosynthetic complexes is associated with concatenated quantum codes. A concatenated code is one that combines two or more codes to construct a hierarchical code that possesses features of all its constituent codes. In photosynthetic complexes, structures at the smallest level use quantum coding techniques to enhance exciton lifetimes, and structures at higher scales possess symmetries that enhance exciton hopping rates. The result is a concatenated quantum code that simultaneously protects excitons and enhances their transport rate. All known quantum codes can be described within the framework of group representation theory. This talk reviews the relationship between symmetry and quantum codes, and shows how photosynthetic bacteria and plants put quantum coding techniques to use to improve the efficiency of photosynthetic transport.

10:36AM H38.00012 A possible mechanisms for quantum coherence assisted ion transport in ion channels , ALIPASHA VAZIRI, Max F. Perutz Laboratories (MFPL), University of Vienna, Austria and the Research Institute of Molecular Pathology (IMP) — Recently it was demonstrated that long-lived quantum coherence exists during excitation energy transport in photosynthesis. It is a valid question up to which length, time and mass scales quantum coherence may extend, how to one may detect this coherence and what if any role it plays for the dynamics of the system. Ion-channels are involved in many physiological processes. In the nervous system their coordinated opening and closing generates action potentials that form the basis for intra-neural communication which are essential for information representation and processing. We have recently suggested that the selectivity filter of ion channels may exhibit quantum coherence which might be relevant for the process of ion selectivity and conduction. I will discuss some of our current experimental efforts in this direction and show that quantum resonances could provide a viable approach to probe these quantum coherences. The emergence of resonances in the conduction of ion channels that are modulated periodically by time varying external fields can serve as signatures of quantum coherence in such a system.

Session H39 DBP: Focus Session: Physics of Cancer A124/127

8:00AM H39.00001 Nanotechnology Approaches to Studying Epigenetic Changes in Cancer , ROBERT RIEHN, NC State University — Placing polyelectrolytes into confined geometries has a profound effect on their molecular configuration. For instance, placing long DNA molecules into channels with a cross-section of about 100 nm^2 stretches them out to about 70% of their contour length. We are using this effect to map epigenetic changes on single DNA and chromatin strands. This mapping on single molecules becomes central in the study of the heterogeneity of cell population in cancer, since rapid change of epigenetic makeup, propagated through rare cancer stem cells, is a hallmark of its progression. We demonstrate the basic building blocks for the single-molecule epigenetic analysis of genomic sized DNA. In particular, we have achieved the mapping of methylated regions in DNA with heterogeneous 5-methyl cytosine modification using a specific fluorescent marker. We further show that chromatin with an intact histone structure can be stretched similar to DNA, and that the epigenetic state of histone tails can be detected using fluorescent antibodies.

8:36AM H39.00002 Cancer Evolution under Drug-Induced Stress-Gradients[1] , GUILLAUME LAMBERT, ROBERT H. AUSTIN, Princeton University — The lack of long term success in eliminating cancer cells while avoiding the evolution of drug resistance indicates that our understanding of how cells evolve in response to stress is still incomplete. We interpret this not as a failure of the current approaches, but rather as an indication that new research venues should be undertaken, where conventional wisdom is challenged in order to drive forward our understanding of cancer. Of particular importance, we believe that the powerful role of evolution in the origin of drug resistance is ill-understood. We do not ask whether evolution occurs, but rather how. We do not describe molecular mechanisms underlying drug resistance at the single cell level, but rather ask how does resistance spread in cancerous tissues and metastatic lesions. We attempt to answer these questions by studying the population-wide dynamics of drug evolution and the collective stress response of cancer cells in a microfluidics device. We use microfluidics technologies to impose high levels of stress on cancer cell metapopulation by create smoothly varying gradients of either oxygen, chemotherapeutic drug, nutrient or pH. We present long-term studies of the adaptation of tumorigenic cancer cells to drug- induced stress gradients.

8:48AM H39.00003 Are biomechanical changes necessary for tumor progression? , JOSEF A. KAS, ANATOL FRITSCH, TOBIAS KIESSLING, DAVID K. NNETU, STEVE PAWLIZAK, FRANZISKA WETZEL, MAREIKE ZINK, University of Leipzig — With an increasing knowledge in tumor biology an overwhelming complexity becomes obvious which roots in the diversity of tumors and their heterogeneous molecular composition. Nevertheless in all solid tumors malignant neoplasia, i.e. uncontrolled growth, invasion of adjacent tissues, and metastasis, occurs. Physics sheds some new light on cancer by approaching this problem from a functional, materials perspective. Recent results indicate that all three pathomechanisms require changes in the active and passive cellular biomechanics. Malignant transformation causes cell softening for small deformations which correlates with an increased rate of proliferation and faster cell migration. The tumor cell's ability to strain harden permits tumor growth against a rigid tissue environment. A highly mechanosensitive, enhanced cell contractility is a prerequisite that tumor cells can cross its tumor boundaries and that this cells can migrate through the extracellular matrix. Insights into the biomechanical changes during tumor progression may lead to selective treatments by altering cell mechanics. Such drugs would not cure by killing cancer cells, but slow down tumor progression with only mild side effects and thus may be an option for older and frail patients.

9:00AM H39.00004 A cellular automaton model for tumor growth in heterogeneous environment[1] , YANG JIAO, Physical Science in Oncology Center, Princeton University, SAL TORQUATO, Dept. Chemistry, Princeton University — Cancer is not a single disease: it exhibits heterogeneity on different spatial and temporal scales and strongly interacts with its host environment. Most mathematical modeling of malignant tumor growth has assumed a homogeneous host environment. We have developed a cellular automaton model for tumor growth that explicitly incorporates the structural heterogeneity of the host environment such as tumor stroma. We show that these structural heterogeneities have non-trivial effects on the tumor growth dynamics and prognosis.

9:12AM H39.00005 Microfabricated Tepui: probing into cancer invasion, metastasis and evolution in a 3D environment[1] , LIYU LIU, Princeton University — Cancer metastasis and chemotherapeutic resistance are the major reasons why cancer remains recalcitrant to long-term therapy. We are interested to know: 1. How cancer cells invade tissues and metastasize in a 3D spatial environment? 2. How cancer cells evolve resistance to chemotherapeutic therapy? Answering these fundamental questions will require spatially propagating cancer cells in a 3D *in vitro* micro environment with dynamically controlled chemical stress. Here we attempt to realize this micro environment with a three-dimentional topology on a micro-chip which consist of isolated highlands (Tepui) and deep lower lands. Cancer cells are patterned in the lower lands and their spatial invasion to the mesas of Tepui is observed continuously with a microscope. Experiments have demonstrated that the cell invasion potential is time dependent, which is not only determined by cell motility, but also cell number and spatial stress. Quantitative analysis shows that the invasion rate fits logistic equation. Further more, we have also imbedded collagen based Extracellular Matrix (ECM) inside these structures and established a robust chemical gradient in a vertical space. With merit of real-time confocal imaging, cell propagation, metastasis and evolution in the 3D environment are studied with time as a model for cell behavior inside tissues.

[1]NCI grant: U54CA143803

9:48AM H39.00006 Study of breast cancer cell behavior under chemical stress using microfluidic gradient generator[1] , AMY WU, KEVIN LOUTHERBACK, GUILLAUME LAMBERT, LIYU LIU, ROBERT AUSTIN, JAMES STURM, PRINCETON PSOC TEAM — Understanding the behavior of cancer cells in gradients of chemotherapeutic agents is important in studying the evolution of cancer drug resistance. Compared to traditional in-vitro methods, microfluidic gradient generators better control temporal and spatial profile of gradients. However, maintaining chemical gradients requires high flow rate of liquid (10ul/hr) in microfluidic chip while culturing mammalian cells demands slow flow rate of liquid (1ul/hr). In this paper, we modify a microfluidic gradient generator (Jeon et al, Langmuir, 2001) to overcome the challenge of maintaining slow flow rate and stable gradients simultaneously based on numerical simulations, and culture metastatic breast cancer cell line (MDA-MB-231) in the chip. To characterize the stability of gradients, we visualize the gradient profile by infusing fluorescein. Finally, we will report the response of the on-chip culture under the stress of chemical gradients, observing for cellular phenotypic changes including death, proliferation, morphology, and migration.

10:00AM H39.00007 Superficial dose distribution in breast for tangential radiation treatment of breast cancer , ROUMIANA CHAKAROVA, MAGNUS GUSTAFSSON, ANNA BAECK, NINNI DRUGGE, ASA PALM, ANDREAS LINDBERG, MATTIAS BERGLUND, Sahlgrenska University Hospital, Dept. of Medical Physics and Biomedical Engineering, Gothenburg, 413 45 Sweden — The superficial (0-2 cm) dose distribution in a cylindrical phantom is examined theoretically and experimentally when irradiated by tangential photon beams. The lateral superficial part of the phantom is shown to receive full dose beyond 2 mm whereas the build-up region is up to 7 mm where the beams enter. Eclipse AAA calculations agree well with the experimental and Monte Carlo data while Eclipse PBC underestimates the entrance dose the first 3-4 mm and fails to give a correct lateral dose close to the surface up to 10 mm depth. The performance of the Eclipse algorithms is evaluated in a number of clinical cases with Monte Carlo results. Examples are given to illustrate how differences in geometrical presentation of the body structure in the treatment planning system and the Monte Carlo simulation as well as the patient voxelization may affect the evaluation results.

10:12AM H39.00008 Origin of using cisplatin over transplatin for cancer treatment: An ab initio study[1] , SA LI, PURU JENA, Virginia Commonwealth University, DEPARTMENT OF PHYSICS, VIRGINIA COMMONWEALTH UNIVERSITY TEAM — Eventhough cisplatin has been used as a chemotherapy anti-cancer drug for over 40 years the thermodynamics and kinetics of the reactions are still largely unknown. Cisplatin molecules are known to be attacked by water molecules before they react with DNA. As a result, two Cl atoms are eliminated. The active piece in the cell, therefore, is not cisplatin but $(NH_3)_2Pt^{2+}$. To explain why only cisplatin but not transplatin functions as anticancer drug, we used first principles method to study the dechlorination process in cis- and transplatin. Although transplatin molecule is more stable than cisplatin by 0.52 eV, we found cisplatin to be more favorable for reaction due to the following reasons: 1) the energy cost to remove a Cl atom is less from cisplatin than transplatin. 2) cis-form $(NH_3)_2Pt^{2+}$ derived from cisplatin with N-Pt-N angle of 97° is lower in energy than trans-form derived from transplatin with N-Pt-N angle of 180°. The rotation barrier for N-Pt-N changing from 180° to 97° is about 1.0 eV. 3) When cis-form of $(NH_3)_2Pt^{2+}$ reacts with two Guanines in DNA, the two N atoms in Guanines can readily bind to the Pt atom in cisplatin. The transplatin due to steric reasons does not provide that opportunity.

10:24AM H39.00009 Actinomycin D binding mode reveals the basis for its potent HIV-1 and cancer activity , THAYAPARAN PARAMANATHAN, IOANA D. VLADESCU, MICAH J. MCCAULEY, Northeastern University, Boston, MA, IOULIA ROUZINA, University of Minnesota, Minneapolis, MN, MARK C. WILLIAMS, Northeastern University, Boston, MA — Actinomycin D (ActD) is one of the most studied antibiotics, which has been used as an anti-cancer agent and also shown to inhibit HIV reverse transcription. Initial studies with ActD established that it intercalates double stranded DNA (dsDNA). However, recent studies have shown that ActD binds with even higher affinity to single stranded DNA (ssDNA). In our studies we use optical tweezers to stretch and hold single dsDNA molecule at constant force in the presence of varying ActD concentrations until the binding reaches equilibrium. The change in dsDNA length upon ActD binding measured as a function of time yields the rate of binding in addition to the equilibrium lengthening of DNA. The results suggest extremely slow kinetics, on the order of several minutes and 0.52 ± 0.06 μM binding affinity. Holding DNA at constant force while stretching and relaxing suggests that ActD binds to two single strands that are close to each other rather than to pure dsDNA or ssDNA. This suggests that biological activity of ActD that contributes towards the inhibition of cellular replication is due to its ability to bind at DNA bubbles during RNA transcription, thereby stalling the transcription process.

Tuesday, March 22, 2011 8:00AM - 10:12AM –

Session H40 DBP: Multi-cellular Processes and Development A122/123

8:00AM H40.00001 Dynamics of asexual reproduction in planarians , EVA-MARIA SCHOETZ, BRYAN LINCOLN, SOFIA QUINODOZ, Princeton University — Planaria research is experiencing a resurgence due to the development of molecular tools, the Planarian genome project and database resources. Despite the resulting progress in planarian biology research, an extensive study of their physical properties remains to be undertaken. We developed a method to collect a large amount of data on the dynamics of clonal reproduction in the freshwater planarian S.mediterranea. The capability of planarians to regenerate an entire organism from a minuscule body part is based on a homogeneously distributed stem cell population that comprises 25-30% of all cells. Due to this stem cell contingent, planarians can reproduce spontaneously by dividing into a larger head and a smaller tail piece, which then will rebuild the missing body parts, including a central nervous system, within about a week. Time-lapse imaging allows us to characterize the fission process in detail, revealing the stages of the process as well as capturing the nature of the rupture itself. A traction force measurement setup is being developed to allow us to quantify the forces planarians exert on the substrate during reproduction, a macroscopic analog to the Traction Force Microscopy setups used to determine local cellular forces. We are particularly interested in the molecular processes during division and the interplay between tissue mechanics and cell signaling.

8:12AM H40.00002 Quantifying cell behaviors during embryonic wound healing[1] , DAVID MASHBURN, XIAOYAN MA, SARAH CREWS, HOLLEY LYNCH, W. TYLER MCCLEERY, M. SHANE HUTSON, Vanderbilt University — During embryogenesis, internal forces induce motions in cells leading to widespread motion in tissues. We previously developed laser hole-drilling as a consistent, repeatable way to probe such epithelial mechanics. The initial recoil (less than 30s) gives information about physical properties (elasticity, force) of cells surrounding the wound, but the long-term healing process (tens of minutes) shows how cells adjust their behavior in response to stimuli. To study this biofeedback in many cells through time, we developed tools to quantify statistics of individual cells. By combining watershed segmentation with a powerful and efficient user interaction system, we overcome problems that arise in any automatic segmentation from poor image quality. We analyzed cell area, perimeter, aspect ratio, and orientation relative to wound for a wide variety of laser cuts in dorsal closure. We quantified statistics for different regions as well, i.e. cells near to and distant from the wound. Regional differences give a distribution of wound-induced changes, whose spatial localization provides clues into the physical/chemical signals that modulate the wound healing response.

8:24AM H40.00003 Keeping track of embryo development: new insights in the coupling between local and global changes , TIMON IDEMA, PHILIP NELSON, ANDREA LIU, University of Pennsylvania, JULIEN DUBUIS, LISA MANNING, THOMAS GREGOR, Princeton University — Modern imaging techniques allow us to study biological systems such as Drosophila in vivo during early development. Between the ninth and fourteenth cell cycles of the Drosophila embryo, nuclei are positioned at the embryo's surface and are observed to divide at the end of each cycle in a highly synchronized fashion. We have implemented a new tracking technique that allows us to determine the shapes of the nuclei as they elongate and divide, and to follow their motion on the surface. We find that during each cycle, the nuclei shapes evolve with time in a consistent way from nucleus to nucleus. These shape changes spread as waves with a well-defined wave velocity through the embryo, coupling local (nucleus) and collective (entire embryo) development. The waves in turn induce collective motions of the nuclei, not just after division but also before it.

8:36AM H40.00004 A cellular Potts model of germband retraction and dorsal closure[1] , M. SHANE HUTSON, JASON ROHNER, SARAH CREWS, W. TYLER MCCLEERY, W. BRADLEY ROBINSON, Vanderbilt University — Germband retraction and dorsal closure are critical morphogenetic events in fruit fly embryogenesis. Both involve the coordinated reshaping of two epitheloid tissues – germband (GB) and amnioserosa (AS). The GB is initially curled into a U-shape with the AS between the arms of the U. Retraction leaves the embryo's dorsal surface covered by AS cells which then contract to pull lateral parts of the GB up to cover the dorsal surface. We have simulated these events using a cellular Potts model. The model is 3D with several generalized cell types: a central yolk; a surrounding monolayer of AS and GB cells with epithelial polarization; and an outer vitelline membrane enclosing the cells and a perivitelline fluid. The model also incorporates several critical cell behaviors: polarized apical constriction of AS cells; controlled relaxation of stretched GB cells; and differentiation of GB cells at the GB-AS interface so that these cells then contract a supracellular purse-string and extend filopodia that reach across the AS and zip together the GB's approaching lateral flanks. We will discuss how all of these components are necessary to reproduce normal tissue motions and those observed during laser microsurgery experiments.

[1]Supported by NSF Grant IOB-0545679.

8:48AM H40.00005 Developmental and Metabolite Transport Strategies to Optimize the Growth of Filamentous Cyanobacteria , AIDAN BROWN, ANDREW RUTENBERG, Department of Physics, Dalhousie University, Halifax, Nova Scotia, Canada — Individual cells of filamentous cyanobacteria share nutrients through cytoplasmic and/or periplasmic connections. Under conditions of low fixed-nitrogen some cells terminally differentiate into heterocysts, which fix nitrogen for the remaining photosynthetic vegetative cells. Heterocysts are observed to occur in a regular pattern separated by clusters of vegetative cells. Using a quantitative model of nitrogen uptake, consumption and transport together with vegetative cell growth and division, we explore how the overall growth rate of the filament depends on different heterocyst positioning patterns and on particular strategies of nitrogen transport.

9:00AM H40.00006 Elasticity of developing cardiac tissue , STEPHANIE MAJKUT, JOE SWIFT, CHRISTINE KRIEGER, DENNIS DISCHER, University of Pennsylvania — Proper development and function of the heart from the tissue to cellular scale depends on a compliant ECM. Here we study the maturation of embryonic cardiac tissue mechanics in parallel with the effects of extracellular mechanics on individual cardiomyocyte function throughout early development. We used micropipette aspiration to measure local and bulk elastic moduli (E) of embryonic avian heart tissue from days 2-12. We observe stiffening of the early heart tube from E = 1 kPa at day 1 to E = 2 kPa at day 4, reaching neonatal values by day 12. Treating heart tubes with blebbistatin led to 30% decrease in E, indicating a significant but partial actomyosin contribution to mechanics at these stages. We performed a proteomic analysis of intact and decellularized 2-4 day heart tubes by mass spectrometry to quantify the ECM present at these stages. Isolated cardiomyocytes from 2-4 day chick embryos were cultured on collagen-coated PA gels of various stiffnesses. Beating magnitude was modulated by substrates with E = 1-2 kPa, similar to physiological E at those stages.

9:12AM H40.00007 ECM ordering effects as a marker for early tissue formation on artificial substrates - a sum-frequency-generation spectroscopy study , PATRICK KOELSCH, MARK-OLIVER DIESNER, Karlsruhe Institute of Technology, BIOINTERFACES TEAM — The in situ monitoring of the interphase between a substrate and a cellular layer is of great interest as it allows determination of changes in surface properties and extracellular matrix (ECM) organization. The latter is an early indicator of major cellular processes like migration, adhesion, proliferation, metastasis, tissue formation, and gain or loss of differentiation. We demonstrated recently that vibrational sum-frequency-generation (SFG) spectroscopy can be used to probe the layer between living cells and a solid substrate. In this contribution we will report on the investigation of ordering phenomena within the ECM of fibroblasts allowing to track early stages of tissue formation. SFG spectroscopy offers a unique way to observe these correlated changes of order in real-time without the need of labeling or disruption.

9:24AM H40.00008 Distinguishing Pattern Formation Phenotypes: Applying Minkowski Functionals to Cell Biology Systems[1] , ERIN RERICHA, CAN GUVEN, University of Maryland, College Park, CAROLE PARENT, National Cancer Institute, National Institutes of Health, WOLFGANG LOSERT, University of Maryland, College Park — Spatial Clustering of proteins within cells or cells themselves frequently occur in cell biology systems. However quantifying the underlying order and determining the regulators of these cluster patterns have proved difficult due to the inherent high noise levels in the systems. For instance the patterns formed by wild type and cyclic-AMP regulatory mutant *Dictyostelium* cells are visually distinctive, yet the large error bars in measurements of the fractal number, area, Euler number, eccentricity, and wavelength making it difficult to quantitatively distinguish between the patterns. We apply a spatial analysis technique based on Minkowski functionals and develop metrics which clearly separate wild type and mutant cell lines into distinct categories. Having such a metric facilitated the development of a computational model for cellular aggregation and its regulators.

9:36AM H40.00009 Measuring the viscosity of embryonic epithelia *in vivo* by magnetic tweezers[1] , XIAOYAN MA, M. PAULA ANGARITA, MERSHARD FRIERSON, DREW SHELDON, M. SHANE HUTSON, Vanderbilt University — During early development, sheets of epithelial cells are reshaped by cellular forces. Several recent investigations in fruit fly (*Drosophila*) embryos have used laser microsurgery and video force microscopy to measure these forces; however, these measurements are actually limited to force/viscosity ratios because the effective viscosity of epithelial cells in a living embryo is largely unknown. This effective viscosity may vary spatially within the embryo and temporally as development progresses. To address this issue, we use microinjection, magnetic tweezers and confocal microscopy to measure the effective viscosity of epithelial cells in fruit fly embryos *in vivo*. We inject fluorescent magnetic beads (2-μm diameter) into GFP-labeled embryos at the multi-nuclear syncytial blastoderm stage. The beads are pulled to embryo's surface by a permanent magnet and become engulfed by individual epithelial cells during cellularization. During later stages of development, we supply current pulses to an electromagnet to apply force pulses to the beads with a magnitude of $\sim$100 pN. The effective viscosity is inferred from the movement of these beads as tracked by confocal microscopy. We will report initial results on amnioserosa cells during dorsal closure.

9:48AM H40.00010 Modeling of Endothelial Glyccalyx via Dissipative Particle Dynamics , MINGGE DENG, Univ. of Science & Technology of China and Brown University, HAOJUN LIANG, Univ. of Science & Technology of China, GEORGE KARNIADAKIS, Brown University — We employ Dissipative Particle Dynamics (DPD) to simulate flow in small vessels with the endothelial glycocalyx attached to the wall. Of particular interest is the quantification of the slip velocity at the edge of glycocalyx and of the increased pressure drop at different crafting densities, stiffness and height of the glycocalyx. Results will be presented for capillaries and small arterioles, and interactions with discrete red blood cells will be included in the modeling. In addition to the physical insight gain for this important but relatively unexplored bioflow, simple models for the slip velocity will be proposed that can be used in continuum simulations of blood flow in micro-vessels.

10:00AM H40.00011 An approach to collective behavior in cell cultures: modeling and analysis of ECIS data , DAVID RABSON, EVAN LAFALCE, DOUGLAS LOVELADY, University of South Florida, CHUN-MIN LO, National Yang-Ming University — We review recent results in which statistical measures of noise in ECIS data distinguished healthy cell cultures from cancerous or poisoned ones: after subtracting the "signal," the $1/f^{\alpha}$ noise in the healthy cultures shows longer short-time and long-time correlations. We discuss application of an artificial neural network to detect the cancer signal, and we demonstrate a computational model of cell-cell communication that produces signals similar to those of the experimental data. The simulation is based on the q-state Potts model with inspiration from the Bak-Tang-Wiesenfeld sand-pile model. We view the level of organization larger than cells but smaller than organs or tissues as a kind of "mesoscopic" biological physics, in which few-body interactions dominate, and the experiments and computational model as ways of exploring this regime.

Session H41 Irving Langmuir Prize Session: Ultrafast Dynamics A115/117

8:00AM H41.00001 Irving Langmuir Prize in Chemical Physics Talk: Attosecond Electron Dynamics[1] , STEPHEN LEONE, University of California Berkeley — Isolated attosecond pulses are produced by the process of high order harmonics, and these pulses are used as a soft X-ray probe in wavelength-dispersed transient absorption. Inner shell core-level spectroscopic transitions are thus used to analyze the chemical and electronic environment of specific atomic states as a function of time following ionization and dissociation. High field ionization processes, using 800 nm pulses, result in spin-orbit electronic state populations, alignment, and electronic wave packet superpositions, all of which are investigated by the spectrally-resolved X-ray probe. By using isolated attosecond pulses as the probe, high field ionization events on a subfemtosecond timescale are investigated. The generality of the transient absorption method for attosecond dyamics is described, as well as the challenges during the pump-probe pulse overlap time period. The results are compared to theoretical calculations by collaborators.

[1]Supported by DOE, NSF and AFOSR.

8:36AM H41.00002 Time- and Angle-Resolved Photoemission Spectroscopy: Ultrafast Dynamics of Electronic Structure , JONATHAN A. SOBOTA, PATRICK S. KIRCHMANN, SHUOLONG YANG, ZHI-XUN SHEN, Stanford University — Angle-resolved photoemission spectroscopy (ARPES) is a powerful experimental tool for condensed matter systems as it measures the single-particle spectral function. Using femtosecond laser pulses in a pump-probe scheme, ARPES can be extended into the time domain. Here we report the construction of a time-resolved ARPES (trARPES) system. We utilize a Ti:Sapphire oscillator to produce infrared pump pulses, while ultraviolet probe pulses are generated by frequency quadrupling. A hemispherical electron analyzer measures the photoemission spectrum as a function of pump-probe delay. We present results on Gallium Arsenide, which displays hot electron dynamics on two distinct timescales in the unoccupied states. Interestingly, the signal in the occupied states has high temporal contrast, resembling a step-function with dynamics at negative delays. These properties make Gallium Arsenide a versatile tool for trARPES system characterization, allowing for calibration of pump-probe temporal and spatial overlap, as well as determination of time resolution.

8:48AM H41.00003 Beyond the Frontiers of Time-Resolved Spectroscopy[1] , THOMAS PFEIFER, Max-Planck Institut fuer Kernphysik — Time-resolved spectroscopy experiments typically require the measurement of at least two ("pump" and "probe") interactions of a field (e.g. a laser pulse) with the spectroscopic target system (e.g. atom, molecule) at variable but known temporal delays. It is often assumed that the shortest dynamics measurable with such techniques is on the order of the pulse duration of the pump and probe events. In this talk, it will be shown that attosecond electron wavefunction beating can, in principle, be resolved by employing a nonlinear interferometry concept with phase-stabilized femtosecond pulses that does not require attosecond pulses for pumping nor probing. The perfectly coherent and reproducible electric fields of the pump and probe pulses thus seem the ultimate technical goal to achieve the highest temporal resolution in science. By contrast, however, it will be shown that statistically varying (colored-noise) partially coherent pulses typically produced at free-electron lasers (FELs) can be beneficial in resolving dynamics beyond their average pulse duration. These findings may carry general implications for the future development of time-resolved spectroscopy.

9:24AM H41.00004 Quantitative imaging of ultrashort photoelectron pulse dynamics[1] , ZHENSHENG TAO, HE ZHANG, PHILLIP DUXBURY, MARTIN BERZ, CHONG-YU RUAN, Michigan State University — Understanding and mitigating the space charge effects is a pressing issue in the development of ultrafast electron diffraction and imaging. Using a novel ultrafast projection imaging technique, quantitative imaging of transient space charge effects in the generation of high density ultrashort electron pulses is performed, which offers a means to directly compare with multi-electron calculations. We establish that the pulse width exhibits a fractional power-law scaling with the sheet density of the emitted electron pulses. By comparing to multi-electron simulations, the initial longitudinal phase space of the photoelectrons is extracted, demonstrating a strong dependence of the initial momentum spread on the sheet density. Multielectron effects are treated using a simple extension of single electron photoemission theory yielding qualitatively correct estimates of the quantum efficiency.

9:36AM H41.00005 Electron and ion dynamics in the melting of two-dimensional charge density waves[1] , TZONG-RU HAN, Michigan State University, CHRISTOS MALLIAKAS, Northwestern University, S.D. MAHANTI, Michigan State University, MERCOURI KANATZIDIS, Northwestern University, CHONG-YU RUAN, Michigan State University — The cause of local lattice distortion in the formation of charge density waves (CDW) in 1D materials is often attributed to the Peierls mechanism, while for 2D system, such as CeTe3, it is not precisely known, due to imperfect nesting of the Fermi surface and a rather large CDW gap observed. Using ultrafast electron crystallography, the femtosecond electronic melting and recrystallization of CDW is investigated by following the superlattice peaks (order parameter) originated from the long-range charge ordering and the accompanying lattice distortion. We find that the reconstitution of CDW is subject to a bottleneck effect that can be attributed to the distinctively separated dynamical properties of electrons and ions in the short time scale, revealing the complexity of 2D CDW formation.

9:48AM H41.00006 Nonperturbative Rydberg excitations triggered by electrons or photons[1] , CHRIS H. GREENE, University of Colorado — Recently investigated processes with autoionizing Rydberg atoms or molecules will be discussed. In one class of processes, two or more Rydberg state are dressed by a laser field that couples them nonperturbatively, after which the coupled states are subsequently probed by XUV photons in a transient absorption experiment. This class will be discussed in the context of two recent experiments involving doubly-excited autoionizing states of atomic helium. In the second class of processes, the Rydberg states are initially created when electrons collide with molecular ions in a plasma environment, then get trapped temporarily in a high Rydberg state after giving up part of their energy to vibrational or rotational degrees of freedom. The Rydberg molecules then have competitive decay pathways, via photon emission, autoionization, or dissociation. The theory will be discussed in the context of experiments that bear on this second class of dynamical processes, which have been performed in Berkeley and also in Prague.

10:24AM H41.00007 Molecular structures studied using laser induced electron diffraction , YUNFEI LIN, Department of Chemistry, Wayne State University, Detroit, MI, 48202, SUK KYOUNG LEE, LU YAN, WEN LI — In a strong laser field, the field ionized electrons from molecules can be returned to the parent molecules by the laser field. These electrons are then scattered off their parent ions. Such phenomena can be used to study molecular structures like the conventional electron diffraction technique, with much better temporal resolution (a few femtoseconds). In this study, we demonstrated its capability to retrieve static structures of molecules using a simple experimental setup. We obtained electron diffraction patterns from spatially aligned oxygen, nitrogen and carbon dioxide in a strong laser field with intensity around $7*10^{13}$ W cm^{-2}. Excellent energy and angular resolutions were achieved by using velocity map imaging detection of electron momentum. The analysis shows that in order to extract the structure information, two kinds of interferences have to be considered: in the first kind, the electrons are ionized and scattered from the same atom; in the second kind, they are ionized from one atom but scattered off another atom in the molecule. We were able to account for the main features in the diffraction patterns of all three molecules and thus obtained the internuclear distances. In the future, we will apply this technique to retrieve structures of polyatomics and also plan to study molecular dynamics exploiting its superb temporal resolution.

Tuesday, March 22, 2011 8:00AM - 11:00AM –

Session H42 DMP DPOLY GERA: Focus Session: Polymers for Energy Storage and Conversion – Physics of Ion Conductivity in Polymers A302/303

8:00AM H42.00001 Polymer Physics Prize Break –

8:36AM H42.00002 Broadband Dielectric Spectroscopy and Quasi-Elastic Neutron Scattering on Single-Ion Polymer Conductors , CHRISTOPHER SOLES, HUA-GEN PENG, KIRT PAGE, CHAD SNYDER, NIST Polymers Division, ASHOUTOSH PANDY, YOUMI JEONG, JAMES RUNT, Pennsylvania State University, NIST POLYMERS DIVISION COLLABORATION, PENNSYLVANIA STATE UNIVERSITY COLLABORATION — The application of solid polymer electrolytes in rechargeable batteries has not been fully realized after decades of research due to its low conductivity. Dramatic increases of the ion conductivity are needed and this progress requires the understanding of conduction mechanism. We address this topic in two fronts, namely, the effect of plasticizer additives and geometric confinement on the charge transfer mechanism. To this end, we combine broadband dielectric spectroscopy (BDS) to characterize the ion mobility and quasi-elastic neutron scattering (QENS) to quantify segmental motion on a single-ion model polymer electrolyte. Deuterated small molecules were used as plasticizers so that the segmental motion of the polymer electrolyte could be monitored by QENS to understand the mechanism behind the increased conductivity. Anodic aluminum oxide (AAO) membranes with well defined channel sizes are used as the matrix to study the transport of ions solvated in a 1D polymer electrolyte.

8:48AM H42.00003 A Quasi Elastic Neutron Scattering study of polymer dynamics in PEO based sulfonate ionomers: Effect of ion content and ion identity , KOKONAD SINHA, JANNA MARANAS, The Pennsylvania State University — We present Quasi Elastic Neutron Scattering (QENS) data for characterizing dynamics in ion containing polymers (ionomers) with varying ion content (cation to ether oxygen ratio) and ion identity. To remove electrode reverse polarization, the anion is immobilized by covalently bonding it to the PEO backbone through an 'ionizable' isophthalate co-monomer unit and only the cation contributes to the conductivity. We vary the ion content in two ways: changing the ratio of neutral to ionized co-monomer units, and changing the length of the PEO spacer separating the co-monomer units. In neutral ionomers, we observe two segmental processes; PEO segments in the spacer midpoint are one order of magnitude faster than those near the isophthalate groups. In ionized samples, cross-linking between ionic groups considerably slows the dynamics of PEO segments near the isophthalate group. The extent of cross linking depends on the ion content and spacer length. This effect is also ion dependent, which indicates that cations have different binding capacities and formation of this complex controls the availability of free cations for conduction.

9:00AM H42.00004 Structure and Dynamics of Proton-Conducting Azoles Confined within Metal-Organic Frameworks , JAMIE FORD, University of Pennsylvania, JASON SIMMONS, NIST Center for Neutron Research, TANER YILDIRIM, University of Pennsylvania/NIST Center for Neutron Research — Efficient polymer electrolyte membrane (PEM) fuel cells are one of the most promising candidates to power our vehicles of the future. Hydrated sulfonated polymers are currently the preferred membrane material because of their excellent conductivity and gas diffusion characteristics. The intrinsic water dependence in these systems limits the operating temperature to 100 C, leading to reduced electrode kinetics and increased CO poisoning. If water can be replaced by a small molecule with a higher boiling point, the overall efficiency of the system can be improved. To this end, we have investigated a set of new host/guest materials based on metal-organic frameworks (MOFs) loaded with a variety of azoles. The thermally and chemically stable frameworks provide a well-defined porous structure that accommodates the proton conduction pathways formed by the azole networks. We will present the structure of the azole networks as well as insight into the proton motion dynamics as a result of a variety of neutron scattering experiments.

9:12AM H42.00005 Ion solvation thermodynamics in polymer blends and block copolymers , ZHEN-GANG WANG, California Institute of Technology — There is much current interest in ion-containing polymers as materials for energy applications. For example, a promising system for rechargeable battery applications consists of diblock copolymers of an ion-dissolving block, typically polyethylene oxide (PEO) and a nonconducting block such as polystyrene. The addition of lithium salts has been shown to significantly alter the order-order and order-disorder transition temperatures, which reflects a change in the miscibility between the two polymer blocks. In this talk, I discuss some simple theoretical ideas for explaining and predicting the change in polymer miscibility due to the addition of salt ions for both polymer blends and block copolymers. A key effect is the solvation energy of the ions by the polymers, which we approximate using the Born solvation model. The difference in the Born energy of the ions between different polymers provides a driving force towards phase separation, whereas the translational entropy of the ions favors keeping the polymers mixed. In the case of lithium salts added to systems containing PEO, we develop a complexation model in which the lithium ions are tightly bound to the oxygen groups in the EO monomers, while the anions can either be free or form ion pairs with the lithium. For PEO-PS blends or block copolymers, we show that adding lithium salts leads to significant increase in the effective χ parameter between the two polymers. Our theory predicts that the effect should weaken with increasing radius of the anion, in agreement with available experimental data. Furthermore, we show that the domain spacing in microphase separated block copolymers should increase, also in agreement with experiments. We also examine the issue of ion distribution using self-consistent field theory.

9:48AM H42.00006 Understanding Ion Transport in Plasticized Polymer Electrolytes using Dielectric Spectroscopy , U. HYEOK CHOI, SIWEI LIANG, JAMES RUNT, RALPH COLBY, Penn State University — A challenge facing the development of new renewable energy storage materials is the low ionic conductivity within polymer matrices. Most materials development must overcome two main hurdles: Increase the ionic mobility and maximize the conducting ion concentration. The main role of small molecule plasticizers is not only to improve flexibility and segmental motion, which consequently lowers the T_g and increase ion mobility, but also to solvate the counterion through some specific interaction, which increase the conducting ion content. In this study, we add plasticizers to polysiloxane-based ionomers that have anions covalently attached to the polymer chain, with Li^+ counterions. Using the 1953 Macdonald model it is possible to separate the conductivity of plasticized ionomers into the number density of conducting ions and their mobility, allowing us to quantify these vital quantities as functions of plasticizer content and temperature.

10:00AM H42.00007 Ionic conductivity of mesoporous block copolymer membranes in liquid electrolyte as a function of copolymer and homopolymer molecular weight[1] , DAVID WONG, SCOTT MULLIN, GREG STONE, University of California, Berkeley, VINCENT BATTAGLIA, Lawrence Berkeley National Labs, NITASH BALSARA, University of California, Berkeley — Mesoporous block copolymer membranes have been synthesized using poly(styrene-block-ethylene-block-polystyrene) (SES). A series of symmetric SES copolymers and PS homopolymers have been studied at different blending fractions. Ionic conductivities of the porous films in a liquid electrolyte, 1.0 M $LiPF_6$ in ethylene carbonate/diethyl carbonate, compare favorably to conventional battery separators and generally increase with internal surface area, as measured by nitrogen adsorption. Characterization of the effects of pore structure and SES morphology on conductivity will be presented.

[1]Support from the U.S. Department of Energy Office of Vehicles Technologies (FCVT) under the Batteries for Advanced Transportation Technologies (BATT) Program

10:12AM H42.00008 Cation/Anion Associations and Transport in Ionic Polymer Membranes , LOUIS MADSEN, JIANBO HOU, ZHIYANG ZHANG, JING LI, Department of Chemistry and Macromolecules and Interfaces Institute, Virginia Tech — Ionic polymer membranes and ionic liquids (ILs) find fruitful applications in a range of ion conduction applications, from electromechanical "artificial muscles" to organic batteries. Various intermolecular interactions determine local structure and dynamics in these ion-dense media. In particular, ion aggregation can drastically affect ion transport, especially since neutral species (dipoles, quadrupoles...) will not be driven by electric fields. We are investigating mixtures of different ILs, ILs with water, and ILs swollen into ionomer membranes, using pulsed-gradient NMR to probe diffusion and electrophoretic mobility. We observe strong dependencies of the cation/anion diffusion coefficient ratio (ranging from 3X to 0.25X) on mixture and membrane properties, which we relate to ion association phenomena. We will further discuss NMR for transport and dynamics studies, especially regarding chemically resolved transport of various mobile species, probing a range of length and time scales, and quantifying ion aggregation.

10:24AM H42.00009 Correlation between cation conduction and ionic morphology in a PEO-based single ion conductor , KAN-JU LIN, JANNA MARANAS, Pennsylvania State University — We use molecular dynamics simulation to study ion transport and backbone mobility of a PEO-based single ion conductor. Ion mobility depends on the chemical structure and the local environment of the ions, which consequently impact ionic conductivity. We characterize the aggregation state of the ions, and assess the role of ion complexes in ionomer dynamics. In addition to solvated cations and pairs, higher order ion clusters are found. Most of the ion clusters are in string-like structure and cross-link two or more different ionomer chains through ionic binding. Ionic crosslinks decrease mobility at the ionic co-monomer; hence the mobility of the adjacent PEO segment is influenced. Na ions show slow mobility when they are inside large clusters. The hopping timescale for Na varies from 20 ns to 200. A correlation is found between Na mobility and the number of hops from one coordination site to another. Besides ether oxygens, Na ions in the ionomer also use the anion and the edge of the cluster as hopping sites. The string-like structure of clusters provide less stable sites at the two ends thus ions are more mobile in those regions. We observed Grotthus like mechanism in our ionomer, in which the positive charge migrates within the string-like cluster without the cations actually moving.

10:36AM H42.00010 Decoupling Between Ionic Conductivity and Segmental Dynamics in Polymers , ALEXANDER AGAPOV, Dept. of Polymer Science, Univ. of Akron and Dept. of Chemistry, Univ. of Tennessee, ALEXEI SOKOLOV, Dept. of Chemistry, Univ. of Tennessee and Chemical Sciences Division, ORNL — The idea of solid polymer-based electrolytes (SPE) with high ionic conductivity at room temperature is known in scientific community for more than three decades. The interest is caused by unique advantages these materials may offer: mechanical flexibility, high power density, enhanced environmental and operational safety, etc. However, even after several decades of studies, the main challenge remains – there is no "dry" SPE with conductivity of $\approx 10^{-2} - 10^{-3}$ S/cm at room temperature. Ionic conductivity is controlled by two parameters, number of ions and their diffusion. Traditional views relate the diffusion of ions in a polymer to the segmental relaxation. Thus, when segmental dynamics freeze the ion motion halts, leading to low conductivity in solid state. A very good example of a material with such behavior is poly(ethylene oxide). In this work we demonstrate that the temperature dependence of ionic conductivity and segmental relaxation can be decoupled in a material specific way. Degree of the observed decoupling exhibits strong correlation with the steepness of the temperature dependence of structural relaxation (fragility). We predict that more fragile materials can have higher ionic conductivity in the solid state than the strong polymers (e.g. PEO).

10:48AM H42.00011 Molecular dynamics simulations of ionic aggregates in a coarse-grained ionomer melt[1] , LISA HALL, MARK STEVENS, AMALIE FRISCHKNECHT, Sandia National Laboratories — Ionomers (polymers with a small fraction of covalently bound ionic groups) have potential application as solid battery electrolytes. Understanding ion transport is essential for such applications. A key question is how molecular properties affect ionic aggregation and counterion dynamics. Recent experimental advances allowed synthesis and extensive characterization of ionomers with a precise spacing of charged groups, which is ideal for comparison with simulations. We use coarse-grained molecular dynamics to simulate ionomers with charged beads placed periodically either in the polymer backbone or pendant to the backbone. The polymers, along with counterions, are simulated at melt densities. Pendant ions at low dielectric form roughly spherical aggregates with liquidlike interaggregate order, qualitatively different from the aggregate morphology of analogous linear ionomers. The effects of dielectric constant and backbone spacing of charged beads on ionic structure and diffusion will be discussed.

[1]Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration, contract DE-AC04-94AL85000.

Tuesday, March 22, 2011 8:00AM - 11:00AM –

Session H43 DPOLY: Focus Session: Thin Film Block Copolymers II A306/307

8:00AM H43.00001 Polymer Physics Prize Break –

8:36AM H43.00002 Directed self-assembly of Si-containing block copolymer thin films in topographical templates , CAROLINE ROSS, Massachusetts Institute of Technology — Block copolymer films in which one block contains Si are attractive for nanolithographic applications due to the high etch contrast and etch resistance of the Si-rich block. We describe the microphase separation of thin films of such polymers on topographic templates made either by electron-beam writing or by etching of another block copolymer film. The self-assembled morphology is governed by the commensurability between the block copolymer and the template, and both periodic and aperiodic patterns such as meanders and junctions can be directed by appropriate template designs. Different morphologies can be formed in one block copolymer film by sequential solvent anneal steps. Results for directed assembly of diblock copolymers and triblock terpolymers are understood through 3D self consistent field theory modeling.

9:12AM H43.00003 Thermal Manipulation of Block Copolymer Morphology by Focused Laser Spike (FLaSk) Annealing[1] , JONATHAN SINGER, KEVIN GOTRIK, STEVEN KOOI, CAROLINE ROSS, EDWIN THOMAS, Department of Materials Science and Engineering, Massachusetts Institute of Technology — Block copolymer (BCP) thin films have a high potential as a pattern transfer medium for ultra-fine (<10nm) features. We introduce a novel technique for performing rapid local annealing of BCP films by focused laser spike (FLaSk) heating using visible wavelengths. This process may be viewed as imposing a local instantaneous landscape in both block mobilities and interaction parameters corresponding to the temperature profile. By controlling the duration and intensity of the dose, either the rapid local perfection of the equilibrium microdomain morphology or the controlled incorporation of metastable architectures is possible. Moreover, the ultra-short FLaSk process can limit polymer degradation, allowing faster microdomain manipulation by enabling higher temperature anneals. Utilization of a direct write stage allows for deliberate control of arbitrary thermal patterns and subsequent BCP ordering, with line width near the diffraction limit. FLaSk can be applied to nearly any BCP system and performed with other ordering techniques. Direct write experiments were combined with thermal finite elements simulations to probe the various material and process parameters necessary to enhance control of spherical and cylindrical BCPs and address challenges such as the use of thicker films.

[1]This research was supported in part by ARO contract W911NF-07-D-0004. JS was supported by the DOD through the NDSEG Program.

9:24AM H43.00004 Tunable Cosolvent Annealing Affects on Block Copolymer Morphology , KEVIN GOTRIK, JEONG GON SON, ADAM HANNON, ALFREDO ALEXANDER-KATZ, CAROLINE ROSS, Massachusetts Institute of Technology — Being able to precisely and reproducibly control block copolymer (BCP) morphology is of interest for lithographic applications due to the techniques ability to result in feature sizes ranging from 10-100nm. We explore the morphological phase behavior that thin films (30-40nm) of poly(styrene-b-dimethylsiloxane) (PS-PDMS, 45kg/mol, ∼0.26 segmental Flory-Huggins interaction parameter) exhibit under different cosolvent vapors of toluene and heptane. Variation in the solvent conditions results in selective swelling of the different blocks of the copolymer depending on relative Hildebrand solubility parameters (e.g. PS- 18.5, toluene-18.3 $(MPa)^{1/2}$) resulting in cylinders, spheres, lamella, and perforatted lamella self-assembled features which can be revealed by selectively etching the PS with an oxygen plasma (50W CF4). Here we describe precision solvent vapor control while doing in situ spectral reflectometry (230-1500nm) to track swelling of the BCP films as a function of time to gain insight into this BCP system.

9:36AM H43.00005 Annealing Techniques for Obtaining Ordered Morphologies in Poly(methacrylic acid)-Poly(methyl methacrylate) Diblock Copolymer Thin Films , YAN SUN, KEVIN HENDERSON, Northwestern University, ZHANG JIANG, JOSEPH STRZALKA, JIN WANG, Argonne National Laboratory, KENNETH SHULL, Northwestern University — The microphase separation of block copolymers in thin films continues to be of great value for the fabrication of nanostructured materials. While highly ordered arrays of microdomains can be easily achieved in some block copolymers, proper processing of others are more challenging. Obtaining ordered morphologies in poly(methacrylic acid)-poly(methyl methacrylate) (PMAA-PMMA), a diblock possessing polyelectrolyte functionality, offers unique associative properties and aqueous reaction chemistries otherwise inaccessible by most other block copolymer films. Due to the limited choices of suitable solvents with sufficiently high vapor pressure and the thermal degradation temperature of PMAA being lower than its glass transition temperature, direct solvent and thermal annealing of PMAA-PMMA are not ideal for generating ordered nanostructures. Here, we begin by solvent annealing poly(tert-butyl methacrylate)-poly(methyl methacrylate) (PtBMA-PMMA) films at room temperature. We then thermally anneal the films to convert the PtBMA block to PMAA. We present results from atomic force microscopy (AFM) and grazing-incidence small-angle x-ray scattering (GISAXS) studies.

9:48AM H43.00006 High-Speed Block Copolymer Self-Assembly under Ambient Conditions , DAE UP AHN, YIFU DING, University of Colorado — Self-assembled block copolymer (BC) nanopatterns have critical application impacts on nanotemplates and scaffolds for the fabrication of nanometer scale periodic arrays, nanostructured networks and membranes for fuel cells, and high-density information storage media in computers and related devices. To achieve such application potentials, well-aligned BC nanopatterns should be reliably engineered in a thin film on a variety of functional substrates within a practical time-scale for industrial production. Here, we illustrate an exceedingly high-speed BC self-assembly under ambient conditions, which is not readily achievable in a vacuum. Only in a few seconds, BC nano-cylinders perpendicular to an energetically preferential surface have been spontaneously developed in a thin BC film under air. The time-scale for the BC self-assembly under air is at least 1000 times faster than that under vacuum. However, a micro-scale film instability that seriously impairs BC nanostructures has also rapidly evolved under air prior to the lateral self-organization of BC nano-cylinders. To suppress the evolution of micro-scale film instability and also to enhance the lateral order of BC nano-cylinders, we have imposed geometric confinements during the thermal annealing process of a thin BC film. Consequently, only in a few minutes, we have prepared hexagonally well-aligned BC nano-cylinders perpendicular to the bottom surface of geometric confinements under ambient conditions.

10:00AM H43.00007 Directed self-assembly with density multiplication of block copolymer via controlled solvent annealing , MIKIHITO TAKENAKA, Kyoto University, HIROSHI YOSHIDA, YASUHIKO TADA, Hitachi Ltd., TERUAKI HAYAKAWA, YOSHIHITO ISHIDA, Tokyo Institute of Technology, HIROKAZU HASEGAWA, GO SAKAGUCHI, KINICHIRO YAMAGUCHI, Kyoto University — We report density multiplication of chemically patterned template employing highly segregating polyhedral oligomeric silsesquioxane (POSS) containing block copolymer (PMMA-bPMAPOSS) for extending the technique to smaller dimensions than that attained by PS-b-PMMA. PMMA-b-PMAPOSS which self-assembles into hexagonally closed packed (hcp) array of dots with lattice spacing d=13nm was spin coated on the chemical template with doubled hcp lattice spacing d=26nm, and annealed under controlled CS_2 atmosphere. By tuning the swell ratio of PMMA-b-PMAPOSS, ordered array of dots with d=13nm, which correspond to 3.5Tbit/in^2 was obtained by multiplying pattern density of the chemical template in a factor of 4. This work was supported by New Energy and Industrial Technology Development Organization, Japan.

10:12AM H43.00008 Temperature Gradient effects in Directed Assembly of Block Copolymer Films via Cold Zone Annealing[1] , GURPREET SINGH, MANISH KULKARNI, Department of Polymer Engineering, University of Akron, Ohio 44325, KEVIN YAGER, Center for Functional Nanomaterials, Brookhaven National Laboratory, Upton, NY 11973, BRIAN BERRY, Department of Chemistry, University of Arkansas at Little Rock, Little Rock, AR 72204, ALAMGIR KARIM[2], Department of Polymer Engineering, University of Akron, Ohio 44325 — Vertically oriented micro-phases of block copolymers (BCPs) are generally preferable for applications like organic photovoltaic devices and nanoscale lithography. Here we demonstrate a Cold Zone Annealing (CZA) technique that produces a very sharp thermal gradient in contrast to our previous studies that produced well-ordered parallel BCP microphases [1]. Under these conditions, initial experiments on cold zone annealed PS-b-PMMA BCP films, yielded long range vertical orientation order in PMMA cylinders. GISAXS analysis indicates that the vertical morphology is maintained throughout the film thickness. Comparison of the CZA with conventional oven annealed samples show a magnitude of improvement in the ordering of BCP phases.

10:24AM H43.00009 The dynamics of lamellar re-orientation in free-standing diblock copolymer films: flipping the morphology from edge-on to flat-on , ROBERT D. PETERS, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada, L8S 4M1 — Many exquisite structures formed by diblock copolymers have been studied rigorously over the past two decades. Using a symmetric polystyrene-poly(methyl methacrylate) diblock copolymer, we prepare thin films on a substrate which form lamellae oriented perpendicular to the film interfaces. These "edge-on" samples are subsequently transferred, by floating onto water, to produce free-standing films with a symmetric boundary condition. Upon annealing these free-standing films, the lamellae switch from edge-on, to "flat-on" such that the domains are oriented parallel to the interface. Using atomic force microscopy, we study the dynamics of pattern formation as lamellae flip from the edge-on to flat-on morphology.

10:36AM H43.00010 New approaches to directing self-assembly and alignment of block copolymer , HANQIONG HU, PAWEL MAJEWSKI, CHINEDUM OSUJI, Yale University, OSUJI LAB TEAM — Directed self-assembly of block copolymers (BCPs) has been explored extensively using a variety of methods to simultaneously develop long-range order and exert orientational control over microphase separated structures. Here we propose two new routes for directing self-assembly in BCPs. First we discuss solvent vapor permeation which is based on pressure driven transport of a solvent vapor through a free-standing film. We demonstrate that alignment of BCP interfaces parallel to the vapor flux may be achieved rapidly in mm-scale thick films of high molecular weight BCP. Secondly, we present the use of electrospray for controlled deposition of block copolymer thin films. We speculate that morphology can be dictated by thermal equilibration in the presence of a pre-existing pattern or substrate template and that the ultra-slow growth afforded by electrospray permits persistence of this pattern beyond the 1 micron scale where conventional surface directed morphologies degenerate.

10:48AM H43.00011 A novel approach to achieve perpendicular long range order alignment in lamella PS-b-PEO system , PARVANEH MOKARIAN- TABARI, Dept of Chemistry, University College Cork; Centre for Research on Adaptive Nanostructures and Nanodevices (CRANN), Trinity College, Ireland, TIMOTHY W. COLLINS, Department of Chemistry, University College Cork, Cork, Ireland, JUSTIN D. HOLMES, MICHAEL A. MORRIS, Dept of Chemistry, University College Cork; Centre for Research on Adaptive Nanostructures and Nanodevices (CRANN), Trinity College, Ireland — Here, we introduce a novel approach for obtaining perpendicular alignment in lamella forming PS-b-PEO system. The vertical alignment of layers in diblock copolymer thin films has great potential for producing nanowires used in nanofabrication of electronic devices. However, due to selective surface interaction of the polymers with the substrate, perpendicular alignment usually requires neutralisation of the surface by means of brushes or making pre-pattern substrates which could be complicated and time consuming. Applying our novel approach named "combinatorial annealing" which consists of two stages of thermal and solvent annealing process, we have successfully created parallel lines (without a brush). After selective etching of one block, the remaining template is pattern transferred to a silicon substrate leading to manufacturing of sub 20 nm silicon nanowires.

8:00AM H44.00001 Polymer Physics Prize Break –

8:36AM H44.00002 Diffusion and Filtration Properties of Self-assembled Close-packed Nanocrystal Membranes , JINBO HE, The University of Chicago, XIAO-MIN LIN, Argonne National Laboratory, LELA VUKOVIC, HENRY CHAN, PETR KRAL, University of Illinois at Chicago, HEINRICH JAEGER, The University of Chicago — Small dyes are known to be able to penetrate through randomly packed nanoparticle monolayers, but a detailed understanding of the mechanisms for transport through the interstices between nanoparticles is still lacking. We report on systematic measurements of molecular transport across monolayers of close- packed, 5 nm diameter gold nanocrystals ligated with dodecanethiol. For water we find a filtration coefficient two orders of magnitude larger than for polymer-based nanofiltration membranes, while the self-diffusion coefficient is more than 100x smaller than in films of pure hydrocarbons. As we confirm by molecular dynamics simulations, larger molecules (tested molecular weight range: 200 - 43000) are unable to diffuse through the ligands. Instead, they most likely move through nm-sized regions of reduced ligand density, which are formed by slight variations in the local packing configuration and orientation of neighboring nanocrystals. In this intermediate size range we also find a pronounced dependence of the rejection rate on the molecules' charge. Molecules with cross-section above 2 nm are totally rejected.

8:48AM H44.00003 Diffusion of Small Penetrants in Polybutadienes , AHMED E. ISMAIL, RWTH Aachen University, FLINT PIERCE, GARY S. GREST, Sandia National Laboratories — The diffusion coefficient D in the dilute limit for three different penetrants—oxygen, water, and methanol—in three different conformations of polybutadiene (all cis-1,4, all trans-1,4, and a random copolymer containing 50% trans-1,4, 40% cis- 1,4, and 10% vinyl-1,2 repeat units) has been computed using molecular dynamics simulations for temperatures in the range $T = 300$–$400\,\mathrm{K}$. Simulations runs of 25 and 50 ns made for each of the 45 combinations of penetrant, conformation, and temperature studied. Over this temperature range the density of the all-cis-1,4 conformation is higher than that of the all-trans-1,4 and random copolymer conformations, which are approximately equal. For all three conformations, D for oxygen and water are comparable and larger than that of methanol. However, for a given penetrant, strong differences were observed in the rate of increase of D for the three conformations. We find that the activation barriers for the three penetrants are generally between 20 and 30 kJ/mol, in agreement with experimental results. The magnitude of the activation energy is directly proportional to the size, rather than the mass, of the penetrant molecule. (Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy under contract DE-AC04-94AL85000.)

9:00AM H44.00004 Control dispersion of water in thin films of semi-fluorinated polymer/POSS nanocomposites , DILRU RATNAWEERA, DVORA PERAHIA, Clemson University, MANISH DUBEY, JAROSLAW MAJEWSKI, Los Alamos National Laboratory — The permeation and distribution of solvents in polymer nanocomposites is governed by the way the nanoparticles (NP) associate within the matrix polymer. We have previously shown that in thin films interfacial effects affect the distribution of the NP. The current work focuses on the response of a semi-fluorinated random copolymer, Biphenyl Perfluorocyclobutane, and Polyhedral Oligomeric Silsesquioxane (POSS) NP modified with fluorinated or protonated side chains, to presence of D_2O. POSS was introduced either as a free NP or tethered to a polymer chain. We found that the presence of POSS reduces the overall uptake of D_2O. It also changes the distribution of water in the film as well. In the pristine polymer film the water mainly accumulated at the substrate/polymer interface. In the nanocomposite, the water distribution is correlated with the NP distribution, where NP at the air interface minimize water penetration.

9:12AM H44.00005 Water Desorption from Ferroelectric and Dipole-Oriented Polymers , CAROLINA ILIE, LILLIE GHOBRIAL, GREGORY MASLAK, MARK STEWART, MICHAEL EVANS, Dept. of Physics, SUNY Oswego, LUIS G. ROSA, Dept. of Physics and Electronics, University of Puerto-Rico - Humacao, PETER A. DOWBEN, Dept. of Physics and Astronomy, University of Nebraska at Lincoln — Herein we compare the water absorption/ adsorption on three different polymer films: the ferroelectric co-polymer poly(vinylidene fluoride with trifluoroethylene) P(VDF-TrFE), the strongly dipole oriented polymer poly(methyl vinylidene cyanide) (PMVC) [1] and the dipole oriented poly(methyl methacrylate) PMMA. We investigate the dipole-dipole interaction of the water molecule and the ferroelectric/ dipole oriented polymer films and we propose that the dipole interactions may affect the surface chemistry at these polymer surfaces. Surface dipoles can affect the binding site of water species adsorbed at the surface and sterically hinder or enhance desorption of adsorbed and absorbed water.

9:24AM H44.00006 Role of Diffusion in Scaling of Polymer Chain Aggregates Found in Vapor Deposition Polymerization[1] , SAIRAM TANGIRALA[2], DAVID LANDAU[3], The University of Georgia — Linear polymer chain aggregates grown by 1+1D Monte Carlo simulations of vapor deposition polymerization (VDP) were studied. The behavior of chain length distribution $n_s(t)$ as a function of chain length (s) and deposition time (t) was examined for relevant model parameters. The scaling of $n_s(t)$ was found to be sensitive to the ratio $G = D/F$ of deposition rate (F) and free monomer diffusion (D). A systematic approach is presented to isolate the dependence of $n_s(t)$ on t, s, and G. We found power law dependence of $n_s(t)$ on t with exponent $\omega = 1.01 \pm 0.02$ that was invariant with changes in G. For small s and deposition time of $t = 1 \times 10^3$, 5×10^3, and 10×10^3, $n_s(t)$ showed a power-law decrease with s and exponent $\tau = -0.58 \pm 0.02$. We observed a strong influence of G on the rescaled $n_s(t)$ data that prevented the manifestation of unique scaling function for varying G. The dependence of scaling function of $n_s(t)$ on G was found to be a characteristic of VDP and elucidates the sensitivity of polymer chain aggregates to G.

9:36AM H44.00007 ABSTRACT WITHDRAWN –

9:48AM H44.00008 Structure and dynamics of dense polymer chains in 2D , HENDRIK MEYER, CNRS Institut Ch. Sadron, JOACHIM P WITTMER, ALBERT JOHNER, JORG BASCHNAGEL — Self-avoiding polymers in two-dimensional melts are known to adopt compact and segregated configurations. Compactness does obviously not imply Gaussian chain statistics nor does segregation of chains impose disk-like shapes minimizing the average perimeter length of the chains. Using scaling arguments and molecular dynamics simulations with chain length up to 2048 we show that the chain perimeters are highly irregular and characterized by a fractal line dimension 5/4. This result may be verified experimentally from the power-law scaling of the intrachain form factor in the intermediate wavevector regime in agreement with a generalized Porod law for a compact object of fractal border [1]. The dynamics of dense polymer chains exhibits two interesting features: the incompressibility induces long range correlations in the displacement auto-correlations and a relaxation channel due to friction at the fractal contours of compact sub-segments leads to relaxation faster than a Rouse model would predict [2].

10:00AM H44.00009 Dynamic surface tension effects from molecular dynamics simulations , ALEX LUKYANOV, University of Reading — Effects of dynamic surface tension have been studied in a model system using molecular dynamics simulations. The model system has been made of an artificially expanding liquid droplet, with the rate of change of the external surface area being comparable with the gas-liquid interface formation characteristic time, obtained from the estimates of macroscopic theories. The size of the liquid droplet has been chosen to have about 5.000-7,000 identical molecules, each having between 10-20 beads, to obtain well developed and separated the bulk and surface phases. The methodology of surface tension evaluation has been verified against the Laplace Law in a stationary state of the liquid drop. The results of the MD simulations will be discussed in comparison with the estimations obtained from macroscopic experiments on dynamic wetting using a sharp interface formation theory for different chain length of molecules and strength of intermolecular interactions.

10:12AM H44.00010 Hierarchical roughness of sticky and non-sticky superhydrophobic surfaces , MUHAMMAD AKRAM RAZA, STEFAN KOOIJ, AREND VAN SILFHOUT, HAROLD ZANDVLIET, BENE POELSEMA, University of Twente, PHYSICS OF INTERFACES AND NANOMATERIALS TEAM — The importance of superhydrophobic substrates (contact angle $>150^\circ$ with sliding angle $<10^\circ$) in modern technology is undeniable. We present a simple colloidal route to manufacture superstructured arrays with single- and multi-length-scaled roughness to obtain sticky and non-sticky superhydrophobic surfaces. The largest length scale is provided by (multi-)layers of silica spheres (1μm, 500nm and 150nm diameter). Decoration with gold nanoparticles (14nm, 26nm and 47nm) gives rise to a second length scale. To lower the surface energy, gold nanoparticles are functionalized with dodecanethiol and the silica spheres by perfluorooctyltriethoxysilane. The morphology was examined by helium ion microscopy (HIM), while wettability measurements were performed by using the sessile drop method. We conclude that wettability can be controlled by changing the surface chemistry and/or length scales of the structures. To achieve truly non-sticky superhydrophobic surfaces, hierarchical roughness plays a vital role.

10:24AM H44.00011 Alkane Self Assembling , TOMAS CORRALES, MPI-P Mainz, Germany, PIA HOMM, PIERO FERRARI, MARIA JOSE RETAMAL, Pontificia Universidad Catolica de Chile, VALERIA DEL CAMPO, Universidad Tecnica Federico Santa Maria, Chile, ULRICH G. VOLKMANN, Pontificia Universidad Catolica de Chile — Self-assembling of organic molecules has awaken scientific and technological interest. In this work we study the self-assembling process of long chain hydrocarbons, mainly n-dotriacontane (n-C32H66). We dip-coated C32 monolayers onto silicon wafers covered by their native silicon oxide layer (Si(100)/SiO2). Our results show that withdrawing speed affects the coverage and morphology of the C32 films. For slow withdrawing speeds, alkanes formed islands with a dragon-fly shape, while for fast withdrawing alkanes assembled in stripes with widths in the order of microns. When we quantified coverage and morphology versus withdrawing speed, we found an inflection, which we associate with a transition between two film deposition kinetics. These transitions have been previously described by de Gennes [1]. For slow withdrawing, film deposition follows the Langmuir-Blodget process and above a threshold speed, solution on the solid enters a Landau-Levich regime. This work opens the possibility for growing microstructures with nanometric thickness using a very simple method. These organic microstructures could be used as templates or as grids for optical diffraction.

10:36AM H44.00012 A Thermodynamic Treatment of Polymer Thin Film Glasses[1] , RONALD WHITE, JANE LIPSON, Dartmouth College — We have recently developed a mean field equation of state (EOS) approach to model the thermodynamic properties of polymer thin films. The model is analytic and transparent yielding characteristic film properties as a "whole sample" average. We focus on the properties of freestanding thin films and, parameterizing only with bulk data, demonstrate how the EOS leads to predictions of film properties as a function of film thickness under varied thermodynamic conditions. We share some thoughts on how to use this model for the prediction of the thickness-dependent depression of the thin film glass transition temperature.

10:48AM H44.00013 Non-equilibrium behavior of spin-cast films , KATHERINE THOMAS, University of Cambridge — The behavior of polystyrene films cast from various solvents using an electric field to weakly perturb the free surface of the polymer melt was examined. The effective viscosity and residual stresses of the as-spun films strongly depend on the casting solvent. As-cast films had a substantially reduced viscosity compared to annealed films, with the greatest reduction in films cast from solutions near θ-temperature. The reduced viscosity is explained in terms of non-equilibrium effects from the film formation process; rapid quenching during spin-coating results in a lower entanglement density of chains compared to an equilibrium melt. The difference in films spun from the various solvents is explained by changes in chain conformations in the initial solutions and the vitrification point. The wavelength of the instabilities in as-cast films was higher than expected, indicating a weak stabilizing pressure. This is attributed to frozen-in normal stresses resulting from an asymmetric deformation of the chains due to evaporation of residual solvent after vitrification. The results show the non-equilibrium nature of as-cast polymer films and that processing conditions strongly influence their behavior.

Session H45 DAMOP: Exotic Quantum Phases in Optical Lattices: FFLO, P-band Physics, and Beyond A310

8:00AM H45.00001 Stable Fulde-Ferrell-Larkin-Ovchinnikov pairing states in 2D and 3D optical lattices[1] , ZI CAI, The department of Physics, Univeristy of California, San Diego, YUPENG WANG, Institute of Physics, Chinese Academy of Sciences, Beijing, P. R. China, CONGJUN WU, The department of Physics, Univeristy of California, San Diego — We present the study of the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) pairing states in the p-orbital bands in both two and three-dimensional optical lattices. Due to the quasi one-dimensional band structure which arises from the unidirectional hopping of the orthogonal p-orbitals, the pairing phase space is not affected by spin imbalance. Furthermore, interactions build up high dimensional phase coherence which stabilizes the FFLO states in 2D and 3D optical lattices in a large parameter regime in phase diagram. These FFLO phases are stable with imposing the inhomogeneous trapping potential. Their entropies are comparable to those of the normal states at finite temperatures.

8:12AM H45.00002 Robust Larkin-Ovchinnikov-Fulde-Ferrell phases in a wide class of lattice models[1] , MENG CHENG, University of Maryland, College Park, CHRISTOPHER VARNEY, Georgetown University, KAI SUN, VICTOR GALITSKI, University of Maryland, College Park — We consider BCS pairing of fermions on lattice whose normal state breaks both time-reversal and spatial inversion symmetries. Due to the asymmetric band structure, unusual pairing states exist: Cooper pairs condense at finite momentum, which is known as the Fulde-Ferrel-Larkin-Ovchinnikov (FFLO) state. A one-dimensional lattice model of spinless fermions is studied in detail and two types of FFLO states are found: (1) a FF state with spontaneous supercurrent and (2) a nodeless LO state where the amplitude of order parameter oscillates. This conclusion is obtained via mean-field theory, bosonization, and exact diagonalization. The transition between the two phases can be tuned by the filling. We also find that the FF state is a topological superconductor. We further consider a generalization to two dimensions, where similar physics is realized.

8:24AM H45.00003 Spectral Functions of FFLO states in coupled chains[1] , NANDINI TRIVEDI, KARIM BOUADIM, YEN-LEE LOH, The Ohio State University, VALERY ROUSSEAU, Louisiana State University — Polarized Fermi gases hold the possibility of an exotic and fragile modulated superfluid known as a Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state. Quasi-one-dimensional systems of ultracold fermions are the ideal place to look for FFLO physics. Using various methods [1] (including determinant quantum Monte Carlo, stochastic Green function, and Bogoliubov-de Gennes methods), we study the correlation functions and quantum dynamics of polarized Fermi gases in single chains and coupled chains. Our results indicate that fluctuating domain walls lead to spectral weight near the Fermi energy in the spin-resolved density of states, that are a signature of Andreev reflections and fluctuating bound states. We derive bounds for the optimal interchain coupling to maximize the critical temperature of the FFLO state, in order to aid detection of these FFLO states in cold atom experiments [2].

8:36AM H45.00004 Understanding the Mass-Imbalanced Highly-Polarized Fermi Gases , MICHAEL KOLODRUBETZ, BRYAN CLARK, Princeton University — The phase diagram of spin-polarized single atomic species Fermi gases has been well-studied theoretically and experimentally. However, cold gases containing multiple atomic species open up the possibility of seeing more exotic states. Recent variational calculations (arXiv:1002.0101v2 [cond-mat.quant-gas]) suggest a complicated phase diagram for a light impurity interacting via a short-range potential with a sea of heavier fermions. In particular, at large mass ratio the polaron is expected to give way to more complicated many-body bound states, such as the trimer or the FFLO molecule. We extend these results beyond this variational ansatz, sampling over many-body states with an arbitrary number of particle-hole pairs. We will discuss the phase diagram resulting from these simulations, including implications for the stability of the trimer and FFLO phases.

8:48AM H45.00005 Spectroscopy of the soliton lattice formation in quasi-one-dimensional fermionic superfluids with population imbalance[1] , ROMAN LUTCHYN, Microsoft Station Q, MAXIM DZERO, Kent State University, VICTOR YAKOVENKO, University of Maryland — Motivated by recent experiments in low-dimensional trapped fermionic superfluids we study quasi-1D superfluid with imbalanced populations between two hyperfine states and analyze its properties using the exact mean field solution for the order parameter. When population imbalance exceeds some critical value the superfluid order parameter develops spatial inhomogeneities and can be described by a soliton lattice formation. Emergence of the soliton lattice is accompanied by the formation of the spin density wave with the majority fermions residing at the points in space where Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) order parameter vanishes. We show that the presence of the spin density wave leads to the formation of the band of the "subgap states," which serves as a hallmark of the quasi-1D FFLO state. We employ the soliton lattice description to discuss the possibilities for the experimental detection of the quasi-1D FFLO phase: elastic and inelastic optical Bragg scattering experiments and radio-frequency spectroscopy. We demonstrate that these measurements allow one to extract necessary information about the inhomogeneous superfluid phase to unambiguously identify quasi-1D FFLO state.

9:00AM H45.00006 $(2k_F, 2k_F)$ density-wave orders of interacting p-orbital fermions in square optical lattice[1] , ZIXU ZHANG, University of Pittsburgh, W. VINCENT LIU, University of Pittsburgh and Kavli Institute for Theoretical Physics, University of California, Santa Barbara — We study instabilities of spinless fermionic atoms in the p- orbital bands in two dimensional optical lattices at non-integer filling against interactions. Stripe charge-density- wave or orbital-density-wave orders are found for attractive and repulsive interactions, respectively. A surprising result is that the superfluid phase, usually expected of attractively interacting fermions, is less energetically favored. Nesting quasi-one-dimensional Fermi surfaces in such systems are independent of filling, which ensures that the stripe density- wave orders occur in a large parameter regime.

[1]This work is supported by ARO (W911NF-07-1-0293) and ARO-DARPA-OLE (W911NF-07-1-0464). We also thank the KITP at UCSB for its hospitality where this research is supported in part by NSF Grant No. PHY05-51164.

9:12AM H45.00007 $U(1) \times Z_2$ transition from the Mott insulator to $p_x + ip_y$ Bose-Einstein superfluid phase , XIAOPENG LI, Department of Physics and Astronomy, University of Pittsburgh, ERHAI ZHAO, Department of Physics and Astronomy, George Mason University, W. VINCENT LIU, Department of Physics and Astronomy, University of Pittsburgh — Motivated by the recent experiment on p-band bosons in optical lattices [arXiv:1006.0509 (2010)], we study theoretically the quantum phases and phase transition of a two-dimensional extended Bose-Hubbard model with p-orbital degrees of freedom. The system features a novel superfluid phase with transversely staggered orbital current at weak interaction, and a Mott insulator phase with antiferro-orbital order at strong coupling and commensurate filling. We derive an effective theory from a microscopic model to describe the quantum phase transition from Mott to superfluid phase. We also calculate the excitation spectra near quantum critical point and find two gapless modes away from the Mott tip but four gapless modes at the tip point. We describe how the phase coherence builds up in the Mott regime when approaching the critical point.

9:24AM H45.00008 Induced p-wave superfluidity at unitarity in strongly imbalanced Fermi gases[1] , KELLY PATTON, DANIEL SHEEHY, Louisiana State University — We compute the induced interaction among the majority spin-up fermions, due to the presence of the minority spin-down fermions, in a population imbalanced Fermi gas. This interaction leads to an instability of the spin-polaron Fermi liquid, favoring a p-wave superfluid. For the majority component, near unitarity, the transition temperature is found to be within experimental reach, of order a few percent of the Fermi energy. As a probe of this phase, the radio-frequency spectroscopic line-shape is calculated for the $p_x + ip_y$ ground state.

[1]Supported by The Louisiana Board of Regents, under grant LEQSF (2008-11)-RD-A-10.

9:36AM H45.00009 Polaron Metastability , KAYVAN SADEGZADEH, University of Cambridge — We investigate the metastability associated with the first order transition from normal to superfluid phases along the BEC-BCS crossover in partially polarised Fermi gases. The momentum thresholds and rates of key decay processes involved are presented in the context of the system's phase diagram, together with metastability regions. In the limit of a single polaron, this region extends from the interaction strength at which a polarised phase of molecules becomes the groundstate ($\frac{1}{k_{F\uparrow}a}0.73$), to the value of the crossing point from a single polaron to molecule groundstate ($\frac{1}{k_{F\uparrow}a}0.9$). Finally, we propose experiments to explore the metastability of this Fermi liquid and the various decay processes, and to observe the $\frac{1}{k_{F\uparrow}a}0.9$ value.

9:48AM H45.00010 Possibility of π-Josephson junction and spontaneous current in a spin-polarized Fermi gas[1] , TAKASHI KASHIMURA, Department of Physics, Keio University, SHUNJI TSUCHIYA, Department of Physics, Tokyo University of Science, JST(CREST), YOJI OHASHI, Department of Physics, Keio University, JST(CREST) — We theoretically propose an idea to realize a π-phase in a superfluid Fermi gas, where the phase of the superfluid order parameter differs by π across a Josephson junction. When a weak nonmagnetic potential barrier is embedded in a superfluid Fermi gas with population imbalance ($N_\uparrow > N_\downarrow$, where N_σ is the number of atoms with pseudospin $\sigma =\uparrow, \downarrow$), this barrier may be $magnetized$ in the sense that some of excess atoms $N_\uparrow - N_\downarrow > 0$ are localized around it. This magnetic barrier behaves like a $ferromagnetic\ junction$ discussed in superconductivity literature, which twists the phase of superfluid order parameter by π. We confirm this idea by solving an attractive Hubbard model within the mean-field theory at $T = 0$. We also show that, when this ferromagnetic barrier is realized in a ring-shaped (or torus) trap, the system becomes the so-called π-Josephson junction, where spontaneous circulating current flows due to the phase twist at the juntion.

10:00AM H45.00011 Many-body spectral moment sum rules for the Bose Hubbard model[1] , JAMES FREERICKS, Georgetown University, VOLODOMYR TURKOWSKI, University of Central Florida, HULIKAL KRISHNAMURTHY, Indian Institute of Science — Exact results for many-body interacting systems are rare. Here we derive a series of exact results for the single-band Bose-Hubbard model. In particular, we derive spectral moment sum rules for the Green's functions of the Bose-Hubbard model. Unlike the fermionic sum rules, the bosonic ones depend on complicated expectation values of the bosons that go beyond just needing to know the local particle density. Nevertheless, they can be used to benchmark the quality of different numerical calculations of spectral functions. These sum rules hold with arbitrary values of the interaction strength and even into nonequilibrium situations, similar to what is seen for the fermionic case. We present some case studies comparing the exact moments to those found with other numerical techniques like the VCA approximation.

10:12AM H45.00012 Bosonic Hubbard-Holstein model and its realization in optical lattices , MAN-HONG YUNG, Harvard University, KUEI SUN, U. of Cincinnati & U. of Illinois at Urbana-Champaign, ALAN ASPURU-GUZIK, Harvard University — The Hubbard-Holstein (HH) model describes the interplay between the Coulomb interaction and the electron-phonon coupling for fermionic systems. Motivated by the recent experimental progresses in optical lattices, we investigate a bosonic version of the HH model, where the two competing many-body interactions of the HH model become a bosonic two-body interaction and a boson-phonon coupling. In the regime of weak boson-phonon coupling, the mean-field phase diagram shows that overall effects of the phonons is to expand the domain of superfluidity. This bosonic Hubbard-Holstein (BHH) model can be realized in a pair of overlapping optical lattices, where bosonic particles trapped in one optical lattice are perturbed by more massive particles trapped in the other lattice.

10:24AM H45.00013 Number Density Distributions of Ultracold Bosons in 3D Optical Lattices[1] , JOE GARRETT, ERIC DUCHON, The Ohio State University, NANDINI TRIVEDI, The Ohio State Univesity — We calculate the probability, $P(n)$, of finding n bosons at a site and the probability of hopping in a uniform optical lattice as a function of the temperature, T, and the repulsive interaction between bosons, U/t, as a function of hopping energy. We examine the characteristic $P(n)$ distribution for the Mott Insulator, quantum critical region and superfluid and determine its behavior across thermal and quantum phase transitions using quantum Monte Carlo. The behavior of the local kinetic energy is estimated using the probability of hopping. These results illuminate number squeezing in the Mott Insulator and the quantum critical region described in [1].

10:36AM H45.00014 Surface Majorana modes in ultra-cold fermion systems with unconventional Cooper pairings , YI LI, CONGJUN WU, Department of Physics, University of California, San Diego — The rapid progress of dipolar fermions provides a new opportunity to investigate unconventional Cooper pairings and exotic topological properties. We study the zero energy modes for the single and multiple-component dipolar gases along the surface perpendicular to the z-direction, which are a flat band of Majorana fermions. Under time-reversal symmetry breaking perturbations, such as vortices, the degeneracy of the surface Majorana modes is lifted. We also investigated the spontaneous time-reversal symmetry breaking effect in such systems.

10:48AM H45.00015 Attractive Bose-Hubbard model with three-body constraint[1] , KWAI-KONG NG, MING-FONG YANG, Tunghai University — We numerically study the quantum and thermal phase transitions of the Bose-Hubbard model with particle numbers per site restricted to less than three. The bosons experience on-site attractions while the nearest-neighbor interactions are repulsive. Using particular two-loops algorithm in the QMC simulations, we study the exotic dimer superfluid at small hopping and low density regime. The nature of the phase transitions between the dimer superfluid and the atomic superfluid will be discussed.

Session J1 DCMP: Toward Single Spin Electronics Ballroom A1

11:15AM J1.00001 Imaging and Manipulating Single and Interacting Spins on Surfaces: Towards Atomic-Scale Spin Devices , ROLAND WIESENDANGER, University of Hamburg — Spin-Polarized Scanning Tunneling Microscopy (SP-STM) provides new insight into spin structures at a length scale and a sensitivity level which are inaccessible by other magnetic-sensitive measurement techniques [1]. The combination of atomic resolution in direct space, single spin sensitivity, and high energy resolution nowadays offers unique possibilities for probing spin-dependent states and interactions in natural or artificially created nanostructures [2]. The ultimate goal has been the combination of spin-resolved imaging with atomic resolution and magnetometry at the single-atom level in order to probe spin states and magnetic interactions of individual adatoms and nanostructures at solid surfaces quantitatively and in a most direct way. This challenging goal has been achieved by operating a SP-STM system at temperatures below 1 Kelvin and in external magnetic fields up to several Tesla. The new method of single-atom magnetometry with an unprecedented degree of magnetization measurement sensitivity is applicable to metallic [3, 4] as well as to semiconducting [5] and molecular systems [6]. The combination of single-atom manipulation techniques and single-atom magnetometry has recently led to the first demonstration of atomic-scale spin logic devices based solely on spin- rather than charge-transport for realizing computation and information transmission at the atomic level.

11:51AM J1.00002 All-electric control of single atom spin states , SANDER OTTE, Delft University of Technology, The Netherlands — The quantum state of a single spin is a great candidate for forming a qubit. Spin systems in various forms are considered for the task, ranging from electrons trapped in artificial quantum dots to magnetic dopants in semiconductors and diamond. In this talk I will review recent progress towards controlling the spins of individual atoms on a surface through local access with an STM probe tip: an intriguing approach in view of the possibility to rearrange the atoms at will so as to build multi-atom structures. Magnetic d-metal atoms, separated from a metal substrate by a thin decoupling layer, are studied through inelastic electron tunneling spectroscopy (IETS): a tool by which transition energies of the spin state can be accurately followed. By addressing the atoms with a spin-filtered probe tip, controlled excitations or de-excitations can be made, effectively pumping the spin into a magnetization direction of choice. In a more recent experiment, spin pumping is performed in short pulses, opening up ways to control atomic spins in the time domain. I will discuss avenues to further develop this technique, eventually leading to coherent control of an atomic spin qubit.

12:27PM J1.00003 Quantum control and nanoscale placement of single spins in diamond[1] , DAVID D. AWSCHALOM[2], Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106 — Diamond is a unique solid state platform for fundamental studies of spintronics and quantum information science that has recently enabled control, readout, and storage of quantum states at the single spin level. Nitrogen-vacancy (NV) center spins can be individually addressed and have remarkably long spin coherence times at room temperature. We show that the spin of single NV centers in both the orbital ground[3] and excited state[4] can be controlled on sub-nanosecond time scales using intense microwave fields. Moreover, coherent light-matter interactions enable non-destructive spin measurement and localized single spin manipulation with near-resonant light.[5] An associated quantum memory is also demonstrated using the intrinsic nuclear spin of nitrogen.[6] Scaling these findings toward a spin network is a key challenge - to this end we present a simple method for patterning NV center formation on 50 nm length scales.[7] These results represent progress toward control, coupling, and scaling of single spins for future spin and photon based quantum information processing.

1:03PM J1.00004 Exploring the quantum frontier of spin dynamics , PATRICK BRUNO, ESRF, Grenoble, France — Our familiar classical concept of a *spin* is that of a system characterized by the *direction* in which the spin is *pointing*. In this picture, we may think of the dynamics of a spin as the motion of a *classical gyroscope*, wich we can aptly describe the spin dynamics as the motion of a point on a sphere. This classical description of the spin dynamics, formalized in the Landau-Lifshits-Gilbert equation, has proved extremely successful in the field micro- and nanomagnetism. However, as the size of the system is further decreased (e.g., when considering molecular magnets such as the Fe_8 or Mn_{12} systems, which have a spin S=10), *quantum* effects such as tunneling, interference, entanglement, coherence, etc., play an essential role, and one must adopt a fully quantum mechanical description of the spin system. The landscape in which the system evolves is then no longer a mere sphere, but rather it is the projective Hilbert space (wich is the projective complex space $\leq \mathrm{P}^{2S}$ for a spin S), as space of considerably greater richness and complexity than the sphere of classical spin dynamics. A very appealing tool to describe a quantum spin system is Majorana's stellar representation, which is the extension for a spin S of the Bloch sphere description of a spin $1/2$. I shall discuss how this representation can help us in improving our understanding of fundamental quantum processes and concept such as Landau-Zener transitions, Rabi oscillations, Berry phase, diabolical points and illustrate this on the example of spin dynamics of molecular magnets.

Tuesday, March 22, 2011 11:15AM - 2:15PM –
Session J2 DCMP: Force Probes of Materials' Structure and Function Ballroom A2

11:15AM J2.00001 Nanoscale Mechanical Resonators for Probing Physical Phenomena: Fluid Dynamics of High-frequency Flows[1] , KAMIL EKINCI, Boston University — With their miniscule sizes, high frequencies, and small force constants, nanoelectromechanical systems (NEMS) resonators are expected to emerge as tools for sensing a variety of analytes, for probing biological entities, and for measuring molecular-scale forces. Because many of these foreseeable applications are in fluids, it is natural to consider the operation of NEMS resonators in fluids. When immersed in a fluid, however, the NEMS resonator loses most of its vibrational energy to the fluid. In other words, the quality factor (Q) of the resonator decreases significantly. Reductions in Q result in a reduction in the resonator's sensitivity to added mass or force. In order to understand the fluid dynamics of NEMS, we have revisited a well-known fluid dynamics problem: Stokes' second problem of the oscillating plate in a fluid. At the typical frequencies of NEMS resonators, Stokes' second problem needs to be reformulated using a relaxation time approach in order to accurately describe the fluidic effects. Our experiments and theory show that the fluid relaxation time in conjunction with the resonator frequency determines the nature of the flow; linear dimension and geometry appear to have weak effects. Our results support a universality in oscillating flows and suggest a deep connection between simple and complex fluids. With this understanding, we are making progress toward reducing NEMS dissipation in water.

[1]Generous support from the US NSF through Grants CBET-0755927, CMMI-0970071 and ECCS-0643178 is acknowledged.

11:51AM J2.00002 Consistency and discrepancy between single molecule force spectroscopy experiments and theoretical models , ROBERT ROS, Department of Physics, Arizona State University, Tempe, AZ 85287-1504 — Single molecule force spectroscopy is a well-established tool to study molecular interactions in a wide range of binding affinities on the single-molecule level. Information about the strength of the molecular bond can be quantified in terms of the dissociation rate k_{off}, and the reaction length x_b (i.e., the distance between potential minimum and maximum along the direction of pulling). The analysis and interpretation of the underlying force-distance curves is still challenging and various models describing the experimental data are under discussion. In this talk, I will present experimental data for a protein-RNA interaction related to posttranscriptional regulation on the single molecule level, and the interaction between DNA bases forming two or three hydrogen bonds. I will use these examples to discuss the advantages and limitations of this technique, and the consistency and discrepancy to theoretical models.

12:27PM J2.00003 Magnetic force microscopy of superconductors: vortex manipulation and measuring the penetration depth , OPHIR AUSLAENDER, Technion - Israel Institute of Technology — We use a low temperature magnetic force microscope (MFM) to image superconductors. The interaction between the magnetic tip and individual vortices allows us to both image vortices and to manipulate them. The manipulation results depend on sample thickness and on the superconducting properties. Here I concentrate on $YBa_2Cu_3O_{6+x}$ (YBCO) samples and on $Ba(Fe_{0.95}Co_{0.05})_2As_2$, an underdoped pnictide. In thin films, if the force exerted by the tip is strong enough to overcome the pinning potential a vortex jumps as a whole to a new pinning site. The behavior in thick YBCO single crystals depends on the doping level. In a slightly overdoped sample vortices stretch rather than jump when we perturb them strongly [1]. The dragging distance in this crystal is anisotropic: it is easier to drag vortices along the Cu-O chains than across them, consistent with the tilt modulus and the pinning potential being weaker along the chains. We also find that when we "wiggle" the top of a vortex we can drag it significantly farther than when we do not, giving rise to a striking dynamic anisotropy between the fast and the slow directions of the scan pattern. In an underdoped YBCO single crystal, where superconductivity is so anisotropic that a vortex should be viewed as a stack of two dimensional pancakes, we show that vortices kink rather than tilt when we perturb them [2]. Since the discovery of the pnictides, a new family of high temperature superconductors, we have also been developing ways to determine the absolute value of the magnetic penetration depth, which is notoriously difficult to measure, as well as its dependence on temperature. For that we either use the Meissner repulsion of the magnetic MFM tip from the sample or the magnetic interaction between the tip and the magnetic field from a vortex. The temperature dependence that we find allows us to comment on the symmetry of the order parameter [3].

1:03PM J2.00004 Nanoscale Magnetic Resonance Imaging[1] , DANIEL RUGAR, IBM Research Division — Magnetic resonance imaging (MRI), based on the sensitive detection of nuclear spins, enables three dimensional imaging without radiation damage. Conventional MRI techniques achieve spatial resolution that is at best a few micrometers due to sensitivity limitations of conventional inductive detection. The advent of ultrasensitive nanoscale magnetic sensing opens the possibility of extending MRI to the nanometer scale. If this can be pushed far enough, one can envision taking 3D images of individual biomolecules and, perhaps, even solving molecular structures of proteins. In this talk we will discuss issues related to nanoscale magnetic resonance imaging, especially its implementation using magnetic resonance force microscopy (MRFM). We will also consider the future possibility of using NV centers in diamond for detection of nanoMRI.

1:39PM J2.00005 Histone Post-Translation Modifications Influence Chromatin Mechanical Stability , MICHAEL POIRIER, Ohio State University — Histone proteins organize the human genome into chromatin fibers while their post-translation modification (PTM) regulates genome replication, expression and repair. The mechanistic connections between histone PTMs and biological functions remain enigmatic. We find with a combination of magnetic tweezers mechanical measurements and biochemical studies that a number of histone PTMs influence the DNA mismatch repair process by mechanically destabilizing chromatin. The location of the PTM within the chromatin structure appears to determine the mechanism by which it alters the mechanical stability. These findings have direct implications for understanding the repair of the human genome.

Tuesday, March 22, 2011 11:15AM - 2:15PM –

Session J3 DMP DCMP: The Kavli Foundation Special Symposium: Nobelist Perspectives on 100 Years of Superconductivity Ballroom A3

11:15AM J3.00001 Theoretical work on superconductivity up to 1956 , ANTHONY LEGGETT, University of Illinois at Urbana-Champaign — In this talk I survey some of the attempts to understand superconductivity which preceded the 1957 work of Bardeen, Cooper and Schrieffer, and conclude by asking if there are any lessons we can draw for our current efforts to understand apparently "non-BCS" superconductors such as the cuprates and ferropnictides.

11:51AM J3.00002 The Exceptional Properties of Superconductivity in Cuprates , K.A. MUELLER, Physics Institute, University of Zurich, Switzerland — Copper oxides are the only materials that have transition temperatures, T_c, *above* the boiling point of liquid nitrogen, with a maximum T_c^m of 162 K under pressure. Their structure is layered, with one to several CuO_2 planes, and upon hole doping, their transition temperature follows a dome-shaped curve with a maximum at T_c^m. In the underdoped regime, i.e., below T_c^m, a pseudogap T^* is found, with T^* always being larger than T_c, a property unique to the copper oxides [1]. In the superconducting state, Cooper pairs (two holes with antiparallel spins) are formed that exhibit coherence lengths on the order of a lattice distance *in the* CuO_2 plane and one order of magnitude less perpendicular to it. Their macroscopic wave function is parallel to the CuO_2 plane near 100% d at their surface, but only 75% d and 25% s in the bulk, and near 100% s perpendicular to the plane in YBCO. There are two gaps with the same T_c [2]. As function of doping, the oxygen isotope effect is novel and can be quantitatively accounted for by a two-band vibronic theory [3]. These cuprates are intrinsically heterogeneous in a dynamic way. In terms of quasiparticles, bipolarons are present at low doping, and aggregate upon cooling [1], so that probably ramified clusters and/or stripes are formed, leading over to a more Fermi-liquid-type behavior at large carrier concentrations above T_c^m.

12:27PM J3.00003 Discovery of Superconductive Tunneling , IVAR GIAEVER, Applied BioPhysics, Inc. — Some times unlikely events happens: How can a mechanical engineer from Norway end up with a Nobel Prize in Physics? I had the great fortune to receive the prize in Physics for using electron tunneling to measure the energy gap in superconductors. In this talk I will recollect some of the events that led to this discovery and hopefully be able to convey to you some of the fun and excitement of that area. My great fortune was really to be at the right place at the right time, where I had access to outstanding and helpful physicists. If you become real interested, you may look up the talk at the web site http://nobelprize.org/ .

1:03PM J3.00004 Superconductivity and particle physics , FRANK WILCZEK, MIT — I will briefly review and give a modern perspective on some classic applications of the ideas of superconductivity theory to fundamental particle physics: spontaneous chiral symmetry breaking in vacuum QCD, the Higgs mechanism in electroweak theory, and color superconductivity in dense hadronic matter; and also the confinement problem. Then I will discuss some frontier topics that carry the ideas further and in new directions: supersymmetry and the superHiggs mechanism, exotic quantum statistics of superconducting vortices.

1:39PM J3.00005 Superfluidity in an Atomic Gas of Strongly Interacting Fermions , WOLFGANG KETTERLE, MIT — What is the benefit of realizing superfluidity in a gas a million times more dilute than air? Such systems consist of well-separated atoms which can be observed and manipulated with the control and precision of atomic physics, and which can be treated with first-principles calculations. By implementing scattering resonances, we have realized the strong-coupling limit of the Bardeen Schrieffer-Cooper (BCS) mechanism and observed a normalized transition temperature of 15% of the Fermi temperature, higher than in any superconductor. By tuning the strength of the interactions, the BEC-BCS crossover is realized. When the population of the two spin states is imbalanced, pairing is frustrated; and superfluidity is quenched at the Chandrasekhar-Clogston limit. These studies illustrate a new approach to condensed-matter physics where many-body Hamiltonians are realized in dilute atomic gases.

Tuesday, March 22, 2011 11:15AM - 2:15PM –

Session J4 DPOLY DBP: Interactions Between Pore Forming Peptides and Membranes Ballroom A4

11:15AM J4.00001 Membrane Disruption Mechanism by Antimicrobial Peptides , KA YEE C. LEE, The University of Chicago — Antimicrobial peptides (AMPs) are a class of small (less than100 residues) host defense peptides that induce selective membrane lytic activity against microbes. To understand the mechanism of membrane disruption by AMPs, we investigated, via atomic force microscopy, topological changes in supported phospholipid bilayers induced by protegrin-1 (PG-1). We have observed that PG-1 induces structural transformations, progressing from fingerlike instabilities at bilayer edges, to the formation of sievelike nanoporous structures and finally to a network of stripelike structures in a zwitterionic dimyristoylphosphatidylcholine (DMPC) model membrane in buffer, with increasing PG-1 concentration. Our results suggest that AMPs act to lower the interfacial energy of the bilayer in a way similar to detergents. By varying the lipid composition, temperature and using AMPs with different secondary structures, we are able to identify factors other than electrostatics that are important for the efficacy of AMPs.

11:51AM J4.00002 Deconstruction of biophysical function in the HIV fusion peptide[1] , DENNIS BONG, The Ohio State University — We have synthesized a library of variants of the 23-residue fusion peptide domain found at the N-terminus of gp-41 glycoprotein of HIV. This sequence is critical for viral infectivity and is thought to be central in the membrane fusion of viral envelope with the host endosomal membrane. There has been extensive discussion in the literature regarding the mechanism by which this viral fusion sequence initiates membrane fusion, with importance placed on glycine-content, particular oligomeric states and secondary structure; both helical and sheet structures have been proposed to be the active fusogenic structure. Our library was designed to address the biophysical importance of secondary structure, peptide flexibility, glycine content and location as well as the nature of the membrane anchor. Each member of this library also bears a positively charged hexapeptide at the C-terminus for solubility and to facilitate binding to negatively charged membranes. We assayed each peptide for its ability to induce lipid-mixing and lysis in both large and giant unilamellar vesicles, and searched for correlations between aggregated peptides and heightened activity. We find that the information encoded in the viral fusion peptide required for may be greatly simplified: glycine is not required for fusion, aggregation is not correlated with activity, and any peptide within a window of hydrophobicity can be an effective fusion catalyst. Given the wide range of sequences which may be effective in catalyzing vesicle membrane fusion, it appears highly unlikely that a particular stably folded secondary structure is important for fusion. Rather, our data show that many flexible, linear, minimally hydrophobic peptides may achieve the biophysical function of fusion.

[1]This research was supported in part by an NSF-CAREER award to D.B.

12:27PM J4.00003 Relation between amino acid sequence and peptide-induced membrane curvature , GERARD WONG, University of California Los Angeles — This abstract not available.

1:03PM J4.00004 Structural Studies of Biological Solids Using NMR , AYYALUSAMY RAMAMOORTHY, Biophysics and Department of Chemistry, The University of Michigan, Ann Arbor, MI 48109-1055 — High-resolution structure and dynamics of biological molecules are important in understanding their function. While studies have been successful in solving the structures of water-soluble biomolecules, it has been proven difficult to determine the structures of membrane proteins and fibril systems. Recent studies have shown that solid-state NMR is a promising technique and could be highly valuable in studying such non-crystalline and non-soluble biosystems. I will present strategies to study the structures of such challenging systems and also about the applications of solid-state NMR to study the modes of membrane-peptide interactions for a better assessment of the prospects of antimicrobial peptides as substitutes to antibiotics in the control of human disease. Our studies on the mechanism of membrane disruption by LL-37 (a human antimicrobial peptide), analogs of the naturally occurring antimicrobial peptide magainin2 extracted from the skin of the African frog Xenopus Laevis, and pardaxin will be presented. Solid-state NMR experiments were used to determine the secondary structure, dynamics and topology of these peptides in lipid bilayers. Similarities and difference in the cell-lysing mechanism, and their dependence on the membrane composition, of these peptides will be discussed. Atomic-level resolution NMR structures of amyloidogenic proteins revealing the misfolding pathway and early intermediates that play key roles in amyloid toxicity will also be presented.

1:39PM J4.00005 How antimicrobial peptides disrupt lipid bilayers? , DURBA SENGUPTA, University of Groningen — The molecular basis for the activity of cyclic and linear antimicrobial peptides is analysed. We performed multi-scale molecular dynamics simulations and biophysical measurements to probe the interaction of antimicrobial peptides with model membranes. Two linear antimicrobial peptides, magainin and melittin and a cyclic one, BPC194 have been studied. We test different models to determine the generic and specific forces that lead to bilayer disruption. We probe whether interfacial stress or local membrane perturbation is more likely to lead to the porated state. We further analyse the reasons that determine specificity and increase of activity in antimicrobial peptides. The results provide detailed insight in the mode of action of antimicrobial peptides.

Tuesday, March 22, 2011 11:15AM - 2:15PM –

Session J5 CSWP: Hildred Blewett Scholars and their Research followed by Panel Discussion

Ballroom C1

11:15AM J5.00001 M. Hildred Blewett and the Blewett Scholarship , BARBARA WHITTEN, Physics Department, Colorado College — M. Hildred Blewett became a physicist at a time when few women were physicists. After beginning her career at General Electric, she became a respected accelerator physicist, working at Brookhaven, Argonne, and eventually CERN. Blewett was married for a time to John Blewett, another accelerator physicist, but the couple divorced without children and she never remarried. She felt that her career in physics was hampered by her gender, and when she died in 2004 at the age of 93, she left the bulk of her estate to the American Physical Society, to found a Scholarship for women in physics. Since 2005 the Blewett Scholarship has been awarded to women in physics who are returning to physics after a career break, usually for family reasons. Family/career conflicts are one of the most important reasons why young women in early careers leave physics—a loss for them as well as the physics community, which has invested time and money in their training. The Blewett Scholarship is one way for the physics community, under the leadership of CSWP, to help these young women resume their careers. I will discuss the life and work of Hildred Blewett, the Blewett Scholarship, and its benefits to the physics community.

11:27AM J5.00002 Atomically Thin Graphene Hall Cross Devices as Sensitive Magnetic Field Probes , JANICE WYNN GUIKEMA, Department of Physics and Astronomy, Johns Hopkins University, Baltimore, MD 21218 — Experimentally realized in 2004, graphene has ignited great interest in physics, material science, chemistry and engineering. Graphene is a one-atom thick sheet of carbon atoms arranged in a hexagonal lattice. This elegantly simple material has excellent electronic and mechanical properties, as well as remarkable physics resulting from its relativistic Dirac electrons. Graphene is a highly promising material for many applications, including sensors. One of my research projects has been investigating graphene for use as a nanoscale magnetic sensor. Such sensors could be used to measure small magnetic particles or as a scanning probe to map out magnetic fields. The Hall cross geometry of the devices gives a noninvasive and straightforward magnetic field probe. I fabricated Hall crosses from mechanically exfoliated single-, bi-, and multi-layer graphene with cross junction widths down to a few hundred nanometers. The devices were tested in a small applied field and the noise spectra of the Hall signal as a function of bias current and back gate voltage was measured at room and cryogenic temperatures. The best field sensitivity at room temperature obtained for a 400 nm graphene Hall cross was 15 $G/Hz^{1/2}$ at 1 Hz and 1 $G/Hz^{1/2}$ at 4 kHz, which is on par with similar crosses made from other materials in the literature. In addition, because they are made from graphene, graphene Hall probes have further advantages such as tunability with a gate, being extremely thin and at the surface, and having mechanical stability for ultra-small device fabrication.

12:03PM J5.00003 When Nano Isn't Small Enough: Lattice Quantum Chromodynamics and My Quest to Understand Particle Physics , ELIZABETH FREELAND, University of Illinois Urbana-Champaign — Although I started my research life as a condensed matter theorist (nanotribology), I now work in the field of high-energy physics. I use effective field theories and Lattice Quantum Chromodynamics (Lattice QCD) to calculate strong-interaction effects in Standard Model processes. I have worked on quark and meson mass calculations, and contributed to decay-process calculations used to probe the weak-interation. After setting the stage for this research, I will briefly describe calculations I have worked on over the past few years and give an introduction to my current research project(s).

12:39PM J5.00004 Lateral Modulation in Antimonide Superlattices[1] , REBECCA FORREST, University of Houston — Lateral modulation is the spontaneous formation of a periodic modulation in structure or alloy composition perpendicular to the growth direction in an epitaxial structure. It has been observed in many epitaxially grown III-V semiconductor alloys, occurring during both the homogenous growth of III-V alloys and in III-V superlattices. In [001] oriented zinc blende structures, lateral modulation typically occurs along one of the [110] directions and is associated with strain and growth kinetics. It begins when strain is relieved through elastic surface undulations, typically in layers much thinner than the critical thickness for dislocation formation. In a superlattice, these undulations can lead to either compositional or purely structural modulation, depending on the relative phase and amplitude of the undulations in the constituent layers. Compositional modulation is by far the most commonly observed form in superlattice structures. We report on the analysis of purely structural lateral modulation in AlSb/AlAs digital superlattices, using x-ray diffraction. This is the first report of lateral modulation in an antimonide superlattice, and a rare observation of purely structural modulation in a superlattice. InAs/Al(In)Sb digital superlattices were also studied, and exhibited no lateral modulation. The composition and strain of the structures and critical thickness for lateral modulation will be discussed.

[1]This research was supported in part by the M. Hildred Blewett Scholarship of the American Physical Society.

1:15PM J5.00005 Panel discussion on the Blewett Scholarship, and how it helps young women achieve career/family balance.[1] , SHERRY YENNELLO, Texas A&M University — This panel discussion will be preceded by talks by three women who have had career interruptions due to family reasons and have restarted their research careers with some assistance from a Blewett Scholarship. They will discuss their experience balancing career and family. Questions from the audience will be encouraged. This session should provide inspiration for young women to pursue their passions and motivation for department chairs to be flexible and accommodating of career/family balance.

[1]The Blewett Scholarship program is administered by CSWP.

Tuesday, March 22, 2011 11:15AM - 1:39PM –

Session J6 DCOMP: The Use of GPUs in Computational Physics

Ballroom C2

11:15AM J6.00001 Fully accelerating quantum Monte Carlo simulations of real materials on GPU clusters[1] , KENNETH ESLER, Stone Ridge Technology — Quantum Monte Carlo (QMC) has proved to be an invaluable tool for predicting the properties of matter from fundamental principles, combining very high accuracy with extreme parallel scalability. By solving the many-body Schrödinger equation through a stochastic projection, it achieves greater accuracy than mean-field methods and better scaling with system size than quantum chemical methods, enabling scientific discovery across a broad spectrum of disciplines. In recent years, graphics processing units (GPUs) have provided a high-performance and low-cost new approach to scientific computing, and GPU-based supercomputers are now among the fastest in the world. The multiple forms of parallelism afforded by QMC algorithms make the method an ideal candidate for acceleration in the many-core paradigm. We present the results of porting the QMCPACK code to run on GPU clusters using the NVIDIA CUDA platform. Using mixed precision on GPUs and MPI for intercommunication, we observe typical full-application speedups of approximately 10x to 15x relative to quad-core CPUs alone, while reproducing the double-precision CPU results within statistical error.[2] We discuss the algorithm modifications necessary to achieve good performance on this heterogeneous architecture and present the results of applying our code to molecules and bulk materials.[3]

11:51AM J6.00002 The Use of GPUs in Lattice Gauge Theory , STEVEN GOTTLIEB, Indiana University — In the past few years, GPUs have been put to use in lattice gauge theory calculations. This talk will consider the successes and challenges of this approach including such issues as how to take advantage of multiple threads, the effort involved in porting, the resulting performance and the challenge of writing multi-GPU code that scales well.

12:27PM J6.00003 Wavelet-Based DFT calculations on Massively Parallel Hybrid Architectures , LUIGI GENOVESE, CEA Grenoble — In this contribution, we present an implementation of a full DFT code that can run on massively parallel hybrid CPU-GPU clusters. Our implementation is based on modern GPU architectures which support double-precision floating-point numbers. This DFT code, named BigDFT, is delivered within the GNU-GPL license either in a stand-alone version or integrated in the ABINIT software package. Hybrid BigDFT routines were initially ported with NVidia's CUDA language, and recently more functionalities have been added with new routines writeen within Kronos' OpenCL standard. The formalism of this code is based on Daubechies wavelets, which is a systematic real-space based basis set. As we will see in the presentation, the properties of this basis set are well suited for an extension on a GPU-accelerated environment. In addition to focusing on the implementation of the operators of the BigDFT code, this presentation also relies of the usage of the GPU resources in a complex code with different kinds of operations. A discussion on the interest of present and expected performances of Hybrid architectures computation in the framework of electronic structure calculations is also adressed.

Session J7 GSNP: The Dynamics of Co-Evolving and Interdependent Networks Ballroom C3

11:15AM J7.00001 Robustness of Interdependent Networks , SHLOMO HAVLIN, Bar-Ilan University — In interdependent networks, when nodes in one network fail, they cause dependent nodes in other networks to also fail. This may happen recursively and can lead to a cascade of failures. In fact, a failure of a very small fraction of nodes in one network may lead to the complete fragmentation of a system of many interdependent networks. We will present a framework for understanding the robustness of interacting networks subject to such cascading failures and provide a basic analytic approach that may be useful in future studies. We present exact analytical solutions for the critical fraction of nodes that upon removal will lead to a failure cascade and to a complete fragmentation of two interdependent networks in a first order transition [1]. Surprisingly, analyzing complex systems as a set of interdependent networks may alter a basic assumption that network theory has relied on: while for a single network a broader degree distribution of the network nodes results in the network being more robust to random failures, for interdependent networks, the broader the distribution is, the more vulnerable the networks become to random failure. We also show [2] that reducing the coupling between the networks leads to a change from a first order percolation phase transition to a second order percolation transition at a critical point. These findings pose a significant challenge to the future design of robust networks that need to consider the unique properties of interdependent networks.

11:51AM J7.00002 Interconnected Financial Networks , GUIDO CALDARELLI, Institute of Complex Systems, CNR, Rome Italy — It is known that different dynamics on a network are associated to different resilient structures. In particular in the case of financial networks the fragility is associated to the kind of relation between the vertices (financial agents). Since the same agents can be connected on different networks for different financial relations, a study on the global resilience can only be obtained by considering the whole structure. Here we present our activity on this topic.

12:27PM J7.00003 Emergent phenomena in interacting networks , RAISSA DSOUZA, University of California, Davis — This abstract not available.

1:03PM J7.00004 Dynamical network approach for social interactions , GINESTRA BIANCONI, Northeastern University — This abstract not available.

1:39PM J7.00005 The Structure and Dynamics of Economic Complexity , CESAR A. HIDALGO, Massachusetts Institute of Technology — Can network science help us understand the structure and evolution of the global economy? In this talk I summarize recent research that uses networks and complexity science to describe and explain the evolution of the mix of products that countries, and cities, produce and export. First, I show how to use information on the network connecting industries to locations to measure the complexity of an economy. Using these measures I demonstrate that countries tend to approach a level of income that is dictated by the complexity of their economies. Next, I study the evolution of economic complexity by showing that it is constrained by a coordination problem that countries, and cities, deal with using three different channels: First, they move to products that are close by, in the Product Space, to the products that they already do. Second, they are more likely to develop a product if a geographical neighbor has already developed it. And third, they follow the nestedness of the network connecting industries to locations. Finally, I introduce a simple model to account for the stylized facts uncovered in the previous sections.

Tuesday, March 22, 2011 11:15AM - 2:15PM –
Session J8 FEd: Physics Education Research in Upper-division Physics Courses Ballroom C4

11:15AM J8.00001 Using research to enhance student learning in intermediate mechanics , BRADLEY AMBROSE, Grand Valley State University — For many undergraduate physics majors the sophomore/junior level course in intermediate mechanics represents their first step beyond the introductory sequence. Over the past several years research has shown that intermediate mechanics students often encounter conceptual and reasoning difficulties similar to those that arise at the introductory level. Many difficulties suggest deeply-seated alternate conceptions, while others suggest loosely or spontaneously connected intuitions. Furthermore, students often do not connect the physics to the more sophisticated mathematics they are expected to use. This presentation will highlight results from research conducted at Grand Valley State University, the University of Maine (by co-PI Michael Wittmann) and pilot sites in the *Intermediate Mechanics Tutorials* project. These results, taken from the analysis of pretests (ungraded quizzes), written exams, and classroom observations, will illustrate specific student difficulties as well as examples of guided-inquiry teaching strategies that appear to address these difficulties. (Supported by NSF grants DUE-0441426 and DUE-0442388.)

11:51AM J8.00002 A Research-Based Approach to Transforming Upper-Division Electricity & Magnetism[1] , STEVEN POLLOCK[2], CU Boulder — We present research on transforming an upper-division undergraduate electricity and magnetism course using principles of active engagement and learning theory. We build on a systematic investigation of student learning difficulties, with the goal of developing useful curricular materials and suggestions for effective teaching practices. We observe students in classroom, help-session, and interview settings, and analyze their written work. To assess student learning, we have developed and validated a conceptual instrument, the CUE (Colorado Upper-division Electrostatics) diagnostic. We collaborate with faculty to establish learning goals, and have constructed a bank of clicker questions, tutorials, homeworks, and classroom activities. We find that students in the transformed courses exhibit improved performance over the traditional course, as assessed by common exam questions and the CUE, but there is still much work to be done. Our work underlines the need for further research on the nature of student learning and appropriate instructional interventions at the upper division.

12:27PM J8.00003 Investigating student understanding in an upper-division analog electronics course[1] , MACKENZIE R. STETZER, University of Washington — The Physics Education Group at the University of Washington has recently begun an in-depth investigation of student understanding of analog electronics. As part of this investigation, we have been examining student learning in an upper-division laboratory course on this subject. In particular, we have administered written questions on fundamental electric circuits concepts (typically covered in introductory physics courses) and on canonical topics in analog electronics (e.g., filters, diodes, transistors, and operational amplifiers). Drawing on the results from such questions, we are investigating the impact of the analog electronics course on student conceptual understanding. Specific examples will be used to illustrate how the findings from this investigation have implications for instruction in both introductory and upper-division courses.

1:03PM J8.00004 Research on Student Learning of Upper-Level Thermal and Statistical Physics[1] , JOHN THOMPSON, University of Maine — Within the last decade, physics education researchers have begun to extend the tools and methods used at the introductory level to conduct systematic investigations of student learning of thermal and statistical physics in the upper division. Most research in thermodynamics has focused on student ideas about the first and second laws and the associated concepts (e.g., work, heat, entropy). Several studies yield insights about broader ideas, such as state functions. Research in statistical physics has focused on the concepts underlying multiplicity and related ideas in probability. Research has identified a number of conceptual difficulties with varied degrees of persistence, some of which are consistent with findings at the introductory level. Some investigations further probe connections between physics and relevant mathematics concepts in these areas, including student interpretation of canonical representations such as pressure-volume (P-V) diagrams. Results from research are guiding the development of curricular materials in order to address several known difficulties.

[1]Supported in part by NSF Grants DUE-0817282 and DUE-0837214.

1:39PM J8.00005 Improving students' understanding of quantum mechanics[1] , CHANDRALEKHA SINGH, University of Pittsburgh — Learning quantum mechanics is especially challenging, in part due to the abstract nature of the subject. We have been conducting investigations of the difficulties that students have in learning quantum mechanics. To help improve student understanding of quantum concepts, we are developing quantum interactive learning tutorials (QuILTs) as well as tools for peer-instruction. The goal of QuILTs and peer-instruction tools is to actively engage students in the learning process and to help them build links between the formalism and the conceptual aspects of quantum physics without compromising the technical content. They focus on helping students integrate qualitative and quantitative understanding, confront and resolve their misconceptions and difficulties, and discriminate between concepts that are often confused. In this talk, I will give examples from my research in physics education of how students' prior knowledge relevant for quantum mechanics can be assessed, and how learning tools can be designed to help students develop a robust knowledge structure and critical thinking skills.

Tuesday, March 22, 2011 11:15AM - 2:15PM –
Session J9 DFD: Liquid Crystals: Nematics, Lyotropics and Vesicles D220

11:15AM J9.00001 Dynamics of chiral liquid-crystal films driven by water transport[1] , JONATHAN V. SELINGER, LENA M. LOPATINA, Liquid Crystal Institute, Kent State University — In previous experimental and theoretical research, Tabe and Yokoyama investigated Langmuir monolayers of chiral molecules on the surface of water, and found that evaporation of water induces collective precession of the molecular orientation [1]. More recently, they have found a similar effect in freely suspended films of chiral smectic liquid crystals, but with one new feature: the molecular rotation is accompanied by large- scale flow of the molecules, indicating a strong coupling between orientation and flow. To model the coupled rotation and flow driven by water transport, we construct the Lagrangian and Rayleigh dissipation function appropriate for a film in the smectic-A or smectic-C phase, derive the equations of motion, and solve these equations in geometries corresponding to the experiments. In particular, we calculate the flow patterns in terms of the viscosity coefficients of the liquid-crystal films, in order to understand the mechanisms that control this dynamic behavior. The theoretical predictions are compared with experimental results, and with related work on granular materials [2].

11:27AM J9.00002 Linear aggregation and liquid-crystalline order: comparison of Monte Carlo simulation and analytic theory , TATIANA KURIABOVA, University of Colorado, M.D. BETTERTON, MATTHEW A. GLASER, University of Colorado at Boulder — Many soft-matter and biophysical systems are composed of monomers that reversibly assemble into rod-like aggregates. The aggregates can then order into liquid-crystal phases if the density is high enough, and liquid-crystal ordering promotes increased growth of aggregates. Systems that display coupled aggregation and liquid-crystal ordering include wormlike micelles, chromonic liquid crystals, DNA and RNA, and protein polymers and fibrils. Coarse-grained molecular models that capture key features of coupled aggregation and liquid-crystal ordering common to many different systems are lacking; in particular, the roles of monomer aspect ratio and aggregate flexibility are not well understood. We study a system of sticky cylinders that interact primarily by hard-core interactions but can stack and bind end to end. We use Monte Carlo simulations and analytic theory. We present results for several different cylinder aspect ratios and a range of end-to-end binding energies. The phase diagrams are qualitatively similar to those of chromonic liquid crystals, with an isotropic-nematic-columnar triple point. Our analytic theory shows improvement compared to previous theory in quantitatively predicting the I–N transition for relatively stiff aggregates, but requires a better treatment of aggregate flexibility.

11:39AM J9.00003 Modeling the Kerr effect in polymer-disordered liquid crystals[1] , LENA M. LOPATINA, JONATHAN V. SELINGER, Liquid Crystal Institute, Kent State University — In the Kerr effect, an electric field applied to an optically isotropic material induces orientational order and hence induces optical birefringence. Recently, many investigators have used the Kerr effect to develop liquid-crystal displays and other electro-optic devices that can operate at high speed and with no need for aligning substrates. This application requires a large and fairly temperature-independent Kerr coefficient. One approach to achieve this goal is by using liquid-crystal blue phases, perhaps with polymer stabilization. As an alternative approach, D.-K. Yang has suggested using a nematic phase within a disordered polymer network. This structure would be disordered and optically isotropic in the absence of a field, but it would develop order and birefringence under an applied field. To assess this approach, we perform Monte Carlo simulations of a nematic liquid crystal in a disordered polymer network, and calculate the response to an applied field. We compare the results with analytic studies of liquid crystals under quenched disorder and with experiments.

11:51AM J9.00004 A nonlocal model of inhomogeneous nematic liquid crystals , PETER PALFFY-MUHORAY, Liquid Crystal Institute - KSU, XIAOYU ZHENG, Dept. of Mathematical Sciences - KSU, ROLAND ENNIS, Pressco Technology Inc. Cleveland, OH — The free energy cost of spatial inhomogeneities in nematic liquid crystals is usually described in terms of gradients of the director field or of the order parameter tensor. The origins of such gradient expansions are not clear; they can also lead to ill-posedness of the variational problem of minimizing the free energy. We propose a simple nonlocal form of the single particle potential from which the free energy may be constructed. Our model reduces to the Maier-Saupe form for homogenous systems, but describes inhomogenous systems in general. We demonstrate the validity of the model by using it to describe the electric field induced Freedericksz transition. We discuss the connection between our non-local model and gradient expansions.

12:03PM J9.00005 Freely Suspended Nematic Films[1] , WILDER IGLESIAS, JEFFREY CHOI, ELIZABETH K. MANN, ANTAL JAKLI, Kent State University — Using one of the most commonly studied synthetic molecule, 4-Cyano-4'-pentylbiphenyl (5CB), we were able to pull freely suspended membranes of different thicknesses into circular frames of up to 20mm diameter. Films pulled this way were distorted using a speaker, while a laser light was shone onto them for studying the far field reflection and learn about resonant frequency modes and subtract valuable information about the viscoelastic terms that hold the membrane stable.

12:15PM J9.00006 Fluctuation Modes of a Bent-Core Nematic Liquid Crystal[1] , MADHABI MAJUMDAR, S. CHAKRABORTY, B. SENYUK, O.D. LAVRENTOVICH, JAMES T. GLEESON, ANTAL JAKLI, SAMUEL SPRUNT, Kent State University — We present a dynamic light scattering study of the bent-core nematic liquid crystal compound *DT6Py6E6*. We utilize a "dark" scattering geometry, which allows us to search for fluctuation modes that are not purely associated with the uniaxial director. Indeed, we observe two modes (hydrodynamic and non-hydrodynamic) in addition to the expected twist-bend director mode. We present a model for the additional modes based on fluctuations of the biaxial order parameter, which leads to an estimate of 10-100 nm for the correlation length associated with these fluctuations.

[1]Acknowledgement: DOE DE-SC0001412 and NSF DMR-0606160.

12:27PM J9.00007 Three dielectric constants and orientation order parameters in nematic mesophases[1] , HYUNG GUEN YOON, SEUNG YEON JEONG, SATYENDRA KUMAR, Kent State University, MIN SANG PARK, JUNG OK PARK, M. SRINIVASARAO, Georgia Instittue of Technology, SUNG TAE SHIN, LCD R&D Center, Samsung Electronics Corp. — Temperature dependence of the three components ε_1, ε_2, and ε_3 of dielectric constant and orientation order parameters in the nematic phase of mesogens with rod, banana, and zero-order dendritic shape were measured using the in-plane and vertical switching geometries, and micro-Raman technique. Results on the well-known uniaxial (N_u) nematogens, E7 and 5CB, revealed two components $\varepsilon_1 = \varepsilon_{||}$ and $\varepsilon_2 = \varepsilon_3 = \varepsilon_\perp$, as expected. The three dielectric constants were different for two azo substituted (A131 and A103) and an oxadiazole based (ODBP-Ph-C12) bent core mesogens, and a Ge core tetrapode. In some cases, two of the components became the same indicating a loss of biaxiality at temperatures coinciding with the previously reported N_u to biaxial nematic transition. This interpretation is substantiated by micro-Raman measurements of the uniaxial and biaxial nematic order parameters.

[1]Supported by the US Department of Energy, Basic Energy Sciences grant ER46572 and by Samsung Electronics Corporation.

12:39PM J9.00008 The interplay between fluctuations in physical structure and power consumption in electroconvecting liquid crystals , JOHN CRESSMAN, ZRINKA GREGURIC, TYRUS BERRY, TIMOTHY SAUER, George Mason University — We will present results from experiments performed on the nematic liquid crystal MBBA. We have made simultaneous measurements of the optical patterns formed in the weakly-driven electroconvective state, as well as the electrical power consumed by the sample. By performing a dimensionality reduction on the optical data we identify the dominant modes in the system and go on to elucidate the role of these modes in the measured power fluctuations. We will conclude by discussing these results in the context of the free energy derived by de Gennes for nematic liquid crystals.

12:51PM J9.00009 Magneto-optical technique for detecting biaxial nematic phase[1] , TANYA OSTAPENKO, J.T. GLEESON, S.N. SPRUNT, A. JAKLI, Kent State University — There have been numerous attempts to find a thermotropic liquid crystal that exhibits a biaxial phase. There have been findings of biaxial order in bent-core nematic liquid crystals; however, there are recent reports that call this into question. One reason for this discrepancy is the difficulty in unambiguously identifying the biaxiality. Based on a previously described electro-optical technique, we have developed a technique that uses magnetic field, thus widening its application to any bent-core nematic material. The field orients the uniaxial director along the optical path length, and we search for birefringence perpendicular to this direction. We expect one of two situations to occur: if the material is uniaxial, the induced phase difference will decrease asymptotically to zero as the field increases. However, if the material is biaxial, the induced phase will extrapolate to a non-zero value. Results on one calamitic liquid crystal show that this method yields the expected result, namely the lack of biaxial nematic phase. We also tested several bent-core nematic liquid crystals and found that none of these materials exhibits a biaxial nematic phase.

1:03PM J9.00010 Nonlinear electrophoresis in nematics: Flows and effects of salts , ISRAEL LAZO-MARTINEZ, OLEG D. LAVRENTOVICH, Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University — Electrophoresis (EP) in a nematic liquid crystal (LC) is dramatically different from its isotropic counterpart, as the EP velocity has a component that is quadratic in the applied electric field [1]. Unlike the regular EP velocity that is linear in the field, this component does not vanish in an ac field with a zero time average, which makes the LC EP attractive for applications where the steady flows are needed. EP propulsion is caused by distortion of the LC orientation around the particles that break the fore-aft (or left-right) symmetry, leading towards an imbalance of field-induced flows around the particles. We visualize the flows and measure the EP velocity by recording 3D trajectories of passive tracers suspended in the LC under the fluorescent confocal polarizing microscope. We demonstrate that doping the LC with organic salts increases the EP velocities. The work was supported by NSF DMR 0906751.

1:15PM J9.00011 Anisotropic Stokes Drag and Dynamic Lift on Cylindrical Colloids in a Nematic Liquid Crystal , JOEL ROVNER, CLAYTON LAPOINTE, DANIEL REICH, ROBERT LEHENY, Johns Hopkins University — Unlike isotropic fluids, nematic liquid crystals exhibit a complex assortment of hydrodynamic properties that can strongly depend on the director field and local boundary conditions set by inclusions. To understand further these characteristics, measurements were taken of the Stokes drag on magnetic nanowires suspended in nematic 4-cyano-4'-pentylbiphenyl (5CB). Effective drag viscosities for wires moving perpendicular and parallel to the nematic director were measured and were found to differ by factors of approximately 0.88 to 2.4, depending on the wire orientation and surface anchoring. Additionally, a lift force was observed when wires were forced at an oblique angle to the director resulting in motion divergent from the line of force. The lift was greater for wires with homeotropic anchoring and smaller for wires with longitudinal anchoring, suggesting that the lift force can act as a mechanism for sorting colloidal particles according to their surface chemistry.

1:27PM J9.00012 Morphology and Rheology of the Liquid Crystal-Colloid Composites , LU ZOU, CHANJOONG KIM, Liquid Crystal Institue, Kent State University — Liquid crystal (LC)-colloid composites form aggregates and are arrested in various network structures. We study viscoelastic properties and three-dimensional structure of nematic LC-colloid composites using fluorescence confocal polarized rheoscope and fluorescence microscope. We observe various morphological transformations of the composites when we cool them down below T_{NI} from the high temperature isotropic phase. We find that colloidal particles are self-organized to ferny structures, and that the morphological characteristics of the ferny structures depend on the applied shear rates, the cooling rate, the particle volume fraction and the particle size. This study may offer a new route to form novel colloidal structures using anisotopic fluid, which could not be obtained from isotropic suspensions.

1:39PM J9.00013 Structural Reorganization of Liquid Crystals Revealled by Fast Scanning Calorimeter[1] , DONGSHAN ZHOU, JING JIANG, XIAOLIANG WANG, GI XUE, Nanjing University — Liquid crystal glass of 4-Cyano-4'-octylbiphenyl is obtained by rapid cooling with rates over 2000 Kelvin per second (K/s) on the chip calorimeter. The glass can crystallize easily upon heated above its glass transition temperature. Depending on the prior cooling rate and annealing history thereafter, melting-structural reorganization-remelting behavior similar to that of semicrystalline polymer can be observed during subsequent heating. The complex melting behavior is attributed to the transformation of metastable crystal forms formed during annealing or heating induced cold crystallization. Increasing the heating rate (>15000 K/s) can suppress the transformation and, additionally, enables us to capture the multiple N-I transition. This implies the coexistence of two different types of nematic states. To avoid above complex structural reorganization, one can anneal the sample at 260K for 2 seconds to get the stable crystal form.

1:51PM J9.00014 Parity breaking in nematic tactoids of lyotropic chromonic liquid crystals[1] , LUANA TORTORA, OLEG D. LAVRENTOVICH, Liquid Crystal Institute, Kent State University — In many colloidal systems, an orientationally ordered nematic phase emerges from the isotropic melt in the form of spindle-like birefringent tactoids. In cases studied so far, the tactoids always reveal a mirror-symmetric non-chiral structure, even when the building units are chiral, as in the case of tobacco mosaic virus [1] and fd virus [2]. We report on parity breaking in the nematic tactoids formed in molecularly non-chiral polymer-crowded solutions of lyotropic chromonic liquid crystals. The effect is manifested by twist of the director and optical activity. Fluorescent confocal polarizing microscopy reveals that the tactoids nucleate at boundaries of cells. We explain the chirality induction by the effect of geometrical anchoring [3] and by increase of the splay elastic constant in condensed nematic regions of crowded solutions.

2:03PM J9.00015 Orientational order and defect structures on curved surfaces[1] , SUBAS DHAKAL, Northwestern University, FRANCISCO J. SOLIS, Arizona State University, MONICA OLVERA DE LA CRUZ, Northwestern University — We study the topological defects in a nematic liquid crystal confined to a surface. Using Monte Carlo simulations, we investigate how the position and number of defects depend on the interaction strength, the shape of the surface and other physical parameters. On a spherical surface, we find that the interaction changes the location of four $+1/2$ defects initially sitting on a great circle of the sphere to the vertices of a tetrahedron. In deformed spheres, we observe the coalescence of defects into two single $+1$ defects.

Tuesday, March 22, 2011 11:15AM - 2:15PM –
Session J10 DCMP: Surface and Interfaces with Metals D221

11:15AM J10.00001 Ordered and disordered surface alloys in Au-Pt(111) and their effect on oxygen adsorption[1] , WEI CHEN, C. WOLVERTON, Northwestern University, DAVID SCHMIDT, WILLIAM SCHNEIDER, University of Notre Dame — Bimetallic surface alloys are considered a promising type of catalyst for improved activity and selectivity. Understanding surface structure and its effect on catalytic performances plays a critical role in designing catalysts from surface alloys. We have studied the surface structure and ordering of AuPt(111) using a first-principles cluster expansion based method. Even though the Au-Pt system is phase-separating in the bulk, we find a series of thermodynamically stable, laterally ordered striped structures of AuPt(111) surfaces. The formation of such ordered structures is the result of a competition between the strain relaxations from stripes and the unfavorable Au-Pt bonds at stripe interfaces. We have also investigated the oxygen adsorption on these structures. The oxygen binding energy is found to be highly correlated with the type of nearest neighbor surface atoms of oxygen.

[1]This work is supported by National Science Foundation under contract No. CBET-0730841 and No. CBET-0731020.

11:27AM J10.00002 Order-Disorder Transitions for Au/Mo(112) , KEISUKE FUKUTANI, University of Nebraska-Lincoln, YAROSLAV LOSOVYJ, NATALIA LOZOVA, Center for Advanced Microstructure and Devices, Louisiana State University, IVAN YAKOVKIN, National Academy of Science of Ukraine, Institute of Physics, NING WU, PETER DOWBEN, University of Nebraska-Lincoln — Order-disorder overlayer phase transitions are observed at the surface of Au/Mo(112) for the nominal Au coverages of 1.66 and 1.75 monolayers. These transitions are characterized by the abrupt change in the surface Debye temperature. In the search for the detailed mechanism of this phase transition, we investigated the electron-phonon coupling (EPC), in the vicinity of the Fermi level, for the surface states of Au-covered Mo(112) surface from high- resolution angle resolved photoemission data taken parallel to the surface corrugation (i.e. $<\underline{11}1>$). The changes of the widths of the surface weighted bands, induced by Au layers, are discussed in terms of electron-electron interactions, electron-impurity scattering and electron-phonon coupling. Gold overlayers suppress the mass enhancement of the Mo(112) surface band crossing the Fermi level at 0.54 $Å^{-1}$. The data indicate that significant contributions from impurity and defect scattering must be considered in any serious analysis of the imaginary part of the self energy and that there interface effects can have a profound influence on the imaginary part of the self energy.

11:39AM J10.00003 Ab initio study of Mg self-diffusion on Mg(0001) terraces and steps[1] , MARAL AMINPOUR, MARISOL ALCANTARA ORTIGOZA, TALAT RAHMAN, Department of Physics, University of Central Florida, Orlando, 32816 — The high density of states (DOS) at the Fermi level and high density of quasi-free electrons result in a singular behavior for Mg surfaces and thin films. We find, however, that the DOS around the Fermi level, surface energy and cohesive energy converge beyond 15 layers. We also show that the Friedel charge density oscillations of Mg(0001) are more complex than depicted previously by 1D and 2D plots. These oscillations are, in fact, responsible for the stacking fault of Mg adatoms and islets on Mg(0001) and also, indirectly, for the low adatom self-diffusion barrier (20 meV) on Mg(0001), which is in agreement with effective-medium theory calculations. [1] We will compare this barrier with that of Mg adatom on a narrow terrace and across the steps on Mg(0001), as well as with predictions from Kinetic Monte Carlo simulations made to fit the growth mode observed for Mg/Mg-thin-films via scanning tunneling microscopy.

11:51AM J10.00004 Theoretical aspects of studies of high coverage oxidation of the Cu(100) surface using low energy positrons , N.G. FAZLEEV, W.B. MADDOX, J.A. REED, Department of Physics, University of Texas at Arlington — The study of adsorption of oxygen on transition metal surface is important for the understanding of oxidation, heterogeneous catalysis, and metal corrosion. The structures formed on transition metal surfaces vary from simple adlayers of chemisorbed oxygen to more complex structures which results from diffusion of oxygen into the sub-surface regions. In this work we present the results of an ab-initio investigation of positron surface and bulk states and annihilation probabilities of surface-trapped positrons with relevant core electrons at the Cu(100) missing row reconstructed surface under conditions of high oxygen coverage. Calculations are performed for various surface and subsurface oxygen coverages ranging from 0.50 to 1.50 monolayers. Calculations are also performed for the on-surface adsorption of oxygen on the unreconstructed Cu(001) surface for coverages up to one monolayer to use for comparison. Estimates of the positron binding energy, positron work function, and annihilation characteristics reveal their sensitivity to atomic structure of the topmost layers of the surface and charge transfer. Theoretical results are compared with experimental data obtained from studies of oxidation of the Cu(100) surface using positron annihilation induced Auger electron spectroscopy.

12:03PM J10.00005 Deposition of metal onto a sulfur loaded substrate , DAEHO KIM, DEZHENG SUN, WENHAO LU, ERIC CHU, JON WYRICK, ZHIHAI CHENG, LUDWIG BARTELS, University of California, Riverside — A Cu(111) surface can be loaded with sulfur to form a variety of surface patterns. In this work, we study the deposition of copper and molybdenum on a Cu(111) surface and the resultant film morphology as a function of the sulfur pre-loading of the substrate. For copper deposition, we find the formation of adstructures of different geometry depending on the sulfur decoration of the substrate. A 0.143 ML S coverage leads to rectangular structure consisting of 6 lobes while a 0.118 ML S coverage leads to 7×7 structure. Notably, annealing allows the sulfur to float up decorating the newly deposited layer. Deposition of molybdenum shows a similar pattern, with ordered MoS2 forming as a result of annealing.

12:15PM J10.00006 Oxides on Nanoscale Platinum Surfaces[1] , DANIEL HENNESSY, Materials Science Division, Argonne National Laboratory, VLADIMIR KOMANICKY, Safarik University, UPJŠ, Košice, Slovakia, MICHAEL S. PIERCE, KEE-CHUL CHANG, HOYDOO YOU, Materials Science Division, Argonne National Laboratory — We demonstrate the existence of oxide layers on nanoscale Pt interfaces annealed in an oxygen environment. The sample is a Pt single crystal cut at the midpoint between the 100 and 111 crystal directions; annealing in Ar produces a smooth surface, while annealing in air produces ∼10 nm-sized 100 and 111 facets. Synchrotron x-ray crystal truncation rod (CTR) measurements indicate a bilayer Pt oxide structure on the nanofacets. Fitted Pt occupancies are consistent with a nearest-neighbor avoidance structure of the surface oxygen atoms. Electrochemical cycling of the faceted surface in CO-saturated solution removes the oxide and leaves clean, ordered facets. Pt single crystals of 100 and 111 surface orientations prepared the same way did not support an oxide layer.

12:27PM J10.00007 The amazing kinetic stability of the high temperature ($\sqrt{3} \times 6$)rect. striped structure of decanethiol SAMs on Au(111) and other interesting properties. A scanning tunneling microscopy study.[1] , LLOYD BUMM, DAMINDA DAHANAYAKA, ABHIJIT BISWAS, RONALD HALTERMAN, The University of Oklahoma — We present an STM study of the properties of the high temperature ($\sqrt{3} \times 6$)rect. phase of decanethiol SAMs on Au (111). Although this phase is known, it has not been extensively studied. We show a simple reliable way to grow the ($\sqrt{3} \times 6$) rect. phase and show that its coverage is 75% of the normal ($2\sqrt{3} \times 3$)rect. phase. Although it has lower density compared to the normal alkanethiol SAM structure, it shows a remarkable kinetic stability with respect to uptake of additional alkanethiol molecules and reversion to the normal ($2\sqrt{3} \times 3$) rect. phase. Other properties of the ($\sqrt{3} \times 6$)rect. phase will be discussed.

12:39PM J10.00008 Epitaxial orientations of para-sexiphenyl platelets grown on alkali halide (001) surfaces , EDWARD KINTZEL, Department of Physics and Astronomy, Western Kentucky University, DETLEF SMILGIES, Cornell High Energy Synchrotron Source (CHESS), Cornell University — Thin film growth of simple aromatic molecules has been researched intensely in recent years in the burgeoning field of organic electronics. Film growth for simple rodlike molecules on the atomically well-defined and nonreactive alkali halide (001) surfaces also constitutes an archetypical model system for the study of molecular epitaxy. We have observed a surprising variety of preferential orientations of para-sexiphenyl platelets on a series of alkali halide surfaces with lattice constants ranging from 4.6 to 6.6 Angstroms. We present a metric that helps to classify the dominant epitaxial orientations and allows us to predict epitaxial orientations on other rocksalt-type substrates, and we identified surface corrugation as the driving force for these preferred relative orientations.

12:51PM J10.00009 Pentacene thin films on vicinal Ag(111) surfaces[1] , FATIH DANISMAN, Middle East Technical University, ILKER DEMIROGLU, ERSEN METE, SINASI ELLIALTIOGLU — Here we present a structural study of pentacene thin films on different vicinal Ag(111) surfaces by helium atom diffraction measurements and density functional theory (DFT) calculations. Our helium atom diffraction results suggest a step flow growth mechanism evidenced by initial slow specular reflection intensity decay rate as a function of pentacene deposition time. This is in agreement with our previous helium diffraction results on flat Ag(111) surfaces with a small miscut angle. In parallel with the experimental findings, our DFT calculations predict the step edges as the most stable adsorption site on the surface. Isolated pentacene molecules adsorb on the step edges in a tilted configuration with a binding energy of 0.615 eV. In addition a complete monolayer with tilted pentacene on the step edges is found to be more stable than one with all lying flat molecules. Hence our results suggest, in agreement with prvious predictions, that step edges can trap the pentacene molecules and act as nucleation sites for the growth of ordered thin films with a crystal structure similar to that of bulk pentacene.

1:03PM J10.00010 Scaled Shell-like Pattern Formation of Selenium-Based Anthracene Derivatives at a Metal Surface , LUDWIG BARTELS, UCR, ZHIHAI CHENG, JONATHAN WYRICK, DEZHENG SUN, DAEHO KIM, YEMING ZHU, MIAOMIAO LUO, ROBERT CARP, MICHAEL MARSELLA — We investigated the behavior of selenium-substituted anthracene molecules at a Cu(111) surface. In our previous work, the sulfur and oxygen counterparts of this molecule exhibited controlled diffusion on Cu(111) violating the substrate's symmetry. In contrast Diseleno-ateanthracene shows an isotropic and very high mobility suggesting very non-local substrate interactions. However, we observe pronounced sensitivity of the diffusion to the oscillation of the Cu(111) substrate surface state. In this talk, we will focus on the coverage-dependent pattern formation of this species: at coverages close to 1 ML, two kinds of hexagonal patterns with large unit cells are formed. Both of them show a shell superstructure with an identical central empty hole. The smaller of the features one molecular shell of 6 molecules the larger a double shells of 6 and 12 molecules. Another kind of rectangular pattern is also observed, which could be an intermediate superstructure between the small and large hexagonal patterns. We will compare these patterns to prior work on sulfur and oxygen based molecules.

1:15PM J10.00011 Stable Carbon Nanoarches in the Nucleation of Graphene on Cu(111)[1] , ROBERT VAN WESEP, HUA CHEN, WENGUANG ZHU, Phys Dept, U of Tennessee; Materials Science & Engineering Division, ORNL, ZHENYU ZHANG, Phys Dept, U of Tennessee; Materials Science & Engineering Division, ORNL; ICQD, USTC — To fully exploit the device potential of graphene, reliable production of large-area, high-quality samples is required. Epitaxial growth on transition metal surfaces have shown promise in this regard, but further improvement would be facilitated by a more complete understanding of the nanoscale processes involved. Using density functional theory calculations, we have investigated the energetics and kinetics of graphene nucleation and growth on a Cu(111) surface. Our calculations have revealed an energetic preference for the formation of stable 1D carbon nanoarches consisting of 3-13 atoms when compared to 2D compact islands. Our findings may provide the structural link between nucleated carbon dimers [1] and larger carbon nanodomes [2], and may also explain some recent experimental observations. We will also present results on estimating the critical cluster size that marks the transition from nanoarch dominance to island dominance in the growth sequence.

1:27PM J10.00012 An *Ab Initio* Study of Bulk γ-U and the (100) Surface[1] , DAYLA MORRISON, ASOK RAY, University of Texas at Arlington — The properties of bcc γ-U have been studied using the formalisms of the generalized gradient approximation to density functional theory (GGA-DFT) and hybrid density functional theory. The computational formalism is the full potential linearized augmented plane wave method as implemented in the suite of software WIEN2k. Computations have been performed both without and with spin orbit coupling (SOC). Results indicate that GGA-DFT with SOC performs comparatively better in the description of the properties of γ-U, such as the non-magnetic ground state, lattice constant, and the bulk modulus. The predicted lattice constant and bulk modulus are 3.463 A and 114 GPa, respectively, to be compared with the experimental values of 3.467 A and 113 GPa, respectively. For the (100) surface, the monolayer exhibited significant contraction but the lattice constants tend to converge after 5 layers. Based on the results of the five layers, we predict the surface energy and the work function to be 1.46 J/m^2 and 3.24eV, respectively.

1:39PM J10.00013 Electronic Structures of Hydrogen and Oxygen Adsorbed Tungsten (3, 2, 0) and Tungsten (8, 7, 0) Surfaces[1] , ZHUO BAO, Physics Department, University of Oregon, AARON BOSTWICK, ELI ROTENBERG, Advanced Light Source, LBNL, STEPHEN KEVAN, Physics Department, University of Oregon — The Valence band electronic structues of Hydrogen adsorbed and Oxygen adsorbed Tungsten stepped surfaces, Tungsten (3, 2, 0) and (8, 7, 0) surface are investigated using angular-resolved photoemission techniques and ab-initio electronic structure calculation methods. The band features of surface states at different Hydrogen and Oxygen coverages are experimentally distinguished by using photon-energy scanning method. Quasi-one- dimensional band features are found in the surface states with saturated Oxygen coverages of both stepped surfaces. The effects of adsorbate coverages on dimensionalities of surface electronic states are studied using high-resolution band mapping methods and ab-initio calculation methods.

1:51PM J10.00014 The suppression surface state near a monostep of Au(111) surface studied by low temperature scanning tunneling microscopy[1] , QING LI, PETER MAKSYMOVYCH, SERGI KALININ, MINGHU PAN, Center for Nanophase Materials Scieces, Oak Ridge National Laboratory — The dynamics of electronic states on metal surfaces is a fundamental probe of electron transport and electronic interactions with practical relevance for nanodevices and reactions. In our study, series of scanning tunneling spectroscopy near a monostep of Au(111) surface are used to investigate the behavior of surface state. We found that the Shockley surface state of Au (111) was suppressed near the step. By carefully analyzing each dI/dV spectroscopy, we determined the lateral tip-step distance dependence of the lifetime of the surface electrons. The lifetime broadening of surface state shows linear decay close to the monostep, possibly due to the electron-electron interactions.

[1]This research was conducted at the Center for Nanophase Materials Sciences, which is sponsored at Oak Ridge National Laboratory by the Division of Scientific User Facilities, U.S. Department of Energy.

2:03PM J10.00015 Low Energy Hot Electron Scattering in Nanometer Scale Metal Films Using Ballistic Electron Emission Microscopy , JOHN GARRAMONE, JOSEPH ABEL, VINCENT LABELLA, College of Nanoscale Science and Engineering, University at Albany, SUNY, Albany, New York 12203, USA — Inelastic and elastic scattering lengths of hot electrons have been measured at low energies (<2 eV) in nanometer thick silver films utilizing ballistic electron emission microscopy (BEEM). BEEM is a scanning tunneling microscopy (STM) based technique that is capable of injecting electrons a few eV above the Fermi level and utilizes a third collector contact on the semiconductor of a Schottky diode[1]. Electrons tunnel from the STM tip into the metal base layer and a small fraction of these electrons travel ballistically to the metal/semiconductor interface. Electrons with energy greater than the Schottky barrier height (SBH) are collected as BEEM current. The silver attenuation length is extracted by measuring the BEEM current as a function of the Ag overlayer thickness over a series of samples for both electron and hole injection. The relative contribution of inelastic and elastic scattering is extracted by modeling the change in attenuation length with respect to the tip bias. A drastic increase in the attenuation length is observed as energies approach the SBH, which we attribute to the ballistic nature of the electrons and holes that are collected at these energies.

Session J11 FIAP: Fractional Quantum Hall Effect I D222

11:15AM J11.00001 The Real-Space Entanglement Spectra of Fractional Quantum Hall States , A. CHANDRAN, Princeton University, PARSA BONDERSON, Microsoft Research, Station Q, NICOLAS REGNAULT, Laboratoire Pierre Aigrain, ENS and CNRS, ANDREI BERNEVIG, Princeton University — We investigate the entanglement spectra arising from a sharp real-space cut on the topologically ordered fractional quantum hall (FQH) ground states. We find that the counting of the real-space entanglement spectra (the number of edge excitations of the liquid) is identical to the number of bulk quasihole excitations, in accordance with the bulk-boundary correspondence. The spectra of cuts with two edges display the shape and counting of counter-propagating non-interacting modes as well. Initial estimates of the topological entanglement entropy seem to be in agreement with theory. The real-space entanglement spectra also allows us to distinguish between particle-hole conjugate states, providing us with a new probe to interacting edge modes.

11:27AM J11.00002 Identification of 331 quantum Hall states with Mach-Zehnder interferometry[1] , CHENJIE WANG, D.E. FELDMAN, Physics Department, Brown University — It has been shown recently that non-Abelian states and the spin-polarized and unpolarized versions of the Abelian 331 state may have identical signatures in Fabry-Pérot interferometry in the quantum Hall effect at filling factor 5/2. We calculate the Fano factor for the shot noise in a Mach-Zehnder interferometer in the 331 states and demonstrate that it differs from the Fano factor in the proposed non-Abelian states. The Fano factor depends periodically on the magnetic flux through the interferometer. Its maximal value is $2 \times 1.4e$ for the 331 states with a symmetry between two flavors of quasiparticles. In the absence of such symmetry the Fano factor can reach $2 \times 2.3e$. On the other hand, for the Pfaffian and anti-Pfaffian states the maximal Fano factor is $2 \times 3.2e$. The period of the flux dependence of the Fano factor is one flux quantum. If only quasiparticles of one flavor can tunnel through the interferometer then the period drops to one half of the flux quantum. We also discuss transport signatures of a general Halperin state with the filling factor $2 + k/(k + 2)$.

11:39AM J11.00003 Bulk excitonic currents in a bilayer quantum Hall system and Andreev reflection , A.D.K. FINCK, J.P. EISENSTEIN, California Institute of Technology, L.N. PFEIFFER, K.W. WEST, Princeton University — Bilayer 2D electron systems in the quantum Hall regime can support a novel interlayer coherent phase which may be viewed as a Bose condensate of interlayer excitons. While numerous experiments over the past decade have revealed a host of remarkable properties of this strongly correlated quantum fluid, heretofore none have directly demonstrated the transport of excitons across the electrically insulating bulk of the system. We report here just such an observation. Our experimental results show that excitons may be launched into the bulk of the 2D system via a process analogous to Andreev reflection. Excitons are emitted into the bulk of the bilayer when electrons are injected into one 2D layer and withdrawn from the other along a common edge of the system. Similarly, we demonstrate that excitons arriving at the edge of the Hall droplet can drive current through external circuitry connected to contacts along that edge.

11:51AM J11.00004 Phase diagram of the even-denominator fractional quantum Hall state at $\nu = 1/2$ in wide quantum wells , JAVAD SHABANI, MANSOUR SHAYEGAN, Princeton University — We have studied the fractional quantum Hall (FQH) effect in very high quality two dimensional electrons confined to GaAs single wide quantum wells. In these systems typically two electric subbands are occupied at zero magnetic field and the electron charge distribution in the quantum well is bilayer-like. For a symmetric charge distribution and appropriate electron density, a unique even-denominator FQH state emerges at filling factor $\nu = 1/2$ which has no counter-part in standard, single-layer systems [1]. We have revisited this problem by studying wide quantum well samples with narrower well widths, $47 \leq w \leq 64$ nm, and hence larger tunneling, Δ (up to 35 K). The new $\nu = 1/2$ data in these narrower samples allow us to expand the d/l_B vs. $\Delta/(e^2/4\pi\epsilon l_B)$ phase diagram for the stability of the $\nu = 1/2$ FQH state (d is the layer distance and l_B is the magnetic length). Based on this phase diagram, we find that, it is not clear whether this state has a Pfaffian or a two-component Halperin origin.

12:03PM J11.00005 When is the fractional quantum Hall effect stable[1] , YANG LIU, JAVAD SHABANI, MANSOUR SHAYEGAN, Dept. of Electrical Engineering, Princeton University — The fractional quantum Hall (FQH) effect, signaled by the vanishing of the longitudinal resistance and the quantization of the Hall resistance, is the hallmark of interacting two-dimensional electrons in a large perpendicular magnetic field. The effect is most prominently observed at low Landau level (LL) filling factors (ν) and is conspicuously absent for $\nu > 4$. We examine the stability of the FQH states at high fillings in a 2D electron system in a wide GaAs quantum well which we can tune the Fermi energy (E_F) to lie, at a given filling factor, in different LLs of two electric subbands. The data provide direct and definitive evidence that the stability of the FQH states is linked to the LL where E_F resides. We observe FQH states at high filling factors such as 13/3, 14/3, 16/3, and 17/3, but only when E_F lies in the ground state ($N = 0$) orbital LLs of either of the two electric subbands, regardless of the underlying, fully occupied levels.

[1]We acknowledge support through the NSF (DMR-0904117 and MRSEC DMR-0819860) for sample fabrication and characterization, and the DOE BES (DE-FG0200-ER45841) for measurements.

12:15PM J11.00006 Evolution of odd-denominator fractional quantum Hall states in a two-subband system[1] , MANSOUR SHAYEGAN, JAVAD SHABANI, YANG LIU, Princeton University — Our magneto-transport measurements reveal that the sequence of fractional quantum Hall (FQH) states observed in two-subband, wide GaAs quantum wells at high fillings ($\nu > 2$) are very different from those of a single-subband system. When the Fermi level lies in the lowest Landau level of either of the two subbands the odd-denominator FQH states following the usual, composite fermion filling sequences are observed. These include states at $\nu = 7/3$, 8/3, 12/5, 13/5, 10/3, 11/3, 17/5, 18/5, and 25/7. The evolution of these states with changing the Zeeman and subband energies is consistent with coincidences of composite fermion Landau levels.

[1]We acknowledge support through the NSF (DMR-0904117 and MRSEC DMR-0819860) for sample fabrication and characterization, and the DOE BES (DE-FG02-00-ER45841) for measurements.

12:27PM J11.00007 Negative spin wave dispersion for composite fermions[1] , U. WURSTBAUER, Columbia Univ., D. MAJUMDER, S. MANDAL, Indian Association for the Cultivation of Science, I. DUJOVNE, A. RIGOSI, T.D. RHONE, Columbia Univ., B. DENNIS, Alcatel-Lucent, K. WEST, Princeton Univ., L. PFEIFFER, Princeton Univ, J. JAIN, Pennsylvania State Univ., A. PINCZUK, Columbia Univ. — The FQHE is a result of strongly interacting electrons that can be understood as QHE of composite fermions. We use inelastic light scattering experiments to study the collective excitations of CF with 2 flux quanta focusing on filling factors $\nu = 4/9$, 3/7 and 2/5. For these fillings, the lowest collective excitation modes are spin-waves, which display a distinct spectral weight below the bare Zeeman energy indicating a negative dispersion relation. The determined energies for these "spin-wave roton minima" are in excellent quantitative agreement with numerical calculations. Using the real experimentally transferred momentum the addressed DOS and hence inelastic light scattering spectra can be modeled. We demonstrate that the observed modes are very similar for positive and negative effective magnetic field at the same CF-filling factor.

[1]Supported by NSF and AvH.

12:39PM J11.00008 Subband Engineering Even-Denominator Quantum Hall States , VITO SCAROLA, Virginia Tech, CHRISTIAN MAY, ETH Zurich, MICHAEL PETERSON, University of California, Santa Barbara, MATTHIAS TROYER, ETH Zurich — Proposed even-denominator fractional quantum Hall effect (FQHE) states suggest the possibility of excitations with non-Abelian braid statistics. Recent experiments on wide square quantum wells observe even-denominator FQHE even under electrostatic tilt. We theoretically analyze these structures and develop a procedure to accurately test proposed quantum Hall wavefunctions. We find that tilted wells favor partial subband polarization to yield Abelian even-denominator states. Our results show that tilting quantum wells effectively engineers different interaction potentials allowing exploration of a wide variety of even-denominator states.

12:51PM J11.00009 Quasiparticle tunneling amplitute in fractional quantum Hall states[1] , ZIXIANG HU, Princeton university, KIHOON LEE, APCTP, Korea, EDWARD H. REZAYI, California State Univ, Los Angeles, XIN WAN, APCTP, Korea & ZheJiang University, China, KUN YANG, NHMFL & Florida State University — We study qp tunneling in the MR state, in which qp of charge e/4 and e/2 may co-exist and both contribute to edge transport. The tunneling amplitude for charge e/2 qp is exponentially smaller than that for e/4 qh, and the ratio between them can be (partially) attributed to their charge difference. The tunneling amplitude shows some scaling behavior which originates from the propagation and tunneling of charged qhs in an effective field analysis. In the ring limit, we conjecture the exact functional form for several cases. The results for Abelian qp tunneling is consistent with the scaling anaysis; this allows for the extraction of conformal dimensions of the qps. We analyze the scaling behavior of both Abelian and non-Abelian qps in the Z_k parafermion states. Interestingly, the non-Abelian qp tunneling amplitudes exhibit nontrivial k-dependent corrections to the scaling exponent.

1:03PM J11.00010 Extracting Excitations From Model State Entanglement , NICOLAS REGNAULT, ANTOINE STERDYNIAK, Ecole Normale Superieure, CNRS, ANDREI BERNEVIG, Princeton University — We extend the concept of entanglement spectrum from the geometrical to the particle bipartite partition. We apply this to several Fractional Quantum Hall wavefunctions on both sphere and torus geometries to show that this new type of entanglement spectra completely reveals the physics of bulk quasihole excita tions. While this is easily understood when a local Hamiltonian for the model state exists, we show that the quasiholes wavefunctions are encoded within the model state even when such a Hamiltonian is not known. As a nontrivial example, we look at Jain's composite fermion states and obtain their quasiholes directly from the model state wavefunction. We reach similar conclusions for wavefunctions described by Jack polynomials.

1:15PM J11.00011 Neutral mode heat transport and fractional quantum Hall shot noise , SO TAKEI, University of Maryland College Park, BERND ROSENOW, University of Leipzig — We study nonequilibrium edge state transport in the fractional quantum Hall (FQH) regime for states with a counter-propagation neutral mode. Focusing on the filling fraction of 2/3, we consider a setup in which the neutral mode is heated by a hot spot, and where heat transported by the neutral mode causes a temperature difference between the upper and lower edges in a Hall bar. This temperature difference is probed by the excess noise it causes for scattering across a quantum point contact (QPC). We find that the excess noise in the QPC provides evidence for counter-propagating neutral modes, and we calculate its dependence on both the temperature difference between the edges and on source drain bias. We generalize our results to the non-abelian Moore-Read quantum Hall state at filling fraction 5/2.

1:27PM J11.00012 Anisotropic quantum Hall liquids - a small system Monte Carlo study[1] , ORION CIFTJA, BRITTNEY CORNELIUS, KESHA BROWN, EMERY TAYLOR, Department of Physics, Prairie View A&M University, Prairie View, Texas 77446, USA — While no fractional quantum Hall effect states were expected to stabilize in the second excited Landau level, the discovery of extreme magneto-transport anisotropy around filling factor 9/2 was found quite surprising. A unidirectional charge density wave is a plausible candidate for the anisotropic states as indicated by the earlier theoretical work. An alternative approach that would be consistent with observed experimental facts would view the onset of anisotropy as signature of a phase transition from an isotropic to an anisotropic liquid crystalline phase. In this work we present a small-system Monte Carlo study for anisotropic quantum Hall liquid states observed at filling factor 9/2. The anisotropic electronic liquid phases are described by a broken rotational symmetry wave function and electrons interact with Landau level-projected interaction potentials. Our small-system Monte Carlo study indicates that such an anisotropic liquid crystalline quantum Hall phase with broken rotational symmetry is energetically favored relative to an isotropic liquid one.

1:39PM J11.00013 Chiral Abelian anyons from interacting non-Abelian vortices , VILLE LAHTINEN, NORDITA, JIANNIS PACHOS, University of Leeds — We demonstrate the existence of a new topologically ordered phase in Kitaev's honeycomb lattice model. This new phase appears due to the presence of a tightly packed vortex lattice and it supports chiral Abelian anyons. We characterize the phase by its low-energy behavior that is described by four Fermi points as opposed to two Fermi points in the absence of the vortex lattice. This doubling is shown to be related to an emergent vortex lattice symmetry that arises due to interactions between the anyonic vortices. By mapping the Hamiltonian of the model to a BCS one, we show that the chiral Abelian phase can be understood as two coupled p-wave superconductors, one living on the original honeycomb lattice and the other on the dual lattice that coincides with the vortex lattice. Finally, we identify two physically distinct types of topological phase transitions in the model and show that the Fermi surface evolution associated with them is described by Dirac fermions coupling to chiral gauge fields. The study of the Fermi point transport across the Brillouin zone enables us to obtain analytic results on the extended phase space.

1:51PM J11.00014 The Weakly Coupled Pfaffian as a Type I Quantum Hall Liquid[1] , S.A. PARAMESWARAN, Princeton University, S.A. KIVELSON, Stanford University, S.L. SONDHI, Princeton University, B.Z. SPIVAK, University of Washington — The Pfaffian phase of electrons in the proximity of a half-filled Landau level is understood to be a $p + ip$ superconductor of composite fermions. We consider the properties of this paired quantum Hall phase when the pairing scale is small, *i.e.* in the weak-coupling, BCS, limit, where the coherence length is much larger than the charge screening length. We find that, as in a Type I superconductor, the vortices attract so that, upon varying the magnetic field from its magic value at $\nu = 5/2$, the system exhibits Coulomb frustrated phase separation. We propose that the weakly and strongly coupled Pfaffian states exemplify a general dichotomy between Type I and Type II quantum Hall fluids.

11:15AM J12.00001 Surface origin of the LO phonon feature in the Raman spectrum of InN , ESTHER ALARCON-LLADO, NATE MILLER, MARIE MAYER, JOEL W. AGER — Wurtzite InN presents an intrinsic Fermi level pinning above the conduction band edge at the surface. For this reason, a large surface electron accumulation (SEA) occurs in InN. The interaction between the free electrons at the surface and the longitudinal optical (LO) phonon has been addressed by previous studies, but questions still remain. Here, we use the insulating nature of the Helmholtz layer that forms on a surface of an object in contact with an an aqueous electrolyte to apply potentials to n-type (undoped) and p-type (Mg-doped) InN. Applying a potential to the electrolyte changes the electric field and distribution of free carriers near the surface. This enables us to perform electrolyte gated Raman spectroscopy on differently doped InN layers and while simultaneously modulating and probing the SEA region in InN. We find that the intensity of the forbidden LO Raman feature is changed by the external potential, showing that this feature is due, at least in part, to the SEA. This is the first experimental evidence of the relation between the LO feature in InN and free electron accumulation at its surface.

11:27AM J12.00002 Hydrogen incorporation in high hole density GaN:Mg[1] , M.E. ZVANUT, Y. UPRETY, J. DASHDORJ, University of Alabama at Birmingham, M. MOSELEY, W. ALAN DOOLITTLE, Georgia Institutute of Technology — We investigate hydrogen passivation in heavily doped p-type GaN using electron paramagnetic resonance (EPR) spectroscopy. Samples include both conventionally grown GaN (10^{19} cm^{-3} Mg, 10^{17} cm^{-3} holes) and films grown by metal modulation epitaxy (MME), which yielded higher Mg (1-4x10^{20} cm^{-3}) and hole (1-40x10^{18} cm^{-3}) densities than found in conventionally grown GaN. The Mg acceptor signal is monitored throughout 30 minute annealing steps in N_2:H_2 (92%:7%)) and subsequently pure N_2. N_2:H_2 heat treatments of the lower hole density films begin to reduce the Mg EPR intensity at 750 ^oC, but quench the signal in high hole density films at 600 ^oC. Revival of the signal by subsequent N_2 annealing occurs at 800 ^oC for the low hole density material and 600 ^oC in MME GaN. The present work highlights chemical differences between heavily Mg doped and lower doped films; however, it is unclear whether the difference is due to changes in hydrogen-Mg complex formation or hydrogen diffusion.

11:39AM J12.00003 Enhancing erbium emission by strain engineering in GaN heteroepitaxial layers , I-WEN FENG, JING LI, ASHOK SEDHAIN, JINGYU LIN, HONGXING JIANG, Texas Tech University, JOHN ZAVADA, North Carolina State University — Rare earth doped III-nitrides have been intensively studied due to their intra-4f transitions covering the window from visible emissions to infrared wavelengths. Trivalent Erbium (Er^{3+}) has driven particular interests since the intra-4f transition from its first excited ($^4I_{13/2}$) to the ground state ($^4I_{15/2}$) gives 1.54 μm emission, which sits in the low optical loss band of silica fibers and potentially affords light emitters and optical amplifiers at optical communication wavelength. Due to the structural and thermal stability of GaN, GaN appears to be the promising candidate as the host semiconductors. We prepared Er doped GaN (GaN:Er) samples by metal organic chemical vapor deposition. GaN:Er epilayers were simultaneously grown on different templates, including GaN/Al_2O_3, AlN/Al_2O_3, GaN/Si(111), and c-GaN bulk. The effects of stress, caused by the lattice mismatch between GaN:Er epilayers and the substrates, on the intensity of 1.54 μm emission were probed. The emission intensity at 1.54 μm increased with greater tensile stress in the c-direction of GaN:Er epilayers. The correlation between stress and 1.54 μm emission will be presented. The results implied the potential to design efficient photonic devices based on GaN:Er semiconductors.

11:51AM J12.00004 Effect of electrostatic image charge effect on the photoluminescence in Gallium droplet coated AlGaAs-GaAs Single Quantum Wells , KAROL GRYCZYNSKI, University of North Texas, JIE LIN, TONY LLOPIS, ZHIMING WANG, G. SALAMO, ARKADII KROKHIN, ARUP NEOGI, UNIVERSITY OF ARKANSAS COLLABORATION, KWANGWOON UNIVERSITY, KOREA COLLABORATION — Gallium (Ga) droplets deposited on the cap layers of AlGaAs-GaAs single quantum wells (QWs) lead to a large blue shift in the observed photoluminescence of quantum wells compared to identical single wells without Ga droplets. Furthermore the intensity of the blue shifted emission peaks is enhanced with respect to the reference QWs. As the emission energies for all depths of QWs used (1.5nm to 10nm) exceed the plasmon resonance energy of the deposited Ga droplets, surface Plasmon polariton interactions cannot account for an increase in exciton recombination energy of about 20meV it is concluded that the blue shift and enhancement from the Ga droplets is not plasmonic in nature. The observed phenomena are described and modeled by applying an additional electrostatic potential to the confined excitons within the QW. An electrostatic attraction between the confined exciton and inhomogeneous nanoscale metal surfaces exert forces on the carriers both parallel and perpendicular to the surface of the well.

12:03PM J12.00005 Polarization induced doping in graded AlGaN films , MORGAN WARE, SHIBIN LI, VASYL KUNETS, MICHAEL HAWKRIDGE, PAUL MINOR, JIANG WU, GREGORY SALAMO, Arkansas Institute for Nanoscale Materials Science and Engineering, University of Arkansas — The fixed polarization field which is intrinsic to nitride based III-V semiconductors in the wurtzite crystal phase can be manipulated during growth by varying the alloy composition. We report on initial experiments to use the space charge field which results from changing the internal polarization field of graded AlGaN films in a simple p-n junction device. Our devices are fabricated from films which are graded from GaN to AlGaN then reverse graded back to GaN without the intentional addition of impurity dopants. Structural characterization of the films is reported through X-Ray diffraction rocking curves and reciprocal space maps, and the rectifying behavior of the device is demonstrated through temperature dependent I-V measurements.

12:15PM J12.00006 Electroluminescence from $n-n$ isotype heterojunctions of graded-band-gap ZnMgO:Al and ZnO films[1] , JONG-GUL YOON, SUNG WOO CHO, University of Suwon, WOO SEOK CHOI, ReCFI, Seoul National University, DAE YEOL KIM, University of Suwon, JOONHEE LEE, Seoul National University, CHANG OH KIM, Kyung Hee University, HOJOON CHANG, HEONSU JEON, Seoul National University, SUK-HO CHOI, Kyung Hee University, TAE WON NOH, ReCFI, Seoul National University — We report room temperature electroluminescence (EL) from $n-n$ isotype heterojunction composed of Al-doped graded-band-gap $Zn_{1-x}Mg_xO$ (g-ZnMgO:Al) and ZnO films fabricated on Pt/Ti/SiO_2/Si substrates. The graded-band-gap of g-ZnMgO:Al film was investigated by spectroscopic ellipsometry and found to change contiuously from 3.22 to 3.56 eV. The EL emission spectra covered visible and near infrared regions under unipolar operation condition, with g-ZnMgO:Al as positive, at the operation voltages as low as 3-5 V. Impact ionization/excitation process in a narrow region of the graded layer was suggested as a possible origin of the EL. We discussed multistep excitation process mediated by defect-related deep levels and the effect of quasi-electric field in the graded-band-gap layer in conjunction with the apparent upconversion EL in the heterojuncition device.

12:27PM J12.00007 Efficiency Droop in III-nitride LEDs: a differential carrier lifetime analysis , AURELIEN DAVID, Soraa Inc — GaN-based LEDs suffer from a phenomenon known as efficiency droop, which causes a (non- thermal) roll-over of the IQE at high current density, and whose underlying physical origin is not well understood. Identifying the correct process is of importance, as it dictates which strategies can be employed to quench or mitigate droop. Among the most often cited hypotheses are: localization effects related to InGaN alloy fluctuations, leakage effects, and Auger scattering. In this contribution, we will present recent experimental results which aim at testing these scenarios. We will first show why droop appears to be a bulk-like phenomenon, rather than transport-related. We will present PL measurements to illustrate how droop scales with carrier density, and biased-PL measurements which quantify the magnitude of the leakage current. In a second part, we will present differential carrier lifetime measurements, which aim at characterizing the various recombination processes in InGaN heterostructures. We will review recently published results, which show that droop is caused by the onset of a high-order non-radiative process, and confirm that lifetimes are quantitatively compatible with the hypothesis of Auger scattering. Finally, we will present new lifetime measurements on QW samples with various In contents, and discuss how the variations in droop can be explained by the impact of piezoelectric fields on the carrier lifetime.

1:03PM J12.00008 MOCVD Growths of Linearly-Shaped Staggered InGaN Quantum Wells Light-Emitting Diodes , HONGPING ZHAO, JING ZHANG, TAKAHIRO TOMA, GUANGYU LIU, JONATHAN POPLAWSKY, VOLKMAR DIEROLF, NELSON TANSU, Lehigh University — High-efficiency InGaN-based quantum wells (QWs) light-emitting diodes (LEDs) play an important role in solid state lighting. However, the existence of both spontaneous and piezoelectric polarization fields in III-Nitride semiconductors leads to severe charge separation in InGaN QWs, which significantly reduces the electron-hole wavefucntion overlap (Γ_{e_hh}) in InGaN QWs. In this work, the growths of linearly-shaped (LS) staggered InGaN QWs LEDs are investigated. The InGaN QWs with LS staggered In-content profile were grown by metalorganic chemical vapor deposition (MOCVD). The use of LS staggered In-contents in InGaN QWs results in improved electron-hole wavefunction overlap (Γ_{e_hh}), in comparison to that of conventional InGaN QW. The power dependent cathodoluminescence (CL) measurement shows 2.5-3.5 times enhancement of CL intensity for LS staggered InGaN QWs as compared to that of the conventional InGaN QWs. Theoretical calculations using self-consistent 6-band **k.p** method were performed for both LS staggered InGaN QWs and conventional InGaN QWs. The experimental measurements show good agreement with the theoretical simulation.

1:15PM J12.00009 Indirect Auger recombination in nitride light emitters , EMMANOUIL KIOUPAKIS, PATRICK RINKE, KRIS T. DELANEY, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara, CA 93106, USA — Nitride-based light emitters suffer from an efficiency loss at high drive currents (droop), which limits their high-power performance. The origin of this efficiency droop is not fully understood, and several loss mechanisms have been suggested as its cause. One such mechanism is Auger recombination, a three-carrier non-radiative recombination process that dominates over the radiative one at high carrier densities. We have employed first-principles computational techniques to show that Auger recombination is strong in nitride materials and therefore a likely cause of the droop in nitride LEDs. The underlying microscopic Auger recombination processes occur in an indirect way, mediated by electron-phonon and alloy scattering. Our work elucidates the origin of the droop and suggests ways to improve the high-power efficiency of nitride LEDs. This work was supported by the Center for Energy Efficient Materials, an Energy Frontier Research Center funded by the U.S. DOE, by the UCSB Solid State Lighting and Energy Center, and by the NSF MRSEC Program.

1:27PM J12.00010 Micro- and Nanostructural Properties of Wide Bandgap Semiconductors , NABIL DAWAHRE, GANG SHEN, SHAWN DAVID WILBERT, NICK HARRIS, WILLIAM BAUGHMAN, LEE BUTLER, JOSEPH BREWER, SEONGSIN MARGARET KIM, PATRICK KUNG, The University of Alabama — Wide bandgap semiconductor materials based on ZnO and GaN have attracted considerable attention in recent years because of the practical applications such as green and blue light emitting and laser diodes, solid-state lighting, photovoltaics, RF and microwave electronics, and gas sensors. However, the resulting device performance strongly depends on the quality, both compositionally and structurally, of the constituent materials. Here we report the combined use of high resolution transmission electron microscopy imaging, micro-Raman and micro-photoluminescence spectroscopy, and local electrode atom probe tomography to understand the micro- and nanostructural properties of materials synthesized by chemical vapor deposition, including defects and impurities. Growth and doping process, sample preparation, and analysis results will be discussed.

1:39PM J12.00011 Auger Recombination in Defect-Free III-Nitride Nanowires[1] , MENG ZHANG, WEI GUO, PALLAB BHATTACHARYA, JUNSEOK HEO, ANIMESH BANERJEE, University of Michigan — Defect free InGaN nanowires (NWs) and InGaN/GaN dot-in-nanowires (DNWs) were grown on (001) Si by plasma assisted molecular beam epitaxy. The nanowires have a density of $\sim$ 1x10^{11}cm^{-2} and exhibit photoluminescence emission peak at λ $\sim$500 nm. The Auger recombination coefficients of these nanowires are determined by excitation power dependent photoluminescence and time-resolved photoluminescence techniques. The measured Auger coefficients are 6.1x10^{-32} cm^6·s^{-1} and 4.1x10^{-33} cm^6·s^{-1}, in the NW and DNW samples, respectively, which are nearly two orders of magnitude lower than those measured in InGaN/GaN quantum wells and agree very well with theoretical calculations. This suggests that the abnormally high Auger coefficients measured in traditional wide bandgap nitride materials is related to the high density of dislocations. InGaN NW and InGaN/GaN DNW light emitting diodes are demonstrated. The external quantum efficiency does not decrease up to an injection current density of 400A/cm^2.

1:51PM J12.00012 Effects of oxygen annealing treatment on formation of ohmic contacts to n-GaN[1] , WENTING HOU, THEERADETCH DETCHPROHM, CHRISTIAN WETZEL, Rensselaer Polytechnic Institute — Low-resistance ohmic contacts are essential for the fabrication of efficient light emitting diodes (LEDs). A commonly used ohmic contact to n-type GaN is a layer sequence of Ti/Al/Ti/Au, followed by rapid thermal annealing (RTA) in nitrogen ambient at a high temperature. We present an ohmic contact on n-GaN by a surface treatment process of rapid thermal annealing (RTA) in oxygen ambient before the n-metal deposition. As deposited n-contacts are not linear. After RTA in nitrogen ambient, ohmic contact are obtained. The annealed n-contact degrades during the p-metal anneal in oxygen ambient. However, if the sample is annealed in oxygen ambient prior to the metal deposition, the as-deposited n-contact on the treated surface is ohmic, similar to or even better than processes optimized for single-type contacts. This benefit was seen for both, mesa-etched and as-grown n-GaN epi layers. Contacts improvement is also found on unintentionally doped GaN (u-GaN). Oxygen ambient is crucial in the treatment and RTA in nitrogen ambient fail to give ohmic contacts. XPS analysis of the surface shall give us more information on the mechanism of the treatment.

2:03PM J12.00013 Strong non-plasmonic mechanism of light emission from semiconductor quantum well , ARKADII KROKHIN, ANTONY LLOPIS, ARUP NEOGI, University of North Texas, SERGIO PEREIRA, Universidade de Aveiro, Portugal, IAN WATSON, University of Strathclyde, UK — We report a new mechanism of enhancement of light emission from InGaN/GaN quantum wells (QW). This mechanism is due to electrostatic attraction of the carriers to gold nanoparticles (NP) imbedded within a QW. Metal equally attracts electrons and holes, causing the carriers to concentrate near its surface. Since the probability of e-h recombination is proportional to carrier densities, the QW with NPs generates a stronger emission than the same QW without the NP. We observed roughly a 60% (80%) enhancement with NPs at room temperature (77K). In these nitride heterostructures, dislocations result in hexagonal pits at the surface. Gold NPs were incorporated inside the pits with no effect on the quality. The same nitride material system used to demonstrate *plasmonic* enhancement [1]. It has been shown that gold film *do not* enhance the emission because of mismatch of surface plasmon energy and the emission energy of the QW. Here we observe the enhancement caused by electrostatic mechanism that does not require energy matching. This mechanism provides another means for enhancing the efficiency of solid- state emitters. This work is supported by the DOE grant # DE-FG02-06ER46312.

Session J13 GSNP: Focus Session: Jamming Theory and Experiment II D225/226

11:15AM J13.00001 Jammed particulate systems are inherently nonharmonic[1] , MARK D. SHATTUCK, Levich Institute and Physics department, The City College of New York — Normal mode analysis in the harmonic approximation underlies most of solid-state physics and applies well to both ordered and dis- ordered systems. Naturally, researches apply this analysis to jammed particulate systems, such as granular media, colloids, and foams, that interact via one-sided interactions, which are nonzero only when particles overlap. However, we find that systems with one-sided repulsive interactions possess no linear, harmonic response regime for large systems ($N \to \infty$) at finite pressures P, and for all N near jamming onset $P \to 0$. We perform simulations on 2D frictionless bidisperse mechanically stable disk packings over a range of packing fractions $\Delta\phi = \phi - \phi_J$ above jamming onset ϕ_J. We apply perturbations with amplitude δ to the packings along each eigen-direction from the dynamical matrix and determine whether the response of the system evolving at constant energy remains in the original eigenmode of the perturbation. For $\delta > \delta_c$, a single contact breaks and fluctuations abruptly spread to all discrete harmonic modes. As δ increases further all harmonic modes disappear into a continuous frequency band. We find that $\delta_c \sim \Delta\phi/N$, and thus jammed particulate systems are inherently nonharmonic with no linear vibrational response regime as $N \to \infty$ over the full range of $\Delta\phi$, and as $\Delta\phi \to 0$ at any N. This breakdown of harmonic behavior dramatically affects all aspects of system response including heat capacity, density of states, elastic moduli, and energy propagation.

11:51AM J13.00002 Vibrational density of states for granular solids , CARL SCHRECK, Yale University, THIBAULT BERTAND, Close École Normale Supérieure de Cachan, MARK SHATTUCK, City College of New York, COREY O'HERN, Yale University — It was recently shown that granular packings composed of frictionless particles with purely repulsive contact interactions are strongly anharmonic. When perturbed along an eigenmode of the static packing (in the harmonic approximation), energy leaks from the original mode of vibration to a continuum of frequencies even when the system is under significant compression due to the breaking of the weakest contact. In light of this, we perform numerical simulations to measure the displacement matrix averaged over fluctuations and the associated eigenspectrum of weakly vibrated frictionless packings, which possess well-defined equilibrium positions that are different than those of the nearest static packing. We find that there is an increase in the number of low-frequency eigenmodes of the displacement matrix in the harmonic approximation (over the number of low-frequency modes in the static case) and these modes provide a more accurate description of the system dynamics. We also investigate the extent to which these results hold for systems with continuous potentials with repulsive and attractive interactions.

12:03PM J13.00003 Spatiotemporally resolved granular acoustics , ELI OWENS, KAREN DANIELS, North Carolina State University — Acoustic techniques provide a non-invasive method of characterizing granular material properties; however, there are many challenges in formulating accurate models of sound propagation due to the inherently heterogeneous nature of granular materials. In order to quantify acoustic responses in space and time, we perform experiments in a photoelastic granular material in which the internal stress pattern (in the form of force chains) is visible. We utilize two complementary methods, high-speed imaging and piezoelectric transduction, to provide particle-scale measurements of the amplitude of the acoustic wave. We observe that the average wave amplitude is largest within particles experiencing the largest forces. The force-dependence of this amplitude is in qualitative agreement with a simple Hertzian-like model for contact area. In addition, we investigate the power spectrum of the propagating signal using the piezoelectric sensors. For a Gaussian wave packet input, we observe a broad spectrum of transmitted frequencies below the driving frequency, and we quantify the characteristic frequencies and corresponding length scales of our material as the system pressure is varied.

12:15PM J13.00004 Edge Effects in Jammed Systems , CARL GOODRICH, WOUTER ELLENBROEK, ANDREA LIU, University of Pennsylvania — Packings of spheres at zero temperature and shear stress exhibit a jamming/unjamming transition as a function of density. For spheres that repel when they overlap and do not otherwise interact, packings are jammed with a nonzero static shear modulus at high densities. As density decreases towards the unjamming transition, the number of interacting neighbors per particle, z, decreases towards a critical value z_c, so that at the unjamming transition the system just has the minimum number of interacting neighbors to be mechanically stable. In 2005, Wyart, et al. [1] proposed that there is a diverging length scale, l^*, associated with this transition, that can be understood from a "cutting argument." Thus, if one cuts a cluster of linear dimension L, the cluster will have zero-frequency vibrational modes (soft modes) only for $L < l^*$, where l^* scales as Δz^{-1}, where $\Delta z = z - z_c$. This cutting argument successfully describes the scaling of jammed systems. However, we find numerically that there are soft modes confined to the surface of the cut system, which should be present even in arbitrarily large cut systems. Naively, this would suggest that $l^* \to \infty$ at all packing fractions. Given this complication, we set out to generalize the cutting argument to understand its success in describing scaling properties near the jamming transition. [1] M. Wyart, S.R. Nagel, T.A. Witten, *Europhys. Lett.* **72**, 486 (2005).

12:27PM J13.00005 Dislocations jam at any density[1] , GEORGIOS TSEKENIS, NIGEL GOLDENFELD, KARIN DAHMEN, University of Illinois at Urbana-Champaign — Crystalline materials deform in an intermittent way via dislocation-slip avalanches. Below a critical stress, the dislocations are jammed due to long-range interactions and the material exhibits plastic response, while above this critical stress the dislocations are mobile (the unjammed phase) and the material fails. We use dislocation dynamics and scaling arguments to show that the critical stress grows with the square root of the dislocation density. Consequently, dislocations jam at any density, in contrast to granular materials, which only jam below a critical density.

[1]We acknowledge funding from NSF grand DMR 03-25939 ITR and computational resources by the University of Illinois and NSF TeraGrid resources by the Texas Advanced Computing Center and the National Center for Supercomputing Applications (RG-DMR090061).

12:39PM J13.00006 Jammed packings of bumpy spherical particles , DOMINIC KWOK, Department of Physics, K. VIJAY KUMAR, Department of Mechanical Engineering & Materials Science and Physics, CARL SCHRECK, Department of Physics, COREY O'HERN, Department of Mechanical Engineering & Materials Science and Physics, Yale University, New Haven, CT 06511, MARK SHATTUCK, Benjamin Levich Institute and Physics Department, The City College of the City University of New York, NY 10031 — Static packings of soft frictionless spheres are a simple model to understand the jamming transition in granular media, and have provided great insight. However, friction in granular media plays an important role in determining the structural and mechanical properties of jammed packings. In particular, the number and location of contacts near the Coulomb sliding threshold is strongly correlated with plastic rearrangements. To better understand friction, we numerically generate jammed packings of bumpy spherical particles as a function of the rms roughness of the particles without incorporating $ad\ hoc$ single contact frictional forces between particles, $i.e.$ frictional contacts in the Hertz-Mindlin (HM) model. The frictional interactions in the bumpy particle model emerge in a natural way via the interdigitation of bumps between contacting particles. We calculate the number of contacts, packing fraction, interparticle forces, eigenmodes of the dynamical matrix, and mechanical properties of jammed packings of bumpy particles and compare our results with those obtained using the HM model.

12:51PM J13.00007 Shock Waves in Jammed Solids , LEOPOLDO GOMEZ, Leiden University, ARI TURNER, UC Berkeley, MARTIN VAN HECKE, VINCENZO VITELLI, Leiden University — We study shock propagation in two-dimensional jammed packings of soft repulsive spheres with Herzian contacts. The critical amplitude above which acoustic waves propagate as shocks displays power law scaling with density and vanishes as the jamming point is approached. Thus close to jamming elastic energy is mainly propagated in the form of shock waves. We determine the characteristic speed and attenuation of the resulting shocks as a function of the amplitude of the initial impulse and applied load.

1:03PM J13.00008 Jamming: A Peek Behind the Curtain , MARTIN VAN HECKE, Leiden University — We will discuss two of the "dirty little secrets" concerning the (anomalous) scaling of the elastic moduli near jamming. First, there is no linear response near jamming, and we propose a novel scaling law for the onset of rearrangements as function of number of particles and distance to the jamming point. Second, the elastic moduli obtained from the dynamical matrix have a very broad distribution, and we discuss how to deal with packings with negative elastic moduli.

1:15PM J13.00009 Local anisotropy in globally isotropic granular packings , KAMRAN KARIMI, CRAIG MALONEY, Carnegie Mellon University — We study local stresses and elastic moduli defined at various coarse-graining scales, R, and volume fractions, ϕ, in a two dimensional (2D) mixture of frictionless granular particle packings. We measure the average deviatoric stress normalized by pressure, τ/p, and normalized anisotropic component of the shear modulus, $\delta\mu/\mu$, as a function of R. As the packings are prepared isotropically, both τ/p and $\delta\mu/\mu$ vanish at large R. However, in local regions, where single force chains dominate, the response can be quite anisotropic. We show that τ/p exhibits two power-law regimes in R with a cross-over that is only weakly dependent on ϕ. In contrast, $\delta\mu/\mu$, behaves like a pure power law up to $R \sim 640D$ (where D is the characteristic particle diameter) at all ϕ.

1:27PM J13.00010 Thermodynamic stability of dense packings of hard, regular tetrahedra , AMIR HAJI-AKBARI, MICHAEL ENGEL, SHARON C. GLOTZER, University of Michigan — The question of how densely regular tetrahedra can pack in three dimensions has attracted many researchers in recent years. In the first thermodynamic study of dense phases of the hard tetrahedron system, we recently reported the spontaneous formation of a dodecagonal quasicrystal [1]. The $(3.4.3^2.4)$ approximant of the quasicrystal, with an 82-particle unit cell, was compressed to a packing fraction of 85.03% [1]. Very shortly after, a much simpler crystal of tetrahedron dimers [2] with a slightly higher packing fraction of 85.63% was discovered [3], the current densest packing [3]. Since the dimer crystal packs more densely than the quasicrystal and its approximant, it is thermodynamically favored in the limit of infinite pressure. However, which structure is stable at finite pressures is an open question. Here, we explore the relative thermodynamic stability of these very different ordered phases as a function of packing density.

1:39PM J13.00011 Jamming of frictional tetrahedra , MAX NEUDECKER, Max-Planck-Institute for Dynamics and Self-Organization, Bunsenstr. 10, 37073 Göttingen, STEPHAN ULRICH, University Göttingen, Institute of theoretical physics, Friedrich-Hund-Platz 1, 37077 Göttingen, STEPHAN HERMINGHAUS, MATTHIAS SCHRÖTER, Max-Planck-Institute for Dynamics and Self-Organization, Bunsenstr. 10, 37073 Göttingen — We present experimental results on the packing of polypropylene tetrahedra with 7mm side length. Analysis via X-ray-tomography allows for a detailed analysis of the radial distribution function and the number and type of geometrical contacts. We focus particularly on the dependence of these packing properties on the bulk packing fraction.

1:51PM J13.00012 Rheology of Minimally Jammed Frictionless Rodpiles[1] , JAMES GRAHAM, SCOTT FRANKLIN, Rochester Institute of Technology — The ability of large aspect ratio granular particles to form solid plugs is now well-documented but, apart from a general phenomenological explanation of geometric entanglement, remains unexplained. Recent experiments on the collapse of granular columns [1] suggest that rods with even moderate aspect ratios can maintain angles of repose of 90° or larger, implying that the shear modulus increases continuously with aspect ratio. Our simulations generate minimally jammed packings of frictionless, aspect ratio 1-48 spherocylinders through an energy-minimization process. Once the minimally jammed state is reached, we continue the process to larger packing fractions in order to determine the bulk modulus. Packings are then subjected to infinitesimal strain in order to calculate the shear modulus as a function of particle aspect ratio. Shear simulations can be extended to large strain and used to investigate the long-time reordering of rod-like particles that accompanies macroscopic shear.

2:03PM J13.00013 Couette Shear for Elliptical Particles Near Jamming[1] , SOMAYEH FARHADI, Duke University, ROBERT. P. BEHRINGER COLLABORATION — We have performed 2D Couette shear experiments on systems of photoelastic particles. The particles are identical ellipses with aspect ratio 2. We use the photoelastic property of the disks to obtain the forces acting on a particle. We use two cameras to simultaneously image the particle motion and the photoelastic force response. Using ellipses enables us to understand the effect of particle shape asymmetry on the large-scale behavior on the rheological behavior of granular systems near jamming. Of particular interest are the nematic ordering of the ellipses, the formation of shear bands and the nature of force transmission.

Session J14 GSNP: Focus Session: Physics of Active Materials D227

11:15AM J14.00001 Active Currents and Stresses on the cell surface: Clustering, Instabilities and Budding[1] , MADAN RAO, Raman Research Institute/National Centre for Biological Sciences, Bangalore — We study the contractile dynamics of a collection of active polar filaments, such as actin, on a two dimensional substrate, using a continuum hydrodynamic description in the presence of spatiotemporal noise. The steady states, characterized by a variety of phases generically consisting of a transient collection of inward pointing asters. We next study the dynamics of particles advected along these active filaments. This is relevant to the dynamics and organization of a large class of cell surface molecules. We make several predictions regarding the statistics of fluctuations of these passive advective particles which we confirm using fluorescence based experiments. We then show how such active patterning of filaments can give rise to membrane stresses leading to membrane shape deformations.

[1]In collaboration with Kripa Gowrishankar and Satyajit Mayor.

11:51AM J14.00002 Pattern formation in Active Polar Fluids[1] , ARVIND GOPINATH, MICHAEL HAGAN, Martin A Fisher School of Physics, Brandeis University, APARNA BASKARAN, Martin A Fisher School of Physics, Brandeis University — Systems such as bacterial suspensions or cytoskeletal filaments and motility assays can be described within the paradigm of active polar fluids. These systems have been shown to exhibit pattern formation raging from asters and vortices to traveling stripes. A coarse-grained description of such a fluid is given by a scalar density field and a vector polarization field. We study such a macroscopic description of the system using weakly nonlinear analysis and numerical simulations to map out the emergent pattern formation as a function of the hydrodynamic parameters in the context of two specific microscopic models - a quasi-2D suspension of cytoskeletal filaments and motor proteins and a system of self propelled hard rods that interact through excluded volume interactions.

12:03PM J14.00003 Non-Equilibrium Dynamics of the Metaphase Spindle , DANIEL NEEDLEMAN, JAN BRUGUES, Harvard University — A wide variety of cellular structures exist in a nonequilibrium steady-state with a constant flux of molecules and energy continuously modifying and maintaining their architecture. Understanding such self-organizing structures is not only crucial for cell biology, but also poses a fundamental challenge for physics, since these systems are materials that behave drastically differently from those that have been traditionally studied in condensed matter physics. Physical theories of active materials have been used to describe the cytoskeleton, but it is still unclear how applicable these theories are to complex biological systems *in vivo*. We are experimentally testing if such phenomenological theories of cytoskeletal behavior can be profitably used to model the metaphase spindle. Our approach is to use polarized light microscopy, spinning disk fluorescence microscopy, single molecule imaging, and magnetic tweezers to quantitatively measure spatial-temporal correlation functions of spontaneous fluctuations in the director, concentration, and internal stress in spindles. We are comparing these measurements with predictions from various continuum theories to determine how best to describe the non-equilibrium dynamics of these structures.

12:15PM J14.00004 Modeling active materials based on self-oscillating gels , VICTOR V. YASHIN, ANNA C. BALAZS, Chemical Engineering Department, University of Pittsburgh, Pittsburgh, PA, 15261 — The Belousov-Zhabotinsky (BZ) reaction in solution is a classical example of an active medium that demonstrates various chemical oscillations and waves, which can be observed visually. Grafting a ruthenium metal-ion complex, the catalyst to the BZ reaction, to a chemo-responsive polymer gel creates an active material (BZ gel), which exhibits periodic volumetric changes in the course of the reaction. The redox oscillations of the catalyst affect the polymer-solvent interactions and cause the periodic swelling and de-swelling of the gel, so that chemo- mechanical energy transduction occurs within the material. We consider a model that couples the polymer gel dynamics and the BZ reaction kinetics; the latter is described by the modified Oregonator model. The model equations are solved numerically in 2D. We demonstrate that the dynamical behavior of the BZ gel can be controlled by a heterogeneous distribution of the catalyst and by such structural features as the solvent-filled voids. The dynamics of an active membrane having the self-oscillating pores is considered as an example.

12:27PM J14.00005 Homeostatic pressure, tumor growth and fingering of epithelial tissues: Some generic physics arguments[1] , THOMAS RISLER, Institut Curie — We propose that one aspect of homeostasis is the regulation of tissues to preferred pressures, which can lead to a competition for space of purely mechanical origin and be an underlying mechanism for tumor growth. Surface and bulk contributions to pressure lead to the existence of a critical size that must be overcome by metastases to reach macroscopic sizes. This property qualitatively explains the observed size distributions of metastases, while size-independent growth rates cannot account for clinical and experimental data. It also potentially explains the observed preferential growth of metastases on tissue surfaces and membranes, suggests a mechanism underlying the seed and soil hypothesis introduced by Stephen Paget in 1889, and yields realistic values for metastatic inefficiency [1]. Treating epithelial tissues as viscous fluids with effective cell division, we find a novel hydrodynamic instability that leads to the formation of fingering protrusions of the epithelium into the connective tissue. Arising from a combination of viscous friction effects and proliferation of the epithelial cells, this instability provides physical insight into a potential mechanism by which interfaces between epithelia and stroma undulate, and potentially by which tissue dysplasia leads to cancerous invasion.

1:03PM J14.00006 Hydrodynamics of an Active Smectic , TAPAN CHANDRA ADHYAPAK, SRIRAM RAMASWAMY, Indian Institute of Science, JOHN TONER, University of Oregon — We show that self-driven particles, in suspension or on a substrate, can support striped phases with long-range order in three dimensions and quasi-long-range order in two dimensions. This is in contrast to the situation for smectic phases at thermal equilibrium, which have the same spatial symmetry. We analyse the fluctuation properties of stable active smectics as well as the nature of characteristic instabilities that these systems can display. Our results apply to any active system that spontaneously develops layers, including apolar orientable cells, monolayers of rods either fluidized or shaken and, most significantly, the Rayleigh-Benard instability.

1:15PM J14.00007 Spontaneous Oscillations in Nonlinear Active Solids[1] , SHILADITYA BANERJEE, Syracuse University, TANNIEMOLA B. LIVERPOOL, University of Bristol, M. CRISTINA MARCHETTI, Syracuse University — We present a generic continuum model of a nonlinear active gel with both passive and active crosslinks. The model is relevant for actin gels with passive elasticity provided by ABPs such as filamin-A or α-actinin and dynamic active crosslinkers such as myosin-II. We consider an one dimensional continuum active solid where compressional deformations are coupled to molecular motor dynamics. Three kinds of nonlinearities are incorporated : (a) nonlinear load dependence of unbinding rate of molecular motors, (b) pressure nonlinearities stemming from excluded volume interactions, and (c) nonlinearity due to convection of bound motors along the gel. Unbinding rate nonlinearity stabilizes the oscillatory instabilities predicted by the linear theory and lead to sustained oscillations at intermediate concentrations of ATP. Pressure nonlinearity due to excluded volume interactions stabilizes the contractile instability and leads to a contracted ground state. Our work provides a generic framework for the description of the large scale properties of nonlinear isotropic active solids.

1:27PM J14.00008 Self-diffusiophoresis in the strongly advecting regime , GARETH ALEXANDER, University of Pennslyvania, ANDREA LIU, University of Pennsylvania — Certain forms of biological motility, such as actin-based propulsion and chromosomal translocation in certain bacteria, have recently been proposed to have their physical origins in the phenomenon of self-diffusiophoresis. In diffusiophoresis, a particle in a fluid with an inhomogeneous concentration of solute will move along the concentration gradient with a well-defined velocity due to surface interactions with the solute. If the particle has the means of generating the concentration gradient itself–by catalyzing a chemical reaction on one side of its surface, for example–then self-diffusiophoresis serves as a mechanism of self-propulsion. Until now, self-diffusiophoresis has been studied under conditions of rapid diffusion, or small Péclet number, where the effects of advection on the solute dispersion can be neglected. However, in the biological examples of interest, the Péclet number is high. We present an analysis of the large Péclet number limit, where diffusion is slow and advection by the fluid flow is the primary means of solute dispersal. The resulting motion is still described in terms of a slip velocity generated in a thin boundary layer, but with a different origin, arising not from diffusion but from local outward flow to carry away the solute together with fluid continuity. A simple model is developed on this basis, contrasted with the rapid diffusion regime, and applied to provide insight into relevant biological processes.

1:39PM J14.00009 Phase transitions and solitons in a rule-based model of active particles , THOMAS IHLE, North Dakota State University — I study the Vicsek model [Phys. Rev. Lett. **75** (1995) 1226] by means of kinetic theory. In this non-equilibrium model, self-driven particles try to align their travel directions with the average direction of their neighbours. At strong alignment, rotational symmetry is spontaneously broken and a global flocking state forms. The alignment is defined by a stochastic rule, not by a Hamiltonian. The corresponding interactions are non-additive and are typically of genuine multi-body nature. Due to this and the discreteness of the time evolution, the kinetic equations are different from the usual ones found in textbooks. I derive the phase diagram for the flocking transition and show that it agrees very well with simulations at large particle velocities and is qualitatively different from the one of a continuous version of the Vicsek-model. The theory starts with the Liouville equation, the hydrodynamic equations are derived by a Chapman-Enskog expansion. These equations contain more terms than previously postulated; their coefficients are given in terms of microscopic parameters. I show how a large-wavelength instability of the flocking state leads to an inhomogeneous soliton state which is very stable and shows a first-order phase transition to the disordered state. I determine the speed of the solitons, investigate the hysteresis of the transition and estimate the system size beyond which the first order nature of the transition should be visible in computer simulations.

1:51PM J14.00010 Collective motion of vibrated polar granular disks[1] , OLIVIER DAUCHOT, DESEIGNE JULIEN, CEA-Saclay / SPEC, HUGUES CHATE, CEA-Saclay / Chate, DYCOACT COLLABORATION — In many interesting situations, the interactions among self-propelled agents lead to the spontaneous emergence of self-organized collective motion. The ubiquity of the phenomenon at all scales raises the question of the existence of some underlying universal mechanisms. Recent numerical and analytical studies have confirmed the existence of a transition from a disordered state at large noise to a state with various collective properties reflecting the local symmetry of the particles and their interactions. Though, there are still very few experimental situations where the onset of collective motion can be attributed to spontaneous symmetry breaking. Here, we report on experiments conducted with both polar self propelled and a-polar Brownian disks and by comparing the dynamics of both systems in the same experimental conditions, we demonstrate without ambiguity that collective motion emerges from the interplay of self-propulsion and hard-core repulsion only [1]. Interestingly the alignment, which has no nematic origin, is effectively induced during the collisions because of the self propulsion.

11:15AM J15.00001 Spin-Seebeck effect: Local nature of thermally induced spin currents in GaMnAs[1]

, ROBERTO MYERS, Department of Materials Science and Engineering, The Ohio State University, Columbus, Ohio — The spin-Seebeck effect refers to a spatial distribution of spins in a ferromagnetic material induced by a thermal gradient. This macroscopic spatial distribution of spins is several orders of magnitude larger than the spin diffusion length [1]. Here we describe measurements of the spin-Seebeck effect in the ferromagnetic semiconductor, GaMnAs [2]. The thermally induced spatial distribution of spins is inferred from the sign and magnitude of the inverse spin Hall voltage generated from local spin currents in platinum bars that are in electrical contact with the ferromagnetic material. From an experimental point of view, GaMnAs provides unique measurement geometries since the magnetic easy axes can be engineered in different directions and the low Curie temperature makes it convenient to perform spin-Seebeck measurements across the magnetic phase transition. Using different experimental configurations we measure either the isolated spin-Seebeck signal, the planar and transverse Nernst effect, or a combination of the spin-Seebeck and Nernst effects. One of the most intriguing aspects of the spin-Seebeck effect is the observation that the spatial distribution of spins is maintained across electrical breaks revealing that the effect does not arise from a longitudinal spin current of charge carriers.

11:51AM J15.00002 Theory of the Anomalous Hall Effect in the Insulating Regime

, XIONG-JUN LIU, XIN LIU, JAIRO SINOVA, Department of Physics, Texas A&M University, College Station, Texas 77843-4242, USA — The anomalous Hall effect (AHE) has been an enigmatic problem that has resisted theoretical and experimental assault for almost one century. The AHE in the metallic regime has been separated into different contributions, i.e. skew scattering side jump and intrinsic contribution. However, the recent experiments on AHE in the insulating regime discover a qualitatively different behavior described by a scaling relation which is different from that in the metallic regime. The new finding cannot be explained by available microscopic theories of metals based on impurity scattering. Here we present a theory to study the anomalous Hall conductivity (AHC) in this regime With this theory we calculate the lower and upper limits for the AHC by taking simple assumptions of the impurity distributions. Our results are quantitatively in agreement with the experimental discoveries, and thus provides the understanding of the AHE in the insulating regime.

12:03PM J15.00003 Strain manipulation of anomalous Hall response in GaMnAs micromechanical buckled Hall beam structure

, CHANUK YANG, Seoul National University, HYUNG KOOK CHOI, TAI HOON KIM, YUN DANIEL PARK — The non-magnetic manipulation of magnetic properties of diluted magnetic semiconductors (DMS) has recently received much attention, such as magnetization by electric field [1], and magnetic anisotropy by strain engineering [2]. Especially, in GaMnAs, the spin-orbit interactions (SOIs) are highly strain-dependent and the applied magnetic field plays a crucial role in determining magnetic anisotropies (MA), anisotropic magnetoresistances (AMR), and the intrinsic anomalous Hall effect (AHE) [3]. Here, we present AHE of local-strain-induced GaMnAs micro-Hallbeam by fabricating mechanical suspended structure. We observe a suppression of the AHE that varies symmetrically about the centre of the buckled beam due to strain-related SOIs.

12:15PM J15.00004 The spin-Seebeck effect in a GaMnAs/MnAs bilayer

, CHRISTOPHER JAWORSKI, Department of Mechanical Engineering, The Ohio State University, JING YANG, Department of Materials Science and Engineering, The Ohio State University, SHAWN MACK, DAVID AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, JOSEPH HEREMANS, Department of Mechanical Engineering and Department of Physics, The Ohio State University, ROBERTO MYERS, Department of Materials Science and Engineering and Department of Physics, The Ohio State University — The spin-Seebeck effect, recently discovered in ferromagnetic metals such as permalloy, semiconductors such as GaMnAs and insulators such as YIG, consists of a thermally generated spin redistribution. This effect is measured by detecting an inverse spin Hall voltage that varies spatially across a sample due to the thermally generated local spin currents. Here, we describe measurements of the spin-Seebeck effect in metallic ferromagnetic MnAs thin films grown on GaMnAs. The difference in H_c and T_c of each layer allows independent measurement of spin-Seebeck signals arising from MnAs from that of GaMnAs. We discuss the effect of the exchange bias between these layers on the spin-Seebeck effect above and below the magnetic phase transition. Work support in parts by NSF, NSF-CBET-0754023, ONR, and DMR-0820414.

12:27PM J15.00005 Magnetoresistance in Lateral GaMnAs devices with Nano-constrictions

, BHIM PAUDEL, GRANT RILEY, Miami University, LEONIDAS OCOLA, Argonne National Lab, XINYU LIU, JACEK FURDYNA, University of Notre Dame, KHALID EID, Miami University — Mn-doped GaAs (or GaMnAs) offers opportunities to demonstrate both new device concepts with added functionality and new phenomena in condensed matter physics, since it is both a ferromagnet and a semiconductor. We will present our recent results on fabricating and characterizing GaMnAs-based nano- devices. The resistance of these deep-nanoscale devices can be manipulated either by varying the applied voltage or via an external magnetic field. The nano-devices were prepared using electron-beam lithography and wet chemical etching. The magnetoresistance of the devices was as high as 50% at 4.2k and the behavior was different from previous results reported in literature.

12:39PM J15.00006 A grate field-dependent change of magnetic damping in Fe/(Ga,Mn)As

, SATOI KOBAYASHI, KEITA SUDA, HIRO MUNEKATA, Tokyo Institute of Technology — Reported here is the field dependence of the magnetic damping in the photo-induced precession of magnetization in three different samples, a simple (Ga,Mn)As, two hybrids Pt/(Ga,Mn)As and Fe/(Ga,Mn)As. The Mn content $x$is $x = 0.045$ for all cases. In (Ga,Mn)As, the precession frequency ω increases and the precession lifetime τ decreases with increasing a lateral, external field applied along the easy axis, whereas the $\omega\tau$ product is hardly changed. Similar trend is observed in Pt/(Ga,Mn)As, except that the $\omega\tau$ product is smaller than that of (Ga,Mn)As. An inverse value of the $\omega\tau$ product, so called the Gilbert damping constant α, is $\alpha = 0.1$ and 0.15, respectively, for (Ga,Mn)As and Pt/(Ga,Mn)As. The enhanced magnetic damping in Pt/(Ga,Mn)As can be understood qualitatively in terms of the spin pumping. In Fe/(Ga,Mn)As, the $\omega\tau$ product around the zero field is even smaller than that of Pt/(Ga,Mn)As, being indicative of a larger damping ($\alpha \sim 0.26$), whereas the $\omega\tau$ product increases steeply with an external field. At around 400 Oe and higher, the $\omega\tau$ product saturates at the value comparable to that of a simple (Ga,Mn)As. Taking magnetization data into account, a great field-dependent change in damping could be attributed to the spin-wave excitation at the Fe/(Ga,Mn)As interface caused by non-parallel magnetization configuration between Fe and (Ga,Mn)As in microscopic scale.

12:51PM J15.00007 Interfacial Spin Filtering at Copper/GaMnAs Contacts[1] , KHALID EID, BHIM PAUDEL, GRANT RILEY, Miami University, XINYU LIU, JACEK FURDYNA, University of Notre Dame — We determine the spin injection efficiency using a single ferromagnetic film without the need for a spin-detection layer. This is accomplished by studying the temperature dependence of the specific contact resistance (AR_C) of a copper/GaMnAs contact using a circular transmission line method. AR_C is as low as $5x10^{-8}$ Ωcm^2, and decreases slowly with decreasing temperature T. However, as T approaches Curie temperature T_C, AR_C abruptly jumps to about double its initial value. We suggest that this behavior arises from the suppression of one of the two spin conduction channels, which results in substantial spin polarization.

1:03PM J15.00008 Spin-dependent Transport in GaAs/MnAs Core/shell Nanowires , J. LIANG, J. WANG, N.S. DELLAS, B.J. COOLEY, S.E. MOHNEY, R. ENGEL-HERBERT, M.H.W. CHAN, N. SAMARTH, Center for Nanoscale Science and Materials Research Institute, Penn State University, University Park PA 16802. — The integration of a metallic ferromagnet (FM) with a semiconductor (S) in axially- and radially modulated nanowires (NWs) has the potential to open up new opportunities in nanospintronics. We describe a comprehensive study of the structure, magnetism and electrical transport in hybrid core/shell S(GaAs)/FM(MnAs) NWs synthesized by molecular beam epitaxy. This is an unusual system where the competition between magnetocrystalline and shape anisotropies in the FM shell creates a magnetic ordering regime which is distinct from conventional FM metal NWs. We report four probe measurements of the temperature dependence of conductivity and the magnetoresistance (MR) in single NWs over a temperature range 0.5 K - 300 K and in magnetic fields ranging up to 80 kOe. Assuming that electrical transport is dominated by the metallic shell, we use the measured anisotropic MR in conjunction with micromagnetic simulations to gain insight into the magnetization reversal process of the FM shell. We also discuss the possible origins of a striking negative linear MR at high field which becomes more pronounced with increasing temperature. Supported by NSF-MRSEC and ONR.

1:15PM J15.00009 Ohmic spin injection from a half-metal at finite temperatures: Is the conductivity mismatch problem relevant? , JAMES GLASBRENNER, ALEKSANDER WYSOCKI, KIRILL BELASHCHENKO, University of Nebraska - Lincoln — Spin injection from a normal ferromagnet into a semiconductor requires a highly-resistive tunnel or Schottky barrier at the interface to overcome the conductivity mismatch problem. This barrier limits the current that can be achieved in a device. A half-metallic ferromagnet used as a spin injector obviously overcomes this problem at zero temperature, but the situation at finite temperatures is nontrivial. We argue that the two-current model is inapplicable to half-metals, and that Ohmic (barrierless) spin injection from a half-metal is possible even at finite temperatures. This conclusion is reached using an intuitive model which sums up multiple scatterings at the interface. To complement this model, we calculate the spin injection efficiency for a half-metallic electrode using a single-band tight-binding model with explicit statistical averaging over thermal spin fluctuations. The results are contrasted with the case of a normal ferromagnet. We also consider a practically interesting case of a CrAs electrode within the tight-binding LMTO method.

1:27PM J15.00010 MnAs/Al(AsSb)/InAs Heterostructure-Based Spin LEDs[1] , H. ZHANG, E.D. FRASER, S. HEGDE, J. KWON, J.B. HATCH, H. LUO, G.P. LINDBERG, B.A. WEINSTEIN, B.D. MCCOMBE, State University of New York at Buffalo — MnAs is a promising spin alignment material for spin-injection into InAs-based structures due to its well studied structural and magnetic properties. A well known difficulty of spin injection from a ferromagnetic metal spin aligner into a semiconductor is the so-called conductivity mismatch, which has been overcome via tunnel barrier contacts.[2,3] Lattice matching the tunnel barrier to the active region is important because a highly strained interface and resulting defects can reduce spin polarization of the injected carriers. We report development of a spin-LED structure with a lattice matched $AlAs_{0.16}Sb_{0.84}$ tunneling barrier between the MnAs spin aligner and an InAs quantum well. The composition was characterized through XRD and Raman spectroscopy. Sample growth, characterization, LED fabrication and optical polarization studies of electroluminescence in the 3 micron spectral region will be discussed.

1:39PM J15.00011 Efficient injection of spin-polarized electrons from MnAs contacts into GaAs quantum well LEDs[1] , EVERETT FRASER, SHRIDHAR HEGDE, LARS SCHWEIDENBACK, ANDREAS RUSS, ATHOS PETROU, HONG LUO, University at Buffalo, The State University of New York, GEORGE KIOSEOGLOU, University of Crete — Recent studies of ferromagnetic MnAs have revealed a wide range of properties desirable for spintronic applications. In this work, ferromagnetic MnAs contacts have been used to inject spin polarized electrons into AlGaAs(n)/GaAs(i)/AlGaAs(p) light emitting diodes. The band-edge electroluminescence emitted from these devices has a saturation circular polarization of 26% at 7K. The circular polarization was found to track the out of plane magnetization of MnAs, confirming spin injection. Using optical pumping measurements, the corresponding electron spin polarization was determined to be 52%. Emission persists up to room temperature, with a saturation circular polarization of 6%. The improved performance over similar structures is attributed to the use of MnAs/AlGaAs Schottky barrier tunneling and minimal interdiffusion of Mn ions near the materials interface.

[1]Work at SUNY was supported by NSF, ONR, and the Rustgi professorship.

1:51PM J15.00012 Oscillatory spin polarization and magneto-optical Kerr effect in Fe_3O_4 thin films on GaAs(001) , YAN LI[1], WEI HAN, A.G. SWARTZ, K. PI, J.J.I. WONG, Dept. of Physics and Astronomy, UC Riverside, S. MACK, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106, R.K. KAWAKAMI, Department of Physics and Astronomy, University of California, Riverside, CA 92521 — Magnetite is an attractive material for spin injection and detection, because the theory predicts completely negative spin polarization at the Fermi level at room temperature. We fabricated high quality Fe_3O_4 films on GaAs (001) by molecular beam epitaxy. The Fermi level spin polarization of the Fe_3O_4 film was probed using the ultrafast optical measurement of ferromagnetic proximity polarization (FPP). The systematic thickness dependence of FPP and MOKE were measured on wedged Fe_3O_4 films on GaAs(001), and similar oscillatory and sign reversing behaviors were observed even though the two measurements rely on different mechanisms (spin dependent electron reflection for FPP, and optical transitions for MOKE). Quantum confinement of the t_{2g} states near the Fermi level provides an explanation for the similar thickness dependences of the FPP and MOKE oscillations.

2:03PM J15.00013 TMR study of GaMnAs/AlGaAs:Be/GaMnAs trilayers[1] , JOSEPH HAGMANN, XINYU LIU, MALGORZATA DOBROWOLSKA, JACEK FURDYNA, Department of Physics, University of Notre Dame, Notre Dame, IN 46556, USA, TAEHEE YOO, SUNGWON KHYM, SANGHOON LEE, Department of Physics, Korea University, Seoul 136713, South Korea — GaMnAs/GaAs:Be/GaMnAs trilayers have recently demonstrated antiferromagnetic (AFM) coupling between the two ferromagnetic (FM) layers, mediated by holes in the spacer layer. In this work, GaMnAs/Al_xGa_{1-x}:Be/GaMnAs trilayer samples with varying Al concentrations were fabricated into magnetic tunnel junction (MTJ) devices with range of pillar diameters to measure tunneling magnetoresistance (TMR) under various conditions. SQUID measurements were use to measure the magnetization of the samples, including switching fields for parallel and antiparallel magnetization alignments of the FM layers. TMR was observed in the sample with $Al_{0.22}Ga_{0.78}As$:Be spacer, but was massively suppressed in the samples with lower Al content. The presence of holes in the spacer layer is shown to suppress TMR. This illustrates the difference in conditions for TMR and for AFM interlayer coupling.

Tuesday, March 22, 2011 11:15AM - 2:15PM –
Session J16 DMP GMAG: Focus Session: Magnetic Nanostructures III D173

11:15AM J16.00001 Studies of isolated and interacting ferromagnetic gapped nanorings[1] , JIE LI, SHENG ZHANG, JASON BARTELL, CHRIS GRIGAS, Penn State University, CRISTIANO NISOLI, Los Alamos National Lab, PAUL LAMMERT, VINCENT CRESPI, PETER SCHIFFER, Penn State University — We have used micromagnetic simulation and magnetic force microscopy (MFM) to study isolated and interacting permalloy nanorings that are lithographically fabricated with gaps that prevent a rotationally symmetric magnetic state. The gapped nanorings have inner and outer radii of 200 and 300 nm respectively, and the gap has a subtended width of ∼20 degrees. The nanorings generate a strong magnetic field only in the gap, and thus the magnetization states of gapped nanorings are much more accessible to MFM imaging than complete rings. We have investigated the properties of these gapped nanorings, including the anisotropy in their coercive field and the relative alignment of the magnetic polarization in coupled pairs.

[1]We acknowledge the financial support from DOE and Army Research Office.We are grateful to Professor Chris Leighton and Mike Erickson for assistance with sample preparation.

11:27AM J16.00002 Broad-Band FMR of Patterned Square Arrays of Square Permalloy Antidots[1] , VINAYAK BHAT, University of Kentucky, JOSEPH SKLENAR, JOHN KETTERSON, Northwestern University, LANCE DELONG, University of Kentucky — We have used electron beam lithography to pattern 25-nm-thick Permalloy films with square arrays of square antidots of size D = 300, 400, 500 and 700 nm and same lattice constant d = 1000 nm, using a lift-off technique. Broadband FMR[2] was used to observe localized modes[3,4] showing four-fold rotational symmetry for in-plane DC magnetic field. We have studied FMR spectra spanning the ferromagnetic hysteresis regime around 250 MHz, up to the saturation regime ending near 14 GHz, and observe the appearance and disappearance of various FMR modes, especially at frequencies below 7 GHz. We have observed history-dependent modes below 3 GHz that may be associated with domain walls.

11:39AM J16.00003 Broadband Magnetic Resonance Measurements on Periodic Patterned Disc and Hole Arrays , J. SKLENAR, Northwestern University, V.S. BHAT, L. DELONG, University of Kentucky, V. METLUSHKO, University of Illinois, Chicago, C.C. TSAI, Chang Jung Christian University, Taiwan, O. CHERNYASHEVSKYY, Northwestern University, K. RIVKIN, Seagate Technologies, J.B. KETTERSON, Northwestern University — We have made broadband ferromagnetic resonance measurements on patterned permalloy arrays consisting of circular dots (discs) and both square and circular anti-dots (holes). We employ a transmission meander line approach as opposed to a resonant cavity technique, and cover the frequency range 10MHz to 20GHz. Experiments are performed at a fixed frequency by sweeping the field (through positive and negative values) and at a fixed field while varying the frequency; both magnetic field and frequency modulation are employed to suppress noise and background effects. Experiments on hole arrays show two dominant resonances which from their symmetry appear to be standing spin waves centered at the X- points of the square Brillouin zone. Low field measurements on disc arrays where the field is swept over varying ranges in the region where the sample is hysteretic while tracking the history dependent disappearance and reappearance of the uniform FMR mode, allows a determination of the phase boundaries separating the single and double vortex states, and are in agreement with simulations by Rivkin.

11:51AM J16.00004 Exciton-Mn ion interaction in CdTe quantum dots[1] , ANNA TROJNAR, MAREK KORKUSINSKI, EUGENE KADANTSEV, PAWEL HAWRYLAK, Institute for Microstructural Sciences, NRC, Ottawa, Canada, K1A0R6 — We develop a microscopic theory of optical properties of quantum dots containing a single magnetic ion [1,2] which includes electron-hole correlations, short range exchange of Mn ion with electron and with heavy hole, long range electron-hole exchange, quantum dot anisotropy and external strong magnetic field. A new quantum interference (QInt) effect between electron-hole Coulomb scattering and scattering by Mn ion is obtained. Special role is played here by configurations with electron and hole on the p-shell and degenerate with it configurations with electron (hole) on s-shell and hole(electron) on a d-shell. QInt is shown to significantly reduce exciton-Mn coupling. The signature of this QInt effect in emission and absorption spectrum is discussed. The effect of strong magnetic field on the characteristic emission spectrum is discussed and the limitations of the spin model are established.

12:03PM J16.00005 Antiferromagnetic coupling in cobalt atomic clusters on (110) surface of tungsten , RENAT F. SABIRIANOV, University of Nebraska at Omaha, PAVEL LUKASHEV, AXEL ENDERS, University of Nebraska - Lincoln — We report results of the first principles calculations on the structural and magnetic properties of cobalt atomic clusters on (110) surface of tungsten. We found that for certain geometry these clusters can exhibit antiferromagnetic order. The result is unexpected, as in the bulk as well as in the thin films and free standing clusters Co always exhibits ferromagnetic structure. We compare results for Co with the ones for the analogues Fe atomic clusters. We found that Fe clusters deposited on (110) surface of tungsten tend to couple ferromagnetically similar to bcc Fe in considered geometries. In our calculations we analyzed different configurations of atomic islands, in particular N=3, 4, 5, 6, 8, 12, where N is the number of atoms in the cluster. We perform full structural and magnetic relaxation, and we show that depending on the geometry and number of cobalt atoms in the cluster, the system can be non-magnetic (N=4, 6, 8), ferromagnetic (N=3, 5) and antiferromagnetic or ferrimagnetic (N=4, 12). We present phenomenological model to explain this intriguing magnetic properties of Co atomic islands on (110) surface of tungsten.

12:15PM J16.00006 Non-liftoff block copolymer nanolithography of magnetic nanodot arrays , A. BARUTH, M.D. RODWOGIN, A. SHANKAR, M.A. TORIJA, M.J. ERICKSON, M.A. HILLMYER, C. LEIGHTON, University of Minnesota — Nanolithographic techniques based on self-assembled block copolymer templates offer exceptional potential for fabrication of large-area nanostructure arrays from a wide variety of functional materials. Despite significant progress with control of the template ordering, and development of pattern transfer schemes, significant issues exist with common techniques such as lift-off and etching. Here, we demonstrate successful execution of a nanolithographic process based on climate-controlled solvent annealing of easily degradable cylinder-forming poly(styrene-*b*-lactide) block copolymer films that avoids both lift-off and the most challenging aspects of etching. Essentially, we use an overfill/planarize/etch-back "Damascene-type" process, exploiting the large Ar ion beam etch rate contrast between polystyrene and typical metals. The process is demonstrated via formation of a large-area array of 12 nm thick, 25 $\pm$ 3 nm diameter $Ni_{80}Fe_{20}$ nanodots ($\sim$0.4 x 10^{12} dots/in^2) with hexagonally-close-packed local order. Extensive microscopy, magnetometry, and electrical measurements provide detailed characterization of the pattern formation and fidelity. We argue that this generic approach can be applied to a wide variety of materials and is scalable to even smaller feature sizes. Funded by NSF MRSEC.

12:27PM J16.00007 Investigating the origin of the magnetic switching field distribution in bit patterned media , OLAV HELLWIG, San Jose Research Center, Hitachi GST, BASTIAN PFAU, CHRISTIAN GUENTHER, Helmholtz-Zentrum Berlin, STEFAN EISEBITT, Technical University Berlin, THOMAS HAUET, Nancy University, ELIZABETH DOBISZ, XIAOYU XU, YANEY DEBORAH, San Jose Research Center, Hitachi GST — Bit patterned media (BPM) is a promising approach for extending densities in magnetic data storage. One critical challenge for BPM is a tight magnetic switching field distribution (SFD), i.e. the bit-to-bit variations in reversal field. The SFD has three components: the dipolar interactions between neighboring islands within the array, pattern non-uniformities, such as variations in island size, position or shape and the so-called intrinsic SFD of each individual island, which is due to variations in the intrinsic magnetic material properties. We use soft X-ray spectro-holography and high resolution transmission electron microscopy (TEM) to study the origin of the magnetic SFD in BPM. For this we fabricated pattern arrays with 80 nm islands by e-beam lithography and integrated these into a SiN membrane design suitable for x-ray transmission studies. After identifying individual easy and hard to switch islands in the tails of the SFD we performed plane-view TEM analysis of these islands and correlate their magnetic with their structural properties, such as misaligned grains or irregular island shapes.

12:39PM J16.00008 Control of Magnetic States of Cobalt Nanorings by an External Azimuthal Field[1] , NIHAR PRADHAN, Mount Holyoke College and UMass Amherst, MA, USA, TIANYU YANG, UMass Amherst, MA, USA, ABBEY LICHT, YIHAN LI, Mount Holyoke College, South Hadley, MA, USA, MARK TUOMINEN, UMass Amherst, MA, USA, KATHERINE AIDALA, Mount Holyoke College, South Hadley, MA, USA — Ferromagnetic nanorings attract interest due to their potential application in high density data storage and Magnetoresistive Random Access Memory (MRAM) devices. These nanorings show multidomain stable states that need to be well controlled by external in-plane or circular magnetic fields. This talk presents a new method to generate circular magnetic fields to control the magnetic states in different geometries of Cobalt nanoring structures, of varying diameter, width and thickness. A solid platinum AFM tip was used to pass current through a single nanoring, generating a circular magnetic field. In applying this field we were able to change the state of the individual ring without affecting the states of other neighboring rings. The evolution of the magnetic states of individual symmetric and asymmetric Cobalt nanorings with applied azimuthal field will be presented.

12:51PM J16.00009 Rotationally induced magnetic chirality in clusters of single-domain permalloy islands and gapped nanorings[1] , SHENG ZHANG, JIE LI, JASON BARTELL, PAUL LAMMERT, VINCENT CRESPI, PETER SCHIFFER, Department of Physics and Materials Research Institute, Pennsylvania State University, University Park, PA 16802 — We have studied magnetic moment configurations of clusters of single-domain ferromagnetic islands in different geometries.[2] The magnetic moments of these clusters are imaged by MFM after rotational demagnetization, following our previous protocols.[3] We observed that two types of the clusters showed a significant imbalance of their two-fold degenerate ground states after demagnetization, and this inequality is correlated to the rotational direction of the demagnetization. A similar imbalance was also found in nano-scale rings with a small gap: the chirality of their magnetic state can be precisely controlled by the rotational direction during demagnetization.

1:03PM J16.00010 Chirality control and vortex manipulation in asymmetric Co dots[1] , KAI LIU, University of California - Davis — Magnetic vortices in sub-micron sized dots have gained considerable interests in recent years due to their fascinating physics and potential applications in information storage, spin-torque oscillators, and magnetic memory and logic devices. Reproducible control of the vortex chirality is of critical importance for these studies. Here we report on two distinctly different chirality control mechanisms in asymmetric Co dots. Arrays of Co dots were fabricated using electron beam lithography and the circular symmetry was broken by introducing a flat edge. Below a critical diameter and/or thickness, chirality control is achieved by the nucleation of a single vortex within each dot, as conventionally observed. The vortex can be manipulated to annihilate at particular sites under different field orientations and cycle sequences. Interestingly, above these critical dimensions a new chirality control mechanism is realized by the nucleation and subsequent coalescence of double vortices, resulting in a single vortex at remanence with the *opposite* chirality as found in smaller dots. Magneto-optical Kerr effect and magnetic force microscopy measurements confirm this new process. Micromagnetic simulations not only reproduce the experimentally observed behavior, but also elucidate the delicate interplay between exchange, demagnetization, and Zeeman energies and the role of fractional vortices bound to the dot edge.

1:39PM J16.00011 Manipulation of Magnetization States of Permalloy Nanorings by an External Azimuthal Field[1] , TIANYU YANG, NIHAR PRADHAN, ABBY GOLDMAN, MOUREEN KEMEI, ABBEY LICHT, YIHAN LI, MARK TUOMINEN, University of Massachusetts Amherst, KATHERINE AIDALA, Mount Holyoke College — This experimental research investigates a new method of manipulating the magnetic states of ferromagnetic nanorings using a circular magnetic field directed along the ring circumference. This type of azimuthal field can naturally select a vortex magnetization of desired chirality. The understanding of the magnetization switching behavior in an azimuthal field could lead to new designs of practical magnetic data storage devices. Symmetric and asymmetric nanorings made of permalloy are fabricated by a standard technique using electron-beam lithography and e-beam evaporation. Azimuthal fields are generated by passing current through an atomic force microscope tip, which is positioned at the center of the ring. The magnetic field direction and magnitude are controlled by the current. We demonstrate control over switching from an onion state to a vortex state, and also between two vortex states, using magnetic force microscopy to image the resulting magnetic states.

1:51PM J16.00012 Magnetization reversal of surface and subsurface Co/Pt multilayers in a porous matrix , B.J. KIRBY, NIST, M.T. RAHMAN, Univ. of Minnesota, R.K. DUMAS, Univ. of Gothenberg, J.E. DAVIES, NVE Corp., KAI LIU, Univ. of California - Davis, C. LAI, Tsing Hua Univ. — Deposition of magnetic multilayers onto porous host matrices has been studied as a simple and cost-effective method for fabrication of nano-patterned magnetic arrays [1]. For such structures, the magnetic reversal properties of the surface multilayer are twofold dependent on the size and depth of the host pores. First, the pore size determines the lateral size of the surface multilayer with respect to that of a single domain. Second, the pore size determines the amount and location of magnetic material within the pore - material that can exchange couple to the surface multilayer. To study these effects, we have used polarized neutron reflectometry to measure the structural and field-dependent magnetic depth profiles of a series of Co/Pt multilayers deposited on nanoporous alumina (diameter: 13, 20, or 28 nm). Despite the film porosity, we observe robust spin-dependent reflectivities, providing strong sensitivity to interfaces throughout the structure. The determined nuclear profiles show impressive agreement with cross-sectional transmission electron microscopy, and the magnetic profiles feature clearly distinct surface and subsurface magnetizations. The surface magnetization reversal and the role of exchange coupling will be discussed. [1] M. T. Rahman, et al., APL. 94, 042507 (2009).

2:03PM J16.00013 Hysteresis-Loop Overskewing , RALPH SKOMSKI, Dept. Physics & Astr. and NCMN, University of Nebraska, T.A. GEORGE, D.J. SELLMYER — The performance of permanent magnets is largely determined by the magnetostatic energy stored in free space (energy product), which depends on both materials properties and magnet geometry. The latter usually differs from laboratory shapes such as spherical samples, and demagnetizing-field corrections must be applied to compare different geometries. However, in nanostructures, especially in thin films, the macroscopic demagnetizing factors D predicted from Maxwell's equations [1] yield unphysical overskewed hysteresis loops [2]. The overskewing is probably a nanoscale effect, but its origin has remained controversial. Our explanation is that nanoscale magnetization processes violate a main condition for the applicability of macroscopy demagnetizing factors, namely the uniform character of the magnetization. In bulk magnets, the magnetization inhomogeneities effectively average to zero, but this is no longer the case if any of the dimension of the magnet becomes small. We explicitly consider granular thin films, where we find a real-structure dependent reduction D, as contrasted to the sometimes assumed infinite slope $M(H)$ at coercivity. — This research is supported by BREM (RS), ARPA-E, DOE (DJS), and NCMN. — **References:** [1] J. Session J17 DMP GMAG: Focus Session: Bulk Properties of Complex Oxides - Ferrites + Vanadates D174

11:15AM J17.00001 New structural phase transition in $Bi_2(Fe_{4-x}Mn_x)O_{10-x}$ complex oxides and it implications in the mullite family of materials[1] , PATRICIA KALITA, ANDREW CORNELIUS, HiPSEC & Dept. of Physics and Astronomy, University of Nevada Las Vegas, Las Vegas, NV, USA, STANISLAV SINOGEIKIN, Geophysical Lab., Carnegie Institution of Washington, Washington, DC, USA, KRISTINA LIPINSKA, OLIVER HEMMERS, Harry Reid Center for Environmental Studies, University of Nevada Las Vegas, NV, USA, MICHAEL LUFASO, ZACHARY KANN, Dept. of Chemistry, University of North Florida, Jacksonville, FL, USA, HARTMUT SCHNEIDER, Inst. of Crystallography, University of Koeln, Koeln, Germany — Complex oxides with the mullite crystal structure belong to the most important phase in both traditional (porcelains and alumino silicate refractories) and advanced ceramics (heat exchangers, shock resistant composites, optical devices). New complex oxides in the mullite family $Bi_2(Fe_{4-x}Mn_x)O_{10-x}$ were synthesized and characterized. Using synchrotron x-ray diffraction we demonstrate a new structural phase transition in $Bi_2(Fe_{4-x}Mn_x)O_{10-x}$ induced by pressure. We contrast it with the structural stability for mullite senso stricto $Al_{4+2x}Si_{2-2x}O_{10-x}$ where we did not observe any phase transition.

11:27AM J17.00002 The role of charge and orbital order for the Verwey transition in Fe_3O_4 , S. DE JONG, R. KUKREJA, M. HOSSAIN, C. BACK, A. SCHERZ, D. ZHU, W. SCHLOTTER, J. TURNER, W. LEE, Y. CHUANG, R. MOORE, O. KRUPIN, M. TRIGO, L. PATTHEY, H. DÜRR, SLAC/ RSXS collaboration, N. PONTIUS, T. KACHEL, A. FÖHLISCH, M. BEYE, Helmholtz Zentrum Berlin, F. SORGENFREI, W. WURTH, Uni. Hamburg & CFEL, C. CHANG, M. DÖHLER, C. TRABANT, C. SCHÜSSLER-LANGEHEINE, Uni. Cologne — Magnetite, Fe_3O_4, displays a strong decrease in resistivity upon heating above $T_C = 123$ K: the Verwey transition. Since long it has been proposed that charge and orbital order (CO/OO), via Fe^{3+} and Fe^{2+} charge disproportionation, play a crucial role. However, the mechanism behind the Verwey transition to date remains unclear. Using pump-probe O K-edge resonant soft X-ray scattering at the new LCLS SXR beamline, we have studied the role of CO/OO for the Verwey transition on ultra-fast time-scales. We focus on the structurally forbidden (00 $^1/_2$) peak. Upon excitation, the charge gap of 200 meV is quenched on resolution limited time-scales, < 250 fs, while we still observe a residual CO/OO signal. This may indicate the existence of a new transient state of matter, displaying charge and orbital order in coexistence with metallic behavior.

11:39AM J17.00003 Pseudogap Phase of Magnetite , YOHANES PRAMUDYA, HANNA TERLETSKA, EFSTRATIOS MANOUSAKIS, VLADIMIR DOBROSAVLJEVIC, NHMFL-Florida State University — Despite extensive experimental and theoretical work, the description of the electrical transport mechanism in magnetite (Fe_3O_4) is still an unresolved issue [1]. This unusual resistivity behavior close to the Verwey transition in magnetite has long been a matter of controversy. In our study, we focus on the temperature regime above Verwey transition and far below the magnetic phase transition, where a nearly charge ordering state (due to the long-range Coulomb frustration) is expected. Here, we expect similar behavior to what has been discussed in a nearly frozen Coulomb liquid [2] with the existence of a pseudogap phase. Following this line of thought, we use extended dynamical mean field theory (EDMFT) and Monte Carlo simulation to study the simplest spinless model describing this system. Our studies do capture the main transport trends in this temperature regime with a typical pseudogap–like behavior.

11:51AM J17.00004 Synchrotron x-ray single-crystal structure analysis of a spinel oxide FeV_2O_4 with spin and orbital degrees of freedom , YOICHI NII, HAJIME SAGAYAMA, TAKA-HISA ARIMA, IMRAM, Tohoku University , RIU SAKAI, SHINOBU AOYAGI, EIJI NISHIBORI, HIROSHI SAWA, Department of Applied Physics, Nagoya University, KUNIHISA SUGIMOTO, SPring-8/JASRI, HIROYUKI OHSUMI, MASAKI TAKATA, RIKEN SPring-8 Center — It has been reported that FeV_2O_4, which has orbital and spin degrees of freedom both in tetrahedral $Fe^{2+}(d^6)$ sites and octahedral $V^{3+}(d^2)$ sites, exhibits successive structural phase transitions, accompanying a ferrimagnetic transition. The origin of the phase transitions is supposed to be a cooperation and/or competition between the orbital and spin degrees of freedom both in Fe^{2+} and V^{3+}. By a synchrotron x-ray single-crystal structure analysis, we determined the space group and atomic coordinate of each phase (cubic- HT-tetra.- HT-ortho.- LT-tetra.). The results suggest that the HT-tetra. (a>c) and HT-ortho. phases should be ascribed to the FeO_4 local compression, whereas VO_6 elongation should be responsible for the LT-tetra. (c>a) phase. We also discuss the orbital ordering (OO) pattern assuming strong electron-lattice coupling. A conceivable OO pattern of V^{3+} at the LT-tetra. (c>a) is *ferroic* one with *yz* and *zx* orbitals occupied, which is unique among spinel-type vanadates.

12:03PM J17.00005 Single-ion Anisotropy, Dzyaloshinskii-Moriya Interaction and Negative Magnetoresistance of the Spin-1/2 Pyrochlores R2V2O7 , HONGJUN XIANG, Fudan University, ERJUN KAN, M.-H. WHANGBO, C. LEE, North Carolina State University, SU-HUAI WEI, National Renewable Energy Laboratory, X.G. GONG, Fudan University — The electronic and magnetic properties of spin-1/2 pyrochlores $R_2V_2O_7$ were investigated on the basis of density-functional calculations. Contrary to the common belief, the spin-1/2 V^{4+} ions are found to have a substantial easy-axis single-ion anisotropy. The $|D/J|$ ratio deduced from the magnon quantum Hall effect of $Lu_2V_2O_7$, where J is the nearest-neighbor spin exchange and D is the Dzyaloshinskii-Moriya parameter, is much greater than the value estimated from our calculations (i.e., 0.32 vs. 0.05). We show that this discrepancy is due to the neglect of the single-ion anisotropy of the V^{4+} ions, and the negative magnetoresistance observed for $R_2V_2O_7$ arises from a new mechanism.

12:15PM J17.00006 Stability of the $Ni_3V_2O_8$ phase diagram on substitution with magnetic and non-magnetic transition metal ions , AKILA KUMARASIRI, AMBESH DIXIT, GAVIN LAWES, Wayne State University — There is considerable interest in understanding the materials properties underlying the development of simultaneous magnetic and ferroelectric order in multiferroics. $Ni_3V_2O_8$ develops strongly coupled ferroelectric and antiferromagnetic order simultaneously at low temperatures and has a rich magnetic phase diagram due to competing magnetic interactions. We investigated how the magnetic phases of $Ni_3V_2O_8$ were affected by systematic doping by transition metal ions. For these studies, polycrystalline $Ni_3V_2O_8$ samples substituted by various concentrations of transition metal ions M (M = Zn, Cu, Co, Mn, Fe) were prepared. Heat capacity, magnetization, dielectric, AC susceptibility, and pyrocurrent measurements were used to track the change in phase transition temperatures. On doping with spin-0 Zn, the system behaves as expected for site dilution consistent with 2-D spins, where the phase transition temperatures are suppressed linearly to lower temperatures. The modifications to the phase diagram for magnetic dopants (Co, Cu, Mn and Fe) show more variation, but the multiferroic phase transition appears to persist over a range of concentrations. This suggests that the specific spin structure in $Ni_3V_2O_8$ responsible for the development of ferroelectric order is relatively robust against perturbations produced by both magnetic and non-magnetic dopants.

12:27PM J17.00007 Orbitally driven trimerization in $LiVO_2$ and $LiVS_2$: a "partial Mott transition" , HUA WU, D.I. KHOMSKII, University of Cologne, Germany — Layered triangular-lattice transition-metal compounds often display interesting magnetic and electronic properties. Here we studied the formation of the trimerized spin-singlet state of the V^{3+} (S=1) in vanadates $LiVO_2$ and $LiVS_2$ and their electronic structure with a special orbital order, using constrained LSDA+U calculations combined with lattice optimization. The obtained results show that the trimerization distortion in $LiVO_2$ increases as the effective U decreases, and the calculated distortion of $\sim$0.3 Å at the small U=1 eV agrees well with the experiments, indicating that $LiVO_2$ is close to a metal-insulator transition. The corresponding distortion in $LiVS_2$ is even stronger, being $\sim$0.4 Å at the U=1 eV, which is due to enhanced electron delocalization via increased V-S covalency, in spite of a lattice expansion. This agrees with the experimental finding that $LiVS_2$ has a metal-insulator transition. The calculated energy gain associated with the trimerization well accounts for the observed structural phase transition temperature in $LiVO_2$ and $LiVS_2$. We conclude that the trimerization in $LiVO_2$ and $LiVS_2$ is due to a partial delocalization of the orbitally ordered electrons—a "partial Mott transition," occurring not in the whole system but in small clusters (here in trimers). This situation is contrasted with that in $NaVO_2$, which is further away from the localized-itinerant crossover and thus remains insulating with different orbital ordering.

12:39PM J17.00008 Simultaneous electrical transport and Raman spectroscopic measurements on individual nanowires of $W_xV_{1-x}O_2$, TAI-LUNG WU, Department of Physics, University at Buffalo-SUNY, LUISA WHITTAKER, C.J. PATRIDGE, S. BANERJEE, Department of Chemistry, University at Buffalo-SUNY, G. SAMBANDAMURTHY, Department of Physics, University at Buffalo-SUNY — Vanadium oxide is a well-know material to study the metal-insulator transition (MIT) in correlated electron systems. Upon heating to about 340 K, VO_2 undergoes orders of magnitude drop in resistance from an insulating phase (I) to a metallic phase (M) and accompanies a lattice structural phase transition from a low-temperature monoclinical phase (M1) to a high-temperature tetragonal phase (R). We present results from combined electrical transport and Raman spectroscopic measurements to discern the effects of doping in controllably tuning the MIT in individual nanowires of single crystal $W_xV_{1-x}O_2$. The MIT temperature (T_c) in our $W_xV_{1-x}O_2$ nanowires can be tuned through a wide range from 280 to 330 K by controlling the dopant concentration. The M-I transition can also driven electrically in these nanowires. Our simultaneous measurement of electrical transport and Raman spectroscopic measurement help us understand the role of structural transition in affecting the macroscopic electrical transition in individual wires.

12:51PM J17.00009 Strain- and temperature-induced phase transitions in single crystalline VO_2 , JOANNA ATKIN, University of Colorado, Boulder, EMILY CHAVEZ, University of Washington, SAMUEL BERWEGER, University of Colorado, Boulder, JINBO CAO, WEN FAN, JUNQIAO WU, University of California, Berkeley, MARKUS RASCHKE, University of Colorado, Boulder — The metal-insulator transition (MIT) of VO_2 exhibits a rich phase behavior involving two monoclinic (M1, M2), triclinic, and tetragonal phases that can form a complex domain structure and accompany the electronic transition. The interplay between these structural variants arises from strain due to differing lattice constants, temperature-dependent phase stability, and possible external strain from the substrate; the coupling between these effects renders a systematic study of the phase behavior difficult. We report on phase mapping of the structural changes through independent control of temperature and uniaxial strain in individual single-crystal nanorods, using Raman spectroscopy and near-field imaging. This allows us to investigate the transformation between the various insulating phases, elucidating the nature of the triclinic phase as a continuously distorted variant of the M1 monoclinic phase, intermediate in the first-order transformation into the monoclinic M2 phase.

1:03PM J17.00010 Discrepancy of structural and electronic transitions in the vicinity of the Metal-Insulator-transition in V_2O_3 , HYUN-TAK KIM, ETRI and UST in Korea, JUN-HWAN SHIN, University of Science and Technology, JUNG-YOUNG CHOI, BONG-JUN KIM, ETRI — Vanadium sesquioxide (V_2O_3), representative of strongly correlated electronic system, has been known as undergoing the MIT (Metal-Insulator-Transition) which is between rhombohedral paramagnetic metallic phase and monoclinic antiferromagnetic insulating phase near the transition temperature, (T_c) ≈150 K. In order to reveal a relation between electronic and structural atomic transition, we has measured the temperature dependence of DC conductivity and structural crystallographic characterization with various temperatures from 90 K to 300 K by using low-temperature X-Ray diffraction (LTXRD). The obtained results show a discrepancy of structural and electronic transitions. This discrepancy can be explained by forming of the metallic puddles whose the size and number increased by nucleation and percolation[1,2] during the electronic transition progress from 120 K to 180 K. The puddles have an insulating monoclinic structure before the structural phase transition at ∼185 K. These metallic puddles are induced by the MIT not related to the SPT (structure phase transition). (1. M. M. Qazilbash et al., Science 318, 1750 (2007); 2. B. J. Kim et al., Phys. Rev. B 77, 235401(2008))

1:15PM J17.00011 Interplay of chemical pressure and spin degrees of freedom on the magnetic properties of the $A\mathbf{Ag}_2M[\mathbf{VO}_4]_2$ type of compounds[1] , ANGELA MÖLLER, NGOZI AMUNEKE, PHILLIP DANIEL, DANA GHEORGHE, Department of Chemistry and Texas Center for Superconductivity, University of Houston, TX, USA, BERND LORENZ, Texas Center for Superconductivity and Department of Physics, University of Houston, TX, USA — A series of layered compounds of the $A\mathrm{Ag}_2M[\mathrm{VO}_4]_2$ type of structures, featuring the magnetic ions on a triangular lattice, have been synthesized by solid state reactions. Studies on the interplay of i) the chemical pressure induced by the differences in cation sizes (A^{II} = Sr, Ba) and ii) the spin system (M^{II} = Mn, Co, Ni, Cu) provide further insights into the structure-properties relationships which have been investigated by specific heat and magnetization measurements. Furthermore, spectroscopic methods have been employed to evaluate vibrational and electronic structural aspects in detail.

[1]We thank the Welch Foundation (Grant G099857) for support.

1:27PM J17.00012 Trimer Formation and Metal-Insulator Transition in Triangular-Lattice Systems $\mathbf{LiV}X_2$ (X=O,Se,S) , JUNKI YOSHITAKE, YUKITOSHI MOTOME, Dept. of Appl. Phys., Univ. of Tokyo — Geometrically-frustrated systems sometimes lift their degeneracy by spontaneous formation of multisite clusters via coupling to other degrees of freedom. A fascinating example is found in a triangular-lattice system $LiVO_2$, which exhibits a three-site trimer formation. The origin was argued to be an orbital ordering under strong electronic correlation [1], however, recent experiments on a series of $LiVX_2$ (X=O,Se,S) suggest that the system is intermediately correlated and rather close to a metal-insulator transition [2]. In this contribution,we revisit this problem within a multiorbital Hubbard model in a wide range of Coulomb interaction by strong-coupling perturbation and Hartree-Fock approximation. We find a new trimer state under substantial trigonal crystal-field splitting; it is located in the vicinity of a metal-insulator transition and not adiabatically connected to the trimer state previously proposed. We discuss the origin of this new trimerization and the relation to experimental results.

1:39PM J17.00013 ABSTRACT WITHDRAWN –

1:51PM J17.00014 Electronic Excitations in Vanadates[1] , WILLIAM THORNTON, Unversity of Tennessee, ANTON KOZHEVNIKOV, ETH Institute for Theoretical Physics, ADOLFO EGUILUZ, University of Tennessee — Vanadates represent an electronic analogue to the cuprates, which have one hole in the 3d shell. There are many realizations of the vanadates, as the solid-state chemistry of the V-O system allows various coordination numbers. Here we probe the electronic structure of vanadates by studying neutral electronic excitations computed within a time-dependent density functional theory framework. We evaluate the dynamical electronic response in both a Bloch basis and a Wannier basis, for both large momentum transfers, and in the optical limit. We compare our results with available experimental data, and assess the importance of many-body (excitonic) interactions.

2:03PM J17.00015 A microscopic view on the Mott transition in chromium-doped V_2O_3 , G. SANGIOVANNI, Institute of Solid State Physics, Vienna University of Technology, Austria, S. LUPI, L. BALDASSARRE, D. NICOLETTI, M. MARSI, P. HANSMANN, N. PARRAGH, A. TOSCHI, T. SAHA-DASGUPTA, O.-K. ANDERSEN, K. HELD — V_2O_3 is the prototype system for the Mott transition, one of the most fundamental phenomena of electronic correlation. Temperature, doping or pressure induce a metal-to-insulator transition (MIT) between a paramagnetic metal (PM) and a paramagnetic insulator. This or related MITs have a high technological potential, among others, for intelligent windows and field effect transistors. However the spatial scale on which such transitions develop is not known in spite of their importance for research and applications. Here we unveil for the first time the MIT in Cr-doped V_2O_3 with submicron lateral resolution: with decreasing temperature, microscopic domains become metallic and coexist with an insulating background. This explains why the associated PM phase is actually a poor metal. The phase separation can be associated with a thermodynamic instability near the transition. This instability is reduced by pressure, that promotes a genuine Mott transition to an eventually homogeneous metallic state.

Session J18 GMAG DMP: Focus Session: Low D/Frustrated Magnetism - Molecular Magnets I D172

11:15AM J18.00001 Magnetic field-induced XY-AFM in 2D Heisenberg Antiferromagnet $[Cu(pyz)_2(pyO)_2](PF_6)$, YOSHIMITSU KOHAMA, NHMFL, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, MARCELO JAIME, NHMFL, Los Alamos National Laboratory, Los Alamos NM 87545, USA, JAMIE MANSON, Dept. of Chem. and Biochem., E. Washington Univ., Cheney, WA 99004, USA — Specific heat (C_p) and magnetic susceptibility (χ) measurements were performed on the two-dimensional spin-1/2 Heisenberg antiferromagnet $[Cu(pyz)_2(pyO)_2](PF_6)_2$ in DC and pulsed magnetic fields up to H = 15 T and 40 T, respectively [1]. We observe no long-range magnetic order down to 500 mK in zero applied magnetic field, suggesting that $[Cu(pyz)_2(pyO)_2](PF_6)_2$ is close to an ideal 2D AFM and instead undergoes a Berezinskii-Kosterlitz-Thouless (BKT) transition. However, the application of a finite magnetic field induces a clear anomaly in C_p, although not in χ. This behavior is known to be a remarkable signature of magnetic field induced XY-AFM [2]. In addition, C_p(H) measurements in pulsed fields, performed down to T = 1.5 K and up to H = 40 T, were used to map out the asymmetric Field-Temperature phase diagram which provides additional support for an ideal realization of field-induced XY-AFM in $[Cu(pyz)_2(pyO)_2](PF_6)_2$.

11:27AM J18.00002 Pressure-induced Jahn-Teller axis switching in $Cu(pyz)F_2(H_2O)_2$? , J.L. MUSFELDT, University of Tennessee, Z. LIU, Carnegie Institute of Washington, S. LI, Virginia Commonwealth University, J. KANG, C. LEE, North Carolina State University, P. JENA, Virginia Commonwealth University, J.L. MANSON, Eastern Washington University, J.A. SCHLUETER, Argonne National Laboratory, G.L. CARR, Brookhaven National Laboratory, M.-H. WHANGBO, North Carolina State University — We employed infrared spectroscopy along with complementary lattice dynamics and spin density calculations to investigate local structure and magnetism through the series of pressure-driven transitions in $Cu(pyz)F_2(H_2O)_2$. Rather than frequency shifts that dovetail with the recently proposed pressure-induced Jahn-Teller switching model, we overall mode hardening, particularly in the Cu–OH_2 bending mode. We combine these findings with a reanalysis of the crystal structure to reveal the series of pressure-induced transitions as a combination of a-axis rotation, c-directed compression that acts to weaken O-H...F hydrogen bonds, and pyrazine ring buckling. The magnetic dimensionality crossover can be understood in terms of changes in magnetic orbital overlap.

11:39AM J18.00003 Lost and found: The missing diabolical points in the Fe_8 molecular magnet[1] , FEIFEI LI, ANUPAM GARG, Northwestern University — The tunneling spectrum of the single-molecule-magnet Fe_8 is known to have diabolical points (DP's). For magnetic fields along the hard axis, there are four such points for tunneling between the ground pair of levels, whereas the simplest model including only second-order anisotropy would predict ten DP's. The difference is due to a very weak fourth-order anisotropy, which in a semiclassical picture generates instantons with endpoint discontinuities, one of which dominates for large enough fields, and having no interfering partner, causes six of the underlying DP's to go away. However, as shown by Bruno, the six missing DP's do not truly disappear, but merely move off the hard axis into the hard-medium plane. In this talk, we report on a numerical search for these "missing" DP's. This search is nontrivial because the energy surface is like a smooth golf course, on which the DP's are extremely localized and deep holes. We therefore locate the DP's by following the lines of the Berry curvature which have monopole singulairities at the DP's. This exercise is performed for tunneling between excited pairs of levels also. An experimental observation of the rediscovered DP's would be an important test of the underlying spin Hamiltonian for Fe_8. (Submitted to the arxiv: Nov. 18, 2010.)

11:51AM J18.00004 Magnetic Superatoms[1] , J. ULISES REVELES, VICTOR M. MEDEL, A.C. REBER, S.N. KHANNA, Virginia Commonwealth University, V. CHAUHAN, P. SEN, Harish-Chandra Research Institute, DEPARTMENT OF PHYSICS, VIRGINIA COMMONWEALTH UNIVERSITY COLLABORATION, HARISH-CHANDRA RESEARCH INSTITUTE COLLABORATION — The electronic states in metal clusters are grouped in shells much in the same way as in atoms. Filling of the electronic shells leads to stable species called magic numbers. This has led to the preposition that selected stable metal clusters can mimic chemical properties of atoms on the periodic table and can be classified as superatoms. Here, we propose an extension of the superatom concept to magnetic species by invoking systems that hybridize localized and delocalized electronic states. Through first principles studies focusing on the electronic structure and magnetic moment, we show that $TMMg_n$ (TM = Sc, Ti, V, Cr, Mn, Fe, Co, and Ni) clusters exhibit a new class of magnetic superatoms stabilized by magnetic supershells. The talk will include possible applications of the new building blocks.

12:03PM J18.00005 Tunnel-diode Resonator Spectroscopy of Quantum Levels in $Cr_{12}Ln_4$ (Ln=Y,Eu,Gd,Tb,Dy,Ho,Yb) Magnetic Molecules , STEVEN YENINAS, MARSHALL LUBAN, RUSLAN PROZOROV, Ames Laboratory, Ames, IA, 50011, WILLIAM A. CONIGLIO, CHARLES C. AGOSTA, Dept. of Physics, Clark University, Worcester, MA 01610, LARRY ENGELHARDT, Dept. of Physics and Astronomy, Francis Marion University, Florence, SC 29501, GRIGORE A. TIMCO, RICHARD E.P. WINNPENNY, School of Chemistry, University of Manchester, Manchester, UK — The differential magnetic susceptibility for a series of $Cr_{12}Ln_4$ (Ln=Y,Eu,Gd,Tb,Dy,Ho,Yb) magnetic molecules was measured in static (up to 16 T) and pulsed (up to 45 T) magnetic fields using a rf tunnel-diode resonator (TDR). At low temperatures, the behavior of these finite spin systems is governed by discrete energy spectra of the individual molecules. In magnetic field, low-energy quantum levels Zeeman-split, crossing at field values where magnetization exhibits a step corresponding to switching between different spin states. In high fields, we detect multiple level crossings which allow for a detailed mapping of the energy diagram. We then perform quantum Monte Carlo (QMC) using a Heisenberg Hamiltonian with three adjustable exchange constants whose values are chosen so as to optimize agreement with the experimental energy spectrum. The variations in results for the studied molecules are correlated to the magnetic properties of the lanthanide ions.

12:15PM J18.00006 Spin-electric coupling in Cu_3, V_{15} and other frustrated molecular magnet rings: a first principle study , M.F. ISLAM, J.F. NOSSA, C.M. CANALI, Linnaeus University, M.R. PEDERSON, Naval Research Laboratory — Frustrated triangular single-molecule magnets (SMMs) without inversion symmetry, such as Cu_3 and V_{15}, are characterized by a doubly degenerate S=1/2 ground-state (GS) with opposite chirality. Recently it has been proposed theoretically [1] and verified by ab-initio calculations [2] that an external electric field can couple these two chiral spin states, even in the absence of spin-orbit interaction (SOI). The efficiency of these coupling depends on the electric dipole moment between chiral states. In this talk we report on first-principle calculations of the coupling strength for the triangular SMMs Cu_3 and V_{15}. The spin-electric coupling is found to be considerably stronger in V_{15} than in Cu_3. We discuss the mechanism leading to an enhanced spin-electric coupling, which can be used as a convenient guide to synthesize SMMs that can respond more efficiently to an external electric field.

12:27PM J18.00007 ABSTRACT WITHDRAWN –

12:39PM J18.00008 Magnetic anisotropy and high-spin effects in single-molecule transistors , ALEXANDER ZYAZIN, TU Delft, JOHAN VAN DEN BERG, EDGAR OSORIO, NIKOS KONSTANTINIDIS, MARTIN LEIJNSE, FALK MAY, WALTER HOFSTETTER, CHIARA DANIELI, ANDREA CORNIA, MAARTEN WEGEWIJS, HERRE VAN DER ZANT — Fabrication of single-molecule transistors where electron transport occurs through an individual molecule has become possible due to the recent progress in molecular electronics. Three-terminal configuration allows charging molecules and performing transport spectroscopy in multiple redox states. Single-molecule magnets combining large spin with uniaxial anisotropy are of special interest as appealing candidates for high density memory applications and quantum information processing. We study single-molecule magnets Fe_4. Three-terminal junctions are fabricated using electromigration of gold nanowires followed by a self-breaking. High-spin Kondo effect and inelastic cotunneling excitations show up in transport measurements. Several excitations feature the energy close to the energy of zero-field splitting (ZFS) of a ground spin multiplet in bulk. This splitting is caused by the anisotropy and is a hallmark of single-molecule magnets. We observe nonlinear Zeeman effect due to a misalignment of an anisotropy axis and a magnetic field direction. The ZFS energy is increased in oxidized and reduced states of the molecule indicating enhancement of the anisotropy in these states.

12:51PM J18.00009 Magneto-optical spectroscopic studies of solid and solution-phase tetraphenyl porphyrin[1] , JACOB WAHLEN-STROTHMAN, ZHEN WEN PAN, LANE MANNING, MADALINA FURIS, KELVIN CHU, University of Vermont — Tetraphenylporphyrin (TPP) is a synthetic heterocyclic compound that serves as a model system for heme proteins and cytochromes. TPP can accomodate a metal ion in the center; D-shell ion porphyrin complexes with a crystalline solid phase are of interest for magnetic studies because of the possibility of macroscopic long range magnetic order of the ion spins. We have investigated the 5K magnetic properties of poly-crystalline thin films of the heme protoporphyrin IX analogue tetra-phenyl porphyrin, complexed with Zn and Mn, deposited through a capillary pen technique that produces 100um to 1 mm sized grains. Our novel experimental setup measures the UV/VIS, linear dichroism and magnetic circular dichorism simultaneously, incorporates a photoelastic modulator and a microscopy superconducting magnet for high-field (5T) measurements. We present solution and crystalline data on metal-complexed TPP; data are analyzed in terms of A and B-type MCD using a perimeter model. We find good agreement with previous solution data, and novel crystalline phase spectra that are correlated to the long range ordering.

1:03PM J18.00010 Chiral molecule for spin filtering purposes: the study of L- and D-Alanine[1] , ESMERALDA YITAMBEN, Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL 60439, RICHARD ROSENBERG, Advanced Photon Source, Argonne National Laboratory, Argonne, IL 60439, NATHAN GUISINGER, Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL 60439 — The field of molecular electronics has attracted scientists by the great opportunities and versatility it offers as a replacement for standard semiconductor electronics with organic materials, thus bringing down the cost, and opening endless possibilities for chemical synthesis, and scientific breakthrough. Of particular interest is the use of chiral molecules, such as alanine, for spin filtering studies in hope of creating highly spin-polarized charge carriers for spintronics applications. Preliminary studies of both L- and D-alanine on Cu(111) were conducted using scanning tunneling microscopy and spectroscopy, revealing the formation of a 2-dimensional phase at low coverage, a hexagonal "flower" pattern at intermediate coverage, and a chain and ring superstructures at high coverage. A model is proposed to explain the surface chemistry and bonding of the molecules on the metallic surface. Current studies of L- and D-alanine on Fe/W show promises in the intermediate coverage regime.

1:15PM J18.00011 DFT and STM studies of magnetism in single Co(TCNE) complexes on an ultrathin insulating film[1] , M. BADAL, T. CHOI, D. STROUD, J.A. GUPTA, Ohio State U. — We present results from large-scale ab initio DFT calculations for geometry and electronic structure of Co(TCNE) complexes on a c$(2 \times 2)$$Cu_2N$ substrate. The long-term aim is to study charge and spin transport in molecular systems. The work is done in concert with STM experiments. In particular, we perform calculations to help explain STM observations indicating that the electronic and magnetic properties of Co(TCNE) complexes vary with apparent molecular orientation. Using plane wave DFT with a GGA functional and spin polarization, we perform geometry optimization to identify the most commonly seen orientations of Co(TCNE). We further study the resulting electronic structure, using calculated LDOS and simulated STM images, to compare with observations. To study the strong in-plane magnetic anisotropy suggestd by spin-flip spectroscopy, we do noncollinear magnetic calculations on the relaxed structure, including spin-orbit coupling effects.

[1]Supported by NSF MRSEC, Grant No. DMR08-20414.

1:27PM J18.00012 Non-equilibrium transport through a single molecular Kondo impurity in a scanning tunneling microscope junction , UNGDON HAM, Department of Physics and Astronomy, University of California, Irvine, WILSON HO, Department of Physics and Astronomy and Department of Chemistry, University of California, Irvine — An unpaired spin from a single electron trapped in a molecular orbital in a double barrier scanning tunneling microscope (STM) junction at sub-Kelvin temperature and high magnetic field showed a non-equilibrium transport through a Kondo impurity. Hysteresis and switching in a conductance allows the spin and charge state of the molecule in the junction to be controlled. Mechanically tuning the coupling of the single spin to STM tip showed a gradual change from lowest order spin-flip inelastic tunneling spectroscopy (IETS) to the Kondo resonance. Using the imaging capability of STM, we observed clear sub-molecular node structures of the spin-flip IETS and the Kondo resonance.

1:39PM J18.00013 Electronic transport through single-molecule magnets by scanning tunneling spectroscopy , SIMRANJEET SINGH, Department of Physics, University of Central Florida, Orlando, Fl, JYOTI KATOCH, Department of Physics and NanoScience Technology Center, University of Central Florida, Orlando, Fl, TAKETO TAGUCHI, GEORGE CHRISTOU, Department of Chemistry, University of Florida, Gainesville, Fl, MASA ISHIGAMI, Department of Physics and NanoScience Technology Center, University of Central Florida, Orlando, Fl, ENRIQUE DEL BARCO, Department of Physics, University of Central Florida, Orlando, Fl — Atomic structure of molecules and electrodes are expected to sensitively influence the properties of molecular spintronics devices. We have studied the transport properties of individual Mn_4 single-molecule magnets bound to a surface using atomic force and scanning tunneling microscopy at cryogenic temperatures Unlike previous scanning probe microscopy experiments, we are able to continuously tune the density of states of individual molecules using novel device geometries in-situ We will discuss transport properties of single-molecule magnets as a function of their atomic structure, coupling to electrodes and the Fermi levels.

1:51PM J18.00014 Magnetic excitations from an S=1/2 antiferromagnetic tetramer system Cu_2PO_4OH , M. MATSUDA, D.L. ABERNATHY, Neutron Scattering Science Division, Oak Ridge National Laboratory, K. TOTSUKA, Yukawa Institute for Theoretical Physics, Kyoto University, Japan, A.A. BELIK, National Institute for Materials Science, Japan — Cu_2PO_4OH is a candidate material for the S=1/2 diamond-shaped antiferromagnetic tetramer system.[1] The magnetic susceptibility shows a spin-gap behavior and the exchange interaction J was estimated to be 138 K. Since there have not been so many experimental studies in the spin tetramer systems, it is important to clarify the magnetism in this compound. We have performed inelastic neutron scattering experiments on a powder sample of Cu_2PO_4OH on a chopper neutron spectrometer ARCS installed at SNS at ORNL in order to study the magnetic excitations from the tetramer spin system. We have clearly observed two magnetic excitations at ∼12 and ∼20 meV, whose widths in energy are broader than the instrumental resolution. It was found that the energy levels cannot be explained with the simple antiferromagnetic tetramer model with only nearest-neighbor interaction. We will discuss the results including further-neighbor interactions.

2:03PM J18.00015 High-field EPR study of a $ReCl_4(CN)_2$ molecular magnet building block , JUNJIE LIU, Department of Physics, University of Florida, T. DAVID HARRIS, JEFFREY LONG, Department of Chemistry, University of Californian, Berkeley, STEPHEN HILL, NHMFL and Department of Physics, Florida State University — Slow magnetic relaxation has been observed in the single-chain magnet $(DMF)_4MReCl_4(CN)_2$ (M = Mn, Fe, Co, Ni) [D. Harris *et al.*, J. Am. Chem. Soc. **132**, 3980 (2010)]. The $ReCl_4(CN)_2$ **(1)** molecule has been synthesized in which the local environment of the Re^{IV} ion is same as in the single-chain magnet. Electron Paramagnetic Resonance (EPR) measurements have been performed on single crystal of complex **1** to determine the magnetic anisotropy of the Re^{IV} ions. Both intra and inter Kramer's doublet transitions are observed in high-field (up to 36T) EPR experiments. The data indicate a significant axial anisotropy of the easy-plane type ($D > 0$), with sizeable rhombic E term. In light of these findings, we are developing a theoretical model to account for the slow relaxation in the single-chain magnet.

Tuesday, March 22, 2011 11:15AM - 2:15PM –

Session J19 GMAG DMP FIAP: Focus Session: Spin Transport & Magnetization Dynamics in Metals IV D170

11:15AM J19.00001 Vortex-Core Reversal Dynamics: Towards Vortex Random Access Memory , SANG-KOOG KIM, Seoul National University — An energy-efficient, ultrahigh-density, ultrafast, and nonvolatile solid-state universal memory is a long-held dream in the field of information-storage technology. The magnetic random access memory (MRAM) along with a spin-transfer-torque switching mechanism is a strong candidate-means of realizing that dream, given its nonvolatility, infinite endurance, and fast random access. Magnetic vortices in patterned soft magnetic dots promise ground-breaking applications in information-storage devices, owing to the very stable twofold ground states of either their upward or downward core magnetization orientation and plausible core switching by in-plane alternating magnetic fields or spin-polarized currents. However, two technologically most important but very challenging issues — low-power recording and reliable selection of each memory cell with already existing cross-point architectures — have not yet been resolved for the basic operations in information storage, that is, writing (recording) and readout. Here, we experimentally demonstrate a magnetic vortex random access memory (VRAM) in the basic cross-point architecture. This unique VRAM offers reliable cell selection and low-power-consumption control of switching of out-of-plane core magnetizations using specially designed rotating magnetic fields generated by two orthogonal and unipolar Gaussian-pulse currents along with optimized pulse width and time delay. Our achievement of a new device based on a new material, that is, a medium composed of patterned vortex-state disks, together with the new physics on ultrafast vortex-core switching dynamics, can stimulate further fruitful research on MRAMs that are based on vortex-state dot arrays.

11:51AM J19.00002 Dynamics of coupled vortices in spin-valve nanostructures , PAOLO BORTOLOTTI, N. LOCATELLI, V. CROS, J. GROLLIER, Unité Mixte de Physique CNRS/Thales, Palaiseau, France, V.V. NALETOV, G. DE LOUBENS, CEA-SPEC Saclay, Gif-sur-Yvette, France, C. ULYSSE, G. FAINI, CNRS Phynano team, Marcoussis, France, O. KLEIN, CEA-SPEC Saclay, Gif-sur-Yvette, France, A. FERT, Unité Mixte de Physique CNRS/Thales, Palaiseau, France — Recently, vortex dynamics driven by spin-transfer torque have been considered for new generation of nano-oscillators and memory devices. In this work we study the coupled vortex dynamics in FeNi(15nm)/Cu(10nm)/FeNi(4nm) samples where one single vortex state is favoured in both magnetic layers. Our experimental data are in good agreement with the corresponding simulations obtained through a 3D spin diffusion approach. Each vortex is characterized by a given chirality and polarity controllable separately by varying the external field (both in-plane and out-of-plane) and by applying a DC current perpendicular to the sample plane. The system modes are detected by static magneto-transport and microwave emissions analysis. In particular, it can be shown that vortex dynamics with large power appear only for configuration characterized by vortex cores pointing in opposite directions. The coupling of those two vortices allows to reach very narrow peak linewidth (down to 50 kHz), two order of magnitude smaller than in the uncoupled case.

12:03PM J19.00003 Statistical Behavior of Formation Process of Magnetic Vortex State in Permalloy Nanodisks[1] , MI-YOUNG IM, PETER FISCHER, cxro/lbnl, YAMADA KEISUKE, Kyoto Univ., SHINYA KASAI, nims — Magnetic vortices in magnetic nanodots, which are characterized by an in-plane (chirality) and an out-plane (polarity) magnetizations, have been intensively attracted because of their high potential for technological application to data storage scheme and their scientific interest for an understanding of fundamental physics in magnetic nanostructures. Complete understanding of the formation process of vortex state in magnetic vortex systems is very important issue in both technical and scientific points of view. In our work, we have statistically investigated the formation process of vortex state in permalloy ($Ni_{80}Fe_{20}$) nanodisks through the direct observation of vortex structure utilizing a magnetic transmission soft X-ray microscopy (MTXM) with a high spatial resolution down to 20 nm. We found a particular selectivity between the circulation sense of chirality and orientation sense of polarity for each other in the formation process of vortex state. Dzyaloshinskii-Moriya interaction inevitably generated in magnetic nanodisks is mainly responsible for the experimentally witnessed selectivity between chirality and polarity.

[1]This work was supported by the Director, Office of Science, Materials Sciences and Engineering Division, of the U.S. Department of Energy.

12:15PM J19.00004 Imaging Magnetic Normal Modes Driven by Spin Transfer Torque in Magnetic Nanopillars using Soft X-ray Microscopy[1] , YONG-TAO CUI, LIN XUE, Cornell University, PETER FISCHER, MI-YOUNG IM, Center for X-ray Optics, Lawrence Berkeley National Laboratory, R.A. BUHRMAN, D.C. RALPH, Cornell University — Motivated by the desire to understand the spatial structure of the high-frequency dynamical magnetic modes that can be excited by spin transfer from spin-polarized currents, we report measurements using X-ray microscopy to image magnetic normal modes in nanopillar devices resonantly excited by spin torque from a microwave frequency current. The frequency of the microwave current is phase locked to the incident X-ray pulses. We achieve 70 ps time resolution and 25 nm spatial resolution, enabling us to study the spatial configuration of the magnetization throughout the cycle of resonant magnetization dynamics. We will discuss the initial results of our measurements and comparisons with micromagnetic simulations.

[1]This work was supported by the U.S. Department of Energy under Contract No. DE-AC02-05-CH11231.

12:27PM J19.00005 Voltage-controlled Spin Wave Logic Device: Ring Interferometer[1] , TIANYU LIU, Department of Physics and Astronomy, GIOVANNI VIGNALE, Department of Physics and Astronomy, University of Missouri-Columbia — Spin wave logic circuitry transmits information by propagating spin waves along magnetically insulating wave guides. This is less power-consuming than ordinary circuits and is expected to work at THz frequency and room temperature. Logical operations are performed by modulating the interference of spin waves through a phase shifter. A great deal of effort has been devoted to the problem of controlling the phase of spin waves by means of a spatially varying magnetic field, either extrinsic or intrinsic (i.e., by passing the spin wave through a non-uniform magnetic texture). Here we introduce a new approach, which exploits the response of spin waves to an external *electric field* via the spin-orbit coupling of this electric field to the electrons that mediate the magnetic interaction. Based on the Heisenberg Hamiltonian modified by spin-orbit coupling, we show how a ring interferometer made of a magnetic insulator (e.g, YIG) can be used to implement NOT logic (and other logic functions) under voltage control.

12:39PM J19.00006 Phenomenology of Current-Induced Dynamics in Antiferromagnets[1] , KJETIL M.D. HALS, Department of Physics, Norwegian University of Science and Technology, NO-7491, Trondheim, Norway, YAROSLAV TSERKOVNYAK, Department of Physics and Astronomy, University of California, Los Angeles, California 900095, USA, ARNE BRATAAS, Department of Physics, Norwegian University of Science and Technology, NO-7491, Trondheim, Norway — In antiferromagnets, an electric current can induce a torque on the staggered magnetization. We derive a novel phenomenology of current-induced dynamics in antiferromagnets. The theory includes effects of damping, external magnetic fields, and both adiabatic and non-adiabatic current-induced torques. We apply our theory to an antiferromagnetic domain wall system, and find an analytic solution for the domain wall motion in the low current density regime. In this regime, the domain wall velocity is proportional to the ratio between the non-adiabatic torque and the damping coefficient. In addition, the domain wall develops a net magnetic moment. This opens the route to an alternative way to observe current-induced effects in antiferromagnets.

[1]This work was partially supported by the European Union FP7 grant no. 251759 "MACALO."

12:51PM J19.00007 Temperature dependence of domain wall dynamics in Permalloy nanowires , JUSANG YANG, JAMES L. ERSKINE, Department of Physics, The University of Texas at Austin — Current-driven [1] and current-assisted field-driven [2] domain wall dynamics in ferromagnetic nanowires have the thermal effects resulting from Joule heating, which make difficult to separate the spin-torque effects on domain wall displacements. To understand the thermal effects on domain wall dynamics, temperature dependence of field-driven domain wall velocity was studied using high-bandwidth scanning Kerr polarimetry. Domain wall velocity curves of 20 nm thick Permalloy nanowires with various widths (from 400 nm to 1000 nm) were measured with increasing temperature from 300 K to 400 K. Walker critical fields decreased with increasing temperature, which can be attributed to thermal excitations, and temperature-induced stochastic dynamics mode changes were observed. The results will be discussed in relation to internal domain wall structures.

1:03PM J19.00008 Voltage induced by domain wall motion in a ferromagnetic nanowire[1] , YANG LIU, OLEG TRETIAKOV, ARTEM ABANOV, Department of Physics, Texas A&M University — We study current-induced domain-wall motion in a narrow ferromagnetic wire. This motion is described by effective equations of motion which depend only on four parameters. These parameters are set by the magnetic Hamiltonian and the shape of the wire. We propose a new way to measure these parameters by measuring time dependent voltage generated by the domain wall motion.

[1] This work was supported by the NSF Grant No. 0757992 and Welch Foundation (A-1678).

1:15PM J19.00009 Discrete positioning of domain walls due to localized pinning sites in current driven motion along nanowires , XIN JIANG, LUC THOMAS, RAI MORIYA, STUART PARKIN, IBM ALMADEN RESEARCH CENTER, SAN JOSE, CA 95120, USA TEAM — Current driven domain wall motion is studied in spin-valve nanowires. The position of the domain wall after nanosecond long driving current pulses is determined with an accuracy of better than 50 nm by measuring the resistance of the nanowire. Although the domain wall displacement scales linearly with the current pulse length, its final position is discretized. This is attributed to relaxation of the domain wall into local pinning potential minima along the nanowire after the current pulse is turned off.

1:27PM J19.00010 Direct imaging of domain wall pinning in artificially created asymmetric potentials , D.E. READ, Imperial College London, L. O'BRIEN, University of Cambridge, S. LADAK, K. ZEISSLER, Imperial College London, T. TYLISZCZAK, Lawrence Berkeley National Lab, A.-V. JAUSOVEC, H.T. ZENG, E.R. LEWIS, J. SAMPAIO, Imperial College London, A. FERNANDEZ-PACHECO, D. PETIT, R.P. COWBURN, University of Cambridge, W.R. BRANFORD, Imperial College London — Domain walls (DWs) in ferromagnetic nanowires are ideal candidates for a wide variety of technological applications including high density data storage devices. To realise functional DW devices the processes associated with DW pinning must be understood and controlled. Magnetostatic pinning of DWs has already been observed experimentally using spatially resolved MOKE measurements. Using high resolution scanning transmission x-ray microscopy (STXM) we were able to directly image DWs in NiFe nanowires pinned in asymmetric potentials which were created by nano-patterning additional ferromagnetic wires perpendicular to the DW conduit. Tailoring the pinning potential in this way allows us to probe the rigidity of the DW in the region of the pinning site, increasing our understanding of DW deformation in magnetostatic traps and paving the way for future commercial applications.

1:39PM J19.00011 Spin-torque-driven ballistic switching with $<$ 50ps pulses , OUKJAE LEE, DAN RALPH, ROBERT BUHRMAN, Cornell University — Spin-torque-driven ballistic switching is a fast, energy-efficient, non-thermal operation in which the magnetization of a nanomagnet rotates from one equilibrium state to the other without any preceding small-angle precession. This reversal scheme can be implemented with a non-collinear structure in which the magnetic free layer is located between an out-of-plane spin polarizer and an in-plane polarizer. Both for achieving better fundamental understanding of magnetic dynamics and for realizing technological advances, it is desirable to demonstrate experimentally that the free layer can be reliably reversed with a current pulse as short as possible. Moreover it is necessary to achieve an asymmetrical response as the function of both the initial state and the pulse current polarity in order to obtain the desired final state with a simple unipolar pulse. We will discuss experimental results that show that the interval of pulse widths giving reliable switching is strongly dependent on the initial magnetic state and on the current. We will also discuss strategies to further improve ballistic switching operations.

1:51PM J19.00012 First-principles calculation of the photon-shortage mystery in femtosecond magnetism[1] , GUOPING ZHANG, Department of Physics, Indiana State University, MINGSU SI, Lanzhou University, YIHUA BAI, Indiana State University, T.F. GEORGE, University of Missouri-St. Louis — Laser-induced femtosecond magnetism needs photons to influence the magnetization in a sample, but there is a debate on whether the photon-shortage really exists [1]. Here we directly compute the number of photons used in ferromagnetic nickel, and we find that for nearly all the experiments, there are enough photons. The key is that one has to compute this number correctly using the surface instead of volume as a parameter [1,2]. Then we use the first-principles method to compute the magnetization for a fixed number of photons. Our results show that the number of photons is not a decisive factor, since for a fixed number, the laser amplitude and pulse duration can be changed systematically. We suggest that it is more appropriate to use the laser amplitude and pulse duration as two decisive parameters to characterize the role of photons, instead of the photon number. [1] M. S. Si and G. 2:03PM J19.00013 *Ab initio* investigation of ultrafast spin-manipulation: Λ processes in charged two-magnetic-center nanostructures with bridging atoms[1] , CHUN LI, Northwestern Polytechnical University, WEI JIN, GEORGIOS LEFKIDIS, WOLFGANG HÜBNER, Kaiserslautern University of Technology — We present a fully *ab initio* investigation of ultrafast laser-induced magnetic switching mechanisms in charged two-magnetic-center nanostructures via Λ processes [1,2]. In order to improve the spin transferability between the magnetic centers and fulfill the energy-difference requirements for the Λ processes [3], a small number of nonmagnetic bridging atoms (O and Mg) is used to connect the magnetic centers. These bridging atoms influence the overlap between the magnetic centers. It is shown that both bridging atoms can redistribute the spin density on the structure by changing either the local spin density or even the total spin localization. Especially, the spin-transfer scenario achieved in [Fe-O(Mg)-Co]$^+$ confirms that using bridging atoms can significantly enhance the spin transferability between the magnetic centers.

Session J20 FIAP: Optoelectronic Devices & Applications D168

11:15AM J20.00001 Scanning Ladar: Spatial Imaging Performance Through Turbulence , MAZEN NAIRAT, Physics Department, New Mexico State University, DAVID VOLEZ, SRINIVASU PUDI, Elecrical and Computer Engeering Department, New Mexico State University — The performance of scanning laser radar is studied for generating two-dimension spatial images at long ranges. Performance is described in terms of the Modulus Transfer Function (MTF). A simple analytic expression for the MTF associated with wave front tilt caused by propagation through atmospheric turbulence is explicitly derived. The derivation includes consideration of the influence of the Fresnel length. A physical optics simulation is employed to demonstrate the applicability of the MTF approach. The results are compatible with theoretical expressions that describe the image.

11:27AM J20.00002 Stimulated Terahertz Smith-Purcell Radiation in Planar Gunn Diodes , ALEXEY BELYANIN, DON D. SMITH, Department of Physics and Astronomy, Texas A&M University — We propose a room-temperature semiconductor source of coherent narrowband Smith-Purcell radiation (SPR) in the spectral range of 0.1-1.2 THz. Spontaneous SPR in semiconductors has been observed at low temperature with very low power. Practical vacuum SPR devices utilize a pre-bunched electron beam to achieve the stimulated mode of operation. However, electron bunches quickly dissipate in semiconductors. We propose to utilize the Gunn instability to form stable charge bunches (Gunn domains) that enable semiconductor sources of stimulated SPR. The device is a planar Gunn diode with a thin dielectric spacer layer and metallic grating deposited on the drift region. The SPR frequency is determined by the domain velocity and the grating period. In contrast to conventional Gunn diodes, the frequency is not limited by the transit time. Our calculations show that technologically relevant power density levels (1-100 nW per micrometer of device width) may be achieved by this method.

11:39AM J20.00003 Correlated photon fluctuations at the onset of first-order optical coherence , PATRICK FOLKES, Army Research Laboratory, Adelphi MD — We report the observation of correlated photon fluctuations over a narrow range of current at threshold of an interband cascade laser using single-detector photon noise measurements. The correlated photon noise is manifested by large fluctuations in the low-frequency photon noise spectral density at certain discrete frequencies which are sensitive to the laser gain characteristics. We observe the concurrent emergence and growth of the lasing mode over the same current range indicating that the correlated photon noise provides evidence of the occurrence of a change in the photon fluctuation statistics and the onset of first-order coherence in the laser emission.

11:51AM J20.00004 Self Generation of Chaos From Electrical Solitons , OZGUR YILDIRIM, DONHEE HAM, Harvard University — The nonlinear transmission line (NLTL) is a structure that can generate electrical solitons of subpicosecond duration. As an autonomous soliton generator utilizing the NLTL, thus far, only periodic electrical soliton oscillators have been reported. These circuits self generate a periodic train of solitons, where an amplifier with a saturable absorber prevents the generation of multiple solitons and hence their nonlinear collisions. However, if the amplifier encourages the generation of multiple solitons and their collisions, the system can attain chaos, because the position of the soliton modulates after each collision, disrupting the periodicity. In this work, for the first time, we experimentally demonstrate such a chaotic system. Our circuit self generates an aperiodic signal, which has a continuous spectral distribution. We confirm its chaotic behavior by calculating the largest Lyapunov exponent, and show that the dimensionality of the generated chaos is high (d>3) by performing a false-nearest-neighbors analysis. Moreover, we explicitly measure the route from periodic soliton oscillation to chaotic oscillation via decreasing the time constant of the saturable absorber, showing the effect of soliton collisions on period-doubling bifurcations and finally the creation of chaos.

12:03PM J20.00005 Harmonic Bloch and dipole oscillations and their transition in elliptical optical waveguide arrays[1] , YUN SAN CHAN, MING JIE ZHENG[2], KIN WAH YU, The Chinese University of Hong Kong — We have studied harmonic oscillations in an elliptical optical waveguide array in which the couplings between neighboring waveguides are varied in accord with a Kac matrix so that the propagation constant eigenvalues can take equally spaced values. As a result, the long-living optical Bloch oscillation (BO) and dipole oscillation (DO) are obtained. Moreover, when a linear gradient in the propagation constant is applied, we achieve a switching from DO to BO and vice versa by ramping up or down the gradient profile [1]. The various optical oscillations as well as their switching are investigated by field evolution analysis and confirmed by Hamiltonian optics. The equally spaced eigenvalues in the propagation constant allow viable applications in transmitting images, switching and routing of optical signals.

12:15PM J20.00006 Bloch-dipole-Zener Oscillations in Binary Parabolic Optical Waveguide Arrays[1] , MING JIE ZHENG[2], YUN SAN CHAN, KIN WAH YU, The Chinese University of Hong Kong — We have studied the propagation and Zener tunneling of light in the binary parabolic optical waveguide arrays (BPOWA) consisting of two evanescently coupled dissimilar optical waveguides. BPOWA attains two minibands with a gap at the zone edge due to Bragg reflections. Various superposition of optical oscillations and Zener tunneling are identified for different parameters on the phase diagram. In particular, both Bloch-Zener oscillation [1] and Bloch-dipole-Zener oscillation are obtained in the BPOWA by the field-evolution analysis. The research results may have potential applications in optical splitting and waveguiding devices and shed light on the coherent phenomena in lattice structures [2].

12:27PM J20.00007 Cavity phase matching for a high efficient sheet optical parametric oscillator , Z.D. XIE, X.J. LV, S.N. ZHU, Department of Physics, Nanjing University — Cavity phase matching (CPM) was first proposed in the early days in nonlinear optics by J. A. Armstrong, N. Bloembergen, J. Ducuing and P. S. Pershan in theory in 1962 as one of the three protocols to realize phase matching in nonlinear medium. The other two protocols have been developed into the well-known quasi-phase matching (QPM) technique. CPM has equivalent capability to compensate for the phase mismatching as QPM in principle and people has been attempting to achieve CPM in several kinds of semi-conductor materials. However, there is no convincing experimental realization up to date. In the work, we manufactured, for the first time, a CPM optical parametric oscillator (OPO) which consisted of a 217μm thick KTP crystal sheet whose two surfaces were optically coated for the resonance recirculation of signal and idler. The sheet OPO could emitted the near-frequency-degenerate signal and idler beams in near-infrared region with a quasi-continuously tunable frequency difference ranging from 0.35 to 26.1THz. This mini-device showed the high slope efficiency up to 22%, and as well the unique spectral and spatial features, like single-longitudinal-mode, single-spatial-mode, narrow linewidth, etc.

12:39PM J20.00008 Variation of Losses with Detuning in Bragg Gratings , SERGIY MOKHOV, DERREK DRACHENBERG, GEORGE VENUS, BORIS ZELDOVICH, LEONID GLEBOV, CREOL, The College of Optics and Photonics, UCF — The optical losses due to small scattering and absorption in Bragg gratings are proportional to the loss coefficient, and also depend on the integral of optical power over grating length. At different resonant conditions this integral of stored optical power inside a grating differs from the product of power by length for transmitted beams far from resonance. We have found an analytical expression for the relative value of this integral in the case of a uniform grating. If it equals unity for a beam propagating out of resonance, then for a grating in Bragg resonance with reflectance of 99% it equals 0.332 due to exponential decay of reflected and transmitted power inside the grating and grows up to 2.027 near the first zero of the reflection spectrum due to increased resonant capacity of the grating similar to a Fabry-Perot resonator. Also, we have found analytically that in the case of spatially modulated grating losses with Bragg period the odd-functional term will be present in the expression for relative losses in addition to the term for averaged losses. We have measured this variation of losses in volume Bragg grating at a small incidence angle, and in this case can resolve the incident and reflected beams and precisely measure the power balance in the experimental setup, and the results show good agreement with theory.

12:51PM J20.00009 Temperature dependence of polaritons in ZnO based hybrid micro-cavity , RYOKO SHIMADA, SANKAR DAVULURI, HADIS MARKOC, ARUP NEOGI — We have studied the temperature dependence of cavity polaritons in bulk ZnO-based hybrid microcavities. The bulk ZnO-based micro cavity is formed by 36 pairs of AlGaN/(Al)GaN distributed Bragg reflector at the bottom of (lambda)/4 thick ZnO cavity and eight pairs of SiO2/SiN DBR as top mirror. Shift in exciton resonances with temperature resulted in shift in the energy levels of upper and lower polariton modes. The magnitude of observed energy shifts in polariton modes is dependent on the angle at which photoluminescence is collected. It can be possible to obtain either a upper or lower polariton mode that is stable over a long range of temperature by selectively collecting the polaritons modes emitted at a particular angle. The temperature dependent carrier dynamics of the upper or lower polariton mode has been studied by time resolved spectroscopy.

1:03PM J20.00010 Study of the Coherent Phonon-Polariton effect on the Terahertz pulse generation in <110> ZnTe crystal[1] , CHIEN-MING TU, JENG-CHUNG CHEN, CHENG-CHUNG CHI, Department of Physics, National Tsing Hua University, Hsinchu, Taiwan — We report a study of the wave form and spectrum of the THz radiation generated by illuminating <110> ZnTe crystal with femto-second optical pulses of 750 nm in wavelength. The co-linearly measured wave form consists of a main W-shaped THz pulse and a trailing quasi monochromatic damped oscillation (QMDO) with a duration of several tens of pico-seconds. In Fourier-transformed spectrum of the measured THz waveform, there are two peaks, one centered at 0.6 THz and the other one at 2.7 THz, which correspond to the main THz pulse and the QMDO respectively. Our calculation of the THz pulse generated by the optical pulse indicates that the QMDO is caused by the phase matching of the optical pulse and the coherent phonon-polariton in ZnTe. We observe that, by increasing the optical pulse width, the duration of the trailing QMDO shrinks in time domain, and the amplitude of the phase-matching component also reduces, both of which are consistent with our calculations. There remain some subtle differences between the experimental results and the theoretical calculations, the origin of which will be discussed.

1:15PM J20.00011 Accurate Formulation and Numerical Calculation of Faraday, Magnetic Circular Dichroism (MCD) and Kerr Effect of Light in Magnetized Cubic Crystal[1] , JIN T. WANG, SEAN HALL, YI ZHEN, DONG-SHENG GUO, Southern University, SUBR-P TEAM — Faraday, magnetic circular dichroism and Kerr effects are three important magneto-optic effects. They are significant in fundamental sciences and applications. Presently, scientists in this field believed that Faraday and Kerr effects are caused by the difference in real parts of the refractive indices of the magnetic crystal for left-and right-circularly polarized light and the magnetic circular dichroism is caused by the difference in the imaginary parts of the refractive index (absorption) of the magnetic crystal for left-and right-circularly polarized light. However, the derived equations for these effects are approximated only. In our paper we obtained accurate formulations for these effects and found that there are mistakes in the present conclusions with respect to the above mentioned these effects. The precise equations, conclusions from our derivation and the results of numerical calculation are presented.

1:27PM J20.00012 Quantum cascade laser with low threshold and high characteristic temperature $T_0 > 300K$ at ~ 14 μm[1] , XUE HUANG, WILLIAM CHARLES, CLAIRE GMACHL, Princeton University, MIRTHE TEAM — High-performance quantum cascade (QC) lasers with wavelength in $4 \sim 12$ μm range are widely used in trace gas sensing. However, lack of high performance for longer wavelength in the $12 \sim 16$ μm range, where exist the strongest absorption lines of BTEX (benzene, toluene, ethylbenzene, and xylenes) and Uranium Hexafluoride, prohibits QC laser applications in sensing these important gases. The QC laser emitting at ~ 14 μm we investigate here is based on a diagonal-transition design. The depletion of the lower laser state is achieved by a one-phonon-continuum scheme instead of the widely used "continuum" lower mini-bands in existing long-wavelength lasers. This scheme reduces LO scattering from the upper laser state, the leakage from the injector and thermal back-filling to the lower laser state, thus attaining population inversion efficiently. The laser shows low threshold (J_{th} =2.4 kA/cm^2 for a 1.97-mm-long laser at room temperature), and a high characteristic temperature T_0 =309K fitted from $J_{th}(T) = J_0 e^{T/T_0}$, which is comparable with the record highest characteristic temperature. The peak power is 1.4W at 80K and 0.25W at 300K.

1:39PM J20.00013 The effect of energy density on laser flyer velocity , H.R. BRIERLEY, Cavendish Laboratory, University of Cambridge, T.A. VINE, QinetiQ Ltd, Fort Halstead — Laser driven flyers are produced on the interaction of a laser pulse with a thin film of metal. When an Nd:YAG laser is focussed through a fused silica substrate onto a 5 micron layer of aluminium, a fraction of the metal is ablated. This causes the remaining aluminium to be punched from the film and launched as a discrete flyer. By varying the energy of the incident laser pulse, the velocity of the resulting flyer is changed. The Nd:YAG laser beam was spatially filtered to remove higher order modes. This improved the beam quality and reduced the focal spot diameter. The resulting higher energy densities led to faster flyer velocities for a given pulse energy.

1:51PM J20.00014 Spatially-sculpted aberrated optical tweezers for delivery of nanoparticles onto cells , SHIVARANJANI SHIVALINGAIAH, SUYASH CHHAJED, SAMARENDRA MOHANTY, UT Arlington — Nanoparticles (NP) are emerging as photochemical and photothermal agents for delivery of drugs and heat onto the targeted cells. Here, we report spatially-sculpting of transverse potential landscape by introducing aberration in the optical tweezers beam for delivery of therapeutic NP on to the prostate cancer PC3 cells. A tunable Ti-Sapphire laser beam was focused to a diffraction limited spot by use of a high numerical aperture microscope objective for optical trapping. A cylindrical lens was used to create the beam profile astigmatic, which led to spatially extended potential landscape. In order to facilitate transport of NP, Comatic potential was created by tilting of the astigmatic beam with respect to the optic axis. NPs were attracted towards the potential minima, transported along the major axis of the elliptic spot and ejected out along the direction having lower stiffness. The Carbon NPs as well as Poly Lactic-*co*-Glycolic Acid NPs were efficiently transported and concentrated near the PC3 cells *in-vitro*. The direction and the speed of transport of nano-particles could be reversed by change in tilt direction and angle. Further, by utilizing the scattering force with the asymmetric gradient force, three-dimensional transport of nanoparticles was achieved. The effect of laser beam power and size / refractive index of the nano-particles on the speed of transport will be presented.

2:03PM J20.00015 Mapping force of interaction between PLGA nanoparticle with cell membrane using optical tweezers , SUYASH CHHAJED, LING GU, HOMA HOMAYONI, KYTAI NGUYEN, SAMARENDRA MOHANTY, UT Arlington — Drug delivery using magnetic (Fe_3O_4) Poly Lactic-*co*-Glycolic Acid (PLGA) nanoparticles is finding increasing usage in therapeutic applications due to its biodegradability, biocompatibility and targeted localization. Since optical tweezers allow non-contact, highly sensitive force measurement, we utilized optical tweezers for studying interaction forces between the Fe_3O_4-PLGA nanoparticles with prostate cancer PC3 cells. Presence of Fe_3O_4 within the PLGA shell allowed efficient trapping of these nanoparticles in near-IR optical tweezers. The conglomerated PLGA nanoparticles could be dispersed by use of the optical tweezers. Calibration of trapping stiffness as a function of laser beam power was carried out using equipartition theorem method, where the mean square displacement was measured with high precision using time-lapse fluorescence imaging of the nanoparticles. After the trapped PLGA nanoparticle was brought in close vicinity of the PC3 cell membrane, displacement of the nanoparticle from trap center was measured as a function of time. In short time scale ($<$ 30sec), while the force of interaction was within 0.2 pN, the force increased beyond 1pN at longer time scales ($\sim$ 10 min). We will present the results of the time-varying force of interactions between PLGA nanoparticles with PC3 cells using optical tweezers.

Tuesday, March 22, 2011 11:15AM - 2:15PM –

Session J21 DMP GIMS DCP: Focus Session: Imaging and Modifying Materials at the Limits of Space and Time Resolution I D161

11:15AM J21.00001 Transformation of carbon nanoparticles under laser microirradiation , NINAD INGLE, VIJAYALAKSHMI VARADARAJAN, ALI KOYMEN, SAMARENDRA MOHANTY, UT Arlington — Functional, mechanical, electrical and thermal properties of carbon nanoparticles (CNP) have been shown to change significantly with change in its shape and structure. Here, we show that shape of the CNPs can be transformed by exposure to tightly focused near-infrared Ti: Sapphire laser beam. The CNPs were prepared using electric plasma discharge generated in an ultrasonic cavitation field of liquid benzene. High resolution TEM image showed nanoparticles with average radius of $\sim$5nm with crystalline structure. A Nanonics Multiview Atomic Force Microscopy (AFM) was integrated on the laser micro-irradiation system to reveal the shape transformation of the CNPs before and after laser irradiation. Since near-IR laser irradiation can lead to significant heat generation in CNP in absence of aqueous solution (sink), the system is far from thermal equilibrium and can curve or bend graphitic layers by introducing topological defects. The photothermally-induced shape transformation can occur below laser power required for complete melting of CNP since surface melting can suffice the observed shape transformation. The results show significant reduction in the volume of irradiated CNP-clusters, which was attributed coalescing of melted CNPs. Raman spectroscopic measurements are being carried out to evaluate possibility of ultrastructural changes.

11:27AM J21.00002 The effect of Au condensation in laser desorption/ionization of organic materials , ANEESH PRABHAKARAN, ARNAUD DELCORTE, Institute of Condensed Matter and Nanosciences, Université catholique de Louvain, Belgium — Matrix-assisted desorption/ionization (MALDI) mass spectrometry, where the analyte is mixed in a low molecular weight matrix, often constitutes a limitation for the analysis and imaging of real world samples. Herein, we investigate the influence of a thin layer of gold (1-15nm) deposited on the surface of different organic materials, in the laser ablation using 355nm wavelength light. We see a significant effect of the condensed metal nanoparticles in the laser ablation process. Compared to pristine samples, the metallized samples show a significant intensity of characteristic fragments as well as metal cationized molecules. Relatively soft desorption/ionization is indicated by the observation of characteristic molecular ions of the different analytes. The observed effects can be explained by the increased laser absorption by the gold nanoparticles in this wavelength range and the increased ionization by the gold. Hence the metallization improves the surface characterization using lasers and also proves to be a novel technique for chemical imaging of organic surfaces.

11:39AM J21.00003 Atomic-level simulations of structural transformations in layered Au-Cu and Ag-Cu metal targets irradiated by a femtosecond laser pulse[1] , CHENGPING WU, University of Virginia, DEREK THOMAS, University of Tokyo, Japan, ZHIBIN LIN, Colorado School of Mines, LEONID ZHIGILEI, University of Virginia — The structural transformations in Ag/Au film - Cu substrate systems irradiated by femtosecond laser pulses are investigated in simulations performed with a model that couples the molecular dynamics method with a continuum-level description of the laser excitation and subsequent relaxation of the excited electrons. The higher strength of the electron-phonon coupling in Cu compared to Ag and Au results in a preferential sub-surface heating and melting of the Cu substrate. The melting is followed by rapid cooling and resolidification. In the case of Cu-Ag system, the rapid resolidification results in a complex structure of the interfacial region, where the lattice-mismatched interface is separated from the Ag-Cu mixing region by an intermediate pseudomorphic bcc Cu layer that grows epitaxially on the (001) face of the fcc Ag film during the final stage of the resolidification process. The new lattice-mismatched interface consists of a periodic array of stacking fault pyramids outlined by stair-rod partial dislocations. The intermediate bcc layer and the stacking fault pyramid structure of the mismatched interface present a barrier for dislocation propagation, resulting in the effective hardening of the layered structure treated by laser irradiation.

11:51AM J21.00004 Optical Antennas for Enhanced Light Absorption and Emission[1] , LUKAS NOVOTNY — The absence of optical antennas in technological applications is primarily associated with their small scale. Antennas have characteristic dimensions on the order of a wavelength, demanding fabrication accuracies better than 10nm for the optical frequency regime. The advent of nanoscience and nanotechnology provides access to this length scale but material challenges associated with optical antennas remain. For example, the penetration of radiation into metals can no longer be neglected. The electromagnetic response is then dictated by collective electron oscillations (plasmons) characteristic of a strongly coupled plasma. These collective excitations make a direct downscaling of traditional antenna designs impossible and demand the careful study of plasmon resonances in metal nanostructures. The introduction of the antenna concept into the optical, infrared and terahertz frequency regime holds promise for a wide range of novel technological applications. Optical antennas can be employed to enhance the eciency of photovoltaics, to release energy from nanoscale light-emitting devices, and to boost the eciency of photochemical or photophysical detectors. In this presentation, I will outline the physical properties of optical antennas, review relevant history and recent work.

12:27PM J21.00005 In Situ 3D Coherent X-ray Diffraction Imaging of Shock Experiments: Possible? , JOHN BARBER, Los Alamos National Laboratory — In traditional coherent X-ray diffraction imaging (CXDI), a 2D or quasi-2D object is illuminated by a beam of coherent X-rays to produce a diffraction pattern, which is then manipulated via a process known as iterative phase retrieval to reconstruct an image of the original 2D sample. Recently, there have been dramatic advances in methods for performing fully 3D CXDI of a sample from a single diffraction pattern [Raines et al, Nature 463 214-7 (2010)], and these methods have been used to image samples tens of microns in size using soft X-rays. In this work, I explore the theoretical possibility of applying 3D CXDI techniques to the in situ imaging of the interaction between a shock front and a polycrystal, a far more stringent problem. A delicate trade-off is required between photon energy, spot size, imaging resolution, and the dimensions of the experimental setup. In this talk, I will outline the experimental and computational requirements for performing such an experiment, and I will present images and movies from simulations of one such hypothetical experiment, including both the time-resolved X-ray diffraction patterns and the time-resolved sample imagery.

12:39PM J21.00006 Lattice dynamics of laser excited self-assembly gold nanocrystals by time resolved X-ray diffraction , KOUHEI ICHIYANAGI, HIROSHI SEKIGUCHI, University of Tokyo, SHUNSUKE NOZAWA, TOKUSHI SATO, SHIN-ICHI ADACHI, High Energy Accelerator Research Organization, YUJI C. SASAKI, University of Tokyo — The self-assembled gold nanoparticle has attracted considerable interest from researchers as the new nanodevices and bio-sensors. Functional groups such as thiols and amines have assembled on the gold nanoparticles in solution. For using the functional optical nanomaterial, it is necessary to reveal the mechanism of interaction between the laser and the functional nanomaterial. In the present work, we observed the effect of photo-excited process of self-assembled gold nanocrystal in ethanol solution using picosecond time-resolved X-ray diffraction. Gold nanocrystals deposited on the NaCl (100) substrate. After isolation of gold nanocrystals from the substrate, these nanocrystals were assembled with 10-Carboxydecyl disulfide molecules in ethanol. The nanocrystals size was the diameter of about 60 – 120 nm. The X-ray energy, pulse width and repetition rate for probing the gold nanocrystals were 15 keV, 100 ps and 945 Hz, respectively. The excitation wavelength and the pulse width were 400 nm and 150 fs. The detailed results of the lattice dynamics inside gold nanocrystals will be presented in the presentation.

12:51PM J21.00007 Ultrafast Laser Matter Interaction and Pump-probe Imaging of Transient Electric Fields , JIAN-MIN ZUO, HYUK PARK, Materials Science and Engineering, University of Illinois — Ultrafast electron diffraction and microscopy use pulsed laser as pump to initiate dynamic processes in solids. Under irradiation of pulsed laser beam of picoseconds or less, electrons inside a solid can be heated to high temperatures for a short period of time (several picoseconds). A part of hot electrons can be emitted from the surface in a similar way of thermionic emission. The emitted electrons, travel at speeds, produce transient electric fields (TEFs) together with the positively charged surface [1]. However, the effect of photoemitted electrons and their electric fields on ultrafast electron diffraction and microscopy has been a subject of debate [2]. Here we report direct measurement of TEFs using time-resolved electron beam imaging techniques based on the pump-probe approach. Results obtained from Pt thin films, Cu and ZnO nanowires will be shown. We demonstrate that TEFs produced by ultrafast laser irradiation can lead to large beam deflections that depend on the electron beam distance to sample surface, laser fluence and laser wavelength. The work shows that there is clearly a critical need for better understanding of TEFs in the field of ultrafast electron microscopy. The work is supported by DOE DEFG02-01ER4592, DEFG02-91-ER45439 and DOE DEFG02-07ER46453. [1] H. Park and J. M. Zuo, Applied Physics Letters 94, 251103 (2009). [2] H. Park and J. M. Zuo, Physical Review Letters 105, 059603 (2010).

1:03PM J21.00008 Femtosecond Nanocrystallography with X-ray Free-Electron Lasers[1] , HENRY CHAPMAN, Center for Free-Electron Laser Science, DESY, and the University of Hamburg — The ultrafast pulses from X-ray free-electron lasers have opened up a new form of protein nanocrystallography. The X-ray pulses are of high enough intensity and of sufficiently short duration that individual single-shot diffraction patterns can be obtained from a sample before significant damage occurs. This "diffraction before destruction" method may enable the determination of structures of proteins that cannot be grown into large enough crystals or are too radiation sensitive for high- resolution crystallography. Ultrafast pump-probe studies of photoinduced dynamics can also be studied. We have carried out experiments in coherent diffraction from protein nanocrystals, including Photosystem I membrane protein, at the Linac Coherent Light Source (LCLS) at SLAC. The crystals are filtered to sizes less than 2 micron, and are delivered to the pulsed X-ray beam in a continuously flowing liquid jet. Millions of diffraction patterns were recorded at the LCLS repetition rate of 60 Hz. Tens of thousands of the single-shot diffraction patterns have been indexed, and combined into a single crystal diffraction pattern, which can be phased for structure determination and analysed for the effects of pulse duration and fluence. Experimental data collection was carried out as part of a large collaboration involving CFEL DESY, Arizona State University, Max Planck Institute for Medical Research, University of Uppsala, SLAC, LBNL, LLNL, using the CAMP apparatus which was designed and built by the Max Planck Advanced Study Group at CFEL.

[1]The LCLS is operated by Stanford University on behalf of the U.S. Department of Energy, Office of Basic Energy Sciences.

1:39PM J21.00009 Plans for an Upgrade of the Advanced Photon Source[1] , DENNIS MILLS, Argonne National Laboratory, APS-U PROJECT TEAM — We are presently developing plans for an upgrade of the Advanced Photon Source facility. Science has formally issued Critical Decision 0 and approved the Mission Need Statement in April of 2010, authorizing the APS to develop a conceptual design for the APS Upgrade (APS-U) project. The proposed upgrade will include enhancements to the accelerator, beamlines, and facility infrastructure. The high brilliance x-ray beams at high photon energy (e.g. $>$ 25 keV) provided by the APS Upgrade will have strong impact on research in energy, the environment, new or improved materials, and biological studies. High-energy x-rays can penetrate into a wide range of realistic and/or extreme environments and allow imaging of structures and processes in unprecedented detail on picosecond time scales and nanometer length scales. The presentation will include some of the essential goals of the APS-U and proposed strategies to attain those goals.

[1]The Advanced Photon Source at Argonne National Laboratory is supported by the U. S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

1:51PM J21.00010 The Jefferson Lab VUV-FEL at 10 eV and above[1] , GWYN WILLIAMS, Jefferson Lab, FEL TEAM — We will present details of the vacuum ultraviolet performance of the Jefferson Lab Free Electron Laser. The JLab FEL is oscillator-based [1] and uses a superconducting energy recovered linac for CW RF operation at up to 75 MHz. Lasing at a fundamental wavelength of 372 nm, the third harmonic is at 124 nm, corresponding to a photon energy of 10 eV. The energy per pulse in the fundamental is 20 microJoules, which at 9 MHz yields an average power of 180 Watts. The pulses have a FWHM of order 300 fs, which essentially determines the optical bandwidth. The third harmonic, which is a 0.1 - 1% fraction of this, is considerably brighter than any other source in the region. Further, being an FEL, there is a wide range of tunability in the 1 eV to 15 eV range. Additional reach is possible with increased electron beam energy, and some options will be discussed in the talk.

[1]We acknowledge funding from ONR, AFRL and DOE-BES under contract AC05-060R23177.

2:03PM J21.00011 Ultrafast optical fiber microbeam for in-depth fabrication, trapping and fluorescence excitation , MERVYN PINTO, UT Arlington, YOGESHWAR MISHRA, CUSAT, NINAD INGLE, SAMARENDRA MOHANTY, UT Arlington — Micro-focused laser beam is finding widespread application in two-photon polymerization (TPP), microsurgery, two-photon fluorescence microscopy and optical trapping of microscale objects. However, limited by short working distance of the microscope objective, it is essential to develop fiber based laser microbeam for in-depth applications. While fiber-optic two-photon fluorescence excitation (TPE) has been explored in past for endoscopic imaging, only recently we demonstrated optical trapping and microsurgery using single fiber optical microbeam. Here, we present use of ultrafast laser coupled to microfabricated single mode optical fiber for in-depth fabrication of microstructures by TPP as well as TPE and manipulation of microscopic objects by fiber optical microbeam tweezers. The microfabrication of fiber optic axicon tip was optimized so as to perform all the four functions, namely fabrication, excitation, manipulation and collection of fluorescence from the trapped object. Owing to the propagation distance of Bessel-like beam emerging from the axicon-fiber tip, relatively longer streak of fluorescence was observed along the microsphere length. Stable trapping of the fluorescent objects was observed due to reduced scattering force as compared to axial gradient force. These results using multifunctional optical fiber will be presented.

Tuesday, March 22, 2011 11:15AM - 2:15PM –
Session J22 DCMP: Theory of Non Fermi Liquids D163

11:15AM J22.00001 Resistivity of a non-Galilean Fermi liquid near Pomeranchuk Quantum Criticality , DMITRII MASLOV, University of Florida, VLADIMIR YUDSON, Russian Academy of Sciences, ANDREY CHUBUKOV, University of Wisconsin-Madison — We analyze the effect of the electron-electron interaction on the resistivity of a metal near a Pomeranchuk quantum critical point (QCP). We show that Umklapp processes are not effective near a QCP, and one must consider the interplay between interaction and disorder. By power counting, the correction to the residual resistivity at low T scales as $AT^{(D+2)/3}$ at QCP ($T^{4/3}$ in 2D). We show, however, that that $A = 0$ for a simply connected and convex Fermi surface in 2D due to hidden integrability of the electron motion. We argue that $A > 0$ in a two-band ($s - d$) model with light and heavy carriers, and propose this model as an explanation for the observed $T^{(D+2)/3}$ behavior.

11:27AM J22.00002 Transport Properties near Quantum Critical Point in 2D Hubbard Model[1] , KUANG-SHING CHEN, SANDEEP PATHAK, SHUXIANG YANG, Louisiana State University, SHI-QUAN SU, Oak Ridge National Laboratory, DIMITRIS GALANAKIS, Nanyang Technological University, Singapore, KARLIS MIKELSONS, Georgetown University, JUANA MORENO, MARK JARRELL, Louisiana State University — We obtain high quality estimates of the self energy $\Sigma(K, \omega)$ by *direct* analytic continuation of $\Sigma(K, i\omega_n)$ obtained from Continuous-Time Quantum Monte Carlo. We use these results to investigate the transport properties near the quantum critical point found in the 2D Hubbard model at finite doping. Resistivity, thermal conductivity, Wiedemann-Franz Law, and thermopower are examined in the Fermi liquid, Marginal Fermi liquid (MFL), and pseudo-gap regions. $\Sigma''(k, \omega)$ with k along the nodal direction displays temperature-dependent scaling similar to that seen in the experiment. A next-nearest neighbor hopping $t' < 0$ increases the doping region where MFL character is found.

[1]NSF OISE-0730290

11:39AM J22.00003 Quantum Phase Transition in Interacting Quantum Wires[1] , MEHUL DIXIT, The Ohio State University, TOBIAS MENG, MARKUS GARST, ACHIM ROSCH, Institute for Theoretical Physics, University of Cologne, JULIA MEYER, SPSMS, CEA-INAC/UJF, Grenoble — We consider the quantum phase transition of interacting electrons in a quantum wire from a one-dimensional (1D) to a quasi-1D state as a function of an external gate voltage. At weak interactions, a Lifshitz transition occurs when electrons start filling the second subband of transverse quantization. The physics in the vicinity of the transition is characterized by pronounced correlations as interactions in the second subband are effectively strong due to the diverging density of states close to the band bottom. Inter-subband interactions lead to the formation of polarons, but the nature of the transition is unchanged, i.e., one finds a Lifshitz transition of impenetrable polarons. By contrast, strongly interacting electrons form a (quasi-)1D Wigner crystal, and the transition corresponds to the linear crystal splitting into a zigzag crystal. This Ising transition in the charge sector is decoupled from the spin excitations in the system.

11:51AM J22.00004 Conductance of Tomonaga-Luttinger liquid wires and junctions with resistances , DIPTIMAN SEN, ABHIRAM SOORI, Indian Institute of Science, Bangalore — We study the effect that resistive regions have on the conductance of a quantum wire with interacting electrons which is connected to Fermi liquid leads. Using the bosonization formalism and a Rayleigh dissipation function to model the power dissipation, we use Green's function techniques to derive the DC conductance. The resistive regions are generally found to lead to incoherent transport. For a single wire, we find that the resistance adds in series to the contact resistance of e^2/h for spinless electrons, and the total resistance is independent of the Luttinger parameter K_W of the wire. We numerically solve the bosonic equations to illustrate what happens when a charge density pulse is incident on the wire; the results depend on the parameters of the resistive and interaction regions in interesting ways. For a junction of Tomonaga-Luttinger liquid wires, we use a dissipationless current splitting matrix to model the junction. For a three-wire junction, there are two families of such matrices; we find that the conductance matrix depends on K_W for one family but is independent of K_W for the other family.

12:03PM J22.00005 Holographic metals and fractionalized Fermi liquids[1] , SUBIR SACHDEV, Harvard University — I show that there is a close correspondence between the physical properties of holographic metals near charged black holes in anti-de Sitter (AdS) space, and the fractionalized Fermi liquid phase of the lattice Anderson model. The latter phase has a "small" Fermi surface of conduction electrons, along with a spin liquid of local moments. This correspondence implies that certain mean-field gapless spin liquids are states of matter at non-zero density which realize the near-horizon, $AdS_2 \times R^2$ physics of Reissner-Nordstrom black holes. I will also go beyond this mean-field theory, and discuss connections between gauge theories of fractionalized Fermi liquids and holographic theories.

12:15PM J22.00006 Dynamically Generated Gap from Holography: Mottness from a Black Hole[1] , KA-WAI LO, MOHAMMAD EDALATI, ROBERT LEIGH, PHILIP PHILLIPS, university of illinois — In the fermionic sector of top-down approaches to holographic systems, one generically finds that the fermions are coupled to gravity and gauge fields in a variety of ways, beyond minimal coupling. In this paper, we take one such interaction – a Pauli, or magnetic dipole, interaction – and study its effects on fermion correlators. We find that this interaction modifies the fermion spectral density in a remarkable way. As we change the strength of the interaction, we find that spectral weight is transferred between bands, and beyond a critical value, a hard gap emerges in the fermion density of states. A possible interpretation of this bulk interaction then is that it drives the dynamical formation of a (Mott) gap, in the absence of any symmetry breaking.

[1]NSF DMR-0940992

12:27PM J22.00007 Quantum phase transitions in the pseudogap Anderson Holstein model[1] , MENGXING CHENG, KEVIN INGERSENT, U. Florida — We study a pseudogap Anderson-Holstein model of a magnetic impurity level that (1) hybridizes with a conduction band whose density of states vanishes in power-law fashion at the Fermi energy, and (2) couples, via its charge, to a nondispersive bosonic mode (e.g., an optical phonon). The model exhibits quantum phase transitions (QPTs) of different types depending on the strength λ of the impurity-boson coupling. For small λ, the suppression of the density of states near the Fermi energy leads to QPTs between strong-coupling (Kondo) and local-moment phases. A sufficiently large λ, however, transforms the bare Coulomb repulsion between a pair of electrons in the impurity level into an effective attraction, leading to QPTs between strong-coupling (charge-Kondo) and local-charge phases. Critical exponents characterizing the response to a local magnetic field (for small λ) or electric potential (for large λ) suggest that the QPTs belong to the same universality class as the QPT of the previously studied pseudogap Anderson model. One specific case of the pseudogap Anderson-Holstein model may be realized in a double-quantum-dot device, where the QPTs manifest themselves in the finite- temperature linear electrical conductance.

[1]Supported by NSF grant DMR-0710540

12:39PM J22.00008 Statistical fluxes and the sodium cobaltate Curie-Weiss metal , KAI WU, ZHENG-YU WENG, Institute for Advanced Study, Tsinghua University, JAN ZAANEN, Instituut Lorentz for Theoretical Physics, Leiden University — A central pursuit in the study of quantum matter is whether non Fermi liquid states exist, as invoked in trying to explain e.g. high-T_c superconductivity. A quite different context is the search for thermodynamic materials in energy applications, which require at the same time a very large thermopower and a low resistivity. Here we predict a new state of matter that descends from a strongly interacting microscopy described by a t-J model on a triangular lattice. Due to the altered role of quantum statistics the spins are "localized" in statistical Landau orbits, while the charge carriers form a Bose metal that feels the spins through random gauge fields. In contrast to the Fermi-liquid state, this state naturally exhibits a Curie-Weiss susceptibility, large thermopower, and linear-temperature resistivity, explaining the physics of Na_xCoO_2 at $x > 0.5$. A "smoking gun" prediction for neutron scattering is presented.

12:51PM J22.00009 Spin-incoherent behavior in the ground state of strongly correlated systems[1] , GREGORY FIETE, Department of Physics, The University of Texas at Austin, Austin, Texas 78712, USA, ADRIAN FEIGUIN, Department of Physics and Astronomy, University of Wyoming, Laramie, Wyoming 82071, USA — It is commonly believed that strongly interacting one-dimensional Fermi systems with gapless excitations are effectively described by Luttinger liquid theory. However, when the temperature of the system is high compared to the spin energy, but small compared to the charge energy, the system becomes "spin-incoherent." We present numerical evidence showing that the one-dimensional "t-J-Kondo" lattice, consisting of a t-J chain interacting with localized spins, displays all the characteristic signatures of spin-incoherent physics, but in the ground state. We argue that similar physics may be present in a wide range of strongly interacting systems.

[1]We gratefully acknowledge funding from ARO grant W911NF-09-1-0527 and NSF Grants DMR-055778, DMR-0955707. A. E. Feiguin and G. A. Fiete, arXiv:1005:4707.

1:03PM J22.00010 DMRG study of the Phase Diagram of the Infinite U Hubbard Model , LI LIU, Stanford University, HONG YAO, UC Berkeley, EREZ BERG, Harvard University, STEVE WHITE, UC Irvine, STEVE KIVELSON, Stanford University, BRIAN MOLTZ COLLABORATION — Despite decades of discussion, the phase diagram of the paradigmatic Hubbard model in the strong coupling limit remains uncertain. Here, we study Hubbard ladders with infinite on site repulsion and electron density ranging from n=0 to n=1 per site. DMRG calculations shows that the phase diagrams of two, three and four-leg laddders share the following similarities: as a function of decreasing n a fully polarized (half metallic ferromagnetic phase is followed by a partially polarized ferromagnetic metallic state, and finally by a paramagnetic (unpolarized) phase for n less than a critical value of roughly n $\sim$ 0.5, but which differs somewhat depending on the number of legs. Unexpectedly, the ferromagnetic metal phase is reentrant in the sense that it is interrupted at a special commensurate density (n=0.75 for the two-leg and 4-leg ladders and n=0.8 for the three leg) by an incompressible commensurate density wave phase with zero net ferromagnetic moment. All results appear to extrapolate smoothly to the limit of infinite ladder length. We conclude with some speculations about the phase diagram of the 2D infinite U Hubbard model.

1:15PM J22.00011 Mobile impurities in ferromagnetic liquids[1] , ADRIAN KANTIAN, Universite de Geneve, ULRICH SCHOLLWOECK, Ludwigs-Maximillian Universitaet Munich, THIERRY GIAMARCHI, Universite de Geneve — Recent work has shown that mobile impurities in one dimensional interacting systems may exhibit behaviour that differs strongly from that predicted by standard Tomonaga-Luttinger liquid theory, with the appearance of power-law divergences in the spectral function signifying sublinear diffusion of the impurity. Using time-dependent matrix product states, we investigate a range of cases of mobile impurities in systems beyond the analytically accessible examples to assess the existence of a new universality class of low-energy physics in one-dimensional systems.

1:27PM J22.00012 ABSTRACT WITHDRAWN –

1:39PM J22.00013 Nonlinear Collective Field Theory for models with inverse square interaction and exchange , FABIO FRANCHINI, SISSA, Trieste (Italy), MANAS KULKARNI, Stony Brook University and Brookhaven National Laboratory, ALEXANDER ABANOV, Stony Brook University — We present fully nonlinear dynamics [1] in inverse square models such as spin-Calogero model and Haldane-Shastry model. Hydrodynamic equations of motion are written for these models in the regime where gradient corrections to the exact hydrodynamic formulation of the theory may be neglected. We then show how this collective field theory allows to calculate correlation functions [2] that cannot be considered with conventional bosonization. We will also present the case of including external harmonic confinement [3] and show that the Calogero family is strikingly similar to models with delta (short-ranged) interaction and can be used as a toy model for cold atom experiments. Including harmonic trap usually ends up destroying integrability. However, Calogero family is special in this regard and the system remains integrable. In addition, we will present results of collective field theory which include gradient corrections thereby enabling us to go beyond gradient catastrophe.

1:51PM J22.00014 Renyi entropy of gapless spin liquids , TARUN GROVER, YI ZHANG, ASHVIN VISHWANATH, UC Berkeley — Spin liquids are exotic quantum states that do not break any symmetry. Though much is known about gapped spin-liquids, critical spin-liquids with strongly interacting gapless excitations in two and three spatial dimensions are less understood. Candidate ground state wave-functions for such states however can be constructed using the Gutzwiller projection method. We use bipartite entanglement entropy, in particular the Renyi entropy S_2 to investigate the quantum structure of these wave-functions. Using the Variational Monte-Carlo technique, we calculate the Renyi entropy of a critical spin liquid - the projected Fermi sea state on the triangular lattice. We find a violation of the boundary law, with S_2 enhanced by a logarithmic factor, an unusual result for a bosonic wave-function reflecting the presence of emergent spinons that form a Fermi surface. The Renyi entropy for algebraic spin liquids is found to obey the area law, consistent with the presence of emergent Dirac fermions in the system. Projection is found to completely alter the entanglement properties of nested Fermi surface states. These results show that the Renyi entropy calculations could serve as a diagnostic for gapless fractionalized phases.

2:03PM J22.00015 Power-Law Behavior of Bond Energy Correlators in a Kitaev-type Model with a Parton Fermi Surface[1] , HSIN-HUA LAI, OLEXEI I. MOTRUNICH, California Institute of Technology — We study bond energy correlation functions in an exactly solvable quantum spin model of Kitaev type on the kagome lattice with stable Fermi surface of partons proposed recently by Chua *et al.*, Ref. [arXiv:1010.1035]. Even though any spin correlations are ultra-short ranged, we find that the bond energy correlations have power law behavior with a $1/r^3$ envelope and oscillations at incommensurate wavevectors. We determine the corresponding singular surfaces in momentum space, which provide a gauge-invariant characterization of this gapless spin liquid.

Tuesday, March 22, 2011 11:15AM - 1:51PM –
Session J23 DCMP: Superconductivity: Fluctuation Phenomena D165

11:15AM J23.00001 Systematic determination of the superconducting fluctuation regime in the cuprates with torque magnetometry , GUICHUAN YU, University of Minnesota, YUAN LI, RUIHUA HE, Stanford University, XUDONG ZHAO, Jilin University, China, MARTIN GREVEN, University of Minnesota — Among the most important temperature scales in the high-$T_c$cuprates are those associated with the normal state pseudogap and the superconducting (SC) gap. Early Nernst effect and torque magnetometry measurements appeared to suggest an onset of SC fluctuations well above T_c in $La_{2-x}Sr_xCuO_4$ (LSCO). Recently, stripe correlations were found to contribute to the observed large Nernst signal in LSCO, leading to a reinterpretation of the earlier Nernst data. We report a systematically torque magnetometry study of the SC fluctuation regime in the simple model compound $HgBa_2CuO_{4+\delta}$, which has the highest T_c (97 K) among all single-layer cuprates, as well as initial results for LSCO. We demonstrate that the SC fluctuation regime is narrow and that it closely tracks T_c, which implies that the higher temperature scale observed in LSCO does indeed not result from SC fluctuations.

11:27AM J23.00002 Superconducting fluctuation regime in $HgBa_2CuO4_{+\delta}$ revealed by microwave measurements , NEVEN BARISIC, University of Minnesota, USA, MIHAEL GRBIC, ANTONIJE DULCIC, University of Zagreb, Croatia, YUAN LI, Stanford University, USA, XUDONG ZHAO[1], Jilin University, PR China, GUICHUAN YU, MARTIN GREVEN, University of Minnesota, USA, MIROSLAV POZEK, University of Zagreb, Croatia — There have been many attempts to measure the fluctuations preceding the superconducting long-range order in the cuprates with various experimental techniques, yet the onset temperature of the fluctuation regime has proven difficult to determine. We used a novel approach to microwave conductivity measurements in order to elucidate the phase diagram of the cuprates. Initial measurements were performed on the single-layer material $HgBa_2CuO_{4+\delta}$. From c-axis data for a sample close to optimal doping, we clearly discern the opening of the pseudogap at T*=185 K, the appearance of the superconducting fluctuations at the much lower temperature T'=105 K, and the transition to the superconducting state at T_c=94.3 K. Our result implies that the superconducting fluctuations extend only to about 10 K above T_c. Using the same approach, a narrow fluctuation regime is also found in other cuprates.

[1]University of Minnesota, USA

11:39AM J23.00003 Superconducting phase diagram and fluctuations in $SmFeAsO_{0.85}F_{0.15}$ single crystals , U. WELP, C. CHAPARRO, W.-K. KWOK, Argonne National Laboratory, A. RYDH, University of Stockholm, Sweden, N.D. ZHIGADLO, J. KARPINSKI, ETH Zuerich, Switzerland, S. WEYENETH, University of Zuerich, Switzerland — We use micro-calorimetry to investigate the anisotropic phase diagram and effects of superconducting fluctuations in sub-micro-gram single crystals of $SmFeAsO_{0.85}F_{0.15}$. Our measurements reveal that $SmFeAsO_{0.85}F_{0.15}$ is characterized by a large anisotropy of $\Gamma \sim$8 and a short in-plane Ginzburg-Landau coherence length of $\xi_{ab}(0) \sim$ 1.3 nm. These materials parameters promote strong superconducting fluctuations which are seen in the zero-field specific heat as clear upwards curvature in C/T at temperatures below T_c = 49.5 K and long tails above T_c. The resulting anomaly is cusp-shaped with height of $\Delta C/T_c$ = 24 mJ/moleK^2, which can be fitted with 3D-Gaussian fluctuations. The transition shows pronounced broadening in magnetic fields applied along the c-axis. The field evolution in fields higher than 3 T is well described in the frame of 3D lowest-Landau-level scaling of fluctuations using an upper critical field slope of -4.4 T/K. We will compare these characteristics to the behavior of other members of the FeAs-family. This work was supported by DOE-BES under Contract No. DE-AC02-06CH11357.

11:51AM J23.00004 A dynamical study of phase fluctuations and their critical slowing down in amorphous superconducting films[1] , WEI LIU, Johns Hopkins University, MINSOO KIM, GANAPATHY SAMBANDAMURTHY , University at Buffalo-SUNY, PETER ARMITAGE, Johns Hopkins University — We report a comprehensive study of the complex AC conductance of amorphous superconducting InO_x thin films. Using a novel broadband microwave "Corbino" spectrometer we measure the explicit frequency dependency of the complex conductance and the phase stiffness over a range from 0.21 GHz to 15 GHz at temperatures down to 350 mK. Dynamic AC measurements are sensitive to the temporal correlations of the superconducting order parameter in the fluctuation range above T_c. Among other aspects, we explicitly demonstrate the critical slowing down of the characteristic fluctuation rate on the approach to the superconducting state and show that its behavior is consistent with vortex-like phase fluctuations and a phase ordering scenario of the transition.

[1]NSF DMR-0847652

12:03PM J23.00005 Superconducting fluctuations in high-Tc cuprate superconductors , BRIGITTE LERIDON, LPEM-UMR8213-CNRS — Experimental results on electrical transport in various high-Tc cuprate superconductors are shown (namely in $YBa_2Cu_3O_{6+x}$, $Bi_2Sr_2CaCu_2O_{8+d}$, $La_{1-x}Sr_xCuO_4$). The part of the conductivity associated to superconducting fluctuations in the vicinity of the transition – also named paraconductivity - is extracted using different techniques for evaluating the normal state conductivity. Whenever possible, the conductivity measured under high pulsed field (50T) is used for the analysis. The results are compared to other experimental probes such as the Nernst effect, and are discussed from one compound to the other. It is shown that some straightforward conclusions can be drawn from relatively simple observations.

12:15PM J23.00006 Pairing associated with a single quantum critical energy in superconducting electron-doped cuprates , KUI JIN, NICHOLAS BUTCH, KEVIN KIRSHENBAUM, PAUL BACH, JOHNPIERRE PAGLIONE, RICHARD GREENE, Center for Nanophysics & Advanced Materials and Department of Physics, University of Maryland, College Park, MD 20742, USA — Though a comprehensive study of magnetotransport on electron-doped $La_{2-x}Ce_xCuO_4$ thin films, we show that an envelope of spin fluctuations yielding non Fermi liquid behavior ($\rho = \rho_0 + AT$) surrounds the superconducting dome in the overdoped region (x =0.15 to 0.21). This behavior survives to zero temperature over a range of fields exceeding the upper critical field. For example, the resistivity of x = 0.15 is linear in temperature over three decades down to 20 mK at 7.5 T. We demonstrate that all of the relevant energy scales in this system: those determining superconducting pairing, spin correlations, and the Fermi liquid metallic state, emanate from one common critical point at the end of the superconducting dome. These observations suggest that the superconductivity pairing is associated with spin fluctuations and with a single quantum critical energy in electron-doped cuprates. This work was partially supported by NSF-DMR 0653535.

12:27PM J23.00007 Shot noise measurements in mesoscopic N-S-N structures[1] , MARTIN STEHNO, D.J. VAN HARLINGEN, University of Illinois at Urbana-Champaign — Nonlocal subgap transport in mesoscopic superconductor-hybrid devices has received attention as a possible route towards creating and detecting entangled electron pairs in solid state devices. We study local and nonlocal transport in multi-terminal Cu/Al structures with transparent interfaces and separation between contacts comparable to the coherence length in the superconductor. The current shot noise in the two branches of the device is measured simultaneously and compared to the shot noise in a single contact. We discuss cross-correlations expected from Crossed Andreev Reflection and Elastic Co-tunneling processes, non-equilibrium transport in the superconductor, and device heating.

[1]Work supported by the National Science Foundation grant DMR 06-05813

12:39PM J23.00008 Transport noise crossovers in disordered electron nematics , WAN-JU LI, BENJAMIN PHILLABAUM, ERICA CARLSON, Purdue University, KARIN DAHMEN, University of Illinois at Urbana Champaign — Recently, low-frequency transport noise in underdoped YBCO was shown to exhibit an enhancement below 250K, consistent with fluctuations associated with a symmetry-breaking collective electronic state [1]. We discuss these results in relation to crossovers associated with the development of local electronic nematic order. Using a mapping of disordered electron nematics to random anisotropic resistor networks, we predict the thermal evolution of the noise power in transport associated with the crossover to local electron nematic behavior.
[1] Caplan et al., Phys. Rev. Lett. **104**, 177001 (2010).

12:51PM J23.00009 Vortex Noise in Thin Nb Films on a Triangular Anti-Dot Lattice[1] , TANNER SCHULZ, Department of Physics and Astronomy, University of Minnesota, LIWEN TAN, BETH STADLER, Department of Electrical and Computer Engineering, University of Minnesota, E. DAN DAHLBERG, Department of Physics and Astronomy, University of Minnesota — Thin Nb films are deposited on a periodic, triangular, anti-dot lattice with a lattice constant of 100nm. The lattice serves as pinning sites where superconducting vortices are trapped. The vortex density is set by an external field. At a vortex density commensurate with the pinning lattice transport measurements show an increase in current density. Interstitial vortex pinning produces similar current features at integer multiples of the matching field. We examine the voltage noise spectra as the applied field and DC current bias are varied. Noise signals appear above a field dependent threshold current and show minima at the matching fields. The noise is due to vortex motion in a pinning potential that varies with vortex density and driving forces. We use our results to study vortex motion and compare our signals to existing vortex noise models.

1:03PM J23.00010 Inelastic scattering effects in current noise for a one dimensional Landauer system[1] , MANOHAR KUMAR, ZHENG P. BAARDMAN, ROEL H.M. SMIT, JAN M. VAN RUITENBEEK, Kamerlingh Onnes laboratory, Leiden University, The Netherlands — Generally, current shot noise is measured at low bias currents, and it reflects the transmission probability of the electrons. Here we present the first measurement at bias currents above the phonon energy of the system, *i.e.* a chain of Au atoms. The onset of phonon emission processes is signaled by an abrupt jump in differential conductance which results from the change in the transmission probability of the electrons due to phonon excitation. One should expect a sign of this change to be visible in shot noise. Indeed, a distinct signature in the current shot noise signal is observed due to inelastic scattering as a linear deviation from the Levitov- Lesovik classical shot noise. Surprisingly, we have observed that the deviation of noise from the classical noise at the phonon frequency is either positive or negative, depending on whether the transmission is above or below 0.96G0. These observations agree with recent predictions of a sign change in the phonon-induced correction to the noise [1-3], but the point of cross-over is higher than predicted. References: *1. 1:15PM J23.00011 AC conductivity across the disorder driven superconductor insulator transition[1] , YEN LEE LOH, KARIM BOUADIM, NANDINI TRIVEDI, MOHIT RANDERIA, The Ohio State University — The superconductor-insulator transition (SIT) is defined, at the most fundamental level, in terms of electromagnetic response. The Mattis-Bardeen theory for conventional superconductors becomes inadequate near the disorder-tuned SIT, where phase fluctuations become important. We present AC conductivity results obtained using determinant quantum Monte Carlo simulations, which include both quantum and thermal phase fluctuations. We find unexpected low-energy weight in the AC conductivity especially near the SIT, and we identify possible sources of this weight. We comment on implications for experiments [1,2].

1:27PM J23.00012 Spectroscopic probes of the disorder-driven superconductor-insulator transition[1] , MOHIT RANDERIA, KARIM BOUADIM, YEN-LEE LOH, NANDINI TRIVEDI, The Ohio State University — In spite of decades of research, the mechanism of the disorder- driven superconductor- insulator transition (SIT) and the nature of the insulator are not understood. We use quantum Monte Carlo simulations that treat, on an equal footing, inhomogeneous amplitude variations and phase fluctuations, a major advance over previous theories. The energy gap in the density of states survives across the transition, but coherence peaks exist only in the superconductor. A characteristic pseudogap persists above the critical disorder and critical temperature, in contrast to conventional theories. Surprisingly, the insulator has a two-particle gap scale that vanishes at the SIT, despite a robust single-particle gap. Our predictions are testable with scanning probe experiments.

1:39PM J23.00013 Fast vortices in the cuprates? A vortex plasma model analysis of the THz conductivity and diamagnetism in $La_{2-x}Sr_xCuO_4$[1] , LUCAS BILBRO, ROLANDO VALDES AGUILAR, Johns Hopkins University, GENNADY LOGVENOV, OSHRI PELLEG, IVAN BOZOVIC, Brookhaven National Labs, N.P. ARMITAGE, Johns Hopkins University — We present measurements of the fluctuation superconductivity in an underdoped thin film of$La_{1.905}Sr_{0.095}CuO_4$ using time-domain THz spectroscopy. We compare our results with the measurements of diamagnetism in a similarly doped crystal of $La_{2-x}Sr_xCuO_4$. Through a vortex-plasma model, we show that if the fluctuation diamagnetism originates in vortices, then we necessarily obtain an anomalously large vortex diffusion constant, more than 100 times larger than estimates from the Bardeen-Stephen model.

Session J24 DCOMP DMP: Focus Session: Multiscale Modeling: Structural Materials D167

11:15AM J24.00001 Origin of Plasticity Length-Scale Effects in Fracture and Deformation , WILLIAM CURTIN[1], Brown University — Engineering design of essentially all metallic components used in structural applications relies heavily on the framework of continuum plasticity. However, many experiments now show that the plastic flow stress in metals increases in micron-scale material volumes, i.e. "smaller is stronger". The failure of conventional plasticity is particularly manifest at a crack tip, where infinite toughness can be predicted. Phenomenological strain-gradient plasticity models and discrete-dislocation models have emerged to handle size effects but there is no clear physical identification of material length scales controlling size-dependence, in spite of wide speculation. Here, we use a new discrete-dislocation/cohesive-zone model to unambiguously demonstrate that the spacing between obstacles to dislocation motion is one dominant material length scale controlling the fracture toughness of plastically deforming metals. With this insight, we propose a new "stress gradient plasticity" concept based on the behavior of dislocations in a "pile-up" at an obstacle under a stress gradient, which (i) rationalizes our fracture results and (ii) predicts size-effects under other loading conditions (bending, torsion, indentation). Quantitative agreement between theory and experiments is then demonstrated in several cases.

11:51AM J24.00002 Chemistry and Deformation: First Principles Studies of Local Plasticity , CHRISTOPHER WOODWARD, Air Force Research Laboratory — In order to understand the how chemistry influences deformation, an adequate description of the strain field near the center of dislocations (i.e. the core) is required. Continuum level descriptions of deformation ignore this short-range coupling between dislocations and the local atomic lattice. Interactions at this scale are non-linear and can strongly influence plastic deformation in fcc and bcc metals. Here, density functional theory is used in conjunction with a flexible boundary condition method to calculate the equilibrium dislocation core structure in a variety of bcc and fcc metals. The problem is divided into two parts: a solution for the nonlinear dislocation-core region and a solution for the long-range elastic response. Solving these individual problems is straightforward and by iteratively coupling the two solutions we can efficiently solve for the strain field in all space. Chemical effects, in the form of local solute-dislocation interactions, can also be calculated using this method. Derived solute-dislocation interactions are used to inform new models of solution hardening (and softening) in bcc Mo-X (X=Re, Pt) and fcc Al-X (X=Mg, Cr, Si, Cu) alloys. Currently, solute dislocation interactions are being assessed in bcc Fe-H alloys using this first principles technique.

12:27PM J24.00003 Ab-initio Concurrent Multiscale Method to Address Defects in Metals , GEORG SCHUSTERITSCH, Harvard University, THOMAS KÜHNE, Johannes Gutenberg University of Mainz, EFTHIMIOS KAXIRAS, Harvard University — We present a concurrent multiscale method for metallic systems based on coupling a region calculated using Kohn-Sham Density-Functional-Theory (KS-DFT) to a macroscopic region employing the Embedded Atom Method (EAM). By construction, our method is particularly well suited for treating defects such as grain boundaries (GBs), dislocations and chemical impurities, where quantum mechanical interactions in a small region near the defect may affect the mechanical properties at the macroscopic scale. Results for two metals, Nickel and Copper, are presented in the context of chemical embrittlement. We study the effects of impurities near GBs and investigate the surrounding strain field. This gives us insights into the role defects play in the underlying physical mechanism of chemical embrittlement.

12:39PM J24.00004 Multiscale Modeling of Irradiation Induced Hardening in Ferritic-Martensitic Steels , HUSSEIN ZBIB, IOANNIS MASTORAKOS, Washington State University, MOHAMMAD KHALEEL, XIN SUN, Pacific Northwest National Laboratory — The development of structural materials for use in new generation nuclear reactors depends critically on predicting and understanding the underlying physical mechanisms responsible for microstructural evolution along with corresponding dimensional instabilities and mechanical property changes. As the phenomena involved are very complex and span in several length scales, a multiscale approach is necessary in order to fully understand the degradation of materials in irradiated environments. The purpose of this work is to study the mechanical behaviour of Fe systems (namely a-Fe, Fe-Cr and Fe-Ni) under irradiation using both Molecular Dynamics (MD) and Dislocation Dynamics (DD) simulations. Critical information is passed from the atomistic (MD) to the microscopic scale (DD) in order to study the degradation of the material under examination. In particular, information pertaining to the dislocation-defects (particularly voids, helium bubbles and prismatic loops) interaction is obtained from MD simulations. This information is used in large scale DD simulations to analyze systems with high dislocation and defect densities, predicting the dependence of strength and ductility on defect density.

12:51PM J24.00005 A QCDFT Study of Hydrogen embrittlement at Crack Tip , QING PENG, Rensselaer Polytechnic Institute — Study of hydrogen embrittlement is of great importance due to widespread availability of hydrogen in all environmentally influenced cracking phenomena. We used QCDFT: Density functional theory based Quasi-continuum method to study the system where hydrogen atoms are presented on crack tip surface in single aluminum crystal under mode-I loading. We found that the presence of 0.1% hydrogen atoms increases the energy for nucleation of dislocations and enhance the brittlement of aluminum by 5%. The presence of hydrogen atoms also makes the geometry of crack tip to be sharp. The bonding and electronic charge transfer between hydrogen atoms and aluminum atoms were studied and the mechanism of hydride-induced embrittlement will be discussed.

1:03PM J24.00006 Models of defects at bi-material interfaces , KIPTON BARROS, TURAB LOOKMAN, Los Alamos National Laboratory — Multi-phase composite materials with a high density of bi-material interfaces can exhibit striking strength and robustness in extreme conditions such as shock and radiation damage. Laminar composites of Ag-Cu, Cu-Nb, and Ag-Fe with submicron to nano-scale layer thicknesses have recently been fabricated, but theoretical models of such systems are lacking. The plastic deformation behavior of nano-scale composites is dominated by defects, such as dislocations and twins, that are controlled by the interfaces. We investigate the phenomenology of defect dynamics at bi-material interfaces using Landau theory based models that span atomic and mesoscales.

1:15PM J24.00007 First Principles Simulations of Beta to Omega Transformation in the Titanium-Molybdenum System , ARUN DEVARAJ, NIRAJ GUPTA, SOUMYU NAG, University of North Texas, HAMESH FRASER, Ohio State University, RAJ BANERJEE, SRINIVASAN SRIVILLIPUTHUR, University of North Texas — The omega phase precipitation in beta titanium (Ti) alloys influence the beta to alpha phase transformation, and ultimately the mechanical properties of these alloys. Molybdenum (Mo) and other alloying additions affect both the relative phase stability and the energy barrier of the transformation. In this work we perform first principle calculations using Nudeged Elastic Band Method(NEB) implemented in Vienna Ab initio Simulation Package (VASP) to determine the minimum energy path, and thereby the energy barrier in beta Ti-Mo alloys with up to 20wt.% Mo. We report the energetics of beta to omega transformation path, proposed by De. Fontaine et al (Acta Metallurgica, vol. 19, p 1153 (1971)). The atomic configurations along the minimum energy transformational path will be compared with our 3D atom probe tomography and probe corrected high-resolution scanning transmission electron microscopy results.

1:27PM J24.00008 Shock-induced Spallation Phenomena in Copper-Niobium Nanolayered Composites , NIRAJ GUPTA, University of North Texas, ALEXANDER STUKOWSKI, Lawrence Livermore National Laboratory, MICHAEL BASKES, Los Alamos National Lab, SRINIVASAN SRIVILLIPUTHUR, University of North Texas — Shock-induced spallation phenomena in Copper-Niobium nanolayered composites conforming to a Kurdjumov-Sach's orientation relation were simulated using molecular dynamics to determine both spallation strength and the nature of void formation. The target structures consisted of varying numbers of alternating copper and niobium layers with thicknesses varying from 1 nm to 22 nm. Flyer velocities ranged from 3.5 to 11.5 A/ps, corresponding to an approximate strain rate of 10^9 s^{-1}. Spallation occurs in the vicinity of the Cu-Nb interface, and always in the copper layer. The proposed factors contributing to spallation will be discussed, as well as what effect the layer morphology has on the strength of the target.

1:39PM J24.00009 A First-Principles Study of Structure and Stability of Nickel Carbides , JOSH GIBSON, JAMAL UDDIN, University of North Texas, NELLI BODIFORD, University of Texas at Arlington, THOMAS CUNDARI, ANGELA WILSON, University of North Texas — Computational studies of nickel carbides, particularly Ni2C, are scarce. A systematic density functional theory study is reported for Ni2C, along with NiC and Ni3C, to understand the stability and electronic structure of nickel carbides of varying stoichiometry. A comprehensive study was executed that involved 28 trial structures of varying space group symmetry for Ni2C. An analysis of the electronic structure, geometry and thermodynamics of Ni2C is performed, and compared with that for Ni3C and NiC as well as several defect structures of varying composition. It is found that the most stable ground state arrangement of Ni2C exists within a simple orthorhombic lattice and that it has metallic character. The calculated formation energies (kcal/mol) of NiC, Ni2C, and Ni3C are 48.6, 7.9 and 6.4, respectively.

1:51PM J24.00010 Atomistic Simulations of Deformation of Nanoscale FCC Materials , SHIVRAJ KAREWAR, NIRAJ GUPTA, University of North Texas, ALEX STUKOWSKI, Lawrence Livermore National Laboratory, MICHAEL BASKES, Los Alamos National Laboratory, SRINIVASAN SRIVILLIPUTHUR, University of North Texas — We compare the deformation behavior of gold single crystal nanospheres with ∼6-30 nm diameters with gold spherical shells of varying inner to outer diameter ratios. Gold nanospheres are modeled with an EAM potential and the indenter is described by a repulsive potential. Yield strength dependence on sample size, geometry and temperature was studied in these nanospheres. The deformation mechanism is aided by the continuous displacement burst accompanying dislocation escape from the nanospheres. Based on this, a dislocation starvation mechanism has been discussed. Extended dislocations are found to be the prominent defect type in both solid and hollow nanospheres. Flow stresses are lower in hollow nanoshells. Low flow stresses are accounted for the presence of additional surface area for dislocation nucleation and emergence at the inner surface of the hollow shell.

2:03PM J24.00011 First-principles investigation of migration barriers in bulk (Cr,Co)-doped Ni_3Al (γ) and Ni_3Al/Ni (γ'/γ) interface , PRIYA GOPAL, SRINIVASAN SRIVILLIPUTHUR, Department of Material Science, University of North Texas — Ni-based super-alloys possess desirable high-temperature properties including ductility, fracture toughness as well as resistance to creep and oxidation mainly due to the precipitation of ordered Ni_3Al γ' precipitates within a γ (Ni,Al) matrix. Various studies have shown that the mechanical properties can be improved by adding substitutional elements. It is thus very important to understand the electronic structure and diffusion kinetics of the substitutional elements and the role each one has on the overall microstructure. \pardthis work we present our results on the systematic study of the energetics and migration barriers of Cr and Co in bulk Ni_3Al and Ni_3Al/Ni (γ'/γ) interface. We did simulations of migration of vacancy and substitutional element in a complete set of migration paths and evaluated the barrier energies in both bulk Ni_3Al and Ni_3Al/Ni (γ'/γ) interface using density functional theory methods. We will briefly discuss our results on the effect of migration barriers on the partitioning behavior of Cr and Co between the and ' phases in Ni-based super-alloy.

Tuesday, March 22, 2011 11:15AM - 2:03PM –

Session J26 DMP DCOMP: Focus Session: Iron Based Superconductors – Vortices & High Fields D162/164

11:15AM J26.00001 Anomalous High-Field Meissner Effect in Pnictide Superconductors , RUSLAN PROZOROV, MAKARIY A. TANATAR, SERGEY L. BUD'KO, PAUL C. CANFIELD, Ames Laboratory, Ames, IA 50011, USA, BING SHEN, PENG CHENG, HAI-HU WEN, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — The Meissner effect has been studied in $Ba(Fe_{0.926}Co_{0.074})_2As_2$ and $Ba_{0.6}K_{0.4}Fe_2As_2$ single crystals and compared to well known, type-II superconductors $LuNi_2B_2C$ and V_3Si. Whereas flux penetration is mostly determined by the bulk pinning (and, perhaps, surface barrier) resulting in a large negative magnetization, the flux expulsion upon cooling in a magnetic field is very small, which could also be due to pinning and/or surface barrier effects. However, in stark contrast with the expected behavior, the amount of the expelled flux increases almost linearly with the applied magnetic field, at least up to our maximum field of 5.5 T, which far exceeds the upper limit for the surface barrier. One interpretation of the observed behavior is that there is a field-driven suppression of magnetic pair-breaking.

11:27AM J26.00002 Flux Creep associated with Strong Pinning in Isovalently Doped Iron-Based Superconductors , M. KONCZYKOWSKI, SULTAN DEMIRDIS, C.J. VAN DER BEEK, Laboratoire des Solides Irradies, Ecole Polytechnique, CNRS UMR 7642 & CEA/DSM/IRAMIS, 91128 PALAISEAU, France, R. PROZOROV, M. TANATAR, P.C. CANFIELD, Ames Laboratory, Ames, IA 50011, U.S.A., S. KASAHARA, T. SHIBAUCHI, YUJI MATSUDA, Department of Physics, Kyoto University, Kyoto 606-8502, Japan — Strong pinning in Iron-Based Superconductors leads to the ubiquitous central peak of the irreversible magnetization. Notably, isovalently doped materials such as $BaFe_2(As_{1-x}P_x)_2$ and $Ba(Fe_{1-x}Ru_x)_2As_2$ offer a paradigm for the study of strong pinning because it is the only contribution to the critical current density j_c. We have studied flux creep rates as function of field and temperature in the low- and high field regimes in which j_c is limited by the line tension of a single pinned vortex, and by vortex interactions, respectively. For $T < \frac{1}{2}T_c$, screening currents j are of the order of 10^9 Am^{-2}, in spite of a creep rate $d\ln j/d\ln t \sim 0.02$. Creep is initially Anderson Kim-like, *i.e.* , creep barriers U depend on j as $U \propto (1 - j/j_c)$ over an order of magnitude in j, before crossing over to a nonlinear behavior. j_c is easily extracted from the high-current, short-time part of the magnetic relaxation. The results cast doubt on the range of applicability of the often-used "interpolation formula" $j \propto [1 + (k_BT/U_c)\ln(t + t_0/\tau)]^{-1/\mu}$ for weak collective pinning.

11:39AM J26.00003 Strong Pinning and Nonlinear Creep Barriers in Iron-Pnictide Superconductors , S. DEMIRDIS, M. KONCZYKOWSKI, C.J. VAN DER BEEK, Laboratoire des Solides Irradies, Ecole Polytechnique, CNRS UMR 7642 & CEA/DSM/IRAMIS, 91128 PALAISEAU, France, R. PROZOROV, Ames Laboratory, Ames, IA 50011, U.S.A., S. KASAHARA, T. SHIBAUCHI, YUJI MATSUDA, Department of Physics, Kyoto University, Kyoto 606-8502, Japan — The irreversible magnetization of Iron-Based Superconductors is characterized by the presence of an ubiquitous peak of the critical current density j_c, centered around zero field. Closer examination shows that the field-dependence of j_c corresponds, in all cases, to a low-field plateau, followed by a power-law decrease, $j_c \propto B^{-\alpha}$ (with $\alpha \sim \frac{5}{8}$) above a cross-over field B^*. This strongly suggests that vortex pinning at low magnetic field is due to strong pinning by nanometer-scale defects. In isovalently doped materials such as $BaFe_2(As_{1-x}P_x)_2$, strong pinning is the only contribution to the critical current. The analysis of j_c allows one to extract, without a priori assumptions, the elementary pinning force and the defect density. In $BaFe_2(As_{1-x}P_x)_2$, the latter quantity is in qualitative agreement with that obtained by H. Shishido *et al.*[Phys. Rev. Lett. **104**, 057008 (2010)]. The temperature dependence of the screening current above B^* is strongly affected by flux creep. The current decays as $j \sim [(k_BT/U)\ln(t+t_0/\tau)]^{-1/\mu}$, with $\mu \sim 1.6$, showing that nonlinear creep barriers are not an exclusive feature of weak collective pinning.

11:51AM J26.00004 Model of vortex states in hole-doped iron-pnictide superconductors , YI GAO, HUAI-XIANG HUANG, CHUN CHEN, C.S. TING, WU-PEI SU — Based on a phenomenological model with competing spin-density- wave (SDW) and extended $s-$wave superconductivity, the vortex states in $Ba_{1-x}K_xFe_2As_2$ are investigated by solving Bogoliubov-de Gennes equations. Our result for the optimally doped compound without induced SDW is in qualitative agreement with recent scanning tunneling microscopy experiment. We also propose that the main effect of the SDW on the vortex states is to reduce the intensity of the in-gap peak in the local density of states and transfer the spectral weight to form additional peaks outside the gap.

12:03PM J26.00005 Angular dependence of the critical current and vortex phase diagram in Co-doped BaFe2As2 films with strong pinning , B. MAIOROV, Los Alamos National Laboratory, NM 87544, T. KATASE, H. HIRAMATSU, H. HOSONO, Tokyo Institute of Technology, Yokohama, Japan, L. CIVALE, Los Alamos National Laboratory, NM 87544 — Studying the angular dependence of the critical current density (Jc) as a function of temperature in superconductors with complex pinning landscapes is very important both from the technical and fundamental points of view. The low anisotropy found in the Ba122 family tightened with strong naturally grown pinning make Ba122 films very attractive. It is also interesting to understand the different factors affecting vortex pinning in different regimes of temperature (T) and magnetic field (H). We present results on iron-arsenide superconducting films with varied pinning landscapes composed of columnar defects and nanoparticles. We analyze different field and angular regimes. We find that the naturally grown correlated defects found in Co-doped BaFe2As2 films are effective up to very high fields (m0H=15T) affecting a very wide region o the angular phase diagram. We also investigate the effects of film's thickness and the addition of defects produced by irradiation

12:15PM J26.00006 Comparative study of flux pinning characteristics of $Ba(Fe_{1-x}Co_x)_2As_2$ and $BaFe_2(As_{1-x}P_x)_2$ single crystals[1]

, NORIKO CHIKUMOTO, Superconductivity RSCH LAB, ISTEC, WATARU HIRATA, SHIGEKI MIYASAKA, SETSUKO TAJIMA, Osaka Univ., KEIICHI TANABE, Superconductivity RSCH LAB, ISTEC — We have studied the magnetization behavior of iron-pnictide superconductor, $Ba(Fe_{1-x}Co_x)_2As_2$ (Co-doped Fe122) with various Co doping and $BaFe_2(As_{0.65}P_{0.35})_2$ (P-doped Fe122) single crystals. All of the Co-doped Fe122 crystals showed a very pronounced "peak effect" in all the temperature range, irrespective of doping state. It is important to mention that a similar peak effect was previously reported for $REBa_2Cu_3O_y$. In order to get further insight into the pinning mechanism of the present system, we analyzed the pinning force density $F_p = J_cB$. A good scaling of the F_p versus the reduced field, $b = B/B_{irr}$, was established for all the Co-doped Fe122 crystals and the scaling curves were well fitted with the function given by $F_p/F_{p,max} = Ab^p(1-b)^q$, where A is a numerical parameter, p and q are describing the actual pinning mechanism. It was found that p value monotonically increases with x, while q value decreases with x. On the other hand, P-doped Fe122 did not show "peak effect". We will discuss about the possible pinning mechanism causing the peak effect.

[1]This work was supported by JSPS through FIRST Program.

12:27PM J26.00007 Dynamics of Vortices in Heavy-ion Irradiated Co-doped $BaFe_2As_2$[1]

, TSUYOSHI TAMEGAI, TOSHIHIRO TAEN, HIDENORI YAGYUDA, TOMOTAKA TANIGUCHI, SHYAM MOHAN, YASUYUKI NAKAJIMA, Dep. of Appl. Phys., The Univ. of Tokyo, SATORU OKAYASU, Advanced Science Research Center, Japan Atomic Energy Agency, MASATO SASASE, The Wakasa-wan Energy Research Center, Research & Development Group, HISASHI KITAMURA, TAKESHI MURAKAMI, National Institute of Radiological Sciences, TADASHI KAMBARA, Nishina Center for Accelerator Based Science, RIKEN, YASUYUKI KANAI, IThe Institute of Physical and Chemical Research, RIKEN — Effects of heavy-ion irradiation on the critical current density, J_c, and vortex dynamics are investigated in $Ba(Fe_{1-x}Co_x)_2As_2$ irradiated by heavy- ions of various kinds. Irradiations induce a large enhancement of J_c in the case of 200 MeV Au creating nearly continuous columnar tracks. On the other hand, in the case of 800 MeV Xe irradiation, despite the enhancement of J_c, clear columnar defects are not observed. In the case of 2.6 GeV U irradiation, new types of structure appears in the M-H loop at high matching field. We also discuss the behavior of vortex dynamics in the irradiated $Ba(Fe_{1-x}Co_x)_2As_2$.

[1]This work is partly supported by JST, Transformative Research-Proiect on Iron Pnictides (TRIP)

12:39PM J26.00008 High critical current density in $BaAs_2(Fe,Co)_2$ thin films up to 35 T

, J. JIANG, National High Magnetic Field Laboratory, FSU, Tallahassee, Florida, C. TARANTINI, J.D. WEISS, J. JAROSZYNSKY, E.E. HELLSTROM, D.C. LARBALESTIER, S. LEE, C.W. BARK, H.W. JANG, C.M. FOLKMAN, S.H. BAEK, J.W. PARK, C.B. EOM, Y. ZHANG, C.T. NELSON, X.Q. PAN — In the Co-doped $BaFe_2As_2$ thin films we intensively investigated field and angular dependences of J_c down 4.2 K in high field. We found a strong correlated c-axis pinning and Jc for field along the c-axis exceeds J_c for H//ab plane up to ∼20T, inverting the expectation of the Hc2 anisotropy. As a consequence the angular dependence is very weak and J_c is still over 10^5 A/cm^2 at 20T. Moreover the maximum pinning force F_p(4.2K) reaches 35-40 GN/m^3 at 15-20T depending on the field configuration, indicative of strong high-field vortex pinning. High resolution transmission electron microscopy reveals that the strong vortex pinning is due to a high density of non-superconducting Ba-Fe-O nanocolumnar defects whose diameter is $\sim 2\xi$, perfect conditions for a strong pinning.

12:51PM J26.00009 Critical current in disordered iron-pnictide superconducting wires[1]

, DUSHKO KUZMANOVSKI, MAXIM VAVILOV, University of Wisconsin - Madison, ANTON VORONTSOV, Montana State University — We evaluate the critical current in narrow wires of disordered iron-based pnictide superconductors. We present the Eilenberger and Usadel equations for a two-band model of a pnictide superconductor which take into account both inter and intra-band scattering events. The intra-band scattering events are responsible for the momentum relaxation of charged excitations, but do not suppress the homogeneous superconducting state. On the contrary, the inter-band scattering acts as the depairing mechanism. We apply the Usadel equation to analyze the dependence of the critical current on the strength of disorder in narrow iron-pnictide wires.

[1]Supported by NSF Grant No. DMR-0955500

1:03PM J26.00010 Upper critical field measured up to 85T in different iron-based compounds

, C. TARANTINI, National High Magnetic Field Laboratory, FSU, Tallahassee, Florida, J. JAROSZYNSKY, A. GUREVICH, D.C. LARBALESTIER, F. BALAKIREV, H.H. WEN, E. BELLINGERI, I. PALLECCHI, C. FERDEGHINI — We report magneto-transport measurements of H_{c2}(T) at very high dc and pulsed magnetic field up to 85T on different families of iron-based single crystals and thin film superconductors with different doping levels and stress. Some of these materials show high H_{c2} extrapolating to ∼100T and extremely high slopes up to 20 T/K for H//c and over 200 T/K for H//ab, indicating significant Pauli pair breaking and a possibility of the Fulde-Ferrel-Larkin-Ovchinnikov state. The superconducting transitions remain sharp also at the highest field showing an irreversibility field close to H_{c2}.

1:15PM J26.00011 Flux Pinning and Quasi-particle Scattering in Charge- Doped Iron-Based Superconductors

, KEES VAN DER BEEK, S. DEMIRDIS, M. KONCZYKOWSKI, Laboratoire des Solides Irradies, Ecole Polytechnique, CNRS UMR 7642 & CEA/DSM/IRAMIS, 91128 PALAISEAU, France, S. KASAHARA, T. TERASHIMA, Research Center for Low Temperature and Materials Sciences, Kyoto University, Sakyo-ku, Kyoto 606-8501, Japan, R. OKAZAKI, T. SHIBAUCHI, YUJI MATSUDA, Department of Physics, Kyoto University, Sakyo-ku, Kyoto 606-8502, Japan — Whereas isovalently doped iron-based superconductors, such as $BaFe_2(As_{1-x}P_x)_2$ and $Ba(Fe_{1-x}Ru_x)_2As_2$ show only strong, "individual-defect" vortex pinning due to nanometer-sized defects, charge-doped iron-pnictide superconductors show a low-field, field-independent contribution to the critical current density j_c that is well described by the collective pinning theory. Quantitative analysis of the magnitude, temperature, and field-dependence of j_c in the $PrFeAsO_{1-y}$ compound shows that the behavior of j_c can be fully explained, if one assumes the oxygen vacancies in this material to be responsible for quasi-particle scattering in the vortex cores. Analysis of j_c of this and other charge-doped compounds such as NdFeAs(O,F), (Ba,K)Fe_2As_2, and $Ba(Fe,Co)_2As_2$ yields estimates for the transport scattering cross-section of the dopant impurities in all these materials. We find scattering to be in the Born limit, with a scattering phase angle δ_0 such that $\sin\delta_0 \sim 0.2 - 0.3$.

1:27PM J26.00012 Nearly Isotropic Critical Currents in SmFeAs(O,F) in High Magnetic Fields

, BERTRAM BATLOGG, Solid State Physics, ETH Zurich, PHILIP MOLL, Solid State Physics, ETH Zurich, Switzerland, ROMAN PUZNIAK, Institute of Physics, Polish Academy of Sciences Warsaw, Poland, FEDOR BALAKIREV, NHMFL, LANL, Los Alamos, NM, LUIS BALICAS, NHMFL, Tallahassee, FL, JANUSZ KARPINSKI, NIKOLAI ZHIGADLO, Solid State Physics, ETH Zurich, Switzerland — The layered structure of SmFeAs(O,F) naturally raises questions about the electronic anisotropy of this 55K superconductor. To investigate the transport anisotropy, we performed electric 4-probe measurements on Focused Ion Beam (FIB) cut single crystals with sub-μm^2 cross-section, with current along and perpendicular to the FeAs layers. The normal state resistivity is indeed anisotropic ($\rho_c/\rho_{ab} \approx 2$ at RT, ≈ 10 at 50K) and consistent with the calculated Fermi velocity anisotropy. In contrast, the dissipation in high fields below T_c is more isotropic. The critical current densities at 4K are nearly isotropic and very high ($> 2\ 10^6$ A/cm^2), and up to 14 T, they are almost independent of the field orientation and strength. These values agree well with magnetization measurements. Additional measurements to much higher fields are presented.

1:39PM J26.00013 Low-energy muons and polarized neutrons for studying superconductivity[1] , VLADIMIR KOZHEVNIKOV, Tulsa Community College, KRISTIAAN TEMST, Katholieke Universiteit Leuven, ANDREAS SUTER, Paul Scherrer Institute, TIMOTHY CHARLTON, Rutherford Appleton Laboratory, HELMUT FRITZSCHE, Chalk River Laboratories, THOMAS PROKSCHA, ELVEZIO MORENZONI, Paul Scherrer Intitut, MARGRIET VAN BAEL, CHRISTIAN VAN HAESENDONCK, JOSEPH INDEKEU, Katholieke Universiteit Leuven — The penetration of the magnetic field into superconductors (SC) in the Meissner state is one of the major resources for studying SC. The merit of this resource will be greatly enhanced by quantitative measurements of the field distribution over the penetration layer, which, in particular, may lead to new insights for unconventional SC. We will report on measurements of the magnetic field profile in In and Sn using low-energy muons (LE-mSR) and polarized neutrons (PNR). The results solidly demonstrate nonexponential decay of the magnetic induction in accord with the Pippard and BCS theories. However, in contrast to In, results on which were reported last year, the data for Sn show significant differences in the values of the London penetration depth and the Pippard coherent length with those known from the literature.

1:51PM J26.00014 Incoherent Interplane Response of $FeTe_{0.55}Se_{0.45}$, S.J. MOON, Department of Physics, University of California, San Diego, La Jolla, California 92093, USA, C.C. HOMES, A. AKRAP, Z.J. XU, J.S. WEN, Z.W. LIN, Q. LI, G.D. GU, Condensed Matter Physics and Material Science Department, Brookhaven National Laboratory, Upton, New York 11973, USA, D.N. BASOV, Department of Physics, University of California, San Diego, La Jolla, California 92093, USA — We investigated the interplane c axis electronic response of iron-chalcogenide superconductor $FeTe_{0.55}Se_{0.45}$ using infrared spectroscopy. We found that the normal-state c axis electronic response of $FeTe_{0.55}Se_{0.45}$ is incoherent. The c axis optical conductivity does not display well-defined Drude response and it becomes further suppressed with decreasing temperature. This normal-state c axis optical response is remarkably similar to that of the mildly underdoped cuprates but is in sharp contrast to the coherent c axis response of $Ba_{1-x}K_xFe_2As_2$. From the analyses on the electronic anisotropy of various layered superconductors, we found a close correlation between the degree of the coherence in the c axis transport and the strength of the dissipation in the *ab* plane response.

Session J27 GQI: Focus Session: Quantum Optics with Superconducting Circuits II C155

11:15AM J27.00001 Tomography and Correlation Function Measurements of Itinerant Microwave Photons[1] , ANDREAS WALLRAFF, ETH Zurich — At optical frequencies the radiation produced by a source, such as a laser, a black body or a single-photon emitter, is frequently characterized by analysing the temporal correlations of emitted photons using single-photon counters. At microwave frequencies, however, there are no efficient single-photon counters yet. Instead, well-developed linear amplifiers allow for efficient measurement of the amplitude of an electromagnetic field. Here, we demonstrate first- and second-order correlation function measurements of a pulsed microwave-frequency single-photon source integrated on the same chip with a 50/50 beam splitter followed by linear amplifiers and quadrature amplitude detectors [1]. We clearly observe single-photon coherence in first-order and photon antibunching in second-order correlation function measurements of the propagating fields [2]. We also present first measurements in which we reconstruct the Wigner function of itinerant single photon Fock states and their superposition with the vacuum. To perform these measurements we have developed efficient methods to separate the detected single photon signal from the noise added by the amplifier by analyzing the moments of the measured amplitude distribution up to 4th order. The techniques and methods demonstrated in this work may find application in quantum optics and quantum information processing experiments at microwave frequencies.

11:51AM J27.00002 An integrated circuit for generating distributable and unconditional entanglement at microwave frequencies , HSIANG-SHENG KU, University of Colorado at Boulder, FRANCOIS MALLET, JILA, WILLIAM F. KINDEL, University of Colorado at Boulder, KONRAD W. LEHNERT, JILA and NIST, KENT D. IRWIN, GENE C. HILTON, LEILA R. VALE, EMANUEL KNILL, SCOTT C. GLANCY, NIST, JILA TEAM, NIST TEAM — Entanglement, the unique feature of quantum mechanics, is the central resource of quantum information. In the strategy of continuous-variables quantum information processing, unconditional and distributable entanglement can be obtained by combining two squeezed states on a balanced beam splitter. Our group has recently demonstrated the generation of squeezed microwave states using a Josephson Parametric Amplifier [1] and implemented on-chip balanced beam splitters [2]. This talk will present a device that combines all these components on a single chip. The design requirements for such an "on-chip entangler" of the electromagnetic field modes will be discussed.

12:03PM J27.00003 Measuring on-chip distributable and unconditional entanglement at microwave frequencies , FRANCOIS MALLET, HSIANG-SHENG KU, JILA, WILL KINDEL, SCOTT GLANCY, EMANUEL KNILL, KENT D. IRWIN, GENE C. HILTON, LEILA R. VALE, NIST, KONRAD W. LEHNERT, JILA — A squeezed mode of the light field exhibits reduced fluctuations, below the vacuum level, along one of its quadratures and conversely amplified fluctuations along the conjugate quadrature. In that sense, it is the electromagnetic analog of the particle states used by Einstein-Podolsky-Rosen to derive their famous paradox. Indeed, by combining two such squeezed modes on a balanced beam splitter, entanglement can be generated, in an unconditional and distributable way. Such experiments have been performed for some years at optical frequencies. This talk will present an experimental attempt to generate and characterize entanglement with squeezed light at microwaves frequencies, using superconducting electrical circuits. We will discuss the achieved degree of entanglement from the perspective of implementing quantum teleportation protocols at microwave frequencies.

12:15PM J27.00004 Observation of photon blockade in circuit QED using second-order correlation function measurements , C. LANG, D. BOZYIGIT, C. EICHLER, L. STEFFEN, J.M. FINK, A.A. ABDUMALIKOV JR., M. BAUR, S. FILIPP, A. WALLRAFF, ETH Zurich — Circuit quantum electrodynamics (QED) provides an attractive platform to effectively study photon-photon interactions mediated by their strong and resonant coupling to a superconducting qubit embedded into a transmission line resonator. Driving the coupled system with a coherent microwave frequency tone the anharmonicity of the Jaynes-Cummings ladder blocks the transmission of more than a single photon through the resonator at a time. Using on-chip microwave beam splitters, linear amplifiers, and quadrature amplitude detectors we observe fluorescence and Rayleigh scattering in Mollow-triplet-like spectra. We investigate the phenomenon of photon blockade in second-order correlation function measurements which show antibunching and signatures of Rabi oscillations induced by the continuous drive coupling the ground and first excited states of the Jaynes-Cummings ladder.

12:27PM J27.00005 Generation and reconstruction of two mode squeezed states in the microwave domain

, CHRISTOPHER EICHLER, DENIZ BOZYIGIT, CHRISTIAN LANG, MATTHIAS BAUR, LARS STEFFEN, JOHANNES FINK, STEFAN FILIPP, ANDREAS WALLRAFF, ETH Zurich — Squeezing between two radiation field modes at optical frequencies has already been used to realize various quantum information processing tasks such as teleportation and quantum key distribution. Here we present measurements at microwave frequencies in which we generate and reconstruct a two mode squeezed state in a circuit QED setup. We prepare the desired state with a Josephson parametric amplifier and detect all four quadrature components simultaneously in a two channel heterodyne setup using amplitude detectors. Recording two dimensional phase space histograms for all possible pairs of quadratures allows for the reconstruction of the full covariance matrix and the four dimensional Wigner function of the squeezed state which shows strong correlations between the quadrature noise in the two modes. Combining parametric amplifier devices in networks with beamsplitters and superconducting qubits could allow for future linear optics quantum computation with propagating microwave photons.

12:39PM J27.00006 Using Superconducting Qubit Circuits to Engineer Exotic Lattice Systems

, DIMITRIS TSOMOKOS[1], Royal Holloway University of London, SAHEL ASHHAB[2], FRANCO NORI[3], Institute of Physical and Chemical Research (RIKEN) Japan and Physics Department, University of Michigan — We propose an architecture based on superconducting qubits and resonators for the implementation of a variety of exotic lattice systems, such as spin and Hubbard models in higher or fractal dimensions and higher-genus topologies. Spin systems are realized naturally using qubits, while superconducting resonators can be used for the realization of Bose-Hubbard models. Fundamental requirements for these designs, such as controllable interactions between arbitrary qubit pairs, have recently been implemented in the laboratory, rendering our proposals feasible with current technology.

12:51PM J27.00007 Microwave Cavity Lattices for Simulating Condensed Matter Systems

, DEVIN UNDERWOOD, ARTHUR SAFIRA, SRIKANTH SRINIVASAN, ANTHONY HOFFMAN, Princeton University, JENS KOCH, Northwestern University, ANDREW HOUCK, Princeton University — Recently, quantum phase transitions of light have been the focus of much theoretical attention. One possible experimental realization relies upon the circuit quantum electrodynamics architecture (cQED); however, in order for this to be successful, coupled arrays of superconducting resonators must first be realized with low disorder. Here we fabricate and characterize an array with low disorder consisting of 12 niobium resonators on a sapphire substrate in a honeycomb pattern with the photonic lattice sites forming a Kagome star. The structure is characterized by measuring transmission through different input-output port pairs and by varying the hopping rate between resonators. A family of resonant peaks corresponding to the various modes of the coupled array is identifiable and agrees well with both a tight-binding Hamiltonian and simulations from a commercial microwave software package. These experiments are an important step in realizing strongly correlated interactions in cQED.

1:03PM J27.00008 Synthetic gauge fields in Jaynes-Cummings-Hubbard ring lattices

, ANDREAS NUNNENKAMP, Yale University, JENS KOCH, Northwestern University, STEVEN GIRVIN, Yale University — Recently there has been much interest in many-body physics with photons in circuit-QED arrays. Here we explore the physics of a Jaynes-Cummings-Hubbard ring lattice subject to a synthetic gauge field, i.e. where the hopping terms carry a complex phase factor due to Josephson couplers between the resonators. There are critical phase twists at which the single-particle spectrum is degenerate so that even weak interactions can give rise to strong correlations. We compare to ultracold bosons in rotating ring lattices and study the out-of-equilibrium physics as relevant for current experiments.

1:15PM J27.00009 Multi-Resonator Circuit QED Part I: The Photon Shell[1]

, MATTEO MARIANTONI, H. WANG, RADOSLAW C. BIALCZAK, M. LENANDER, ERIK LUCERO, M. NEELEY, A.D. O'CONNELL, D. SANK, M. WEIDES, J. WENNER, T. YAMAMOTO, Y. YIN, J. ZHAO, JOHN M. MARTINIS, A.N. CLELAND, Department of Physics, UC Santa Barbara — The generation and control of quantum states of light constitute fundamental tasks in cavity quantum electrodynamics (QED). The superconducting realization of cavity QED, circuit QED, enables on-chip microwave photonics, where superconducting qubits control and measure individual photon states. A long-standing issue in cavity QED is the coherent transfer of photons between two or more resonators. Here, we use circuit QED to implement a three-resonator architecture on a single chip, where the resonators are interconnected by two superconducting phase qubits. We use this circuit to shuffle one- and two-photon Fock states between the three resonators, and demonstrate qubit-mediated vacuum Rabi swaps between two resonators. This illustrates the potential for using multi-resonator circuits as photon quantum registries and for creating multipartite entanglement between delocalized bosonic modes.

1:27PM J27.00010 Multi-resonator circuit QED - Part 2: Generation and detection of NOON states[1]

, FRANK WILHELM, fwilhelm@iqc.ca, SETH MERKEL, University of Waterloo — NOON states, states between two modes of light of the form $|N,0\rangle + e^{i\phi}|0,N\rangle$ allow for super-resolution interformetry. We show how NOON states can be efficiently produced in circuit quntum electrodynamics using superconducting phase qubits and resonators. We propose a protocol where only one interaction between the two modes is required, creating all the necessary entanglement at the start of the procedure. This protocol makes active use of the first three states of the phase qubits. Additionally, we show how to efficiently verify the success of such an experiment, even for large NOON states, using randomly sampled measurements and semidefinite programming technique. This is more efficient that the full tomography implemented to-date, allowing to reliably verify higher NOON-states. Based on New J. Phys. **12**, 093036 (2010).

1:39PM J27.00011 Multi-Resonator Circuit QED Part III: Two-Resonator Entanglement

, HAOHUA WANG, MATTEO MARIANTONI, RADOSLAW C. BIALCZAK, M. LENANDER, ERIK LUCERO, M. NEELEY, A.D. O'CONNELL, D. SANK, M. WEIDES, J. WENNER, Y. YIN, J. ZHAO, JOHN M. MARTINIS, A.N. CLELAND, Department of Physics, UC Santa Barbara, T. YAMAMOTO, Green Innovation Research Laboratories, NEC, Japan — Quantum entanglement, a defining feature of quantum mechanics, has been demonstrated in a variety of nonlinear spin-like systems. Quantum entanglement in linear systems has proven significantly more challenging, as the intrinsic energy level degeneracy associated with linearity makes quantum control more difficult. Here we demonstrate the quantum entanglement of photon states in two independent linear microwave resonators utilizing two superconducting phase qubits coupled through a band-pass resonator. After entangling two qubits into a Bell state, we demonstrate the controlled sequential photon amplification and transferring procedures, creating N quanta excitations distributed in two resonators. We completely characterize the two-resonator states with bipartite Wigner tomography and prove the existence of entanglement.

1:51PM J27.00012 Observation of Collective Strong Coupling between a Superconducting Resonator and Bismuth Dopants in Silicon , NATANIA ANTLER, R. VIJAY, UC Berkeley, CHRISTOPH WEIS, Lawrence Berkeley National Laboratory, ELI LEVENSON-FALK, UC Berkeley, THOMAS SCHENKEL, Lawrence Berkeley National Laboratory, IRFAN SIDDIQI, UC Berkeley — All electrical readout and control of spin systems with superconducting circuitry is an attractive route for implementing hybrid quantum information processing. Isolated spins, in general, have much longer coherence times than present day superconducting qubits, and thus could be utilized as memory elements. Species with a zero-field splitting (ZFS), such as bismuth doped silicon or NV centers in diamond, are particularly attractive as the absence of a strong magnetic bias field facilitates compatibility with low loss superconducting circuitry. We present results on the interaction of a tunable superconducting resonator and an ensemble of Bi spins implanted in an epitaxial layer of 28Si. As the resonator tunes through the ZFS, we observe an avoided crossing indicative of collective strong coupling. We discuss coherence properties as a function of spin density as well as progress on the detection of a small number of spins using a dispersive nanoSQUID magnetometer.

2:03PM J27.00013 Qubit-oscillator systems in the ultrastrong-coupling regime and their potential for preparing nonclassical states[1] , FRANCO NORI, SAHEL ASHHAB, RIKEN and University of Michigan — We consider a system composed of a two-level system (i.e. a qubit) and a harmonic oscillator in the ultrastrong-coupling regime, where the coupling strength is comparable to the qubit and oscillator energy scales. We explore the possibility of preparing nonclassical states in this system, especially in the ground state of the combined system. The nonclassical states that we consider include squeezed states, Schrodinger-cat states and entangled states. We also analyze the nature of the change in the ground state as the coupling strength is increased, going from a separable ground state in the absence of coupling to a highly entangled ground state in the case of very strong coupling. Reference: S. Ashhab and F. Nori, Phys. Rev. A 81, 042311 (2010).

Session J28 DCOMP DMP: Focus Session: Computational Materials Design - Data-Driven

C156

11:15AM J28.00001 Distributed Strategies for Materials Development , STEFANO CURTAROLO, Duke University — Through appropriate combinations of "ab-initio," "data-mining-high-throughput," "cluster expansion," "vibrational," and "electronic structure" techniques, we have parameterized the whole set of transition-metal binary intermetallics (435 alloys) and a list of ∼10,000 inorganic crystals. The presentation will introduce the method, the tools, the standards, and the approach for automatic discovery of trends in material development. We will analyze rules for miscibility in metallic catalytic materials, electronic structure correlations in scintillators, and high-throughput search of thermoelectric materials and topological insulator through the distributed network of data, accessible to the scientific community. The presentation will also extend the hybrid method to study phenomena at the nanoscale, like size-induced viscosity effects on the catalytic rate, self-consistent variational approaches to the shape of nano-catalysts and size-dependent Wulff plots for tailoring catalysts compositions and size (Sponsors: ONR, NSF, DHS, Teragrid).

11:51AM J28.00002 A database survey to search for new candidate *p*-type TCOs[1] , GIANCARLO TRIMARCHI, K. POEPPELMEIER, A. J. FREEMAN, Northwestern U., Evanston, IL — New *p*-type TCOs are often produced by reacting the prototype binary *p*-type oxides, i.e., Ag_2O and Cu_2O, with binary oxides of other transition metals or main-series elements. Yet, so far only a small part of all the multi-cation Cu and, in particular, Ag oxides have been assessed as candidate *p*-type TCOs. Furthermore, numerous multi-species Cu and Ag oxide systems are poorly characterized, which leaves ample scope for discovery of yet unknown compounds belonging to them, and, likely, of unsuspected new TCOs, too. Here, we survey a *complete* database of known multicomponent Ag and Cu oxides, without restrictions on element composition, to search for new candidate TCOs. We indexed all the compounds in this database by applying selected crystal structure descriptors as structure type, stoichiometry, and coordination environment of the Cu and Ag cations. Chemical insight points to a significant likelihood that 2- and 4-fold coordination of the noble metal cations yield band structure properties suitable for the transparency and hole conductivity needed in TCOs. We scanned the indexed database to find compounds that could match these requirements and identified a set of materials that could be interesting candidate *p*-type TCOs.

[1]Supported by the U.S. DOE EFRC for Inverse-Band Design.

12:03PM J28.00003 Ab-Initio Prediction of Phase Diagrams Using a Genetic Algorithm , WILL TIPTON, Cornell University, RICHARD HENNIG — The computational design and prediction of materials' properties is a goal on which much progress has been made. However, it is generally necessary to first determine a material's crystal structure, and this remains a difficult problem. Previously, genetic algorithms have been successful in searching for stable crystal structures at particular compositions. However, when approaching a new material system, it is often unknown at which compositions stable structures might form. In order to search all of composition space simultaneously, Trimarchi and Zunger have recently suggested a modification to the traditional GA approach. In this method candidate structures are evaluated according to their formation energies with repect to structure found previously. We have implemented this technique in our genetic algorithm code and are investigating the practical details of its use. We have predicted previously-unknown phases in the Li-Be and elemental Eu systems under high pressure.

12:15PM J28.00004 The Harvard Clean Energy Project. Large-scale computational screening and design of molecular motifs for organic photovoltaics on the World Community Grid , JOHANNES HACHMANN, ROBERTO OLIVARES-AMAYA, SULE ATAHAN-EVRENK, Harvard University, CARLOS AMADOR-BEDOLLA, UNAM Mexico, ALAN ASPURU-GUZIK, Harvard University — Organic solar cells are one of the promising approaches to ubiquitously establishing renewable energy sources; alas the necessary 10% energy conversion efficiency remains elusive. We present the Harvard Clean Energy Project (CEP, http://cleanenergy.harvard.edu) which is concerned with the screening and design of organic photovoltaics (and organic electronics in general) by means of first-principles computational quantum chemistry. We use modern DFT to assess the quality of candidate structures and systematically improve upon these based on the gathered understanding of structure-property relations. The CEP is a high-throughput investigation which utilizes the massive computational resource of the IBM World Community Grid, which allows us to characterize millions molecules of interest in the course of the next year. We address the combinatorial generation of our molecular library, our database, workflow organization and automation, data calibration and cheminformatics analysis, and the closure of the development cycle provided by our experimental collaborators.

12:27PM J28.00005 Computational design of new A2BX4 materials[1] , VLADAN STEVANOVIC, NREL, Golden CO — The A2BX4 family of ternary compounds represents an important class of materials. Members of this group, in addition to being among the earth most abundant materials, also span a significant range of physical properties including ferromagnetism, coexistence of transparency and p-type conductivity, ferroelectricity, etc. Today we know for about 800 A2BX4 compounds that have been characterized experimentally. This is only a portion of nearly 5000 A2BX4 combinations that could be constructed throughout the periodic table. In this talk I will present a systematic theoretical approach, based on ab initio calculations, for predicting new A2BX4 compounds. For a given new A2BX4 combination we find the candidate crystal structures from the classification of the existing A2BX4 in terms of the atomic orbital radii of the constituent A and B atoms (Zhang and Zunger, Adv. Funct. Mat. 20, 1944, 2010). This step is followed by the set of high-throughput ab initio calculations which are used to sort out the ground-state structure and compute the corresponding heat of formation. The stability of a given A2BX4 with respect to decomposition into competing phases is then tested against all possible combinations of known compounds involving the same elements. This is done by comparing the heat of formation of the new ternary and the heats of formation of the competing (existing) binary and ternary compounds. I will also discuss the algorithms for searching the chemical space of ternary compounds in order to find the materials with target properties.

[1]The work has been performed in collaboration with X. Zhang, M. d'Avezac, S. Lany and A. Zunger and is supported through the Center for Inverse Design, an EFRC funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences

1:03PM J28.00006 Discovering potentially overlooked Filled Tetrahedral Structure compounds by high-throughput first-principles calculation[1] , XIUWEN ZHANG, ALEX ZUNGER, National Renewable Energy Lab, SOLID STATE THEORY GROUP TEAM — Filled Tetrahedral Structures (FTS) such as LiZnP are derived from the binary zincblende family by splitting a cation such as Ga in GaP into two lower-valent cations Li+Zn, placing one on the original cation site and the other on one of the empty interstitial sites. Generalizing this process, it is possible to generate a few hundred of ABX compounds. Depending on the position of A, B, and X in the periodic table, the structure of such ABX can deviate from the parent tetrahedral framework. Using high-throughput total-energy calculation in GGA+U we have examined the stable structures and possible metastable structures of a few hundred ABX compounds, establishing the basic regularities relating structure to chemical identity. Their thermodynamical stability has been checked by taking into account the competing binary and ternary phases. We identify dozens of ABX compounds likely to have large band gaps, potentially suitable as solar absorbers and transparent conductors.

[1]This work was supported through the Center for Inverse Design, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences.

1:15PM J28.00007 GW band gap of Filled Tetrahedral Structuctures: absorbers and topological insulators ?[1] , JULIEN VIDAL, XIUWEN ZHANG, JUN-WEI LUO, ALEX ZUNGER, National Renewable Energy Laboratory, Golden, CO 80401, USA — Filled Tetrahedral Structures (FTS) such as LiZnP are derived from the binary zincblende material such as GaP by splitting a cation such as Ga into two lower-valent cations Li+Zn, placing one on the original cation site and the other on one of the empty interstitial sites. Generalizing this process, it is possible to generate a few hundred of ABX compounds. Their electronic structure has been previously calculated by bandgap-underestimating DFT assuming a zincblende-derived crystal structure. We use instead GW to establish (i) which ABX materials are potentially suitable as absorbers in solar cells and (ii) which of the ABX materials previously proposed as topological insulators based on DFT may not be so in a better approximation such as GW.

1:27PM J28.00008 Quantum Monte Carlo for Materials Design , TIM MUELLER, LUCAS WAGNER, JEFFREY GROSSMAN, Massachusetts Institute of Technology — When designing new materials it is important to have an accurate measure of the material's formation energy to assess thermodynamic stability and chemical activity. Computational materials science holds the potential to accurately predict formation energies, but widely-used methods such as density functional theory often yield large errors when calculating energy differences between compounds with significantly different electronic structures. More accurate quantum chemical methods tend to scale poorly with system size, making it infeasible to apply them to many materials. One exception is quantum Monte Carlo (QMC), which effectively scales linearly or better with system size when calculating formation energy per atom. QMC scales perfectly with the number of processors, making it ideally positioned to take advantage of the rapidly growing core count in central and graphics processing units. It has been shown that quantum Monte Carlo can successfully predict formation energies for some solid state materials, but a broad assessment has been lacking. We have run QMC calculations on a variety of different materials for which high-quality experimental data exists. We present data on the cost and accuracy of QMC, providing insight into the role QMC will play in materials design.

1:39PM J28.00009 Off-lattice self-learning kinetic Monte Carlo: application to 3D island decay on fcc(100) surface[1] , GIRIDHAR NANDIPATI, ABDELKADER KARA, SYED ISLAMUDDIN SHAH, TALAT S. RAHMAN, University of Central Florida — We report the development of an off-lattice kinetic Monte Carlo (KMC) method with a new three-dimensional (3D) pattern recognition scheme to better identify the local environment and processes involving 3D motion which was not possible in the earlier approach [1]. In the present scheme, to uniquely identify the 3D neighborhood around the central atom or leading atom we split it into 3D rectangular boxes whose dimensions dictate the accuracy with which the motion of the diffusing entity to be accounted. This technique combines the idea of self-learning KMC (SLKMC) [2] method with the new pattern-recognition scheme fitted to an off-lattice model. We present application of this off-lattice SLKMC to 3D island decay on fcc (100) surface and compare the results and computational efficiency to that available in the literature.

1:51PM J28.00010 Density-functional study of U-Mo alloys , ALEXANDER LANDA, PER SODERLIND, PATRICE E.A. TURCHI, Lawrence Livermore National Laboratory, Livermore, USA — The U-Mo and U-Zr alloys proved to be very promising fuels for advanced fast nuclear reactors. According to numerous experiments, the main advantages of U-Mo fuels over U-Zr fuels lies in a much lower constituent redistribution due to the existence a single γ-U-Mo phase with body-centered cubic structure over typical fuel operation temperatures. Density-functional theory (EMTO-CPA technique) previously used to describe phase equilibria in U-Zr alloys [A. Landa, P. Söderlind, P. E. A. Turchi, Journal of Alloys and Compounds, 478 (2009) 103] is extended to investigate the ground-state properties of U-Mo solid solutions. Calculated heats of formation of bcc U-Zr and U-Mo alloys are compared with CALPHAD assessments. We discuss how the heat of formation in both alloys correlates with the charge transfer between the alloy components, and how the specific behavior of the density of states in the vicinity of the Fermi level promotes the stabilization of the U_2Mo compound. Our calculations prove that, due to the existence of a single γ-phase over the typical fuel operation temperatures, γ-U-Mo alloys should indeed have much lower constituent redistribution than γ-U-Zr alloys for which binodal decomposition causes a high degree of constituent redistribution. This work was performed under the auspices of the US Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

2:03PM J28.00011 Inverse band design of SiGe superlattices with direct band-gaps[1] , MAYEUL D'AVEZAC, NREL, JUN-WEI LUO, ALEX ZUNGER, NREL, Golden, Co, THOMAS CHANIER, University of Iowa — Integrating optoelectronic functionalities directly into the mature Silicon-Germanium technology base would prove invaluable for many applications. Unfortunately, both Si and Ge display indirect band-gaps unsuitable for optical applications. It was previously shown (Zachai *et al.* PRL **64** (1990)) that epitaxially grown $[(\mathrm{Si})_n(\mathrm{Ge})_m]_p$ (i. e. a single repeat unit) grown on Si can form direc-gap heterostructures with weak optical transitions as a result of zone folding and quantum confinement. The much richer space of *multiple-period* superlattices $[(\mathrm{Si})_{n_1}(\mathrm{Ge})_{n_2}(\mathrm{Si})_{n_3}(\mathrm{Ge})_{n_4}\ldots Ge_{n_N}]_p$ has not been considered. If $M = \sum n_i$ is the total number of monolayers, then there are, roughly, 2^M different possible superlattices. To explore this large space, we combine a (i) genetic algorithm for effective configurational search with (ii) empirical pseudopotential designed to accurately reproduce the inter-valley and spin-orbit splittings, as well as hydrostatic and biaxial strains. We will present multiple-period SiGe superlattices with large electric dipole moments and direct gaps at Γ yielded by this search.

Session J29 GQI: Focus Session: Quantum Information for Quantum Foundations - Structures in Hilbert Space C148

11:15AM J29.00001 Proofs of the Kochen-Specker theorem based on two qubits , MORDECAI WAEGELL, P.K. ARAVIND, Worcester Polytechnic Institute — The observables for a pair of qubits yield a system of 60 rays and 105 bases in a complex Hilbert space of four dimensions that contains over a hundred million parity proofs of the Kochen-Specker theorem. An overview of these proofs is given and they are compared with those in other 4-d systems, such as the 600-cell. The significance of the results is discussed.

11:27AM J29.00002 Proofs of the Kochen-Specker theorem based on the 600-cell , P.K. ARAVIND, MORDECAI WAEGELL, Worcester Polytechnic Institute, NORMAN MEGILL, Boston Information Group, MLADEN PAVICIC, ITAMP, Harvard University — It is shown that the system of 60 rays and 75 bases derived from the vertices of a 600-cell (a regular polytope in four dimensions) contains over a hundred million parity proofs of the Kochen-Specker theorem. An overview of the proofs is given, some examples of them are presented and the significance of the results is discussed.

11:39AM J29.00003 MUB Entanglement Patterns by Transformations in Phase Space , JAY LAWRENCE[1], Dartmouth College, Hanover, NH 03755 — All possible MUB entanglement patterns for systems of N prime-state particles are obtained from standard ones by unitary transformations in the Hilbert space, thus preserving the relationships between the generalized Pauli operators, the phase point operators, and the MUB projectors. The transformations are described geometrically in discrete phase space. Illustrative examples show the invariance of the total entanglement content and the connection of entanglement with Galois fields. Different field representations for the same dimension may produce inequivalent MUB sets. This work provides alternative constructions and generalizes previous work on qubit systems [1,2].

11:51AM J29.00004 Entanglement in Mutually Unbiased Bases[1] , MARCIN WIESNIAK, University of Vienna, TOMASZ PATEREK, CQT Singapore, ANTON ZEILINGER, University of Vienna — Higher-dimensional Hilbert spaces are still not fully explored. One issue concerns mutually unbiased bases (MUBs). For primes [1] and their powers (e.g. [2]), full sets of MUBs are known. The question of existence of all MUBs in composite dimensions is still open. We show that for all full sets of MUBs of a given dimension a certain entanglement measure of the bases is constant. This fact could be an argument either for or against the existence of full sets of MUBs in some dimensions and tells us that almost all MUBs are maximally entangled for high-dimensional composite systems, whereas this is not the case for prime dimensions. We present a new construction of MUBs in squared prime dimensions. We use only one entangling operation, which simplifies possible experiments. The construction gives only product states and maximally entangled states.

12:03PM J29.00005 Qutrits under a microscope[1] , GELO NOEL TABIA, University of Waterloo, Perimeter Institute for Theoretical Physics, Institute for Quantum Computing — Gleason's theorem states that the set of quantum states is complete, in the sense that density operators specify the unique probability measure definable on the lattice of Hilbert space of projection operators according to the Born Rule. Particularly, Gleason showed that the theorem holds in all finite dimensions if and only if it holds in dimension 3. This suggests that the essential features defining the probability structure of quantum theory can already be found in 3-dimensional quantum systems. Hence, we establish key geometric properties of qutrit state space as they are expressed in terms of symmetric, informationally-complete (SIC) measurements. We provide a variety of important results, which include an elegant formula for describing pure qutrits, affine plane symmetries and the Hesse configuration in qutrit SICs derived from algebraic structure constants for $\mathrm{GL}(3, C)$, and a comparison of the SIC and generalized Bloch representations by analyzing plane cross-sections of qutrit state space. In addition, we present a new way of implementing SIC-POVMs using multi-port devices built from waveguide-based micro-optics, in particular, by proposing experimental circuits for qubits and qutrits.

12:15PM J29.00006 A Linear Dependency Structure Arising from Weyl-Heisenberg Symmetry[1] , HOAN BUI DANG, Perimeter Institute and University of Waterloo, MARCUS APPLEBY, Perimeter Institute, INGEMAR BENGTSSON, KATE BLANCHFIELD, Stockholm University, ASA ERICSSON, CHRISTOPHER FUCHS, Perimeter Institute, MATTHEW GRAYDON, GELO TABIA, Perimeter Institute and University of Waterloo — The Weyl-Heisenberg (WH) group was used by Hermann Weyl to construct finite-dimensional quantum mechanics in the earliest days of the theory and, through its ubiquitous use in quantum information theory, is even more important today. While investigating properties of symmetric informationally-complete (SIC) measurements, we found a linear dependency structure in a class of Weyl-Heisenberg covariant sets when certain conditions on the dimensionality of the Hilbert space are met. This result reveals more structure in WH symmetry than previously noted and helps us gain a better understanding of quantum state space. For example in the Quantum Bayesian framework of Fuchs and collaborators, the number of zeros of a quantum state in a SIC representation is directly related to this linear dependency.

[1]This work was supported in part by the U. S. Office of Naval Research (Grant No. N00014-09-1-0247).

12:27PM J29.00007 Regrouping phenomena of SIC POVMs covariant with respect to the Heisenberg–Weyl group[1] , HUANGJUN ZHU, Centre for Quantum Technologies, National University of Singapore — Symmetric informationally complete positive operator valued measures (SIC POVMs) covariant with respect to the Heisenberg–Weyl (HW) group form disjoint orbits under the action of the normalizer of the HW group—the (extended) Clifford group. Additional SIC POVMs can be obtained by a suitable regrouping of the fiducial vectors on certain orbits, for example, in Hilbert spaces of dimension three, four, eight and twelve. To understand these SIC POVM regrouping phenomena, we need to go beyond the Clifford group and consider a larger group, in particular the normalizer of the Clifford group. We prove that, when the dimension of the Hilbert space is not a multiple of four, the HW group is a characteristic subgroup of the Clifford group, and the normalizer of the Clifford group is itself; when the dimension is a multiple of four, there are exactly two normal subgroups in the Clifford group that are isomorphic to the HW group, which are conjugated to each other in the normalizer of the Clifford group. Based on this observation, we provide a unified framework for understanding the regrouping phenomena mentioned above and those potential candidates.

12:39PM J29.00008 Quantum Computational Geodesic Derivative , HOWARD BRANDT, U.S. Army Reseaarch Laboratory — In recent developments in the differential geometry of quantum computation, the quantum evolution is described in terms of the special unitary group of n-qubit unitary operators with unit determinant. The group manifold is taken to be Riemannian. In the present work the geodesic derivative is clarified. This is applicable to investigations of conjugate points and the global characteristics of geodesic paths in the group manifold, and the determination of optimal quantum circuits for carrying out a quantum computation.

12:51PM J29.00009 Affine Maps of the Polarization Vector for Quantum Systems of Arbitrary Dimension[1] , MARK BYRD, Southern Illinois University, C. ALLEN BISHOP, YONG-CHENG OU, Physics Department, Southern Illinois University — The operator-sum decomposition (OS) of a mapping from one density matrix to another has many applications in quantum information science. To this mapping there corresponds an affine map which provides a geometric description of the density matrix in terms of the polarization vector representation. This has been thoroughly explored for qubits since the components of the polarization vector are measurable quantities (corresponding to expectation values of Hermitian operators) and also because it enables the description of map domains geometrically. Here we extend the OS-affine map correspondence to qudits, briefly discuss general properties of the map, the form for particular important cases, and provide several explicit results for qutrit maps. We use the affine map and a singular-value-like decomposition, to find positivity constraints that provide a symmetry for small polarization vector magnitudes (states which are closer to the maximally mixed state) which is broken as the polarization vector increases in magnitude (a state becomes more pure). The dependence of this symmetry on the magnitude of the polarization vector implies the polar decomposition of the map can not be used as it can for the qubit case. However, it still leads us to a connection between positivity and purity for general d-state systems.

1:03PM J29.00010 Pseudo-unitary freedom in the operator-sum representation , YONG CHENG OU, Department of Chemistry, Texas Tech University, Lubbock, Texas 79409, MARK S. BYRD, Department of Physics and Department of Computer Science, Southern Illinois University, Carbondale, Illinois 62901 — A general dynamical map can be written in an operator-sum representation (OSR) by using a spectral decomposition, which needs not be completely positive. The OSR is not unique; there is freedom to choose a different set of operators in the OSR, yet still obtain the same map. We will show that, whereas the freedom for completely positive maps is unitary, the freedom for not completely positive maps is pseudo-unitary.

1:15PM J29.00011 Long-range spin-coupled interactions: a *Gedankenexperiment* on the nature of spin , IAN DURHAM, Saint Anselm College — What is intrinsic spin? It is at the heart of the quantum information revolution and yet it defies many of the efforts to better understand it, even to the point of pushing particle physics beyond the Standard Model. Long assumed to require the relativistic theory of Dirac, in 1967 Lévy-Lablond demonstrated that this was not the case: it is not necessarily a relativistic effect. In this article, we apply the Lévy-Lablond model to a simple *Gedankenexperiment* that suggests the existence of a quasi-fundamental long-range spin-coupled interaction. Calculations of the eigenfunctions of a test particle and the coupling constant of the force gives insight into the behavior of the potential that gives rise to this interaction. For large separation distances the potential looks like a simple potential well while for very small separation distances it exhibits a more complex nature. This, in turn, sheds additional light on the nature of intrinsic spin and a suggests a path for future research.

1:27PM J29.00012 Quantum simulation of time-dependent Hamiltonians and the convenient illusion of Hilbert space[1] , ROLANDO SOMMA, Los Alamos National Laboratory, DAVID POULIN, University of Sherbrooke, ANGIE QARRY, FRANK VERSTRAETE, University of Vienna — We consider the manifold of all quantum many-body states that can be generated by arbitrary time-dependent local Hamiltonians in a time that scales polynomially in the system size, and show that it occupies an exponentially small volume in Hilbert space. This implies that the overwhelming majority of states in Hilbert space are not physical as they can only be produced after an exponentially long time. We establish this fact by making use of a time-dependent generalization of the Suzuki-Trotter expansion, followed by a counting argument. This also demonstrates that a computational model based on arbitrarily rapidly changing Hamiltonians is no more powerful than the standard quantum circuit model.

[1]We acknowledge support from NSF, NSERC, and FQRNT

1:39PM J29.00013 Mathematical Constraint on Realistic Theories , JAMES FRANSON, University of Maryland at Baltimore County — We consider realistic theories in which some physical property f(r,t) is assumed to exist regardless of whether or not we measure it. It is shown that the value of f(r,t) at position r and time t is completely determined by its value at all other locations r′ and earlier times t′ < t provided that f(r,t) has continuous second partial derivatives [1]. Mathematical functions of this kind are sufficiently general to describe many situations of physical interest. These results are based on a mathematical identity that is similar in some respects to Cauchy's integral theorem and it can be viewed as a generalization of Green's third identity. The physical implications of weak determinism of this kind will be discussed and it will be contrasted with the properties of quantum systems.

[1] J.D. Franson, arXiv: 1007.1941.

1:51PM J29.00014 Construction of optimal witness for unknown two-qubit entanglement , S.-S.B. LEE, Department of Physics, Korea Advanced Institute of Science and Technology, H.S. PARK, H. KIM, S.-K. CHOI, Korea Research Institute of Standards and Science, H.-S. SIM, Department of Physics, Korea Advanced Institute of Science and Technology — Whether entanglement in a state can be detected, distilled, and quantified without full state reconstruction is a fundamental open problem. We demonstrate a new scheme encompassing these three tasks for arbitrary two-qubit entanglement, by constructing the optimal entanglement witness for polarization-entangled mixed-state photon pairs without full state reconstruction. With better efficiency than quantum state tomography, the entanglement is maximally distilled by newly developed tunable polarization filters, and quantified by the expectation value of the witness, which equals the concurrence. This scheme is extendible to multiqubit Greenberger-Horne-Zeilinger entanglement. This work is to appear in Physical Review Letters.

2:03PM J29.00015 ABSTRACT WITHDRAWN –

Tuesday, March 22, 2011 11:15AM - 2:15PM –

Session J30 DCMP: Nanowires & Nanotubes: Electronic Properties C147/154

11:15AM J30.00001 Interplay between structural and electronic properties of bundled $Mo_6S_{9-x}I_x$ nanowires: an *ab initio* study , SEOUNG-HUN KANG, YOUNG-KYUN KWON, Kyung Hee University, DAVID TOMANEK, Michigan State University — We use first principles density functional theory to investigate the structural, electronic and magnetic properties of isolated and bundled $Mo_6S_{9-x}I_x$ nanowires with $x = 3, 4.5$, and 6. The skeleton of these nanowires consists of linear arrays of Mo_6 octahedra decorated with S and I atoms that are connected by flexible S_3 linkages. Due to the bi-stability of each sulfur linkage, free-standing and bundled nanowires are capable of stretching or compressing axially at almost no energy cost, giving rise to many structural minima. We explore the structural stability, elastic behavior and electronic structure at all these minima for different compositions. We find that axial strain and inter-wire interaction in bundles modify significantly the electronic structure. Most intriguing changes occur in nanowires with $x = 4.5$ and 6, which change from metal to semiconductor or undergo a magnetic transition upon axially stretching or compressing the nanowires or upon changing the inter-wire separation.

11:27AM J30.00002 A Hybrid Density Functional Study of Capped Silicon Carbide Nanotubes[1] , KAPIL ADHIKARI, ASOK RAY, Department of Physics, University of Texas at Arlington — A systematic study of fullerene hemisphere capped finite SiC nanotubes of type 1 using cluster approximation is presented. Nanotubes (3,3) and (5,0) are capped by C_{20}-fullerene hemisphere(C_{10}) and (5,5) and (9,0) are capped by C_{60}-fullerene hemisphere (C_{30}). Geometries of the tubes have been spin optimized using the functional B3LYP, 3-21G* basis set and the GAUSSIAN 03 software. The study indicates that fullerene capping of a SiC nanotube changes the electronic and geometric structure properties of SiC nanotubes. For example, the binding energy per atom for infinite nanotube (5,5) is 4.993eV whereas the same nanotube with C- and Si-caps has the binding energy per atom of 5.989eV and 4.812eV, respectively. C-capped nanotubes are energetically more preferable compared to Si-capped. The HOMO-LUMO gaps of the capped nanotubes are significantly lower compared to those of infinite nanotubes.

11:39AM J30.00003 Low-energy spectral weights of the 1D Hubbard chain , STEFAN SOEFFING, Dept. of Physics and Research Center OPTIMAS, Univ. of Kaiserslautern, Germany, IMKE SCHNEIDER, Univ. of Dresden, Germany, ALEXANDER STRUCK, SEBASTIAN EGGERT, Dept. of Physics and Research Center OPTIMAS, Univ. of Kaiserslautern, Germany — We investigate the low-energy spectral weights of the 1D Hubbard chain by means of Density Matrix Renormalization Group (DMRG) calculations in comparison with Bosonization results. We identify the bosonic excitations of the underlying Luttinger liquid and analyze their evolution upon increasing the interaction strength in terms of their density of states (DOS). Comparing analytical and numerical results we point out the competition of spin/charge degrees of freedom vs. non-interacting spin up and down particles, which here become important due to the lattice nature of the model and higher order operators. Furthermore, we discuss the spatially resolved (local) DOS that can be calculated analytically by a recursive formula vs. numerically using DMRG.

11:51AM J30.00004 Implications of time-reversal symmetry for band structure of single-wall carbon nanotubes , SERGUEI GOUPALOV[1], Jackson State University — When electron states in carbon nanotubes are characterized by two-dimensional wave vectors with the components K_1 and K_2 along the nanotube circumference and cylindrical axis, respectively, then two such vectors symmetric about a $\mathbf{M}$-point in the reciprocal space of graphene are shown to be related by the time-reversal operation. To each nanotube there correspond five relevant $\mathbf{M}$-points with the following coördinates: $K_1^{(1)} = \mathcal{N}/2R$, $K_2^{(1)} = 0$; $K_1^{(2)} = \mathcal{M}/2R$, $K_2^{(2)} = -\pi/T$; $K_1^{(3)} = (2\mathcal{N}-\mathcal{M})/2R$, $K_2^{(3)} = \pi/T$; $K_1^{(4)} = (\mathcal{M}+\mathcal{N})/2R$, $K_2^{(4)} = -\pi/T$, and $K_1^{(5)} = (\mathcal{N}-\mathcal{M})/2R$, $K_2^{(5)} = \pi/T$, where $\mathcal{N}$ and $\mathcal{M}$ are the integers relating the chiral, $\mathbf{C}_h$, symmetry, $\mathbf{R}$, and translational, $\mathbf{T}$, vectors of the nanotube by $\mathcal{N}\,\mathbf{R} = \mathbf{C}_h + \mathcal{M}\,\mathbf{T}$, $T = |\mathbf{T}|$, and R is the nanotube radius. We show that the states at the edges of the one-dimensional Brillouin zone which are symmetric about the $\mathbf{M}$-points with $K_2 = \pm\pi/T$ are degenerate due to the time-reversal symmetry. Explicit expressions are obtained for the coördinates of the $\mathbf{K}$-points in the reciprocal space of graphene relevant to a given nanotube.

12:03PM J30.00005 Ab initio simulations of the eletronic and transport properties of nanotube bundles used as gas sensors , ALEXANDRE ROCHA, RODRIGO AMORIM, Universidade Federal do ABC, Brazil, ADALBERTO FAZZIO, ANTÔNIO J.R. DA SILVA, Instituto de Física, Universidade de São Paulo, Brazil — Carbon nanotubes (CNT) have exceptional mechanical and - particularly - electronic properties that make this material of great potential interest for applications in different areas of materials science. One of the possibilities which raises the highest hopes is the area of nanotube-based gas sensors. From the fabrication point of view, one is probably going to use bundles of CNTs instead of a single tube. In this work we initially use density functional theory (DFT) calculations to determine the electronic structure properties of different molecules interstitially positioned between the nanotubes in a bundle. From the most stable structures we couple the DFT calculations to a recursive Green's function method to simulate. The electronic transport properties of a disordered nanotube bundle containing a large number of molecules randomly distributed along the different tubes forming the ropes. This way one is able to simulate a realistic sensor based on three-dimensional nanotube bundles taking into consideration the effects of disorder.

12:15PM J30.00006 Theoretical studies of the electronic and transportation properties of Gd disilicide nanowires on Si(001)[1] , WENJIE OUYANG, YANNING ZHANG, University of California, Irvine, SHENGYONG QIN, ANPING LI, Oak Ridge National Lab, RUQIAN WU, University of California, Irvine — The scanning tunneling microscopy data demonstrate the successful growth of isolated $GdSi_2$ nanowires and wire bundles on Si (100) surface and the nano transport measurement shows the isolated nanowires exhibit a metal-insulator transition (MIT) upon cooling while the wire bundles maintain a metallic state. We investigate the structural and electronic properties of isolated $GdSi_2$ nanowires and wire bundles surface through extensive density functional calculations. A 8aSi-wide supercell was used to mimic the environment of a single nanowire, and a 5aSi-wide supercell was used for wire bundles. Interestingly, we found that the bundle structures frustrate the Perils-type structural transition that occurs easily in single nanowires. This can be regarded as the reason for the observed MIT. We also explored the effect of Si adatoms on top of wires and wire bundles. The electrical transport behaviors of $GdSi_2$ nanowires are further explained using the calculated local electronic density of states and band structures. The special magnetic ordering and its effect on other properties of nanowires will also be discussed.

[1]Work was supported by DOE, Basic Energy Science, and NERSC.

12:27PM J30.00007 Structural and Electronic properties of a bismuth nanowire encapsulated inside a boron nitride nanotube[1] , CHI-HSUAN LEE, CHIH-KAI YANG, Graduate Institute of Applied Physics, National Chengchi University, Taipei, Taiwan, ROC — The structural and electronic properties of a bismuth nanowire (BiNW) encapulated inside the boron nitride nanotube (BNNT) are investigated by first principles calculation. The results show that they depend both on the configuration of BiNW and the diameter of the BNNT. The interaction between the two constituents induces hybridization of energy bands from each subsystem, causing unexpected variation of dispersion and splitting of energy bands near the Fermi level. The role of spin-orbit interaction is especially decisive in the later outcome. It enhances the stability of the hybrid structure and produces more band-edge states. These results should be observable with the tool of scanning tunneling spectroscopy.

[1]Supported by the National Science Council of the Republic of China.

12:39PM J30.00008 Jastrow-Correlated Wavefunctions for Flat-Band Lattices , HAO WANG, V.W. SCAROLA, Department of Physics and Astronomy, Virginia Tech — The electronic band structure of many compounds, e.g., carbon-based nanostructures, can exhibit essentially no dispersion. Models of electrons in such flat-band lattices define non-perturbative strongly correlated problems by default. We construct a set of Jastrow-correlated ansatz wavefunctions to capture the low energy physics of interacting particles in flat bands. We test the ansatz in an example honeycomb ribbon. The model Hamiltonian is projected on a flat band of the ribbon, thus containing only the Coulomb interaction term. The properties of the ground states are studied using numerical diagonalization. We find that the ansatz wavefunction accurately captures the ground state in a transition from a crystal to a uniform quantum liquid.

12:51PM J30.00009 Electronic structures of potassium-doped C_{60} encapsulated in BN nanotubes , TAKASHI KORETSUNE, SUSUMU SAITO, Department of Physics, Tokyo Institute of Technology, JESSE NOFFSINGER, MARVIN L. COHEN, Department of Physics, University of California, Berkeley — Boron-nitride nanotubes have large band gap independent of chirality and are promising candidates for nanostructure control. Here, we investigate the electronic structure of potassium-doped C_{60} encapsulated in boron-nitride nanotubes using first-principles methods based on the density functional theory. We demonstrate that the material is one-dimensional metal where conducting electrons are only in the C_{60} chain. Interestingly, the material can have a large Fermi-level density of states, which indicates the possibility of various phase transitions including superconductivity as in the case of fcc K_3C_{60}. We therefore discuss the electron-phonon couplings as well as the pressure dependence of the electronic structures of this material.

1:03PM J30.00010 Effect of atomic defects and interwire coupling on the electronic properties of one-dimensional Gd silicide nanowires , SHENGYONG QIN, TAE-HWAN KIM, ARTHUR P. BADDORF, AN-PING LI, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, HANNO H. WEITERING, Department of Physics and Astronomy, The University of Tennessee, Knoxville, CHIH-KANG SHIH, Department of Physics, The University of Texas at Austin, WENJIE OUYANG, YANNING ZHANG, RUQIAN WU, Department of Physics and Astronomy, University of California, Irvine — Metallic nanowires have attracted great interest for understanding the electronic interactions and conductivity in one dimension. Electron transport is often dictated by quantum instabilities and strong localization at low temperature. Well-ordered and uniformly oriented GdSi2 nanowires are self-assembled on Si(100) in the form of either isolated nanowires or wire bundles with atomic interwire spacing. The effects of interwire coupling and atomic defects in these quasi-one-dimensional systems are studied by correlating the 4-probe STM electrical transport with STM local density of states of individual nanowires. While the isolated nanowires exhibit a metal-insulator transition associated with atomic defects, the wire bundles remain metallic at low temperature which we believe the interwire coupling suppress the lattice disorder and stabilize a robust metallic conductance. This research at ORNL's CNMS was sponsored by the Scientific User Facilities Division, Office of BES, U.S. DOE.

1:15PM J30.00011 Negative curvature energy in magnesium-boride nanotubes , HUI TANG, SOHRAB ISMAIL-BEIGI, Department of Applied Physics, Yale University — Mg-boride nano-materials have attracted much attention due to constant quest for novel superconducting materials on nanoscale. A recent experiment on Mg borides nanostructures has hinted at a possible superconducting temperature as high as 80K. More generally, studying the physics of pure and metal-doped boron nanosystems enhances understanding of novel properties that emerge in reduced dimensions. Here, based on first principles calculations, we describe an unusual nanoscale curvature effect in Mg-boride nanotubes and discuss its origin. We show that a number of 2D Mg-boride sheets prefer to spontaneously curve themselves into small diameter nanotubes and thus have negative curvature energies. This is rather unique when compared to other nanotubular materials: usually, curving the parent 2D sheet to create a nanotube imposes an energy cost. We explain the reason for the negative curvature energy by analyzing the charge state of the Mg atoms, its relation to the type of boron sublattice present in the nanostructure, and its consequences for the Mg-Mg interactions and hence the energetics.

1:27PM J30.00012 Quantum Size Effect and Electronic Stability of Freestanding Metal Atom Wires[1] , HAIPING LAN, PING CUI, U. of Sci. & Tech. of China, JUN-HYUNG CHO, Hanyang U., QIAN NIU, U. of Texas at Austin, JINLONG YANG, U. of Sci. & Tech. of China, ZHENYU ZHANG, Oak Ridge Nat. Lab, U. of Tennessee, U. of Sci. & Tech. of China — Using DFT calculations, we present a thorough study of the quantum size effects on the stability of freestanding metal atom wires. Our systems include Na, Ag, Au, In, Ga and Pb atom wires, i.e. s, sd, and sp electron prototypes. We found that the total energy always oscillates with the wire length, which clearly indicates the existence of preferred lengths. Increasing the length, the s-system exhibits even-odd oscillations following a 1/x decay law in the stability, which can be attributed to electron band filling and quantum confinement along the wire. The sd-system exhibits a similar oscillation pattern, even in the presence of sd hybridization. In sp-system, the energy oscillations are beyond the simple even-odd nature, likely due to unpaired p orbitals and the corresponding nontrival band filling. Our findings clearly demonstrate that electronic contribution is quite critical to the stability of freestanding wires, and this stability may be important even when wires are deposited on substrates or strained. This study sheds light on the underlying formation mechanism of metal atom wires.

1:39PM J30.00013 Gate controlled donor activation in silicon nanowires , ADAM GALI, Research Institute for Solid State Physics and Optics of the Hungarian Academy of Sciences, BINGHAI YAN, THOMAS FRAUENHEIM, Bremen University — Due to the proximity to an embedding medium with low dielectric constant (e.g., oxides), semiconductor nanowires have higher impurity ionization energy than their bulk counterparts, resulting lower free carrier density. Using ab initio calculations within density functional theory, we propose a way to reduce the ionization energy in nanowires by fabricating a special cross section with appropriate engineering of doping and an applied gate voltage. We demonstrate on a phosphorus-doped silicon nanowire that the ionization energy can be effectively tuned and the impurity backscattering can also be reduced. For instance, the free carrier density may increase by 40% in a silicon nanowire with 15 nm diameter and special cross section without special engineering of doping. Our proposal has profound implications to fabricate nanowire devices with high carrier density. Our proposed Si NW device realizes a fine manipulation of the interaction between electron and nuclear spins by using an external electric field which is a fundamental step to a silicon-based nuclear spin quantum computer. Moreover, with a negative voltage the ionization energy of P-donors can be increased even in larger silicon nanowires which opens up the possibility to manipulate the donor electron spin at room temperature [1]. [1] B. Yan, Th. Frauenheim and A. Gali, *Nano Lett.*, 2010, 10, 3791

1:51PM J30.00014 Non-Collinear Ferromagnetic Luttinger Liquids , NICHOLAS SEDLMAYR, SEBASTIAN EGGERT, JESKO SIRKER, TU Kaiserslautern — In the now classic Tomonaga-Luttinger model the presence of the electron-electron interaction in one dimension is shown to profoundly change the properties of the system. We consider here the magnetic and electronic properties of a *ferromagnetic* Luttinger liquid when it has a region of non-collinearity present, i.e. a domain wall. Spin-charge separation does not survive in this system, and the absence of both spin-charge separation and coherent spin-charge excitations has consequences for the spin-transfer-torque effects which cause domain wall motion. Furthermore the presence of the domain wall introduces a spin dependent scatterer into the problem, which will alter both the transport, and the static electronic, properties of the system. Finally we show how the magnetization dynamics of the domain wall will be modified for a Luttinger liquid.

2:03PM J30.00015 How to Extract Luttinger Liquid Velocity from Carbon Nanotubes , DARRYL H. NGAI, Cornell University, CHANG-YU HOU, Universiteit Leiden, EUN-AH KIM, Cornell University — We propose direct detection of Luttinger Liquid velocity of the charge collective mode in carbon nanotubes using optical conductivity and Coulomb blockade effect. We note that detection of such fractionalized excitation needs to exploit the energy or frequency scale tied to the finite length of the nanotube. This is why previous experimental attempts have been unsuccessful.[1] We will discuss features in the optical conductivity sensitive to the velocity of the collective mode which would be observable in the high temperature limit. In the low temperature limit, spacing between the Coulomb blockade peaks in the conductance as a function of gate voltage will be a sensitive probe.

Session J31 DMP GSCCM DCOMP: Focus Session: Materials at High Pressure II: Elements

C145

11:15AM J31.00001 Multi-Scale Shock Compression Simulations of Metals and Metallic Phase Transitions[1] , NIR GOLDMAN, LARRY FRIED, Lawrence Livermore National Laboratory — We present a straightforward method for efficient molecular dynamics (MD) simulation of shock compression of materials that experience thermal electronic excitations at high pressure and temperature. Previous studies have shown that exclusion of the electronic temperature at extreme conditions can result in incorrect computation of dynamic and equation of state properties. The Multi-Scale Shock Technique (MSST) is a simulation methodology based on the Navier–Stokes equations for compressible flow that enables MD simulation of a shock wave with relatively small computational cost. We extend MSST to allow for changes in the electronic entropy during shock compression while conserving Hugoniot conditions. This allows for simulation of significantly higher shock velocities than previously possibly with MSST. We have used our simulation methodology in density functional tight binding simulations of shock compressed silicon. We observe that at high shock velocities inclusion of a non-zero electron temperature results in lower computed shock Hugoniot temperatures and pressures. Our methodology is well suited for shock compression simulations of any material that experiences changes in its electronic entropy under extreme thermodynamic conditions.

[1]Prepared by LLNL under Contract DE-AC52-07NA27344.

11:27AM J31.00002 Large-Scale Molecular Dynamics Simulations of Shock-Induced Plasticity in Tantalum Single Crystals[1] , R. RAVELO[2], University of Texas-El Paso, QI AN, California Institute of Technology, T.C. GERMANN, B.L. HOLIAN, Los Alamos National Laboratory — We report on large-scale non-equilibrium molecular dynamics (NEMD) simulations of shock wave compression in Ta single crystals. The atomic interactions are modeled via a recently developed and optimized embedded-atom method (EAM) potential for Ta, which reproduces the equation of state up to 200 GPa. We examined the elastic-plastic transition and shock wave structure for wave propagation along the low index directions: (100), (110) and (111). Shock waves along (100) and (111) exhibit an elastic precursor followed by a plastic wave for particle velocities below 1.1 km/s for (100) and 1.4 km/s for (111). The nature of the plastic deformation along (110) is dominated by twinning for pressures above 40 GPa.

11:39AM J31.00003 Transport of particulate matter from a shocked interface[1]

W.T. BUTTLER, J.E. HAMMERBERG, D. ORO, C. MORRIS, F. MARIAM, C. ROUSCULP, Los Alamos National Laboratory — We have performed a series of shock experiments to measure the evolution and transport of micron and sub-micron Tungsten particles from a 40 micron thick layer deposited on an Aluminum substrate. Densities and velocity distributions were measured using proton radiography at the Los Alamos Neutron Science Center for vacuum conditions and with contained Argon and Xenon gas atmospheres at initial pressures of 9.5 bar and room temperature. A common shock drive resulted in free surface velocities of 1.25 km/s. An analysis of the time dependence of Lithium Niobate piezo-electric pin pressure profiles is given in terms of solutions to the particulate drag equations and the evolution equation for the particulate distribution function. The spatial and temporal fore-shortening in the shocked gas can be accounted for using reasonable values for the compressed gas shear viscosities and the vacuum distributions. The detailed form of the pin pressure data for Xenon indicates particulate breakup in the hot compressed gas.

11:51AM J31.00004 Thermal Emission Determination of Argon under Extreme Pressure and Temperature

D. ALLEN DALTON, MICHAEL WONG, ALEXANDER F. GONCHAROV, JULIUS OJWANG, VIKTOR V. STRUZHKIN, Geophysical Laboratory, Carnegie Institution of Washington, ZUZANA KONOPKOVA, PETER LAZOR, Department of Earth Sciences, Uppsala University — Argon is a common pressure-transmitting medium in diamond anvil cell (DAC) experiments, and is often used as thermal insulation in the laser heated DAC. A more thorough understanding of the thermal properties of argon under extreme conditions is essential for measuring thermal properties of materials under similar conditions. A transient heating technique was applied to a symmetric DAC up to 50 GPa and 2500 K. A 1 μm thick iridium foil positioned within a recessed gasket hole filled with argon served as a laser absorber to pump thermal energy into the sample. Pump pulses of 6 μs temporal width were provided from an electronically modulated Yb-based fiber laser. We determined the temperature of the coupler with 500 ns time resolution by applying a Planckian fit to the thermal emission spectrum. Finite element calculations were also used to simulate thermal diffusion in the DAC cavity. The experimental results show slightly larger thermal conductivity with theory, but the results converge in the limit of high temperature. This work is supported by NSF EAR 1015239, NSF-REU, Carnegie Institution of Washington, and DOE-NNSA (CDAC).

12:03PM J31.00005 Thermal diffusivity of metals at high pressure[1]

BRUCE BAER, WILLIAM EVANS, Lawrence Livermore National Laboratory — Very few measurements of thermal diffusivity have been taken at high pressure. This is especially true of metals above 2 GPa. In earlier experiments, the Angstrom method has been employed for these types of measurements. However, this method is limited for high pressure because it requires a relatively large sample. We will discuss the use of sinusoidally modulated laser heating to measure thermal diffusivity in the diamond-anvil-cell.

[1]This work was performed under the auspices of the US DOE by LLNL under Contract DE-AC52-07NA27344.

12:15PM J31.00006 Pressure-Induced Structure Transitions in Europium Metal to 92 GPa[1]

W. BI, J. SCHILLING, Department of Physics, Washington University in Saint Louis, Y. MENG, HPCAT, Carnegie Institution of Washington, Argonne National Laboratory, R. KUMAR, A. CORNELIUS, Y. ZHANG, C. CHEN, HiPSEC and Department of Physics, University of Nevada, Las Vegas, R. HENNIG, Department of Materials Science and Engineering, Cornell University — Motivated by the recent discovery of pressure-induced superconductivity in Eu for pressures above 80 GPa [1], we have carried out high pressure angle-dispersive synchrotron x-ray diffraction measurements on Eu metal in a diamond anvil cell to 92 GPa. Our experiments confirm the bcc-to-hcp transition at 12 GPa reported in previous studies and identify two further phase transitions. The predictions of two independent density functional theory calculations are compared to the experimental results.

12:27PM J31.00007 Electronic structure and dynamics of elements at high pressures[1]

HO-KWANG MAO, Carnegie Institution of Washington — Electronic structure and dynamics information of materials under high pressure has been very scarce due to the experimental difficulties. The standard electronic probes using electron energy loss spectroscopy (EELS) is limited to vacuum pressures. The optical probes that can reach high-pressure samples through the diamond windows, on the other hand, are limited by the energy accessibility ($<$ 5 eV) and near-zero momentum transfer, $q = (4\pi/\lambda_0)\sin\theta$. These problems can be overcome by the newly advanced, two-photon, inelastic, xray, scattering (IXS) spectroscopy which uses high energy xrays ($\sim 10^4$ eV) to provide the atomic-level momentum transfer and to enter (with energy E) and exit (with energy E_0) the pressure vessel. The electronic spectra are revealed by analyzing the xray energy loss between the two photons, $\hbar\omega = E - E_0$. Using IXS facilities at third-generation synchrotron source, we studied electronic structure and dynamics of two elements at high pressures in a diamond-anvil cell: i.e., He, the widest-gap insulator, and Na, the archetypal free-electron metal. At 11.9-17.9 GPa in a single crystal ^{4}He, we observed rich electron excitation spectra, including a cut-off edge above 23 eV, a sharp exciton peak showing linear volume dependence, and a series of excitations and continuum at 26 to 45 eV. We determined electronic dispersion along the 100 direction over two Brillouin zones, and provided a quantitative picture of the helium exciton beyond the simplified Wannier-Frenkel description. At 1.6-4.39 GPa in a polycrystalline Na sample, we observed the sharp plasmon peak at low q and its dispersion beyond the critical q_c. The plasmon shifts to higher energy under compression and drastic reduction of r_s. *Ab-initio* theoretical calculations are conducted for interpretation of the experimental results.

1:03PM J31.00008 Diffusion Monte Carlo calculations of Xenon melting under pressure[1]

L. SHULENBURGER, T.R. MATTSSON, Sandia National Laboratories — The slope of the melting temperature as a function of pressure yields, via the Clausius-Clapeyron equation, important information regarding the changes in density, energy, and entropy. It is therefore crucial to resolve the long-standing differences in melt lines under pressure between Diamond Anvil Cell data (low/flat melt line) and other methods, including density functional theory (DFT) simulations[1] (high/steep melt line). The disagreement for Ta was recently resolved[2] and although a similar situation exists in the literature on Xe,[3] the resolution may be quite different. For example, DFT with its lack of van der Waals forces is a prima facie less credible simulation method for Xe, although excellent agreement has been obtained between calculations of the Hugoniot of Xe and experiments.[4] We investigate whether this theoretical shortcoming is significant for the melting transition by applying diffusion Monte Carlo. The energy differences obtained in this way are compared to the DFT results in order to address any systematic errors that may be present near the melting transition. [1] Taioli et al. [1]Sandia National Laboratories is a multiprogram laboratory managed and operated by Sandia Corp. for the US Dep. of Energy's National Nuclear Security Administration under Contract DE-AC04-94AL85000.

1:15PM J31.00009 Lattice dynamics at ultra-high pressures using high-resolution inelastic x-ray scattering , DANIEL FARBER, Lawrence Livermore National Laboratory — While our understanding of many physical properties is enhanced by the large body of neutron, the restrictions on sample size imposed by the technique relegated the achievable information to low or at most, moderate pressures (∼10 GPa) and to materials readily available in reasonable large quantities. The advent of third generation synchrotron sources and the construction of beamlines dedicated for inelastic x-ray scattering experiments (IXS), these limitations have to a great degree been overcome. Over the past few years our group has focused a large experimental and theoretical effort on quantifying the vibrational energies in metals at high-pressures and high-temperatures. Most recently, we have determined the phonon dispersions across the isostructural gamma- to alpha-cerium transition. Our new data place important thermodynamical and theoretical constraints on the underlying physics of this important transition.

1:27PM J31.00010 High-pressure phases of calcium[1] , AMANUEL TEWELDEBERHAN, JONATHAN DOBOIS, Lawrence Livermore National Laboratory, STANIMIR BONEV, Lawrence Livermore National Laboratory and Dalhousie University — The high-pressure phases of calcium have been investigated using a combination of density functional theory and diffusion quantum Monte Carlo calculations. Finite-temperature Gibbs free energies of several competing structures are computed at pressures near 50 GPa. The discrepancy between theory and experiment both at low and room temperature is resolved with input from diffusion quantum Monte Carlo. Furthermore, diffusion quantum Monte Carlo calculations are performed on 0 K crystalline structures up to 150 GPa. The resulting structures differ from those obtained with density functional theory.

1:39PM J31.00011 Lifshitz transition in *cI*16 Li at high pressures: Unfolding first-principles Fermi surfaces , CHIA-HUI LIN, TOM BERLIJN, WEI KU, Brookhaven National Laboratory/ Stony Brook University — The Fermi surface topology of *cI*16 Li is investigated using the recently developed first-principles band structure unfolding method [1]. The resulting unfolded Fermi surfaces display a clear Lifshitz transition at 47 GPa, explaining the anomalous change of superconducting transition temperature [2]. The unfolded Fermi surfaces also reveals a more complete picture of the driving force of the *cI*16 phase starting at 39 GPa [3]. In addition to the previously proposed "nesting" effect [3] along $[1\frac{1}{2}\frac{1}{2}]$, both [100] and $[\frac{1}{2}\frac{1}{2}0]$ wavevectors are found to contribute significantly to the structural instability as well, due to their large phase space, a more effective effect in 3D. We expect a wide range of applications of this Fermi surface unfolding method to the study of high pressure electronic structure.

1:51PM J31.00012 On the role of quantum ion dynamics for the anomalous melting of lithium[1] , SABRI ELATRESH, Department of Physics, Dalhousie University, Halifax, NS, B3H 3J5, Canada, STANIMIR BONEV, Lawrence Livermore National Laboratory, Livermore, California 94550 — Lithium has attracted a lot of interest in relation to a number of counterintuitive electronic and structural changes that it exhibits under pressure. One of the most remarkable properties of dense lithium is its anomalous melting. This behavior was first predicted theoretically based on first-principles molecular dynamics (FPMD) simulations, which treated the ions classically [1]. The lowest melting temperature was determined to be about 275 K at 65 GPa. Recent experiments measured a melting temperature about 100 K lower at the same pressure. In this talk, we will present FPMD calculations of solid and liquid lithium free energies up to 100 GPa that take into account ion quantum dynamics. We examine the significance of the quantum effects for the finite-temperature phase boundaries of lithium and, in particular, its melting curve.

2:03PM J31.00013 Graphite under high pressure , YUEJIAN WANG, Yale University — As one of the longest-known forms of carbon, graphite has been extensively studied for several decades. However, its phase diagram under high pressures is still poorly understood. Here we use both in-situ high-pressure Raman spectroscopy and synchrotron x-ray diffraction, collected on both compression and decompression, to elucidate the high-pressure behavior of highly-ordered pyrolitic graphite (HOPG) at room temperature. The Raman spectra show that G band (1580 cm^{-1} at ambient pressure) of HOPG shifts to higher frequency with increased pressure, which has been attributed to pressure-induced in-plane lattice contraction. Above 19 GPa the broadening of this Raman peak indicates a reordering of the atomic structure, and is consistent with synchrotron x-ray diffraction measurements that also show a slight change in symmetry.

Session J32 DMP: Focus Session: Electron, Ion, and Exciton Transport in Nanostructures: Nanowires C144

11:15AM J32.00001 Finite Size Effects in Electrical Transport in Nanowires and Nanowire-like Devices. , ALEC TALIN, NIST — Semiconductor nanowires posses many unique qualities including high crystallinity, simple growth techniques compatible with variety of low cost substrates, increased ability to accommodate strain, and nanoscale dimensions not easily accessible by 'top-down' lithographic means. These and other interesting characteristics have made nanowires an attractive topic for fundamental research, as well as for potential applications in nanoelectronics, photonics, sensors, and more recently energy conversion and storage. Most of these applications rely on charge transport, which can be profoundly affected by the high aspect ratio, high surface to volume ratio and nanoscale diameter typical of semiconductor nanowires. Properly identifying the factors that influence electrical transport characteristics is important for device design but also because extraction of material parameters such as the mobility relies on analysis with specific models. In my talk I will discuss several specific examples where nanoscale dimensions and geometry profoundly affect transport and device characteristics, including GaN and GaN/III-N core/shell nanowires; Si radial pn-junction photovoltaics; and all-nanowire Li-ion batteries..

11:51AM J32.00002 Photocurrent Spectroscopy of single ZB, WZ InP Nanowire devices , K. PEMASIRI, S. PERERA, A. WADE, H.E. JACKSON, L.M. SMITH, University of Cincinnati, Cincinnati, OH, J.M. YARRISON-RICE, Miami University, Oxford, OH, S. PAIMAN, Q. GAO, H.H. TAN, C. JAGADISH, Australian National University, Canberra, Australia — Photocurrent spectroscopy was performed on single InP nanowire devices having either zinc-blende (ZB) or wurtzite (WZ) crystal structures at 300 K and 10 K. Photolithography was used to fabricate Ohmic Ti/Al metal contact pads separated by 5 μm. Using a monochromatic white light set up or a tunable (1.30 to 1.55 eV) CW laser, the photocurrent is measured as a function of bias voltage and excitation energy. At room temperature, the lowest energy band of In WZ (1.408 eV) is found to be 70 meV above the ZB band gap (1.338 eV), consistent with previous photoluminescence measurements. At low temperatures (10 K), the ZB device shows strong evidence for a broadened excitonic resonance peak at 1.432 eV and the WZ device shows three excitonic peaks at 1.504 eV, 1.56 eV, and 1.65 eV corresponding to the A,B and C valence band energies, respectively, which coincide with recent photoluminescence excitation measurements. Support for this work was provided by the NSF (#0701703, #0806700 and #0806572) and the Australian Research Council.

12:03PM J32.00003 Photoresponse of solution-synthesized PbSe nanowire devices , TODD BRINTLINGER, EDWARD E. FOOS, JOSEPH G. TISCHLER, JANICE E. BOERCKER, THOMAS J. ZEGA, RHONDA M. STROUD, STEVE C. ERWIN, U.S. Naval Research Laboratory — PbSe nanowires are of interest for photovoltaic applications due to their variable band gap in the near infrared and potential for efficient multiexciton generation. Contributing to this effort, we present our ongoing studies of the photoresponse of PbSe nanowire devices. These materials are synthesized in solution by reaction of Pb and Se precursors in the presence of stabilizing organic ligands, and possess 10-20 nm diameters with lengths >1 μm. The nanowires are then dispersed on transparent silicon nitride membranes, allowing for both transmission electron microscopy and optical spectroscopy of individual devices. Devices show up to two-fold increases in current under illumination, with current density in the $\sim$1x10^9 A/m^2 range. Electrical transport and characterization of nanowires will be presented.

12:15PM J32.00004 Energy and Spatially Resolved Measurements of Plasmonically Enhanced Photocurrent in a Single Si Nanowire with Au Nanoparticles , JEROME HYUN, LINCOLN LAUHON, Department of Materials Science and Engineering, Northwestern University — Hybrid assemblies of nanowires and metallic particles have attracted great interest because of their potential as light harvesting systems. Optoelectronic measurements of the most basic light absorbing unit in such systems, consisting of a single nanowire and plasmonic particles, would provide further guidance for performance optimization schemes. Here, we present spatially and energy resolved photocurrent measurements across the visible spectrum on a Si nanowire device with Au nanoparticles using a confocal scanning microscope and a tunable wavelength laser source. A 50 nm diameter nanowire was used due to its monotonic optical response in the wavelength range of interest, and 50 nm size Au nanoparticles were selected in order to neglect the effects of Mie scattering. The photocurrent is shown to depend on the azimuthal location of the nanoparticles on the nanowire. Nanoparticles resting on the substrate adjacent to the nanowire can significantly modify the absorption with a strong polarization-dependent plasmonic response while nanoparticles resting directly in the line of sight between the nanowire and light source show minimal contribution to the photocurrent.

12:27PM J32.00005 Charge injection and transport in nanowires , FRANCOIS LEONARD, Sandia National Laboratories — Semiconductor nanowires show promise in electronic, optoelectronic, and sensing devices. To realize this promise, a fundamental understanding of charge injection and electronic transport in these novel nanomaterials is necessary. In this presentation, I will discuss recent work that couples experiment and theory to address this topic. For example, in GaN and InAs nanowires, we achieve efficient charge injection and find that space-charge-limited currents are unusually strong. In contrast, charge transport across individual Au-nanoparticle/Ge-nanowire interfaces is injection-limited, and surprisingly, the conductance increases with decreasing nanowire diameter due to a dominance of electron-hole recombination. Furthermore, we find that transport in GaAs nanowires is governed by charge traps, which can be activated to reveal the nature of the charge injection at the contacts. More generally, our results indicate that a broad range of electronic transport regimes can be observed in semiconducting nanowires depending on the particular material system and growth process.

1:03PM J32.00006 Photocurrent spectroscopy of CdS nanosheets , P. KUMAR, A. WADE, H.E. JACKSON, L.M. SMITH, University of Cincinnati, J. YARRISON RICE, Miami University, Y.-J. CHOI, J.-G. PARK, Korea Institute of Science and Technology, Seoul — We study the photocurrent from photoexcited charge carriers in CdS nanosheet (NS) structures. Metal-semiconductor-metal nanodevices are made with both Schottky and Ohmic contacts using photolithography followed by Ti/Al (20nm/200nm) metal evaporation and lift-off. Ohmic contacts are formed by Ar ion bombardment before the metal deposition to create donor sulfur vacancies which increases the electron concentration. Photocurrent spectra using a white light source filtered by a monochrometer show excitonic resonances at low temperatures corresponding to each of the A, B, and C hole bands. The photocurrent increases linearly with power for above gap excitation, and nonlinearly (quadratic) with laser power for below gap excitation, consistent with two-photon absorption with a nonlinear coefficient of $\beta = 2$ cm/GW. A wavelength dependence of the photocurrent with sub-band gap excitation to find the resonances and hence band structure is in progress. We acknowledge the financial support of the National Science Foundation through grants DMR-0806700, 0806572 and ECCS-0701703, and the KIST institutional research program 2E21060R.

1:15PM J32.00007 Electronic Devices with Dichalcogenide Nanolayers[1] , ANDRAS KIS, BRANIMIR RADISAVLJEVIC, MOHAMED BENAMEUR, JACOPO BRIVIO, EPF Lausanne — We have exfoliated single, two-dimensional layers 6.5 Angstrom thick from a number of dichalcogenide materials such as MoS2, using the micromechanical cleavage technique commonly used for the production of graphene. Optical microscopy together with AFM was used to characterize the nanolayers and establish optimal conditions for rapid identification of monolayers using optical methods. Our nanolayers are mechanically and chemically stable under ambient conditions. We have electrically contacted nanolayers using electron-beam lithography and fabricated field-effect transistors. Electrical transport measurements show that our devices have high on/off ratios and high mobilities. Our results indicate that two-dimensional dichalcogenide nanolayers could be interesting building blocks for nanoelectronic applications.

[1]Supported by a grant from ERC, no. 240076

1:27PM J32.00008 Electric Field Dependent Photocurrent Decay Length in Single Lead Sulfide Nanowire Field Effect Transistors , DONG YU, RION GRAHAM, CHRIS MILLER, U.C. Davis, EUNSOON OH, Chungnam National University, Korea — We determined the minority carrier diffusion length to be $\sim$1 μm in single PbS nanowire field effect transistors by scanning photocurrent microscopy. PbS nanowires grown by the vapor-liquid-solid method were p-type with hole mobilities up to 49 cm^2/Vs. We measured a photo-response time faster than 14 μs with near-unity charge separation efficiency at the contacts. For the first time, we also observed a field dependent photocurrent decay length, indicating a drift dominant carrier transport at high bias.

1:39PM J32.00009 Exciton Diffusion Measurements in III/V Nanowires using Spatially and Time Resolved Photoluminescence[1] , M.A. FICKENSCHER, L.M. SMITH, H.E. JACKSON, University of Cincinnati, J.M. YARRISON-RICE, Miami University, J.H. KANG, Q. GAO, H.H. TAN, C. JAGADISH, Australian National University — We present an optical investigation of transport in GaAs/AlGaAs core shell nanowires utilizing low temperature spatial and time resolved photoluminescence (PL). We use a solid immersion lens (SIL) to achieve a laser spot size and image resolution of 600 nm. With the laser spot fixed on the nanowire, the image of the wire is scanned across the entrance slit of the spectrometer taking time-decays at each point. Thus, we measure the spatial profiles of the exciton distribution in the wire as a function of time. We then extract the diffusion constant from the width squared of each spatial distribution as a function of time. The measured exciton diffusion constants are of the order of 100 cm^2s^{-1}, equivalent to a mobility of 100,000 $cm^2\ V^{-1}s^{-1}$ by using the Einstein relation. These values are comparable to the best hole mobilities seen in modulation doped two dimensional GaAs/AlGaAs heterostructures.

[1]Support for this work was provided by the NSF (0701703, 0806700 and 0806572) and the Australian Research Council.

1:51PM J32.00010 Electron transport in coupled InGaAs quantum wires[1] , VASYL KUNETS, SERGEY PROSANDEEV, SABINA KOUKOURINKOVA, VITALIY DOROGAN, YURIY MAZUR, MARCIO TEODORO, MORGAN WARE, MOURAD BENAMARA, PETER LYTVYN, GREGORY SALAMO, University of Arkansas, Physics Department, Fayetteville, AR 72701 — Remotely doped InGaAs/GaAs heterostructures were grown by molecular beam epitaxy on the (311)A plane of GaAs. Applying strain driven epitaxy on the (311)A GaAs surface, two-dimensional quantum wells (QW) and quasi-one-dimensional quantum wires (QWr) were formed by varying InGaAs coverage between 6 and 11 monolayers. Polarization dependent photoluminescence and electrical conductivity experiments revealed a remarkable anisotropy in the QWr samples, which was insignificant in the QWs, the dimensionality of which was confirmed by atomic force and cross-sectional transmission electron microscopies. The resulting complex behavior of the electric current anisotropy as function of InGaAs coverage, doping and temperature is explained through a multi-band conductivity model, which is supported by magneto-transport measurements at low and high magnetic fields along with the Hall effect theory in anisotropic media with multi-band conduction.

[1]This work was supported by the NSF under Grant No. DMR 0520550

2:03PM J32.00011 Probing charge density wave transition at the nanoscale in $NbSe_2$using NEMS resonators , SHAMASHIS SENGUPTA, HARI SOLANKI, VIBHOR SINGH, SAJAL DHARA, MANDAR DESHMUKH, Tata Institute, Mumbai, India — We study nanoelectromechanical (NEMS) resonators fabricated from suspended flakes of $NbSe_2$ (thickness $\sim$ 30–50 nm) to probe charge density wave (CDW) physics at nanoscale. Variation in elastic and electronic properties accompanying the CDW phase transition (around 30 K) are investigated simultaneously using the devices as self-sensing heterodyne mixers. Elastic modulus is observed to change by 10%, an amount significantly larger than what had been reported earlier in the case of bulk crystals. We also study the modulation of conductance by electric field effect, and examine its relation to the order parameter and the CDW energy gap at the Fermi surface.

Tuesday, March 22, 2011 11:15AM - 2:15PM –

Session J33 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides: Multiferroics & Magnetoelectrics II C143/149

11:15AM J33.00001 Correlation between magnetocapacitance effect and polarization flop direction in a slanted magnetic field in $Tb_{1-x}Dy_xMnO_3$, NOBUYUKI ABE, HAJIME SAGAYAMA, HIROSHI UMETSU, TAKA-HISA ARIMA, IMRAM, Tohoku University, KOUJI TANIGUCHI, Department of Advanced Materials Science, The University of Tokyo — Recent extensive studies show that the cycloidal spin system can possess electric polarization through the spin-orbit coupling. The magnetoelectric coupling in multiferroics is enhanced by the clamping of helimagnetic and ferroelectric domain walls. For example, $DyMnO_3$ shows a gigantic magnetocapacitance effect caused by the microscopic motion of multiferroic domain walls at a magnetic field induced **P**-flop transition. In contrast, the enhancement of capacitance at the **P**-flop transition is much smaller in $TbMnO_3$. Here, we show the systematic control of magnetocapacitance effect in helimagetic ferroelectric $Tb_{1-x}Dy_xMnO_3$ as a function of the composition ratio x and the intensity of the applied magnetic field. It has been also found that the rotation direction of **P** in a slanted magnetic field changes with x and H. The crossover between small and large enhancement in magnetocapacitance corresponds to the switch in the **P**-flop direction. The correlation can be explained by assuming the mobility of domain wall would be dominated by the thickness of domain walls in a helical magnet.

11:27AM J33.00002 Giant Magnetoelectric Effect in Antiferromagnetic $BaMnO_{3-\delta}$ and Its Derivatives[1] , M. GE, O.B. KORNETA, T.F. QI, S. PARKIN, L.E. DELONG, G. CAO, University of Kentucky, P. SCHLOTTMANN, Florida State University — Hexagonal perovskite 15R-$BaMnO_{2.99}$ with a ratio of cubic to hexagonal layers of 1/5 in the unit cell is an antiferromagnetic insulator that orders at a Néel temperature T_N= 220 K. Here we report structural, magnetic, dielectric and thermal properties of single crystal $BaMnO_{2.99}$ and its derivatives $BaMn_{0.97}Li_{0.03}O_3$ and $Ba_{0.97}K_{0.03}MnO_3$. The central findings of this work are: **(1)** these materials possess a usually large, high-temperature magnetoelectric effect that amplifies the dielectric constant by more than an order of magnitude near their respective Néel temperature; **(2)** Li and K doping can readily vary the ratio of cubic to hexagonal layers and cause drastic changes in dielectric and magnetic properties. These findings provide a new paradigm for developing *novel, high-temperature magnetoelectric materials* that may eventually contribute to technology.

11:39AM J33.00003 Electric-field control of magnetic orderings in the tetragonal $BiFeO_3$[1] , CHUN-GANG DUAN, East China Normal University — We present a systematic first-principles study on the magnetic properties of the tetragonal $BiFeO_3$ (P4mm) with various in-plane lattice constants. The Heisenberg model is applied to study the behaviors of exchange constants (J_{1a}, J_{1c}, J_{2a}, J_{2c}) under the influence of the in-plane strain. We find that in certain region of the in-plane lattice constant, switching the direction of polarization from out of plane to in-plane by electric field could result in transition of magnetic orderings, e.g., from G-type to C-type antiferromagnetic states in tetragonal $BiFeO_3$. This may open a new avenue to controlling magnetoresistance using electric field.

11:51AM J33.00004 Ferroelectric polarization in the magnetic world , JUN HEE LEE, Department of Physics and Astronomy, Rutgers University — Switchable spontaneous polarization in ferroelectrics is produced by a structural distortion of a high-symmetry reference phase which lowers the symmetry to a polar space group. Under certain conditions, this structural distortion and symmetry breaking can also induce ferromagnetism and other changes, such as a metal-insulator transition, allowing the possibility of electric and magnetic field control. In this talk, I will present first-principles illustrations of specific materials realizations of the rich variety of this behavior in magnetic perovskite oxides, identified using a database of first-principles calculations of the full phonon dispersions of a range of magnetic perovskites, including the d3 compounds SrMnO3and SrCaO3, the d5 compounds BiFeO3, and the series SrMO3 (M= V, Cr, Mn, Fe, Co). First, I will discuss an epitaxial-strain-induced multiferroic phase produced by large spin-phonon coupling in SrMnO3 [1]. Then, I will turn to colossal magnetoresistance based on a ferromagnetic- metal/antiferromagnetic-ferroelectric phase boundary with epitaxial strain in SrCoO3, which exhibits typical ferromagnetic metallic character in room-temperature but with a large spin-phonon coupling by which antiferromagnetic ordering favors a polar distortion. Lastly, I will discuss the identification of perovskite superlattice systems in which the symmetry lowering produced layer-by-layer ordering produces a phase with ferroelectrically-induced weak ferromagnetism. I will present first-principles calculations demonstrating these behaviors in BaMnO3/SrMnO3 superlattices and other systems which could provide robust experimental realizations.

12:27PM J33.00005 Magnetic and multiferroic phases of single-crystalline $Mn_{1-x}Co_xWO_4$, K.-C. LIANG, R.P. CHAUDHURY, Y.-Q. WANG, Y.Y. SUN, B. LORENZ, TCSUH and Department of Physics, University of Houston, Houston, Texas 77024-5002, USA, F. YE, J.A. FERNANDEZ-BACA, H.A. MOOK, Neutron Scattering Science Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831-6393, USA, C.W. CHU, TCSUH and Department of Physics, University of Houston, Houston, Texas 77024-5002, USA — The recent interest of $MnWO_4$ system is due to the strong correlation between the long-wavelength magnetic structure and the ferroelectric polarization. To understand the effects of Co substitutions on magnetic and multiferroic phases of $MnWO_4$, we studied the magnetic and dielectric properties of the single-crystalline $Mn_{1-x}Co_xWO_4$ compounds. At lower Co substitution, the commensurate (CM) AF1 phase was found suppressed but could be restored in external magnetic fields along b axis. We also observed the ferroelectric polarization along b axis suppressed by a b-axis magnetic field. On the other hand, the higher Co substitution such as 15% showed more complex magnetic phases, which warrants future investigation. With Neutron scattering data, more detailed magnetic orders of the various phases would be revealed, and the relationship between magnetic phases and ferroelectric polarization will be discussed.

12:39PM J33.00006 Magnetoelectricity in $BiFeO_3$ films - first-principles-based computations and phenomenology[1] , SERGEY PROSANDEEV, University of Arkansas, IGOR KORNEV, Ecole Centrale Paris, LAURENT BELLAICHE, University of Arkansas, UNIVERSITY OF ARKANSAS TEAM, ECOLE CENTRALE PARIS TEAM — A first-principles-based effective Hamiltonian is used to compute linear and quadratic magnetoelectric (ME) coefficients in epitaxial (001) $BiFeO_3$ thin films. Its predictions are analyzed within a phenomenological model that provides analytical expressions of the ME coefficients in terms of polarization, as well as, dielectric and magnetic susceptibilities. Main discoveries are: (i) the quadratic ME coefficient is dramatically enhanced by increasing the magnitude of the compressive strain within the Cc phase, as similar to the previously reported enhancement of the linear ME coefficient in these films; (ii) the enhancements of the linear and quadratic ME coefficients have the same macroscopic origin, namely an increase in the dielectric permittivity; and (iii) the relative contribution of two different free-energy terms on the total linear ME coefficient is extracted from the simulations. The analytical expressions also help in understanding other ME effects.

[1]ONR N00014-08-1-0915 and N00014-07-1-0825, DOE DE-SC0002220, NSF DMR-0701558 and DMR-0080054. Thanks to MRI NSF 0722625 providing computer facilities.

12:51PM J33.00007 First Principles Study on Magnetoelectric Effects in $Ba_2CoGe_2O_7$, KUNIHIKO YAMAUCHI, ISIR-SANKEN, Osaka University, Japan, SILVIA PICOZZI, CNR-SPIN, L'Aquila, Italy — Magnetoelectric (ME) effects, or magnetically-induced ferroelectricity, are attracting large interests due to promising applications for novel type of devices. While the microscopic origin of ME effects is mostly classified as relate to spin current and/or exchange striction, a novel mechanism originating in spin- dependent p-d hybridization has been proposed and well explained ME effects observed in antiferromagnetic $Ba_2CoGe_2O_7$. In this study, we theoretically confirmed the magnetically induced electric polarization, whose size is dependent on the direction of Co spins. By means of both Landau theory and density functional calculations, the behavior of the experimentally observed polarization was well reproduced. Microscopically, we suggest single-site spin orbit coupling to slightly change the Co-d orbital shape upon changing the direction of Co spins, resulting in "asymmetric" p-d hybridization and consequent change in the electric polarization.

1:03PM J33.00008 Magnetoelectric resonance in S=3/2 two-dimensional antiferromagnet $Ba_2CoGe_2O_7$, SHIN MIYAHARA, Multiferroics Project (MF), ERATO, Japan Science and Technology Agency (JST), NOBUO FURUKAWA, Aoyama Gakuin University — We have investigated dynamical magnetoelectric effects in S = 3/2 two-dimensional antiferromagnet $Ba_2CoGe_2O_7$. It is a quasi two-dimensional antiferromagnet. Below T_N = 6.7 K, the Co magnetic moments show an antiferromagnetic ordering [1]. Recently, the material is paid attention to due to the magnetic field induced ferroelectric polarization [2,3]. Such multiferroics behaviors can be explained well by considering a spin-dependent metal-ligand hybridization mechanism on a Heisenberg model with strong uniaxial anisotropy term [3,4]. Through the spin dependent polarization, electric component of light can modulate the spin structures. As a result, electric component of light can excite magnetic excitations. We can clarify selection rules and resonance peak positions in absorption. When both magnetic and electric components induce the same magnetic excitation, cross correlated term, where electric component induced excitation is deduced to the ground state by magnetic component and vice versa, is realized. The effects of such cross correlation can be observed directly as linear directional dichroism in absorption process.[1] A. Zheludev *et al.*, Phys. Rev. B **68** 024428 (2003). [2] H.T. Yi *et al.*, Appl. Phys. Lett. **92** 212904 (2008). [3] H. Murakawa et al., Phys. Rev. Lett. **105** 137202 (2010). [4] T. Arima, J. Phys. Soc. Jpn. **76** 073702 (2007).

1:15PM J33.00009 Investigation of Multiferroic properties of the Co doping $SrBi_2Nb_2O_9$, WILLIAM PEREZ, NORA ORTEGA, ASHOK KUMAR, RAM KATIYAR, University of Puerto Rico — Multiferroics (MF) are novel class of next generation multifunctional materials, however there are very few single-phase MF materials existing in nature. Thin films (TF) of $(Sr_xCo_{1-x})Bi_2Nb_2O_9$ (SCBN) with x = 0, 0.05, 0.1, 0.15, 0.2, 0.25, 0.3 with thickness ∼400 nm were fabricated from individual SCBN targets on $Pt/Ti/SiO_2/Si$ substrate by pulsed laser deposition technique. The x-ray diffraction studies revealed orthorhombic structure of SCBN for up to 20% Co doped TF without any phase segregation, the splitting in (200) peak was observed above 25% of Co doping. The room temperature (RT) Raman spectra of SCBN TF showed $SrBi_2Nb_2O_9$ peaks in all compositions, however additional modes appeared in the 600-800 cm^{-1}frequency region. The dielectric constant of all SCBN films showed linear frequency dispersion above 1 kHz, and their values are in the range of 400 to 650 at 1 kHz. An increase in tangent loss from ∼ 0.040 to 0.135 at 1 kHz was observed with increase in Co concentration. All SCBN TF show well defined hysteresis loop with remanent polarization of about 16 $\mu C/cm^2$. However, less saturation in the ferroelectric loop was observed with increase of Co content. Both magnetic and magneto-electric behavior of TF along with the ferroelectric properties will be discussed.

1:27PM J33.00010 Large crystal-symmetry-induced magnetoelectric coupling in the quadruple perovskite $BiMn_3Mn_4O_{12}$, A. GAUZZI, G. ROUSSE, Univ. Pierre et Marie Curie, F. MEZZADRI, G. CALESTANI, Parma Univ., G. ANDRE, F. BOUREE, LLB CEA-CNRS, M. CALICCHIO, E. GILIOLI, R. CABASSI, F. BOLZONI, A. PRODI, IMEM-CNR, P. BORDET, Inst. Neel-CNRS, M. MAREZIO, CRETA-CNRS — The remarkable properties of manganese oxides AMnO$_3$ with perovskite structure, such as the colossal magnetoresistance and the multiferroicity, arise from peculiar charge, spin and orbital orderings of the Mn e_g electrons driven by cooperative Jahn-Teller distortions of the MnO$_6$ octahedra. Mastering these orderings remains a challenge owing to local structural distortions and electronic inhomogeneities enhanced by chemical substitutions and oxygen defects. We show that these difficulties are absent in *quadruple* perovskites AMn$_3$Mn$_4$O$_{12}$. These compounds share with *simple* perovskites AMnO$_3$ a similar pseudo-cubic network of corner-sharing MnO$_6$ octahedra and similar electronic properties associated with the Mn^{3+} and Mn^{4+} ions. However, they display smaller distortions thanks to the higher crystal symmetry an no defects. For A=Bi, by means of neutron powder diffraction we give direct crystallographic evidence of a large coupling between the electric dipole of the 6s lone pair of Bi^{3+} and the magnetic structure of the Mn^{3+} ions, which provides a hint for enhancing the magnetoelectric coupling in proper ferroelectrics in view of multiferroic applications.

1:39PM J33.00011 Micorscopic theory of temperature-dependent magnetoelectric effect in Cr_2O_3 , ANDREA SCARAMUCCI, MAXIM MOSTOVOY, Zernike Institute for Advanced Materials, University of Groningen, NICOLA A. SPALDIN, Materials Department, University of California Santa Barbara / Department of Materials, ETH Zurich, KRIS T. DELANEY, Materials Research Laboratory, University of California Santa Barbara — We study the temperature dependence of the magnetoelectric effect in Cr_2O_3 by considering the coupling between electric polarization and spins induced by Heisenberg exchange interactions. The form of the coupling is obtained by symmetry analysis and its strength is calculated by *ab initio* methods. Using Monte Carlo simulations, we evaluate the temperature dependence of the largest component of the magnetoelectric susceptibility. The quantitative agreement of our results with experimental measurements shows that the dominant contribution to the linear magnetoelectric effect originates from nonrelativistic exchange interactions and spin fluctuations. The approach used can be applied to study other magnetoelectrics with collinear spin ordering and opens a new route for the design of materials with large magnetoelectric effect at high temperatures.

1:51PM J33.00012 Pressure- and field-dependent Raman studies of magnetodielectric behavior in Mn_3O_4[1] , M. KIM, S. YUAN, S.L. COOPER, Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois, Urbana, Illinois, 61801 — We present simultaneous pressure- and field-dependent Raman scattering studies of the magnetodielectric spinel, Mn_3O_4, which allow us to investigate both the microscopic origins and pressure dependence of magnetodielectric phenomena in this material. We identify the specific phonon modes responsible for the dramatic magnetodielectric behavior observed in this material, and show that these modes provide quantitative information regarding magnetodielectric behavior in Mn_3O_4 via the Lyddane-Sachs-Teller (LST) relationship. We also show that pressure can induce monoclinic distortions accompanied with magnetic ordering in Mn_3O_4. Finally, by exploring the field-dependent phonon spectrum at different pressures, we are able to map out the pressure-field structural phase diagram of Mn_3O_4 and explore the pressure-dependence of magnetodielectric behavior in this material.

2:03PM J33.00013 Infrared optical properties of multiferroic $FeTe_2O_5Br$ single crystal[1] , KEVIN H. MILLER, C. MARTIN, X. XI, University of Florida, H. BERGER, Ecole Polytechnique Federal de Lausanne, G.L. CARR, Brookhaven National Laboratory, D.B. TANNER, University of Florida — Reflection as a function of temperature has been measured on a single crystal of the anisotropic multiferroic $FeTe_2O_5Br$ utilizing light spanning the far infrared to the visible portions of the electromagnetic spectrum. The complex dielectric function and optical properties along all three principal dielectric axes were obtained via Kramers-Kronig analysis and by fits to a Drude-Lorentz model. Transmission in the terahertz region as a function of temperature and magnetic field is also described, with particular focus on temperatures around the $\sim$10 K transition to the multiferroic state.

Session J34 DMP: Focus Session: Interfaces in Complex Oxides - Microscopy and Local Structure C141

11:15AM J34.00001 Unexpected ordering at the atomic scale interface of $SrRuO_3$ and $BaTiO_3$[1] , ARTHUR P. BADDORF, Oak Ridge National Laboratory — Atomically engineered oxide multilayers and superlattices display unique properties responsive to the electronic and atomic structures of the interfaces. Interfaces can exhibit not only two-dimensional functionality, but have the power to dictate the properties of thin films. A clear example is found in ferroelectric thin films, where the domain size, orientation, and transport properties are controlled by top and buried interfaces. We have explored a prototypical ferroelectric - bottom electrode interface by characterizing $BaTiO_3$ grown on $SrRuO_3$. Films were grown on $SrTiO_3$ substrates by pulsed laser deposition, monitored by high-pressure reflection high-energy diffraction, exhibited high crystalline quality in electron diffraction and cross-sectional transmission electron microscopy (STEM), and were flat according to atomic force microscopy. Despite multiple indicators commonly accepted to confirm a sharp interface, atomically the structure is more complex. When grown in a typical oxygen pressure, at or below 10 mTorr, in situ scanning tunneling microscopy (STM) revealed the $SrRuO_3$ surface is littered with oxygen vacancies. For growth or post-annealing above $\sim$100 mtorr, vacancies were removed, but STM and low energy electron diffraction (LEED) disclosed a surface reconstruction consisting of parallel rows with periodicity doubled in one direction. Density function theory (DFT) suggests these rows are chains of Sr and O raised by excess oxygen. Both LEED and cross-sectional STEM revealed that this reconstruction persists at the buried interface and modifies the structure of subsequent $BaTiO_3$ layers. By four layers, the $BaTiO_3$ surface returns to a bulk-like structure with upward polar distortion. This study emphasizes the importance of atomic scale structural studies of what may otherwise appear as sharp interfaces.

[1]Research at ORNL's CNMS was sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. DOE.

11:51AM J34.00002 Highly confined 2D electron gas in $SrTiO_3/SrRuO_3$ superlattices[1] , MARCOS VERÍSSIMO-ALVES, CITIMAC, Universidad de Cantabria, Spain, DANIEL BILC, Universite de Liège, Belgium, PABLO GARCÍA-FERNÁNDEZ, CITIMAC, Universidad de Cantabria, Spain, PHILIPPE GHOSEZ, Universite de Liège, Belgium, JAVIER JUNQUERA, CITIMAC, Universidad de Cantabria, Spain — In recent years, experimental advances in the creation of atomically smooth interfaces between complex oxides have made possible the observation of unusual electronic phenomena such as the formation of 2D electron gases confined to the interface between insulating compounds. In this work, we explore an alternative for creating a 2D electron gas in oxide interfaces by means of a $(SrTiO_3)_5/(SrRuO_3)_1$ superlattice. LSDA+U and hybrid functional B1-WC DFT calculations with full relaxation of atomic geometry show the presence of a 2D electron gas, and the system can be described with $U = 4$ eV. Electronic correlations thus become important with quantum confinement: the system is a minority spin half metal with a magnetic moment of $\mu = 4\mu_B$. Degenerate Ru $4d_{(xz,yz)}$ states are the main responsible for the DOS at the Fermi level, whose shape strongly resembles that of 1D free-electron gases. Our results suggest that the material could find uses in spintronic devices.

[1]We thank financial support from FIS2009-12721-C04-02 and CP-FP 228989-2 Projects.

12:03PM J34.00003 Ferroelectric thickness effects on LaSrMnO3/PbZrTiO3 Heterostructures , JINLING ZHOU, West Virginia University, EVAN WOLF, CHARLES FRYE, DISHENG CHEN, SRINIVAS POLISETTY, MIKEL HOLCOMB, DAVID LEDERMAN COLLABORATION, YING-HAO CHU COLLABORATION — Magnetoelectric (ME) coupling is the coupling of magnetic and electric properties within a material. It allows the possibility of dual control of the material through the manipulation of either electric or magnetic fields and therefore could potentially revolutionize the current technology. However, little is known about the factors that influence the strength of this magnetoelectric coupling. In the presented research, ferromagnetic LSMO and ferroelectric PZT are constructed as wedged adjacent layers for the purpose of studying the coupling effects and physical properties in each layer and the resulting interface. X-ray absorption spectroscopy (XAS) and photoemission electron microscopy (PEEM) are used as the major techniques to map out magnetism, ferroelectricity, and the interfacial coupling. The XAS spectra illustrate a strong effect on the magnetic properties depending on ferroelectric thickness. PEEM images display the magnetic and ferroelectric domains in each material layer, allowing further insight into why the coupling depends on layer thickness. This research will aid the understanding of coupling in not only magnetoelectric heterostructures, but also in other similar complex oxide systems.

12:15PM J34.00004 $SrTiO_3$ on silicon: interface chemistry, polarization pinning, and electronic states , SOHRAB ISMAIL-BEIGI, Yale University, ALEXIE KOLPAK, Massachusetts Institute of Technology, FRED WALKER, JIM REINER, CHARLES AHN, Yale University — We use $SrTiO_3$/Si as a model system to examine the effects of interface atomic structure and composition on the functional properties of epitaxial oxide films on silicon. Using first-principles computations, we show that intrinsic chemo-mechanical boundary conditions at the interface fix a single polarization direction in the SrTiO3 thin film independent of the interface composition, inhibiting ferroelectric functionality. In contrast, the transport properties of the interface are quite sensitive to the interface composition, which can be used to tune the interface from an insulator to an interfacial 2D electron gas. We describe the origins of both functionalities and discuss their applicability to the general class of epitaxial oxides on semiconductors.

12:27PM J34.00005 First Principles Study of Resonant Phonon Coupling across the LSMO / STO Interface , KEVIN F. GARRITY, YARON SEGAL, CARLOS A.F. VAZ, JASON D. HOFFMAN, FRED J. WALKER, CHARLES A. AHN, SOHRAB ISMAIL-BEIGI, Yale University — Epitaxial interfaces permit dynamical modification of the properties of a thin film via coupling to the substrate. In particular, the coupling of phonons between two materials allows one to manipulate the atomic structure and vibrational modes near an interface. We use first principles density functional theory (DFT) to study the octahedral oxygen rotations at and across an interface between $La_xSr_{(1-x)}MnO_3$ (LSMO) and $SrTiO_3$. By performing finite temperature Monte Carlo sampling on a classical potential built to reproduce our DFT energetics, we demonstrate that as the $SrTiO_3$ is driven through the phase transition where its octahedral rotations become frozen in place, phonons from the $SrTiO_3$ couple into the interfacial LSMO. These couplings can then modify the LSMO transport properties, as observed in our experiments. The decay length of the phonon coupling into the LSMO agrees with our experimental determinations on this system. We demonstrate that the observed changes in resistance are not due to static changes in the LSMO structure, confirming the phonon coupling.

12:39PM J34.00006 Coupling of strain and magnetism in LPCMO films[1] , SURENDRA SINGH, M. FITZSIMMONS, Los Alamos National Laboratory, HYOUNGJEEN JEEN, AMLAN BISWAS, University of Florida — Complex oxides show extraordinary structural, magnetic and magneto-transport properties and these properties are closely coupled with atomic structure and strain. The temperature- magnetic field phase diagram and transport studies of $La_{0.27}Pr_{0.40}Ca_{0.33}MnO_3$ (LPCMO) films suggest the existence of two phases at low temperatures, i.e. ferromagnetic metallic (FMM) phase and charge order insulating (COI) phase. We report the magneto transport properties of LPCMO films on application of external strain using mechanical jig. The study shows the shift in metal to insulator transition (MIT) temperature on application of external strain. To understand the effect of strain as well as kinematics of formation of FMM phase from COI phase of LPCMO films and vice versa, we have performed detailed in situ transport and specular polarized neutron reflectivity measurements across the MIT as functions of temperature, magnetic field and applied strain. The study reveals a variation of magnetic scattering length density along the depth of the film, which may be attributed to chemical inhomogeneity of the film as a function of depth.

[1]This work is supported by Department of Energy and National Science Foundation.

12:51PM J34.00007 Coupling between oxygen octahedron rotations, Jahn-Teller distortion, magnetic ordering and epitaxial strain in LaMnO3 from first principles , JUN HEE LEE, KARIN M. RABE, Rutgers University, KRIS DELANEY, ERIC BOUSQUET, NICOLA SPALDIN, University of California Santa Barbara — LaMnO3 is known to have rich physics due to coupling among orbital ordering, Jahn-Teller distortions and magnetism. However, less attention has been paid to the role of oxygen octahedron rotations and epitaxial strain. In this talk, we show from first principles calculations that oxygen octahedron rotations induce weak ferromagnetism in *Pbnm* LaMnO3 and that octahedral rotations are cooperatively coupled to the Jahn-Teller distortion.. Furthermore, we predict that compressive epitaxial strain drives bulk A-type antiferromagnetic Pbnm insulating phase to a ferromagnetic metallic phase. At the phase boundary between the ferromagnetic-metallic and antiferromagnetic-insulating phases, colossal magneto-resistance is expected.

1:03PM J34.00008 Local Octahedral Distortions and Magnetic Properties Controlled by Substrate Symmetry at Perovskite Oxide Interfaces[1] , JUN HE, Vanderbilt University, ALBINA BORISEVICH, SERGEI KALININ, STEPHEN PENNYCOOK, Oak Ridge National Laboratory, SOKRATES PANTELIDES, Vanderbilt University — We have investigated the oxygen octahedral distortions and local magnetism at the interfaces of magnetic perovskite oxide heterostructures using first principles calculations. The studied prototype oxide heterostructures include $La_{0.7}Sr_{0.3}MnO_3$, $SrRuO_3$, and $BiFeO_3$. The results show that the symmetry mismatch at interfaces between two perovskite oxides imposes an interfacial layer with distortion modes that do not exist in either bulk material, creating new interface properties by symmetry alone. The thickness of such interface layer depends on the resistance of the octahedra to deformation.

1:15PM J34.00009 Atomic Resolution and First Principles Study of the Structure and Bonding at $SrTiO_3$/GaAs Hetero-interfaces[1] , QIAO QIAO, ROBERT KLIE, SERDAR OGUT, University of Illinois at Chicago — Ultrathin metal-oxide films on polar semiconductor surfaces have received much attention in recent years due to occurrence of novel functional properties, including ferroelectricity, superconductivity and the presence of an interfacial 2-dimensional electron gas. In this study, we examine the atomic and electronic structures of epitaxial ultrathin $SrTiO_3$ (100) films on GaAs (001) using aberration corrected atomic-resolution Z-contrast imaging and electron energy loss spectroscopy (EELS) in combination with first principles calculations to develop a fundamental understanding of the interfacial structure-property relationships. Using atomic-column resolved EELS, we show that Ti diffuses into the first few monolayers of GaAs depending on the thin film growth condition. The effects of Ti diffusion into subsurface GaAs (001) with (4x2)-β2 surface reconstructions will be investigated via first principles calculations. We will also discuss the results for the formation energies of Ti-related impurity defects in the bulk and surface regions of GaAs to help in the interpretation of electron microscopy experiments.

[1]Supported by NSF Grant No. DMR-0846748

1:27PM J34.00010 Accessing hidden isosymmetric phase transitions in perovskite thin films , JAMES RONDINELLI, Argonne National Laboratory, SINISA COH, Rutgers University — Isosymmetric phase transitions (IPT), which show no change in occupied Wyckoff positions or crystallographic space group, are exceedingly rare in crystalline matter because most condensed systems respond to external stimuli by undergoing "conventional" symmetry-lowering displacive, martensitic or reconstructive transitions. In this work, we use first-principles density functional calculations to identify an elusive IPT in orthorhombic ABO_3 perovskite oxides with tendency towards rhombohedral symmetry. Using perovskite $LaGaO_3$ as our prototypical system, we show that the latent isosymmetric phase transition, which manifests as an abrupt change in the octahedral rotation axis, is accessible only with an external elastic constraint—bi-axial strain. We show the transition originates from a soft phonon that describes the geometric connectivity and relative phase of the GaO_6 polyhedra. By connecting the origin of IPT to a chemical and structural incompatibility between the lattice and the elastic constraints, we describe how subtle changes in bulk orthorhombic and monoclinic symmetries are critical to the complete engineering of structure-correlated electronic properties in thin films. Because bi-axial strain is the critical parameter controlling the IPT, we suggest heteroepitaxial synthesis of IPT materials is a plausible route to realize high-κ dielectric actuators with variable band gaps and dielectric anisotropies.

1:39PM J34.00011 Electronic properties of ultrathin GdTiO3 thin films and GdTiO3/SrTiO3 interfaces , POUYA MOETAKEF, BHARAT JALAN, JACK ZHANG, University of California, Santa Barbara, S. JAMES ALLEN, SUSANNE STEMMER, University of California, Santa Barbara — Interfaces between Mott insulators, such as the rare earth titanates, and band insulators, such as SrTiO3, have recently attracted much attention. We report on the transport properties of epitaxial rare earth titanate thin films, GdTiO3, grown by molecular beam epitaxy (MBE) and those of heterostructures with SrTiO3 and GdTiO3. Growth of GdTiO3 was performed by shuttered growth of alternating titanium tetra isopropoxide (TTIP) and Gd fluxes, in the absence of any additional oxygen. We show that to stabilize the GdTiO3 perovskite phase, SrTiO3 buffer layers are needed for growth on perovskite substrates, such as LSAT ((LaAlO3)0.3(Sr2AlTaO6)0.7). The contribution of n-type SrTiO3 buffer layers and that of the SrTiO3/GdTiO3 interfaces to the transport properties are determined by measurements of the electrical resistance and Hall coefficient as a function of temperature and magnetic field.

1:51PM J34.00012 Atomically-resolved mapping of polarization and electric fields across ferroelectric-oxide interfaces by Z-contrast imaging[1] , ALBINA BORISEVICH, HYE JUNG CHANG, SERGEI KALININ, Oak Ridge National Laboratory, ANNA MOROZOVSKA, NAS Ukraine, YING-HAO CHU, PU YU, RAMAMOORTHY RAMESH, University of California Berkeley, STEPHEN PENNYCOOK, Oak Ridge National Laboratory — Polarization, electric field, charge and potential across ferroelectric-oxide interfaces are obtained from direct atomic position mapping by aberration corrected scanning transmission electron microscopy combined with Ginsburg-Landau-Devonshire theory. We compare two antiparallel polarization orientations, which allows separation of the polarization and intrinsic interface charge contributions. Using the Born effective charges, the complete interface electrostatics is obtained in real space, providing an alternative method to holography. The results provide new microscopic insight into the thermodynamics of polarization distribution at the atomic level.

2:03PM J34.00013 Inherited (In)stabilities in Transition Metal Superlattices , SVEN RUDIN, Los Alamos National Lab — Many transition metals exhibit a solid phase with a body-centered cubic (bcc) crystal structure. For some elements, e.g., tungsten (W), bcc is the only solid phase; for others, e.g., titanium (Ti), the bcc phase only appears at high temperatures. Titanium's high-temperature bcc phase exhibits soft phonon modes. These reflect the atomic movements upon transformation into the low-temperature phases. One such mode shows atomic displacements that also appear in the top few layers of tungsten's surface reconstruction. Superlattices constructed from alternating nanometer-thick layers of W and Ti would allow the two displacement patterns to interact. The work presented here uses density functional theory calculations to predict how the structure and mechanical response of such superlattices depends on the choice of transition metal elements and the layer thicknesses.

Session J35 DCMP: Topological Insulators: Optics C140

11:15AM J35.00001 Far-infrared magneto-spectroscopy study of ultrathin Bi^2Se^3 layers in high magnetic field , WENLONG YU, GA Inst Tech, LI-CHUN TUNG, NHMFL, XUNCHI CHEN, DMITRY SMIRNOV, IRENEUSZ MIOTKOWSKI, HELIN CAO, YONG P. CHEN, ZHIGANG JIANG — We present a far-infrared (FIR) magneto-spectroscopy study of thin Bi2Se3 layers. Transmittance and reflectance measurements are performed in the Faraday geometry at 4.2 K and in a magnetic field up to 17.5 T. The thin samples (much less than 1 micron) are stabilized on the Scotch tape, which enable us to obtain reliable FIR transmission signals. A pronounced electron-phonon coupling, i.e., the coupling of a FIR phonon of Bi2Se3 with the continuum free-carrier spectrum, is observed and strongly enhanced by the applied magnetic field. The phonon lineshape is asymmetric and can be fit by a Fano formula. After examining the fitting parameters, we find no systematic broadening of the lineshape in our measurements.

11:27AM J35.00002 Terahertz and magneto-optical studies of HgTe films , JASON HANCOCK, University of Geneva, GEORGY ASTAKHOV, CHRISTOPHE BRUENE, Wuerzburg, DIRK VAN DER MAREL, University of Geneva, LAURENS MOLENKAMP, Wuerzburg — We present a frequency-domain infrared, time-domain terahertz, and magneto- optical study of thin films of high-mobility HgTe. The conductivity at low frequency and a wide range of temperature is described, and clear cyclotron effects are observed at low temperature and frequency. The context of these findings to the possible 3D topological phase will be discussed.

11:39AM J35.00003 Magneto-Optics in the search for the topological insulating state , ALEXANDER SCHAFGANS, Department of Physics, University of California, San Diego, ANDREW LAFORGE, Department of Physics, University of California, Santa Cruz, A. TASKIN, YOICHI ANDO, Institute of Scientific and Industrial Research, Osaka University, Ibaraki, Osaka 567-0047, Japan, DIMITRI BASOV, Department of Physics, University of California, San Diego — We present infrared spectroscopic data for the thermoelectric material Bi-Sb at the insulating composition, taken in magnetic field applied both in the Voight and Faraday geometries, in order to gain insight into the recently discovered topological insulating state. We observe a metallic plasma edge that displays significant blue shift at high temperatures. The form of the plasma edge shows broadening suggestive of sample inhomogeneities. The plasma edge is remarkably sensitive to the applied magnetic field, resulting in a complicated spectral lineshape. We compare these results with magneto-optics of the topological insulator Bi_2Se_3.[1]

[1]A. D. LaForge, *et. al.*, Phys. Rev. B 81, 125120 (2010).

11:51AM J35.00004 Magneto-optical spectra of topological insulators Bi_2Te_3, Sb_2Te_3 and Bi_2Se_3 in magnetic fields up to 18 Tesla , M.S. WOLF, S.V. DORDEVIC, The University of Akron, N. STOJILOVIC, University of Wisconsin Oshkosh, HECHANG LEI, C. PETROVIC, Brookhaven National Lab, L.C. TUNG, National High Magnetic Field Lab — Topological insulators are a novel class of materials that behave as insulators in the bulk, but have conducting states on the surface. Studies of their behavior in magnetic field is an important avenue towards understanding their complex properties. We will report the results of our magneto-optical measurements of topological insulators Bi_2Te_3, Sb_2Te_3 and Bi_2Se_3 in magnetic fields up to 18 Tesla. In all three compounds we detect magnetic-field induced changes in optical properties, which are most pronounced around the plasma edge. The induced changes are much bigger in Bi_2Se_3 than in Bi_2Te_3 and Sb_2Te_3.

12:03PM J35.00005 Optical properties of novel topological insulators[1] , ANDREI SUSHKOV, G.S. JENKINS, H.D. DREW, N.P. BUTCH, J. PAGLIONE, University of Maryland at College Park, K.R. CHOI, S.-W. CHEONG, Rutgers University — The recent discovery of topological insulators (TI) with the spin-polarized Dirac-like electrons on their surfaces have attracted a lot of attention and theoretical and experimental research efforts. One of the fascinating properties of TIs is the presence of the linear magneto-electric coupling which is responsible for coupled charge-spin modes in dynamical response. We will report our results on the search for such modes together with the conventional optical properties of materials predicted to be TI such as 5d oxide Na_2IrO_3, SmB_6, and Bi_2Se_3 and other materials. Measurement results include optical reflectance and/or transmission in the frequency range 5 - 50,000 cm^{-1} and Faraday or Kerr rotation and circular dichroism at selected THz frequencies.

[1]This work was supported in part by the NSF MRSEC under Grant No. DMR-0520471.

12:15PM J35.00006 Terahertz Kerr and Reflectivity Measurements on the Topological Insulator Bi_2Se_3[1] , GREGORY S. JENKINS, A.B. SUSHKOV, D.C. SCHMADEL, N.P. BUTCH, P. SYERS, J. PAGLIONE, M.-H. KIM, H.D. DREW, Center for Nanophysics and Advanced Materials, University of Maryland, College Park, J.G. ANALYTIS, I.R. FISHER, Geballe Laboratory for Advanced Materials, Departments of Physics and Applied Physics, Stanford University, Stanford — We report the first terahertz Kerr measurements on bulk crystals of the topological insulator Bi_2Se_3 with and without Fe doping at 4 K and magnetic fields up to 8 T. Transport evidence and characterization of the surface states will be presented. By employing a gate that creates a small depletion layer, the optical signals from the surface state carriers are modulated with no contribution arising from the bulk carriers. The real and imaginary parts of the Kerr angle yeild the transport scattering rate, spectral weight, and mass of the surface state carriers. FTIR and magneto-optical measurements characterize the bulk carriers. Comparisons with ARPES and other transport measurements will be discussed.

[1]Work supported in part by DOE grant #DESC0005436.

12:27PM J35.00007 Magneto-optical and Magneto-electric Effects of Topological Insulators in Quantizing Magnetic Fields[1] , WANG-KONG TSE, A.H. MACDONALD, University of Texas, Austin — Topological insulators show novel magneto-electric effect when the surface Dirac cone dispersion is gapped by a weak Zeeman field. In this talk, we present our study of the magneto-optical and magneto-electric effects of a thin-film topological insulator in the presence of a strong quantizing magnetic field. We find that low-frequency magneto-optical properties depend only on the sum of top and bottom surface Dirac-cone filling factors, whereas the magneto-electric response depends only on the difference. The Faraday rotation is quantized in integer multiples of the fine structure constant α and the Kerr effect exhibits a full-quarter rotation. Strongly enhanced cyclotron-resonance features appear at higher frequencies that are sensitive to the filling factors of both surfaces. When the product of the bulk conductivity and the film thickness in e^2/h units is small compared to α, magneto-optical properties are only weakly dependent on accidental doping in the interior of the film.

[1]This work was supported by the Welch grant F1473 and by DOE grant DE-FG03-02ER45985.

12:39PM J35.00008 Photo-Induced Kerr Rotation in the Bulk and Surface of a Topological Insulator , FAHAD MAHMOOD, DAVID HSIEH, JAMES MCIVER, DILLON GARDNER, YOUNG LEE, NUH GEDIK, Department of Physics, Massachusetts Institute of Technology, Cambridge MA 02139 — We report ultrafast bulk- and surface-sensitive optical pump-probe spectroscopy from Bi_2Se_3 (111). Using second harmonic generation, we demonstrate that the bulk and surface electronic contributions can be separated and exhibit qualitatively different relaxation dynamics. Ultrafast surface-sensitive optical measurements reveal a large photo-induced Kerr rotation from the surface that is dependent on the helicity of the circularly polarized excitation pulse. We will discuss the microscopic origin of this observation and how it relates to the strong spin-charge coupling on the surface of a topological insulator.

12:51PM J35.00009 Infrared studies of topological insulators Bi_2Te_3, Sb_2Te_3 and Bi_2Se_3 , S.V. DORDEVIC, M.S. WOLF, The University of Akron, N. STOJILOVIC, University of Wisconsin Oshkosh, HECHANG LEI, C. PETROVIC, Brookhaven National Lab — In this study we have used infrared spectroscopy to probe the electrodynamic response of topological insulators Bi_2Te_3, Sb_2Te_3 and Bi_2Se_3. Infrared spectra are collected over a broad frequency and temperature range. The results reveal similar spectra in all three compounds, with well defined plasma edge located in the far-infrared part of the spectrum. However there are some important differences in the temperature evolution of the spectra. Namely, as temperature decreases the plasma edge shifts to lower frequencies in Bi_2Se_3, whereas in Bi_2Te_3 and Sb_2Te_3 it shifts to higher frequencies.

1:03PM J35.00010 Surface optical study of topological insulator Bi2Se3 , DAVID HSIEH, JAMES MCIVER, DARIUS TORCHINSKY, DILLON GARDNER, YOUNG LEE, NUH GEDIK, Department of Physics, Massachusetts Institute of Technology, Cambridge MA 02139 — We report the observation of optical surface second harmonic generation from the (111) surface of Bi2Se3 using ultrafast laser pulses. We demonstrate that second harmonic generation is sensitive to both the surface crystal structure as well as the surface carrier density, which we tune through surface molecular doping. Protected nodes in the second harmonic circular dichroism spectroscopy provide a method to study time-reversal symmetry breaking effects from a single surface in a contact free manner.

1:15PM J35.00011 Ultrafast carrier and phonon dynamics in Bi_2Se_3 crystals , XUNCHI CHEN, GA Inst of Tech, JINGBO QI, GA Inst of Tech, NHMFL, WENLONG YU, GA Inst of Tech, PAUL CADDEN-ZIMANSKY, DMITRY SMIRNOV, NHMFL, NORMAN TOLK, Vanderbilt University, IRENEUSZ MIOTKOWSKI, HELIN CAO, YONG P. CHEN, Purdue University, YIZHENG WU, SHAN QIAO, Fudan University, ZHIGANG JIANG, GA Inst of Tech — Ultrafast time-resolved differential reflectivity of Bi_2Se_3 crystals is studied using optical pump-probe spectroscopy. Three distinct relaxation processes are found to contribute to the initial transient reflectivity changes: a sub-ps and a few-ps electron-phonon relaxation process due to different phonon modes and a defect-induced charge trapping process. After the crystal is exposed to air, the relative strength of these processes is altered and becomes strongly dependent on the excitation photon energy. We argue that the observed behavior is likely due to the presence of Se vacancies. Further, weaker charge trapping process and vanishing air doping effect are observed in magnetically doped samples, supportive of our argument. Part of this work is published on Appl. Phys. Lett. 97, 182102(2010).

1:27PM J35.00012 Photo-induced currents in the topological insulator Bi2Se3 , JAMES MCIVER, DAVID HSIEH, HADAR STEINBERG, PABLO JARILLO-HERRERO, NUH GEDIK, Department of Physics, MIT, Cambridge, MA 02139 — We report the observation of photo-induced currents in micro-devices built from exfoliated single crystals of Bi2Se3. Our experiments are performed using ultrashort laser pulses at 800 nm and in the absence of an applied bias. We find that the induced currents scale quadratically with laser field strength, confirming their second order nature. We will present the temperature dependence of these second order currents and discuss their microscopic origin.

1:39PM J35.00013 Circular photogalvanic effect on topological insulator surfaces: Berry curvature-dependent response[1] , PAVAN HOSUR, University of California at Berkeley — Strong spin-orbit coupling is commonly exploited for generating electric currents using circularly-polarized light. We study, theoretically, the direct current generated by circularly-polarized light on the surface of a topological insulator, focusing on the part that reverses on switching the light-helicity. Interestingly, the dominant current, due to an interband transition, is controlled by the Berry curvature of the surface bands. This extends the connection between photocurrents and Berry curvature beyond the quasiclassical approximation where it has been shown to hold. Explicit expressions are derived for the (111) surface of the topological insulator Bi_2Se_3 where we find significant helicity-dependent photocurrents when the rotational symmetry of the surface is broken by an in-plane magnetic field or a strain. Moreover, the dominant current grows linearly with time until a scattering occurs, which provides a means for determining the scattering time. DC spin density is generated on the surface as well, and is also dominated by a linear-in-time, Berry curvature-dependent contribution.

[1]This work was supported by LBNL DOE-504108

1:51PM J35.00014 Raman studies of irradiation-induced defects in thin flakes of Bi2Se3 and related materials , ISAAC CHILDRES, JIFA TIAN, IRENEUSZ MIOTKOWSKI, YONG P. CHEN, Purdue University — We report a Raman spectroscopy study of exfoliated Bi2Se3 flakes of various thicknesses after exposure to irradiation by lasers, electron-beam and oxygen plasma. We observe little effect of irradiations on Raman spectra of thicker (>50 nm) Bi2Se3 flakes, which exhibit characteristic Raman peaks at ∼130 cm-1 and ∼170 cm-1 similar to bulk Bi2Se3. However, spectra from irradiated thinner (<20 nm) flakes show the appearance of an extra Raman peak (∼250 cm-1) and attenuation and broadening of the peaks at ∼130 cm-1 and ∼170 cm-1. This additional peak is not seen in flakes exposed to electron-beam irradiation and lower-power lasers. We interpret the new peak in the Raman spectra as due to irradiation-induced disorder. We also performed similar Raman studies on Bi2Te3, Sb2Se3 and Sb2Te3.

2:03PM J35.00015 Tuning optical and electrical transport properties of Bi2Se3 with Ca[1] , ZHIYONG WANG, TAO LIN, PENG WEI, XINFEI LIU, Department of Physics and Astronomy, UC Riverside, RANDY DUMAS, KAI LIU, Department of Physics, UC Davis, JING SHI, Department of Physics and Astronomy, UC Riverside — We have systematically tuned the carrier type and density in Bi_2Se_3 single crystals by introducing a calcium dopant. By controlling Ca-concentration x in $Ca_xBi_{2-x}Se_3$, a minimum carrier density of $\sim 1 \times 10^{17}$ cm^{-3} is achieved in both n- and p-type materials. The Fourier transform infrared (FTIR) measurements were carried out in samples with different doping levels to obtain the inter-band transition energy, sample thickness, and the plasma frequency. The band gap and reduced effective mass of carriers were determined from the relation between the inter-band transition energy and carrier density. The undoped samples show a high electron density ($\sim 5 \times 10^{18}$ cm^{-3}) and the electrical resistivity shows a typical metallic behavior. At high magnetic fields (up to 14 T), the undoped samples show the Shubnikov-de Haas oscillations. Near the compensation point or x=1.2%, the electrical resistivity shows an insulating behavior with a low temperature saturation. This work was supported in part by DOE and NSF.

Tuesday, March 22, 2011 11:15AM - 2:03PM –

Session J36 DMP: Focus Session: Graphene Growth, Characterization and Devices: SiC and Metal Substrates C142

11:15AM J36.00001 SiC structuring and step bunching for C-face epitaxial graphene growth , JOHN HANKINSON, Georgia Tech, YIKE HU, MING RUAN, BAIQIAN ZHANG, CLAIRE BERGER, WALT DE HEER — Recent research at Georgia Tech has focused on understanding and improving the epitaxial graphene growth process. Electronic experiments have demonstrated the excellent properties that high quality epitaxial graphene can posses when grown by the confinement controlled sublimation (CCS) method in an induction furnace [1]. Here we focus on the mechanisms at work in the early stages of graphitization. Experimental observations of C-face epitaxial graphene growth have revealed that when step-pinning defects are present they seem to act as preferential graphene nucleation sites. In addition we have observed preferential graphene growth on silicon carbide sidewalls and mesas. Ongoing work seeks to take advantage of the correlation between silicon carbide structure and graphene growth by pre-patterning the SiC substrate in order to better control the graphene grown on it. With CCS growth we have created flat graphene regions extending over tens of microns with RMS roughness below 2.5 angstroms. Growth results and electronic measurements on graphene grown on structured SiC mesas will be presented.

11:27AM J36.00002 Novel epitaxy of graphene using substrate microfabrication , HIROKAZU FUKIDOME, MASATO KOTSUGI, TAKUO OHKOUCHI, TOYOHIKO KINOSHITA, THOMAS SEYLLER, KARSTEN HORN, YUSUKE KAWAI, MAKI SUEMITSU, YOSHIO WATANABE — Epitaxy of graphene on SiC is promising for device applications owing to the capability to produce large-area film. For the further applications toward integrated devices, the microscopic thickness variation of graphene should be minimized because the thickness of graphene critically determines the electronic properties, such as carrier mobility and bandgap. One of the effective solutions is the epitaxy on microfabricated substrates to spatially control surface reactions involved in the epitaxy. The controllability of the epitaxy using substrate microfabrication has been already proven for the homoepitaxy on microfabricated Si substrates. We therefore study heteroepitaxy of graphene on microfabricated 6H-SiC(0001) substrates as a model system to produce epitaxial graphene without thickness variation. It has been in fact demonstrated by using photoemission and low energy electron microscopies that the epitaxial graphene exhibits no thickness variation when the size of microfabrication pattern is small (below 10 micrometer). Further the shape of the microfabrication pattern is also influential to the microscopic variation of the graphene. The controlled epitaxy of graphene by substrate microfabrication is thus demonstrated to be vital for future integrated graphene devices.

11:39AM J36.00003 Selective Epitaxial Graphene Growth on SiC via AlN Capping , FARHANA ZAMAN, MIGUEL RUBIO-ROY, MICHAEL MOSELEY, JONATHAN LOWDER, WILLIAM DOOLITTLE, CLAIRE BERGER, RUI DONG, JAMES MEINDL, WALT DE HEER, Georgia Institute of Technology, GEORGIA INSTITUTE OF TECHNOLOGY TEAM — Electronic-quality graphene is epitaxially grown by graphitization of carbon-face silicon carbide (SiC) by the sublimation of silicon atoms from selected regions uncapped by aluminum nitride (AlN). AlN (deposited by molecular beam epitaxy) withstands high graphitization temperatures of 1420^{o}C, hence acting as an effective capping layer preventing the growth of graphene under it. The AlN is patterned and etched to open up windows onto the SiC surface for subsequent graphitization. Such selective epitaxial growth leads to the formation of high-quality graphene in desired patterns without the need for etching and lithographic patterning of graphene itself. No detrimental contact of the graphene with external chemicals occurs throughout the fabrication-process. The impact of process-conditions on the mobility of graphene is investigated. Graphene hall-bars were fabricated and characterized by scanning Raman spectroscopy, ellipsometry, and transport measurements. This controlled growth of graphene in selected regions represents a viable approach to fabrication of high-mobility graphene as the channel material for fast-switching field-effect transistors.

11:51AM J36.00004 Multi-Layer Epitaxial Graphene Formed from Poly-Crystalline Silicon Carbide Grown on C-Plane Sapphire[1] , TIMOTHY MCARDLE, JACK CHU, YU ZHU, ZIHONG LIU, MAHADEVAIYER KRISHNAN, CHRIS BRESLIN, CHRISTOS DIMITRAKOPOULOS, ROBERT WISNIEFF, ALFRED GRILL, IBM T. J. Watson Research Center, Yorktown Heights, NY — Growth of epitaxial graphene on substrates as large as eight inches in diameter is of great interest for integration with current CMOS technology. We use ultra-high vacuum chemical vapor deposition to grow poly-crystalline silicon carbide (SiC) on c-plane sapphire wafers, which are then annealed at high temperature in vacuum to create multi-layer epitaxial graphene films. Despite the roughness and small domain size of the poly-crystalline SiC films, a thick, conformal layer of graphene is formed. Reducing the surface roughness by chemical-mechanical polishing the SiC surface prior to the anneal results in a dramatic reduction of the Raman defect band observed in the final graphene film. Additionally, the graphene formed on polished SiC demonstrates significantly more ordered layer-by-layer graphene growth and increased carrier mobility for the same carrier density as the unpolished samples.

[1]This work is supported by DARPA under Contract FA8650-08-C-7838 through the CERA program.

12:03PM J36.00005 Theory of the Growth of Epitaxial Graphene on Silicon Carbide , FAN MING, ANDREW ZANGWILL, School of Physics, Georgia Institute of Technology, Atlanta, GA 30332 — We present a one-dimensional kinetic Monte Carlo model for the growth of epitaxial graphene on 6H-SiC. The model parameters are effective energy barriers for the nucleation and subsequent propagation of graphene at step edges. For growth on vicinal substrates with half-unit-cell height steps, we predict first and second layer graphene coverages and the distribution of first-layer graphene strip widths as a function of total coverage, vicinal angle, and the model parameters. Comparing our results to experiment will provide the first quantitative insights into the kinetics of growth for this unusual epitaxial system.

12:15PM J36.00006 A density-functional theory study for the mobility of carbon atoms on 6H SiC(0001) , CHRISTIAN RATSCH, UCLA — Graphene is a very promising material for many microelectronic applications because of its unique electronic properties. Among the several proposed routes to fabricate (single) layers of graphene, the growth of epitaxial graphene on 4H and 6H SiC(0001) appears to be particularly promising. The 6H SiC(0001) surface has 3 different polytypes. In this talk, results from density-functional theory calculations will be presented for the potential energy surfaces and different diffusion rates of C atoms on these different polytype surfaces. Both, the Si or C terminated surfaces will be investigated. Results for the adsorption of single and multiple graphene layers will also be presented.

12:27PM J36.00007 Epitaxial graphene on SiC(0001) , THOMAS SEYLLER, University of Erlangen-Nuremberg — Epitaxial graphene on SiC is considered to open a route towards graphene based electronics such as, e.g., high frequency transistors. Recently considerable progress has been made in the growth of epitaxial graphene on SiC. On the Si-face of SiC, where the growth is slower as compared to the C-face, monolayers can be grown reliably. However, several open questions remain. Transport studies as well es photoelectron spectroscopy has shown that the pristine layers on SiC(0001) are heavily electron doped ($n = 1 \times 10^{13}$ cm^{-1}). This results in rather low electron mobilities of the order of 2000 cm^2/Vs at 25 K. In addition, the carrier mobility shows a strong temperature dependence so that it drops to around 1000 cm^2/Vs at 300 K. In my presentation I will first show how chemical gating of graphene by deposition of F4TCNQ affects the carrier mobility. Hall effect measurements on samples close to charge neutrality show a carrier mobility of 29,000 cm^2/Vs at 25 K. Then I will discuss measurements demonstrating inertial-ballistic transport in nanoscale cross junctions fabricated from epitaxial graphene on SiC(0001). Finally, I will review recent results obtained by hydrogenation of the interface between graphene and SiC(0001). The latter process leads to a decoupling of the bufferlayer which is converted into quasi-freestanding graphene (QFMLG). The electronic, structural, and transport properties of QFMLG will be discussed in detail.

1:03PM J36.00008 Structural and Electronic Properties of Graphene on Cu(111) and SiC(0001) , LI GAO, PAOLO SESSI, JONGWEON CHO, JEFFREY R. GUEST, NATHAN P. GUISINGER, Center for Nanoscale Materials, Argonne National Laboratory — Graphene has shown attractive physical properties and is a promising new material. The structural and electronic properties of graphene on Cu(111) and SiC(0001) have been investigated by scanning tunneling microscopy and spectroscopy and Raman spectroscopy. The growth of graphene on these two substrates was achieved by thermal decomposition of ethylene on Cu(111) and thermal decomposition of SiC(0001) surface, respectively, in an ultra high vacuum chamber. On Cu(111), the nucleation of monolayer islands and two predominant domain orientations have been observed, which leads to the formation of numerous domain boundaries with increasing coverage [1]. Raman spectroscopy verifies the single layer thickness and shows the defect-induced bands for graphene on Cu(111). On SiC(0001), the electronic structure of the first two carbon layers on top of the $6\sqrt{3}$ surface reconstruction has been studied by scanning tunneling spectroscopy.

1:15PM J36.00009 Wafer scale synthesis of bilayer graphene film[1] , KYUNGHOON LEE, SEUNGHYUN LEE, ZHAOHUI ZHONG, Department of Electrical Engineering and Computer Science, University of Michigan, Ann Arbor, MI 48109, USA — The discovery of electric field induced bandgap opening in bilayer graphene paves the way for making semiconducting graphene without aggressive size scaling, or using expensive substrates. Despite intensive research, synthesizing homogeneous bilayer graphene in large size has proven extremely challenging, and the size of bilayer graphene was limited to micrometer scale by exfoliation Here we demonstrate homogeneous bilayer graphene films over at least square inch area, synthesized by chemical vapor deposition on copper foil and subsequently transferred to arbitrary substrates. Bilayer coverage of over 99% is confirmed by spatially resolved Raman spectroscopy. The result is further supported by electrical transport measurements on bilayer graphene transistors with dual-gate configuration, where field induced bandgap opening is observed in 98% of the devices. The size of our bilayer graphene film is only limited by the synthesis apparatus and can be readily scaled up, thus enabling wafer scale graphene electronics and photonics.

[1]Authors Kyung-Hoon Lee and Seunghyun Lee contributed equally to this work.

1:27PM J36.00010 Visualizing graphene grown by chemical vapor deposition on metal substrates at the atomic scale , LIUYAN ZHAO, KWANG RIM, CHRISTOPHER GUTIERREZ, RUI HE, KEUNSOO KIM, HUI ZHOU, TONY HEINZ, PHILIP KIM, ARON PINCZUK, GEORGE FLYNN, ABHAY PASUPATHY, Columbia University — We present an atomic-scale scanning tunneling microscopy (STM) study of large-area graphene films grown by chemical vapor deposition (CVD) on metal substrates. We will first describe experiments where pristine graphene is grown in UHV conditions on single crystal Cu(111) and Cu(100) surfaces. We will compare this with graphene grown on copper foils and thin films in a typical low-pressure tube furnace. We will describe the effect of substrate quality and orientation on the quality and electronic structure of the graphene film produced. Finally, we will describe experiments where the graphene film is doped by nitrogen during growth. We will describe the bonding environment and the local electronic structure caused by the incorporation of nitrogen atoms into the graphene lattice.

1:39PM J36.00011 Graphene Growth and Defects on Ni(111) , MATTHIAS BATZILL, University of South Florida, JAYEETA LAHIRI — Using scanning tunneling microscopy (STM) and Auger electron spectroscopy (AES) we have investigated the growth of graphene on Ni(111) surfaces by carbon segregation from the bulk. We reveal two distinct growth modes for graphene growth. Between 480 and 650 C graphene forms on clean Ni(111) and below 480 C graphene grows by an in-plane conversion of a surface carbide phase. This is the first time that graphene formation is observed by transformation of a surface carbide. STM indicates that a lattice-matched, one-dimensional in-plane domain boundary between graphene and the carbide forms and graphene grows by replacing Ni-atoms with carbon at this interface. In addition to the growth of graphene we will also briefly discuss atomic-scale defects that can be synthesized in Ni-supported graphene. In particular we emphasize the formation of an extended line-defect with metallic properties [1].

1:51PM J36.00012 Atomic Structures and Electronic Scattering of Graphene Edges , JIFA TIAN, HELIN CAO, Department of Physics, Purdue University, JONGWEON CHO, LI GAO, JEFFREY R. GUEST, NATHAN P. GUISINGER, Center for Nanoscale Materials, Argonne National Laboratory, WEI WU, QINGKAI YU, Center for Advanced Materials, University of Houston, YONG P. CHEN, Department of Physics, Purdue University — The success of growing monolayer gaphene on Cu foils has stimulated intense interests to study its structural and electronic properties at the atomic scale. Here we present a scanning tunneling microscopy (STM) investigation on single crystalline graphene islands synthesized on polycrystalline Cu foils by chemical vapor deposition (CVD). Our studies reveal that most of the graphene edges are macroscopically parallel to the zigzag directions with microscopic roughness. The observed rough edges follow the zigzag directions at atomic scale and make many 120-degree turns. Strong electron scattering was observed from a rarely-occurring armchair-oriented edge, and there is little such scattering observed from zigzag-oriented edges. In addition, we also observed nearly periodic parallel lines attributed to the surface dislocations of the Cu underneath graphene.

Tuesday, March 22, 2011 11:15AM - 2:15PM –

Session J37 DMP: Focus Session: Graphene Growth, Characterization, and Devices: Surface Studies C146

11:15AM J37.00001 Scanning Tunneling Microscopy of Graphene on a Boron Nitride Substrate , YANG WANG, Dept. of Physics at U.C. Berkeley, REGIS DECKER, VICTOR BRAR, Dept. of Physics at U.C. Berkeley / Lawrence Berkeley National Lab, WILLIAM REGAN, HSIN-ZON TSAI, QIONG WU, Dept. of Physics at U.C. Berkeley, ALEX ZETTL, MICHAEL CROMMIE, Dept. of Physics at U.C. Berkeley / Lawrence Berkeley National Lab — Graphene placed on a boron nitride (BN) substrate has been shown to result in increased mobility and improved Quantum Hall measurements.[1] It is therefore of great interest to understand how BN substrates differently influence graphene compared to more standard SiO_2 substrates. I will present new scanning tunneling microscopy measurements of graphene placed on a BN substrate. Differences in the local behavior of graphene on a BN substrate versus a SiO_2 substrate will be discussed.

11:27AM J37.00002 STM study of graphene on boron nitride , JIAMIN XUE, Department of Physics, University of Arizona, Tucson, Arizona 85721, USA, DANNY BULMASH, JAVIER SANCHEZ-YAMAGISHI, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA, K. WATANABE, T. TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, 1-1 Namiki, Tsukuba, 305-0044, Japan, PABLO JARILLO-HERRERO, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA, B.J. LEROY, Department of Physics, University of Arizona, Tucson, Arizona 85721, USA — We have performed low-temperature STM topographic and spectroscopic measurements of graphene on h-BN. We found that the topographic variations are reduced as compared to graphene on SiO2. We also performed scanning tunneling spectroscopy measurements to study the spatial variation of the Dirac point. We will present our latest results on the topographic and spectroscopic features for graphene on h-BN and compare them with similar measurements for graphene on SiO2.

11:39AM J37.00003 Atomic-Scale Topographic and Electronic Structure of Graphene Films on Ultraflat Insulating Materials , CHRISTOPHER GUTIERREZ, LIUYAN ZHAO, FERESHTE GHAHARI, CORY DEAN, KWANG RIM, JAMES HONE, GEORGE FLYNN, PHILIP KIM, ABHAY PASUPATHY, Columbia University — Graphene, a unique two-dimensional material, has attracted much attention for its exotic electronic properties. But owing to its nature as a single monolayer, many of these interesting properties depend heavily on the substrate on which the graphene rests. Scanning tunneling microscope (STM) experiments offer the unique ability to investigate the effect of the substrate on the surface roughness (via topography maps) as well as the local electronic properties (via spectroscopy maps) of graphene. In this talk we will present such experimental results of graphene on atomically flat insulating substrates such as mica and boron nitride, as well as suspended graphene sheets. We will describe experiments performed both on exfoliated graphene flakes as well as large-area graphene films grown by chemical vapor deposition (CVD).

11:51AM J37.00004 Structural and electronic properties of epitaxial graphene on SiC(0001): Growth, transfer doping and atomic intercalation , ULRICH STARKE, Max-Planck-Institut fur Festkorperforschung, Stuttgart, Germany — Epitaxial graphene on SiC(0001) promises a scalable graphene technology. Growth methods and experimental techniques for layer counting will be reviewed. The graphene layers are n-doped due to the influence of a covalently bonded carbon interface layer. This doping level can be precisely tailored and completely neutralized by functionalizing the graphene surfaces with electronegative molecules. In particular the Fermi level can be shifted into the band gap of bilayer graphene. The influence of the interface can be completely eliminated by hydrogen intercalation. Hydrogen migrates under the interface layer, passivates the underlying SiC layer and decouples the graphene from the substrate. The interface layer alone transforms into a quasi-free standing monolayer and epitaxial monolayer graphene turns into a decoupled bilayer. By intercalation of Germanium the graphene layers can also be decoupled. In this process both p- and n-doping can be obtained, depending on the amount of Ge intercalated. Both phases can be prepared simultaneously on the surface, so that lateral p-n junctions can be envisioned.

12:27PM J37.00005 Scanning Tunneling Spectroscopy of Suspended Graphene in the Quantum Hall Regime , NIKOLAI N. KLIMOV, Maryland NanoCenter, UMD / CNST, PML, NIST, MD, SUYONG JUNG, Maryland NanoCenter, UMD / CNST, NIST, MD, GREGORY M. RUTTER, NIKOLAI B. ZHITENEV, CNST, NIST, Gaithersburg, MD, DAVID B. NEWELL, PML, NIST, Gaithersburg, MD, JOSEPH A. STROSCIO, CNST, NIST, Gaithersburg, MD — The discovery of graphene, a unique two-dimensional electron system with extraordinary physical properties, has ignited tremendous research activity in both science and technology. Graphene interactions with a substrate such as, for example, SiO_2/Si are known to strongly limit the electrical performance of graphene devices. Suspended graphene devices, where interaction with substrates can be strongly reduced, have been studied by macroscopic transport measurements and shown to have a 10-fold increase in mobility. However, a detailed investigation on a microscopic scale is still missing. In this talk we present a scanning probe microscopy (SPM) study of a free-standing graphene membrane. The device was fabricated from a graphene flake exfoliated over an array of 1μm holes etched in SiO_2/Si substrate. Electronic spectra of both suspended and supported regions of single-layer graphene can be probed using SPM in a perpendicular magnetic field and in varying back gate voltages applied to the Si substrate. The significant differences found in electronic spectra of suspended and non-suspended graphene will be discussed.

12:39PM J37.00006 Quantized Landau level spectrum and its density dependence in graphene supported by SiO_2[1] , ADINA LUICAN, GUOHONG LI, EVA ANDREI, Department of Physics and Astronomy, Rutgers University, DEPARTMENT OF PHYSICS AND ASTRONOMY, RUTGERS UNIVERSITY TEAM — Scanning tunneling microscopy and spectroscopy in magnetic field was used to study Landau quantization in graphene and its dependence on charge carrier density. Measurements were carried out on exfoliated graphene samples deposited on a chlorinated thermal SiO_2 which allowed observing the Landau level sequence characteristic of single layer graphene while tuning the carrier density through the Si back-gate. Upon changing the carrier density we find abrupt jumps in the Fermi level after each Landau level is filled. Moreover, at low doping levels a marked increase in the Fermi velocity is observed which is consistent with the logarithmic divergence expected due to the onset of many body effects close to the Dirac point.

12:51PM J37.00007 The effect of the tip in scanning tunneling spectroscopy of graphene Landau levels[1] , KEVIN KUBISTA, DAVID MILLER, MING RUAN, WALT DE HEER, PHILLIP FIRST, Georgia Institute of Technology, GREGORY RUTTER, JOSEPH STROSCIO, NIST-Gaithersburg — Landau Level (LL) spectroscopy measurements were performed on multilayer epitaxial graphene using 4 K scanning tunneling spectroscopy in magnetic fields up to 8 T. Fits of the LL energies to the form expected for graphene show a slight difference in the Fermi velocity of hole and electron states. We show that this may be a consequence of the work function difference between graphene and the tip material (iridium). Data sets consisting of LL energies versus magnetic field are used to fit a model tip potential. The calculated spectrum of tip-perturbed LLs reveals the possible source of some "extra" peaks.

1:03PM J37.00008 Scanning tunneling spectroscopy of adsorbates and vacancies on graphene , JYOTI KATOCH, MASA ISHIGAMI, Department of Physics and Nanoscience Technology Center, University of Central Florida, Orlando, FL 32816 — Adsorbates and vacancies sensitively influence transport properties of graphene. We have investigated the impact of adsorbates, such as atomic hydrogen and potassium, and vacancy defects on electronic properties of graphene at atomic scale using scanning tunneling microscopy and spectroscopy Our results will be discussed in comparison with previous transport measurements to understand the effect of extrinsic disorder on transport properties of graphene.

1:15PM J37.00009 A Scanning Tunneling Microscopy and Spectroscopy Study of K-doped Graphene , JEONGHOON HA, HONGWOO BAEK, BEOMYONG HWANG, MINJUN LEE, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea, JUNGSEOK CHAE, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, Gaithersburg, Maryland 20899, USA, YOUNG KUK, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea — Understanding the role of impurity scattering is crucial in explaining the carrier transport phenomena in a graphene device. Although unique two-dimensional Dirac fermion behavior have been confirmed by many transport experiments, direct observation of the local electronic structure around impurities may provide detailed picture of carrier scattering. In this study the local electronic structure of potassium deposited graphene film were studied using scanning tunneling microscopy (STM) and spectroscopy (STS). Chemical vapor deposition (CVD) graphene were transferred on a SiO_2 substrate after confirming the thickness and flatness by Raman spectroscopy and atomic force microscopy. STM images show relatively long-range screening around K impurities and the spatially resolved STS revealed unique electronic structure within the screening range. It was found that the screen range varies with the applied back gate bias, suggesting carrier density dependence.

1:27PM J37.00010 Scanning Tunneling Microscopy Study of Fluorinated Graphene on Copper , SCOTT SCHMUCKER, JOSHUA WOOD, RICK HAASCH, JOSEPH LYDING, University of Illinois at Urbana-Champaign — We probe by ultrahigh vacuum scanning tunneling microscopy (UHV-STM) the structural and electronic properties of monolayer fluorinated graphene (C_xF, $x \approx 4$) synthesized by chemical vapor deposition on copper substrates and fluorinated by xenon difluoride gas [1]. The chemical composition and structure of the resulting film is probed by x-ray photoelectron spectroscopy (XPS), Raman spectroscopy, and scanning tunneling spectroscopy (STS). In contrast to metallic graphene, this material exhibits a large (>3 eV) band gap with a muted gap state corresponding to a copper surface state near -0.4 eV. We further investigate by STM alignment between the fluorographenic surface layer and copper substrate, uniformity of fluorination, and stability of fluorinated graphene under electron bombardment and thermal annealing.

1:39PM J37.00011 Scanning tunneling spectroscopy of chemical vapor deposition grown graphene , DANIEL CORMODE, COLLIN REYNOLDS, BRIAN LEROY, University of Arizona — The electronic properties of CVD grown graphene were investigated by scanning tunneling microscopy. Mono and multi layered samples were prepared by growth on copper and transferred to 300 nm SiO_2 substrates. Raman spectroscopy mapping was used to determine the thickness of the samples as well as characterize regions of higher disorder as evidenced by an increased D peak. The samples were then measured in ultra high vacuum by scanning tunneling spectroscopy at 5 K. The type and density of defects measured with the STM were compared with measured D peak intensity. We have examined the correlation between changes in the local density of states and disorder in monolayer graphene.

1:51PM J37.00012 Directed Assembly of Iron Phthalocyanine and Pentacene Molecules on a Graphene Monolayer Grown on Ru(0001) , SHIXUAN DU, Institute of Physics, CAS, PR China, H.G. ZHANG, J.T. SUN, L.Z. ZHANG, Q. LIU, J.H. MAO, Y. PAN, M. GAO, H.T. ZOU, H.M. GUO, W.A. HOFER, H.-J. GAO, INSTITUTE OF PHYSICS, CHINESE ACADEMY OF SCIENCES, PR CHINA TEAM, SURFACE SCIENCE RESEARCH CENTRE, UNIVERSITY OF LIVERPOOL, UK COLLABORATION — Monolayer graphene was successfully fabricated on 4*d*transition metal surfaces. The resulting ordered Moiré pattern was found to be an ideal template for the formation of ordered nanoclusters and molecules. Using scanning tunneling microscopy we show the selective adsorption process and assembly of iron phthalocyanine and pentacene molecules with different structural symmetries on a graphene monolayer, epitaxially grown on Ru(0001). The combination of first principles calculations and experimental measurements suggests that the lateral dipole field is the main driving mechanism for assembling molecules into ordered arrays. These findings should be important for achieving a large scale well-defined molecule-graphene interface. And such a detailed understanding of the molecular assembly will be essential in the actual fabrication process.

2:03PM J37.00013 Ab initio scanning tunneling spectroscopy simulation of graphene with metal adatoms: weak and strong coupling regimes[1] , GUNN KIM, Department of Physics, Kyung Hee University, Korea, JAE-HYEON PARQ, JAEJUN YU, Department of Physics & Astronomy, Seoul National University, Korea, YOUNG-KYUN KWON, Department of Physics, Kyung Hee University, KYUNG HEE UNIVERSITY COLLABORATION, SEOUL NATIONAL UNIVERSITY COLLABORATION — Metal atoms on graphene, when ionized, can act as a point-charge impurity to probe a charge response of graphene with the Dirac cone band structure. To understand charge and spin polarization in graphene, we present scanning tunneling spectroscopy STS simulations based on density-functional theory calculations. We find that a Cs atom on graphene is fully ionized with a significant band-bending feature in the STS whereas the charge and magnetic states of Ba and La atoms on graphene appear to be complicated due to orbital hybridization and Coulomb interaction. By applying external electric field, we observe changes in charge donations and spin magnetic moments of the metal adsorbates on graphene.

Session J38 DCP: Focus Session: Ultrafast Dynamics and Imaging II A130/131

11:15AM J38.00001 Probing Ultrafast Solution-Phase Chemistry in the X-ray Water Window and beyond via Soft X-ray Spectroscopy[1] , NILS HUSE[2], Chemical Sciences Division, Lawrence Berkeley National Laboratory — A prerequisite for a microscopic understanding of chemical reactions is knowledge of the ultrafast interplay of valence charge distributions, spin states, and nuclear degrees of freedom. These degrees of freedom are often intricately coupled, leading to very complex dynamics. Femtosecond core-level spectroscopy is very well suited to study such dynamics via x-ray absorption near-edge structure (for information on changes in valence charge distribution / spin-state) and via the extended x-ray absorption fine structure (for information in nuclear arrangements) due to the very localized nature of the initial states of well-defined symmetry and the high chemical specificity of core-level excitations. We have employed femtosecond core-level spectroscopy to study metal-ligand interactions in solvated transition metal complexes as an important class of model systems to demonstrate the feasibility and merit of ultrafast solution-phase soft X-ray spectroscopy.[3,4] Laser-induced charge transfer reactions on sub-100 fs time scales trigger structural dynamics in first-row transition-metal complexes that display multiple spin-state changes within 300 fs upon photo-excitation. The combined analysis of vibrational, optical, and core-level spectroscopy reveals a complex interplay of nuclear, electronic, and spin degrees of freedom in these systems that leads to detailed insights into the underlying reaction mechanisms. These are prototypical in nature for a variety of organometallic systems. The chemical specificity of core-level spectroscopy is exploited by probing metal-centered transitions to elucidate the "metallic view." We have very recently succeeded in also following the "ligand view" via soft X-ray spectroscopy in the X-ray water window. The later experiment has far-reaching consequences as it demonstrates the feasibility of studying ultrafast processes and short-lived species of solvated organic compounds via Nitrogen K-edge spectroscopy to deliver a detailed picture of the evolving valence charge density in chemical reactions.

11:51AM J38.00002 Ultrafast Dynamics in Helium Nanodroplets Probed by Femtosecond Time-Resolved EUV Photoelectron and Ion Imaging , OLEG KORNILOV, Max-Born-Institut, OLIVER BÜNERMANN, Georg-August-University, ALI EFTEKHARI-BAFROOEI, Lawrence Berkeley National Laboratory, STEPHEN R. LEONE, DANIEL M. NEUMARK, University of California-Berkeley, OLIVER GESSNER, Lawrence Berkeley National Laboratory — Femtosecond time-resolved EUV photoelectron and ion imaging are employed to study the relaxation dynamics of electronically excited helium nanodroplets. Excitation into a broad droplet absorption band ($\sim$23.8 eV) is followed by ionization with a delayed IR pulse. The transient photoelectron spectra and angular distributions indicate that electronically excited helium atoms are predominantly emitted in either an aligned 1s4p Rydberg state within less than $\sim$100 fs or in a non-aligned 1s3d state within $\sim$200 fs. The transient ion imaging results suggest that different Rydberg atoms are emitted with significantly different kinetic energy distributions that closely resemble Maxwell-Boltzmann distributions with temperatures of 2700 K (1s3d) and 490 K (1s4p). The results are interpreted in terms of a dynamic model that is based on the local density dependent blue shift of atomic Rydberg states in the droplet environment.

12:03PM J38.00003 "Molecular spectrometers" in the condensed phase: local THz-FIR response from femtosecond fluorescence , NIKOLAUS ERNSTING, Humboldt University Berlin — We examine dye molecules whose color depends on the polarity of the environment. Following fast optical excitation, their fluorescence band typically red-shifts by 0.5 eV on femtosecond to nanosecond time scales. This "dynamic Stokes shift" reflects the joint molecular and environmental reorganisation of the system. Solvation dynamics has been studied for decades in the hope that the dynamics of the environment itself can be extracted. We contribute with two research lines: (1) development of rigid polar solvation probes whose vibrational response is removed from that of water, for example, and (2) fluorescence techniques which measure the dynamic Stokes shifts more precisely. Two results will be shown. The frequency-dependent permittivity $\varepsilon(\omega)$ of water surrounding N-Methyl-6-Quinolone is extracted up to about 100 cm^{-1} from the time-resolved fluorescence shift R(t). The key consists in an analytical connection $\varepsilon(\omega) \quad \rightarrow$ R(t) which is needed for data fitting. Measurements with the cryoprotectant disaccharide trehalose in water serve to establish the method. Its unique feature is locality, *i.e.* the possibility to measure $\varepsilon(\omega)$ around a supramolecular structure with a covalently connected or embedded probe. THz vibrational activity of a biopolymer is thus measured locally, on the effective length scale for polar solvation, with an embedded molecular probe. For this purpose 2-hydroxy-7-nitro-fluorene was linked into a 13mer duplex opposite an abasic site. The NMR solution structure shows that the fluorene moiety occupies a well-defined position in place of a base-pair. The dynamic Stokes shifts for solution in H_2O and D_2O are quantified. Their difference is much larger than expected for free water, suggesting that only bound water is observed. A weak 26 cm^{-1} spectral oscillation of the emission band is observed which is not present when the probe is free in solution, and is therefore caused by the supramolecular structure (DNA and hydration water).

12:39PM J38.00004 Tunable acoustic terahertz generation in InGaN quantum wells effected by metal nanocrystals , MEG MAHAT, ANTONIO LIOPIS, Department of Physics, University of North Texas, Denton, TX, 76201,USA, SERGIO PERIERA, CICECO, University of Aveiro, 3810-193 Aveiro, Portugal, IAN WATSON, Institutes of Photonics, SUPA, University of Strathclyde, Glasgow, G4NW, UK, TAE CHOI, Departments of Mechanical Engineering, University of North Texas, Denton, TX, 76203, USA, ARKADII KROKHIN, ARUP NEOGI, Department of Physics, University of North Texas, Denton, TX, 76201,USA — The strained semiconductor multiple quantum wells have the capability to generate acoustic terahertz emission via coherent acoustic phonon oscillations. The frequency of the THz emission is usually limited by the periodicity of the quantum wells or superlattice structures. We propose a novel technique to modify the frequency and amplitude of THz oscillations by the inclusion of the metal nanocrystals (NCs) within InGaN/GaN multiple quantum wells via the self-assembled inverted hexagonal pits. Time resolved differential transmission measurements demonstrate a four-five folds decrease in the THz frequency under band edge excitation conditions. A theoretical model predicts a strong dependence of the amplitude and period of the oscillations on the radius of the metal NCs.

12:51PM J38.00005 "Making the Molecular Movie": First Frames , R.J. DWAYNE MILLER, Max Planck Research Group for Atomically Resolved Dynamics, University of Hamburg, CFEL/DESY and University of Toronto — Femtosecond Electron Diffraction has enabled atomic resolution to structural changes as they occur, essentially watching atoms move in real time–directly observe transition states. This experiment has been referred to as "making the molecular movie" and has been previously discussed in the context of a gedanken experiment. With the recent development of femtosecond electron pulses with sufficient number density to execute single shot structure determinations, this experiment has been finally realized. A new concept in electron pulse generation was developed based on a solution to the N-body electron propagation problem involving up to 10,000 interacting electrons that has led to a new generation of extremely bright electron pulsed sources that minimizes space charge broadening effects. Previously thought intractable problems of determining t=0 and fully characterizing electron pulses on the femtosecond time scale have now been solved through the use of the laser pondermotive potential to provide a time dependent scattering source. Synchronization of electron probe and laser excitation pulses is now possible with an accuracy of 10 femtoseconds to follow even the fastest nuclear motions. The camera for the "molecular movie" is well in hand based on high bunch charge electron sources. Several movies depicting atomic motions during passage through structural transitions will be shown. Atomic level views of the simplest possible structural transition, melting, will be presented for a number of systems in which both thermal and purely electronically driven atomic displacements can be correlated to the degree of directional bonding. Optical manipulation of charge distributions and effects on interatomic forces/bonding can be directly observed through the ensuing atomic motions. New phenomena involving strongly correlated electron systems will be presented in which an exceptionally cooperative phase transitions has been observed. The primitive origin of molecular cooperativity has also been discovered in recent studies of molecular crystals. These new developments will be discussed in the context of developing the necessary technology to directly observe the structure-function correlation in biomolecules–the fundamental molecular basis of biological systems.

1:27PM J38.00006 Two-dimensional dynamical reconstruction of the valence exciton in LiF[1] , XIAOQIAN M. CHEN, YU GAN, PETER ABBAMONTE, University of Illinois at Urbana-Champaign, CHEN-LIN YEH, Tamkang University, Taiwan, DIEGO M. CASA, Argonne National Laboratory, WEI KU, Brookhaven National Laboratory — The structure and dynamics of excitons are interesting because excitons are model many-body excitations with technological relevance, e.g. to the behavior of photocells. In a previous study, we used inelastic X-ray scattering, together with inversion techniques, to reconstruct one-dimensional projection images of exciton propagation in LiF in real space and time, and showed that the exciton in LiF is of the Frenkel type. Here we generalize our previous work to a two dimensional plane in LiF. Our new images of exciton propagation show intricate shape changes arising from scattering off of the crystal lattice. Our results are compared to model Wannier function calculations for a more detailed test of the Frenkel model.

Session J39 DBP: Physics of Proteins III: Folding, Structure and Stability A124/127

11:15AM J39.00001 The Speed Limit of Protein Folding: Alpha-Helix Initiation Modeled and Observed[1] , MILO LIN, OMAR MOHAMMED, AHMED ZEWAIL[2], Physical Biology Center for Ultrafast Science and Technology, California Institute of Technology — As a primary event of protein folding, alpha-helix initiation is the starting point of macromolecular complexity. In this work, an analytic coarse-grained model which predicts the initiation rate as a function of temperature, is presented. Helix initiation was measured via ultrafast temperature-jump fluorescence refolding experiments on two penta-peptides, and the measured rates agreed well with those of the model. In addition, the temporal separation of rate-limiting diffusion from fast annealing stipulated by the model was confirmed via ensemble-converging all-atom molecular dynamics simulations, which reproduced both the diffusion and the picosecond annealing processes and rates observed experimentally. Some of these results were published in: Mohammed OF, Jas GS, Lin MM, Ma H, Zewail AH (2009) Primary peptide folding dynamics observed with ultrafast temperature jump. Angew Chem 48: 5628-5632.

11:27AM J39.00002 Protein folding microenvironments within the cytoplasm of living cells , MINGHAO GUO, APRATIM DHAR, MARTIN GRUEBELE, University of Illinois at Urbana-Champaign — The protein folding kinetics in a living cell strongly depends on the local environment. Viscosity of cytoplasm and crowding by macromolecules modulate stability, folding rates and folding mechanism in the folding progresses. We use Fast Relaxation Imaging (FRel) to map out the stability and folding kinetics of a FRET-labeled phosphoglycerate kinase (PGK) in the cytoplasm of individual eukaryotic cells with 500 nm spatial resolution. It shows that this modulation results in large variation of folding mechanism compared to in vitro experiment. We have developed the folding-diffusion model of protein folding in cell with hetergenous microenvironment, which includes spatial hetergenous of folding rates of the multiple-state folding of PGK and diffusion between pixels. It is shown that diffusion contributes little to the large variation of folding kinetics, which can only result from the change of folding mechanism due to microenvironment.

11:39AM J39.00003 First step in folding of nonconstitutive membrane proteins: spontaneous insertion of a polypeptide into a lipid bilayer and formation of helical structure[1] , YANA RESHETNYAK, ALEXANDER KARABADZHAK, DHAMMIKA WEERAKKODY, Physics, URI, DONALD ENGELMAN, Yale Univ., VLADISLAV MARKIN, Univ of Texas Southwestern Med School, OLEG ANDREEV, Physics, URI — There are two questions we would like to address: 1) what is the molecular mechanism of a polypeptide insertion into a lipid bilayer and formation of transmembrane helix? 2) Are there any transient changes of a lipid bilayer in process of a polypeptide insertion and folding? As a convenient system we are studying pHLIP (pH (Low) Insertion Peptide) insertion into a membrane and folding, which is modulated by pH. The insertion of pHLIP occurs with rapid (0.1 sec) interfacial helix formation followed by a much slower (100 sec) insertion pathway to form a transmembrane helix. The reverse process of unfolding and peptide exit from the bilayer core proceeds much faster than folding/insertion and through different intermediate states. Our kinetic studies with pHLIP variants indicate that insertion can occur 100 times faster and with less number of intermediate states. To study changes, which might occur with a lipid bilayer in a process of peptide insertion and folding, we employed stopped-flow SAXS.

11:51AM J39.00004 Protein barrel fluctuations and the barrel permeability: A comparison between Green and Red Fluorescent proteins , CHOLA REGMI, PREM CHAPAGAIN, BERNARD GERSTMAN, Department of Physics, Florida International University, THEORETICAL BIOPHYSICS TEAM — As compared to the Green Fluorescent Proteins (GFP), the monomeric variants of the Red Fluorescent Proteins (RFP), also known as mFruits, are substantially less photostable, possibly due to the barrel permeability for molecular oxygen into the protein barrel. We performed molecular dynamics simulations to compare the protein barrel fluctuations of the GFP as well as a monomeric variant of the RFP. We also performed implicit ligand sampling for uncovering the pathways for molecular oxygen entry into the barrels. We found that, as compared to the GFP barrel, the RFP barrel has significantly larger structural fluctuations and these large barrel fluctuations lead to clear pathways through which molecular oxygen or other ions can enter the barrel more easily.

12:03PM J39.00005 Heterogeneous helical propensity and its effects on dimerization and the stability of a model protein dimer , YUBA BHANDARI, PREM CHAPAGAIN, BERNARD GERSTMAN, Department of Physics, Florida International University, THEORETICAL BIOPHYSICS TEAM — We will present the results of Monte Carlo simulations of the dimerization and unfolding of a helical protein dimer. Using a three dimensional lattice model, we investigate the role of including sections of amino acids with strong alpha-helix propensity at different locations along the helices on the dimerization kinetics and the dimer stability. Specifically, we focus on the rate limiting steps in both folding and unfolding processes. We find that these processes can be optimized by tuning the ease of access through diffusion to the metastable intermediate state and its stability. The kinetics and thermodynamical stability is tuned by a combination of the locations of the amino acids with the high helical propensity and the salt bridges.

12:15PM J39.00006 Protein-like folding and free energy landscape of a homopolymer chain[1] , MARK TAYLOR, Dept. of Physics, Hiram College, Hiram, OH, WOLFGANG PAUL, Martin-Luther-Universitat, Halle, Germany, KURT BINDER, Johannes-Gutenberg-Universitat, Mainz, Germany — Many small proteins fold via a first-order "all-or-none" transition directly from an expanded coil to a compact native state. We have recently reported an analogous direct coil-to-crystallite transition for a flexible homopolymer [1]. Wang-Landau sampling was used to construct the 1D density of states for square-well chains up to length 256 and a microcanonical analysis shows that for short-range interactions the usual polymer collapse transition is preempted by a direct freezing transition. A 2D configurational probability landscape, built via multi-canonical sampling, reveals a dominant folding pathway and an inherent configurational barrier to folding. Despite the non-unique homopolymer ground state, the thermodynamics of this direct freezing transition are identical to those of two-state protein folding. Homopolymer folding proceeds over a free energy barrier via a transition state folding nucleus, displays a protein-like Chevron plot, and satisfies the van't Hoff two-state criterion.

12:27PM J39.00007 Unfolding Kinetics of Egg Protein , DIPTI SHARMA, UML — This study explores denaturing kinetics of egg white using high resolution calorimetric technique. Fresh egg was scanned fro heating and cooling to see the thermodynamics 10° C to 100° C at different heating ramp rates varying from 1 to 20° C/min. An endothermic peak was found on heating scan showing denaturing of protein which was found absent at the cooling indicating the absence of any residue after heating. The denature peak shifted towards higher temperature as ramp rate increases following Arrhenius behavior and shows an activated denaturing kinetics of the egg protein. This peak was also compared with the water to avoid water effects. Behavior of denaturing peak can be explained in terms of Arrhenius theory.

12:39PM J39.00008 Probing the dynamics of biomolecules in liquid water by terahertz spectroscopy[1] , NGUYEN VINH, JIM ALLEN, Physics Department, UCSB, KEVIN PLAXCO, Department of Chemistry and Biochemistry, UCSB — Decades of molecular dynamics and normal mode calculations suggest that proteins are rife with collective vibrational modes with ps to ns time constants. Given that proteins are "decorated" with charged groups, these motions should lead to oscillating dipoles that, in turn, will lead to strong gigahertz to terahertz absorption. Investigation of these harmonic motions by absorption spectroscopy, however, is extremely challenging due to the strong absorption of water. In response, we have developed a sensitive Vector Network Analyzer based spectrometer that operates from 65 to 700 GHz and can measure both the absorbance and refractive index of protein solutions. In order to extract the complex dielectric response of the protein in solution we employ an effective medium approximation for the mixture of the protein and aqueous buffer. The extracted dielectric response suggests that each protein molecule is surrounded by a tightly held layer of 164 +/- 5 water molecules that behave as if they are an integral part of the protein. The size of this hydration shell and the dielectric response of the solvated protein are all independent of protein concentration. Our measured dielectric response, however, does not agree with published computation models of the protein: the measurements indicate a low frequency cutoff in the density of modes of $\sim$250 GHz.

[1]Supported by W.M. Keck Foundation.

12:51PM J39.00009 MD-simulations of Beta-Amyloid Protein Insertion Efficiency and Kinetics into Neuronal Membrane Mimics , LIMING QIU, CREIGHTON BUIE, MARK VAUGHN, KWAN CHENG, Texas Tech University — Early interaction events of beta-amyloid (Aβ) peptides with the neuronal membranes play a key role in the pathogenesis of Alzheimer's disease. We have used all-atom MD simulations to study the protein insertion efficiency and kinetics of monomeric Aβ_{40} and Aβ_{42} into phosphatidylcholine lipid bilayers (PC) with and without 40 mole% cholesterol (CHOL) that mimic the cholesterol-enriched and depleted lipid nanodomains of the neuronal plasma membranes. Independent replicates of 200-ns simulations of each protein pre-inserted in the upper lipid layer were generated. In PC bilayers, only 25% of Aβ_{40} and 50% of Aβ_{42} in the replicates showed complete insertion into the lower lipid layer, whereas the percentages increased to 50% and 100%, respectively, in PC/CHOL bilayers, providing evidence that cholesterol improves the protein insertion efficiency into the bilayers. The rate of protein insertion was proportional to the hydrophobic, transmembrane helix length of the inserted peptide and depended on the cholesterol content. We propose that the lysine snorkeling and C-terminus anchoring of Aβ to the PC headgroups at the upper and lower lipid/water interfaces represent the dual-transmembrane stabilization mechanisms of Aβ in the neuronal membrane domains.

1:03PM J39.00010 Characterization of Polyethylene Glycol Modified Hemoglobins , GIL SALAZAR, JAMES BARR, WAYNE MORGAN, LI MA, Physics Department Georgia Southern University — Polyethylene glycol modified hemoglobins (PEGHbs) was characterized by liquid chromatography and fluorescence methods. We prepared four samples of two different molecular weight PEG, 5KDa and 20KDa, modified bovine and human hemoglobin. We studied the oxygen affinities, stabilities, and peroxidase activities of PEGHbs. We have related oxygen affinities with different degrees of modifications. The data showed that the modification on the beta subunits was less stable than that of the alpha subunits on the human Hb based samples especially. We also compared peroxidase activities among different modified PEGHbs.

1:15PM J39.00011 Multi-scale structure of a protein (histone H3.1) via a knowledge-based potential[1] , RAS PANDEY, University of Southern Mississippi, BARRY FARMER, Air Force Research Laboratory — A coarse-grained computer simulation model is used to investigate the multi-scale structures of a histone H3.1, a protein with 136 residues in an effective solvent medium. The protein chain consisting of residues (nodes) tethered together by fluctuating bonds on a cubic lattice where empty lattice sites constitute the effective solvent matrix. Each residue interacts with surrounding solvent sites and other residues via Lennard-Jones (LJ) potential. A knowledge-based interaction matrix is used for the residue-residue interaction coefficient of the LJ potential. Interaction between the residue and solvent sites, a measure of the solvent quality, is varied. Each residue executes its stochastic motion with the Metropolis algorithm. We examine a number of local and global physical quantities some of which include mobility and energy profiles of each residue and their local structural histogram, radius of gyration (R_g), radial distribution function, and structure factor of the protein for a range of the solvent interactions. Variation of R_g with the solvent quality of solvent exhibits a maximum.

1:27PM J39.00012 Calculating the shift in pKa of the position 66 for an Staphylococcal nuclease mutant with the Replica Exchange Free Energy Perturbation method , DANIAL SABRI DASHTI, Physics Department and Quantum Theory Project at University of Florida, ADRIAN ROITBERG, Quantum Theory Project at University of Florida — The Experimental pKa value of Glutamate66 in a hyperstable mutant of Staph Nuclease, which has been measured by Moreno et al., shows a large shift of around 5 pKa units with respect to a glutamate in solution. In order to reproduce the large experimental shift by single structure continuum solvent computational methods, it is required that the dielectric constant of the interior of the protein be set to around ten in the simulations. The physical reason behind this is not understood as of yet and hypotheses have been produced by the Moreno group regarding solvent penetration, protein reorganization etc. We tried to resolve this inconsistency between experimental and continuum methods by introducing a four-state thermodynamic cycle that has couples conformational states with protonation state of the side chain of E66. We propose that what the experimental methods, (which are mostly sensitive to configurational changes) are measuring is actually the equilibrium constant between the two configurational states rather than between the two protonation states. In this regard we applied our recently developed Replica Exchange method Free Energy Perturbation (REFEP) in implicit solvent to calculate the pKa value of E66 for each of the configurational states as well as the mixed configuration, and our results are in almost perfect agreement with the experiments of Moreno.

1:39PM J39.00013 Brownian dynamics simulations of amelogenin microribbons formation[1] , WEI LI, ANTHONY PEREZ LOPEZ, YA LIU, Lehigh University, AMIT CHAKRABARTI, Kansas State University, JAMES GUNTON, Lehigh University — Recent advances in chemical particle synthesis have emphasized the fundamental role of surface colloidal heterogeneities and their detailed chemical composition, which is particularly significant for an important subclass of colloidal systems, namely, proteins. Recently, the process of self-assembly of amelogenin monomers with a hydrophobic/hydrophilic bipolar nature into ordered ribbon structures has been studied experimentally. In this work, we study this dynamical process by means of a Brownian dynamic simulation of a simple model which represents the bipolar character of the globular amelogenin molecule and the hydrophilic C-terminal tail. We monitor the kinetics of self-assembly through a study of the structure factor. We also calculate the phase diagram of the model using Gibbs ensemble Monte Carlo simulation and thermodynamic perturbation theory.

1:51PM J39.00014 Stability of proteins inside a hydrophobic cavity , MITHUN RADHAKRISHNA, Columbia University, SUMIT SHARMA, Princeton University, SANAT K. KUMAR, Columbia University — Previous studies have shown that enclosing a protein in an athermal cavity stabilizes the protein against reversible unfolding by virtue of eliminating many open chain conformations. Examples of such confined spaces include pores in chromatographic columns, Anfinsen's cage in Chaperonins, interiors of Ribosomes or regions of steric occlusion inside cells. However, the situation is more complex inside a hydrophobic cavity. The protein has a tendency to adsorb on the surface of the hydrophobic cavity, but at the same time it loses conformational entropy because of confinement. We study this system using a simple Hydrophobic Polar (HP) lattice protein model. Canonical Monte Carlo (MC) simulations at different temperatures and surface hydrophobicity show that proteins are stabilized at low and moderate hydrophobicity upon adsorption. The range of surface hydrophobicity over which a protein is stable increases with a decrease in radius of the cavity.

2:03PM J39.00015 Wang-Landau sampling of protein adsorption using the HP model[1] , YING-WAI LI, D.P. LANDAU, Center for Simulational Physics, University of Georgia, T. WUEST, Swiss Federal Research Institute — We have applied Wang-Landau sampling[2] with appropriate trial moves[3] to investigate the thermodynamics and structural properties of lattice hydrophobic-polar heteropolymers (commonly known as the HP protein model) interacting with an attractive substrate. We estimate the density of states of the system, from which the partition function and all thermodynamic quantities, e.g. specific heat, radius of gyration, end-to-end distance and surface contacts, can be calculated. "Transitions" between "phases" are then identified based on a comprehensive analysis of these observables. Generally speaking, three transition processes are observed: adsorption-desorption, collapse (formation of hydrophobic core), and "flattening" of adsorbed structures. These have been confirmed by "snapshots" of typical states of the system. Depending on the surface attractive strength, these transitions take place in different order upon cooling, giving rise to different thermodynamic behaviors. Such dependence of folding hierarchy on the surface attraction is found to be universal for different HP sequences.

Session J40 DCP: Theory of Clusters and Nanoscale Systems A122/123

11:15AM J40.00001 Nanomaterials synthesized by electrochemical discharges: qualitative and quantitative performance , ANIS ALLAGUI, ROLF WUTHRICH, Concordia University — During the electrochemical discharges in aqueous solutions, the electronic avalanches induce several reactions of dimerization and recombination of the hydrated electrons and H* and OH* radicals, generated by the radiation of water molecules. With the introduction of metallic ions M^{z+}, the successful manufacture of nanoparticles is controlled by the continuous competition of reduction of M^{z+}, by the powerful reducing agents e_H^- and H* to lower levels of valency, and the back reaction of oxidation by OH*. With the assumption that the concentration of metal ions is high enough when compared to those of species e_H^-, H* and OH*, the differential yield G between the formation and consumption of M^{z+} in a given finite volume around the electron-emitting electrode is modeled by homogeneous kinetics. It is found G to be proportional to the concentration of metal ions, the speed and penetration depth of the electrons, and the ratio of rate constants of reactions of nucleation and polymerization, which are supported by previous contributions on the dynamics and stability of the phenomenon.

11:27AM J40.00002 ABSTRACT WITHDRAWN —

11:39AM J40.00003 Structural Oscillation in Pd_{13} During Oxidation/Reduction[1] , D.R. ROY, J. ULISES REVELES, S. VINCENT ONG, S.N. KHANNA, Virginia Commonwealth University, A.M. KÖSTER, P. CALAMINICI, CINVESTAV, DEPARTMENT OF PHYSICS, VIRGINIA COMMONWEALTH UNIVERSITY COLLABORATION, DEPARTAMENTO DE QUíMICA, CINVESTAV COLLABORATION — First principles electronic structure calculations within a gradient corrected density functional formalism have been carried out to investigate the electronic structure and magnetic properties of bare and oxidized Pd_{13} clusters. It is shown that the ground state of neutral Pd_{13} is a bilayer structure that can be regarded as a fragment of the bulk, while a compact icosahedron is higher in energy. The addition of an electron, however, reverses the ordering of structures and Pd_{13}^- has an icosahedral ground state. Similar reordering of structure occurs as an O_2 molecule is added to the neutral cluster. The talk will focus on the oscillations between the two structures during catalysis process.

11:51AM J40.00004 Computational Studies on the Energy Landscape of Pt-Pd nanoparticles , ALVARO POSADA-AMARILLAS, Dept. de Inv. en Física, Unison, RAFAEL PACHECO-CONTRERAS, Dept. de Química, Cinvestav, DORA J. BORBÓN-GONZÁLEZ, LAURO OLIVER PAZ-BORBÓN, Fritz Haber Institut, ROY L. JOHNSTON, School of Chemistry, University of Birmingham, J. CHRISTIAN SCHÖN, Max Planck Institute for Solid State Research — Bimetallic nanoparticles such as Pt-Pd are currently the subject of intense research mainly due to their important catalytic properties. Clusters structure, composition and degree of mixing or segregation all play important roles in determining their chemical activity. It is presented here an exhaustive study of the structure of Pt-Pd nanoparticles, obtained by a Genetic Algorithm (GA) which incorporates the Gupta potential to mimic interaction for bimetallic atoms. This procedure provided an icosahedral structure as the lowest in energy. The threshold method (TM) is used to analyze the energy landscape of 13-atom $Pt@Pd_{12}$ nanoparticle, as well as the transition probabilities for those structures with pentagonal symmetry found by the TM. Disconnectivity graphs are obtained for both a vast exploration of the potential energy surface (PES) and the exploration around the lowest energy structure. We found low interconversion transition rates for the putative global minimum provided by the GA code, which was confirmed by the TM algorithm.

12:03PM J40.00005 Negative ions of transition metal-halogen clusters[1] , KALPATARU PRADHAN, Department of Physics, VCU, Richmond, VA, 23284, USA, GENNADY L. GUTSEV, Department of Physics, Florida A&M University, FL 32307, USA, PURUSOTTAM JENA, Department of Physics, VCU, Richmond, VA, 23284, USA — A systematic density functional theory based study of the structure and spectroscopic properties of neutral and negatively charged MX_n clusters formed by a transition metal atom M (M=Sc, Ti, V) and up to seven halogen atoms X (X=F, Cl, Br) has revealed a number of interesting features: (1) Halogen atoms are bound chemically to Sc, Ti, and V for $n < n_{max}$, where the maximal valence n_{max} equals to 3, 4, and 5 for Sc, Ti, and V, respectively. For $n > n_{max}$, two halogen atoms became dimerized in the neutral species, while dimerization begins at n = 5, 6, and 7 for negatively charged clusters containing Sc, Ti, and V. (2) Magnetic moments of the transition metal atoms depend strongly on the number of halogen atoms in a cluster and the cluster charge. (3) The number of halogen atoms that can be attached to a metal atom exceeds the maximal formal valence of the metal atom. (4) The electron affinities of the neutral clusters abruptly rise at $n=n_{max}$, reaching values as high as 7 eV. The corresponding anions could be used in the synthesis of new salts, once appropriate counterions are identified.

[1]We acknowledge the DTRA grant.

12:15PM J40.00006 Crystal Field Splitting and Stabilization of CuMgx- Clusters[1] , VICTOR M. MEDEL, J. ULISES REVELES, A.C. REBER, M.C. QIAN, S.N. KHANNA, Virginia Commonwealth University, DEPARTMENT OF PHYSICS, VIRGINIA COMMONWEALTH UNIVERSITY TEAM — The electronic states in clusters group into shells much in the same way as in atoms. Clusters with filled electronic shells exhibit enhanced stability as manifested through observed magic numbers in metal clusters. An important issue is if stable species can be attained at sub-shell fillings. In this work we have carried out first principles electronic structure calculations on $CuAl_x^-$ and $CuMg_x^-$ clusters to demonstrate this intriguing effect. It is shown that the ionic cores in the clusters can order to generate internal electric fields that lead to splitting of the supershells, much in the same way as the crystal field splitting of atomic states in crystals. The studies offer a new approach to forming magic species though control of the composition and the arrangement of atoms. The talk will highlight these effects and how they can be seen in experiments.

[1]We gratefully acknowledge support from the Air Force Office of Scientific Research through a grant FA9550-09-1-0371.

12:27PM J40.00007 *Ab initio* study of dimer and one-dimensional chain structures of $M@Au_{12}$ (M = W, Mo) clusters , SORA PARK, GUNN KIM, YOUNG-KYUN KWON, Kyung Hee University — Using density functional theory, we investigate the structural and electronic properties of the dimer and one-dimensional (1D) chain structures composed of metal-encapsulated Au_{12} nanoclusters ($M@Au_{12}$, M = W, Mo) with icosahedral (I_h) and cuboctahedral (O_h) symmetries. We consider various dimer configurations with different compounds and symmetries to find the most stable dimer structure in each case. We find that during dimerization (either homogeneous or heterogeneous dimer), Au atoms in the one cluster tend to form triangular bonds with counterpart Au atoms in the other. By maximizing the number of Au-Au bonds by dimerization, any cluster is stabilized by about 3 eV. We further find their stable 1D chain structures by considering various 1D chain configurations with different compounds and symmetries. Our results demonstrate that the spin-orbit coupling effects are significant on the electronic and magnetic properties as well as the structural stability due to 5*d* electrons in a transition metal atom M of the $M@Au_{12}$ nanocluster. We also present interesting differences in electronic and magnetic properties between I_h- and O_h-symmetric 1D polymerized $M@Au_{12}$ chain structures.

12:39PM J40.00008 Interpretation of Cp(*) - protected Aluminum Clusters as Superatom Complexes[1] , P. ANDRE CLAYBORNE, OLGA LOPEZ-ACEVEDO, Department of Chemistry, NSC, University of Jyväskylä, ROBERT WHETTEN, University of Jyväskylä and Georgia Insitute of Technology, HENRIK GRÖNBECK, Competence Centre for Catalysis and Department of Applied Physics, Chalmers University of Technology, HANNU HÄKKINEN, Department of Chemistry and Department of Physics, NSC, University of Jyväskylä — Metal clusters stabilized by a surface ligand shell represent an interesting intermediate state of matter between molecular metal-ligand complexes and bulk metal. Such "metalloid" particles are characterized by the balance between metal-metal bonds in the core and metal-ligand bonds at the exterior of the cluster. In previous studies, the electronic stability observed for selected ligand-protected aluminum clusters is not fully understood. By density functional theory calculations, we illustrate here that the electronic stability of various experimentally isolated Cp(*) – protected aluminum clusters can be explained using the electron shell model for the aluminum core, coupled with an ionic Al-Cp(*) interaction at the surface. Thus, one may classify ligand-protected aluminum clusters as "superatom complexes" similar to the ligand-protected gold clusters.

12:51PM J40.00009 Probing the existence of energetically degenerate cluster isomers by chemical tagging , QIAN WANG, Virginia Commonwealth University, QIANG SUN, PURU JENA — Current methods for identifying the ground state geometry of a cluster require synergy between theory and experiment. However, this becomes a difficult problem when the accuracy of the theoretical methods is not sufficient to distinguish between nearly degenerate isomers. Using density functional theory based calculations we show that the near degeneracy between the planar and cage structures can be lifted by tagging these with halogens and superhalogens moieties such as Cl and BO_2. The energy of the planar Au16- isomer is lowered from 0.15 eV before tagging to 0.51 $\sim$ 0.55 eV after tagging, thus providing a way to probe its coexistence.

1:03PM J40.00010 Gold clusters at finite temperature: influence of fluxionality on ligand adsorption , LUCA M. GHIRINGHELLI, ELIZABETH C. BERET, JÖRG MEYER, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin, Germany — Metal clusters, in particular in relation with their catalytic properties, have been the object of intensive experimental and theoretical studies, in the recent years. A great deal of effort has been devoted by many theoretical groups to understanding the zero kelvin properties of such clusters. Here, by focusing on small gas phase An_N clusters $(3 \leq N \leq 20)$ and their interaction with CO and O_2 as a showcase, we illustrate a methodology for the study of small clusters and their interaction with atoms and molecules at finite temperature. We combine all-electron density functional theory, including scf-density dependent van-der-Waals tail corrections, with finite temperature sampling techniques, like Biased MD and Parallel Tempered MD. We find an unusual flexibility of the clusters, at room and lower temperature. At certain sizes, Au_N clusters at room temperature are liquid droplets. This has an important implication, when accounting for the dynamics of ligand adsorption. One has to consider that the energy released by an exothermic ligand adsorption heats up the newly formed complex, and the equilibration with the environment is much longer than the typical timescale for conformational rearrangement. In this respect, the very concept of a preferred adsorption site in the bare cluster might be meaningless.

1:15PM J40.00011 Pseudohalogens as Building Blocks of Hyperhalogens: A Case Study with $Au(CN)_x$ Complexes , DEVLEENA SAMANTA, Virginia Commonwealth University, MIAO MIAO WU, Peking University, China, PURUSOTTAM JENA, Virginia Commonwealth University, VIRGINIA COMMONWEALTH UNIVERSITY TEAM, PEKING UNIVERSITY, CHINA COLLABORATION — Electron affinity (EA) is one of the major factors that govern reactivity. Halogen atoms possess the highest electron affinities among the elements in the periodic table since it takes only one electron to close their shell. Pseudohalogens also require one electron to close their shell and thus mimic the properties of halogens. A typical example is the CN moiety whose electron affinity (3.8 eV) is slightly larger than that of Cl. Using calculations based on density functional theory we show that when a Au atom is surrounded by CN moieties, the electron affinity of $Au(CN)_x$ complexes rise above that of CN for $x \geq 2$ and reach a value as high as 8.4 eV, thus forming hyperhalogens. Electron affinities also show odd even alternation with the clusters with even x having higher EA values. Equilibrium geometries, electronic structure and spectroscopic properties of these complexes will be presented and results will be compared with available experimental data.

1:27PM J40.00012 Chirality in Metallic Clusters , IGNACIO L. GARZON, LUIS A. PEREZ, Universidad Nacional Autonoma de Mexico — In this work, we present a theoretical study on the structural, vibrational, electronic, and optical properties of chiral bare gold clusters. We consider the case of the Au_{34}^- cluster for which extensive experimental studies on its structural and electronic behavior had been published recently. Our results show that the lowest-energy isomers of the Au_{34}^- cluster correspond to two chiral structures with C_1 and C_3 point symmetry groups, being the C_1 isomer slightly more stable than the C_3 one. The calculated structure factors, which have been measured using trapped ion electron diffraction, indicate that these isomers are almost indistinguishable. On the other hand, their electronic DOS show different features around the HOMO-LUMO energy gap, which may be detected through optical spectroscopies. In fact, our calculated absorption and circular dichroism spectra show clear differences in the optical behavior of these chiral clusters. Another important property that distinguishes the C_1 and C_3 isomers is the different spatial distribution of the atomic coordination on the cluster surface, which would generate distinct enantiospecific adsorption patterns with chiral molecules. These results confirm the existence of intrinsically chiral bare gold clusters.

1:39PM J40.00013 Free gold clusters in CO and O_2 atmosphere: an ab initio study , ELIZABETH C. BERET, LUCA M. GHIRINGHELLI, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin — The marked catalytic activity of gold nanoparticles has inspired a large number of scientific contributions from different fields. However, many questions still lack a satisfying answer, for example what are the structures and stoichiometries of the gold particles in the presence of the reactive gases, and how do their catalytic properties depend on the particle size [1]. We answer these questions for neutral gold clusters modeled in a gas phase atmosphere containing CO and O_2 in variable compositions, and in a temperature range between 100 and 600 K. To this aim, DFT (PBE)–based *ab initio atomistic thermodynamics* technique [2] is applied, including full account of the vibrational contribution to the free energy. As a result, the preferred cluster+adsorbate structures for different environmental conditions are obtained and interpreted as candidate intermediates in the catalytic CO oxidation reaction.

1:51PM J40.00014 Structure-specific spectroscopy of plasmon-supporting nanoparticles , KENNETH KNAPPENBERGER, Florida State University — Recent advances in the development of sensitive ultrashort laser-based spectroscopic probes to investigate dynamics of high surface-to-volume metal and alloy nanostructures will be discussed. Electronic relaxation and interparticle electromagnetic coupling processes in hollow gold nanospheres (HGNs) and HGN aggregates were studied using femtosecond pump-surface plasmon probe and second harmonic generation spectroscopies, including single-particle measurements. In the case of HGNs, an unexpected, but systematic, blue shift of the spectral position of the surface plasmon resonance was observed upon nanoparticle aggregation. Femtosecond time-resolved measurements, high-resolution TEM, and Finite-Difference Time-Domain calculations demonstrate that this blue shift results from interparticle cavity coupling, an effect not possible for solid nanospheres. The efficiency of this coupling was tailored by controlling HGN aspect ratio over a vast range of sizes (20 nm to 80 nm outer diameters). This effect may be applied to developing more efficient optical and electronic devices, including photovoltaics.

2:03PM J40.00015 Rare Earth Doped Magnetic Clusters of Gold for Medical Application , BRAHM DEO YADAV, VIJAY KUMAR, Dr. Vijay Kumar Foundation — In recent years gold clusters have been studied extensively due to their unusual properties and applications in cancer treatment and catalysis. Small gold clusters having up to 15 atoms are planar as shown in figure 1. Thereafter a transition occurs to 3D structures but the atomic structures continue to have high dispersion. Doping of these clusters could transform them in to new structures and affect the properties. Gold clusters with cage structures such as W@Au12 can be prepared with large highest occupied-lowest unoccupied molecular orbital (HOMO-LUMO) gap by doping with a transition metal atom such as W. By changing the transition metal atom, cage structures of different sizes as well as different HOMO-LUMO gaps can be formed which could be useful in different optical applications. In these structures gold clusters are generally non-magnetic. However, it is also possible to form magnetic clusters of gold such as Gold clusters have been found to be good for cancer treatment. We have performed ab initio calculations on doping of rare earths in small gold clusters to obtain magnetic clusters using projector augmented wave pseudopotential method within generalized gradient approximation for the exchange-correlation energy. Elemental gold clusters having up to 15 atoms are planar and thereafter 3D structures become favorable. We have explored the changes in the growth behavior when a rare earth atom is doped and studied the variation in the magnetic behavior as a function of size. Our results suggest that gold clusters may have twin advantage of treating cancer as well as be helful in magnetic imaging such as by MRI.

Session J41 DMP DPOLY GERA: Focus Session: Polymers for Energy Storage and Conversion – Structure in Organic Semiconductor Blends A115/117

11:15AM J41.00001 Organic devices. New perspectives provided from soft x-ray characterization , CHRIS MCNEILL, University of Cambridge — Organic semiconductors are continuing to receive significant interest for application in photovoltaic cells, field-effect transistors and light-emitting diodes. Conjugated polymers in particular offer the convenience of solution processibility with the flexibility of materials design afforded by synthetic chemistry. One of the disadvantages of conjugated polymers is the complexity of their film structure that, while key for understanding and optimizing device performance, is difficult to characterize. Here I will present new insights into the structure of films based on conjugated polymers using synchrotron-based soft x-ray techniques. By exploiting molecular resonances near the carbon K-edge, soft x-ray techniques such as x-ray spectromicroscopy and resonant soft x-ray scattering afford enhanced material contrast with high spatial resolution. This enhanced material specificity has been exploited to reveal the complex, hierarchical structure of conjugated polymer blends used in polymer solar cells. Furthermore, we have recently demonstrated a significant degree of miscibility of fullerene derivatives used in high-efficiency polymer/fullerene blends calling into question the assumed paradigm of phase-separated, pure phases. The polarized nature of synchrotron radiation can also be exploited to probe local molecular orientation and order using soft x-rays. This facilitates mapping of domain orientation and molecular order important for understanding charge transport in polycrystalline polymer films used in field-effect transistors.

11:51AM J41.00002 Systematic Multiscale Modeling of Polymers , ROLAND FALLER, UC Davis, DAVID HUANG, Univ of Adelaide, BESTE BAYRAMOGLU, ADAM MOULE, UC Davis — The systematic coarse-graining of heterogeneous soft matter systems is an area of current research. We show how the Iterative Boltzmann Inversion systematically develops models for polymers in different environments. We present the scheme and a few applications. We study polystyrene in various environments and compare the different models from the melt, the solution and polymer brushes to validate accuracy and efficiency. We then apply the technique to a complex system needed as active layer in polymer-based solar cells. Nano-scale morphological information is difficult to obtain experimentally. On the other hand, atomistic computer simulations are only feasible to studying systems not much larger than an exciton diffusion length. Thus, we develop a coarse-grained (CG) simulation model, in which collections of atoms from an atomistic model are mapped onto a smaller number of "superatoms." We study mixtures of poly(3-hexylthiophene) and C_{60}. By comparing the results of atomistic and CG simulations, we demonstrate that the model, parametrized at one temperature and two mixture compositions, accurately reproduces the system structure at other points of the phase diagram. We use the CG model to characterize the microstructure as a function of polymer:fullerene mole fraction and polymer chain length for systems approaching the scale of photovoltaic devices.

12:03PM J41.00003 Exploiting solvent additives to introduce processability to organic solar cells , JAMES ROGERS, KRISTIN SCHMIDT, University of California, Santa Barbara, MICHAEL TONEY, Stanford Synchrotron Radiation Lightsource, GUILLERMO BAZAN, EDWARD KRAMER, University of California, Santa Barbara — Solution processable, highly efficient, organic photovoltaics typically consist of a two component donor-acceptor type system composed of a low bandgap conjugated polymer donor blended with a fullerene acceptor. Efficient charge extraction from these blends demands that donor and acceptor components form nanoscale phase separated percolating pathways to their respective electrodes. Although post deposition thermal annealing has been shown to degrade device performance in low bandgap polymer systems, the incorporation of a small concentration of solvent additive (e.g. diiodooctane) into the solution from which a bulk heterojunction solar cell is cast has been shown to nearly double device efficiency without the need for subsequent thermal annealing. In situ grazing incidence wide angle x-ray scattering measurements as a function of time after spin coating suggest that the role of additives is to induce nucleation of crystals of the polymeric component and to facilitate changes in the correlation length (size and/or perfection) of these crystallites during the film drying process. The resulting structural order in additive processed films suggests novel processing routes for existing organic photovoltaics.

12:15PM J41.00004 Kinetics of Structure Formation in Polymer-Fullerene Solutions for Organic Photovoltaics , MARGARET SOBKOWICZ, RONALD JONES, R. JOSEPH KLINE, DEAN DELONGCHAMP, National Institute of Standards and Technology — Bulk heterojunctions (BHJs) composed of poly(hexylthiophene) (P3HT) and phenyl-C61-butyric acid methyl ester (PCBM) are promising active layers for organic photovoltaics. The nanoscale morphology of the BHJ is critical to the performance of solar devices because exciton diffusion, charge separation, and carrier transport require domains that have specific optimal sizes and connectivity. Processing parameters have been shown to influence the morphology and thus device performance. Because P3HT crystallization during film formation is the driving force for phase segregation, casting solution properties are vital to film electronic properties. Small angle neutron scattering (SANS) is an ideal measurement technique to study the blend morphology and phase formation in P3HT:PCBM solutions due to the large difference in neutron scattering length density between P3HT and PCBM, the length scale probed, and the excellent sensitivity of SANS to concentration fluctuations. In this work SANS and solution rheology are developed as characterization tools for organic photovoltaic materials. Scattering data from P3HT:PCBM solutions are correlated to gelation kinetics to develop a picture of the nanoscale organization and the influence of processing on morphology.

12:27PM J41.00005 Molecular-Scale and Nanoscale Morphology of P3HT:PCBM Bulk Heterojunctions: Energy-Filtered TEM and Low-Dose HREM , LAWRENCE DRUMMY, Air Force Research Laboratory, ROBERT DAVIS, DIANA MOORE, Sandia National Laboratory, MICHAEL DURSTOCK, RICHARD VAIA, Air Force Research Laboratory, JULIA HSU, Sandia National Laboratory — The performance of bulk heterojunction organic photovoltaic devices is critically dependent on the morphology of the active layer. Here we describe the combination of two electron microscopy techniques to quantitatively examine the molecular level structure and mesoscopic domain morphology of the active layer of P3HT:PCBM bulk heterojunction solar cells. Energy-filtered transmission electron microscopy (EFTEM) revealed the nanoscopic, interpenetrating fibrillar structure of the phase separated blend, providing unique assignments of the P3HT-rich and PCBM-rich regions. Low-dose high-resolution electron microscopy (LD-HREM) provided direct images of the P3HT crystals and their orientation within the P3HT-rich domains.

12:39PM J41.00006 Neutron Scattering Provides a New Model for Optimal Morphologies in Organic Photovoltaics: Rivers and Streams , MARK DADMUN, NATHAN HENRY, WEN YIN, University of Tennessee, KAI XIAO, JOHN ANKNER, Oak Ridge National Laboratory — The current model for the ideal morphology of a conjugated polymer bulk heterojunction organic photovoltaic (OPV) is a phase-separated structure that consists of two pure phases, one an electron donor, the other an acceptor, that form an interpenetrating, bicontinuous, network on the length scale of 10-20 nm. In this talk, neutron scattering experiments that demonstrate that this model is incorrect for the archetypal conjugated polymer bulk heterojunction, poly[3-hexylthiophene] (P3HT) and the fullerene 1-(3-methyloxycarbonyl)propy(1-phenyl [6,6]) C_{61} (PCBM) will be presented. These studies show that the miscibility of PCBM in P3HT approaches 20 wt%, a result that is counter to the standard model of efficient organic photovoltaics. The implications of this finding on the ideal morphology of conjugated polymer bulk heterojunctions will be discussed, where these results are interpreted to present a model that agrees with this data, and conforms to structural and functional information in the literature. Furthermore, the thermodynamics of conjugated polymer:fullerene mixtures dominate the formation of this hierarchical morphology and must be more thoroughly understood to rationally design and fabricate optimum morphologies for OPV activity.

12:51PM J41.00007 Organic Photovoltaic Interfaces: Back Contact Study , BRETT GURALNICK, MICHAEL MACKAY, RAUL LOBO, University of Delaware — Charge transfer between the polymer and contact greatly affects organic photovoltaics' (OPV) performance. The processing conditions are key since depositing the contact incorrectly reduces the polymer cell efficiency by up to fifty percent. The back contact, typically aluminum, is thermally evaporated onto the OPV active layer which has long been suspected to be affected by the process. To analyze this, the aluminum layer was dissolved after deposition and the resulting surface was imaged with an atomic force microscope. A fast aluminum deposition rate pitted the polymer surface creating regions of high resistivity thereby reducing cell efficiency. The addition of a LiF blocking layer between the active layer and aluminum was found to eliminate pitting allowing faster deposition. Interestingly, thermally annealing the active layer prior to aluminum deposition was also found to eliminate pitting. Neutron reflectivity experiments were used to determine that the fullerene derivative, used as the electron acceptor in the active layer, migrated to the surface during the annealing step and apparently act as a shielding layer preventing damage. With this knowledge the optimum deposition conditions were determined and has led to the highest efficiencies from OPVs.

1:03PM J41.00008 Long-range Order in Self-assembled Poly(3-alkylthiophene)-Diblock Copolymers , VICTOR HO, BRYAN BOUDOURIS, RACHEL SEGALMAN, University of California, Berkeley — Poly(3-alkylthiophenes) (P3ATs) are used commonly as active layer components in plastic electronic devices due to their relatively high hole mobilities, low optical band gaps, and their ability to be processed from solution. To date, however, block copolymers containing these molecules as a functional component predominantly have shown nanofibrillar morphologies identical to that of the P3AT homopolymers due to the large thermodynamic driving force for crystallization. We show that by decreasing rod-rod interactions through rational side chain substitution, well-ordered ($e.g.$, lamellar and hexagonally-packed) geometries can be obtained with P3AT-containing diblock copolymers as evidenced by x-ray scattering and electron microscopy. Additionally, we demonstrate that the structural and optoelectronic properties of the P3EHT domains remain in place. The ability to pattern these functional macromolecules on the nanoscale opens many doors for advanced design of organic electronic active layers.

1:15PM J41.00009 P3HT-based copolymers as interfacial compatibilizers in P3HT/PCBM system , S. MICHAEL KILBEY II, JIHUA CHEN, XIANG YU, KAI XIAO, MARK DADMUN, DEANNA PICKEL, BOBBY SUMPTER, CENTER FOR NANOPHASE MATERIALS SCIENCES, OAK RIDGE NATL LAB; DEPT. OF CHEMISTRY, UNIV. OF TENNESSEE COLLABORATION — To lower the interfacial tension and control the donor-acceptor phase separation in organic photovoltaic devices, a poly(3-hexylthiophene)-*block*-poly(ethylene oxide) (P3HT-*b*-PEO) diblock copolymer compatibilizer was added to a binary blend of regioregular P3HT and the fullerene derivative 6,6-phenyl C_{61} butyric acid methyl ester (PCBM). We systematically examined the ternary phase behavior of spin-coated films of P3HT/ P3HT-*b*-PEO/ PCBM before and after annealing with selected area electron diffraction, grazing-incidence X-ray diffraction, AFM, optical and transmission electron microscopy. Neutron reflectivity experiments were also carried out to study thermodynamic behaviors of P3HT/P3HT-*b*-PEO/PCBM trilayer films. The addition of 5% P3HT-*b*-PEO (block molecular weights of 10kDa and 3kDa, respectively) to a 1:1 P3HT/PCBM blend reduces the size of P3HT-rich domains in P3HT/PCBM films by up to 40% while the $\pi - \pi$ stacking of P3HT (i.e. (020) crystallinity) remains nearly unchanged. In addition we will discuss the effect of compatibilizer type, additive concentration, and thermal annealing conditions on power conversion efficiencies of compatibilized organic photovoltaic cells.

1:27PM J41.00010 Cooperative Assembly of Hydrogen-bonded Block Copolythiophenes/Fullerene Blends for Photovoltaic Devices[1] , JAMES J. WATKINS, YING LIN, JUNG AH LIM, QINGSHUO WEI, ALEJANDRO L. BRISENO, Polymer Science and Engineering Department, University of Massachusetts Amherst — The current work provides a general approach to obtain reliable donor acceptor morphologies by H-bonding cooperative assembly and to achieve efficient photovoltaic devices with enhanced device stability. Herein, we utilize P3HT-based block copolymer (BCP), in which one block is P3HT and the other block is a P3HT derivative containing a poly(ethylene oxide) (PEO) oligomer side chain. This design both enables self-assembly of the devices via microphase segregation into lamellar, cylindrical or spherical morphologies depending on the relative volume fractions of the blocks and provides a means for establishing strong preferential interaction between fullerene derivatives containing hydrogen bond donating groups (such as COOH groups) and the PEO side chain. One advantage of this approach is excellent device stability due to the suppression of macrophase separation resulting from fullerene crystallization under harsh annealing condition.

1:39PM J41.00011 Enhanced Photovoltaic Performance of All-Conjugated Poly(3-alkylthiophene) Diblock Copolymers , MING HE, WEI HAN, JING GE, YULIANG YANG, FENG QIU, ZHIQUN LIN — Control of the ratio of blocks in the all-conjugated poly(3-butylthiophene)-b-poly(3-hexylthiophene) (P3BHT) diblock copolymer provides a simple route to precisely tune the molecular organization and nanoscale morphology in the resulting bulk heterojunction (BHJ) solar cells made of P3BHT/ $PC_{71}BM$. An attractive high PCE of 4.02 % was found in P3BHT21 (i.e., P3BT/P3HT block ratio of 2:1 mol/mol)/$PC_{71}BM$, compared to that of 1.08 % in P3BT and 3.54 % in P3HT homopolymer-based devices. The enhanced performance is attributed to improved phase separation, interpenetrating pathway and the formation of crystalline domain size of 10.4 nm in the active layer; the latter also elucidated the importance of alkyl side-chain lengths in the molecular organization and final film morphology. In the P3BHT21/$PC_{71}BM$ blend films, P3BT block facilitated the self-assembly of P3BHT chains into interpenetrating crystalline pathway for efficient charge transport, while P3HT block provided P3BHT chains with necessary flexibility to form improved phase separation at the nanoscale with maximum interfacial areas for charge generation.

1:51PM J41.00012 Morphological Characterization of Low-Bandgap Crystalline Polymer:PCBM Bulk Heterojunction Solar Cells[1] , HAIYUN LU, THOMAS RUSSELL, University of Massachusetts Amherst, UNIVERSITY OF MASSACHUSETTS AMHERST TEAM — Understanding the morphology of polymer-based bulk heterojunction (BHJ) solar cells is key to improving device efficiencies. Blends of a low-bandgap silole-containing conjugated polymer, poly[(4,4'-bis(2-ethylhexyl)dithieno[3,2-b;2',3'-d]silole)-2,6-diyl-alt-(4,7-bis(2-thienyl)-2,1,3-benzothiadiazole)-5,5'-diyl] (PSBTBT) with phenyl-C61-butyric acid methyl ester (PCBM) were investigated using different processing conditions. Scanning force microscopy, X-ray photoelectron spectroscopy, near-edge X-ray absorption fine structure spectroscopy, dynamic secondary ion mass spectrometry and neutron reflectivity studies showed that thermal annealing did not induce obvious changes in the structure of the active layer. Grazing-incidence X-ray diffraction and small-angle neutron scattering showed that the crystallization of PSBTBT and segregation of PCBM occurred during spin coating, and a brief thermal annealing increased the ordering of PSBTBT and enhanced the segregation of the PCBM, forming domains with 10-nm in size, leading to an improvement in photovoltaic performance.

2:03PM J41.00013 Donor-acceptor conjugated polymers used as electron acceptors in bulk heterojunction photovoltaics , CHRISTOPHER BAILEY, BARNEY TAYLOR, JIANGUO MEI, JOHN REYNOLDS, JOHN HENDERSON, BENJAMIN LEEVER, MICHAEL DURSTOCK — Synthetic control over the Highest Occupied Molecular Orbital (HOMO) and Lowest Unoccupied Molecular Orbital (LUMO) has been of significant importance in organic photovoltaics due to the nature of charge separation in donor/acceptor blends. One technique for obtaining tunability of the HOMO and LUMO levels with polymer synthesis is to combine electron donating and electron accepting moieties separated by a conjugated linkage unit. This technique has been utilized to produce highly efficient devices reaching power conversion efficiencies above 8% in polymer/fullerene blends. In this work, we report the characterization of poly(2,7divinylene fluorenecobenzothiadiazole) (F10DVBT), and performs best as an electron acceptor when mixed with poly(3-hexylthiophene) (P3HT) with an open circuit voltage of 1.2V. A combination of morphological and photo-physical studies highlights interesting properties of this material and its interactions with P3HT. The donor-acceptor conjugated structure of F10DVBT appears to strongly affect the photocurrent of these devices, and may result from the interactions between intramolecular and intermolecular charge transfer processes.

Tuesday, March 22, 2011 11:15AM - 1:03PM –

Session J42 DPOLY: Padden Award Symposium A302/303

11:15AM J42.00001 Directing crystallization of organic semiconductors around corners in solution-processed thin films , STEPHANIE S. LEE, SAMUEL TANG, Department of Chemical and Biological Engineering, Princeton University, MARSHA LOTH, JOHN E. ANTHONY, Department of Chemistry, University of Kentucky, DETLEF-M. SMILGIES, ARTHUR WOLL, Cornell High Energy Synchrotron Source, YUEH-LIN LOO, Department of Chemical and Biological Engineering, Princeton University — We demonstrate the ability to pre-specify the crystallization direction of triethylsilylethynyl anthradithiophene (TES ADT), an organic semiconductor, in solution-processed thin films. Manipulating the substrate surface energy allows us to control the crystallization rate of TES ADT, which ranges from 9 to 25 μm/s, during solvent-vapor annealing. Grazing-incidence x-ray diffraction experiments on as-spun TES ADT films indicate that the initial in-plane orientation of TES ADT is influenced by the surface energy of the underlying substrate, likely due to the competition between strong molecule-molecule interactions and its wettability on the substrate. By imposing surface energy specific patterns on the substrate prior to the deposition of TES ADT, we can preferentially direct TES ADT crystallization around bends and sharp corners to form channels with high hole mobility for charge transport.

11:27AM J42.00002 Solid-State Structure and Crystallization in Double-Crystalline Diblock Copolymers , SHENG LI, SASHA MYERS, RICHARD REGISTER, Princeton University — Crystalline-crystalline block copolymers, containing two or more chemically distinct crystallizable blocks, can potentially exhibit a rich array of complex solid-state structures. Double-crystalline diblock copolymers of linear polyethylene (LPE) and hydrogenated polynorbornene (hPN) were synthesized, and their crystallization behavior and morphology were examined using two-dimensional simultaneous time-resolved synchrotron small-angle and wide-angle x-ray scattering. Previously, we showed that in symmetric diblock copolymers of hPN and LPE, with molecular weights above 50 kg/mol, the hPN block crystallizes first and sets the solid-state microstructure. In the present work, we extend these studies to lower molecular weights, and more importantly, we examine the structural relationship between the crystals formed by the two blocks under different conditions of confinement. When the diblock molecular weight is reduced to 20 kg/mol, the LPE block crystallizes first, even when LPE is the minority component, and restricts hPN to crystallize between the LPE lamellae. Furthermore, in both the high and low molecular weight diblock copolymers, the second-to-crystallize block always orients its crystals orthogonally to the first-to-crystallize block.

11:39AM J42.00003 Electric Field Induced Ordering of a Battery Electrolyte , SCOTT MULLIN, NITASH BALSARA, University of California, Berkeley — A disordered mixture of a symmetric poly(styrene-*block*-ethylene oxide) (SEO) copolymer and lithium bis(trifluoromethanesulfonimide) (a lithium salt) was placed between two lithium metal electrodes. Application of a 3V potential across the electrodes results in a current density of 15 mA/cm^2 and order formation as evidenced by the instantaneous development of a sharp small-angle X-ray scattering (SAXS) ring and Bragg spots due to the presence of a few large coherent grains. With time, radial streaks emanated from the ring, leading to a scattering pattern that resembles a sun dial. Our preliminary hypothesis is that these streaks are due to salt concentration gradients that occur when the current is passed. This gradient results in coherent grains within which the domain size changes continuously. To our knowledge, this kind of structure has not been observed previously in block copolymers. The disordered phase is recovered in the bulk when the applied potential is turned off, and the open circuit voltage of the cell and the SAXS invariant relax with similar time constants. This work represents the first step toward designing responsive battery electrolytes wherein structure and ion transport depends on the state-of-charge of the battery.

11:51AM J42.00004 Gradient Solvent Vapor Annealing of Thin Films , JULIE ALBERT, TIMOTHY BOGART, RONALD LEWIS, THOMAS EPPS, University of Delaware — The development of block copolymer materials for emerging nanotechnologies requires an understanding of how surface energy/chemistry and annealing conditions affect thin film self-assembly. Specifically, in solvent vapor annealing (SVA), the use of solvent mixtures and the manipulation of solvent vapor concentration are promising approaches for obtaining a desired morphology or nanostructure orientation. We designed and fabricated solvent-resistant devices to produce discrete SVA gradients in composition and/or concentration to efficiently explore SVA parameter space. We annealed copolymer films containing poly(styrene), poly(isoprene), and/or poly(methyl methacrylate) blocks, monitored film thicknesses during annealing, and characterized film morphologies with atomic force microscopy. Morphological changes across the gradients such as the transformation from parallel cylinders to spheres with increasing solvent selectivity provided insight into thin film self-assembly, and the gradient device has enabled us to determine transition compositions and/or concentrations.

12:03PM J42.00005 Injectable solid peptide hydrogel: shear-thinning and instant recovery , CONGQI YAN, Materials Science and Eng., U. of Delaware, JOEL SCHNEIDER, National Cancer Institute, NIH, DARRIN POCHAN, Materials Science and Eng., U. of Delaware — Peptides were designed to fold into β-hairpins once exposed to physiological conditions and consequently self-assemble into rigid hydrogel. The network consists of branched and entangled 3nm-wide fibrils. These physical gels shear thin and flow under a proper shear stress but immediately recover back into solids on removal of stress with further rigidity restoring over time. To elucidate mechanisms of these physical properties, gel behavior during and after flow was investigated. Gel stiffness recovered immediately after shear, as well as gel stiffening over time post-recovery, were found dependent on shear rate and shear duration. From scattering measurements during flow, the gel network structure was observed unchanged from the static state at all shear rates investigated. Thus, the peptide gel networks fracture into gel domains (>200nm as determined by scattering) during shear thinning/flow but can instantly percolate back into a solid hydrogel after cessation of shear, stiffening further as particle boundaries relax. As these gels are essentially the same solid material, before and after shear, they offer great potential as well-defined, injectable carriers of biomedical therapies where a desired encapsulated therapeutic payload is delivered to an *in vivo* site by simple syringe injection.

12:15PM J42.00006 Transport properties of mechanically deformed polymer networks[1] , HASSAN MASOUD, ALEXANDER ALEXEEV, Georgia Institute of Technology — We develop a hybrid computational method to probe how the permeation and hindered diffusion change when an isotropic polymer network is deformed by an externally applied force. We use a bond-bending lattice spring model to capture the micromechanics of random networks of interconnected elastic filaments coupled with the dissipative particle dynamics to explicitly model the viscous fluid and diffusive solutes. Our simulations reveal that the network transport properties are defined by the network porosity and by the degree of network anisotropy due to network mechanical deformations. We also show that the internal network structure does not affect the permeation and diffusion of stressed and unstressed networks. Furthermore, our results indicate that permeability of mechanically deformed networks can be predicted based on the alignment of network filaments that is characterized by a second order orientation tensor. Our findings have implications for designing drug delivery agents, tissue engineering, and understanding the function of certain biological systems.

[1]Financial support from the Donors of the PetroleumResearchFund, administered by theACS, is gratefully acknowledged.

12:27PM J42.00007 Numerical coarse-graining of polymer field theories , MICHAEL VILLET, GLENN FREDRICKSON, University of California, Santa Barbara — Field theoretic models of polymers are widely used to investigate polymer self-assembly, but numerical simulations of these models that include full fluctuation physics are computationally demanding and infrequently conducted. To enable efficient multi-scale simulations, we propose the use of systematically coarse-grained field theories that can be simulated on coarse computational lattices while accurately incorporating the effects of important sub-lattice-scale physics. We present a rigorous formalism for generating such coarse-grained theories from data obtained from small-scale fine-grained simulations, and demonstrate our methodology's effectiveness for a representative polymer solution model.

12:39PM J42.00008 Molecular mobility and cation conduction in sulfonated polyester copolymer ionomers , GREGORY TUDRYN, DANIEL KING, Penn State, MICHAEL O'REILLY, KAREN WINEY, UPenn, RALPH COLBY, Penn State — Poly(ethylene oxide) ionomers are candidate materials for electrolytes in energy storage devices due to the ability of ether oxygen to solvate cations. Copolyester ionomers are synthesized via condensation of sulfonated phthalates with mixtures of PEG and PTMG to make random copolymer ionomers with identical ion content. Variation of the PEG/PTMG composition changes Tg, dielectric constant and ionic aggregation; each with consequences for ion transport. Dielectric spectroscopy is used to determine number density of conducting ions, their mobility and extent of aggregation. Conductivity and mobility show Vogel temperature dependence and increase with PEG content; even though PTMG ionomers have lower Tg. Conducting ion densities show Arrhenius temperature dependence and are nearly identical for polymers containing PEG. SAXS confirms the extent of aggregation and temperature response from dielectric results, and exposes phase separation as PTMG content is increased. The tradeoff between ion-solvation and low Tg in this study provides fundamental understanding of ionic aggregation and ion transport in polymer electrolytes.

12:51PM J42.00009 Strain Localization and Sliding Friction in Physically Associating Networks , KENDRA A. ERK, KENNETH R. SHULL, Northwestern University — Experimental evidence, constitutive models, and scaling law arguments are presented for shear-induced strain localization in triblock copolymer gels deformed at reduced rates spanning almost four orders of magnitude. Strain-stiffening behavior proceeded by rapid softening is believed to result from the formation of highly localized regions of deformation in the macromolecular network. This behavior is described by a constitutive model that incorporates the strain energy and relaxation of individual strands in the network. Flow curves predicted from the model are non-monotonic, consistent with the onset of flow instabilities at high shear rates. Connections are established between the stress response of the gel at large strain and traditional sliding friction experiments of gelatin gels on glass. The gel's well-defined network structure and tunable range of relaxation times allow for these gels to be useful model systems for future studies of flow instabilities in physically associating solutions.

Tuesday, March 22, 2011 11:15AM - 2:15PM –

Session J43 DPOLY: Physics of Copolymers II A306/307

11:15AM J43.00001 Coil-globule Transitions in Model Bioinspired Polymers , HANNAH MURNEN, ADRIANNE ROSALES, University of California Berkeley, RONALD ZUCKERMANN, The Molecular Foundry, Lawrence Berkeley National Laboratory, RACHEL SEGALMAN, University of California Berkeley — The monomer sequence of a polypeptide chain has a profound effect on the coil to globule transition of the protein. Both theoretical and experimental efforts to probe the effect of monomer sequence have included the use of chemical modifications post chain collapse in a homopolymer/solvent system followed by further analysis of the chain to understand the resulting sequence. Polypeptoids, or N-substituted glycines, are a far more precise sequence specific model system that can be used to test the effect of monomer sequence on the coil to globule transition. In this study, we synthesized 50mer sequences of a blocky protein-like copolymer using 40 monomers of N-(methyl)glycine and 10 of N-(carboxyethyl)glycine). As predicted in theoretical simulations, the protein like copolymer forms a smaller globule than the periodic control sequence. In addition, decreasing the relative hydrophobicity of the two comonomers results in a looser globule size at room temperature. Future work will focus on using polypeptoids to further probe this transition and to gain insight into the fundamental forces at play in polypeptide folding.

11:27AM J43.00002 Modeling the Heat Capacity of Spider Silk Inspired Di-block Copolymers[1] , W. HUANG, S. KRISHNAJI, D. KAPLAN, P. CEBE, Tufts University — We synthesized and characterized a new family of di-block copolymers based on the amino acid sequences of Nephila clavipes major ampulate dragline spider silk, having the form HABn and HBAn (n=1-6), comprising an alanine-rich hydrophobic block, A, a glycine-rich hydrophilic block, B, and a histidine tag, H. Using temperature modulated differential scanning calorimetry (TMDSC), we captured the effect of bound water acting as a plasticizer for copolymer films which had been cast from water solution and dried. We determined the water content by thermogravimetry and used the weight loss vs. temperature to correct the mass in TMDSC experiments. Our result shows that non-freezing bound water has a strong plasticization effect which lowers the onset of the glass transition by about 10°C. The reversing heat capacities, Cp(T), for temperatures below and above the glass transition were also characterized by TMDSC. We then calculated the solid state heat capacities of our novel block copolymers below the glass transition (Tg) based on the vibrational motions of the constituent poly(amino acid)s, whose heat capacities are known from the ATHAS Data Bank. Excellent agreement was found between the measured and calculated values of the heat capacity, showing that this model can serve as a standard method to predict the solid state Cp for other biologically inspired block copolymers.

[1]Support was provided from the NSF CBET-0828028 and the MRI Program under DMR-0520655 for thermal analysis instrumentation.

11:39AM J43.00003 Effect of chain shape and monomer sequence on self-assembly of polypeptoid-polystyrene block copolymers , ADRIANNE ROSALES, HANNAH MURNEN, University of California, Berkeley, RONALD ZUCKERMANN, Molecular Foundry, Lawrence Berkeley National Laboratory, RACHEL SEGALMAN, University of California, Berkeley — Polymer chain shape has profound effects on block copolymer self-assembly. In nature, chain shape is controlled by the monomer sequence of biological polymers, but such precise control is difficult with classical synthetic systems. Polypeptoids, a class of sequence-specific bioinspired polymer, are shown to have a chain shape which can be tuned by the introduction of monomers with bulky, chiral side chains. Here, it is shown that introducing chiral monomers into the peptoid chain increases chain stiffness, as reflected by a 20C increase in the glass transition temperature for a chiral polypeptoid compared to its achiral analog. Incorporation into block copolymers enables systematic study of the effect of chain shape while maintaining similar enthalpic interactions. For two otherwise analogous block copolymers, conformational asymmetry is shown to affect both the self-assembled morphology and its order-disorder transition temperature. The ability to tune polymer properties with this biomimetic system will lend insight to the relationship between monomer sequence and self-assembled nanostructures.

11:51AM J43.00004 Self-Assembly of Globular Protein-Polymer Diblock Copolymers , C.S. THOMAS, B.D. OLSEN, MIT — The self-assembly of globular protein-polymer diblock copolymers into nanostructured phases is demonstrated as an elegant and simple method for structural control in biocatalysis or bioelectronics. In order to fundamentally investigate self-assembly in these complex block copolymer systems, a red fluorescent protein was expressed in *E. coli* and site-specifically conjugated to a low polydispersity poly(N-isopropyl acrylamide) (PNIPAM) block using thiol-maleimide coupling to form a well-defined model globular protein-polymer diblock. Functional protein materials are obtained by solvent evaporation and solvent annealing above and below the lower critical solution temperature of PNIPAM in order to access different pathways toward self-assembly. Small angle x-ray scattering and microscopy are used to show that the diblock forms lamellar nanostructures and to explore dependence of nanostructure formation on processing conditions. Circular dichroism and UV-vis show that a large fraction of the protein remains in its folded state after conjugation, and wide angle x-ray scattering demonstrates that diblock copolymer self-assembly changes the protein packing symmetry.

12:03PM J43.00005 Phase Behavior and Significantly Enhanced Toughness in Polylactide Graft Copolymers , MEGAN ROBERTSON, University of Houston, GRAYCE THERYO, FENG JING, MARC HILLMYER, University of Minnesota — Polylactide (PLA), a biodegradable polyester derived from plant sugars, is commercially available and used in a variety of applications ranging from serviceware to resorbable sutures. One limitation to diversifying the applications of the material is its inherent brittleness. Graft copolymers containing PLA arms and a rubbery aliphatic polymer backbone were synthesized by a combination of ring-opening metathesis and ring-opening transesterification polymerizations. The high degree of incompatibility between the arms and backbone resulted in microphase separation of the graft copolymer at increasingly low fractions of the backbone polymer, as evidenced by small-angle x-ray scattering. In graft copolymers with a rubbery content of only 5 wt percent, the tensile strain at break was observed to be as high as twenty times that of neat PLA. Studies are underway to provide insight into the critical polymer molecular parameters for enhanced toughness and the deformation mechanisms.

12:15PM J43.00006 Thermoresponsive Polymers and Block Copolymers in Ionic Liquids , HAUNAN LEE, University of Minnesota, ZHIFENG BAI, NAKISHA NEWELL, TIMOTHY LODGE — We recently discovered that poly(ethylene oxide) (PEO) and poly(n-butyl methacrylate) (PnBMA) exhibit two completely different types of lower critical solution temperature (LCST) phase behavior in certain ionic liquids (ILs). While typical LCST type phase diagrams were shown in PnBMA/IL systems, we observed unusual temperature-composition phase diagrams in the PEO/IL systems, in which the cloud point curves are strongly asymmetric, with the critical composition located at 80 wt % of PEO. In addition, an important feature of these thermosensitive polymer/IL systems is that the LCST can be easily tuned over a wide range by blending different ILs, without changing the chemical structure of the polymers. On the basis of the LCST of PEO and the upper critical solution temperature (UCST) of poly(N-isopropylacrylamide) (PNIPAm) in ILs, we designed a PEO-PNIPAm block copolymer that exhibits interesting doubly thermosensitive self-assembly. The block copolymer forms PNIPAm-core micelles at low temperatures and transforms into PEO-core micelles at high temperatures. The critical micellization temperatures (CMT) of both blocks can be manipulated by adjusting the mixing ratio of ILs.

12:27PM J43.00007 Effect of homopolymer additives on texture evolution in block copolymer composites , HYUNG JU RYU, JANE SUN, MICHAEL BOCKSTALLER, Carnegie Mellon University — This contribution presents a systematic study of the effect of homopolymer (hP) addition on the texture evolution in block copolymer (BCP) blends. The microstructures of poly(styrene-b-isoprene) based symmetric di-BCP blended with homopolystyrene additives at various filling fraction were analyzed after different thermal annealing time. For the analysis we utilized serial electron imaging in conjunction with image reconstruction & stereological analysis. Particular emphasis was on the elucidation of the evolution of type and frequency of grain boundary (GB) formation as well as average grain size and orientation. Relative GB energies were determined from triple junction analysis. The results demonstrate that the presence of even small amount of hP impurities significantly reduce grain growth and annealing of high energy GB surfaces. This is interpreted as a consequence of selective segregation of the fillers within high energy GB regions and the associated stabilization of the GB surfaces. These results have important implication on the use of BCPs in areas ranging from plastic electronics to tunable photonic crystals.

12:39PM J43.00008 Influence of Chemical Heterogeneity on the Viscoelastic Properties of Polystyrene-b-Poly(alkyl methacrylate) Baroplastics[1] , ASEM ABDULAHAD, CHANG Y. RYU, Rensselaer Polytechnic Institute — The development of purification and fractionation techniques of block copolymers is important for overcoming the synthetic difficulty of preparing well-defined block copolymers using various living polymerization techniques. A large scale separation technique would lead us to obtaining sufficient amounts of homopolymer-free block copolymers for subsequent physical characterization. This can potentially aid in the elucidation of the role of chemical heterogeneity on the thermodynamic transitions and viscoelastic properties of block copolymer materials. Atom transfer radical polymerization by the activators regenerated by electron transfer method (ARGET-ATRP) was used to prepare a series of polystyrene-b-poly(alkyl methacrylate) copolymers that would inherently consist of homopolymers and a high polydispersity. Leveraging the understanding of polymer adsorption/desorption in solution onto silica and C18-modified silica surfaces during HPLC, we demonstrate how a large scale purification and fraction is achievable using flash chromatography. Finally, the viscoelastic properties of the purified, homopolymer-free block copolymers will be discussed.

[1]NSF PIRE Polymer Program

12:51PM J43.00009 Effects of B Segment Polydispersity on ABA Triblock Copolymer Phase Behavior , MAHESH MAHANTHAPPA, JOAN SCHROEDER, ANDREW SCHMITT, ADAM SCHMITT, KYUHYUN IM, University of Wisconsin-Madison — Advanced polymerization techniques enable the synthesis of a variety of polymeric materials with well-defined chain architectures, compositions, and tunable molecular weights and molecular weight distributions. The inherent chain length polydispersity of polymers derived from these syntheses affects their ultimate materials properties and applications. Relying on tandem ring-opening metathesis polymerization with chain transfer (ROMP-CT) and atom transfer radical polymerization (ATRP), we have synthesized a series of poly(styrene-b-1,4-butadiene-b-styrene) triblock copolymers in which the polybutadiene blocks are polydisperse (Mw/Mn = 1.7-2.0) and the polystyrene end blocks are monodisperse (Mw/Mn = 1.05-1.30). We systematically explore the role of block polydispersity, a molecular chain length heterogeneity, on the melt-phase self-assembly behavior of these block copolymers. Using a combination of temperature-dependent X-ray scattering and transmission electron microscopy, we demonstrate that monodispersity is not a necessary condition for molecular self-assembly into well-defined supramolecular morphologies. The origins of these effects are discussed and a preliminary experimental phase portrait for this system is presented.

1:03PM J43.00010 Elucidation of an Unusual Pull Out Mechanism for the Additive-Driven Assembly of Poly(ethylene oxide)-Poly(propylene oxide)-Poly(ethylene oxide)Tri-block Copolymers , VIKRAM DAGA, University of Massachusetts Amherst, HUA-GEN PENG, Polymers Division, NIST, YING LIN, University of Massachusetts Amherst, WEN-LI WU, CHRISTOPHER SOLES, Polymers Division, NIST, JAMES WATKINS, University of Massachusetts Amherst — The addition of poly(acrylic acid) (PAA) to disordered poly(ethylene oxide)-poly(propylene oxide)-poly(ethylene oxide) tri-block copolymers induces microphase segregation to yield well ordered blends with sub-10 nm domain sizes. Unexpectedly, even with large changes in the chain length (up to 10 times that of tri-block copolymer) and loading of PAA (>40%), the domain spacing of the ordered blend remains nearly invariant although order-to-order transitions are still observed. Here we use neutron scattering and selective deuteration of the tri-block copolymer to probe phase segregation and structure in these systems. One interesting observation is the emergence of a pullout mechanism during ordering in which PEO chain segments are drawn across the interface of a mixed PEO-PPO phase to stabilize the addition for PAA and to create a mixed PAA-PEO phase.

1:15PM J43.00011 Influence of thermal fluctuations on nucleation in a diblock copolymer melt , RUSSELL SPENCER, ROBERT WICKHAM, University of Guelph — We study the effect of thermal fluctuations on the kinetics of nucleation of lamellar droplets from a metastable cylinder phase in a diblock copolymer melt by simulating the time-dependent Landau-Brazovskii model in three dimensions. We investigate the shift in the location of phase coexistence, due to fluctuations, as well as changes in nucleus shape, critical size and interfacial velocity. We also examine the kinetics of the transition in the spinodal regime.

1:27PM J43.00012 Disorder-to-Order Transition Induced by Alkyne/Azide Click Chemistry in Diblock Copolymer Thin Films , XINYU WEI, Department of Polymer Science and Engineering, University of Massachusetts Amherst, WEI CHEN, Center for Nanoscale Materials, Argonne National Laboratory, JOSEPH STRZALKA, Advanced Photon Source, Argonne National Laboratory, THOMAS RUSSELL[1], Department of Polymer Science and Engineering, University of Massachusetts Amherst — The thin film morphology of binary blends of poly(ethylene oxide)-*block*-poly(n-butyl methacrylate-*random*-propargyl methacrylate) (PEO-*b*-P(nBMA-*r*-PgMA)) diblock copolymer and Rhodamine B azide was investigated. During thermal annealing, the click reaction between the alkyne-bearing diblock copolymer and the azide lead to a significant increase in non-favorable segmental interaction and thus microphase separation of the block copolymer. Different morphologies were realized by controlling block copolymer composition and the mole ratio between the alkyne and azide groups. The effects of film thickness and annealing temperature on microdomain orientation and lateral ordering were also revealed. Our studies suggest a promising approach to fabricate nanostructured materials with long-range lateral ordering.

1:39PM J43.00013 Correlation in SANS χ upon heating and pressurization for a diblock copolymer[1] , JUNHAN CHO, JUMI LEE, Dankook University, DU YEOL RYU, Yonsei University — The response of phase behavior to pressure for an A-*b*-B diblock copolymer in the disordered state has been studied by small-angle neutron scattering (SANS). Deuterated polystyrene-*b*-poly(n-propyl methacrylate) (dPS-*b*-PPrMA) copolymer, which possesses ordering transition upon heating and baroplasticity (suppressed demixing by pressurization), was taken as our model system. It was shown that effective Flory-Huggins parameter χ_F from scattering intensity profiles upon heating and pressurization forms a characteristic curve that is a function of pressure increment ΔP ($\equiv P - P_0$) divided by temperature dependent bulk modulus B_0 at a reference pressure P_0. Each isotherm of χ_F is superposed into the curve by a scale factor τ determined by B_0. The scattering intensity maxima I_{max}, which is governed by χ_F, were also shown to reveal a similar superposition.

1:51PM J43.00014 Rouse and Entangled Dynamics in Coarse Grain Polymeric Systems[1] , ABELARDO RAMIREZ-HERNANDEZ, DARIN PIKE, Department of Chemical and Biological Engineering, University of Wisconsin-Madison, USA, FRANCOIS DETCHEVERRY, Universite Lyon 1 and CNRS, France, JUAN DE PABLO, Department of Chemical and Biological Engineering, University of Wisconsin-Madison, USA — The understanding of the kinetics of microphase ordering of block copolymers is important for controlling the morphology of these polymeric materials. Much of our current understanding of the equilibrium morphologies of block copolymers has emerged from studies using Self-Consistent Field Theory (SCFT), in which the effect of non-crossability of chains is not taken into account. In this work, we use a particle-based coarse grain model of block copolymers, and introduced elastic slip-links to model the effect of entanglements on the dynamics of the melts. These effects can be important when the self-assembly occurs in non-equilibrium conditions. We show that our model is able to reproduce both Rouse and Entangled dynamical behavior for a homopolymeric melt. We apply our computational approach to block copolymer systems under equilibrium and non equilibrium (shear flow) conditions.

2:03PM J43.00015 Facile Synthesis and Characterization of Well-Defined Rod-Coil Block Copolymers Composed of Regioregular Poly(3-hexyl thiophene) , HONG CHUL MOON, JIN KON KIM, Pohang University of Science and Technology — We synthesized rod-coil block copolymers composed of regioregular poly(3-hexyl thiopene) (P3HT) block via anionic coupling reaction. Three different coil blocks (poly(2-vinyl pyridine) (P2VP) and polyisoprene (PI)) and poly(methyl methacrylate) (PMMA)) were selected. For the synthesis of P2VP-*b*-P3HT-*b*-P2VP and P2VP-*b*-P3HT-*b*-P2VP, the chain ends of the P3HT were capped by the aldehyde group. On the other hand, phenyl acrylate (PA)-capped P3HT was prepared for coupling reaction with living PMMA anions. When the excess amount of the used living anions was removed by column chromatography, all of the neat block copolymers showed lower PDI without leaving any homopolymers. We also investigated the optical property and thin film morphology of synthesized various block copolymers.

Session J44 DPOLY DFD: Focus Session: Kinetic Control of Solution Assemblies A309

11:15AM J44.00001 Helical Assembly of Janus Particles , JONATHAN WHITMER, Department of Physics, University of Illinois at Urbana-Champaign, QIAN CHEN, SHAN JIANG, SUNG CHUL BAE, STEVE GRANICK, Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign, ERIK LUIJTEN, Department of Materials Science and Engineering and Department of Engineering Sciences and Applied Mathematics, Northwestern University — Amphiphilic Janus particles, which have hydrophobic and hydrophilic hemispheres, assemble into a variety of clusters depending on salt concentration and particle volume fraction. At low salt concentration, repulsion due to surface charges keeps cluster sizes small, whereas at higher salt concentrations beautiful elongated helices of tetrahedra emerge. We demonstrate that the emergence of these helical structures is a nonequilibrium effect, and that kinetic selection drives formation of polytetrahedral shapes relative to polyhedral shapes which are entropically more favorable.

11:27AM J44.00002 Nucleation of Nanoparticle Superclusters from Solution[1] , SIDDIQUE J. KHAN, C.M. SORENSEN, A. CHAKRABARTI, Dept. of Physics, Kansas State University — Colloids of surface ligated nanoparticles (NP) often act as solutions with the NP displaying reversible temperature and solvent dependent solubility. In many cases when the nanoparticles are highly uniform, the precipitating solid is a two- or three-dimensional superlattice of the nanoparticles. Thus there is strong analogy to the phase behavior of molecular solutions, and it is reasonable to ask what controls the phase behavior of nanoparticle solutions and what is the nature of nucleation and growth of the insoluble phase? We have recently developed [1] a phenomenological model for the effective interaction potential between two ligated gold nanoparticles. In the current work, we carry out Brownian Dynamics simulations using this NP-NP interaction potential. We will report results from our simulations for both dynamics and shape of pre- nucleating and post-nucleating superclusters.

11:39AM J44.00003 Directing the self-assembly of polyhedral silver nanocrystals , MICHAEL GRUENWALD, University of California at Berkeley, JOEL HENZIE, ASAPH WIDMER-COOPER, PHILLIP GEISSLER, PEIDONG YANG — Self-assembly of nanocrystals with complex shapes requires precise control of nanoscale interactions and driving forces. Here we show with experiment and simulation that large 3D supercrystals with exceptional order can be assembled by tuning the shape and attraction between polyhedral building blocks. When passivated with adsorbing polymer, Ag nano-polyhedra can behave as quasi-hard particles, and assemble into their densest known packings under a simple gravitational driving force. Excess polymer in solution induces depletion attractions that can stabilize less dense, ordered packings. In the case of octahedra, controlling polymer concentration allows us to tune between the well-known Minkowski lattice, and a novel packing with complex helical motifs. Such large-scale ordered arrangements of Ag nanocrystals provide many possibilities for designing scalable 3D plasmonic metamaterials with applications including chemical and biological sensing, nanophotonics and photocatalysis.

11:51AM J44.00004 Nanoscale systems assembled with DNA: from principles to rational design , OLEG GANG, Brookhaven National Laboratory-Center for Functional Nanomaterials — This abstract not available.

12:27PM J44.00005 A direct comparison of crystallization transitions and glassy dynamics in polymers and colloids[1] , ROBERT S. HOY, COREY S. O'HERN, Yale University — Using computer simulations, we compare the freezing transitions in systems composed of N spherical particles with and without covalent-bonding constraints. Linear polymer chains with $N-1$ permanent covalent bonds are compared to "colloidal" systems with the same nonbonded interactions but no covalent bonds. In the "sticky hard sphere" limit, where covalent bonds act as holonomic constraints, the melting temperatures $T_{\rm melt}$ for both polymers and colloids (with the same N) are inversely proportional to the number of unconstrained degrees of freedom. We also examine the effect of the thermal quench rate $|\dot{T}|$ on collapse. At $|\dot{T}|$ below a lower "critical" value, which decreases rapidly with increasing N, polymers and colloids form similar ground states. This critical value is lower for polymers than colloids and has different N-dependence. In both cases, the dynamics of the systems slow down near $T_{\rm melt}$ as the system approaches isostaticity. For high $|\dot{T}|$, glassy dynamics produces disordered final states. At intermediate $|\dot{T}|$, we find complex nonmonotonic behavior in T, which we relate to the very different rearrangement kinetics of polymeric and colloidal clusters.

12:39PM J44.00006 Dynamics of Fatty Acid Single Molecule Islands on Metal-exchanged Mica , MOURAD CHENNAOUI, ALEKS PONJAVIC, JANET WONG, Imperial College London, London, UK — Under certain conditions, surface-active molecules are known to self-organise into SAMs according to two main driving forces: molecular surface adsorption via diffusive/convective transport, and surface reorganisation and growth. For the latter in-situ methods are required to deconvolute the complex underlying kinetics and dynamics. To this end, a single molecule fluorescence imaging technique is used to observe the dynamics of fatty acid molecules on different metal-exchanged Mica substrates (K, Li, H). It is shown that the molecular surface re-organisation proceeds via an initial islandisation step. These islands spread and grow until forming a stable and organised SAM. Islands formation kinetics/dynamics according to different surface metal types is investigated. Diffusive mechanisms within and between the islands are also explored.

12:51PM J44.00007 Multicompartment and multigeometry nanostructures with block copolymers and kinetic control , DARRIN POCHAN, University of Delaware — The combination of charged block copolymer architecture with the kinetic control of solvent processing offers great flexibility for the creation of new assembled morphologies in solution and outstanding ability to control and manipulate those morphologies. When charged, acidic blocks are present, assembled structures are tunable in a well-defined way via co-assembly of organic bases with adjustable chain structure and control of the solution assembly pathway. A rich variety of polymeric micelles have been made such as toroids, disks, and helical cylinders from poly(acrylic acid)-*block*-poly(methyl acrylate)-*block*-polystyrene (PAA-*b*-PMA-*b*-PS) triblock copolymers in THF/water mixtures with multiamines to complex with the PAA. Both the type and amount of multiamine were found to be critical for formation of specific micelles. Kinetic pathways and temporal stabilities of different micelles and nanoscale aggregates have also been studied. Due to low chain exchange dynamics between block copolymeric micelles in solution, global thermodynamic equilibrium is extremely difficult, if not impossible, to achieve. In our block copolymer/THF/water/multiamine quaternary systems, thermodynamics and kinetics of morphological evolution are governed by three important factors, including chain length of hydrophobic blocks, ratio of THF to water, and the interaction of multiamine with hydrophilic PAA block in the corona. Slow kinetics associated with these factors in solution greatly hinders the system from reaching a global equilibrium. However, by taking advantage of slow kinetics behavior of polymeric micelles in solution, one can purposely produce multicompartment micelles and mulitgeometry micelles by now mixing different PAA-containing block copolymers together but forcing them to ultimately reside in the same nanoscale structure through kinetic processing. While kinetically trapped in common nanostructures, local phase separation can occur producing compartments. This compartmentalization can be used within common micelle geometries to make complex spheres and cylinders or can be used to make new nanostructures such as multigeometry aggregates (e.g. hybrid cylinder-sphere aggregates). All is possible through the kinetic control of the assembly process.

1:27PM J44.00008 Determination of critical micelle concentrations in ionic liquid/block copolymer systems , MICHELLE MOK, TIMOTHY LODGE, University of Minnesota — The micellization of block copolymers in ionic liquids is of great interest, due to their potential as cargo carriers for separations, transfer and extraction applications. In this study, we investigate the critical micelle concentration (cmc) of block copolymers in ionic liquids using fluorescence-based techniques. Specifically, the cmcs of poly(styrene-b-ethylene oxide) and poly(styrene-b-methylmethacrylate) copolymers were determined from the polarity-sensitive emission spectra of pyrene probes. At the onset of micellization, the probes preferentially partition to the non-polar styrene cores, analogous to pyrene-based cmc studies of aqueous micelle systems. The cmcs are explored as a function of copolymer block molecular weight and composition, as well as ionic liquid composition.

1:39PM J44.00009 Hierarchical Helical-Assembly of Conjugated Poly(3-hexylthiophene)-*b*-poly(3-triethylene glycol-thiophene) Diblock Copolymers , EUNJI LEE, BRENTON HAMMER, TODD EMRICK, RYAN C. HAYWARD, Department of Polymer Science and Engineering, University of Massachusetts, Amherst — One-dimensional crystalline fibrillar assemblies of poly(3-hexylthiophene) (P3HT)-based materials hold significant potential for fabrication of low-cost optoelectronic devices. We have studied the crystallization-driven assembly of a series of poly(3-hexylthiophene)-*block*-poly(3-triethylene glycol-thiophene) (P3HT-*b*-P3TEGT) diblock copolymers, which provide a large contrast in solubility due to the presence of non-polar (hexyl) and polar (TEG) side-chains. P3HT-*b*-P3TEGT diblock copolymers were found to form well-defined fibrillar structures in mixed solvents of chloroform and methanol, with lengths could be tuned easily by changing the solvent composition or relative block lengths. For polymers containing relatively short P3TEGT blocks, the resulting fibers show twisted ribbon-like structures. For appropriate block ratios, complexation of the TEG side chains to alkali metal cations drives formation of clearly defined single helical ribbons and superhelical structures.

1:51PM J44.00010 Molecular simulation study of random block copolymer films prepared through solvent evaporation , DMITRY BEDROV, KEITH HAMBRECHT, GRANT SMITH, University of Utah — Molecular simulations have been used to study equilibrium and non-equilibrium morphologies of random block copolymer films prepared through solvent evaporation. The polymer chains are comprised of "A" and "B" beads connected by FENE springs. Chains comprised of six blocks (ten beads each) and representing all possible combinations of A and B blocks were used to form films with 50/50 A/B fraction. Bead-bead interactions were chosen such that one of the blocks had higher glass transition temperature than the other and that the A and B blocks were incompatible in absence of the solvent. Initially the polymer chains were dissolved in a monomeric solvent at 75/25 solvent/polymer ratio. Then, polymer films were formed through solvent evaporation at various processing parameters. The nanoscale structure and viscoelastic properties of the polymer were investigated as a function of solvent quality, segment incompatibility and rate of evaporation. It was found that when the temperature is below the glass transition temperature of one of homopolymers, the morphology and properties of the film are strongly dependent on evaporation rate.

2:03PM J44.00011 Blood Clotting-Inspired Control of Single-Chain Molecules in Flows , CHARLES SING, ALFREDO ALEXANDER-KATZ, MIT — Recent experimental evidence has demonstrated a clear link between mechanical stimuli and the activation of von Willebrand Factor (vWF), a protein that plays a critical role in the blood clotting cascade. This protein exhibits counter-intuitive conformational and adsorption responses that suggest novel ways of controlling the single-chain dynamics of polymer chains. Specifically, we are using simulation and theoretical approaches to elucidate the fundamental physics that govern globule-stretch transitions in collapsed polymers due to the effect of fluid flows. We begin to extend this general approach to the case of globule adsorption-desorption transitions in the presence of fluid flows, and demonstrate how kinetic considerations must be taken into account to describe the basic features of these transitions. We expect that these results will both allow the development of novel techniques for single-chain targeting and assembly and offer insight into the physiological behavior of vWF.

Session J45 DAMOP: Focus Session: Non-equilbrium Physics with Cold Quantum Gases A310

11:15AM J45.00001 Universal Dynamics Near Quantum Critical Points , ANATOLI POLKOVNIKOV, Boston University — asp@physics.bu.edu

11:51AM J45.00002 Dynamics of a finite-rate quantum quench in an ultra-cold atomic BCS superfluid[1] , CHIH-CHUN CHIEN, BOGDAN DAMSKI, Los Alamos National Laboratory — We study dynamics of an ultra-cold atomic BCS superfluid driven towards the BCS superfluid-Fermi liquid quantum critical point by a gradual decrease of the pairing interaction. We analyze how the BCS superfluid falls out of equilibrium and show that the non-equilibrium gap and Cooper pair size reflect critical properties of the transition. We observe three stages of evolution: adiabatic where the Cooper pair size is inversely proportional to the equilibrium gap, weakly non-equilibrium where it is inversely proportional to the non-equilibrium gap, and strongly non-equilibrium where it decouples from both equilibrium and non-equilibrium gap. These phenomena should stimulate future experimental characterization of non-equilibrium ultra-cold atomic BCS superfluids.

12:03PM J45.00003 Slow quench dynamics of a trapped one-dimensional Bose gas confined to an optical lattice , JEAN-SEBASTIEN BERNIER, Centre de physique theorique, Ecole Polytechnique, GUILLAUME ROUX, LPTMS, Universite Paris-Sud, CORINNA KOLLATH, Centre de physique theorique, Ecole Polytechnique — We analyze the effect of a linear time-variation of the interaction strength on a trapped one-dimensional Bose gas confined to an optical lattice. The evolution of different observables such as the experimentally accessible onsite particle distribution are studied as a function of the ramp time using time-dependent exact diagonalization and density-matrix renormalization group techniques. We find that the dynamics of a trapped system typically display two regimes: for long ramp times, the dynamics are governed by density redistribution, while at short ramp times, local dynamics dominate as the evolution is identical to that of an homogeneous system. In the homogeneous limit, we show that the energy absorbed scales non-trivially with the ramp time.

12:15PM J45.00004 Quench dynamics of paired states of fermions in two dimensions with breaking of parity and time-reversal symmetries[1] , NOAH BRAY-ALI, Joint Quantum Institute, National Institute of Standards and Technology-Gaithersburg and University of Maryland, College Park — Resonantly paired fermions in two spatial dimensions with breaking of parity and time-reversal symmetry are believed to exhibit two topologically distinct phases at low temperature: the weak-pairing (Bardeen-Cooper-Schrieffer or BCS) phase and the strong-pairing (Bose-Einstein condensate or BEC) phase. We examine the dynamic response of each phase to a rapid quench towards and away from the quantum critical regime. The weak-pairing (BCS) phase has a higher residual defect concentration after the quench than the strong-pairing (BEC) phase. We relate this to the presence of a topologically protected, Majorana fermion edge excitation in the weak-pairing phase, and propose quench dynamics as a practical, experimental probe of this excitation in these systems.

12:27PM J45.00005 Title: Time-Dependent Mean Field Theory for Quench Dynamics in correlated electron systems , MARCO SCHIRO', Princeton Center for Theoretical Science, Princeton University, MICHELE FABRIZIO, SISSA, International School for Advanced Studies — A simple and very flexible variational approach to the out-of-equilibrium quantum dynamics in strongly correlated electron systems is introduced through a time-dependent Gutzwiller wavefunction. As an application, we study the simple case of a sudden change of the interaction in the fermionic Hubbard model and find at the mean field level an extremely rich behaviour. In particular, a dynamical transition between small and large quantum quench regimes is found to occur at half-filling, in accordance with the analysis of Eckstein *et al.*, Phys. Rev. Lett. **103**, 056403 (2009), obtained by dynamical mean field theory, that turns into a crossover at any finite doping.

12:39PM J45.00006 Non-equilibrium dynamics and heating of cold atoms in optical lattices , ANDREW DALEY, University of Pittsburgh, HANNES PICHLER, PETER ZOLLER, University of Innsbruck — We study the dissipative many-body dynamics of cold atoms in optical lattices that is induced by incoherent scattering of light from the lattice lasers. The resulting heating process is intrinsically non-equilibrium, and involves an important interplay between the atomic physics of the spontaneous emission process and the many-body physics of the state present in the system. In particular, we observe important differences for strongly and weakly interacting regimes, as well as a strong dependence on the sign of the laser detuning from the excited atomic state. We compute heating rates and changes to characteristic correlation functions based on a microscopic master equation. In 1D this equation can be propagated exactly by combining time-dependent density matrix renormalization group (t-DMRG) methods with quantum trajectory techniques.

12:51PM J45.00007 Quantum effects on Fermi-Pasta-Ulam recurrence in ultracold lattice bosons[1] , IPPEI DANSHITA, RIKEN, RAFAEL HIPOLITO, Boston University, VADIM OGANESYAN, City University of New York, ANATOLI POLKOVNIKOV, Boston University — We propose an experimental scheme for studying the Fermi-Pasta-Ulam (FPU) problem in a quantum mechanical regime with use of ultracold one-dimensional Bose gases in an optical lattice. In the classical limit, we identify parameter regions in which FPU recurrence can occur in this system. The strength of quantum fluctuations can be widely controlled by tuning the number of atoms per lattice sites (filling factor). To investigate the effects of quantum fluctuations on the FPU recurrence, we simulate the real time dynamics of the Bose-Hubbard model by means of the exact numerical method of time-evolving block decimation. We show that strong quantum fluctuations cause significant damping of the FPU oscillation.

1:03PM J45.00008 Dynamic Stimulation of Phase Coherence in Lattice Bosons[1] , ANDREW ROBERTSON, VICTOR GALITSKI, University of Maryland, GIL REFAEL, California Institute of Technology — The existence of superfluidity depends on the energy distribution of excitations in a system. However, the distribution at thermal equilibrium is rarely optimal for the manifestation of long-range phase coherence. We show that by pushing a system of lattice bosons out of equilibrium with periodic driving, it is possible to increase or decrease the phase coherent region in the phase diagram of the Bose-Hubbard model. We demonstrate this by calculating the non-equilibrium spatial correlation function using a synthesis of Keldysh and Floquet theories. This work is supported by DARPA-MTO.

[1]Supported by DARPA-MTO

1:15PM J45.00009 Phase Kink Dynamics in fluctuating Bose condensates , AMY CASSIDY, LUDWIG MATHEY, CHARLES CLARK, Joint Quantum Institute, NIST and University of Maryland — We study the dynamics of Bose gases following a phase imprint. Numerical results within truncated Wigner approximation, which includes both quantum and thermal fluctuations, are compared with analytical predictions. In order to emphasize the effects of fluctuations in these approximations, we also compare our results with dynamics governed by the Gross Pitaevskii equation. We study the dynamics of several observables, including the density and single-particle and density-density correlation functions, with particular focus on experimentally relevant quantities.

1:27PM J45.00010 Exploring topological phases with quantum walks[1] , TAKUYA KITAGAWA, MARK RUDNER, EREZ BERG, EUGENE DEMLER, Harvard University — The quantum walk was originally proposed as a quantum mechanical analogue of the classical random walk, and has since become a powerful tool in quantum information science. In this talk, we show that the dynamical protocols called discrete time quantum walks provide a versatile platform for studying topological phases, which are currently the subject of intense theoretical and experimental investigation. In particular, we demonstrate that recent experimental realizations of quantum walks simulate a non-trivial one dimensional topological phase. With simple modifications, the quantum walk can be engineered to realize all of the topological phases which have been classified in one and two dimensions. We further discuss the existence of robust edge modes at phase boundaries, which provide experimental signatures for the non-trivial topological character of the system. 1:39PM J45.00011 Universal energy distribution in thermally isolated driven systems , LUCA D'ALESSIO, Boston University, GUY BUNIN, Technion, Haifa, ANATOLI POLKOVNIKOV, Boston University, YARIV KAFRI, Technion, Haifa — The evolution of the energy distribution of a thermally isolated and repeatedly driven system is studied. A general formalism to calculate the width of the energy distribution is derived and the result is compared with the thermal width. This comparison allow us to identify two regimes: quasi-thermal and run-away. In the quasi-thermal regime the width on the energy distribution of the driven system is proportional to the thermal width with a protocol-dependent universal coefficient. In the run-away regime the width of the energy distribution is an universal function of the energy with an exponent different from the thermal case. A simple formulation in terms of entropy production allow us to distinguish these two regimes. Examples and application to both classical and quantum system (mainly cold atoms) are presented.

1:51PM J45.00012 Ramping through Superfluid-to-Mott transition in the Bose-Hubbard Model , BERNHARD WUNSCH, DAVID PEKKER, TAKUYA KITAGAWA, Harvard University, EFSTRATIOS MANOUSAKIS, Florida State University, EUGENE DEMLER, Harvard University — We discuss equilibrium and dynamic properties of cold bosonic atoms in optical lattices which can be described by the Bose-Hubbard Model. Motivated by recent experiments we study local density fluctuations and their correlations both in equilibrium and for a ramp from the superfluid to the Mott regime. We compare mean-field Gutzwiller approach with exact diagonalization studies and analyze the effect of a trapping potential. In order to describe fluctuations and finite temperature we include quadratic fluctuations on top of the mean field.

2:03PM J45.00013 Dynamics of thermalisation: a Gaussian regime[1] , SAM GENWAY, Imperial College London, ANDREW HO, Royal Holloway, University of London, DEREK LEE, Imperial College London — We study numerically the thermalisation and temporal evolution of subsystems in a fermionic Hubbard model prepared far from equilibrium at a definite energy. Taking motivation from cold atoms in optical lattices with single-site addressability, we consider measurements on a two-site subsystem. We ask the question: how do observables on the subsystem thermalise when the total system is in a pure state? Even for very small systems near quantum degeneracy, the subsystem can reach a steady state resembling thermal equilibrium. This occurs for a non-perturbative coupling between the subsystem and the rest of the lattice where relaxation to equilibrium sharply contrasts perturbative results. To examine the extent to which this behaviour is generic for small quantum systems, we also investigate small Bose-Hubbard model systems and fermionic systems with random couplings between the subsystem and the rest of the lattice.

K1.00003 Drag effects in a system of electrons and microcavity polaritons , OLEG BERMAN, ROMAN KEZRASHVILI, New York City College of Technology of the City University of New York, YURII LOZOVIK, Institute of Spectroscopy — The theory of the drag effects in the system of spatially separated electrons and excitons in coupled quantum wells (QWs) embedded in an optical microcavity is developed. It is shown that for systems of spatially separated interacting quasiparticles is the possibility of controlling the motion of the quasiparticles of one subsystem by altering the parameters of state of the quasiparticles in the other subsystem, for example, controlling the flow of polaritons or exciton using a current of electrons. At low temperatures, the electron current dragged by the polariton flow is strongly suppressed and hence, the absence of the electron current indicates the superfluidity of polaritons. However, the polariton flow can be dragged by the electrons, and, therefore, there is a transport of photons along the microcavity, which decreases with rise of the superfluid component and can be observed through the change in angular distribution of photons discussed above. At high temperatures, from one hand, the existence of the electric current in the electron QW indicates the exciton flow in the other QW, and from the other hand, the electron current in one QW induces the exciton flow in the other QW via the drag of excitons by the electrons. The drag coefficients for the polariton-electron systems are calculated and analyzed.

K1.00004 UNDERGRADUATE RESEARCH / SOCIETY OF PHYSICS STUDENTS –

K1.00005 Celebrating Five Years of SPS: A lesson in building physics outreach from scratch , JEROME T. MLACK, ROBERTO RAMOS, Drexel University — It has been almost five years since SPS was revived at Drexel University. Until 2006 Drexel SPS had been inactive for two decades. In this poster we report the challenges of building a chapter from scratch and turning it into an active and award-winning group. The students are constantly involved in mentorship programs in the underserved Philadelphia school district, while regularly seeking opportunities to perform and present research. We report the various activities we have initiated, and the lessons we have learned from them.

K1.00006 Exploring the Depletion Layer: An Investigation into How Water Reacts when Confined to a Hydrophobic Surface , ISAAC MARX, ADELE POYNOR, Allegheny College Physics Department — We observe water interacting with surfaces everyday. It forms spherical drops on hydrophobic surfaces, such as a freshly waxed car, and it spreads out on hydrophilic surfaces. However, water acts much differently when it is confined to a hydrophobic area. In our experiment, Surface Plasmon Resonance (SPR) is utilized to find differences in surface conditions. Tests are done for the interface of a hydrophobic surface surrounded by water and also for a hydrophobic surface surrounded by methanol, which we know will not form a depletion layer. With this data we are able to analyze the optical properties of the depletion layer in much greater detail.

K1.00007 Exploring Isothermal Layers in the Stable Atmospheric Boundary Layer[1] , JOSEPH WILKINS, University of Louisville — Simulating the stable atmospheric boundary-layer presents a significant challenge to numerical models due to the interactions of several processes with widely varying scales. The goal of this project is to more clearly define the cause of isothermal layers observed during the Meteorological Experiment in Arizona's Meteor Crater and to test the National Taiwan University/Purdue University (NTU/P) model in stable environments with complex terrain. The NTU/P model is able to utilize the actual terrain data with minimal smoothing for stability. We have found that isothermal profiles can be generated by the standing wave that develops due to weak wind flowing over the crater. However, the horizontal heterogeneity is greater than observed. Continued effort will explore enhancing horizontal mixing due to turbulence and radiative transfer.

[1]Louis Stokes Alliances for Minority Participation Program, Summer Research Opportunities Program.

K1.00008 Drug Loading of Mesoporous Silicon[1] , ANNE MOFFITT, JEFF COFFER, MENGJIA WANG, Texas Christian University — The nanostructuring of crystalline solids with low aqueous solubilities by their incorporation into mesoporous host materials is one route to improve the bioavailability of such solids. Earlier studies suggest that mesoporous Si (PSi), with pore widths in the range of 5-50 nm, is a candidate for such an approach. In this presentation, we describe efforts to load curcumin into free-standing microparticles of PSi. Curcumin is a compound extracted from turmeric root, which is an ingredient of curry. Curucmin has shown activity against selected cancer cell lines, bacteria, and other medical conditions. However, curcumin has a very low bioavailability due to its extremely low water solubility (0.6μg/mL). Incorporation of curcumin was achieved by straightforward loading of the molten solid at 185°C. Loading experiments were performed using PSi particles of two different size ranges, 45-75 μm and 150-250 μm. Longer loading times and ratio of curcumin to PSi leads to a higher percentage of loaded curcumin in both PSi particle sizes (as determined by weight difference). The extent of curcumin crystallinity was assessed by x-ray diffraction (XRD). The solubility and release kinetics of loaded curcumin from the PSi was determined by extraction into water at 37°C, with analysis using UV-VIS spectrometry.

K1.00009 Identification of gram-negative and gram-positive bacteria by fluorescence studies , JONATHAN DEMCHAK, JOSEPH CALABRESE, MARIAN TZOLOV, Lock Haven University of PA — Several type strains of bacteria including Vibrio fischeri, Azotobacter vinelandii, Enterobacter cloacae, and Corynebacterium xerosis, were cultured in the laboratory following standard diagnostic protocol based on their individual metabolic strategies. The bacterial cultures were not further treated and they were studied in their pristine state (pure culture - axenic). The fluorescent studies were applied using a continuous wave and a pulsed excitation light sources. Emission and excitation spectra were recorded for the continuous wave excitation and they all show similar spectral features with the exception of the gram positive bacteria showing vibronic structures. The vibrational modes involved in these vibronic bands have energy typical for carbon-carbon vibrations. The fluorescence is quenched in addition of water, even a very thin layer, which confirms that the observed spectral features originate from the outer parts of the bacteria. These results allow to conclude that the fluorescence spectroscopy can be used as a method for studying the membranes of the bacteria and eventually to discriminate between gram positive and gram negative bacteria. The pulsed experiments show that the fluorescence lifetime is in the sub-microsecond range. The results indicate that the observed spectra are superposition of the emission with different lifetimes.

K1.00010 Electrocardiogram analysis through time discrete Fourier transform[1] , CAMERON LANCASTER, GUOPING ZHANG, Department of Physics, Indiana State University — The motivation for this research is to find an alternative method to diagnose heart conditions. This can be accomplished by analyzing wave patterns in EKG data, and using the Fourier Transform to compare steady wave patterns against fibrillating wave patterns. The two main contributors are the following: heart electricity and Fourier Transform. Also, it is recognized that ion movement has potential to change the frequency in any heart beat signal. This effect is caused due to a strong electrostatic attraction that causes the membrane capacitance to build charge. For a single ion focus, the Nernst Potential influences the equilibrium potential for the membrane of an ion. If two or more ions are contributing to an electric field charge, the Goldman-Hodgkin-Katz will find the membrane equilibrium potential. If a membrane has an efflux, or influx, of ions, then it is possible to get the passive flow of the electric current to zero. In continued research, we will gain knowledge of solving equations; such as ionic flux, quantitative diffusion, electric current density, and more. The finishing portion of this research will be to compare the Fourier Transformed wave graphs to determine heart conditions.

K1.00011 In-Vivo Proton Therapy Dosimetry Using Scintillating Fiber Technology , ASHLEY CETNAR, Grove City College, PAUL GUEYE, Hampton University — Proton therapy is a cancer treatment modality that uses high-energy proton beams to irradiate cancerous cells while minimizing the radiation to healthy tissue. Because of its Bragg peak distribution, a proton is more efficient in localizing doses than conventional x-ray therapy. When the protons interact within the body, there are many reactions that induce secondary radiation. To date, there is still no accurate device available that is capable of measuring the beam profile and effective dose delivery during the treatment. This research focused on the use scintillating fibers technology to measure the secondary emitted radiation exiting a water phantom tank and the delivery system bombarded by proton beams. A realistic Geant4 Monte Carlo simulation was also developed to provide additional information to further optimize our prototype. This poster presents the results obtained from preliminary experimental and simulated studies for a possible real time radiation detection system using scintillating fibers.

K1.00012 Approximating the Production Rate for Neutrino-Induced Pair-Production in Intense Magnetic Fields[1] , JORDAN RUSSELL, Hendrix College — We consider the production of electron-positron pairs by neutrinos in an intense magnetic field. Calculating the total production rate of these pairs requires summing over all of the allowed Landau levels of the electron and positron for a range of incoming neutrino energies. Because of the computationally challenging nature of this summation, the focus of my research has been to institute a set of estimations and calculate the total rate over the dominant region of Landau-level space. I will present an approximate relationship for field strengths in excess of the critical field.

[1]Supported by Hendrix College and Arkansas Space Grant Consortium Grant No. HC20066

K1.00013 The Optimization and Implementation of the Qweak Database , UDAI GARIMELLA, DAMON SPAYDE, Hendrix College, QWEAK COLLABORATION — The Qweak experiment at Thomas Jefferson National Accelerator Facility (J-Lab) is an attempt to precisely measure the parity violation observed in low energy electron-proton scattering events. Specifically, the weak charge of the proton will be measured to 4% error, which will, in turn, be used to calculate the "running" Weinberg mixing angle $(\sin^2(\theta_w))$. Since the Standard Model makes a firm prediction for $(\sin^2(\theta_w))$ at low energies, the experiment presents an opportunity to test the limits of this model. Any significant variation in$(\sin^2(\theta_w))$ from the expected value would be indicative of new physics, while an agreement would place strict constraints upon the existing model. In order to make an exact measurement of the weak charge, large amounts of data (almost 2200 hours worth) will be gathered. A large, robust database is needed to store and organize this data, so it can be analyzed in an easy and effective manner. The optimization and implementation of this database will be discussed.

K1.00014 Optimizing the Josephson Parametric Amplifier - A numerical study , ZLATKO MINEV, RAJAMANI VIJAYARAGHAVAN, IRFAN SIDDIQI, QNL, UC Berkeley — Recent progress in quantum information processing using superconducting circuits has stimulated interest in low noise amplifiers which operate at the quantum limit. Josephson parametric amplifiers (paramp) based on low quality factor (Q) non-linear resonators are a promising candidate for quantum state readout. We present a numerical study to optimize the paramp for dynamic range and bandwidth by investigating the lowest resonator Q compatible with high gain and low noise performance in the 4– 8 GHz range. We also investigate designs involving multiple junctions and weak-link junctions to further optimize the dynamic range. Such an amplifier can be used for single shot readout of superconducting qubits and real time detection of the quantum state—crucial developments for implementing quantum feedback and error correction.

K1.00015 Image processing of transmission ion microscopy webcam video with Iris software , NICOLE NEWTON[1], ARTHUR PALLONE[2], Murray State University — Scientists and engineers build simple, low-cost, webcam-based instruments for use in many disciplines. Analysis of the optical signal received through the three broadband color filters – red, green and blue – form the basis of many of those instruments. The CMOS sensors in webcam pixels also produce signals in response to ionizing radiations – such as alpha particles from a radioactive source. Simple alpha radiography has been demonstrated with a commercially available antistatic Po-210 source and a webcam modified to expose the pixel sensors. Analysis of webcam video with the Iris software is presented as a way to demonstrate other transmission ion microscopy imaging modes.

K1.00016 Cathodes with modified morphology for polymer light emitting devices[1] , JACOB COX, MARIAN TZOLOV, Lock Haven University of PA — This work is the result of a junior year research project on fabrication and characterization of Polymer Light Emitting Devices (PLEDs). The PLEDs were created on top of indium tin oxide coated glass substrates, starting with a 60 nm thick hole injection layer, followed by an 80 nm layer of PPV-MEH polymer. The structures were finalized by a thermally evaporated aluminum film acting as the cathode for the device. We have concentrated on modifying the structure and morphology of the aluminum cathode in conjunction with the variation of the polymer film thickness. The devices were tested using current- voltage and light-voltage characteristics, light emission spectroscopy, device lifetime testing, profilometry, and optical microscopy of device degradation. The structure of the aluminum films was evaluated by SEM imaging. The results from this complex study showed a correlation between the morphology of the metal electrodes with the performance of the PLEDs.

[1]This work was partly supported by the NSF grant # 0923047.

K1.00017 Spatio-temporal beam profiling of pulsed infrared laser sources , IAN REEVES, JEFFREY OLAFSEN, LINDA OLAFSEN, Baylor University — Development of viable infrared lasers relies not only on the power and wavelength generated by the source, but also on the spatial and temporal profile of the output beam. Thermal imaging is of particular interest to researchers working in the field of optically pumped semiconductor analysis as the output from many of these devices falls in the mid-infrared range. While knife edge and other beam profile analysis techniques typically are unable to capture the temporal evolution of beam profiles, real time imaging is employed in this work, using a thermal camera synchronized with a Nd:YAG pump laser via LabVIEW-controlled triggering. Coupling the synchronization with detailed image analysis using IDL, this new methodology is applied to the near-infrared output of an optical parametric oscillator and ultimately will be extended to mid-infrared semiconductor lasers.

K1.00018 Development of a Portable Automated Gas Environment System (PAGES2) , NATHAN CAMPBELL, JACOB BAXLEY, EDWARD KINTZEL, Western Kentucky University, BRUCE HILL, LOUIS SANTODONATO, KENNETH HERWIG, Oak Ridge National Laboratory — For the user community at the Spallation Neutron Source (SNS), a portable automated gas environment system (PAGES2), capable of remote operation at pressures up to 100 bar has been built and programmed. The function of this system will be to characterize a variety of high surface area materials and allow studies of energy significant gases such as methane on these surfaces to be carried out. Understanding the fundamental physics of interaction at the gas-surface interface is key for the generation of application-minded products such as fuel cells. PAGES2 can generate adsorption isotherms to determine surface area of the material as well as the number of gas molecules required for a specific surface coverage. This system will not only produce new science, but also allow for better experimental design. PAGES2 system testing is currently underway, and initial results indicate the system is operating as designed. Future tests will be done prior to use at the SNS.

K1.00019 Realization of a closed-cycle dilution refrigerator for nanoscale magnetometry , RAVI NAIK, ANIRUDH NARLA, YU-DONG SUN, NATANIA ANTLER, IRFAN SIDDIQI, QNL, UC Berkeley — We present the implementation of a mechanical pump-free, dilution refrigerator with an automatic cool-down protocol. The cooling process utilizes a liquid nitrogen pre-cool circuit, a pulse tube cooler, and a custom internal dilution unit manufactured by Chase Cryogenics. The dilution unit employs charcoal sorption pumps and electronic heat switches to regulate the condensation and subsequent evaporative cooling of ^{3}He, ^{4}He, and a mash of both in three separate chambers. We achieve a base temperature of 85 mK with a 10-15 hour hold time. The unit presents a simple, compact, low vibration platform for conducting a wide spectrum of low temperature transport experiments. As an example, we present microwave frequency SQUID magnetometry data collected in this unit.

K1.00020 Phase cycling for optical two-dimensional Fourier-transform spectroscopy[1] , TRAVIS AUTRY, Department of Physics, University of Texas, Austin TX 78712, GALAN MOODY, HEBIN LI, MARK SIEMENS, STEVEN CUNDIFF, JILA, University of Colorado and National Institute of Standards and Technology, Boulder CO 80309 — Phase-cycling has been implemented in optical two-dimensional Fourier-transform spectroscopy to extract signals from quantum wells and quantum dots and to eliminate noise such as pump scatter co-propagating with the four-wave mixing signal. Experiments using actively phase-stabilized interferometers to cycle the excitation pulse optical phases suffer from partial noise cancellation because excitation and phase-control laser wavelengths are incommensurate. To obtain full noise elimination, we have incorporated liquid crystal variable retarders capable of imposing a π phase shift for wavelengths 650-950 nm. We present non-rephasing spectra of potassium vapor contained in a $\sim$20 μm transmission cell and show that this phase cycling method removes all noise from pump scatter while drastically reducing the data acquisition time compared to mechanical phase-delay techniques.

K1.00021 ABSTRACT WITHDRAWN –

K1.00022 Designing an Optical Dipole Trap for the Creation of Bose-Einstein Condensates[1]

, AMY VAN NEWKIRK, Grove City College, Department of Physics, L.S. LESLIE, University of Rochester, Institute of Optics, A. HANSEN, University of Rochester, Department of Physics and Astronomy, N.P. BIGELOW, University of Rochester, Department of Physics and Astronomy; University of Rochester, Institute of Optics — Bose-Einstein condensates have been produced with many different configurations of magnetic, optical, and hybrid traps. Pure optical dipole traps have the possibility of providing a spin state independent trapping potential, which is necessary in many BEC experiments. We are currently designing a red-detuned, single focused-beam dipole trap to be used in the production of BECs. The BEC is to be formed from rubidium-87 atoms. The lab currently has a magneto-optical trap and an Ioffe-Pritchard magnetic trap in place. The dipole trap will be the last step in the process to create a BEC. It will be formed with a single pass of a Yb fiber laser at 1064 nm. We developed a model for the dipole trap potential in mathematica. Using this model, we were able to see that our current lab configuration has the possibility of producing a dipole trap that will allow for Bose-Einstein condensation.

K1.00023 SEM and EDX Study of Al alloy Precipitant Surface Segregation due to Annealing[1]

, AUSTIN MOHNEY, INDRAJITH SENEVIRATHNE, Department of Geology and Physics, Lock Haven University of Pennsylvania — In Al alloys, precipitation hardening by impurity phase metallic microstructures in the main bulk metal is a norm. This results in resilience against dislocations, and improvement in other favorable attributes. We have studied Al 2024, Al 5052, Al 6061, and Al 7075 systems and their constituent precipitant migration due to thermal annealing. Scanning Electron Microscopy (SEM) was used to study the structure/morphology. Electron Dispersive X ray Spectroscopy (EDX) was used to study the near surface elemental variations. At annealing these alloys systems exhibit temperature activated relative segregation of the precipitants. Considering main constituents, it was observed Cu precipitant in 2024, and Mg precipitant in 6061 segregated to the surface. Further, increment in the ambient C absorption and O desorption on the surface layers were observed. Surface morphology variations were also studied at annealing using SEM. The data obtained will be discussed in terms of standard diffusion models for the alloys and corresponding diffusion coefficients.

K1.00024 AFM and EDX Study of Self Assembled Pt Nanostructures on PEDOT Thin Films under Ambient Conditions[1]

, INDRAJITH SENEVIRATHNE, AUSTIN MOHNEY, JOSHUA BUCHHEIT, ANURA GOONEWARDENE, Department of Geology and Physics, Lock Haven University of Pennsylvania — Noble metal nanostructure systems on conductive polymer thin films under ambient conditions are interesting due to their use in BioMEMS and hybrid systems further and considering the physics of the polymer - metal interactions The observed nanostructures have deformed spherical shape. The Pt was magnetron sputter deposited at RT (300K), PEDOT Baytron P 60nm thick, spin coated on glass slides cleaned with acetone and IPA. The system was studied using ambient IC mode Atomic Force Microscopy (AFM) for its structure. Elemental composition/distribution of the system was measured with Energy Dispersive X ray Spectroscopy (EDX). Pt nanostructures on the surface observed to be likely Volmer - Weber growth mode At Pt coverage of 120 ML, nanostructures had a mean diameter of 32 nm and mean height of 5 nm. When annealing at 15min at 473K systems changes to smaller nanostructures coexisting with bigger structures of mean diameter of 120 nm and mean height of 36 nm. Elemental/morphological variations when annealed at successively higher temperatures were also investigated.

[1]NSF Grant #: 0923047 and PASSHE FPDC (LOU # 2010-LHU-03).

K1.00025 AFM, and EDX Study of Self Assembled Au Nanostructures on P doped Si(100) Under Ambient Conditions[1]

, JOSHUA TATHAM, JOSHUA BUCHHEIT, INDRAJITH SENEVIRATHNE, Department of Geology and Physics, Lock Haven University of Pennsylvania — Noble metal nanostructures systems on semiconductor surface under ambient conditions are interesting but complex due to the presence of surface adsorbed species. Apart from various possible plasmonic and catalytic applications and these may give insights into thermodynamics and kinetics of such systems. The observed nanostructures have deformed spherical shape. The Au was magnetron sputter deposited at RT (300K), on Si(100) P doped cleaned with acetone and IPA. Ambient IC mode Atomic Force Microscopy (AFM) used to elucidate structure. Elemental composition and distribution on the deposited system was measured with Energy Dispersive X ray Spectroscopy (EDX). Self assembled Au nanostructures on the surface was observed with likely Stranski - Krastanov growth mode At 30 ML Au coverage of nucleated nanostructures observed to have a mean diameter of 2 nm and mean height of 2 nm. At Au coverage of 120 ML, nanostructures had a mean diameter of 25 nm and mean height of 4 nm. Observed variations when annealed at successively higher temperatures will also be discussed

[1]NSF Grant #: 0923047 and PASSHE FPDC (LOU # 2010-LHU-03).

K1.00026 Pt Nanostructures Self Assembled on P doped Si(100) Under Ambient Conditions: AFM, and EDX Study[1]

, ZACHARY BARCIKOWSKI, AUSTIN MOHNEY, INDRAJITH SENEVIRATHNE, Department of Geology and Physics, Lock Haven University of Pennsylvania — Noble metal nanostructures on surface support under ambient conditions are interesting but complex due to the presence of surface adsorbed species. System may have plasmonic and catalytic uses from the applications standpoint and may give insights into thermodynamics/kinetics of such systems. Observed Pt nanostructures have deformed spherical shape. The Pt was magnetron sputter deposited at RT (300K), on Si(100) P doped cleaned with acetone and IPA. The system was studied using ambient IC mode Atomic Force Microscopy (AFM) for its structure. Elemental composition / distribution were measured with Energy Dispersive X ray Spectroscopy (EDX). Self assembled Pt nanostructures on the surface was observed with a likely Stranski - Krastanov type growth mode At Pt 30 ML coverage nucleated nanostructures observed to have a mean diameter of 15 nm and mean height of 1.5 nm. At Pt coverage of 120 ML, structures exhibited mean diameter of 40 nm and mean height of 3 nm. System was also observed at incremental annealing as well

K1.00027 Thermal conductivity of a two-gap superconductor MgB_2in High Magnetic Field and Low Temperatures[1]

, MICHAEL GARMAN, SASHA DUKAN, Department of Physics and Astronomy, Goucher College — We calculate the thermal conductivity for a single MgB_2 crystal in a mixed state, placed in high magnetic field at zero temperature. We plot the thermal conductivity in the superconducting state κ(H) rescaled by the normal state value κ_N as a function of magnetic field for a realistic *i.e.* disordered MgB_2 superconductor. Our theoretical curve exhibits good qualitative agreement with the experimental data. We report on the self-consistent calculation of the influence disorder has on the thermal conductivity.

[1]This work was supported by the NSF grant No. DMR-0856415.

K1.00028 Low Temperature Study of the Electrical Properties of Sb-SnO_2 Nanofibers[1]

MARITZA REYNA, IDALIA RAMOS, NICHOLAS PINTO, University of Puerto Rico at Humacao — Antimony-doped tin oxide (ATO) can be used for many applications including the development of gas sensors, energy storage devices, and transparent electrodes. ATO nanofibers with sizes from 200 - 600 nm and a bandgap of 4.4 e.V were produced using the electrospinning method. The precursor was composed of tin chloride solution mixed with cellulose acetate solution and antimonium chloride. The XRD spectra of the nanofibers showed the characteristic peaks of Sb:SnO_2 with rutile structure. The electrical properties of single ATO nanofibers were studied following a cycle of cooling from 295 - 15 K and then heating from 15 - 295 K. These measurements were done in cold finger (close cycle helium refrigerator) in a vacuum. The conductivity measured at room temperature was 4.3 S/cm and decreases monotonically from 295 to 15K. As the temperature increases an anomalous peak is observed in the range of 250 to 300 K. This anomaly has been attributed to the chemi-absorbed molecules on the surface of the fiber and could be reduced by improving the vacuum conditions.

K1.00029 Modification of the growth mechanism of Zno nanowires by addition of oxidizing agents[1]

ERIC DRISCOLL, BRADLEY GOLDER, MARIAN TZOLOV, Lock Haven University of PA — Zinc oxide nanowires were grown catalytically on silicon (100) and (111) surfaces by means of chemical vapor deposition. A very thin layer of sputter deposited gold was used as the catalyst. Nanowires of different compositions were obtained by varying the ratio of carbon to zinc oxide in the source material and the flow rates of oxidizing gases. Results showed that the additional oxidizing gas changed the composition as well as the growth mode of the nanowires. The existence of several growth steps was observed. These steps were induced by the continuous presence of the source material during the system's heating and cooling processes. Remnants of gold found on the tips of the nanowires provided evidence for catalytic growth. The composition was analyzed by energy dispersive x-ray spectroscopy. Imaging by scanning electron microscopy showed random growth directions of nanowires, formation of sheets, and some instances of transitions from sheet to wire growth. The formation of defects was studied by photoluminescence spectroscopy.

[1]This work was partly supported by the NSF grant # 0923047.

K1.00030 Microstructure and Transport Studies of Functionalized Graphene[1]

RON GAMBLE, DARRYL LEWIS, NC A&T State University, DEREJE SEIFU, Morgan State University, JORGE CAMACHO, MYRON STRONGIN, Brookhaven National Laboratory, LIYUAN ZHANG, Brookkaven National Laboratory — The microstructure and transport studies of fuctionalized graphene are reported. These studies reveal that the minimum conductivity is sample dependent and within the range (2-12)e^2/h independent of gate voltage. The variation of the minimum conductivity is attributed to sample impurities, apparent in Atomic Force Microscopy and Raman Spectroscopy. The Raman peaks are in general consistent with graphene, but show shifts in the G and 2D peaks. These shifts are associated with strain and doping. The dependence of the current (I) on the bias voltage (V_{SD}) is linear for most samples. The current dependence on gate voltage (V_g)curves show asymmetric behavior, showing the imbalance between the hole and electron carriers. A 16 A deposition of Fe leads to a significant modification in the transport properties due mostly the formation of iron oxide. The AFM clearly shows the formation of Fe clusters.

[1]DOE/NSF Faculty-Student Teams Program

K1.00031 Thermal analysis study of polysterene-poly(methyl methacrylate) (PS-PMMA) diblock copolymer thin films morphologies when annealed and sheared under vacuum in inert atmosphere

LUIS POMALES, MELISSA DAVILA-SANTANA, MIRNA RIVERA-CLAUDIO, JOSEE VEDRINE-PAULEUS, University of Puerto Rico at Humacao — Diblock copolymers are made of two chemically bonded blocks, with incompatible monomers. This incompatibility gives the block the property to phase separate at temperatures above the glass transition (Tg). The ability to self-assemble into different mesophase structures is of great importance in nanolithography and nanofabrication. This research involves the morphological study of PS-PMMA thin films annealed under inert atmosphere. Our objective is to determine the microstructure properties of the PS-PMMA diblock copolymer as a function of film thickness, annealing temperature, and applied shear force. The PS-PMMA thin film is spin casted onto silicon substrates, and annealed under an inert atmosphere. Our initial results show that the samples have an incomplete formation of the microstructures. However, further film analysis is needed to study the morphological properties when annealed. Futures studies will focus on the effects of a shear force during annealing, to align the film microstructures.

K1.00032 Growth and characterization of $Ba_8Ga_{16}Ge_{30}$ Type I clathrate thin films grown by pulsed laser deposition[1]

JACOB DUSCHA, Macalester College/ University of South Florida, ROBERT HYDE, DEVAJYOTI MUKHERJEE, SARATH WITANACHCHI, University of South Florida — $Ba_8Ga_{16}Ge_{30}$thin films were successfully grown on Si (100) substrates using pulsed laser deposition process. Clathrates are studied for potential thermoelectric (TE) applications with few reports of thin film growth due to intrinsic difficulty in growing the caged structures in thin film form. Growth of stoichiometric $Ba_8Ga_{16}Ge_{30}$thin films is complicated by non-congruent evaporation during the ablation process resulting in Ga or Ge deficient films, degrading their properties. We report a systematic study of the growth parameters for stoichiometric $Ba_8Ga_{16}Ge_{30}$thin films. The laser ablated plasma plumes were analyzed using ICCD imaging and optical emission spectroscopy enabling optimization of growth parameters. Film thickness profiles of various target-substrate distances were plotted to estimate an optimum deposition rate. Surface morphologies and structure of the as-deposited films were examined using a scanning electron microscope and x-ray diffraction technique. This investigation provides a new direction towards the growth of high quality thin films for potential TE device applications.

[1]Supported by NSF REU,award No DMR-1004873.

K1.00033 Investigation of Silver Thin Film Reactivity via STM[1]

JEHOVANI LOPEZ, Department of Chemistry, California State University San Marcos, STEPHEN TSUI, Department of Physics, California State University San Marcos — The operation of a scanning tunneling microscope (STM) to some extent is nearly as much art as it is science. A recent attempt was made to examine the surface topography of glass by depositing a thin conducting silver film over the surface via plasma sputtering. Preliminary results show our instrument's inability to image this silver. Our hypothesis is that the silver nanoparticles may react in air, thereby creating a tunneling barrier that impedes the STM current. Silver nanoparticles deposited on highly orientated pyrolitic graphite at varying layers of thickness were imaged to analyze scatter patterns and deposition. Over time, STM images of the silver nanonclusters on HOPG showed some inconsistency in the diameters of the deposited clusters, possibly due to an artifact from the suggested reactivity of the silver. To confirm this, we also investigate depositions of gold, which is nonreactive.

[1]Support provided in part by the OBRT at CSUSM and the CTBP at UCSD.

K1.00034 Thin Film and Free Crystallite Formation of ZnO Nanorods from Solution Under Extreme Crystallization Conditions , ANAMIKA GOPAL, CHELSI KWITOSKI, MARIAN TZOLOV, Lock Haven University, Pennsylvania — ZnO nanorods, grown by the established Hexamethylenetetramine (HMTA) process, through the reaction of Zinc Nitrate with HMTA, are investigated. The nanorod morphology dependence on temperature, initial solution concentration and crystallization time is studied. Crystal growth on glass and ITO substrates and free crystallite precipitation in solution are characterized by SEM and EDX. Low concentrations and temperatures are investigated for production of rod-clusters with a high aspect ratio and low surface nucleation density. Such morphology is expected to enhance charge transport while preserving light transmissivity, for use in efficient ZnO photovoltaic devices. Free crystallite formation in solution with varied initial parameters is characterized by a time dependent light scattering study, supported by SEM and EDX data. A high aspect ratio of solitary, free crystallites is sought, which we believe would be most effective in solution processed, concentration gradient solar cells.

K1.00035 Time-resolved Four-terminal probe of ion transport in Schefflera leaves[1] , NICOLE PERIGO, GUOPING ZHANG, Department of Physics, Indiana State University — Plant growth relies on efficient ion transport. The rate of the ion transport depends on the concentration of each ion in the leaf. A common method is to use two-lead geometry. Here we employ a four-electrode set-up orienting the electrodes either parallel or perpendicular to each other. When the electrodes are parallel, two are at each end, with electric current running along the direction of the veins. When they are perpendicular, there are two along the direction of the veins (tip-tip) and two are perpendicular to the veins (side-side). The parallel set-up is similar to the Franck-Hertz experiment, but instead of using a vacuum tube we use a leaf. By using the parallel set-up, we find that two inner leads can directly control the movement of the ions in the time domain. By switching on/off the control current, a clear time-resolved current change is observed, where the signal decays less than one second. This time scale is similar to that of a typical ECG decay signal. Therefore, our method may be potentially a powerful tool to ion diffusion and transport in many biological and medical systems.

K1.00036 PHYSICS EDUCATION —

K1.00037 Energy-Efficient Cooking of Spaghetti , AKASH LEVY, Allderdice High School — Spaghetti is a dual-career family dinner favorite. But how much energy is consumed in the process, and how can it be optimized? I performed an experiment to test two methods for preparing a spaghetti meal. In both cases, the water was rapidly heated to the boiling point. The flame was kept at maximum for the first experiment until the spaghetti was cooked. In the second experiment, the flame was reduced and the top covered, such that the water was kept at 100C. The two methods are compared in terms of the total time required to prepare the meal and amount of energy required. A discussion of potential savings for the latter method–and possible uses for that savings–is discussed.

K1.00038 Snail Mail: Kinematics Applied to an International Letter's Seventeen-Year Journey , ISHAN LEVY, Pittsburgh Obama 6-12 School — The average and instantaneous velocity of a letter sent in 1990 from India and arriving in 2007 in New York City is analyzed using the equations of kinematics. An important question to be addressed is: how does the average speed of "snail mail" compare with that of an actual snail? The distinction between instantaneous versus average kinematic quantities are highlighted in the process.

K1.00039 Heuristic Deduction of the Newton's Second Law , GREGORIO RUIZ-CHAVARRIA, JONAS TORRES-MONTEALBAN, Universidad Autonoma Chapingo — In this work we present a heuristic justification about the form of the second law of Newton. We start with a basic definition of force as the interaction between the body of study and everything that surrounds it. We define the mechanical state of a body through the momentum, because this gives us a measure of the ability to carry out an interaction. Now with this definition, the variation of the state of the body over time gives a measure of the intensity of this interaction. From this variation in time, we can establish Newton's second law. The approach described above can be used with students in pre-university and university.

K1.00040 Obtaining the Thermal Efficiency of a Steam Railroad Machine Toy According Dale's Cone of Learning , OMAR TOMAS BAUTISTA-HERNANDEZ, GREGORIO RUIZ-CHAVARRIA, Universidad Autonoma Chapingo — Physics is crucial to understanding the world around us, the world inside us, and the world beyond us. It is the most basic and fundamental science, hence, our interest in developing innovative strategies supported by the imagination and knowledge to make the learning process funny, attractive and interesting to people, so, we can help to change the general idea that Physics is an abstract and complicated science. We all know this instinctively, however, turn-of-the-century educationist Edgar Dale illustrated this with research when he developed the Cone of Learning - which states that after two weeks we remember only 10% of what we read, but we remember 90% of what we do. Based on that theory, we obtain the thermal efficiency of a steam railroad machine -this is a toy train that could be bought at any department store-, and show you the great percentage of energy lost when moving this railroad machine, just as the real life is. While doing this practice we don't focus on the results itself, instead, we try to demostrate that physics is funny and it is not difficult to learn. We must stress that this practice was done with pre-universitary and univesitary students, however, can be shown to the community in general.

K1.00041 Statistical evidence of predation by theropods , SCOTT LEE, University of Toledo — Dinosaurs hold a great fascination for everyone and provide an interesting venue for teaching many elementary concepts of kinematics. Dinosaur trackways provide interesting information about the locomotion of these extinct animals. A statistical analysis of the known trackways made by theropods (carnivorous dinosaurs) shows that they usually moved by walking with an average speed of 2.4 $\pm$ 1.5 m/s. Fast running, determined by the relative stride length greater than 3, is observed in about 10% of the trackways, with speeds on the order of 10 m/s. These trackways are believed to have been formed during predation.

K1.00042 Surveying Students' Understanding of Quantum Mechanics[1] , CHANDRALEKHA SINGH, GUANGTIAN ZHU, University of Pittsburgh — Development of research-based multiple-choice tests about quantum mechanics is important for assessing students' difficulties and for evaluating curricula and pedagogies that strive to reduce the difficulties. We explore the difficulties that the undergraduate and graduate students have with non-relativistic quantum mechanics of one particle in one spatial dimension. We developed a research-based conceptual multiple-choice survey that targets these issues to obtain information about the common difficulties and administered it to more than a hundred students from seven different institutions. The issues targeted in the survey include the set of possible wavefunctions, bound and scattering states, quantum measurement, expectation values, the role of the Hamiltonian, time-dependence of wavefunction and time-dependence of expectation value. We find that the advanced undergraduate and graduate students have many common difficulties with these concepts and that research-based tutorials and peer-instruction tools can significantly reduce these difficulties. The survey can be administered to assess the effectiveness of various instructional strategies.

K1.00043 Theoretical model to explain the problem-solving process in physics[1] , CARLOS LOPEZ, Universidad del Valle ee Mexico — This work reports a theoretical model developed with the aim to explain the mental mechanisms of knowledge building during the problem-solving process in physics using a hybrid approach of assimilation- formation of concepts. The model has been termed conceptual chains and represents graphic diagrams of conceptual dependency, which have yielded information about the background knowledge required during the learning process, as well as about the formation of diverse structures that correspond to distinct forms of networking concepts Additionally, the conceptual constructs of the model have been classified according to five types of knowledge. Evidence was found about the influence of these structures, as well as of the distinct types of knowledge about the degree of difficulty of the problems.

[1]I want to be grateful to Laureate International Universities, Baltimore M.D., USA, for the financing granted for the accomplishment of this work.

K1.00044 Graphical representation of the process of solving problems in statics , CARLOS LOPEZ, Instituto Tecnologico de Queretaro — It is presented a method of construction to a graphical representation technique of knowledge called Conceptual Chains. Especially, this tool has been focused to the representation of processes and applied to solving problems in physics, mathematics and engineering. The method is described in ten steps and is illustrated with its development in a particular topic of statics. Various possible didactic applications of this technique are showed.

K1.00045 Physics Education at University of Houston Clear Lake , SAMINA MASOOD, Univ. of Houston Clear Lake — We are developing a physics education program to prepare teachers to teach Physics in High Schools. The science teachers training needs to be brought to the level where they can motivate children and young adults in their classrooms to take interest in science learning to adopt science and engineering career. The early selection of career path helps the better preparation for the career.

K1.00046 GENERAL THEORY (THEORETICAL METHODS) –

K1.00047 Variational Study of a Finite Heisenberg Chain , ERIC ASHENDORF, JOE WEINER, JAY D. MANCINI, Kingsborough College of CUNY, VASSILIOS FESSATIDIS, Fordham University, SAMUEL P. BOWEN, Chicago State University — Here we wish to study the ground-state of the $1D$ Heisenberg chain

$$H=-\frac{1}{2}J\sum_{l=1}^{N}\left[2\left(\sigma_l^+\sigma_{l+1}^+ + \sigma_l^-\sigma_{l+1}^-\right)+\sigma_l^z\sigma_{l+1}^z\right],$$

where the σ's are the usual Pauli spin matrices and J is the strength of the spin-spin interaction. The purpose of our revisiting such a well known system is to use it as a benchmark for our variational ansatz in which a trial vector is chosen $|\psi_0(\alpha)\rangle=\exp\left(\alpha\sum_{l=1}^{N}\sigma_l^+\sigma_{l+1}^z\right)|0\rangle_N$, where α is the variational parameter and $|0\rangle_N$ is an appropriately chosen initial array of spins. We then construct a basis according to the prescription $|\psi_m\rangle=\partial_\alpha^m|\psi_0(\alpha)\rangle$ creating an energy matrix with elements $h_{ij}=h_{ij}(\alpha,J)$ whose eigenvalues are then evaluated.

K1.00048 Anharmonic Energy Spectrum for $V(x)=\pm x^4,\pm x^6,\pm x^8$, SAMUEL P. BOWEN, Chicago State University, JAY D. MANCINI, Kingsborough College of CUNY, VASSILIOS FESSATIDIS, Fordham University — In this work we wish to revisit the energy spectrum for the anharmonic potentials

$$H=\frac{p^2}{2m}\pm x^N,$$

where $N=4,6,8$. Using the second quantized operator formalism of Dirac, we have evaluated matrix truncations of up to 100×100. Our results for the energy spectrum are in disagreement with the work of Bender and Boettcher (PRL 80, 5243). They studied a *PT* symmetric Hamiltonian whose potential is given by $V(x)=-(ix)^N$ and who maintain that "when $N\geq2$, the spectrum is infinite, discrete and entirely real and positive". We find, for the potentials with $N=4,6,8$ that the spectrum is not completely positive and in fact has no lower bound.

K1.00049 Moments based calculations of PT-symmetric Hamiltonians , ROBERT MURAWSKI, Drew University, JAY MANCINI, Kingsborough College of CUNY, VASSILIOS FESSATIDIS, Fordham University — PT-symmetric Hamiltonians have gained recent interest in optics and particle physics [Phys. Rev. A **82**, 031801 (2010), Phys. Rev. Lett. **105**, 031601 (2010)] . These Hamiltonians remain invariant under the reflection of parity and time. What makes them surprisingly interesting is that PT-Hamiltonians have real positive spectra. In this paper, we calculate the moments of the PT Hamiltonian H=p^2+x^2 (ix)^r with r>0. We will use these moments to compute the ground state energy by the generalized moments expansion (GMX) and the canonical sequence method (CSM). Comparisons will be made to the Lanczos tridiagonalization scheme as well as to other published results.

K1.00050 Ab initio approach to magnon-electron coupling , PAWEL BUCZEK, ARTHUR ERNST, LEONID M. SANDRATSKII, HARDY GROSS, Max Planck Institute of Microstructure Physics, Weinberg 2, Halle/S., Germany — The electronic properties of magnets and exchange-enhanced paramagnets are strongly influenced by the spin-flip fluctuations. In particular, their important role in the pnictide high-temperature superconductivity is has been conjectured [Mazin & Johannes, *Nat. Phys.* **5**, 141 (2009)]. To formulate a parameter free model of electron-electron interaction involving emission and absorption of magnons we combine our recently developed implementation of the linear response time dependent density functional theory for spin fluctuations [Buczek *et al.*, *Phys. Rev. Lett.* **105**, 097205 (2010)] with the methods of many body perturbation theory [Vignale & Singwi, *Phys. Rev. B* **32**, 2156 (1985); Zhukov *et al.*, *Phys. Rev. Lett.* **93**, 096401 (2004)]. This theoretical toolbox is applied to the description of recent inelastic tunneling spectroscopy experiments [Balashov *et al.*, *Phys. Rev. Lett.* **97**, 187201 (2006)], which have shown that the emission of magnons by electrons can open additional tunneling channels and increase conductivity. As second application, we discuss a scheme of the magnon mediated Cooper pair formation in PdH_x and LaFeAsO.

K1.00051 Classification of Gapped Symmetric Phases in 1D Spin Systems , XIE CHEN, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA, ZHENG-CHENG GU, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, CA 93106, USA, XIAO-GANG WEN, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA — Topological phases exist in quantum many-body systems beyond the usual symmetry breaking understanding of phase and phase transition. The question of what kind of topological phases exist seems hard especially for strongly interacting systems. Here we make an attempt to answer this question for gapped interacting quantum spin systems whose ground states are short-range correlated. Based on the local unitary equivalence relation between short-range correlated states in the same phase, we classify possible quantum phases for 1D matrix product states, which represent well the class of 1D gapped ground states. We find that in the absence of any symmetry all states are equivalent to trivial product states, which means that there is no topological order in 1D. However, if certain symmetry is required, many phases exist with different symmetry protected topological orders. Understanding about topological order and symmetry breaking order in spin systems also allows us to obtain a classification of 1D fermion topological phases.

K1.00052 Effective equilibrium theory of non-equilibrium quantum transport , PRASENJIT DUTT, Yale University, New Haven, CT., JENS KOCH, Northwestern University, Evanston, IL., JONG HAN, SUNY Buffalo, Buffalo, NY., KARYN LE HUR, Yale University, New Haven, CT. — We establish a rigorous theoretical foundation for an effective equilibrium description of electronic transport through quantum impurity models out of equilibrium. An imaginary time framework involving the Lippmann-Schwinger operators of the system is proposed and expounded. This forms the basis for the implementation of standard equilibrium many body techniques, effectively avoiding the complexities of the Keldysh contour, and is used to compute transport observables. We present a novel perturbative scheme for treating interactions, which we use to study the Anderson impurity model out of equilibrium. Generalizations to non-perturbative methods are also explored. We use this formalism to investigate the effect of voltage bias, temperature and a magnetic field on the fate of the Abrikosov-Suhl resonance and make a comparison with numerics and experimental results.

K1.00053 Magnetic properties of $CuZrTiO_5$, H.M. ALYAHYAEI, Department of Physics and Astronomy, University of California, Riverside, Riverside, California 92521, USA, R.A. JISHI, D.M. GUZMAN, Department of Physics, California State University, Los Angeles, California 90032, USA, O. TA, A.A. SHARIF, Department of Mechanical Engineering, California State University, Los Angeles, California 90032, USA — $CuZrTiO_5$ is a newly synthesized crystal that contains copper oxide planes [1]. We have carried out first-principles calculations using density functional theory in order to determine the ground state of this crystal. We considered various nonmagnetic and magnetic phases and calculated the corresponding total energies. We found that in the ground state, the magnetic moments on the copper ions adopt an antiferromagnetic arrangement. The effects of doping on the electronic properties of this crystal are investigated.

[1] U. Troitzsch et al., Journal of Solid State Chemistry 183, 668(2010).

K1.00054 Vacillation in density of correlated electron-electron pair confined in 2D quantum dot , TAKUMA OKUNISHI, ATSUSHI TSUBAKI, TOMOKI TAGAWA, KYOZABURO TAKEDA, Waseda University, WASEDA UNIV. TAKEDA LABORATORY TEAM — We studied an electronic structure of charged particles confined in a 2D quantum dot (QD), taking into account an electron correlation through a configuration interaction (CI) by employing resonating unrestricted Hartree-Fock (res-UHF) approach. The UHF solutions for the QD are nonorthogonal mutually but are appropriate for a basis functions of a res-UHF CI calculation because they represent a conceivable electron- spin configurations rationally. Consequently, the res-UHF CI provides intuitive understandings for an electron correlation with narrowing down the number of employed Slater bases, although at an expense of orthogonality among the Slater bases. We further embedded this res-UHF CI approach to solve a time- dependent (TD) Schroedinger equation, and studied the TD features caused by an electron correlation computationally. We found that the electron correlation induces the characteristic vacillation in the total charge density. We then employed a projection analysis and investigated the change in the vacillation frequencies by varying the confinement length and also the initial charge distribution.

K1.00055 Ground state instability in spin polarization for electrons confined in 2D square quantum dots , KYOZABURO TAKEDA, MASAMU ISHIZUKI, TAKUMA OKUNISHI, YHUKI NEGISHI, Waseda University — We present a theoretical study of the ground state electronic structure and the spin polarization for four electrons confined in 2D square quantum dots (2D SQDs). We employ standard mean field theory (MFT) approaches using the unrestricted Hartree-Fock (UHF) and density functional theory (DFT) calculations. The resonant UHF configuration interaction (res-UHF CI) calculation was also performed in order to understand the electron correlation more intuitively. The MFT ground state is expected to be fully spin-polarized when square SQDs have a small confinement length L or aspect ratio, in agreement with Hund's rule. In contrast, the spin-unpolarized ground state singlet is expected in all in other SQDs, the MFT anti-Hund state is produced by the spin-density wave having the zero total spin. The res-UHF CI calculation restores the geometrical symmetry in the resulting ground state, but the res- UHF CI ground state maintains the zero total spin. Thus, ground state instability is expected in the spin-polarization of the SQD system, which eventually violates Hund's rule in accordance with the Coulomb interaction.

K1.00056 Real-space Green's function calculations of valence Compton profiles for Nonresonant Inelastic X-ray Scattering[1] , BRIAN MATTERN, JOSHUA KAS, JOHN REHR, U. Washington — Nonresonant inelastic x-ray scattering (NIXS) from core- and semi-core shells at 50-1000 eV binding energies is an emerging field of synchrotron light source science, with applications in high pressure science, electrical energy storage, f-electron materials, and catalysis, etc. In such experiments, the Compton scattering of x-rays by valence electrons produces a significant background signal that spans the energy loss range of interest for NIXS. Thus, first-principles theoretical calculations of the double-differential cross-section for Compton scattering in the energy loss and momentum transfer ranges of interest are needed to account for this background. Here, we report an approach using a real space Green's function method to calculate the valence Compton profile in the impulse approximation. Illustrative calculations are presented and compared with experiment.

[1]This research is supported by a grant from the US Department of Energy Office of Basic Energy Sciences.

K1.00057 Exchange-correlation energy functionals for low-dimensional electronic nanostructures: Recent developments and applications[1] , STEFANO PITTALIS, University of Missouri-Columbia, U.S.A., E. RÄSÄNEN, Nanoscience Center, University of Jyvaskyla, Finland, C.A. ROZZI, University of Modena, Italy, G. VIGNALE, University of Missouri-Columbia, U.S.A. — In the analysis of low-dimensional electronic nanostructures, the evaluation of the consequence of the electron-electron interaction is a challenging task. In particular, an accurate determination of the exchange-correlation energy in two-dimensional systems is of great importance in understanding the many-body physics of modern electronic devices. Here we review several approaches within density functional theory, spanning from the bottom to the top of the ladder of functional approximations. Considering applications to quantum dots, rings, slabs, and periodic systems, we conclude that the presented approaches form a valuable first-principle toolkit for dealing with the many-body physics of such devices.

[1]S.P. and G.V. are supported by DOE grant DE-FG02-05ER46203.

K1.00058 Exchange energy and potential using the Laplacian of the density , CHRIS WAGNER, ANTONIO CANCIO, Ball State University — abstract- The challenge of density functional theory is the useful approximation of the exchange correlation energy. This energy can be approximated with the local electron density and the gradient of the density. Many different GGA's have been made recently and there is controversy over the best overall functional. Recent Monte Carlo simulations give evidence that the Laplacian of the density might be a better starting place than the gradient to correct the local density approximation. It also gives a better representation of the exchange potential at the nuclear cusp and of bonding between atoms. We have tested several Laplacian based GGA models for exchange for small atoms. We use known constraints on the exchange energy used in current GGA's. In many models unphysical oscillations occur in the potential, and understanding and eliminating them is part of the focus of this research. Preliminary results suggest that smaller values for short and long range constraints in the literature give more physically reasonable results in the Laplacian models.

K1.00059 Hybrid Density Functional Studies of a Promising Photovoltaic Material: Zinc Phosphide , STEVEN DEMERS, AXEL VAN DE WALLE, Dept. of Applied Physics and Materials Science, California Institute of Technology — Although Zinc phosphide is a semiconductor which has high absorption in the visible spectrum that is made from abundant elements, its use as a low-cost photovoltaic is limited by difficulties in n-doping the material. We study this compound via Density Functional Theory calculations based upon recently developed hybrid functionals designed to accurately describes band gaps. We explore the effects of various point defects with energy levels near the fermi energy on the electronic band structure in an effort to identify suitable dopants in this system. The thermodynamic stability of these defects is also assessed.

K1.00060 Mass-Energy Relationship Must Include Factors For Vibrational and Rotational Kinetic Energies as Well as Various Potential Energies , STEWART BREKKE, Northeastern Illinois University (former grad student) — Einstein proposed that at low speeds $E = M_0c^2 + 1/2M_0v^2$. However, a mass may also have vibrating and rotating kinetic energies and may also have various potential energies such as gravitational, electric and magnetic potential energies which must be part of the total mass-energy equivalence. Therefore, the basic equation for the mass-energy equivalence should be $E = M_0c^2+1/2M_0v^2+1/2I\omega^2+1/2kx^2+(GM_0M_2)/r+(KQ_0Q_2)/r+(Um_0m_2)/r$ where the last three terms are the gravitational, electrostatic and magnetic potential energies of the mass and the second, third and fourth terms are the linear, rotational and vibrational kinetic energies of the mass.Also, Einstein did not include the rotational and vibrational kinetic energies in his relationship for relativistic kinetic energy and therefore the kinetic energy T cannot equal $(E - E_0) = 1/2M_0v^2$, but rather must equal $T = 1/2M_0v^2 + 1/2I\omega^2 + 1/2kx^2$ including the vibrational and rotational kinetic energies besides the linear kinetic energy alone.

K1.00061 A Theory of Frozen Light According to the General Theory of Relativity , DMITRI RABOUNSKI, LARISSA BORISSOVA — We suggest a theory to frozen light, which was first registered in 2000 by Lene Hau. Frozen light is explained here as a new state of matter. The explanation is given through space-time terms of the General Theory of Relativity. We consider a fully degenerate region of space (space-time), which is the ultimate case of the isotropic region (home of photons), where the metric is particularly degenerate. Both the space-time interval, the observable time interval, and the observable three-dimensional interval are zero in a fully degenerate region. Therefore, we refer to such a region and particles which inhabit it as zero-space and zero-particles. Moving to the coordinate quantities inside zero-space shows that real speed therein is that of light, depending on the gravitational potential and the rotation of space. It is shown that the eikonal equation for zero-particles is a standing wave equation: zero-particles are standing light waves, while zero-space is filled with a system of standing light waves (light-like hologram). With these, zero-particles appear to a regular (external) observer as mere stopped light. This paper has been submitted to The Abraham Zelmanov Journal.

K1.00062 Symplectic Integrator and its Applications , HIROTO KOBAYASHI, Chubu University — The first- and the second-order symplectic integrators for the one-dimensional harmonic oscillator are reconstructed on the basis of effective Liouville operators, which can be defined only within the convergence radius. The first-order one for the q^4-potential system breaks down for different time steps depending on the initial condition, which indicates that no conservation value exists for the system in the first- order symplectic integrator.

K1.00063 Interacting many-body simulations including contacts using graphics processing units (GPU) , TOBIAS KRAMER, University of Regensburg, Germany — Already the solution of the interacting classical many-body problem is difficult to achieve, since the integration of the equations of motions couples all positions of the particles contained in the system. Transport calculations require to include the contacts within the simulation and to study the effect of interactions there. Classical and quantum-mechanical equations of motions can be related by the time-dependent variational principle for Coulombic interacting electrons in a magnetic field [1]. Interacting systems require to carefully consider the questions of self-consistency. The emergence of an mean-field potential out of a large (10000 electrons!) many-body calculation is shown in [2]. The calculation is only possible due to our usage of graphics processing units, which are ideal tools to study interacting systems.

[1] Two interacting electrons in a magnetic field: comparison of semiclassical, quantum, and variational solutions, T. Kramer, AIP in press (2010), arxiv:1009.6051
[2] Self-consistent calculation of electric potentials in Hall devices, T. Kramer, V. Krueckl, E. Heller, and R. Parrott Phys. Rev. B, 81, 205306 (2010)

K1.00065 Mesoscale simulation of the rheology of high molecular weight polymer gels , YELENA SLIOZBERG, JOHN BRENNAN, TIMOTHY SIRK, JAN ANDZELM, U. S. Army Research Laboratory — Polymer gels are comprised of physically or chemically cross-linked polymers that are highly swollen with solvent. The rheology of these gels depends on their morphological properties, such as the number of bridging chains and trapped entanglements. The prediction of structural and mechanical properties of gels using computational approaches is challenging and requires advanced particle-based mesoscale methodologies. Recently, we have implemented an approach to predict mechanical properties of high molecular weight block copolymers by allowing for chain entanglement behavior within the dissipative particle dynamics (DPD) methodology. Diffusion coefficients have been evaluated to locate the crossover from the Rouse to reptation dynamics. In this talk, we will demonstrate that including a segmental repulsive potential in addition to the usual DPD framework can prevent chain crossings and leads to an improved representation of mechanical and structural properties of polymer gels.

K1.00066 Resiliency of the Mixed-State Wigner Function , TOMAS MATERDEY, University of Massachusetts Boston — Numerical solution of the quantum Vlasov equation showed details of the phase-space dynamics of the Wigner function. Resiliency of the mixed-state Wigner function over changes of external electric and magnetic fields will be discussed.

K1.00067 Perhaps Gravitational Waves do not Exist , ORVIN WAGNER, Wagner Research Laboratory — I have recently been working with waves that appear to penetrate everything including mountains. I call these waves "waves in dark matter" because of their penetrating qualities. These waves seem to indicate that dark matter interacts more than just with gravity and may be important in supporting life, for example. These waves may dissipate energy in binary orbitting systems, such as paired pulsars, and explain their orbital decay. Many authors, including Einstein, provide supporting evidence that gravitational waves do not exist. Recent experiments indicate the same. See the website: "Darkmatterwaves.com"

K1.00068 The mass, energy, space and time systemic theory-MEST-energy balance system of wave-particle duality , DAYONG CAO, Beijing Natural Providence Science & Technology Development Co., Ltd — The paper suppose that the probability of displacement is the space and the probability of cycle is the time. And accroding to the quantum mechanics, the paper get the equation of the space : $S = P(r) = f^2$, (1) Among it, S: the space, f: the amplitude of wave, r: the displacement, P(r): probability function of displacement. Accroding to the Benford's law, the paper get the equation of the time equation: $T = P(2\pi t) = ln(1 + \frac{1}{2\pi t}) = \nu$, (2) Among it, T: the real time, t: date of clock, ν: the frequence of wave, P(t): probability function of date of the clock. $E = h\nu$, (3) $m = \frac{h}{\lambda c}$, (4) Among it, E: the energy of particle, m: the mass of particle, c: the velocity of particle, ν: the frequence of particle, λ: the wavelengh, h: the Planck constant. $E'\psi = i\hbar\frac{\partial\psi}{\partial t}$, (5) $m'\psi = -i\hbar\frac{\partial\psi\partial t}{(\partial x)^2}$, (6) Among it, $E'\psi$: the energy of wave, $m'\psi$: the mass of wave, c′: the velocity of wave, ψ: the Wave Functions. The paper give new idea that unlike mass repel each other, like mass attract; And like energy repel each other, unlike energy attract. So there is a mass-energy duality too. The energy radiate the repulsive (energy) wave and the mass absorb the absorptive (mass) wave. And there is a balance system between the energy wave and mass wave. $E + E'\psi = mc^2 + m'\psi c'^2, (c'^2 = -\frac{(\partial x)^2}{(\partial t)^2})$, (7)

K1.00069 Computational study on ionic diffusion and dynamic properties in silicate and bioactive glasses

, YE XIANG, JINCHENG DU, University of North Texas — Ionic diffusion and dynamic properties in silicate glasses have been extensively studied experimentally due to its importance in understanding ion conduction and glass dissolution. In this study, computational study on ionic diffusion and dynamic properties was carried out using molecular dynamics simulations with effective partial charge potentials. The simulated structure models were validated by comparing with experimental data and systematic discussions on effects of system size, simulation thermal ensemble and temperature range were carried out. The dynamic properties were also related to structural changes with the glass. Finally, investigation of SrO/CaO substitution effect on the diffusion behaviors in 45S glasses is provided.

K1.00070 ENERGY RESEARCH AND APPLICATIONS –

K1.00071 Optimization of open circuit voltage in parallel solar cell tandems[1]

, ALEXANDER KUZNETSOV, ANVAR ZAKHIDOV, Nanotech Institute, University of Texas at Dallas — Significant improvement of the solar cell efficiency is achieved by combining solar cells into tandems. Matching of the open circuit voltages (V_{oc}) of individual cells is required in order to maximize the efficiency of the parallel tandem. However practically it is hard to achieve because usually individual cells of the tandem absorb light at different wavelengths and produce very different V_{oc}. Mismatch of open circuit voltages results in deteriorated performance of a parallel tandem. In this work we use circuit analysis to determine parameters of parallel tandem's individual cells that guarantee its most efficient operation. The results of our calculations can be used for optimization of individual solar cells when designing a parallel tandem.

K1.00072 Degradation of CIGS Devices Studied using Controlled Moisture Ingress

, RAJALAKSHMI SUNDARAMOORTHY, JOHN PERN, JIAN LI, TIM GESSERT, National Renewable Energy Laboratory, NATIONAL CENTRE FOR PHOTOVOLTAICS TEAM — The damp heat (DH) study at 85˚C and 85% relative humidity of unencapsulated standard CIGS devices fabricated at NREL exhibited various degradation modes. In the initial 20 h of exposure there is a steep decrease in efficiency, followed by a gradual decrease until 1000 h. The devices in this study were subjected to controlled moisture ingress. Periodic light and dark current-voltage (JV), capacitance-voltage (CV) measurements were carried out before, during, and after the course of exposure. Initial trends in CV and JV data show that the decrease in the device performance correlates to the degree of degradation of the TCO and the buffer layer during the first 20 h of exposure. However, from 20-100 h of exposure the abrupt changes in CV and decrease in Voc suggest the moisture penetration deeper into the junction which might alter junction interface. This paper attempts to correlate the JV and the CV data to understand the degradation mechanism during the initial hours of DH exposure in CIGS devices.

K1.00073 Tunable Surface Energy Morphologies of P3HT-PCBM Bulk Heterojunction OPV's[1]

, ABUL M.A. HUQ, ALAMGIR KARIM, Department of Polymer Engineering, University of Akron, USA — In this study we used the commonly studied blend of Phenyl-C61-butyric acid methyl ester (PCBM) and Poly(3-Hexylthiophene) (P3HT) and studied their morphological development (1:1 ratio) under different substrate surface energy conditions. Confined and tunable surface energy can direct the morphology of immiscible blends which can be successfully utilized to gain desired properties of the semiconducting organic materials. We first show that solvent and temperature of film casting have equally dominant effect on the final P3HT:PCBM morphology. We observe that P3HT crystal size and size distribution depend upon the nature of substrate, thickness of the film, temperature of casting solution, and overall blend concentration in solvent. We can also tune P3HT:PCBM morphology by sandwiching the blend films between two PDMS films with well defined surface energies. These studies offer insights for development of highly controlled bulk heterojunction morphology for improving the efficiency of organic photovoltaics (OPVs).

K1.00074 Markedly Enhanced Performance of Dye Sensitized TiO_2 Nanoparticle Solar Cells via Rational Surface Treatment

, MARGARET SCHEINER[1], Cornell University, XUKAI XIN, Iowa State University, ZHIQUN LIN, Iowa State Univeristy — Dye sensitized solar cell (DSSC) was fabricated with the P-25 TiO_2 nanoparticle film sensitized with N719 dye. $TiCl_4$ treatment was found to increase the power conversion efficiency of DSSC. More importantly, subsequent treatment with O_2 plasma further enhanced the efficiency, while the O_2 plasma processing of an untreated TiO_2 photoanode resulted in a lower efficiency. With $TiCl_4$ and O_2 plasma treatments, dye sensitized TiO_2 nanoparticle solar cell with 21 μm thick active layer illuminated under 100 mW/cm^2 exhibited a markedly enhanced power conversion efficiency of 8.35% as compared to 3.86% for untreated cells.

K1.00075 Structural and Electrical Characterization of Pulsed Laser Deposited CdS/CdTe Thin Films

, MICHAEL NEWBY, M. ALPER SAHINER, SAMUEL EMERY, MICHELLE JAMER, JEFFREY SERFASS, Seton Hall University, MARK CROFT, Rutgers University — The thin films of CdS/CdTe were deposited on ITO coated glass substrates using pulsed laser deposition (PLD). The film growth conditions were systematically varied and the thin film structural properties were determined using a x-ray diffraction (XRD) x-ray absorption spectroscopy (XAS). The effect of the thicknesses of the CdS and CdTe layers, laser energy and the deposition temperature on the film quality and structure were investigated. The photovoltaic properties of the film were then tested using a Keithley sourcemeter and an accompanying Labview program. The results of variation of thickness and growth conditions on the photovoltaic output of the films will be presented.

K1.00076 Monte Carlo Simulations for Charge Transport in Bulk-Heterojunction Solar Cells: Effect of Morphology on Charge Carrier Mobility

, YOUNG MIN NAM, WON HO JO, Department of Materials Science and Engineering, Seoul National University, Seoul, Republic of Korea — Although it is well understood that the nano-scaled morphology of active layer is critical for determining the efficiency of bulk-heterojunction solar cells, the effect of the variation in morphology upon the local mobility of charge carriers and the performance of solar cell has largely been unknown. Since the computer simulation is a powerful method to provide important information for the relationship between mobility and morphology, we use a Monte Carlo to reveal the dependence of mobility upon the morphology. As the domain size and the blend composition of morphology across the active layer are systematically varied, the mobility of charge carriers and the solar cell performance are calculated. The result of simulation reveals that the charge carrier mobility and the performance of solar cell improved largely due to the efficient extraction of charge carriers at the electrodes, when the domain size is optimized and the blend composition becomes donor-rich at the anode and acceptor-rich at the cathode.

K1.00077 Exciton Energy Transfer from Halide Terminated Nanocrystals to Graphene in Solar Photovoltaics

, OBAFUNSO AJAYI, JUSTIN ABRAMSON, NICHOLAS ANDERSON, JONATHAN OWEN, YUE ZHAO, PHILLIP KIM, FELICE GESUELE, CHEE WEI WONG, Columbia University — Graphene, a zero-gap semiconductor, has been identified as an ideal electrode for nanocrystal solar cell photovoltaic applications due to its high carrier mobility. Further advances in efficient current extraction are required towards this end. We investigate the resonant energy transfer dynamics between photoexcited nanocrystals and graphene, where the energy transfer rate is characterized by the fluorescent quenching of the quantum dots in the presence of graphene. Energy transfer has been shown to have a d^{-4} dependence on the nanocrystal distance from the graphene surface, with a correction due to blinking statistics. We investigate this relationship with single and few layer graphene. We study halide-terminated CdSe quantum dots; where the absence of the insulating outershell improves the electronic coupling of the donor-acceptor system leads to improved electron transfer. We observe quenching of the halide terminated nanocrystals on graphene, with the quenching factor ρ defined asI^Q/I^G (the relative intensities on quartz and graphene).

K1.00078 ABSTRACT WITHDRAWN –

K1.00079 Electrical and Optical Properties of ITO thin films prepared by Dual Ion Beam Sputtering[1]

, ALAN WOODALL, WIM GEERTS, ANUP BANDYOPADHYAY, Department of Physics, Texas State University, San Marcos, TX 78666 — Indium Tin Oxide (ITO) thin films find application as transparent electrodes in photodetectors and solar cell devices. We prepared ITO thin films by dual ion beam sputtering from an ITO target on glass microscope slides. During the deposition the substrate was exposed to an atomic oxygen beam. We investigated the influence of the oxygen flow and RF power on the optical and electrical properties of the thin films. The substrates were cleaned ultrasonically in IPA prior to being loaded in the vacuum system (background pressure in 1E-7 torr range). The argon sputtering pressure as well as the beam and acceleration voltages were kept constant during deposition. The RF power of the assist beam was kept at 200 Watt. The oxygen atomic beam was varied by varying the oxygen flow from 0 to 5 sccm. The RF power of the main gun was varied from 64 to 110 Watt. The resistivity of the samples were measured by linear 4pp. The optical properties of the samples were measured by transmission spectroscopy and ellipsometry. The resistivity and the absorption of the films appeared to be minimum at 5 sccm and 86 Watt.

K1.00080 DNA-Templated Synthesis of Pt Nanoparticles on Single-Walled Carbon Nanotubes and their Electrocatalytic Properties

, QIANQIAN LIU, LIFENG DONG[1], Missouri State University — Platinum (Pt) supported on single-walled carbon nanotubes is one of the most efficient catalysts for both methanol and ethanol electroxidations. However, there is lack of a facile and environmental method to synthesize Pt nanoparticles on SWCNTs. In this study, we investigated a novel method to synthesize Pt nanoparticles on SWCNTs using DNA molecules as dispersing agent for nanotubes and templates for Pt nanoparticles. Morphology and structure of Pt nanoparticles and their distributions along SWCNTs as well as interactions between SWCNTs and DNA molecules were studied with the use of scanning electron microscopy, transmission electron microscopy, UV-vis spectroscopy, and X-ray diffraction spectrometer. Electrocatalytic activities of Pt nanoparticles for methanol and ethanol oxidations were characterized using cyclic voltammetry and impedance spectroscopy. With this study, we conclude effects of DNA molecules on synthesis of Pt nanoparticles on SWCNTs and electrocatalytic activity of Pt nanoparticles supported on SWCNTs for methanol and ethanol oxidations.

K1.00082 First-Principles Study of LiPON Solid Electrolyte

, SANTOSH K.C., Department of Physics, University of Texas at Dallas, Richardson, Tx 75080, KA XIONG, KYEONGJAE CHO, Department of Material Science & Engineering, University of Texas at Dallas, Richardson, Tx 75080 — There has been much interest in the thin-film solid electrolyte for solid state battery and ionics applications. LiPON is a representative material developed by Oak Ridge National Laboratory [1]. In this work, we use first principles calculations based on the density functional theory to investigate the Li- ion migration mechanisms of LiPON family materials [2]. We investigate atomic structures, electronic structures and defect formation energies of these materials. To determine the migration path of Li diffusion, the activation energies are calculated. This study helps us to understand fundamental mechanisms of Li-ion migration and to improve Li ion conductivity in the solid electrolytes.

K1.00083 Electrical and electrochemical characterization of nano-sized $LiFePO_4$ cathode materials synthesized by a lauric acid-based sol–gel method

, KHADIJE BAZZI, AMBESH DIXIT, M. B. SAHANA, C. SUDAKAR, Wayne State University, M. NAZRI, Applied Sciences Inc., Cedarville, Ohio, P. P. VAISHNAVA, Kettering University, Flint, Michigan, V. NAIK, University of Michigan-Dearborn, G. A. NAZRI, R. NAIK, Wayne State University — We synthesized pure $LiFePO_4$ and C-$LiFePO_4$ nanoparticles by sol-gel technique. Carbon coating was accomplished by including Lauric acid in the sol-gel precursor solution. Three C-$LiFePO_4$ samples of particle sizes 29, 27, 23 nm, were prepared by varying lauric acid concentration in the precursor solution. All the samples were characterized by X-ray diffraction, Raman, conductivity, and electrochemical measurements. The micro-Raman measurements showed two major bands at $\sim$1585 cm^{-1} (G) and at $\sim$1345 cm^{-1} (D) in all the C-$LiFePO_4$ samples. The 23 nm particle size sample showed minimum (D/G) band ratio and the maximum electrical conductivity among the three samples. The measured value of the capacity for 23 nm sized sample, $\sim$170 mAh/g, approached the theoretical capacity limit value for $LiFePO_4$

K1.00084 Templated electrodeposition of nanoporous silicon for battery applications

, STEPHANIE LIM, Bryn Mawr College, PA, USA, KARINE NAMUR, FLORIE MARTINEAU, JEREMY MALLET, Universite de Reims, France, JIABIN LIU, QIAN WU, HAN-CHANG YANG, X. M. CHENG, Bryn Mawr College, PA, USA — While battery technology has improved greatly in the last several years, the ability of batteries to store energy is still small compared to that of fossil fuels. In lithium ion batteries, the key issue is insufficient energy density, which is related to the interfacial surface area of the battery electrode. There is an urgent need to develop high capacity electrode materials and among the most promising candidates are Si based anode materials with specific energy capacities up to ten times greater than those of conventional graphite-based materials. We report the fabrication of nanoporous Si using templated electrochemical deposition method. The fabrication involves the following steps: self-assembly of monodispersed polystyrene spheres, electrochemical deposition of Si into the self-assembled template, and sphere removal by a dissolution process. The pore size of the nanoporous Si was tuned by using various sizes of template polystyrene spheres. Scanning electron microscopy images confirmed the high porosity of the samples. The templated electrochemical deposition technique provides a promising alternative approach to preparing highly porous anode materials for battery applications.

K1.00085 Li ion migration of lithium thiophosphate solid electrolyte materials[1] , ROBERTO LONGO PAZOS, KA XIONG, WEICHAO WANG, KYEONGJAE CHO, Materials Science & Engineering Dept, The University of Texas at Dallas, Richardson, TX 75080 — Li_2S-P_2S_5-based glasses are of great interest to be used as electrolytes in solid-state batteries. However, a detailed understanding on their structures and diffusion mechanisms is still missing. In this work, we investigate the atomic structures and ion diffusion mechanisms of various thiophosphate composites. These materials show intriguing structural similarities to their analogous Li phosphates. As a high ion conductivity battery material, interstitial and vacancy Li point defects should be reasonably stable within the host system. Besides, system with charged defect must be insulating to prevent electronic conduct which may low the ion conductivity. Our results show that interstitial Li has lower formation energy than Li vacancy, thus indicating that the ion conductivity may arise from the migration of interstitial Li. We propose possible solutions to optimize it. This study will help us to gain fundamental understanding on the Li ion diffusion process.

K1.00086 Simulating Dendritic Formation and Possible Prevention Within Lithium-ion Batteries , JOSEPH ORTIZ, Stony Brook University, ARPON RAKSIT, Commack High School, NING SUN, DILIP GERSAPPE, Stony Brook University — As technology advances and becomes more dependent on lithium-ion batteries for power, the formation and subsequent separation of dendrites along the cathode may shorten the lifespan and efficiency of these batteries. However, not much is known about the mechanisms that cause dendrite formation within the battery or how to prevent their occurrence. Using a three-dimensional lattice-Boltzmann simulation, a lithium-ion battery was simulated that would allow for dendritic formation and separation. The simulation was carried out using several pre-existing cathode morphologies, and the hindrance and prevention effects of these changes were examined.

K1.00087 Luminescent Properties of $Ca_3Sc_2Si_3O_{12}$: Mn^{2+} and Ce^{3+} for a White LED , WILLIAM COGGINS, JESSICA LANG, LI MA, Physics Department Georgia Southern Univ. — In this experiment, we studied the excitation and emission properties, as well as the fluorescence decay of the doubly doped $Ca_3Sc_2Si_3O_{12}$: Mn^{2+} and Ce^{3+} phosphor. The phosphor is coated on a GaN LED chip, and the Mn^{2+} and Ce^{3+} centers give red and green emissions, respectively, subject to the blue excitation from the chip. Together with the transmitted blue light from the LED chip, the system yields an ideal white light, with a potential application for lighting. The red emission from Mn^{2+} ions has a longer decay time than that of the green emission from the Ce^{3+}. The color composition and stability along with the input power have also been studied.

K1.00089 Introduction to SC-Potential , FLORENTIN SMARANDACHE, University of New Mexico, Gallup, VICTOR CHRISTIANTO — A new type of potential for nucleus, which is different from Coulomb potential or Yukawa potential, is introduced. This new called Smarandache-Christianto potential may have effect for radius range within r = 5-10 fm. For experimental verification of this potential, we find possible applications in the context of Condensed Matter Nuclear reaction. According to Takahashi's research, it is more likely to get condensed matter nuclear reaction using cluster of deuterium (4D) rather than using D+D reaction (as in hot-fusion, in this process Coulomb barrier is very high). In recent work, Takahashi shows that in the TSC framework it is also possible to do CMNS reaction not only with DDDD, but also with DDDH, DDHH, DHHH, or HHHH, where the reaction can be different. In other words, TSC can be a mixture of heavy and light water (as in neutrosophic logic). More interestingly, his EQPET/TSC (*tetrahedra symmetric condensate*) model, Takahashi can predict a new potential called STTBA (*sudden-tall thin barrier approximate*) which includes negative potential (reverse potential) and differs from Coulomb potential. The SC-potential, which has sinusoidal form, can be viewed as a generalization of Takahashi's TSC/STTBA potential.

K1.00090 "Force Field" for Plasma Confinement[1] , CARLOS ORDONEZ, University of North Texas — Theoretical research associated with producing an electromagnetic field referred to as a "force field" is reported. A force field is defined at present as a static electromagnetic field that has the following characteristics: (1) It has an effective range that is much smaller than the dimensions of a cloud, plasma or beam of charged particles that is confined by the field. (2) It can simultaneously reflect incident charged particles of either sign of charge. A force field could consist of a spatially periodic sequence of magnetic cusps that are electrostatically plugged using applied electrostatic potential variations similar to that found in nested Penning traps. For plasma confinement, a possible configuration consists of a sequence of coaxial ring cusps. The diameter of the ring cusps varies axially, with the smallest rings located near the axial ends of the confinement volume. Two point cusps that are coaxial with the ring cusps are located at the axial ends of the confinement volumes. A current-carrying wire placed along the axis of symmetry could be used to produce a minimum-B configuration. In the work reported, a theoretical understanding is developed of the single-particle reflection properties of a force field that confines a non-drifting, isotropic plasma.

[1]This material is based upon work supported by the Department of Energy under Grant No. DE-FG02-06ER54883.

K1.00091 Charged Particle Interactions with a Static Electromagnetic "Force Field"[1] , JOSE PACHECO, DUNCAN WEATHERS, CARLOS ORDONEZ — Experimental research associated with producing an electromagnetic field referred to as a "force field" is reported. A force field is defined at present as a short-range static electromagnetic field that can simultaneously reflect incident charged particles of either sign of charge. The charged particles can originate from a cloud, plasma or beam. A force field consisting of a spatially periodic sequence of magnetic cusps is investigated, where the magnetic cusps are electrostatically plugged using applied electrostatic potential variations similar to those found in nested Penning traps. Such a configuration could in principle be utilized to trap an effectively unmagnetized or minimum-B configuration plasma. The aim of the work reported is to understand the plasma-particle reflection properties of a planar force field created with straight, parallel line cusps. Initial experimental results are presented.

[1]This material is based upon work supported by the Department of Energy under Grant No. DE-FG02-06ER54883.

K1.00092 Energy Transfer Between Antiprotons and Leptons Within a Strong Magnetic Field[1] , JOSE CORREA, JONATHAN WURTELE, CARLOS ORDONEZ — Some experiments conducted at the CERN Antiproton Decelerator are aimed at creating and confining antihydrogen. In many of the experiments, energetic antiprotons are cooled by collisions with electrons within a strong magnetic field. The cold antiprotons are subsequently made to interact with positrons under a strong magnetic field leading to some recombination. In the work to be reported, an analytical model for strongly magnetized collisions is developed and applied to investigate the energy loss of antiprotons interacting with cold and warm leptons under a strong magnetic field. In this model, the strong magnetization constrains the momentum transfer to one dimension, which is parallel to the magnetic field. Thus, collisional energy transfer is dominated by short-range collisions. The result is remarkably different from the unmagnetized case. The theoretical expectations are compared with prior and new computer simulations. The agreement found reveals that the model captures important features of the interaction of electrical charges of disparate masses such as antiprotons and leptons within a strong magnetic field.

[1]This material is based upon work supported by the Department of Energy under Grant No. DE-FG02-06ER54883.

K1.00093 Isothermal Expansion of a Solid-Particle-Entrained Gas and Plasma-Based Energy Conversion

, ERIC LESSMANN, MATTHEW TRAUM, DUNCAN WEATHERS, CARLOS ORDONEZ — Experimental and theoretical research is reported on the expansion of a two-phase fluid consisting of a mixture of compressed gas and solid particles. Experimental temperature measurements indicate that the expansion is describable as isothermal for the conditions studied. During the expansion, the energy of the compressed gas is converted into kinetic energy of the solid particles. The solid particles travel at a subsonic speed, serve as a heat exchange medium, and are recycled. In the experiment, the gas-solid two-phase fluid travels through a nozzle during the isothermal expansion. Conversion of the energy of a compressed gas has been demonstrated experimentally using a turbine to convert the kinetic energy of the solid particles into other forms. A second method is also being studied for converting the kinetic energy of the solid particles after the gas expansion. The second method, which would replace the turbine, would convert the kinetic energy of the solid particles into electrical energy by charging the solid particles (e.g., by passing them through an electron plasma or by reflection off one plate of a capacitor). The charged solid particles would then carry a current across a change in electric potential inertially (without collisions with a wall) and then be discharged (e.g., by passing them through an ion plasma or by reflection off one plate of a second capacitor).

K1.00094 Nanostructure Control of P3HT:PCBM Bulk Hetero-junction Polymer Solar Cells[1]

, J. SEOK, E. GANN, C.M. BALIK, H. ADE, NCSU, B. OCKO, X. LU, H. HLAING, BNL — Highly regioregular Poly(3-hexyl thiophene) (P3HT) and [6,6]-phenyl-C61-butyric acid methyl ester (PCBM) are a widely used model system for Bulk hetero-junction (BHJ) solar cells. For optimized P3HT:PCBM BHJ solar cells, not only is a small domain size on the order to the exciton diffusion length ($\sim$10nm) required, but the orientation of P3HT crystallites should be optimized as well. Small domains result in effective charge separation and minimize charge recombination at the interface between P3HT and PCBM. Additionally, face-on crystalline orientation of P3HT in which the $\pi - \pi$ stacking direction is parallel to the electric field enhances the hole charge carrier mobility. We are presenting a new strategy to achieve somewhat increased face-on P3HT crystalline orientation and smaller domain size in P3HT/PCBM BHJ solar cells than what is readily achievable with thermal annealing alone. This improved nanostructure control is achieved by in-situ polymerization of 2,5-dibromothiophene present in the thin films after short vapor annealing. Improvements in power conversion efficiency of approx. 30% relative to thermal annealing alone were achieved.

[1]DOE DE-FG02-98ER45737

K1.00095 First-Principles Studies on Lattice Dynamical Properties of Zn_4Sb_3 Compounds[1]

, YI ZHANG, CHANGFENG CHEN, Physics Department and HiPSEC, University of Nevada, Las Vegas, JIHUI YANG, Electrochemical Energy Research Lab, GM R&D Center — The origin of extremely low lattice thermal conductivity in Zn_4Sb_3 compound has attracted great interests but remains not fully understood due to its complex crystal structure. We have performed extensive first-principles calculations on the lattice vibration modes and thermodynamics of Zn_4Sb_3 based on its experimental crystal structure. The low frequency modes and structural inhomogeneity that could be responsible for the low thermal conductivity have been discussed.

[1]This work is supproted by DOE Agreements DE-FC52-06NA26274 and DE-FC26-04NT42278 and by GM. Computation resource in NCCS is supported by DOE.

K1.00096 Impact of impurities on the electronic structures of thermoelectric material Mg_2Si[1]

, KA XIONG, SABINA SOBHANNI, RAHUL GUPTA, WEICHAO WANG, BRUCE GNADE, KYEONGJAE CHO, University of Texas at Dallas — Thermoelectric (TE) materials have attracted a lot of attention because of its capability of converting heat into electricity or vice versa. In this work, we investigate the effects of dopants in Mg_2Si, which is a promising TE material candidate. We calculate the electronic structures and stability of various dopants (Al, In, P, As, Sb, Bi, Ag, Cu, Zn, and Cd) in Mg_2Si with different charge states, using density functional theory (DFT) method with HSE functional which gives accurate band gap prediction. This DFT study helps us to gain insights on the defect states of these dopants in Mg_2Si and the mechanisms which cause the modulation of the Mg_2Si TE efficiency.

[1]This work is supported by the II-VI Foundation, a private foundation.

K1.00097 Neutron Scattering Measurements of Temperature-Dependent Phonon Spectra in Thermoelectric Materials PbTe and (Ag,Sb)Te_2[1]

, JIE MA, OLIVIER DELAIRE, BRIAN SALES, KAROL MARTY, DOUGLAS ABERNATHY, MATTHEW STONE, GEORG EHLERS, ORNL COLLABORATION — The thermoelectric materials PbTe and (Ag,Sb)Te_2, which both crystallize in the rocksalt structure, have attracted much attention due to their high zT values. Prior theoretical and experimental studies have investigated the phonon dispersions of PbTe, and the importance of the electron-phonon and phonon-phonon couplings has been recognized. However, phonons have not been investigated in details in (Ag,Sb)Te_2. Also, little is known about the phonon linewidths, which directly correlate with the lattice thermal conductivity. In order to better understand the microscopic origins of the lattice thermal conductivity, time-of-flight and triple-axis inelastic neutron scattering measurements were performed as a function of temperature in both compounds. The results of phonon linewidths and their systematic dependence on temperature are presented, providing a direct measurement of the contribution of phonons to the total thermal conductivity.

[1]O.D. acknowledges funding from US DOE/BES as part of an Energy Frontier Research Center, DOE DE-SC0001299.

K1.00098 $Gd_{116}Co_{49}Sn_{118}$: A Complex Intermetallic Phonon-Glass/Electron-Crystal[1]

, DEVIN SCHMITT, NEEL HALDOLAARACHCHIGE, YIMIN XIONG, RONGYING JIN, DAVID YOUNG, JULIA CHAN, Louisiana State University — State-of-the art thermoelectric devices today operate at very low efficiencies and are expensive to produce. However, the growing need for alternate energy sources based on novel technologies has brought thermoelectrics to the forefront of applied materials research. Thermoelectrics could have a significant impact in this area, if their performance is significantly enhanced to a figure of merit (ZT) above 1.5. Our research focuses on the growth and structure-property relationships of intermetallics, specifically crystal structures with large lattice parameters that contain heavy atoms. These materials may be good thermoelectric candidates due to their potentially low lattice thermal conductivities and enhanced Seebeck values resulting from polar intermetallic properties. We have recently grown $Gd_{116}Co_{49}Sn_{118}$ (*Fm-3m*, $a \cong 30.2$ Å), a compound related to the $Dy_{117}Co_{57}Sn_{112}$ structure type. Physical property measurements indicate that this is an ambipolar semiconductor with an exceptionally low lattice thermal conductivity ($\kappa_l \cong 0.5$ W/m-K). The observed phonon-glass/electron-crystal properties make $Gd_{116}Co_{49}Sn_{118}$ and its analogues potential thermoelectric candidates.

K1.00099 Bipolar Membranes for Acid Base Flow Batteries , MITCHELL ANTHAMATTEN, SUPACHAREE RODDECHA, JACOB JORNÉ, ANNA COUGHLAN, University of Rochester — Rechargeable batteries can provide grid-scale electricity storage to match power generation with consumption and promote renewable energy sources. Flow batteries offer modular and flexible design, low cost per kWh and high efficiencies. A novel flow battery concept will be presented based on acid-base neutralization where protons (H+) and hydroxyl (OH-) ions react electrochemically to produce water. The large free energy of this highly reversible reaction can be stored chemically, and, upon discharge, can be harvested as usable electricity. The acid-base flow battery concept avoids the use of a sluggish oxygen electrode and utilizes the highly reversible hydrogen electrode, thus eliminating the need for expensive noble metal catalysts. The proposed flow battery is a hybrid of a battery and a fuel cell—hydrogen gas storing chemical energy is produced at one electrode and is immediately consumed at the other electrode. The two electrodes are exposed to low and high pH solutions, and these solutions are separated by a hybrid membrane containing a hybrid cation and anion exchange membrane (CEM/AEM). Membrane design will be discussed, along with ion-transport data for synthesized membranes.

K1.00100 ATOMIC, MOLECULAR AND OPTICAL (AMO) PHYSICS –

K1.00101 Universal contact of strongly interacting Fermi gases , MARK DELLOSTRITTO, THEJA DE SILVA, Binghamton University — We study strongly interacting two component Fermi gas near a Feshbach resonance. By using a ground state energy functional constructed based on asymptotic limits and Monte Carlo calculations, we calculate the contact, structure factor, and collective oscillation frequencies in the BCS-BEC crossover region. The calculated contact and structure factor show excellent agreement with recent experiments. We show that the upper bounds of the collective modes have universal form in the sense that they depend only on the contact and the homogenous energy. In other words, the collective modes of the Fermi atoms trapped near Feshbach resonance can be calculated without the explicit knowledge of trapping potential.

K1.00102 Spin-charge separation in one-dimensional fermion systems beyond Luttinger liquid theory , THOMAS SCHMIDT, Yale University, ADILET IMAMBEKOV, Rice University, LEONID GLAZMAN, Yale University — We develop a nonperturbative zero-temperature theory for the dynamic response functions of interacting one-dimensional spin-1/2 fermions. In contrast to the conventional Luttinger liquid theory, we take into account the nonlinearity of the fermion dispersion exactly. We calculate the power-law singularities of the spectral function and the charge- and spin-density structure factors for arbitrary momenta and interaction strengths. The exponents characterizing the singularities are functions of momenta and differ significantly from the predictions of the linear Luttinger liquid theory. We generalize the notion of the spin-charge separation to the nonlinear spectrum. This generalization leads to phenomenological relations between threshold exponents and the threshold energy.

K1.00103 Control the spin coherence of a spin-1 Bose-Einstein Condensate with dynamical decoupling approach , BOYUAN NING, JUN ZHUANG, WENXIAN ZHANG, Department of Optical Science and Engineering, Fudan University, Shanghai 200433, China, J.Q. YOU, Department of Physics, Fudan University, Shanghai 200433, China — The coherence of spinor Bose-Einstein condensates (BECs) is determined by the dynamically unstable collective modes. Recently, Uhrig Dynamical Decoupling (UDD), a sequence containing n π-pulses, has been applied to eliminate the decoherence of a qubit in the spin-boson (SB) model up to the order of $\mathcal{O}(t^{n+1})$ and proved to be a universal method. Stimulated by its promising power, we conjecture whether the UDD sequence could also preserve the coherence of a spinor BEC by modulating the spin exchange interaction through optical Feshbach resonance. In this work, we theoretically analyze the effect of UDD, periodic DD (PDD) and concatenated DD (CDD) to maintain the coherence of a ^{87}Rb spin-1 BEC and a scalar BEC. Our numerical results show that the CDD, as n increases, suppresses the decoherence more than the other two DD sequences in both the spinor and the scalar BECs. However, it is interesting that all three sequences only remove the decoherence up to the same order $\mathcal{O}(t)$. We further carry out analytical works for the scalar BEC, which confirms our numerical results that UDD, compared to the case of SB model, is not as superior as expected at coherence control in BECs.

K1.00104 Bosonic matter inside a periodic array of tubes , P. SALAS, UNAM, F.J. SEVILLA, M. FORTES, M.A. SOLIS, Instituto de Fisica, UNAM — We report the Bose-Einstein Condensation critical temperature, internal energy and specific heat per particle of an ideal boson gas in periodically trapping channels. These are simulated by two perpendicular external Kronig-Penney delta potentials applied on the x-y plane and allowing the particles to move freely in the remaining direction. We obtain the Bose-Einstein condensation critical temperature of the system as a function of the separation between deltas and as a function of their intensity which models the penetrability of the tube walls. It is shown that T_c decreases monotonically, from the 3D ideal boson gas T_0 for vanishing delta strenght, down to 0 as the intensity grows to infinity while keeping the channel's cross section constant. The quotient T_c/T_0 as a function of the width of the tubes starts at 1, reaches a minimum value that depends on the permeability and returns to 1 as the widths vary from infinity to 0. We observe that the specific heat as a function of the temperature is modified by the tubular structure, showing a set of maxima and minima for different values of permeability of the walls and widths of the tubes. In particular, when half the wave-length of the boson gas is the same as the tubes' square cross section, the system clearly exhibits the trapping effect due to the tubes. In this case the specific heat has a minimum very similar to that of the one- dimensional case.

K1.00105 Specific heat of bosons in periodical bilayers , O.A. RODRIGUEZ, P. SALAS, UNAM, M.A. SOLIS, Instituto de Fisica, UNAM — We report the specific heat at constant volume of an ideal boson gas inside a periodical bilayer structure modeled with a generalized Kronig-Penney (KP) delta potential in the z-direction while the particles are free in the other two directions. The generalized KP potential has two different strength delta potentials by unit cell, and they are separated βa, where a is the unit cell length and $0 \leq \beta \leq 1$. After calculating the energy band structure we use it to obtain the Bose-Einstein condensation critical temperature besides the chemical potential, the internal energy and the specific heat, as functions of the temperature, for different values of the parameters a, β and the delta strengths. For any parameter set we observe a Bose-Einstein condensation at a lower temperature than that of an infinite ideal Bose gas in the thermodynamic limit and with the same particle density. From the specific heat we distinguish at least four characteristic lengths. They are associated to the thermal wave length values at: the BEC critical temperature where the specific heat shows a peak and a discontinuity in their derivative; two minima of the specific heat where the thermal wave lengths are equal to two times the plane separations βa and $(a - \beta a)$; and about 0.7 times the minimum plane separation, where the specific heat behavior returns to that of an ideal Bose gas. Also the delta strength effects on the specific heat are discussed.

K1.00106 Probing and Manipulating Fermi Gases Using Classical Impurities[1] , LEI JIANG, LESLIE O. BAKSMATY, HAN PU, Department of Physics and Astronomy, and RQI, Rice University, Houston, TX, USA, HUI HU, ARC Centre of Excellence for Quantum-Atom Optics, Swinburne University of Technology, Melbourne, Australia, YAN CHEN, Laboratory of Advanced Materials and Department of Physics, Fudan University, Shanghai, China — Impurities can be used as probes to detect material properties and to understand quantum phenomena. Here we study the effect of a single classical impurity in ultracold s-wave Fermi superfluids. We use T-matrix and B-dG method to study both 1D and 3D cases to mean-field level. A magnetic impurity can induce a mid-gap bound state located inside the pairing gap. In addition, magnetic impurity can locally induce population imbalance in the system, potentially providing a method to realize FFLO-like state in a controlled way. We further extend the 1D impurity case to strong correlated region using DMRG. We also propose a modified RF spectroscopy to measure the local density of states, as a cold-atom analog of STM.

K1.00107 Generating sodium Bose-Einstein condensates in hybrid magnetic quadrupole and optical traps

, ZONGKAI TIAN, JIE JIANG, JARED AUSTIN, JOHN JEPSON, YINGMEI LIU, Department of Physics, Oklahoma State University, Stillwater, OK 74078 — We present the design and construction of a novel apparatus to rapidly and simply generate ^{23}Na Bose-Einstein condensates in hybrid magnetic and optical traps. Sodium atoms are collected in a magnetic-optical trap, captured in a magnetic quadrupole trap, and then cooled through forced radio-frequency evaporation. To avoid Majorana spin-flip losses at the center of the magnetic quadrupole trap, the cold dense atomic cloud is transferred to a crossed red-detuned optical dipole trap. By reducing the optical trap depth, sodium Bose-Einstein condensates are generated from forced evaporation and rethermalization in the crossed optical trap. This hybrid approach combines the advantages of both magnetic quadrupole and optical traps.

K1.00108 Construction and Implementation of a Low-Cost Rubidium Magneto-Optical Trap[1]

, JUDITH OLSON, Ithaca College — A low-cost magneto-optical trap (MOT) for ultra-cold atoms is a wonderful tool for undergraduate research and teaching laboratories that highlights many topics in modern physics. We researched and created such a MOT using two external-cavity diode lasers, two laser locking systems, optics, magnetic coils, and Rubidium vapor cells. At our undergraduate institution, we chose a combination of equipment that we fabricated ourselves together with some purchased items as an optimum balance between cost and building time. However, an emphasis was placed upon self-construction of components, such as machining the laser cavities and constructing the majority of the circuitry within the institution. The total cost of our MOT was about $25,000. We were successfully able to trap more than 10 million Rubidium atoms in 1 cubic centimeter. Such a MOT is a feasible addition to any undergraduate course of study. The theory of operation and construction methods of our MOT will be presented along with our first measurement results.

[1]Many thanks to Ithaca College and the Ithaca College Department of Physics.

K1.00109 Ultracold Realization of AntiFerromagenteic Order[1]

, UTTAM SHRESTHA, University of California, Irvine — We investigate numerically the experimental feasibility of observing the antiferromagnetic (AF) order in the bosonic mixtures of rubidium (^{87}Rb) and potassium (^{41}K) in a two-dimensional optical lattice with external trapping potential. Within the mean-field approximation we have found the ground states which, for a specific range of parameters such as inter-species interactions and lattice height, interpolate from phase separation to the AF order. For the moderate lattice heights the coexistence of the Mott and AF phase is possible for rubidium atoms while the potassium atoms remain superfluid with overlapped AF phase. In our view there has not been any study on AF order in two-component systems when one component remains in the superfluid phase while the other is in the Mott phase. Therefore, this observation may provide a novel regime for studying quantum magnetism in ultracold systems.

K1.00110 FFLO phase on an optical lattice: a quantum Monte Carlo study[1]

, CHIA-CHEN CHANG, SHIWEI ZHANG, Department of Physics, College of William and Mary — Recent experimental progress in cold Fermi gases has demonstrated the possibility of realizing exotic quantum phases in optical lattices. One example is the Fulde-Ferrel-Larkin-Ovchinnikov (FFLO) state arising from pairing across the Fermi surfaces in a spin-imbalanced system with attractive interaction. We study ground state magnetic properties in 2D and 3D repulsive Hubbard models at intermediate interaction strengths by means of a highly accurate auxiliary-field quantum Monte Carlo method [1] coupled with Twist-averaged boundary conditions. The sign problem is controlled by a generalized constrained path approximation. It is found that the ground state shows incommensurate spin density wave order with periodic spatial modulation when the model is slightly doped away from $n = 1$. We present our results in 2D [2] and 3D, and discuss their implications, through a particle-hole transformation, on the FFLO phase on an optical lattice of spin-imbalanced fermions with an attractive interaction. This work is supported by ARO. Reference: [1] Chia-Chen Chang and Shiwei Zhang, Phys. Rev. B 78, 165101 (2008) [2] Chia-Chen Chang and Shiwei Zhang, Phys. Rev. Lett. 104, 116402 (2010).

K1.00111 Progress toward realization of antiferromagnetic ordering of cold atoms in an optical lattice[1]

, P.M. DUARTE, R. HART, T.L. YANG, J.M. HITCHCOCK, T.A. CORCOVILOS, R.G. HULET, Department of Physics and Astronomy and Rice Quantum Institute, Rice University, Houston, TX 77005 — We present progress toward the observation of antiferromagnetic (AFM) ordering of fermionic atoms in an optical lattice using Bragg scattering of light. We first laser cool ^{6}Li atoms using the $2S_{1/2} \rightarrow 2P_{3/2}$ transition and then further cool using the $2S_{1/2} \rightarrow 3P_{3/2}$ transition to T $\sim$ 65 μK, leading to enhanced loading into a far detuned optical dipole trap. After forced evaporative cooling, an incoherent spin mixture of the two lowest magnetic sublevels of the ground state is adiabatically loaded into a 3D optical lattice. By adjusting the s-wave scattering length and the depth of the lattice, we tune the interaction and hopping terms of the Hubbard Hamiltonian. Bragg scattering of light from the lattice planes can be used to detect sample ordering such as in the Mott insulator state. At low temperatures and weak interactions, a phase transition to AFM ordering of the two spin states is predicted to occur. The increased symmetry of the AFM state allows for Bragg scattering of light from the ordered spin planes, $\pm(^1/_2\,^1/_2\,^1/_2)$, and hence unambiguous detection of the AFM state. We present our progress in detecting the Mott insulator and AFM states.

K1.00112 A Qauntum Theory of Ultracold Atoms in Spatially Inhomogenoues Optical Lattices

, DAGIM TILAHUN, BYOUNGHAK LEE — Ultracold atoms in optical lattices undergo a quantum phase transition from a superfluid to a Mott insulator as the potential depth is increased. But the interpretations of most cold atoms experiments are complicated by the fact that the experimental systems are inhomogeneous, for example due to the harmonic trapping potential that is always present. Or the focus of the study itself could be what causes the non-uniformity, such as disorder. Here We apply a theory developed by one of the authors and a collaborator to these inhomogeneous systems to discuss their ground state and elementary excitations.

K1.00113 Geometric Unitary Gates in Cold Atom Ensembles on an Atom Chip

, YICONG ZHENG, TODD BRUN, University of Southern California, QUANTUM COMMUNICATION TEAM — We propose a feasible scheme to achieve quantum computation based on geometric manipulation of ensembles of atoms, and analyze it for neutral rubidium atoms magnetically trapped in planoconcave microcavities on an atom chip. The geometric operations are accomplished by optical excitation of a single atom into a Rydberg state in a constant electric field. Strong dipole-dipole interactions and incident lasers drive the dark state of the atom ensembles to undergo some specified cyclic evolutions that realize a universal set of quantum gates. Such geometric manipulation turns out naturally to protect the qubits from the errors induced by non-uniform laser illumination as well as cavity loss. The gate performance and decoherence processes are analyzed by numerical simulation.

K1.00114 A closed-cycle dilution refrigerator with free-space and fiber optical access for quantum optomechanics experiments at 25mK , SIMON GROEBLACHER, WITLEF WIECZOREK, University of Vienna, Austria, PETER CHRIST, MATTHIAS BUEHLER, Oxford Instruments, Munich, Germany, DOREEN WERNICKE, Entropy GmbH, Munich, Germany, JENS HOEHNE, Oxford Instruments, Munich, Germany, MARKUS ASPELMEYER, University of Vienna, Austria — We report on the operation of a closed-cycle dilution refrigerator for quantum optomechanics experiments at 25mK. The dilution fridge is accessible both via free-space as well as fiber coupling, allowing us to perform a variety of optical experiments at low temperatures. It is designed to vibrationally isolate the experiment allowing for stable operation of a high-finesse optical cavity. This enables us to perform cavity-optomechanics experiments at ultra-low temperatures.

K1.00115 Correlation energy of a homogeneous dipolar Fermi gas[1] , BO LIU, LAN YIN, School of Physics, Peking University, Beijing 100871, China — We study the normal state of a 3-D homogeneous dipolar Fermi gas beyond the Hartree-Fock approximation. The correlation energy is found of the same order as the Fock energy, unusually strong for a Fermi-liquid system. As a result, the critical density of mechanical collapse is smaller than that in the Hartree-Fock approximation. An new energy functional including the correlation energy is constructed to describe inhomogeneous cases, and its properties are explored.

K1.00116 Quantum Phases of Fermionic Cold Atoms Through Pairing and Dissociation , NICOLAS LOPEZ, SHAN-WEN TSAI, UCR, E. TIMMERMANS, LANL, CHI-YONG LIN, National Dong Hwa University, Taiwan — Cold atom experiments have realized molecule creation consisting of paired fermions and dissociation of weakly bound molecules into correlated fermions by tuning of the interactions with external fields [1,2]. We study many-body correlations in such system where molecules are weakly bound and therefore pairs of fermionic atoms convert into and dissociate from the bound molecule state. This exchange mediates a long-range interaction between the fermions. We consider a simple many-body Hamiltonian that includes the destruction of fermionic atom pairs to form single bosonic molecules and vice versa [3]. We employ a functional renormalization-group approach to search for instabilities from the disordered quantum liquid phase that may arise from a boson mediated fermion-fermion interaction. We calculate the renormalized frequency-dependent fermion interactions vertices and renormalized molecular binding energy.

K1.00117 Influence of Non-Linear Interactions on the Propagation of Electromagnetic Fields in Moving Many-Electron Atomic Systems[1] , VERNE JACOBS, Naval Research Labortory — Reduced-density-matrix descriptions are developed for the propagation of electromagnetic fields in moving many-electron atomic systems, taking into account the center-of-mass motions, atomic collision processes, and applied magnetic fields. The time-domain (equation-of-motion) and the frequency-domain (resolvent- operator) formulations are developed in a unified manner. A semiclassical perturbative treatment of the electromagnetic interaction is employed to derive compact Liouville- space operator expressions for the general n'th-order non-linear macroscopic electromagnetic-response tensors. Coherent atomic excitations and the full tetradic- matrix form of the collision-radiative self-energy operator in the Markov approximation are taken into account.

K1.00118 Analysis of two simultaneous EITs in a four-level atomic system in a W-scheme using a dressed-state representation , CRISTIAN BAHRIM, Department of Physics, Lamar University — A four-level atomic system in a W-scheme is used for slowing down *simultaneously* two circularly polarized optical fields using a linearly polarized coupling field. Our four-level atomic system is composed by the $^1S_0$ ground state and three Zeeman levels of the $^1P_1$ excited state of any alkali-metal atom introduced in a weak magnetic field. When the coupling field is stronger than both probe fields, the electromagnetic induced transparency (EIT) is observed in the coherences associated to the two probes, while the coherence associated to the coupling field shows opacity. We calculate the quantum coherences from the steady-state solutions of the density matrix master equation, in which we neglect the collisional dephasing (we consider ultra-cold atoms), but we include the radiative decays from each Zeeman state to the ground state. The coupling mechanism between the atomic states and the optical fields in our W-system and the evolution of the EIT features with the intensity of the coupling field is done using an intuitive dressed state representation. We also analyze the transit time from the normal dispersive region to the EIT region: when a weak probe field is used, the transit time is the shortest and the width of the Autler-Townes doublet equals the lifetime of the excited atomic state which experiences EIT, but it increases rapidly as the intensity of the probe field increase.

K1.00119 Infrared Spectrum of the Astrophysical Molecule SiC_5 , T.H. LE, W.R.M. GRAHAM, Texas Christian University — An infrared spectrum of SiC_5, one of many Si-C molecular species expected to play roles in the atmospheres of late carbon stars and in the interstellar medium, has been observed for the first time. The Fourier transform infrared spectrum (FTIR) was recorded for SiC_5 produced by trapping, in solid Ar, the products of the Nd:YAG laser ablation of a sintered, silicon-carbon rod enriched with ^{13}C. Based on excellent agreement between measured frequencies of ^{13}C and $^{29,30}Si$ isotopomers and the predictions of DFT (density functional theory) B3LYP/cc-pVDZ calculations, the linear geometry of SiC_5 has been confirmed and the $\nu_4(\sigma_u)$ asymmetric stretching fundamental of SiC_5 has been identified at 936.9 $\pm$ 0.2 cm $^{-1}$.

K1.00120 Vibrational Spectroscopy and Structures of Novel Metal-Carbon Species of Astrophysical Interest , MICHELINE BEJJANI, WILLIAM GRAHAM, MAGNUS RITTBY, Texas Christian University — This study on metal-carbon molecules is part of an ongoing investigation of the structures and vibrational frequencies of small metal carbide clusters using Fourier transform infrared spectroscopy (FTIR) and density functional theory (DFT). These studies are motivated by the potential presence of small metal carbide molecules in astrophysical environments. Binary carbon compounds containing silicon and sulfur, including SiC_2, SiC_3, and SC_3, have been observed in interstellar space and circumstellar shells. In addition several metal-containing molecules, such as MgCN and MgNC have also been detected. Hence, metal carbides have been suggested as possible interstellar molecules although a lack of information on their spectral properties may so far have prevented their detection. Recent studies by this laboratory on the infrared spectroscopy of matrix-isolated metal tricarbide clusters, such as fanlike TiC_3 and ScC_3, linear CrC_3 and CoC_3 and floppy NiC_3Ni have begun to provide some of this information. Here, we report the structures and vibrational spectra of MnC_3, ZnC_3 and MgC_3^-.

K1.00121 The two-dimensional and three dimensional confinement of the hydrogen molecular ion, inside ellipses and spheroids, respectively[1] , MARTIN MOLINAR, GERMAN CAMPOY-GÜEREÑA, DIFUS, Universidad de Sonora — The Schrödinger equation for the confinement of the hydrogen molecular ion in the Born – Oppenheimer is solved. The molecule is confined by rigid and non-rigid ellipses and spheroids. The energies for the ground state and the first excited states are determined.

[1]Martin Molinar-Tabares acknowledge to Universidad de Sonora for supporting the attendance.

K1.00122 Variational wave function approach to quantum quenches in bosonic systems , FEDERICO BECCA, GIUSEPPE CARLEO, STEFANO BARONI, CNR, Istituto Officina dei Materiali and SISSA, Trieste — Recent experiments with ultracold atomic gases have opened the possibility for studying non-equilibrium quantum dynamics of many-body systems. In particular, the high degree of tunability allows one to rapidly change system parameters and observe the subsequent quantum evolution. We present a new variational approach to deal with time-dependent problems where quantum quenches of the microscopic parameters induce a highly non-trivial dynamics. We show to what extent a generalization of the Jastrow wave function may accomplish this task, even for two-dimensional models, where standard Lanczos or density-matrix renormalization group methods are highly limited. Examples for interacting hard-core and soft-core bosons are shown. The generalization to fermionic models is also discussed.

K1.00123 Phase diagram of a population-imbalanced attractive Fermi gas in the 1D-3D crossover regime , SATYAN BHONGALE, George Mason University, LESLIE BAKSMATY, LEI JIANG, HAN PU, Rice University — Phase diagram of a population imbalanced attractive Fermi gas in the 1D-3D dimensional crossover regime is obtained via deriving a multi-channel inter-atomic scattering pseudopotential. Such a phase diagram has strong implications for the observation of FFLO superfluidity within trapped fermions. Recent experiment with ultra-cold Li6 have mapped the phase diagram for 1D attractive fermions [Nature 467, 567 (2010)], however the superfluid property is yet to be confirmed. While the signature of FFLO in 1D is predicted to coincide with micro-phase separated domains, the feasibility of direct experimental identification of the domain walls remains questionable due to strong fluctuations. On the other hand, in 3D, fluctuations may be neglected, but the FFLO corresponds to just a tiny sliver of the phase diagram. Moreover, the topology of the phase diagram is drastically different in the two extreme dimensional limits. We show how the 1D and 3D dimensional limits are connected and indicate the possible new physics in the crossover regime.

K1.00124 Controllable optical switch using a Bose-Einstein condensate in an optical cavity , SHUAI YANG, Institute for Quantum Studies and Department of Physics, Texas A&M University, College Station, Texas 77843, USA, M. AL-AMRI, The National Center for Mathematics and Physics, KACST, P.O. Box 6086, Riyadh 11442, Saudi, JÖRG EVERS, Max-Planck-Institut für Kernphysik, Saupfercheckweg 1, D-69117 Heidelberg, Germany, M. SUHAIL ZUBAIRY, Institute for Quantum Studies and Department of Physics, Texas A&M University, College Station, Texas 77843, USA — The optical bistability of an ultra cold atomic ensemble located in a small volume ultra-high finesse optical cavity is investigated. We find that the transverse pumping field can be used to control the bistable behavior of the intra cavity photons induced by the input pumping along the cavity axis. This phenomenon can be used as a controllable optical switch.

K1.00125 QUANTUM INFORMATION, CONCEPTS AND COMPUTATION –

K1.00126 Quantum Mechanics as Dualism , ROBERT JONES, Emporia State University — I do not agree with mind-body dualism. Today the consensus view is that thought and mind is a combination of processes like memory, generalization, comparison, deduction, organization, induction, classification, feature detection, analogy, etc. performed by computational machinery. (R. Jones, Trans. of the Kansas Acad. Sci., vol. 109, # 3/4, 2006 and www.robert-w-jones.com, philosopher, theory of thought) But I believe that quantum mechanics is a more plausible dualist theory of reality. The quantum mechanical wave function is nonphysical, it exists in a 3N space (for an N body system) not in (x,y,z,t) 4-space, and does not possess physical properties. But real physical things like energy (which do exist in our 4-space world) influence the wave function and the wave function, in its turn, influences real physical things, like where a particle can be found in 4-space. The coupling between the spirit-like wave function and things found in the real (4-space) world (like energy) is via mathematical equations like the Schrodinger equation and Born normalization.

K1.00127 Some Statistical Measures and Analytical Results of Quantum Walks under Weak Measurement and Weak Values Regime , DEBABRATA GHOSHAL, George Mason University, MARCO LANZAGORTA, ITT Corportation, SALVADOR VENEGAS-ANDRACA, Tecnológico de Monterrey Campus Estado de México (ITESM-CEM) — Motivated by experimental results on quantum weak measurements and weak values as well as by the need to develop new insights for quantum algorithm development, we study the behavior of quantum walks under the regime of quantum weak measurements and weak values of pre- and post-selected measurements (QWWM hereinafter). In particular, we investigate the limiting position probability distribution and several statistical measures (such as standard deviation) of a QWWM on an infinite line, and compare such results with corresponding classical and quantum walks position probability distributions and statistical measures, stressing the differences provided by weak measurements and weak values with respect to results computed by using canonical observables. We start by producing a concise introduction to quantum weak values and quantum weak measurements. We then introduce definitions as well as both analytical and numerical results for a QWWM under Hadamard evolution and extend our analysis to quantum evolution ruled by general unitary operators. Moreover, we define a 2-walker QWWM on an infinite 2D lattice and explore its behavior on limiting probability distribution, standard deviation and degree of entanglement between walkers.

K1.00128 Generating Entangled States With Hybrid Parity Gates[1] , ZHI-MING ZHANG, FENG MEI, YA-FEI YU, XUN-LI FENG, South China Normal University — We propose a scheme for generating entangled states among different single atoms trapped in separated cavities. In our scheme, by reflecting an input coherent optical pulse from a cavity with a single trapped atom, a controlled phase-shift gate between the atom and the coherent optical pulse can be achieved. Based on this gate and homodyne detection, we construct an n-qubit parity gate and show its use for distribution of a large class of entangled states, including the GHZ states, the W states, the Dicke states, and certain sums of the Dicke states. We also show that such distribution can be performed with high success probability and high fidelity even in the presence of channel loss.

[1]This work was supported by the National Natural Science Foundation of China (No. 60978009), and the National Basic Research Program of China (Nos. 2007CB925204 and 2009CB929604).

K1.00129 Optical Engineering for Quantum Computing Over the Optical Frequency Comb , MORAN CHEN, OLIVIER PFISTER, University of Virginia — The optical frequency comb (OFC) of a single optical parametric oscillator (OPO) has shown a spectacular, if theoretical, scalability potential as a continuous-variable one-way quantum register. Indeed, an arbitrarily large, square-grid cluster state, suitable for universal quantum computing, can in principle be generated in one fell swoop in the OPO, by use of a triply concurrent nonlinear crystal (already demonstrated) and a 15-mode pump. Here we present a precise and feasible implementation plan for this complex pump spectrum, using single-sideband, suppressed-carrier (SSB-SC) electrooptic modulation. Another requirement is the proper termination of the set of interacting entangled modes within the OFC. We show that OFC dispersion can be realistically managed, by use of microcavity OPO mirrors, so as to shift the frontier modes out of resonance and essentially annihilate their interaction. Solving these two "optical engineering" problems paves the way to the experimental realization of scalable cluster-state entanglement "over the rainbow."

K1.00130 Implementing quantum phase gates with Ising anyons , DAVID J. CLARKE, KIRILL SHTENGEL, University of California, Riverside — Non-Abelian anyons of Ising type are likely to occur in a number of physical systems, including quantum Hall systems, where recent experiments support their existence. In general, non-Abelian anyons may be utilized to provide a topologically error-protected medium for quantum information processing. However, the topologically protected operations that may be obtained by braiding and measuring topological charge of Ising anyons are not computationally universal. Nevertheless they can be made universal when supplemented with a single-qubit phase gate. We propose a method of implementing arbitrary single qubit phase gates for Ising anyons by utilizing interference of auxiliary anyons around computational anyons. While this gate is not topologically protected, our estimates show that its error rate can be made lower than the threshold for error correction. The error rate for systems with neutral Ising anyons (e.g. topological insulator) is inherently lower than that for systems in which the anyons carry charge (e.g. quantum Hall systems).

K1.00131 Finding edge permutations in a graph using quantum walks , ZLATKO DIMCOVIC, Department of Physics, YEVGENIY KOVCHEGOV, Department of Mathematics, Oregon State University — The problem of graph structure discovery is important in many fields of science. Quantum walks are expected to bring significant algorithmic improvements to quantum computing. More generally, random walks (Markov chains on graphs) can be very useful as a different approach to problems. We use a specific quantum walk to address unknown permutations in a graph. Consider two matching graphs, with unknown permutations of edges that connect them. For example: a vertex on the left is connected to a set of vertices to its right; on the far right is another vertex, connected to another set of nodes, to its left. These two sets of nodes are connected in the middle, but we do not know which left nodes connect to which right ones. We construct a quantum walk on such a graph structure that allows us to gain a surprising amount of information, or completely determine permutations, often in a single pass over the graph. We detect classes of interesting properties of our walk on such unknown graphs. Classical walks cannot resolve some cases at all, implying a formally "infinite" speed up. This walk is an example of use of our recent framework for building quantum walks, based on classical walks with memory. The framework contains all major known walks, while it can also build walks on structures prohibitively difficult for current techniques.

K1.00132 Decoherence in a Dynamical Quantum Phase Transition , SARAH MOSTAME, Harvard University, GERNOT SCHALLER, TU Berlin, RALF SCHUETZHOLD, University of Duisburg-Essen — Motivated by the similarity between adiabatic quantum algorithms and quantum phase transitions, we study the impact of decoherence on the sweep through a second-order quantum phase transition for the prototypical example of the Ising chain in a transverse field. For site-independent and site-dependent coupling strengths as well as different operator couplings, the results show that (in contrast to first-order transitions) the impact of decoherence caused by a weak coupling to a rather general environment increases with system size which might limit the scalability of the corresponding adiabatic quantum algorithm. We also propose a physical setup that can be used to simulate the quantum dynamics of the Ising model.

K1.00133 Quantum Phase Transitions in Cavity Coupled Dot systems , VIJAY KASISOMAYAJULA, ONOFRIO RUSSO, New Jersey Institute of Technology — We investigate a Quantum Dot System, in which the transconductance, in part, is due to spin coupling, with each dot subjected to a biasing voltage. When this system is housed in a QED cavity, the cavity dot coupling alters the spin coupling of the coupled dots significantly via the Purcell Effect. In this paper we show the extent to which one can control the various coupling parameters: the inter dot coupling, the individual dots coupling with the cavity and the coupled dots coupling with the cavity as a single entity. We show that the dots coupled to each other and to the cavity, the spin transport can be controlled selectively.[1] We derive the conditions for such control explicitly. Further, we discuss the Quantum phase transition effects due to the charge and spin transport through the dots.[2] The electron transport through the dots, electron-electron spin interaction and the electron-photon interaction are treated using the Non-equilibrium Green's Function Formalism.

K1.00134 Efficient control of the NV center spin in diamond[1] , ZHI-HUI WANG, Ames Laboratory US DOE, DOMENICO D'ALESSANDRO, Iowa State University, Dept. of Mathematics, VIATCHESLAV DOBROVITSKI, Ames Laboratory, US DOE — Fast and accurate control of the spin of a nitrogen-vacancy (NV) center in diamond is a key for realization of diamond-based quantum information processing. We investigate time-optimal rotation [1] of a qubit implemented with the spin of a NV center. We examine performance of the control, and show that one can achieve a gain of 25% in rotation time compared to the broadly used rotating wave approximation. At certain values of the bias field, noticeable population accumulates on the third energy level and the fidelity of the control is degraded. We show that this is due to the transitions induced by the higher-order harmonics in the control field, which can be suppressed by frequency filtering of the control field at the expense of increased rotation time.

[1]Work at Ames Laboratory was supported by the Department of Energy - Basic Energy Sciences under Contract No. DE-AC02-07CH11358

K1.00135 Observation of σ_x coupling signal in a gap-tunable flux qubit , XIAOBO ZHU, NTT Basic Research Laboratories, ALEXANDER KEMP, SHIRO SAITO, HAYATO NAKANO, KOUICHI SEMBA — We experimentally demonstrate the *in situ* tunability of the gap of a superconducting flux qubit, which was achieved by replacing the smallest Josephson junction of the qubit with a dc-SQUID. We observe different gaps as a function of the external magnetic pre-biasing field and the local magnetic field through the dc-SQUID controlled by high-bandwidth on chip control lines. The persistent current and gap behavior agree well with the numerical simulation results. We set the sensitivity of the gap on the control lines during the sample design stage. With a tuning range of several gigahertz on a qubit dynamics timescale, we observe coherent system dynamics at the degeneracy point [1]. We measured the microwave amplitude dependence of Rabi frequency at the same resonant frequency but at different flux bias of the gap-tunable flux qubit. It showed a systematical deviation between these two set of data, which indicated we observed σ_x coupling signal between the flux qubit and the microwave-line. Different from conventional σ_z coupling, this σ_x coupling has a remarkable merit toward realization of idea QND measurement.

K1.00136 Characterization of flux-driven Josephson parametric amplifiers[1] , A. BAUST, E.P. MENZEL, T. NIEMCZYK, E. HOFFMANN, M. HAEBERLEIN, F. DEPPE, A. MARX, R. GROSS, Walther-Meissner-Institut and TU Muenchen, Garching, Germany, E. SOLANO, Universidad del Pais Vasco and IKERBASQUE Foundation, Bilbao, Spain, K. INOMATA, RIKEN, Wako, Japan, T. YAMAMOTO, Y. NAKAMURA, NEC, Tsukuba and RIKEN, Wako, Japan — Phase sensitive linear amplifiers receive increasing interest for applications in the field of circuit QED as they allow for the amplification of one signal quadrature without, in principle, adding noise. The flux-driven Josephson parametric amplifier characterized in this work is formed by a SQUID- terminated transmission line resonator with resonant frequency that can be varied by applying an ac magnetic flux signal through the SQUID. We have characterized two Josephson parametric amplifiers with different design parameters with respect to the center frequency and quality factor of the resonator, phase-dependent and phase-independent gains, as well as compression points and bandwidths.

K1.00137 Towards ultrastrong coupling of superconducting transmission line resonators[1] , F. DEPPE, T. WEISSL, E. HOFFMANN, M. HAEBERLEIN, A. BAUST, Walther-Meissner-Institut and TU Muenchen, Garching, Germany, E. MENZEL, M. SCHWARZ, T. NIEMCZYK, A. MARX, Walther-Meissner-Institut, Garching, Germany, D. ZUECO, CSIC-Universidad de Zaragoza, Zaragoza, Spain, J. J. GARCIA RIPOLL, Instituto de Fisica Fundamental, CSIC, Madrid, Spain, R. GROSS, Walther-Meissner-Institut and TU Muenchen, Garching, Germany — Coupled superconducting transmission line resonators have potential applications in quantum information processing and fundamental quantum mechanics. Experimentally, high coupling strengths are desirable for a clear demonstration of quantum effects. We achieve coupling strengths of 10% of the resonator frequency (ultrastrong coupling) by distributed coupling. We find that, differently from the case of point-like coupling, the normal modes are no longer arranged symmetrically with respect to the single resonator frequency. Nevertheless, a detailed theoretical analysis shows that the system can still be described by a beam splitter Hamiltonian for two effective resonators. We expect that this result will allow for straightforward experimental access to exciting effects such as thermal entanglement in our samples.

K1.00138 Observation of 0.2 ms Lifetime in a Cooper-pair Box , Z. KIM, B. SURI, V. ZARETSKEY, Dept. of Physics, Univ. of Maryland, S. NOVIKOV, K. OSBORN, A. MIZEL, Lab. for Physical Sciences, F. WELLSTOOD, JQI, CNAM, Dept. of Physics, University of Maryland, B. PALMER, Lab. for Physical Sciences — We have coupled a quasi-lumped element superconducting microwave resonator with a resonant frequency of 5.44 GHz to an Al/AlO_X/Al Cooper-pair box (CPB) charge qubit. The resonator is in turn weakly coupled to a transmission line and shows no higher resonant modes up to 20 GHz. By monitoring perturbations of the resonant frequency, we have measured the spectrum and lifetime (T_1) of the CPB at the charge degeneracy point while the CPB was detuned from the resonator by up to 3.5 GHz. The maximum T_1 of the CPB was 200 μs for $f = 4$ to 4.5 GHz, while T_1 decreased to 4 μs around 8 GHz. Our measured T_1's imply that the loss tangent in the AlO_X junction barrier must be less than about 4×10^{-8} at 4.5 GHz, about 4 orders of magnitude less than reported in larger area Al/AlO_X/Al tunnel junctions.

K1.00147 MAGNETISM (EXPERIMENT, THEORY, APPLICATIONS) –

K1.00148 Impurity effects in excitonic insulators[1] , JIAN LI, Texas Center for Superconductivity, University of Houston, Houston, Texas 77204, NINGNING HAO, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, PR China, BEIJING NATIONAL LABORATORY FOR CONDENSED MATTER PHYSICS TEAM — Both nonmagnetic and magnetic impurity effects in spin singlet and triplet excitonic insulators were investigated. The bound state energies caused by single impurity were given. The different compositions of the bound states can be used to detect the symmetry of the excitonic insulators. In finite concentration problems, nonmagnetic impurities showed same pair-breaking effect in singlet and triplet excitonic insulators while magnetic impurities showed weaker pair-breaking effect in triplet excitonic insulators than in singlet ones. The pair-breaking effects suppressed the ferromagnetic range via doping and gave a natural explaination for experimental results.

[1]This work was financially supported by NSFC, CAS and 973-project of MOST of China.

K1.00149 Origins of Asymmetric Magnetization Reversal in Exchange Biased Multilayers[1] , YANG LIU, SHUOGUO WANG, YANG LI, NING CHEN, SHUAI LIU, MINGHUA LI, GUANGHUA YU, DEPARTMENT OF MATERIALS PHYSICS AND CHEMISTRY, UNIVERSITY OF SCIENCE AND TECHNOLOGY BEIJING TEAM, STATE KEY LABORATORY OF MAGNETISM, BEIJING NATIONAL LABORATORY FOR CONDENSED MATTER PHYSICS, INSTITU TEAM, UNIVERSITY OF PUERTO RICO AT MAYAGUEZ TEAM — Novel asymmetric magnetization reversal behaviors (ARBs) as well as positive exchange bias (EB) are observed by using the alternating gradient force magnetometer (AGM) in both Co/FeMn bilayer with an oblique out-of-plane exchange anisotropy and the Co/FeMn bilayer in which Co layer has a quite heavy thickness. There are two different ARBs, arised from the ferromagnetic and the antiferromagnetic layer respectively under the perpendicular magnetization. Our results show that two intrinsic origins of the ARBs (i.e. the competing anisotropy and the inhomogeneity of the magnetic structure) coexist. Both of them are indispensable for the development of the ARBs in our Co/FeMn multilayers.

K1.00150 Magnetic properties of $FeCl_3$ investigated by ^{57}Fe NMR , BYEONGKI KANG, SOONCHIL LEE, KAIST — $FeCl_3$ crystallizes in a hexagonal layered structure and has a spiral antiferromagnetic phase below $T_N = 8.8K$, where the spins are spirally ordered with $2\pi/15$ period along [140] direction. It is reported that the magnetic phase changes to an order with two sublattices above $1.5T$ and there is a spin-flop transition above $4.0T$. We observed ^{57}Fe ferromagnetic nuclear magnetic resonance(NMR) signal for $FeCl_3$ for the first time at low temperature. The sublattice magnetization $M(T)$ obtained from the temperature dependence of the NMR frequency is well fit by the Bloch's T^2 law for antiferromagnets. The spectral change with external field provided a microscopic evidence for the spin-flop transition. The transition was not abrupt but progressive with increasing field.

K1.00151 Investigations of Exchange and Magnetic Anisotropic Interactions of Magnetic Ions in Antiferromagnetic Materials , ALEXANDER BAZHAN, P.L.Kapitza Institute for Physical Problems, RAS, ul. Kosygina 2, 119334 Moscow, Russia — Investigations of exchange and magnetic anisotropic interactions of magnetic ions, which determine antiferromagnetic orderings in materials, used in HTS, are of interest due to investigations of transformations of antiferromagnetic orderings, when additional two dimensional systems of correlated electrons, holes carriers are introduced. Discussions of states, which can appear before HTS, are of interest in such investigations. In experimental investigations of, determined by exchange and magnetic anisotropic interactions, magnetic phase transitions, investigations of separate components of samples magnetic moments, which determine orientations of samples magnetic moments, are useful. Investigations of, determined by orientations of ordered magnetic moments, magnetic phase transitions in antiferromagnetic materials and states with weak ferromagnetism at selected orientations of ordered magnetic moments in antiferromagnetic materials using vector vibrating sample magnetometer with horizontal magnetic field, up to 90kOe, and liquid helium temperatures, which can investigate separately magnetic field dependencies of three perpendicular components of samples magnetic moments, demonstrate possibilities of such magnetometers in investigations of exchange and magnetic anisotropic interactions of magnetic ions.

K1.00152 Kinetic properties of small one-dimensional Ising magnetic , VLADIMIR UDODOV, DMITRIY SPIRIN, Katanov Khakas State University, KATANOV KHAKAS STATE UNIVERSITY TEAM — Within the framework of a generalized Ising model, a one-dimensional magnetic of a finite length with free ends is considered. The correlation length critical exponent ν and kinetic critical exponent z of the magnet is calculated taking into account the next nearest neighbor interactions and the external field. Of special interest are non-equilibrium processes taking place within the critical temperature interval, which are characterized critical exponent y and dynamic critical index z. Due to significant difficulties encountered in the experimental investigations (e.g., measurement of z), a natural solution to this complex problem would be modeling of those non-eqilibrium processes. This work addresses non-equilibrium processes in one-dimensional magnetics. Using the Monte Carlo method, an equilibrium critical exponent of the correlation length ν and the dynamic critical index z are calculated for a finite-size magnetic.

K1.00153 On the critical behaviour of two-dimensional liquid crystals , ANA I. FARIÑAS-SÁNCHEZ, Departamento de Fisica, Universidad Simon Bolivar, Venezuela, ROBERT BOTET, Laboratoire de Physique des Solides, Universite Paris-Sud, France, BERTRAND BERCHE, Groupe de Physique Statistique, Institut Jean Lamour, France, RICARDO PAREDES, Laboratorio de Simulacion, Instituto de Matematicas. Unidad Cuernavaca. UNAM, Mexico — The Lebwohl-Lasher (LL) model is the traditional model used to describe the nematic-isotropic transition of real liquid crystals. In this paper, we develop a numerical study of the temperature behaviour and of finite-size scaling of the two-dimensional (2D) LL-model. We discuss two possible scenarios. In the first one, the 2D LL-model presents a phase transition similar to the topological transition appearing in the 2D XY-model. In the second one, the 2D LL-model does not exhibit any critical transition, but its low temperature behaviour is rather characterized by a crossover from a disordered phase to an ordered phase at zero temperature. We realize and discuss various comparisons with the 2D XY-model and the 2D Heisenberg model. Having added finite-size scaling behaviour of the order parameter and conformal mapping of order parameter profile to previous studies, we analyze the critical scaling of the probability distribution function; hyperscaling relations and stiffness order parameter and conclude that the second scenario (no critical transition) is the most plausible.

K1.00154 Re-entrant spin glass state in $(Ce_{1-x}Tb_x)Fe_2$ compounds , A. HALDAR, K.G. SURESH, Department of Physics, Indian Institute of Technology Bombay, Mumbai- 400076, India, A.K. NIGAM, Tata Institute of Fundamental Research, Homi Bhabha Road, Mumbai- 400005, India — Doped $CeFe_2$ compounds are well known for their unique features like first order magneto-structural transition, metastability, supercooling/superheating effects, phase co-existence, glassiness etc. $4f$ band magnetism and the antiferromagnetic ground state as a consequence of this are the interesting features of this system Though doping at the Fe site has been studied extensively, the effect of rare earth (R) substitution at the Ce site is not investigated in detail. We have recently shown that Er substitution causes a spin glass state below its ordering temperature. In this paper, we show that a similar re-entrant spin glass (RSG) phase can be achieved with Tb substitution as well. Characteristic experimental evidences, like large thermo-magnetic irreversibility and strong frequency dependence of ac-susceptibility have been observed. Spin freezing temperature has been found to obey critical slowing down mechanism with relaxation time of the order of 10^{-6}s. The relaxation behavior is also investigated using time variation of dc magnetization. Theoretical fitting of the relaxation data suggests that that the RSG state is made of clusters and not of atomic moments. The RSG state is attributed to the random substitution of Tb in the nearly nonmagnetic Ce sublattice and the modulation of the R-Fe exchange.

K1.00155 The first-Order phase transition in β-MnO_2 studied by ^{55}Mn Nuclear Magnetic Resonance , CHANGSOO KIM, EUNA JO, SOONCHIL LEE, Korea Advanced Institute of Science and Technology — β-MnO_2 has a conductivity due to negative charge carriers generated from slight off-stoichiometry of oxygens. We obtained 55Mn antiferromagnetic nuclear magnetic resonance (NMR) signal for β-MnO_2 at low temperature for the first time. The resonance frequency of the main peak centered at 254 MHz is nearly unchanged from 4.2 K to 130 K though it is known that the magnetic phase changes near 94 K from the antiferromagnetic state to the paramagnetic state. This suggests that the magnetic phase transition is a first order transition and the mixed phases coexist both below and above the phase transition temperature. Side peaks were found at 161 MHz, 181 MHz and 297 MHz. Through annealing β-MnO_2, which generates oxygen defects, we investigated whether these peaks originate from manganese ions with their valence other than 4+. However, the NMR spectra of the annealed β- MnO_2 showed no difference in side peaks.

K1.00156 ^{55}Mn NMR for Antiferromagnetic α-Mn_2O_3 , EUNA JO, KAIST, CHANGSOO KIM, SOONCHIL LEE, KAIST — The zero-field ^{55}Mn NMR spectrum for antiferromagnetic α-Mn_2O_3 was measured at low temperatures. Manganese sesquioxide (Mn_2O_3) is used in combustion catalysis, a method of reducing the emissions of organic compounds and nitrous oxide from waste gas, as an environmentally - friendly and inexpensive catalyzer instead of Pt and Pd. The magnetic moment estimated from the resonance frequency was $2.6\mu_B$ per Mn^{3+} ion. The temperature dependence of the sublattice magnetization fits not Bloch's T^2 law well but the exponential form applicable because there is an initial energy gap in the dispersion relation of the spin wave. From the fitting, an energy gap of 1.82 meV and an anisotropy energy of 0.22 meV were obtained. The spin-spin relaxation rate was measured as a function of the frequency and the Suhl-Nakamura interaction is suppressed by this energy gap.

K1.00157 Hysteresis in weak ferromagnets[1] , YA. B. BAZALIY[2], University of South Carolina, L.T. TSYMBAL, O. Galkin Donetsk Physics and Technology Institute, G.N. KAKAZEI[3], Universidade do Porto, S.V. VASILIEV, O. Galkin Donetsk Physics and Technology Institute — Magnetic hysteresis is studied in the orthoferrites ErFeO3 and TmFeO3 using the single crystal samples of millimeter dimensions. It is shown that in both materials one observes a temperature transition manifesting itself through the temperature hysteresis of the magnetic moment and a peculiar temperature evolution of the field hysteresis loop shapes near this transition. Experiments rule out the hypothesis that the ordering of the orthoferrite's rare earth magnetic moments plays an important role in these phenomena. The hysteresis curves can be explained by a few-domain magnetic state of the samples that results from the weak ferromagnetism of the orthoferrites. The phenomenon is generic for weak ferromagnets with temperature dependent magnetization. A large characteristic magnetic length makes the behavior of the relatively big samples analogous to that observed in the nano-size samples of strong ferromagnets.

K1.00158 Measurements of charge localization effects in uranium and plutonium intermetallic compounds from $L_{\rm III}$ X-ray absorption spectroscopy , YU JIANG, C.H. BOOTH, Lawrence Berkeley National Laboratory, E.D. BAUER, J.N. MITCHELL, P.H. TOBASH, J.D. THOMPSON, J.L. SARRAO, Los Alamos National Laboratory, M.A. WALL, P.G. ALLEN, Lawrence Livermore National Laboratory, D. NORDLUND, Stanford Synchrotron Radiation Lightsource — At the heart of the complex behavior of $5f$-electrons in uranium and plutonium is the variable localization of the $5f$ orbital. Plutonium, in particular, can behave like a localized lanthanide system or a delocalized transition-metal system, depending on its coordination environment. This behavior gives rise to a variety of novel physical properties in U and Pu compounds: unexpected magnetic susceptibilities, non-Fermi-liquid behavior, superconductivity, etc. To understand the dual nature of U and Pu $5f$ orbitals, we report measurements of the actinide $L_{\rm III}$-edge X-ray absorption spectra, including high-resolution partial fluorescence yield measurements, for a wide variety of intermetallics, including α-U, $UCoGa_5$, UCd_{11}, $\alpha-$ and $\delta-$Pu, $PuCoGa_5$, and $PuCoIn_5$. A systematic shift of the $L_{\rm III}$-edge energy is observed, and is correlated to the Sommerfeld coefficient from heat capacity measurements. Based on these results, we argue that this type of experiment is a direct measure of the degree of $5f$ orbital localization for U and Pu.

K1.00159 Anisotropic magnetic behavior of single crystalline CeGe , SUDESH DHAR, PRANAB KUMAR DAS, NEERAJ KUMAR, ARUMUGAM THAMIZHAVEL, RUTA KULKARNI, Condensed Matter Physics and Materials Science, Tata Institute of Fundamental Research, Mumbai — We report the anisotropic magnetic properties of a Czochralski grown single crystal of CeGe, which crystallizes in the orthorhombic structure with the space group Pnma (#63). The compound orders antiferromagnetically at TN = 10.9 K, in agreement with the value reported previously on a polycrystalline sample. A metamagnetic transition at $\sim$ 6.5 T followed by saturation at higher fields is observed along [010], the easy axis of magnetization. The heat capacity data confirm the bulk nature of magnetic ordering with a peak of nearly 13 J/mol K at 10.9 K. The peak decreases in height and shifts to lower temperatures in applied magnetic field, consistent with the antiferromagnetic ordering of Ce ions. Subtraction of phonon heat capacity, as measured for LaGe, reveals a broad hump around 30 K, suggesting the existence of low lying crystal electric field levels, which is well reproduced by two doublets located at 45 and 152 K, respectively. The electrical resistivity shows normal metallic behavior indicating the absence of Kondo interaction. At TN the resistivity measured along the three principal directions shows an upturn which is tentatively attributed to the gaps opened in the antiferromagnetic state. A magnetic phase diagram has been constructed based on the magnetization data.

K1.00160 Spin-polarization and transmission properties in heterostructures with magnetic nano elements , ARMEN KOCHARIAN, Department of Physics, California State University, AVAG SAHAKYAN, RUZAN MOVSESYAN, The State Engineering University of Armenia — The problem of electron resonant and non-resonant scatterings on two magnetized barriers is studied in the one-dimension. The transfer-matrix is built up to exactly calculate the coefficient of the electron transmittance through the system of two magnetic barriers with non-collinear magnetizations. The polarization of the transmitted electron wave for resonance and non-resonance transmittances is calculated [Kocharian, et al, JMMM 322, L42, 2010]. The transmittance coefficient and spin polarization can be drastically enhanced and controlled by the angle between the barrier magnetizations. Our result for spin transmission is analogous to Malus's law for passing light polarization through crossed polarizers. This provides efficient control of spin polarization via the applied magnetic field which is an apparent manifestation of the spin- valve effect. The strong dependence of magnetoconductance on the non-colinearity angle in two magnetized barriers resembles the corresponding effects in noncollinear spintronics for a number of other magnetic multilayer heterostructured systems and layered magnetic nanostructures.

K1.00161 Nb doped TiN as a superconducting electrode for spin polarization measurements of oxides , DIPANJAN MAZUMDAR, MANJIT PATHAK, XING ZHONG, VIJAY KARTIK, ARUNAVA GUPTA, PATRICK LECLAIR, Center for Materials for Information Technology, University of Alabama, Tuscaloosa, AL 35487, MINT ALABAMA SPINTRONICS TEAM — Spin Polarized tunneling (SPT) measurements are an unambiguous way of measuring the interface spin polarization (SP) of oxide thin films and interfaces. SPT uses a superconducting electrode as a spin detector, probing within $\sim$1 meV of the Fermi level. However the commonly used superconductor, namely Al, is not suitable for oxides due to its strong chemical affinity for oxygen. Nitrides like TiN and NbN alleviates this problem. Here we propose the use of Nb doped TiN. The critical temperature (T_c) and magnetic field (H_c) for TiN are too low for practical SPT measurements. While NbN has a higher T_c and H_c, its high spin-orbit scattering rate makes it less ideal for SPT [1]. TiNbN should provide a sufficiently high H_c and T_c while maintaining a sufficiently low spin-orbit scattering rate for high-resolution SPT measurements. We present measurements of known high SP oxides ($LaSrMnO_3$) and of all-oxide spin-filter devices (LSMO/STO/NFO).

K1.00163 Investigation of spin torque driven magnetization reversal in elliptical elements[1] , ANGELIQUE MONTGOMERY, CLAUDIA K.A. MEWES, TIM MEWES, The Unversity of Alabama — Spin transfer torque [1, 2] can be utilized to switch the magnetization in small ferromagnetic elements, which can be used to implement a magnetic random access memory [3]. One crucial parameter for spin torque switching is the critical current required to achieve switching. To investigate spin transfer torque we simulate the magnetization dynamics using our Matlab based micromagnetic code (M^3), which uses a fast Fourier transform method to evaluate the longrange magnetostatic field, exchange interaction is implemented using 6, 12 or 26 neighbor methods [4] and also includes adiabatic and non-adiabatic spin torque terms. We have performed simulations using different mesh sizes to examine the influence of the cell size on the micromagnetic results. We have investigated the influence of the current density and pinned layer orientation on the magnetization dynamics and in particular on the switching time.

K1.00164 Demagnetization field distribution in paramagnetic materials , NEIL BAUMANN, MICHAEL MALLERNEE, ROSS DICKINSON, GUOQING WU, Physics Department, University of West Florida, Pensacola, FL 32514 — A general method for the calculation of distribution of demagnetization field in paramagnetic materials is described, and the demagnetization field is calculated for samples with rectangular geometries. The results show high non-uniformity for the demagnetization field inside the sample depending on the sample aspect ratio and the direction of the externally applied magnetic field. Application is made to the modeling of the NMR spectra, providing good fit to the measured NMR spectra.

K1.00165 Magnetic Damping in Individual Cobalt Nanoparticles[1] , WENCHAO JIANG, Georgia Tech, FELIPE TIJIWA BIRK, DRAGOMIR DAVIDOVIC — Magnetization precession in ferromagnets is subject to damping by means of coupling between the magnetization and the environment. In a ferromagnetic metallic particle, the damping changes in a fundamental way when the electron-in-a-box level spacing becomes larger than the magnetization precession energy. Damping has crucial significance in magnetic storage technology, so understanding its size dependence is important for the miniaturization of electronics. Here, we present an electron tunneling technique to study damping in single Cobalt nanoparticles tunnel coupled to non-magnetic leads. Injecting a tunnel current into the particle raises its magnon temperature and induces magnetization dynamics. Tunnel currents as low as a few pA are able to excite or even reverse the particle's magnetization. Using the magnetic switching field as a magnon thermometer, we obtain very low values (10^{-8}) for the dimensionless damping parameter, α, indicating weak dissipative coupling to the environment.

K1.00166 Thin Film Study of YFeO3 Deposited Via Pulsed Laser Deposition for Use in Spintronic Applications , ADAM HINCKLEY, RAM GUPTA, YESAPPA KOLEKAR, KARTIK GHOSH, PAWAN KAHOL, Missouri State University — Recently, rare-earth orthoferrites have received much attention. Their propensity for multiferroic capabilities could play a key role in the fabrication of an efficient spintronic system. Such materials as BiFeO3 and CeFeO3 have already shown promise for uses in microphotonics as well as acting as spin valves, where YFeO3 has been shown to exhibit weak ferromagnetic tendencies in bulk. However, research conducted on the magnetic and electrical properties of YFeO3 thin films are sparse and in need of further investigation. Hence we have developed bulk YFeO3 for the purpose of investigating these thin film properties. Films will be grown via KrF Pulsed Laser Deposition on LaAlO3 substrates due to their similar lattice constant values and characterized via X-Ray Diffraction, Hall Effect Analysis and SQUID Magnetometer examinations. Previous SQUID results from the bulk material display an inverted hysteresis loop, indicating the existence of differing magnetic phases in bulk. Our goal is to examine the effects from thin film construction on these magnetic phases and examine whether thin films of YFeO3 exhibit a coupling between magnetic and electrical phases. This work is supported by National Science Foundation (Award Number DMR- 0907037).

K1.00167 Quntum beat generated by an acoustic wave in single-molecule magnets , GWANG-HEE KIM, Sejong University, Seoul 143-747, South Korea — The Spin oscillation is studied for the case where a standing acoustic wave is delivered to two level states in single-molecule magnets. In order to obtain such states, we first saturate the sample in strong negative magnetic field and increase the field until it reaches zero. Maintaining zero field, we begin to apply the standing acousitc wave to the sample and see the change of the magnetization between the ground state and the excited state. Taking $\langle S_z \rangle$ averaged over the wavelength of the sound where $\langle S_z \rangle$ is the expectation value of the projection of the spin onto the easy anisotropy axis, we present the analytic form of $\langle S_z \rangle$ at $\hbar\omega = \Delta$ where ω is the frequency of sound and Δ the energy gap between two states. In addition, we find the optimal condition for quatnum beat strucuture and discuss the possibility of the future experiment.

K1.00168 Unusual Magnetic Behaviors with Large Anisotropy and 1/3 Magnetization Plateau in the CoV_2O_6 , S.-Y. PARK, T.-H. JANG, Department of Physics, Pohang University of Science and Technology, Pohang 790-784, Korea, B.-G. PARK, Pohang Accelerator Laboratory, Pohang University of Science and Technology, Pohang 790-784, Korea, K.-P. HONG, Korea Atomic Energy Research Institute, Daejon 350-600, Korea, Y.-H. JEONG, Department of Physics, Pohang University of Science and Technology, Pohang 790-784, Korea — The pseudo-one dimensional brannerite type CoV_2O_6 has been studied by magnetization measurement, heat capacity and neutron powder diffraction between 300 and 1.5K. CoV_2O_6 crystallizes in two modifications; a low-temperature γ- form of triclinic structure and high-temperature α-form of monoclinic structure. α-CoV_2O_6 of monoclinic structure shows a large magnetic anisotropy and an antiferromagnetic transition at T_N=14K. Furthermore, the magnetization measurement up to 9T shows 1/3 magnetization plateau below 10K and saturated magnetic moment $4.5\mu_B/Co^{2+}$, which is much larger than the spin-only value of $3.0\mu_B/Co^{2+}$ for the full moments of Co^{2+} ions. On the contrary, γ-CoV_2O_6 of triclinic structure shows saturated magnetic moment $3.0\mu_B/Co^{2+}$ with antiferromagnetic trantion at T_N=6.2K. We discuss the different magnetic behaviors of the α- and γ- phase of CoV_2O_6.

K1.00169 Magnetic Carbon Nanotubes Tethered with Maghemite Nanoparticles , IL TAE KIM, GRADY NUNNERY, KARL JACOB, School of Materials Science and Engineering, Georgia Institute of Technology, Atlanta, GA, 30332, JUSTIN SCHWARTZ, XIAOTAO LIU, National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL, 32310, RINA TANNENBAUM, School of Materials Science and Engineering, Georgia Institute of Technology, Atlanta, GA, 30332 — We describe a novel, facile method for the synthesis of magnetic carbon nanotubes (m-CNTs) decorated with monodisperse γ-Fe_2O_3 magnetic (maghemite) nanoparticles and their aligned feature in a magnetic field. The tethering of the nanoparticles was achieved by the initial activation of the surface of the CNTs with carboxylic acid groups, followed by the attachment of the γ-Fe_2O_3 nanoparticles via a modified sol-gel process. Sodium dodecylbenzene sulfonate (NaDDBS) was introduced into the suspension to prevent the formation of an iron oxide 3D network. Various characterization methods were used to confirm the formation of well-defined maghemite nanoparticles. The tethered nanoparticles imparted magnetic characteristics to the CNTs, which became superparamagnetic. The m-CNTs were oriented parallel to the direction of a magnetic field. This has the potential of enhancing various properties, e.g. mechanical and electrical properties, in composite materials.

K1.00170 The spin -1 anisotropic Heisenberg antiferromagnet on a square lattice at low temperatures[1] , ANTONIO PIRES, UFMG — In the last years the quantum two dimensional spin 1/2 Heisenberg antiferromangnet has been extensively studied. However, new physical features, such as quantum phase transitions, due to additional terms, as for instance single ion anisotropy, are possible when S = 1. Here we study the low temperature behavior of the quantum spin-1 Heisenberg antiferromagnet with exchange and single site anisotropies on the square lattice. The properties of the model change drastically as the single ions anisotropy D varies from very small to very large values. A quantum phase transition takes place at a critical value of D. Two techniques are used to study the model. In the low D region we use a self consistent harmonic approximation. For D above the critical value a bond operator formalism is used. We present the phase diagram for the model.

K1.00171 Critical theory of the topological quantum phase transition in the AKLT–SZH chain

, HONG-CHEN JIANG, Microsoft Research, Station Q, University of California, Santa Barbara, CA 93106, STEPHAN RACHEL, Yale University, Department of Physics, New Haven, CT 06520, ZHENG-YU WENG, Institute for Advanced Study, Tsinghua University, Beijing, 100084, P. R. China, SHOU-CHENG ZHANG, Department of Physics, McCullough Building, Stanford University, Stanford, CA 94305, ZHENGHAN WANG, Microsoft Research, Station Q, University of California, Santa Barbara, CA 93106 — We systematically study the phase diagram of $S = 2$ spin chain by means of density-matrix renormalization group and exact diagonalization. We find two gapped phases which are topologically distinct: the AKLT phase is characterized by $S = 1$ edge spins while the SZH phase by $S = 3/2$ edge spins. Except from a multicritical point where a direct topological quantum phase transition occurs, we identify a dimer phase between both gapped phases. The whole phase boundary between dimer and SZH phases, including the multicritical point, is a critical line with central charge $c = 5/2$. Finally, we propose and confirm that this line corresponds to $\mathrm{SO}(5)_1$ Wess–Zumino–Witten conformal field theory.

K1.00172 Deuterated vs Normal Hydrogen Magnetism of M (Mn,Co) Dichloride Monohydrate, and Crystal Structure

, S. PAGOLA, K.T. TROWELL, K.C. HAVAS, Z.D. REED, D.G. CHAN, G.C. DEFOTIS, College of William and Mary — Presented here are susceptibility data for fully deuterated forms of the title materials, and comparison with normal hydrogen forms. Also shown is the first structure determination for any monohydrate compound, for the Mn system with the simplest magnetic behavior to analyze. Interesting similarities and contrasts appear relative to normal hydrogen analogs. For the Co system the location of an enhanced susceptibility maximum, and its magnitude, match very well those of the normal hydrogen form. The deuterated Mn material shows a similar very broad susceptibility maximum as normal material, implying low-dimensional (probably d=1) magnetism, and with indication of a transition somewhat below T(max), presumably due to weak interchain interactions. But, the location of the maximum is at significantly lower temperature than in normal material, and the size is larger; both findings suggest a weaker intrachain interaction. Yet, the apparent transition, near 2.17 K, differs hardly at all in location from that in the normal material. The crystal structure determination for the normal Mn system provides the first evidence of a structural reason for the low dimensional magnetism observed, in that somewhat isolated magnetic chains are apparent.

K1.00173 Effects of Magnetic Correlation of Localized Spins in Graphene

, YURIY SEMENOV, JOHN ZAVADA, KOSTYANTYN BORYSENKO, KI WOOK KIM, Department of Electrical and Computer Engineering, North Carolina State University, Raleigh, NC 27695-7911 — Prior analysis of the indirect exchange interaction between localized spins (LS) in graphene reveals an alternate sign depending on whether two LS belong to the same graphene sublattice or not. Prompted by these findings, we explored the role of the carrier-impurity exchange interaction in formation of magnetic phase states in graphene with vacancies and modification in graphene-based composite structures. Analysis of free energy F shows the anti-ferromagnetic (AF) ordering with partial compensation of the magnetizations M_A and M_B in two graphene sublattices. The difference M_A-M_B is caused by difference of the number of LS randomly distributed over the sublattices A and B. This effect of weak ferromagnetism becomes significant in multi-domain structure, provided a mean domain size is around 2 μm; it can explain the available experimental results. The proximity to ferromagnetic dielectric layers in a sandwich configuration results in an indirect magnetic interaction that can be expressed in terms of exchange bias field. The latter strongly depends on vacancy concentration x and even can reverse the direction of exchange bias field with x increasing. At the temperature of AF ordering the minimum of F corresponds to a tilt of M_A and M_B and even a collapse of the AF vector.

K1.00174 Magnetic impurities in spin-spiral multiferroic materials

, TRINANJAN DATTA, Augusta State University — We investigate the effect of magnetic impurities in the magnetic-spiral-induced multiferroic phases using an effective multiferroic Hamiltonian. We model the impurities as a two- level system and consider the regimes when the impurity spins relax both slowly and fast. Using realistic material parameters we study the effect of impurities on ferroelectricity for varying impurity strength. We find that when the impurity strength is weak the electric polarization is not affected. However as the impurity strength is increased the amplitude of the host spin components is reduced and the ferroelectricity suppressed. We also discuss the role of impurities on a realistic multiferroic spin Hamiltonian for the rare-earth- metal Mn perovskites.

K1.00175 Magnetism of Co/Mn/Ni Dichloride Dihydrate[1]

, G.C. DEFOTIS, A.S. HAMPTON, J.M. POTHEN, T.J. WALLIN, E.A. WELSHHANS, K.C. HAVAS, K.T. TROWELL, College of William and Mary — Many unusual kinds of behavior have appeared in well selected binary magnetic mixtures. It is also of interest to explore suitable ternary mixtures. Surveyed here are magnetic susceptibility and magnetization measurements for a range of compositions of the title system. This is only the second ternary insulating mixed magnet to be examined with systematic composition variation. Intrachain exchange is ferromagnetic in the Co and Ni components and antiferromagnetic in the Mn (chemical/structural metal-dichloride...infinite chains). Interchain interactions are comparable in size to intrachain, and antiferromagnetic in each component. Competing interactions occur in mixtures, as well as different kinds of spin anisotropy. Remarkable variety appears in the form of susceptibility vs temperature plots for different compositions, reflecting effects of random mixing. Different compositions display a susceptibility maximum located differently from any pure component's, or two maxima, or no maximum. Magnetization vs field isotherms also display contrasting behavior for different compositions, and varying degrees of hysteresis.

K1.00176 Coercivity, Anisotropy, and Relaxation in Nanocrystalline $Gd_{1-x}Fe_x$ Alloys with $x \leq 0.3$[1]

, P.M. SHAND, A.L. MEYER, M.W. STREICHER, U. Northern Iowa, V.J. LITWINOWICZ, J.E. SHIELD, U. Nebraska, D.L. LESLIE-PELECKY, U. Texas at Dallas — We have performed extensive dc and ac magnetization measurements on nanocrystalline $Gd_{1-x}Fe_x$($x \leq 0.3$) alloys at temperatures below the ferromagnetic Curie temperature. The coercivity for all x values generally increases with decreasing temperature. The temperature variation is similar to that of unalloyed Gd; however, the size of the coercivity at a given temperature varies with x in a non-monotonic fashion. The anisotropy as a function of temperature was extracted by applying the random anisotropy model to magnetization vs. field data. The variation of the anisotropy with temperature was very similar to the behavior of the coercivity, indicating that anisotropy is the dominant mechanism that drives the coercivity. The imaginary part of the ac susceptibility exhibited a peak at low temperatures. The temperature T_p at which the peak occurred shifts with frequency in a manner analogous to a cluster glass. For a given frequency, T_p increases with x. These phenomena can be explained in terms of the microscopic structure of the $Gd_{1-x}Fe_x$ alloys, which consists of nanoscale grains of Gd surrounded by disordered grain-boundary regions where the Fe atoms preferentially locate.

K1.00177 Suppressing local hot spots due to eddy currents in magnetic coil systems[1]

, ZHEN YAO, AARON SHOJINAGA, YONG WU, Case Western Reserve University, SHMARYU SHVARTSMAN, TIMOTHY EAGAN, THOMAS CHMIELEWSKI, ViewRay Inc., ROBERT BROWN, Case Western Reserve University — A particular goal in magnetic field applications is to avoid eddy current heating in coils and shields. It is important, in MRI, for example, to avoid hot spots near the patient to be imaged as well as in the vicinity of soldering joints. We develop effective analytical formulas for the eddy current behavior of sources close to surrounding conductors, we verify these via numerical simulations, and we make successful comparisons to corresponding experimental temperature distributions. Optimized patterns of incisions made in the conductors are discovered for addressing particularly troublesome heating locations. The criteria include the need to minimize the number and length of the cuts. Theory and experiment are in agreement on the efficacy of this method for reducing steady-state temperatures. An example of results in the practical design of commercial coils and shields is that a single cut parallel to the long edge of rectangular conductors reduces the temperatures much more than making multiple cuts parallel to the short edge.

[1]Supported by Ohio Third Frontier Program

K1.00178 Anomalous remanent magnetization dependence of exchange bias effect in Ni50Mn37In13[1] , BAOMIN WANG, YONG LIU, School of Mechanical and Aerospace Engineering, Nanyang Technological University, 639798, Singapore, LAN WANG, Division of Physics and Applied Physics, School of Physical and Mathematical Sciences, Nanyang Technological University, 637371, Singapore — Here, we report an anomalous remanent magnetization dependence of exchange bias effect in Ni50Mn37In13 alloy. Both the value of exchange bias field and its sign can be tuned by the amplitude of remanent magnetization without changing its sign. This tunability is strongly dependent on the direction of initial magnetizing field for the hysteresis loop measurements. These results can be explained well by our recent proposal of isothermal field-induced transition from superspin glass to superferromagnetic state in Ni50Mn37In13 alloy.

[1]Support for this work came from Singapore National Research Foundation (RCA-08/018) and MOE Tier 2 (T207B1217).

K1.00179 Indirect spin-spin interaction mediated by cavity photons , GUILLERMO QUINTEIRO, Univ de Buenos Aires — I theoretically investigate the spin-spin indirect interaction mediated by photons, and compare the results with previous work on the indirect interaction mediated by excitons and/or polaritons in bulk semiconductor and two-dimensional cavities. The systems consist of a cavity, either 0D or 2D, containing two QDs, each one coupled to a donor impurity. The neutral QDs are excited by a cavity photon, and the resulting exciton interacts with the impurity via exchange between the electron in the donor and the electron in the exciton. In the case of a 2D cavity, where the system is optically excited by an off-resonance monochromatic laser field, I deduce an effective Ising Hamiltonian for the spin-spin interaction using a perturbation theory approach. In the case of a 0D cavity, the exact eigenvalues and eigenvectors of the complete Hamiltonian involving the donors, excitons and cavity photons were determined by numerical diagonalization. The eigenvectors and energies were then used to calculate the spin-spin correlation and an effective donor-donor Hamiltonian was deduced. The numerical calculations performed for all admissible values of the physical constants revealed that the in-plane or xy correlation is zero; thus, I concluded that the effective interaction is of the Ising type. In addition, I found that the largest effective coupling J_{eff} corresponds to a situation where the excitons and the cavity photon are completely mixed, forming a polariton.

K1.00180 Characterizing Multiferroics: Analyses through X-Ray Diffraction , EVAN WOLFE, HARLEY HART, SHELDON BLACKSHIRE, SRINIVAS POLISETTY, DISHENG CHEN, JINLING ZHOU, CHARLES FRYE, MIKEL HOLCOMB — Theory and experiments support that magnetoelectric coupling (electrical control of magnetism and vice versa) can be enhanced by taking advantage of interfacial coupling between magnetic and ferroelectric films. The interface between ferroelectric PZT and ferromagnetic LSMO is a promising candidate for storage and magnetic sensing devices. For example, LSMO, when exposed to a magnetic field, will contract; while PZT when strained will produce a voltage. Combining properties, the PZT/LSMO composite can be utilized to detect magnetic fields, and also be used as an energy scavenging device. In order to maximize the coupling across this interface, proper measurements and characterizations must be taken to detail how the materials interact on the atomic level. X-ray diffraction allows us to determine thickness, composite, and strain of the samples used. By analyzing the peak shift in XRD scans along our samples we can detail the amount of strain placed on the sample, aiding in discovering of the mechanisms responsible for interfacial magnetoelectric coupling. Through analysis, we can ensure the quality of the interface, thus allowing further advances for increases in magnetic sensitivity and higher voltage output.

K1.00181 Effect of annealing on the local structure of Fe and Co in CoFeB/MgO based magnetic tunnel junction: An extended X-ray absorption fine structure study , ABDUL RUMAIZ, Brookhaven National Laboratory, JOSEPH WOICIK, NIST, WEIGANG WANG, Johns Hopkins University, CHERNO JAYE, NIST, HASSNAIN JAFFARI, C.L CHIEN, JEAN JORDAN-SWEET, IBM T.J. Watson Research Center, JOHN XIAO, University of Delaware — The evolution of the local structure of Fe and Co as a function of annealing time in CoFeB/MgO/CoFeB magnetic tunnel junctions was studied using extended x-ray-absorption fine structure (EXAFS). EXAFS indicates B depletion and crystallization of the CoFeB layers within a few seconds of the post growth high temperature anneal. The decrease in first-shell Debye–Waller factor and hence the increase in structural order during annealing explains the increase in tunnel magnetoresistance observed as a result of post deposition annealing. Although the diffusion of B has also been confirmed by several other experiments, there has not been much consensus on where the B diffuses after high temperature anneal. Recent results from B Near edge x-ray absorption fine structure (NEXAFS) will also be discussed.

K1.00182 Anisotropy Energy, Spin-Atomic Vibration Interaction, and Spin-Flip Hamiltonian of a Single Atomic Spin in a Crystal Field , SATOSHI KOKADO, Faculty of Engineering, Shizuoka University, Japan, KIKUO HARIGAYA, Nanosystem Research Institute, AIST, Japan, AKIMASA SAKUMA, Graduate School of Engineering, Tohoku University, Japan — We derive the anisotropy energy $V_{\rm A}$, the spin-atomic vibration interaction $V_{\rm SA}$, and the spin-flip Hamiltonian $V_{\rm SF}$ of a single atomic spin system, "Fe^{2+} ($3d^6$) in a crystal field of tetragonal symmetry" [1,2]. We here apply the perturbation theory to a model with the spin- orbit interaction and the kinetic and potential energies of electrons. The model also takes into account the difference in vibration displacement between an effective nucleus and electrons, Δr. We first find conditions to enhance a coefficient $|D|$ of $V_{\rm A}$=$-|D|S_Z^2$, where D is an anisotropy constant and S_Z is the Z component of a spin operator. Second, we show that $V_{\rm SA}$ appears for $\Delta r \neq 0$, while $V_{\rm SF}$ is present independently of Δr. Also, the magnitudes of the coefficients of $V_{\rm SA}$ can be larger than those of the conventional spin-phonon interaction depending on vibration frequency.

[1] S. Kokado *et al.*, J. Phys. Soc. Jpn. **79**, 114721 (2010).

K1.00183 Synthesis and Analysis of Rare-Earth Nanoparticles Gd and Nd , JOSE AMARAL, CARMIN LIANG, DULCE ROMERO, PEI-CHUN HO, Physics/California State Univ, Fresno, SAEED ATTAR, Chemistry/California State Univ, Fresno, DENNIS MARGOSAN, USDA/Agriculture Research Service — We have synthesized sub-micron gadolinium particles using sodium borohydride reduction of gadolinium chloride in an inverse micelle solution of the surfactant didodecyldimethylammonium bromide (DDAB) and toluene. Gadolinium and neodymium are paramagnetic rare earth metals at room temperature and become ferromagnetic and anti-ferromagnetic below 293K and 19K, respectively. A liquid-liquid extraction using two immiscible solvents can separate the magnetic nanoparticles from unwanted by-products of the reduction. SEM images show spherical Gadolinium clusters less than one micrometer were produced. Nd nanoparticles do not synthesize using toluene and water and results using methanol and hexane are on-going. Magnetic nanoparticles can have enhanced magnetization and increased density in a finite region compared to their bulk material. Possible applications include high-density magnetic storage, high-density recording media, contrast agents to improve medical magnetic resonance imaging, and magnetic refrigeration.

K1.00184 High-temperature performance of bulk nanocomposite $SmCo_5$/-Fe(Co) magnets , CHUANBING RONG, NARAYAN POUDYAL, J. PING LIU, Department of Physics, University of Texas at Arlington, Arlington, TX 76019, USA, YING ZHANG, M.J. KRAMER, Division of Materials Science and Engineering, Ames Laboratory, Iowa State University, Ames, IA 50011, USA — Permanent magnetic materials capable of operating at elevated temperatures are highly required for advanced power systems. In this work, a new processing technique has been adopted to produce $SmCo_5$-based bulk nanocomposite magnets with high thermal stability. The processing consists of severe plastic deformation and warm compaction. The structure and high-temperature magnetic property characterizations show that the microstructure does not change with heating temperature up to 500 °C which ensures effective inter-phase exchange coupling at elevated temperature. It was also found that the thermal stability of the bulk nanocomposite magnets can be significantly improved with increasing density (decreasing porosity). The room temperature energy product drops fast with heating temperature above 300 °C for the magnets with 80% density, and with minimum decrease for the magnets with full density. Energy product about 11.1 MGOe can be obtained at 300 °C in the fully dense isotropic bulk $SmCo_5$/Fe nanocomposite magnets.

K1.00185 Unusual Structure and Magnetism in MnO Nanoclusters[1]

SHREEMOYEE GANGULY, Ph.D. student, S. N. Bose National Center for Basic Sciences, Kolkata, India, MUKUL KABIR, Postdoctoral researcher, MIT, USA, BIPLAB SANYAL, Associate Professor, Uppsala University, Sweden, ABHIJIT MOOKERJEE, Professor, S. N. Bose National Center for Basic Sciences, Kolkata, India — We report an unusual structural and magnetic evolution in stoichiometric MnO nanoclusters by an extensive and unbiased search through the potential energy surface within density functional theory. The $(MnO)_n$ nanoclusters adopt two-dimensional structures in size ranges in which Mn_n nanoclusters are three-dimensional and regardless of the size of the nanocluster, the magnetic coupling is found to be antiferromagnetic, and is strikingly different from Mn-based molecular magnets. Both of these features are explained through the inherent electronic structures of the nanoclusters.

[1]We gratefully acknowledge financial support from Swedish Research Links program funded by VR/SIDA and Carl Tryggers Foundation, Sweden.

K1.00186 The Effect of Magnetic Anisotropy on Colossal Electroresistance in Manganites[1]

ALESSANDRA GALLASTEGUI, RAFIYA JAVED, HYOUNGJEEN JEEN, AMLAN BISWAS, Department of Physics, University of Florida, Gainesville, FL 32611 — The combined effect of long range strain interactions and disorder on a first order transition leads to micrometer scale phase separation in hole-doped manganese oxides (manganites). The coexisting phases are ferromagnetic metallic (FMM), charge ordered insulating (COI), and paramagnetic insulating (PMI) and at certain temperatures these phases behave like a fluid under the influence of magnetic and electric fields. We will present magnetotransport data on nano/micro-structures of the manganite $(La_{1-y}Pr_y)_{0.67}Ca_{0.33}MnO_3$ (LPCMO) which show that the FMM phase behaves like a fluid in an electric field. In fact, due to the magnetic anisotropy of our materials, the behavior of the coexisting phases is reminiscent of a ferrofluid.

[1]NSF DMR-0804452

K1.00187 Metal-terminated carbon based nanostructures[1]

SAHAR MIRSHAMSI, YAN WANG, HAI-PING CHENG, Dep of Physics and Quantum Theory Project. Uni. of Florida — Carbon based structures have attracted immense interest in many different fields and among them graphene has attracted more attention because of its unique physical properties. Hybrid metal-Carbon nanostructures are of interest because of their electronic and magnetic properties. We have studied magnetic correlations at zigzag edges of metal terminated graphene nanoribbons by calculating the transverse and longitudinal fluctuations of magnetic moments from first-principles. With inclusion of non-collinear spin-orbit coupling, we have investigated the continuous rotation of the electron spin which occurs along the ribbon edges (spin waves). Also, we report here effects of edge disorders and finite size effects. Finally, we extend our model to include multiple layers and studying the inter-layer magnetic coupling and the effect to the inter-edge magnetic coupling of the ribbon.

[1]Supported by DOE/BES-DE-FG02-02ER45995 and NSF/DMR-0804407 and computed at UF-HPC center.

K1.00188 Temperature-dependent properties of the magnetic order in single-crystal $BiFeO_3$

V. KIRYUKHIN, M. RAMAZANOGLU, S-W. CHEONG, Rutgers Univ., W. RATCLIFF, NIST, S. LEE, KAERI — Neutron scattering studies of the magnetic structure of multiferroic $BiFeO_3$ are presented. We report temperature dependence of the magnetic order parameter, the period of the cycloidal modulation of the antiferromagnetic order, and the populations of the equivalent magnetic domains in the monodomain ferroelectric state. No anomalies below room temperature are found, excluding the spin-reorientation transitions proposed elsewhere.

K1.00189 Polarized micro Raman spectroscopy of multiferroic $BiFeO_3$ single crystals

C. BEEKMAN, University of Toronto, SANG-WOOK CHEONG, Rutgers University, KENNETH BURCH, University of Toronto — In Bismuth ferrite ($BiFeO_3$) antiferromagnetic and ferroelectric order parameters coexist at room temperature, making this material an excellent candidate for new functionalities, such as electrical control of ferromagnetism. Despite extensive reports on Raman scattering experiments on single crystals and thin films, controversy still remains in the observation and assignment of the phonon modes. However, proper Raman mode assignment to describe the phonons critical for the multiferroic behavior is necessary. We present polarized micro Raman spectroscopy of single crystals with uniform ferroelectric polarization. Careful examination of the Raman spectra upon crystal rotation enables us to unambiguously assign several (A_1, E_x and E_y) modes.

K1.00190 Effect of doping and strain on Néel temperature of Cr_2O_3: An ab initio study

SAI MU, ALEKSANDER WYSOCKI, KIRILL BELASHCHENKO, Department of Physics and Astronomy, University of Nebraska-Lincoln — Cr_2O_3 is a promising material for applications involving electrically switchable exchange bias [1]. For practical purposes it is desirable to enhance its Néel temperature (308K). Here we employ first principles calculations to elucidate the effect of substitutional doping and epitaxial strain on electronic structure and magnetism of Cr_2O_3. We use the supercell method and consider both transition metal (V, Ti, Mn, Fe, Co, Ni) and anion (N, B) impurities. We deduce the effect of doping on Néel temperature (T_N) by calculating the total energy change when the local moment on a transition metal impurity or on the Cr atoms near the anion impurity is flipped. We found that the transition metal impurities and N are detrimental to T_N. On the other hand, B impurities are expected to increase the Neel temperature.

K1.00191 High-pressure synthesis and unusual metallic conductivity of the A-site-ordered perovskite $CaCu_3Ir_4O_{12}$[1]

J.-G. CHENG, J.-S. ZHOU, J.B. GOODENOUGH, University of Texas at Austin — Recently, much attention has been paid to the A-site-order perovskites $AA'_3B_4O_{12}$ due to the observation of a large variety of intriguing physical properties. We have prepared an A-site-ordered perovskites $CaCu_3Ir_4O_{12}$ under 9 GPa and 1250 °C with a Walker-type Multianvil module. Rietveld refinements to the room-temperature x-ray diffraction pattern confirmed the cubic structure with lattice parameter a = 7.47380(6) Å in the space group Im-3. Magnetic and transport properties measurements show that $CaCu_3Ir_4O_{12}$ is a paramagnetic metal with unusual temperature dependence. The inverse magnetic susceptibility χ^{-1}(T) above 80 K follows the Curie-Weiss law with μ_{eff} = 4.23 μ_B/f.u. and θ_W = –233 K, while an unusual should-like feature is observed below 80 K. At the same temperature, the resistivity ρ(T) deviates from a T-linear behavior and exhibits a strong downward temperature dependence down to 4 K.

K1.00192 Magnetoresistance measurements in Ferro – Antiferromagnetic bilayers based on the Ca-doped lanthanum manganite system[1]

, M.E. GOMEZ, L. MARIN, G. RAMIREZ, Physics Department Universidad del Valle Cali, Colombia , P. PRIETO, CENM Colombia — We studied the isothermal magnetic field dependence of the resistance behavior in ferromagnetic–antiferromagnetic interface based on the Ca-doped lanthanum manganite system at temperatures below Neel temperature of the antiferromagnetic layer. We studied the influence of the thickness of the AF-layer, t_{AF}, and F-layer, t_F, on the ZFC and FC magnetoresistance (MR) in $La_{2/3}Ca_{1/3}MnO_3(t_F)$/ $La_{1/3}Ca_{2(3}MnO_3(t_{AF})$ bilayers. H_{FC} was 400 Oe and the applied magnetic field, H. We systematically varied the t_F and t_{AF} thickness, maintaining constant the total bilayer thickness ($d = t_F + t_{AF}$). We found that MR has hysteretic behavior as observed in $[La_{2/3}Ca_{1/3}MnO_3(t_F)/La_{1/3}Ca_{2(3}MnO_3(t_{AF})]_N$ superlattices, but; MR increases with the increasing field from H=0 to a maximum and then decreases continuously. This behavior also appears for negative fields in both ZFC and FC loops. The position and magnitude of the maximum is not symmetric with respect to the axis H=0.

K1.00193 Characterization of EuO_{1-x} thin films grown by oxidation of metallic Eu[1]

, B. COLWELL, A. KINSEY, S. SCHLOTTER, M. EBLEN-ZAYAS, Carleton College — EuO_{1-x} is of interest due to the similarities between its magnetic and transport properties and those of the manganites, and it also holds potential for spintronics applications. We have grown polycrystalline EuO_{1-x} films by oxidizing metallic Eu films. The films are characterized by x-ray diffraction, as well as measuring the resistivity and magnetization responses as a function of temperature. We will report on the relationship between the growth conditions and the properties of these samples, including a description of how annealing impacts the film properties.

[1]This work has been supported by the Research Corporation and NSF DMR-0804715.

K1.00194 Composition Dependence of the Anomalous Hall Effect in L10 FePt Thin Films[1]

, M. ALLISON, T. GEORGE, P. KHAREL, D. SELLMYER, Y. HUH, Department of Physics, South Dakota State University — FePt multi-layered thin film systems were investigated as to its composition effect on the anomalous hall effect. Thin bilayers of FePt were sputter-deposited in series of variable thicknesses on to a thermally oxidized substrate of SiO2. The total thickness of samples was controlled to be 12 nm. XRD and SEM were used to confirm structure and composition of thin films for systematic characterization. Resistivity and Magnetization measurements were studied at room temperature and low temperature using SQUID magnetometer. The minimal resistivity exists near 54% of Fe concentration. The anomalous hall effect dominates as Fe concentration increases. Hall angles drop rapidly at the both high and low Fe concentration while it exhibits a plateau-like dip near 54% of Fe concentration.

K1.00195 Imaging and Electric Control of Boundary Magnetization and Exchange Bias in Chromia and Chromia/CoPd

, XI HE, Univ. of Nebraska, Lincoln, NE, NING WU, Univ. of Nebraksa, Lincoln, NE, YI WANG, ALEKASANDER WYSOCKI, TAKASHI KOMESU, KIRILL BELASHCHENKO, PETER DOWBEN, CHRISTIAN BINEK, Univ. of Nebraska, Lincoln, NE, UDAY LANKE, Canadian Light Source Inc., Saskatoon, Canada, ANTHONY CARUSO, Univ. of Missouri, Kansas City, ELIO VESCOVO, Brookhaven National Lab. NY — Promising spintronic concepts utilize electric control of boundary magnetization. Symmetry arguments predict that the magnetoelectric antiferromagnet (AF) Cr_2O_3, has a roughness insensitive surface magnetization which is coupled to the bulk AF order parameter. We provide macroscopic and microscopic evidence for this surface magnetization and its electric control. The latter is exploited in perpendicular exchange bias heterostructures where a ferromagnetic Pd/Co multilayer is deposited on the (0001) surface of a Cr_2O_3 single crystal. These heterostructures show reversible, room-temperature voltage-controlled switching of the exchange-bias field between positive and negative values.[1] This work is supported by NSF Career, NSF MRSEC, NRI, and Research Corporation.

K1.00196 Effect of carbon doping on optical constants of half-metallic ferromagnet Mn_5Ge_3

, N. STOJILOVIC, University of Wisconsin Oshkosh, RONGWEI HU, The Johns Hopkins University, C. PETROVIC, Brookhaven National Laboratory, S.V. DORDEVIC, The University of Akron — Mn_5Ge_3 is an intermetallic ferromagnetic compound with the high Curie temperature (T_C = 296 K), a high spin polarization (P = 42%), and a good lattice match to germanium. Doping of Mn_5Ge_3 with carbon increases T_C above room temperature and makes these compounds promising candidates for spin injectors for potential spintronics applications. In this study we employ optical spectroscopy to measure near-normal reflectance in the frequency range from far-infrared to ultraviolet (70 – 50000 cm^{-1}) at temperatures between 10 and 300 K. In particular, we study the effect of carbon doping on the optical constants to gain a better insight into how it affects the electronic properties of the parent compound.

K1.00197 Spin polarization measurements in Fe_4N/MgO/NbN tunnel junctions using quasiparticle tunneling spectroscopy

, TAKAYUKI HOHJO, KEITA SAKUMA, TETSUYA MIYAWAKI, KENJI UEDA, Department of Crystalline Materials Science, Nagoya University, HIDEFUMI ASANO, YOSUKE KOMASAKI, MASAKIYO TSUNODA, Department of Electronic Engineering, Tohoku University — In spintronic applications, it is thought that Fe_4N is useful because it has been theoretically expected to have high spin polarization. Fe_4N/MgO/CoFeB magnetic tunnel junctions (MTJs) were fabricated, and an inverse tunnel magnetoresistance (TMR) effect was reported by our groups. However, spin polarization of Fe_4N is yet incompletely understood. We investigated spin polarization of Fe_4N, using quasiparticle tunneling spectroscopy (QTS), and the measured spin polarization of Fe_4N was compared with that in Fe_4N/MgO/CoFeB MTJs. Spin polarization of ferromagnetic materials can be directly measured by QTS. By using NbN and MgO as superconducting electrode and barrier layers, respectively, Fe_4N/MgO/NbN tunnel junctions were fabricated by magnetron sputtering. The thickness of MgO barrier layer was varied from 1.0 to 1.5 nm. The areal resistances of the Fe_4N/MgO/NbN tunnel junctions were close to those of Fe_4N/MgO/CoFeB MTJs, which had the same thickness of MgO barrier layer as those Fe_4N/MgO/NbN tunnel junctions. In QTS, spin polarization of Fe_4N was estimated to be ~ -0.68. This value is larger than spin polarization in MTJs.

K1.00198 Temperature and temporal evolution of nonlocal spin signals[1]

, YI JI, HAN ZOU, University of Delaware — An unusual temperature evolution of spin signals has been previously reported by others for metallic nonlocal spin valves (NLSV): The spin signal increases as the temperature decreases from room temperature, reaches a maximum value around 50 K, and then decreases as the temperature approaches 4 K. This has been interpreted as due to a high surface spin-flip rate, but the origins of which are yet to be understood. In this work, we show that for an as fabricated Py-Cu NLSV device this temperature dependence is clearly observed. The device was then stored in the ambient environment for a period of 5 months. Afterwards, we found an increase of the spin signals, and more interestingly the spin signal levels off at 27 miliohms, instead of decreasing, below 50 K. Based on this and our other experiments, we conclude that the surface spin-flip scattering originates from the magnetic impurities embedded in the Cu channel near the side surfaces. Upon oxidizing the Cu, the surface impurities are buried in the copper oxide and become less accessible to the conduction electrons. Therefore the surface spin-flip rate is reduced over time.

[1]Work supported by DOE Grant No. DE-FG02-07ER46374.

K1.00199 Spin-transfer induced vortex dynamics with non-standard angular dependence torque , PAOLO BORTOLOTTI, NICOLAS LOCATELLI, VINCENT CROS, JULIE GROLLIER, CNRS/Thales, Palaiseau, France, RITA MACHEDO, RICARDO FERREIRA, SUSANA CARDOSO, INESC-MN, Lisbon, Portugal, ALBERT FERT, CNRS/Thales, Palaiseau, France — Microwave emissions driven by spin-transfer were firstly observed on FeNi/Cu/FeNi pillars (standard samples) characterized by uniform magnetization. Interestingly, by tuning the spin accumulation profile, i.e., choosing Co/Cu/FeNi pillars with opportune ratio of thickness/spin diffusion length (non-standard samples), it is possible to obtain strong modification of the torque angular dependence and, more generally, of the magnetization dynamics itself. Eventually, oscillations at zero applied field were observed for these non-standard pillars, again for uniform magnetization. However, when a large current density is applied, the uniform hypothesis is broken and vortex states are favoured. In this work we want to stress that non standard-angular dependence, obtained for such Co/Cu/FeNi samples, plays an important role also for vortex dynamics. By the combined study of static and dynamic response, we can discriminate among all possible combinations of vortex chiralities and polarities. The evolution with field and current of such configurations clearly differs from samples with standard spin-torque angular dependence, resulting in a different dynamics for such non-standard samples.

K1.00200 Size effect on $GdMn_2O_5$ nanoparticles , CHENG-YU WENG, CHUN CHUEN YANG, WEI-LUEN HUANG, ZHE-AN JIAN, Department of Physics, Chung Yuan Christian University, YANG YUAN CHEN, Institute of Physics, Academia Sinica, DEPARTMENT OF PHYSICS, CHUNG YUAN CHRISTIAN UNIVERSITY COLLABORATION, INSTITUTE OF PHYSICS, ACADEMIA SINICA COLLABORATION — We fabricated six difference sizes of $GdMn_2O_5$ nanoparticles/nanobrick by hydrothermal method. Purity and particle size were determinate by x-ray diffraction and TEM/SEM images. Two Mn antiferromagnetic ordering peaks at around 38 and 40 K were observed in ac magnetic susceptibility experiments, where as particle size is larger than 60 nm. Curie-Weiss fitting revealed that the Néel temperatures are increased with increasing size. Similar phenomena were also found in the saturate magnetic moments obtaind from M-H experiments at 5 K. No hysteresis loops were found in any particle size. We believe these magnetic behaviors are correlated with size confinement effects. The estimated magnetic correlation length of Mn is in between 60 and 84 nm.

K1.00201 Anisotropic paramagnetism in monoclinic $Nd_2Ti_2O_7$ single crystals[1] , HUI XING, Zhejiang University, GEN LONG, SUNY at Buffalo, HANJIE GUO, YOUMING ZOU, CHUNMU FENG, GUANGHAN CAO, Zhejiang University, HAO ZENG, SUNY at Buffalo, ZHUAN XU, Zhejiang University — The anisotropic paramagnetism and specific heat in Nd2Ti2O7 single crystals are investigated. Angular dependence of the magnetization and Weiss temperatures show the dominant role of the crystal field effect in the magnetization. By incorporating the results from the diluted samples, contributions to Weiss temperature from exchange interactions and crystal field interactions are isolated. The exchange interactions are found to be ferromagnetic, while the crystal field contributes a large negative part to the Weiss temperature, along all three crystallographic directions. The magnetic specific heat reveals a two-level Schottky ground state scheme, due to the Zeeman splitting of the ground state doublet, and the g-factors are thus determined. These observations provide solid foundations for further investigations of Nd2Ti2O7.

K1.00202 Magnetic Order and Spin Dynamics in a Hexagonal Rare Earth Manganite , J.S. HELTON, D.K. SINGH, NIST Center for Neutron Research, S. ELIZABETH, S. HARIKRISHNAN, Indian Institute of Science, Bangalore, J.W. LYNN, NIST Center for Neutron Research — Hexagonal rare earth manganites, RMnO$_3$ (R = Dy, Ho, Er, Tm, Yb, Lu, Y, or Sc), have attracted a great deal of recent attention as magnetoelectric multiferroics as most of these systems are ferroelectric at room temperature and display magnetic order below $T_N \approx 100$ K. This magnetic order can be quite complex, as both the R and Mn ions lie on geometrically frustrated triangular lattices. DyMnO$_3$ is typically orthorhombic, but can also be grown in the hexagonal phase; $Dy_{0.5}Y_{0.5}MnO_3$ displays the hexagonal phase and is magnetically diluted at the rare earth site. We have used neutron scattering experiments to explore the magnetic structure and spin dynamics of $Dy_{0.5}Y_{0.5}MnO_3$.

K1.00203 Z_2 topological classification of the $S = 1/2$ Heisenberg model on the two dimensional pylochlore lattice , SHO TANAYA, MITSUHIRO ARIKAWA, University of Tsukuba, ISAO MARUYAMA, Osaka University, YASUHIRO HATSUGAI, University of Tsukuba — We have investigated the $S = 1/2$ Heisenberg model on the two dimensional pyrochlore lattice [1] by using the Z_2 Berry phase [2] which is quantized due to the time reversal invariance. Since these Z_2 Berry phases are adiabatic invariants against change of the physical parameters, one can distinguish ground states when the quantized values are different. By suitably choosing ways of local $U(1)$ twists to define the Berry phases, one can show that the ground state in this system is adiabatically connected to a direct product state of local singlets or plaquette singlets. We have described the basic formulation and demonstrate the validity for finite systems using a Lanczos diagonalization.

K1.00204 Chirality waves in two-dimensional magnets , DMITRY SOLENOV, DMITRY MOZYRSKY, IVAR MARTIN, Los Alamos National Laboratory — Electron, as a particle with spin 1/2, moving though a magnetic material with non-coplanar magnetization pattern accumulates quantum mechanical (Berry) phase, characterized by the degree of non-coplanarity of the magnetic texture, or chirality. Until now metallic chiral magnets were thought to be quite rare and require either a fine tuning of the electron spectrum (nesting) or spin-orbit interactions. We show that two-dimensional magnets within a simple model of magnetism – a Kondo lattice model – favor a non-coplanar order (a distorted skyrmionic lattice) with unidirectional modulated chirality. Unlike recently observed chiral triangular skyrmion lattices supported by spin-orbit interaction and finite magnetic field (e.g. in MnSi), the chirality-wave order emerge at small-to-intermediate Kondo coupling strength in the absence of magnetic field or spin-orbit coupling

K1.00205 Non-polar electromagnon in hexa-$YMnO_3$, J.R. SIMPSON, Towson University, A.B. SUSHKOV, H.D. DREW, University of Maryland, M. MOSTOVOY, University of Groningen, A. GOZAR, Brookhaven National Laboratory, G. BLUMBERG, N. LEE, S.-W. CHEONG, Rutgers University — Coupled magnon-phonon excitations in magnetic materials have been observed in multiferroic materials and involve the polar optical phonons. Such excitations may be more general, occurring in non-ferroelectric magnets and involving non-polar (Raman or silent) phonons. Temperature-dependent Raman spectra of low-frequency excitations in single-crystal h-YMnO$_3$ are measured using a triple-grating spectrometer. We compare the spectral intensity of magnons to changes in the Raman-active phonons above and below the Neel temperature. Raman and infrared experimental results on h-YMnO3 demonstrate that the 5 meV hybrid mode observed in neutron scattering is an example of a Raman electromagnon.

K1.00206 T1-limited Nitrogen-Vacancy magnetometry of fluctuating AC magnetic fields[1] , CARLOS MERILES, ABDELGHANI LARAOUI, Department of Physics, City College of New York - CUNY, JONATHAN HODGES, Department of Electrical Engineering, Columbia University — Nitrogen-Vacancy (NV) centers in diamond are being actively investigated as a platform for nanoscale magnetic field sensing. In many of the envisioned applications the target AC magnetic field fluctuates over time and cannot be triggered in synchrony with the pulse protocol controlling NV evolution. Here we introduce a scheme to characterize the time correlation of the unknown field over a time interval limited by the NV spin-lattice relaxation time. Our approach uses two consecutive Hahn-echo sequences separated by a time interval of variable duration. We present an initial experimental demonstration of the technique using an engineered AC field and discuss possible extensions to the monitoring of slowly fluctuating spin ensembles.

K1.00207 SUPERCONDUCTIVITY —

K1.00208 ^{13}C NMR Study of Graphite Intercalated Superconductor CaC_6 Crystals in the Normal State , MOOHEE LEE, SUNG HOON KIM, KI HYEOK KANG, B. J. MEAN, B. NDIAYE, Konkuk University, Seoul, South Korea, JUN SUNG KIM, POSTECH, Pohang, South Korea — ^{13}C NMR(Nuclear Magnetic Resonance) measurements have been performed to investigate the local electronic structure of a superconducting graphite intercalation compound CaC_6 (T_c = 11.4 K). A large number of single crystals were packed and sealed in a quartz tube for naturally abundant ^{13}C NMR. Spectrum, Knight shift, linewidth, spin-lattice relaxation time T_1, and the spin-spin relaxation time T_2 were measured in the normal state as function of temperature down to 70 K at 4.8 T and 8.0 T. ^{13}C NMR spectrum shows a narrow peak with a very small Knight shift. Knight shift and linewidth of the ^{13}C NMR are almost temperature-independent around, respectively, 0.012% and 1.2 kHz. The spin-lattice relaxation rate $1/T_1$ is proportional to temperature confirming a Korringa behavior as for nonmagnetic metals. The Korringa product is measured to be T_1T= 210 s.K. From this value, the Korringa ratio is deduced to be $\xi = 0.73$, close to unity, which suggests that the independent-electron description works well for CaC_6, without complexity arising from correlation and many-body effects.

K1.00209 Oxygen staging in phase separated $La_{2-x}Sr_xCuO_{4+y}$, HASHINI MOHOTTALA, University of Hartford, 200, Bloomfield Ave. West-Hartford, CT-06117, LINDA UDBY, e-Science and Nanoscience Centres, Niels Bohr Institute, Universistetsparken 5, 2100, S. EMERY, B.O. WELLS, J.I. BUDNICK, University of Connecticut, 2152, Hillside road, Storrs, CHRISTOF NIDERMAYER, ETHZ & PSI, CH-5232 Villigen PSI, Switzerland, KIM LEFMANN, e-Science and Nanoscience Centres, Niels Bohr Institute, Universistetsparken 5, 2100, N.H. ANDERSON, Ris DTU, Frederiksborgvej 399, 4000 Roskilde, Denmark, F.C. CHOU, Center for Condensed Matter Sciences, National Taiwan University,Taipei 10617, Taiwan — We studied oxygen staging in a series of $La_{2-x}Sr_xCuO_4$ (LSCO) samples using neutron scattering. The samples were oxidized using electrochemistry. Electronic phase separation was previously reported in the oxygen rich LSCO system with two stable phases identified as optimally doped superconducting phase and a magnetic phase (1/8th like) with the same ordering temperatures at 40 K . Our present studies show staging in this system. Although staging was observed and extensively studied in the samples with no Sr, it has not been reported or systematically studied in the systems with both Sr and oxygen. We do find staging in the oxygenated LSCO system, but the staging peaks evolve as Sr concentration increases and excess oxygen concentration decreases.

K1.00210 Muon probing in optimal and under- doped GdBCO , C. BOEKEMA, San Jose State University, H. SIO, Harvey Mudd College, M.C. BROWNE, San Jose State University — By means of MaxEnt-Burg, transverse-field (TF) μSR data of underdoped (δ1; T_c= 81 K) and optimal doped (δ0; T_c= 93 K) $GdBa_2Cu_3O_{7-\delta}$ (GdBCO) are analyzed. Site search studies for RBCO generated plausible candidates for muon sites [1] called the Balmer and Lin sites. We wish to confirm the muon-probe sites in GdBCO. One of the two Balmer sites and the Lin site are located near O vacancies. These two sites become unstable in underdoped GdBCO(δ1). Positive muons are repelled by the positive O vacancies. This repulsion effects would be more pronounced as temperature increases. At 120 K, three signals are present in GdBCO(δ1), while at roomtemperature (RT), only one dominant signal remains. In contrast, three signals occur at 120 K and RT for GdBCO(δ0), which has much less O vacancies. These results support earlier studies [1] of muon-O sites. Thus, the muons probe away from the CuO_2 plane, allowing μSR to detect magnetic fields originating from potential loop currents in these planes. [2] By ME-μSR analysis, the Balmer & Lin sites in GdBCO are confirmed. Research supported by NSF-REU.

K1.00211 Strongly anisotropic flux pinning in superconducting PbBi thin films covered by periodic ferromagnet stripes , DONALD NAUGLE, ZYXIN YE, WENHAO WU, IGOR LYUKSYUTOV, Department of Physics and Astronomy, Texas A&M University — We have studied the vortex pinning via their magnetic interaction with a periodic structure of parallel magnetic stripes. Superconducting lead-bismuth (82% Pb and 18% Bi) alloy films were covered by an insulating Ge layer and periodic a Ni array of magnetic stripes fabricated on the top of the Ge layer by electron-beam lithography and thermal evaporation. The critical current density was significantly stronger when the current was applied parallel to the stripes than when the current was perpendicular to the stripes. This is attributed to the barrier to the vortex motion provided by the magnetic interaction with magnetic stripes. The enhancement in critical current was most significant at temperatures close to the superconducting transition temperature.

K1.00212 Effect of current on the dc I-V characteristic of polycrystalline $YBa_2Cu_3O_{7-X}$ near Tc , SNEHADRI OTA, Institute of Physics, Bhubaneswar, Orissa — The dc I-V characteristic of polycrystalline $YBa_2Cu_3O_{7-X}$ high temperature superconductors (HTSC) is measured near the transition temperature (T_c). The T_c was found to be 90 K with a width of 2 K. The voltage was measured at various current values and with reversing the current. A difference in voltage was found, for forward and reverse current direction near T_c. This can be understood qualitatively as due to the d-wave superconductivity as predicted by the RVB theory. This can also be understood qualitatively as due to the presence of proximity junctions, which is generally indicated by finite transition width in HTSC or A15 superconductors. The observed directionality of the I-V characteristic can be understood in terms of trapped flux by the self-field of the current and the proximity junctions in these materials.

K1.00213 Superconducting and transport properties of $Y_3Ba_5Cu_8O_X$ and $Y_3Ca_2Ba_5Cu_8O_x$ prepared by sol-gel method , ALI ER, Old Dominion University, YUKSEL UFUKTEPE, AHMET EKICIBIL, Cukurova University, ALI OSMAN AYAS, Adiyaman University, SELDA KILIC CETIN, KERIM KIYMAC, Cukurova University — The influence of substitution of Ca has been studied using electrical resistivity (ρ), X-ray diffraction (XRD), atomic force microscopy (AFM), energy dispersive analysis (EDX), differential thermal analysis (DTA), thermogravimetric analysis (TGA), Hall coefficient (R_H), Hall mobility (μ_H) and magnetoresistance measurements. The XRD spectra showed that they almost have the same crystal structure of $Y_3Ca_2Ba_5Cu_8O_x$ as $Y_3Ba_5Cu_8O_x$with some impurities peaks. The resistivity measurements were made by the four-probe method. The $Y_3Ba_5Cu_8O_x$ and $Y_3Ca_2Ba_5Cu_8O_x$ have the highest T_c-onset at about 92.7 and 86.6 K, respectively. The Hall coefficient R_H and Hall mobility μ_H are measurement between 10-300 K temperatures at magnetic field of 0.55 T. The sign of R_H and μ_H are positive for two samples which indicate that the conduction is p-type for the samples. A small change of normal state resistivity and superconducting transition are observed in the resistivity curve with the magnetic field.

K1.00214 Dynamical conductivity at the dirty superconductor-metal quantum phase transition[1] , J.A. HOYOS, Universidade de São Paulo, ADRIAN DEL MAESTRO, Johns Hopkins University, BERND ROSENOW, University of Leipzig, THOMAS VOJTA, Missouri University of Science and Technology — We study the transport properties of ultrathin disordered nanowires in the neighborhood of the superconductor-metal quantum phase transition. To this end we combine numerical calculations with analytical strong-disorder renormalization group results. The quantum critical conductivity at zero temperature diverges logarithmically as a function of frequency. In the metallic phase, it obeys activated scaling associated with an infinite-randomness quantum critical point. We extend the scaling theory to higher dimensions and discuss implications for experiments.

K1.00215 Spatially resolved NMR spectra for the Swiss cheese model in heavy fermion $PuCoGa_5$ superconductor , TANMOY DAS, JIAN-XIN ZHU, A.V. BALATSKY, M.J. GRAF, Theoretical Division, Los Alamos National Laboratory — Spatially resolved NMR experiments, which probe the local electronic excitations, play a vital role for studying the pairing symmetry of unconventional superconductors. Here we calculate the spatial modulation of the NMR spin-lattice relaxation rate (1/T1) for the Swiss cheese model as a function of impurity concentration in PuCoGa5 superconductor. The local suppression of the superconducting order parameter due to impurities is related to the number of holes in the Swiss cheese model. Our results indicate that Friedel-like oscillations,as seen in the local-density of states near an impurity, are also present in the behavior of 1/T1 as one moves away from the impurity site. We demonstrate that the gap nodes, which are filled by disorder, can be probed by NMR through the local information encoded in the spectra. The advantage of spatially resolved NMR compared to STM measurements is that the former probe is not sensitive to surface states. Work is supported by US DOE.

K1.00216 Sun Oven Grown Cuprates Superconductivity and Periodic Lattice Distortions PLD[1] , JUANA V. ACRIVOS, San Jose State University, J.G. CHIDVINADZE, Andronikashvili Institute Tbilisi, D.D. GULANOVA, Sun Physics Acad Sci Uzbekistan, D. LOY, San Jose State University — $Bi_{1.7}Pb_{0.3}Sr_2Ca_{n-1}Cu_nO_{4+2n+\delta}$ identified by the layer heavy element composition with substitution, s (2_s:2:n-1:n$\geq$2) cuprates grown by green chemistry, transition temperatures to superconductivity T_c=87 to 150K are related to their structure. Enhanced XRD at energies near but below the Cu K, and Pb and Bi L3-edges for pure n=2, 3 phases show Darwin shaped preferred [HKL] reflections that identify the magnitude of the allowed transition moment from the core state to extended unoccupied states determined by the electron density symmetry in that plane, confirmed by XAS of 3μm thick films. Weak PLD are still detected, but the stability gained by substitution of Bi by Pb is the formation of nearly symmetric Pb_8 cubes in $(2_s$:2:1:2$)_{13}$and $(2_s$:2:2:3$)_{17}$ super-lattices. The preferred 2D [HKL] reflection planes play the same role in the chemical activity of 3D solids as the linear bonds do in molecular reactions, governed by scattering dependent on the electron density symmetry in their highest and lowest unoccupied states.

K1.00217 Distribution of Co-dopants in LaFe1-xCoxAsO single crystals , JIAQIANG YAN, Ames laboratory, US-DOE, Ames, IA 50010, R.W. MCCALLUM, T.A. LOGRASSO — LaFe1-xCoxAsO single crystals have been grown in NaAs flux under ambient pressure. The content and distribution of Co-dopants were studied with wavelength dispersive x-ray spectroscopy. The plate-like single crystals consisit of multilayers with the thickness about 2 μm. No variation of Co content was observed in one single layer. However, Co content was observed to change gradually along the thickness (or z-) direction, which suggests layer-by-layer growth mechanism. The relation between the Co-content in crystals and starting materials was developed and the distribution coefficient of Co-dopants was estimated to be around 0.60.

K1.00218 Epitaxial growth of the electron-doped $Sr_{1-x}La_xCuO_2$ by magnetron spattering , KEITA SAKUMA, HIROYUKI AKATSUKA, TETSUYA MIYAWAKI, KENJI UEDA, HIDEFUMI ASANO, Department of Crystalline Materials Science, Nagoya University — The electron-doped $Sr_{1-x}La_xCuO_2$ (SLCO) has the simplest structure among high temperature superconductors (HTS). In addition, transition temperature of SLCO is the highest among electron-doped HTS. Therefore, SLCO is suitable for fundamental researches and electronic applications. Several groups reported growth of c-axis oriented SLCO thin films on various substrates, however a-axis oriented SLCO thin films, which are useful for superconductor junctions, have not been obtained. In this study, we deposited SLCO thin films on various substrates [(001) $KTaO_3$(KTO), $SrTiO_3$(STO), MgO and $LaAlO_3$(LAO)] by magnetron sputtering. KTO and STO have better lattice matching to SLCO[100] compared with MgO and LAO. SLCO thin films on KTO and STO were c-axis obtained. On the other hand, SLCO thin films on MgO and LAO were (101) and$a$-axis oriented, respectively. We considered that the differences of crystal orientations in these films were caused by lattice matching to the substrates. These results indicated that we can control crystal orientation of SLCO thin films using substrates with various lattice constants.

K1.00219 Superconductivity in $Zr_2(Co_{1-x}M_x)$ (M = Cu, Ga)[1] , K.J. SYU, C.H. WU, H.H. WU, S.C. CHEN, H.H. SUNG, W.H. LEE, National Chung Cheng University, W.H. LEE TEAM — As revealed in the powder x-ray diffraction and crystallographic data, the body-centered tetragonal structure of the parent compound Zr_2Co is retained in both $Zr_2(Co_{1-x}Cu_x)$ and $Zr_2(Co_{1-x}Ga_x)$ systems with the solubility limit near $x = 0.3$. The refined lattice parameters indicate that there is a movement for c to decrease and a to increase, due to the doping with Cu or Ga in the compound. Since the percentage change in lattice parameters c and a is comparable, a prominent peak in the unit cell volume v versus x curve therefore appears around$x = 0.15$ and $x = 0.2$ for $Zr_2(Co_{1-x}Cu_x)$ and $Zr_2(Co_{1-x}Ga_x)$ systems, respectively. Magnetic and electrical measurements show that there is an explicit maximum T_c close to $x = 0.05$ for both systems. As compared with the $Zr_2(Co_{1-x}Ni_x)$ system[1], it may imply that the superconducting transition temperature in $Zr_2(Co_{1-x}Cu_x)$ and $Zr_2(Co_{1-x}Ga_x)$ relate more to the spin density fluctuations than to the density of states at the Fermi level. [1]M. Takekuni, H.Sugita and S. Wada, Phys. Rev. B **58**, 11698 (1998).

K1.00220 Plausible loop currents in the GdBCO pseudogap phase , C. BOEKEMA, San Jose State University, T. SONGATIKAMAS, Santa Clara University, M.C. BROWNE, San Jose State University — For the cuprate pseudogap phase, Varma [1] predicts loop currents above T_c. We search for fields near 100 Oe, created by such currents in $GdBa_2Cu_3O_{7-\delta}$ (GdBCO). Using MaxEnt-Burg (ME) we analyze zero-field (ZF) muon-spin-rotation (μSR) data of underdoped (δ1; T_c= 81 K) and optimal doped (δ0; T_c= 93 K) GdBCO. [2] ME-μSR applied to ZF-GdBCO data yields T-dependent signals at 0-MHz (f0) and 0.3-MHz (f1) and hints of 1.4-MHz signals. To cancel any systematic (f1) effect, we analyze DS(t,T) = S(t,T>T_c) - S(t,T'<<T_c). This ME-Burg analysis of GdBCO(δ0 & δ1) indicates weak signals near 1.4 MHz above T_c (and f1 disappears). These ME-peaks occur at $\sim$1.3 MHz (95 Oe) for GdBCO(δ1) and $\sim$1.5 MHz (110 Oe) for GdBCO(δ0). These μSR signals, plausibly due to fields created by loop currents, appear only above T_c. Below T_c, only ME background noise exist in DS(t,T) transforms. The $\sim$1.4-MHz peak intensity to background ratio at its maximum is $\sim$5 for GdBCO(δ1) and $\sim$4 for GdBCO(δ0) at $\sim$10 degrees above T_c. Validating predicted loop currents is essential for understanding the pseudogap phase. Research supported by REU NSF & DOE LANL. K1.00221 Modeling Superconducting properties of an inhomogeneous mixture of doped metallic and semiconductor carbon nanotubes , ILYA GRIGORENKO, Penn State University, ANVAR ZAKHIDOV, The University of Texas at Dallas — We considered theoretically the superconducting properties of a bundle of boron-doped carbon nanotubes, which consists of two types of nanotubes: semiconducting and metallic. The tubes are assumed to be close-packed, making a hexagonal lattice in the transverse section of the bundle. The properly doped semiconducting nanotubes are assumed to have a higher transition temperature than metallic because of the lower lying Van Hove singularities in the DOS (proven in experimentally found Kataura plot). We used an inhomogeneous microscopic model to describe the proximity effects between the two different types of tubes, and calculated the averaged superconducting critical temperature for the bundle given a ratio between the metallic and semiconductor nanotubes. We found that the critical temperature scales approximately quadratically as a function of the ratio. We also discuss briefly the possible effect of metallic nanotubes on the suppression of the phase fluctuations in 1-D superconducting pairing in properly doped semiconducting nanotubes.

K1.00222 Study of Mini-Gap Regime in Au Nanowires[1] , BRIAN COOPER, The Pennsylvania State University, JIAN WANG[2], MOSES CHAN, MEENAKSHI SINGH, MINGLIANG TIAN, JAINENDRA JAIN, The Pennsylvania State University — The inducement of superconductivity in 70nm single crystal Au nanowires (AuNWs) via the Proximity Effect was reported in 2009 [Wang, J. et al. *Phys. Rev. Lett.* **2009**, 102, 247003]. This study, carried out on 3 AuNWs of different lengths (1.0, 1.2 and 1.9 μm), showed a precipitous drop in the resistance to a fully superconducting state of the 1.0um wire; while the 1.2μm wire made the transition in 2 steps, and the 1.9μm wire never fully transitioned to a zero resistance state. This behaviour lead to the coinage of the so-called "mini-gap" phase in proximity induced superconducting nanowires. We are currently investigating the robustness of this "mini-gap" regime by parametric variations to the gold nanowire system. Looking at features such as crystallinity, AuNW diameter, electrode material, and directional magnetic field dependence, we are attempting to further illuminate the nature of this new "mini-gap" state.

K1.00223 Coherent pairing and phase separation in small negative U Hubbard nanoclusters away from half filling , KALUM PALANDAGE, Trinity College, Hartford, GAYANATH FERNANDO, Department of Physics, University of Connecticut, Storrs, ARMEN KOCHARIAN, Department of Physics, California State University, Los Angeles — The similarities and differences in the mechanism of electron pairing instabilities, driven by attractive and repulsive electron interaction, are studied in the ensemble of small clusters for one hole off half filling under variation of interaction strength and temperature. These exact calculations of charge and spin collective excitations, and corresponding critical transition temperatures yield intriguing insights into the level crossing degeneracies, phase separation transitions, condensation and formation of spatial inhomogeneities in various cluster geometries [Ultramicroscopy 109, 1066 (2009)]. Separate condensation of electron charge and spin degrees in negative U model away of half filling offers a new route for the mechanism of superconductivity in inhomogeneous systems, different from the quasi-particle BCS scenario for electron condensation. Phase diagrams resemble a number of inhomogeneous, coherent and incoherent nanoscale phases seen in various positive Hubbard cluster geometries in high Tc cuprates, iron pnictides, and other transition metal oxides.

K1.00224 Dynamics of an RF-driven Josephson junction near the bifurcation point , AMRIT POUDEL, MAXIM VAVILOV, University of Wisconsin-Madison — We investigate the dynamics of an RF driven Josephson junction coupled to thermal heath bath. We present a stochastic semiclassical equation of motion for the junction, obtained from a microscopic Hamiltonian of the system. We discuss conditions when the Langevin forces in this equation can be approximated by Markovian white noise. For this case, we obtain the Fokker-Planck equation, which we numerically solve to describe the switching process between two stable states near the bifurcation point.

K1.00225 Effects of 3d magnetic metal substitutions (Fe, Co, Ni) for V on superconducting T_c of the ZrV_2 system[1] , WUN-HSIN LEE, D.H. CHEN, K.J. SYU, S.C. CHEN, H.H. SUNG, National Chung Cheng University, W.H. LEE TEAM — The effects of Fe, Co and Ni substitution on the crystallographic data and superconducting transition temperature (T_c) of ZrV_2 have been investigated through powder x-ray diffraction, static magnetization and electrical-resistivity measurements. Variation of the room temperature refined lattice parameters indicate that there is a movement for a and unit cell volume v to decrease, linearly with increasing x up to 0.4, for the $Zr(V_{2-x}T_x)$ (T = Fe, Co and Ni) alloys. Magnetic and electrical measurements show that the superconducting transition temperature (T_c) of ZrV_2 is reduced by the doping of Fe, Co and Ni with depression rate $dT_c/dx \sim$ -14, -17.5, and -15 K/atom %, respectively. The doping of Co has a larger effect than Fe and Ni on the decrease of T_c.

K1.00226 Superconducting Properties of Lead-Bismuth Films Controlled by Ferromagnetic Nanowire Arrays , ZUXIN YE, IGOR F. LYUKSYUTOV, WENHAO WU, DONALD G. NAUGLE, Department of Physics and Astronomy, Texas A&M University — Superconducting properties of lead-bismuth (82% Pb and 18% Bi) alloy films deposited on ferromagnetic nanowire arrays have been investigated. Ferromagnetic Co or Ni nanowires are first electroplated into the columnar pores of anodic aluminum oxide (AAO) membranes. Superconducting $Pb_{82}Bi_{18}$ films are then quench-condensed onto the polished surface of the AAO membranes filled with magnetic nanowires. A strong dependence of the $Pb_{82}Bi_{18}$superconducting properties on the ratio of the superconducting film thickness to the magnetic nanowire diameter and the material variety was observed.

K1.00227 Magnetic nanorod - superconductor hybrid near the superconducting transition temperature , K. KIM, I. LYUKSYUTOV, D.G. NAUGLE, Department of Physics, Texas A&M University, College Station, TX77843, USA — We report measurements of the magnetoresistance and phase diagram of a lead-bismuth (82% Pb and 18% Bi) superconducting film with an embedded square array of Ni nanorods near the superconducting transition temperature. Magnetoresistance above Tc demonstrates oscillations compatible with flux quantization through the unit cell of the magnetic nanorod array. Strong hysteresis of the superconducting properties and an apparent increase of the second critical field is found.

K1.00228 Description of a primitive valley scattering unit cell to understand anisotropic inter-valley scattering in AlAs quantum wells , S. PRABHU-GAUNKAR, M. GRAYSON, Northwestern University — Valley degenerate systems have an extra scattering channel not present in single valley systems, namely inter-valley scattering. To help classify anisotropic inter-valley scattering in degenerate multi-valley systems, such as AlAs quantum wells (QWs), we define a valley scattering primitive unit cell in momentum space which allows one to distinguish purely in-plane momentum scattering from scattering requiring an out-of-plane momentum component. The standard depiction of a 2D Brillouin zone of a quantum confined valley-degenerate system projects all valleys to a single plane and this depiction loses information about the momentum scattering component that was projected out. Because QW confinement potentials are inherently anisotropic, the disorder potential characteristic of quantum confinement can create anisotropic short-wavelength inter- valley scattering potentials favoring in-plane momentum scattering. We demonstrate that the valley scattering cell for AlAs QWs grown along various orientations is particularly useful in identifying relevant scattering vectors. Initial estimates will be shown of the role of strong electron-electron interactions in AlAs QWs on inter-valley scattering parameters such as inter-valley scattering time, probabilities and rates.

K1.00229 Analytical approach to neutron scattering on solitons in low dimensional systems , IRINA BARIAKHTAR, APS/Boston College, YAROSLAV NAZARENKO, Brown University — It is well known that neutron scattering, along with x-ray scattering, allows for the study of condensed matter system structures. Recently, it was revealed that in magnetic materials some nonlinear formations such as solitons of the topological type of excitation - kinks, solitons with zero topological charge - breathers, and solitons with linear excitation, analogous to spin waves, may arise. In this paper, we present the polarized neutron scattering approach for the study of such formations in magnetic materials. The formulas for the cross sections of scattering in the low-dimensional systems with solitons were obtained. We have presented the calculations for kink type solitons. Similar calculations can also be presented for breather-type solitons. We have shown that the study of neutron polarization after scattering provides for the possibility of gathering information on the static and dynamic properties of the solitons and allows for restoring of the magnetic momentum distribution in the solitons. We hope that such calculations will stimulate the formulation of a series of experiments where solitons can be experimentally observed.

K1.00230 THz imaging system with the IJJ emitter[1] , MANABU TSUJIMOTO, HIDETOSHI MINAMI, MASASHI SAWAMURA, KAVEH DELFANAZARI, TAKASHI YAMAMOTO, TAKANARI KASHIWAGI, KAZUO KADOWAKI, University of Tsukuba — The intrinsic Josephson junction (IJJ) emitter consisted of thousands of IJJs uniformly stacked in single crystalline high-T_c superconductor $Bi_2Sr_2CaCu_2O_{8+\delta}$ (Bi-2212) [L. Ozyuzer *et al.*, Science **318**, (2007) 1291.] is expected to be a novel source of the continuous terahertz electromagnetic waves (THz-waves). The maximum emission power of tens of microwatts recently obtained with the mesa structure of IJJs seems to be sufficient to make use of the IJJ emitter for some practical applications such as THz imaging. According to the cavity resonance condition, we can control the radiation frequency by changing the geometrical size of the mesa. In this study, we develop the THz imaging system with IJJ emitter. In the presentation, we will show some transparent images of standard specimens obtained by the raster scanning method. Also, we will mention some problems to be solved for the future applications of the IJJ emitter.

K1.00231 Front instabilities, confinement effect and fracture in drying colloidal nanoparticle , DEEDER AURONGZEB, The University of Akron, Department of Polymer Science. — Drying colloidal suspension of oxide nanoparticle can fracture in fractal patterns. While similar in size TiO_2 and Al_2O_3 particles can fracture differently. We found that Alumina nanoparticle forms radially inward crack from the edge of the droplet or planer film like fluid while Titania nanoparticle form fractal cracks. Using polarized light we observe stress field formation during evaporation and crack growth. We find that crack direction is driven by surface tension rather than thermal energy of the suspended nanoparticle. Evaporation based nanoparticle assemble and effect of confinement and electric current will be also discussed.

K1.00232 High-Pressure Studies of Valence and Magnetic State in Europium Metal[1] , W. BI, G. FABBRIS, J. SCHILLING, Physics Department, Washington University in Saint Louis, N. SOUZA-NETO, D. HASKEL, J. ZHAO, E. ALP, Advanced Photon Source, Argonne National Lab, Y. MENG, HPCAT, Carnegie Institution of Washington, Argonne National Laboratory, A. ALSMADI, Hashemite University — The strong local-moment magnetism in divalent Eu metal ($4f^7$) suppresses superconductivity. At extreme pressure Eu is expected to become trivalent and nonmagnetic ($4f^6$). Recently, superconductivity in Eu was discovered by Debessai *et al.* for pressures above 80 GPa [1]. However, Eu's transition temperature lies near 2 K, nearly an order of magnitude lower than for comparable trivalent d-electron metals, possibly because Eu is not fully trivalent but rather mixed valent. Here we report recent experimental results on Eu's valence and magnetic state to Mbar pressures through synchrotron x-ray absorption near edge structure (XANES), synchrotron x-ray magnetic circular dichroism (XMCD), and synchrotron Mössbauer spectroscopy (SMS).

[1] M. Debessai, T. Matsuoka, J. J. Hamlin, J. S. Schilling, and K. Shimizu, Phys. Rev. Lett. 102, 197002 (2009).

[1]This research is supported by NSF grant DMR-0703896 and by the Carnegie/DOE Alliance Center (CDAC) through NNSA/DOE grant number DE-FC52-08NA28554.

K1.00233 Hybrid Rings for circuit Quantum Electrodynamics , E. HOFFMANN, F. DEPPE, T. NIEMCZYK, E. P. MENZEL, G. WILD, H. HUEBL, M. MARIANTONI, A. MARX, R. GROSS, Walther-Meissner-Institut and TU Muenchen, Garching, Germany, T. WIRTH, A. LUKASHENKO, A. USTINOV, Karlsruher Institut fuer Technologie (KIT), Karlsruhe, Germany, A. P. ZHURAVEL, B. I. Verkin Institute for Low Temperature Physics and Engineering, Kharkov, Ukraine — Experiments in the field of circuit QED require detection schemes for microwave signals on the single photon level. In particular, devices acting as microwave beam splitters are necessary. Using Nb thin films on silicon and sapphire substrates, we fabricated superconducting 180° microstrip hybrid rings acting as beam splitters with center frequencies of about 6 GHz. For the magnitude of the coupling and isolation we find -3.5 ± 0.5 dB and at least -15 dB, respectively, in a bandwidth of 2 GHz. We also investigate the effect of reflections at the contact between the superconducting hybrid ring and the normal conducting wiring using low temperature laser scanning microscopy. Our measurements indicate that our hybrid rings are well suited for on-chip applications in circuit QED experiments. We acknowledge financial support by the DFG via SFB 631, as well as support by and CFN, EU project SOLID and the German Excellence Initiative via NIM.

K1.00234 Magnetic behaviors in Fe(Se,Te) system , HONGLIANG SHI, Beijing Computational Science Research Center, BEIJING COMPUTATIONAL SCIENCE RESEARCH CENTER TEAM — The magnetic behaviors in Fe(Se,Te) system are investigated systematically by using the density functional theory. Our results show that for FeSe and FeTe in their respective ground state with different magnetic configurations, the easy axis of magnetization does not have any obvious preference. As for $FeSe_{0.5}Te_{0.5}$, in the collinear calculation only setting the values of magnetic moments, the ground state is in the "double stripe" magnetic phase; while the "single stripe" magnetic arrangement is found to be the ground state if the easy axis of magnetization is considered in our calculations. Our spiral calculations also successfully predict the commensurate (0.5, 0.5) ordering observed in $FeSe_{0.5}Te_{0.5}$ system experimentally. Furthermore, two incommensurate excitations near (0.5, 0.5) are also reproduced in the spin spiral states compared with the diagram of scattering plane obtained by neutron scattering.

K1.00235 Synthesis and superconductivity in Li-Fe-As-N[1] , H.H. SUNG, K.J. SYU, S.C. CHEN, W.H. LEE, National Chung Cheng University, W.H. LEE TEAM — The preparation of LiFeAs compound either in polycrystal or single crystal form is difficult to handle due to its reactivity with air and sensitivity to moisture of lithium. In this report we use Li_3N, Fe and As as starting materials. During the heating process, no high pressure, no Ta, Nb or W tube, is required to synthesize the polycrystalline sample. The crystallographic data and superconducting transition temperature (T_c) of the samples as prepared have been investigated through powder x-ray diffraction, magnetization and electrical-resistivity measurements. Discussion will be directed toward the influence of N on the superconductivity in Li-Fe-As from the viewpoint of pinning or substitute effect.

[1]Supported by the National Science Council of Republic of China under grant numbers NSC 99-2112-M-194-006-MY3 and NSC99-2811-M-194-021.

K1.00236 Evidence for intrinsic vortex pinning in 1111 Fe arsenides single-crystals , GANG LI, GAEL GRISONNANCHE, BENJAMIN CONNER, National High Magnetic Field Lab, NIKOLAI ZHIGADLO, SERGIY KATRYCH, ZBIGNIEW BUKOWSKI, JANUSZ KARPINSKI, Laboratory for Solid State Physics, ETH Zürich, CH-8093 Zürich, Switzerland, LUIS BALICAS, National High Magnetic Field Lab — We performed a study of the angular dependence of the magnetic torque $\tau(\theta)$ in $LaFeAsO_{0.9}F_{0.1}$ and in $SmFeAsO_{0.9}F_{0.1}$ single crystals. Here, θ is the angle between the magnetic field and inter-plane c-axis. As the temperature is lowered, one observes the emergence of sharp features in the magnetic torque for fields nearly aligned along the conducting planes. In particular, one observes two sharp peaks at a critical angle θ_c placed respectively slightly above and below $\theta = 90^\circ$, in the reversible component of the torque. Their position in angle, relative to $\theta = 90^\circ$, decreases as the field increases, and increases as the temperature is lowered. We conclude that θ_c corresponds to a critical pinning angle whose behavior is consistent with theoretical predictions for the intrinsic pinning of vortices by a layered crystallographic structure. However, in sharp contrast with the cuprates, in the region of temperatures where this behavior is observed the superconducting anisotropy of 1111 Fe arsenides is rather small, as measured by torque magnetometry.

K1.00237 Investigation of the role of spin-orbit coupling on transport properties of iron pnictide materials[1]

, SUDHAKAR PANDEY, HIROSHI KONTANI, DAI HIRASHIMA, Nagoya University, Japan, RYOTARO ARITA, HIDEO AOKI, University of Tokyo, Japan — A generic feature associated with the electronic structure of iron pnictides and chalcogenides, which are currently under intense investigation for their superconducting properties, is that the 3d orbitals of Fe make dominant contribution to density of states near the Fermi level. Incorporating this along with other realistic band features within a multiband tight-binding model, we investigate the role of atomic spin- orbit coupling associated with the 3d orbitals on the transport properties of these materials. Our investigation highlights the importance of some characteristic features associated with the electronic band, such as accidental degeneracy, Dirac cone, and orbital hybridization. we find significantly large spin Hall conductivity in the paramagnetic state that is comparable with Pt. We also find finite anomalous Hall conductivity in the ferromagnetic state.

[1]S P acknowledges the financial support from JSPS .

K1.00238 Anisotropic structural and magnetic properties of the field-aligned superconducting system $SmFeAsO_{1-x}F_x$ (x = 0.05, 0.1, 0.2, 0.25, and 0.3)[1]

, Y.B. YOU, J.W. WANG, M.F. TAI, H.C. KU, Dept. of Physics, National Tsing Hua University, Hsinchu, Taiwan, Y.Y. HSU, Dept. of Physics, National Taiwan Normal University, Taipei, Taiwan — Anisotropic structural and magnetic properties of the field-aligned superconducting system $SmFeAsO_{1-x}F_x$ (x = 0.05, 0.1, 0.2, 0.25, 0.3) are reported. Due to the Fe spin-orbital related anisotropic exchange coupling, all the tetragonal microcrystalline powders in epoxy were aligned at room temperature using the field-rotation method where the tetragonal ab-plane is parallel to the magnetic alignment field B_a of 0.9 T and the c-axis parallels to the rotating axis. Anisotropic magnetic properties are studied through low temperature magnetic measurements along the c-axis and paralleled to the ab-plane of aligned samples in both ZFC and FC modes. The under-doped compound (x = 0.1) is not superconducting with an antiferromagnetic Néel temperature $T_N \sim$ 40K, while the two optimum-doped compounds (x = 0.2 and 0.25) show high superconducting transition temperatures T_c of 49K and 50K, respectively. The variation of anisotropic structural and magnetic properties for this system are discussed and compared with the previously reported 52 K anisotropic superconductor $Sm_{0.95}La_{0.05}FeAsO_{0.85}F_{0.15}$.

K1.00239 COMPLEX STRUCTURED MATERIALS II —

K1.00240 The effects of asymmetric configurations on electronic properties of bilayer graphene nanoribbons[1]

, Y. -C. HUANG, Center for General Education, Kao Yuan University — Low-energy electronic properties of bilayer graphene nanoribbons subject to the effects of asymmetric configurations are studied by using the tight-binding model. They are strongly dependent on the interlayer interactions, the ribbon edges, the ribbon width (N_y), and the upper ribbon displacement (N_D). The interlayer interactions significantly modify the energy dispersions, alter the subband spacing, change the subband curvature, produce the new edge state, and induce asymmetry of energy bands. There are partial flatbands at the Fermi level and one-dimensional parabolic bands at others. These make density of states (DOS) exhibit delta- function-like structure and asymmetric prominent peaks, respectively. Energies of the extra band-edge states can be tuned by varying the upper ribbon displacement. As N_D grows from zero, the new edge states show a tendency to increase near low energy, while the curvature of the extra band-edge states display bold change about Fermi level E_F. The above-mentioned effects are completely reflected in the features of DOS, such as the generation of special structures, the shift of peak position, and the change in peak height. The predicted electronic properties could be examined by the experimental measurements on absorption spectra.

K1.00241 Kronig-Penney Model of Graphene in a Magnetic Field of Arbitrary Strength

, NORMAN HORING, Stevens Inst. Tech., SINA BAHRAMI, Stevens Inst. Tech — We address the magneto-dynamics of a 2D graphene sheet with a one dimensional periodic array of quantum wires, using a Kronig-Penney type model. In particular we examine the role a normal magnetic field inducing Landau quantization effects in terms of a closed form integral representation involving only elementary functions which incorporates the full spectrum of magnetic-quantized graphene states and energies.

K1.00242 Effective Magnetic Fields in Graphene Superlattices[1]

, HERBERT FERTIG, JIANMIN SUN, Indiana University, LUIS BREY, Instituto de Ciencia de Materiales de Madrid — We demonstrate that the electronic spectrum of graphene in a one-dimensional periodic potential will develop a Landau level spectrum when the potential magnitude varies slowly in space [1]. The effect is related to extra Dirac points generated by the potential whose positions are sensitive to its magnitude. We develop an effective theory that exploits a chiral symmetry in the Dirac Hamiltonian description with a superlattice potential, to show that the low energy theory contains an effective magnetic field. Numerical diagonalization of the Dirac equation confirms the presence of Landau levels. Possible consequences for transport are discussed.

K1.00243 Graphene Energy Loss Spectroscopy for Perpendicular Particle Incidence

, VASSILIOS FESSATIDIS, ANTONIOS BALASSIS, Fordham University, NORMAN J.M. HORING, Stevens Institute of Technology — In this work we determine the energy loss of a fast charged particle probe moving perpendicular to a two-dimensional ($2D$) graphene sheet. The response dynamics of the $2D$ graphene sheet are modeled using the random phase approximation in the degenerate limit (zero temperature). We analyze the energy loss of the probe particle for normal incidence to the graphene sheet as a function of its velocity, examining contributions from both the particle-hole and plasmon excitations.

K1.00244 Ab initio Calculations of Geometric and Electronic Structure of Graphene-Au System

, ROBERTO NUNEZ-GONZALEZ, Dept. de Matemáticas, Universidad de Sonora, DONALD H. GALVAN, Centro de Nanociencias y Nanotecnología,Unam, ALVARO POSADA-AMARILLAS, Dept. de Inv. en Física, Unison — Structural and electronic properties of graphene with one gold atom at top were calculated using the Full-Potential Augmented Plane Waves with Local Orbitals Method and the local density approximation (LDA), within the Density Functional Theory. For the calculations, we use a 3x3x1 supercell of graphene, calculating the stability of the system with the gold atom at three different sites: Hole, Bridge and Top sites. For each site, the atoms are relaxed minimizing forces. An analysis of the structural properties is performed for each site, calculating the density of states (DOS). A comparison with pure graphene is realized.

K1.00245 Geometric and Electronic structures of deformed bilayer graphenes , JEN-HSIEN WONG, Department of Physics, National Cheng Kung University, Tainan, Taiwan, BI-RU WU, Department of nature science, Center for General Education, Chang Gung University, Taoyuan, Taiwan, MING-FA LIN, Department of Physics, National Cheng Kung University, Tainan, Taiwan — The electronic properties of bilayer AB-stacked graphene are investigated with a first-principles method when homogeneous and uniaxial strains are exerted. The two types of strains can be either tensile or compressive. The maximum deformation ratio is 36% for tensile strain, and 20% for compressive strain. The uniaxial strains along the armchair (A strain) or zigzag (Z strain) directions are considered. Bilayer AB-stacked graphene belongs to semimetal essentially. One pair of π bands owns two intersections near the Fermi level. One intersection lies at K point; the other one is near K point along the path of Γ to K. The π band overlap is approximately 2.6meV. No gap will be developed for bilayer graphene under homogenous strain or A strain. Nevertheless, tensile Z strain results in a tiny indirect band gap near R point.

K1.00246 Magneto-electronic specific heat of graphene[1] , SHIH-YANG LIN, Physics, National Cheng Kung University, Tainan, Taiwan, YEN-HUNG HO, Physics, National Sun Yat-Sen University, Taiwan, MING-FA LIN, Physics, National Cheng Kung University, Tainan, Taiwan, YUAN-CHENG HUANG, Center for education, Kao Yuan University, Kaohsiung, Taiwan — The electronic specific heat related to the Landau levels of monolayer graphene is studied by the Peierls tight-binding model. The low-temperature thermal properties are dominated by the two low-lying Landau levels with the Zeeman splitting. They give rise to rich temperature and magnetic-field dependence. The T-dependent specific heat reveals the composite form of 1/T and exponential function. Also, a prominent peak appears in the T-dependent (B-dependent) spectrum with its critical temperature T_c (critical magnetic field B_c). Moreover, there has a simple linear relationship between $T_c$and B_c. In a slightly doped graphene, there exists an extra shoulder structure in the specific heat. Such structure mainly comes from the Zeeman effect and temperature-dependent carrier distribution.

[1]NSC 99-2112-M-244-001-MY2

K1.00247 Electronic structure of a realistic model of amorphous graphene , VITALIY KAPKO, AVISHEK KUMAR, Arizona State University, DAVID DRABOLD, Ohio University, MICHAEL THORPE, Arizona State University — We calculate the electronic properties of a realistic atomistic model of amorphous graphene. The model contains odd-membered rings, particularly five and seven membered rings and no coordination defects.We show that odd-membered rings increase the electronic density of states at the Fermi level relative to crystalline graphene; a honeycomb lattice with semimetallic character. Some graphene samples contain amorphous regions, which even at small concentrations, may strongly affect many of the exotic properties of crystalline graphene, which arise because of the linear dispersion and semi-metallic character of perfectly crystalline graphene. Estimates are given for the density of states at the Fermi level using a tight-binding model for the π states. We also report preliminary density functional results for the electronic structure.

K1.00248 Vibration analysis of Graphene embedded in ordered fluids using Raman spectroscopy , MIN SANG PARK, School of Material Science and Engineering, Georgia Institute of Technology, KARTHIK NAYANI, School of Material Science and Engineering, Georgia Institute of Technolgy, JUNG OK PARK, MOHAN SRINIVASARAO, School of Material Science and Engineering, Georgia Institute of Technology — We studied the vibrational characteristics of both single- and multi-layered Graphene embedded in liquid crystal (LC), possessing various ordered phases, by polarized micro-Raman spectroscopy. The evolution of the vibrational modes (G and 2D bands) was studied in 8CB in the isotropic, nematic and smectic A phases. The shifts in the vibrational modes are discussed in the context of the phase transition in the LC system.

K1.00249 localization of plasmonic excitations in graphene induced by nanoscale potential , JUNG-JUNG SU, Theoretical Div., Los Alamos Natl. Lab., HARI DAHAL, American Physical Society, RODRIGO MUNIZ, STEPHAN HAAS, Dept. of Phys. and Astro., Univ. of Southern California, ALEXANDER V. BALATSKY, Theoretical Div., Los Alamos Natl. Lab. — The near-ballistic transport property at close to room temperature makes graphene a strong candidate for integrated nanoelectronic application. Graphene-based plasmonics is one of the devices proposed that integrate electronic and light transport. By utilizing localized plasmonic excitation, plasmonics can transport light with a sub-wavelength dimension. We report our calculation on plasmonic excitation induced by different local structures. The polarization obtained by random-phase-approximation (RPA) is diagonalized to extract plasmon modes. We have also studied the effect due to gating and due to tunning of local potential structure geometry. These prediction can be tested by scanning tunneling microscope and is important both in fundamental and in application aspects.

K1.00250 Adsorption of water on a carbon-gold surface[1] , FERNANDO MAGAÑA, GERARDO J. VAZQUEZ, Instituto de Física, Universidad Nacional Autónoma de México — Density functional theory and molecular dynamics were used at 300 K to study first the interaction of a gold atom (Au) with a graphene layer with a vacancy. The Au Atom is adsorbed on the vacancy then we studied the adsorption of H_2O on the Au anchored on the vacancy of graphene. We found that the water molecule is adsorbed on such configuration and it is not even dissociated at high temperatures like 1000 K.

[1]We acknowledge partial finantial support by DGAPA-UNAM through grant. No. IN111807 and the technical assistance Kanbalam supercomputer center, UNAM.

K1.00251 The interaction of mercury with halogenated graphene[1] , ABIGAIL KIRCHOFER, ERDEM SASMAZ, JENNIFER WILCOX, Stanford University — The interaction of mercury with halogenated graphene was studied using plane-wave density functional theory. Various configurations of H, Hg, O and Br or Cl on the zigzag edge sites of graphene were investigated. Although Hg-Br (or -Cl) complexes were found to be stable on the surface, the most stable configurations found were those with Hg adjacent to O. The surface atoms Hg, O, and Br tend to repel each other during geometric optimization, moving towards an H atom nearest-neighbor where possible. The strength of the Hg-graphene interaction is very sensitive to the local environment. The Hg-graphene binding energy is strongest when the Hg is located next to a surface O but not immediately next to a bound Br. DOS analysis revealed that Hg adsorption involves a gain in Hg 6 p-states and a loss in Hg 5 s electron density, resulting in an oxidized surface-bound Hg complex. DOS analysis suggests that Br strengthens the Hg-graphene interaction by modifying the surface carbon electron density; however, when Br is adjacent to Hg, a direct Hg-Br interaction weakens the Hg-C bond. These investigations provide insight into the mechanism associated with enhanced Hg adsorption on Br-functionalized carbon materials for Hg emissions reductions from coal-fired power plant applications.

K1.00252 Electric-field induced modification of Landau levels in graphene nanoribbon[1] , HSIEN-CHING CHUNG, Department of Physics, National Cheng Kung University, YUAN-CHENG HUANG, Center for General Education, Kao Yuan University, MING-FA LIN, Department of Physics, National Cheng Kung University — The low energy magneto-ectronic properties of one-dimensional graphene nanoribbons are investigated by the Peierls tight-binding model with uniform magnetic and electric fields. They are mainly determined by the quantum confinement effects and the external fields. Magnetic fields result in the Landau levels (LLs), lead to the Landau wavefunctions, and enhance partial flat bands. Electric fields significantly modify the dispersionless LLs, change the band symmetry, induce more band-edge states, split the partial flat bands, and drastically alter the distribution of wavefunctions. The density of states directly reflects the main features of energy bands, such as the numbers, frequencies, heights and divergence forms of prominent peaks, which can be confirmed experimentally. The magneto-optical absorption spectra are predicted to be dramatically changed under the influence of external electric fields.

K1.00253 Spin-polarized energy gap opening in asymmetric bilayer graphene nanoribbons , GYUBONG KIM, Korea Institute of Science and Technology, SEUNG-HOON JHI, Pohang University of Science and Technology — Electronic and magnetic properties of bilayer zigzag graphene nanoribbon (bZGNR) are studied with the use of pseudopotential density functional method. The edge atoms in the top and bottom layers of bZGNR make a weak hybridization, which leads to band dispersion and magnetization different from monolayer ZGNR. For asymmetric bZGNR, where the top and bottom layers have different width, one edge is pinched by the interlayer bonding and the other edge sustains anti-ferromagnetic spin polarization. A small amount of charge transfer occurs from narrower to wider layer, and the band structure for each spin near the Fermi level exhibits an asymmetry. External electric field perpendicular to asymmetric bZGNR produces different energy-gap opening for each spin component, inducing half-metallicity.

K1.00254 Synthesis and Characterization of Graphene Sheets Covalently Functionalized with Polyaniline , SANJEEV MANOHAR, SRIKANTHRAO AGNIHOTRA, AKSHAY PHULGIRKAR, University of Massachusetts Lowell — Herein we report covalent functionalization of graphene oxide (GO) with conducting polymer polyaniline and aniline tetramer for the first time. The covalently functionalized rGO is electrically conducting, shows improved electrochemical properties and enhanced specific capacitance compared to rGO. We also observed enhanced thermal stability and antistatic properties can be obtained on addition of these covalently functionalized composites into the polymer matrix such as PMMA.

K1.00255 Thermoelectric Power in Dual-Gated Bilayer Graphene , CHANG-RAN WANG, VINCENT LU, WEI-LI LEE, Institute of Physics, Academia Sinica, INSTITUTE OF PHYSICS, ACADEMIA SINICA TEAM — We have performed thermoelectric transport measurements of dual-gated bilayer graphene device. The thermopower reached a maximum value of |Sm| when tuning its carrier density by gates. The |Sm| was found to monotonically increase with displacement field D introduced through the top and bottom gates. At 100K, |Sm| attains a value of $\sim$ 110 uV/K at D $\sim$ 1V/nm, which is nearly two-fold larger than that at D = 0. The detailed temperature-dependence of Sm and comparison to the resistivity data will be presented.

K1.00256 Trigonal Distortion of Valley Current in Bilayer Graphene[1] , PATRICIO VARGAS, Departamento de Física, Universidad Tecnica Federico Santa María, ALVARO NUÑEZ, Departamento de Física, FCFM, Universidad de Chile, ERIC SUAREZ, Departamento de Física, Universidad Tecnica Federico Santa María — Bilayer Graphene (BLG) is extensively explored due to its remarkably electronic properties. Its band structure has two inequivalent but degenerate points K and K' at the corners of the Brillouin Zone, because their large separation there have been proposition to use a valley index, or pseudospin to generate valley dependent currents. In BLG these currents can be created by applying an step like bias, the topology of BLG in the two zones leads to the formation of a 1D chiral zero modes transverse to the applied bias. There are two such modes per spin per valley and the current have opposite direction in each valley. We explore how the trigonal warping of BLG affects these modes. Breaking the symmetry of the unit cell in BLG opens a gap, the shape of the Berry Curvature depends of the bias applied, for very low bias (few meV) the topological charge breaks in four well defined peaks, three having the same sign and magnitude and the fourth with opposite value, the overall charge remains unaltered, these fraction charges lead to a distortion of the chiral zero modes. We calculate the currents and show how the system evolves by tuning the effect of the trigonal warping.

[1]We acknowledge FONDECYT-1100508 and CEDENNA grants from CONICYT-CHILE.

K1.00257 A Way from GHz to THz Graphene Nanosensor , YUICHI OCHIAI, AKRAM MAHJOUB, NOBUYUKI AOKI, Chiba University, JUNG WOO SONG, SUNY Buffalo, GREGORY AIZIN, CUNY Kingsborough, JONATHAN BIRD, SUNY Buffalo, DAVID FERRY, Arizona State University, YUKIO KAWANO, KOJI ISHIBASHI, ADLab, RIKEN, G-COE COLLABORATION — The unique bandstructure, and associated carrier properties, of graphene make this material of ideal interest for application as a broadly tuneable sensor, for specific application to the microwave and terahertz (THz) regime. The gapless spectrum characteristic of single-layer graphene, as well as the small forbidden gap that appears in bilayer graphene, is ideally matched to the low (meV) energy of photons near the THz regime, in marked contrast to conventional semiconductors whose relevant bandgaps are typically several orders of magnitude larger. In this presentation, we describe the results of ongoing research that is being undertaken with the objective of developing upto THz nanosensors based on graphene. We describe the preparation of graphene devices by mechanical exfoliation, after which we discuss the characterization of their electrical properties using low-temperature magneto-transport investigations [1]. These studies demonstrate the formation of open quantum-dot structures in small graphene flakes, contacted by sub-micron scale metal electrodes. The observation of quantum fluctuations in the magneto-resistance of these structures indicates the presence of quantized dot states, whose characteristics may be of use in THz sensing. [1] Y. Ujiie et al., J. Phys.: Condens. Matt. 21 (2009) 382202.

K1.00258 Photoluminescence from hydrogenated graphene[1] , VOLODYMYR TURKOWSKI, TALAT S. RAHMAN, Physics Department and NSTC, University of Central Florida, Orlando FL 32816 — We consider the optical properties of hydrogenated graphene as a function of hydrogen concentration between the graphene and graphane limits. In particular, we show that with increasing hydrogen concentration the gap in the electron density of states grows from 0 to approximately 5eV in the case of graphane. For intermediate concentrations, additional electronic states with energies smaller than 5eV appear. These states make the system optically active in the visible range. We pay special attention to the possibility of ultrafast photoluminescence in the system for different values of hydrogen concentration and hole doping. For example, for excitations by ultrafast laser pulses, the system demonstrates significant visible range photoluminescence driven by the electron-phonon interaction. In the case of graphane, the effect can be significantly enhanced by hole doping, when the phonon spectrum demonstrates a Kohn anomaly, which results in a faster partial equilibration between the electrons and an optical phonon subsystem.

K1.00259 Controllable p-n Junction Formation in Monolayer Graphene Using Electrostatic Substrate Engineering , HSIN-YING CHIU, VASILI PEREBEINOS, YU-MING LIN, PHAEDON AVOURIS, IBM Thomas J. Watson Research Center — The p-n junction is the basic element of modern electronics, providing the non-linear response essential for rectifying and switching currents. In conventional semiconductors, p-n junctions are produced by inserting donor and acceptor atoms in the crystal lattice. This approach, however, fails to produce effective results in nanoscale or low-dimensional electronic materials, such as graphene. Graphene itself is attracting much attention due to its unique electronic properties. In addition to having outstanding carrier mobilities graphene offers opportunities extending beyond CMOS technology, such as p-n junction electron (Veselago) lenses. Thus, graphene electronics depends on the ability to fabricate high-quality p-n junctions. Doping of graphene has been previously achieved by using multiple electrostatic gates, or charge transfer from adsorbants. Here we demonstrate a novel approach to create p-n junctions by changing the local electrostatic potential in the vicinity of one of the contacts without the use of extra gates. It is based on the electronic modification of the substrate and produces a well-behaved, sharp junction whose position and height can be controlled.

K1.00260 Opto-Electronic Properties of Nano-Structured Graphitic Carbon Measured Using Micro-Raman Spectroscopy , LOGAN SCHEEL, KEVIN MEAD, JEFFERY DEMERS, JEFF SIMPSON, Towson University — Nano-structured graphitic carbon allotropes offer promise for next generation optical and electronic devices. Graphene, a single atom layer of hexagonally arranged carbon atoms, is particularly interesting as the basis for other forms of graphitic carbon, e.g., single-wall carbon nanotubes (SWCNTs). The unique linear energy versus momentum band structure of graphene leads to interesting fundamental physics and potential device applications. We report on the design and implementation of a micro-Raman spectroscopy system used to measure the opto-electronic properties of graphene and SWCNTs. Using mechanical exfoliation, single and multilayer graphene flakes are deposited on Si/SiO_2 substrates. Our Raman system consists of multiple laser sources including, HeNe, Argon, and dye lasers, which provide excitation light to samples mounted in an optical microscope. Inelastically scattered light is collected and directed to a grating spectrometer with CCD detection. Analysis of the Raman spectra reveal specific phonons known as the D, G, G'_{2D} modes common to graphitic carbon. We fit the modes with Lorentzians in order to quantify the layer number and analyze electron-phonon coupling.

K1.00261 Comparing the Inner and Outer Double-resonance Raman Scattering Processes in Bilayer Graphene , DANIELA MAFRA, Universidade Federal de Minas Gerais, ELIE MOUJAES, RICARDO NUNES, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil., STEVEN DOORN, HAN HTOON, Chemistry Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA., MARCOS PIMENTA, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil. — The Raman spectroscopy has been widely used to study carbon materials. In this work the dispersion of phonons and the electronic structure of graphene systems can be obtained experimentally from the double-resonance (DR) Raman features by varying the excitation laser energy. The electronic structure was analyzed in the framework of the Slonczewski-Weiss-McClure (SWM) model, considering both the outer and inner DR process and the SWM parameters was obtained for each model. We show that the parameters obtained when we consider the inner DR process are in better agreement with those obtained from other experimental techniques, despite the fact that several previous studies about the DR process in graphene usually pay atention solely to the one-dimensional outer (DR) process. This result possibly shows that there is still a fundamental open question concerning the double resonance process in graphene systems.

K1.00262 A search for the dominant heat conducting phonon modes in graphene: An atomistic simulation study , HENGJI ZHANG, Department of Physics, University of Texas at Dallas, KYEONGJAE CHO, Department of Physics and Department Materials Science and Engineering, University of Texas at Dallas — We have performed an equilibrium molecular dynamic (MD) simulation study to investigate phonon thermal transport in graphene at 300K with Green-Kubo method. Using a newly optimized reactive empirical bond order carbon potential (Lindsay, et al. Physical Review B 81, 205441, 2010), our calculated thermal conductivity (TC) of defect free graphene is about 3000 W/mK in good agreement with experiments($\sim$3000-5000 W/mK). A maximum of $\sim$1000 fold reduction in TC is possible to achieve for graphene with defects and surrounding viscous medium. As we decompose the in-plane and out-plane phonon vibration modes of graphene in MD simulations, the out of plane vibration modes (ZA phonon) contribute to about 50% of the overall TC. This large contribution from ZA modes is explained with density of states analysis. We have clarified a recent controversy on which polarization mode in graphene is the main heat carrier.

K1.00263 Polarized Nonresonant Raman Spectra of Graphene Nanoribbons , GUANGFU LUO, JING LU, LU WANG, LIN LAI, JING ZHOU, RUI QIN, HONG LI, ZHENGXIANG GAO, State Key Laboratory for Mesoscopic Physics and Department of Physics, Peking University, Beijing 100871, People's Republic of China, WAI-NING MEI, Department of Physics, University of Nebraska at Omaha, Omaha, Nebraska 68182-0266 — We study the non-resonant Raman scattering of armchair- and zigzag-edged graphene nanoribbons using density functional perturbation theory. We find that in both types of nanoribbon, the Raman spectrum is extremely polarized along the ribbon length direction, over 102 times larger than those of the other orientations. Also we discover that the scattering intensity of this major polarization exhibits conspicuous quantum oscillation with the ribbon width in armchair-edged nanoribbons. While in zigzag-edged nanoribbons, the Raman spectra shows relatively weak dependence on the ribbon width. We propose employing the surface-enhanced Raman spectroscopy to detect these features, a procedure which has been applied in the studies of graphene.

K1.00264 A broadband microwave study of CVD grown graphene[1] , WEI LIU, Johns Hopkins University, CARL MAGNUSON, YUFENG HAO, RODNEY RUOFF, The University of Texas at Austin, PETER ARMITAGE, Johns Hopkins University — We apply a broadband microwave Corbino spectrometer to study the complex conductivity of CVD grown graphene deposited on a high resistivity Si substrate. Explicit frequency dependency of the complex conductivity are obtained down to 300 mK and in a frequency range from 100 MHz to 20 GHz. We compare our data to the low frequency limit of the conductance of different theoretical models and make connection to other experimental results. We will also report measurements of the conductivity using time domain terahertz spectroscopy.

[1]NSF DMR-0847652

K1.00265 Graphene grown on Ni surface: quantitative analysis , IRMA KULJANISHVILI[1], DMITRIY DIKIN, Northwestern University, ALICE RILEY, Hendrx College, PAVAN PATEL, VENKAT CHANDRASEKHAR, Northwestern University — CVD growth of graphene on various substrates, e.g. Copper or Nickel, has become an increasingly popular method for production of large films. Unlike copper mediated growth, the CVD growth process of graphene on Nickel film is not self-limiting, hence understanding the main factors and/or conditions that influence the growth of one or few layers of graphene on Nickel is important. We will present our results on CVD growth of graphene on Nickel films deposited on Si/SO2 substrates. We will discuss our results of single and few layer graphene synthesis and our attempts to explain the growth mechanism of graphene. Correlation between SEM and AFM/EFM studies and optical characterization of graphene will be presented. A.R. acknowledges the support of International Institute of Nanotechnology REU Program

[1]Department of Physics

K1.00266 Experimentally determined optical-properties of monodisperse graphene quantum dots with controlled size and geometry , VIKAS BERRY, Kansas State University, NIHAR MOHANTY, ASHVIN NAGARAJA — In this talk, we will present a novel route for high throughput production of monodisperse GQDs with controlled spatial dimensions (5 nm - 100 nm at 1 nm resolution) and geometry (squares, rectangles, and triangles). We would show the first detailed experimental demonstration of the GQD optoelectronic-property-tuning via tailoring of their spatial dimensions and geometry. Further, we would be presenting the detailed structural, optical and electronic characterization of the as-obtained GQDs via various microscopic and spectroscopic techniques. While the top down methods of fabrication including lithography-based methods or sonochemical methods are either extremely low throughput or have limited control on GQDs' dimensions and geometry; the bottom-up fabrication methods are limited by the achievable size ($<$ 3 nm).

K1.00267 Magneto-transport of graphene quantum dots , KUEI-LIN CHIU, CHARLES SMITH, MALCOLM CONNOLLY, SIMON CHORLEY, JONATHAN GRIFFITHS, University of Cambridge — Graphene nanostructures continue to attract attention due to their customizable electronic properties and compatability with existing semiconductor device processing. The promise of long spin relaxation times makes graphene quantum dots small islands of confined charge - particularly suited to quantum computing architectures that manipulate the spin degree of freedom. In order to probe the spin and charge dynamics of geometrically confined Dirac quasiparticles, we have performed magneto-transport measurements on a single dot and a series-coupled double dot at temperatures down to 100 mK and magnetic fields up to 12 T. In the single dot structure we follow the energy required to add electrons to the dot in the many-electron regime. The energy levels show a rich structure of "kinks" as a function of the magnetic field, and we analyze this result in terms of Landau level formation in the quantum dot. In the double quantum dot structure we find that the conductance of the device as a function of the energy levels in the dots exhibits the typical honeycomb pattern. From the dimensions of the honeycomb we extract the capacitive coupling strength between dots and the gates, and examine how this evolves as a function of magnetic field. We analyze this result in terms of magnetic field induced changes in the capacitive coupling between the quantum dot and the plunger-gates.

K1.00268 Impurity and phonon scattering in silicon nanowires , W. ZHANG, Beijing National Laboratory for Condensed Matter Physics, China, M.P. PERSSON, H. MERA, CEA-UJF, INAC, SP2M/L-Sim, Grenoble, France, C. DELERUE, IEMN - Dept. ISEN, Lille, France, Y.M. NIQUET, CEA-UJF, INAC, SP2M/L-Sim, Grenoble, France, G. ALLAN, IEMN - Dept. ISEN, Lille, France, E. WANG, School of Physics, Peking University, Beijing, China — We model the scattering of electrons by phonons and dopant impurities in ultimate [110]-oriented gate-all-around silicon nanowires with an atomistic valence force field and tight-binding approach. All electron-phonons interactions are included. We show that impurity scattering can reduce with decreasing nanowire diameter due to the enhanced screening by the gate. Donors and acceptors however perform very differently : acceptors behave as tunnel barriers for the electrons, while donors behave as quantum wells which introduce Fano resonances in the conductance. As a consequence the acceptors are much more limiting the mobility than the donors. The resistances of single acceptors are also very dependent on their radial position in the nanowire, which might be a significant source of variability in ultimate silicon nanowire devices. Concerning phonons, we show that, as a result of strong confinement, i) electrons couple to a wide and complex distribution of phonons modes, and ii) the mobility has a non-monotonic variation with wire diameter and is strongly reduced with respect to bulk. French National Research Agency ANR project QUANTAMONDE Contract No. ANR-07-NANO-023-02 and by the Délégation Générale pour l'Armement, French Ministry of Defense under Grant No. 2008.34.0031.

K1.00269 ARTIFICIALLY STRUCTURED MATERIALS –

K1.00270 Spin splitter in a quantum ring with Rashba coupling[1] , B. TANATAR, Bilkent University, Department of Physics, 06800, Ankara, Turkey, V. MOLDOVEANU, National Institute of Materials Physics, P.O. Box MG-7, Bucharest-Magurele, Romania — We use non-equilibrium Greens' function formalism to calculate the spin currents in a one-dimensional ring coupled to three leads in the presence of perpendicular magnetic flux F and Rashba spin-orbit coupling. A finite bias is applied between the input lead and the other two output leads. We demonstrate that the spin-orbit coupling allows one to operate this system as a spin splitter, i.e. the output leads deliver spin-polarized currents with different orientations. We find that the spin splitter operation can be tuned at integer multiples of F/F_0. Efficiency depends not only on the value of the Rashba coupling but also on the bias applied between the input and output leads. The selected spin orientation of the output leads can be reversed by a slight change of their contact position. We also discuss the connection between the spin splitter operation and the spectral properties of the ring.

K1.00271 Nanoscale engineering of photoelectron kinetics in quantum dot structures , ANDREI SERGEEV, VLADIMIR MITIN, NIZAMI VAGIDOV, SUNY at Buffalo — We investigate photoelectron kinetics in advanced quantum dot (QD) structures, which combine quantum tuning of localized and conducting states with controllable photoelectron properties. Our unique approach is based on engineering of photoelectron capture processes using various configurations of manageable potential barriers around single QDs and collective barriers around QD planes (lateral structures) and QD clusters (vertical structures). Potential barriers around QDs are formed by electrons bounded in dots and ionized impurities in the depletion region. These potential barriers separate the conducting electron states from the localized intra-dot states. Besides manageable photoelectron lifetime, the novel structures will also provide high scalability, low generation-recombination noise in sensing applications and low recombination losses in QD solar cells.

K1.00272 Long-range exciton-exciton interactions in metal-semiconductor hybrid structures , ANSHU PANDEY, HSINHAN TSAI, HSING-LIN WANG, JEFFREY M. PIETRYGA, VICTOR I. KLIMOV — Establishment of long-range communication between semiconductor nanocrystals (NCs) is an important step towards their use in real-life devices. Most research towards enhancing inter-NC coupling has followed two strategies: attempts to enhance charge transfer rates in NC assemblies, and enhancement and control of energy transport via exciton transfer. We have explored the second strategy for obtaining strong coupling between distant NCs. For this purpose, we have studied the optical properties of colloidal NCs tethered to spherical gold particles coated with a silica shell. These structures exhibited clear signatures of long range coupling between the NCs which manifested in the form of cooperative decay of excitons separated by large distances (up to 40 nm apart). We further show that this coupling does not alter the overall emission efficiency of the excitons, though it significantly modifies emission rates. The observation of this regime of exciton interaction has potential applications in existing NC based devices such as lasers, and may also lead to novel applications that involve defect-tolerant energy transfer between distant chromophores

K1.00273 How to select quantum dots with smallest fine structure splitting under uniaxial stress for entangled photon sources , MING GONG, WEIWEI ZHANG, GUANGCAN GUO, LIXIN HE, Key Laboratory of Quantum Information, University of Science and Technology of China, Hefei, 230026g, HE TEAM — We propose a microscopic theory to build an exact relationship between the fine structure splitting (FSS) of exciton, the polarization of the emission lines and the amount of asymmetry in self-assembled quantum dots (QDs). Based on our model, strategy to select QDs with smallest FSS from large amount of QDs is proposed. The predilection in this work is supported by million atom empirical pseudo-potential calculation. Our theory can greatly simply the method to generate entangled photon sources using single QD.

K1.00274 Tunable Optical Switching/Routing by Negative Refraction in Liquid Crystal filled Opal and Inverted Opal Photonic Crystals , RABIA MOUSSA, Nanotech Institute, University of Texas at Dallas, RYOTARO OZAKI, Department of Electrical and Electronic Engineering, National Defense Academy of Japan, A. EFROS, ANVAR ZAKHIDOV, Nanotech Institute, University of Texas at Dallas, DEPARTMENT OF ELECTRICAL AND ELECTRONIC ENGINEERING, NATIONAL DEFENSE ACADEMY OF JAPAN TEAM, NANOTECH INSTITUTE, UNIVERSITY OF TEXAS AT DALLAS TEAM, NANOTECH INSTITUTE, UNIVERSITY OF TEXAS AT DALLAS TEAM — In this study, we investigate the optical characteristics and negative index of liquid crystal (LC) infiltrated inverse opal as a 3D photonic crystal (PC). We demonstrate that it is possible to achieve a tunable negative, by infiltrating LC into porous synthetic opal and inverted opal type PC. Using the optical anisotropy of LC and field sensitivity, the optical properties of porous PC infiltrated with LC can be easily controlled. The design of a simple and efficient wide angle optical switch/router is considered. Changing the electric field across the LC-PC, with the use of transparent electrodes, the refractive index of Opal-PC can be modulated within several percent, shifting the light beam between photonic bands with negative and positive dispersion. The calculations reveal that LC molecular orientation in the inverse opal strongly influences light propagation in 3D PC.

K1.00275 Analysis of Self-Assembled Monolayers in Nanoscale Switching Elements , MATTHEW ROBERSON, LAM YU, University of Memphis — Molecular junctions consisting of gold and silver electrodes and a self-assembled monolayer (SAM) have been shown to act as voltage-controlled electrical two-state switches due to the electrochemical migration of silver ions. In these junctions the SAM is sandwiched between the two metal electrodes. When a certain bias voltage is applied across the metal electrodes, atoms on the silver electrode surface are electrochemically oxidized, and the resulting silver ions are drawn by the local electric field toward the gold electrode. Upon deposition onto the gold electrode the silver ions are reduced to silver atoms. As more silver atoms are deposited onto the gold electrode, a metallic connection is formed between the electrodes resulting in a closed-circuit state between the two electrodes. The silver metallic bridges are metastable in these junctions, and they are dissolved when the voltage between the electrodes is swept back toward zero volts. When the silver filaments retract, the switch returns to an open-circuit state. Varying the functional group of the SAMs induces different switching characteristics in the junctions. We are analyzing the transition voltages at which this switching occurs for different SAMs under different temperature and humidity, and plotting the data to observe trends in order to isolate the key factors involved in this switching.

K1.00276 ABSTRACT WITHDRAWN —

K1.00278 Angle- and position-resolved plasmon coupling in gold nanocrystal dimers , LEI SHAO, JIANFANG WANG, The Chinese University of Hong Kong — Interactions between the localized plasmons of metal nanocrystals have attracted much attention, because of their applications ranging from photonic devices to biomolecular detection. Gold nanorods (NRs) exhibit both the transverse and longitudinal plasmon modes, with the latter being strongly polarization-dependent. We have studied the coupling in Au NR homodimers and Au NR-Au nanosphere (NS) heterodimers. Experimental observations, as well as simulations, have revealed a number of interesting phenomena in the plasmon coupling. First, both the antibonding and bonding modes are existent in the NR dimer system and their intensity ratio decreases exponentially as the NR angle increases. Second, the NR-NS heterodimers exhibit Fano resonance properties and a NS-site-dependent coupling behavior. We believe that our results will be useful for developing complex plasmon-based photonic devices and ultrasensitive plasmonic sensors. The NR-based dimers can also potentially function as building blocks for the construction of metamaterials.

K1.00279 Strain Effects in Thermoelectric $Ca_3Co_4O_9$ Thin Films[1] , ROBERT KLIE, QIAO QIAO, AHMET GULEC, TADAS PAULAUSKAS, University of Illinois - Chicago, STANISLAW KOLESNIK, BOGDAN DABROWSKI, Northern Illinois University, CIHAT BOYRAZ, MEHMET OZDEMIR, DIPANJAN MAZUMDAR, ARUN GUPTA, University of Alabama — Thermoelectric oxides have attracted increasing attention due to their high thermal power and temperature stability. In particular, $Ca_3Co_4O_9$(CCO), a misfit layered structure consisting of single layer hole-doped CoO_2 sandwiched between insulating Ca_2CoO_3 rocksalt layers, exhibits a high Seebeck coefficient at 1000 K.It was suggested that the Seebeck-coefficient can be further increased by growing doped thin films with controlled defects structures. This study combines pulsed layer deposition thin film synthesis of pristine CCO on several oxide substrates, as well as CCO thin films doped with Ti, Bi or La, with aberration-corrected scanning transmission electron microscopy and electron energy loss spectroscopy (EELS) to examine the effects of interfacial strain and doping on the atomic and electronic structures of CCO. The thermoelectric properties will be measured and correlated to the local changes in the atomic and electronic structures. We will further evaluate the role of CoO_2 stacking faults, as well as film thickness on the thermoelectric properties of CCO.

K1.00280 First principle investigation of ZrO_2-CeO_2 heterojunction properties , MARCO FRONZI, Materials Nanoarchitectonics Department, National Institute for Material Science, ALESSANDRO DE VITA, Physics Department, King's College London, Strand,London, YOSHITAKA TATEYAMA, ENRICO TRAVERSA, Materials Nanoarchitectonics Department, National Institute for Material Science — Here we present a computational Density Functional Theory approach to analyze the structural and electronic properties of the (100) and (111) ZrO_2-CeO_2 interface. Optimization of the lattice geometry for the separate ZrO_2 and CeO_2 bulks as well as the interface is carried out and the structural morphology is analyzed. The energy formation of the oxygen vacancies are analyzed at different values of lattice parameter, in order to verify its dependency on the strain. Activation energy of the oxygen migration are also calculated in the bulk as well as at the interfaces level. The effect of the doping on the lattice geometry is analyzed for the (111) and (100) interfaces in order to verify its influence on the morphologic disorder.

K1.00281 Structure, Vibrational Dynamics and Thermodynamics of silver thin-films on Cu(100) , SAMUEL ROBERTS, JAMES WESTOVER, ABDELKADER KARA, University of Central Florida — We use a Real Space Green's function and the embedded atom method for interaction potentials, to examine the structural and vibrational properties of a silver thin-film (from one to four monolayers) on Cu(100). Due to the lattice mismatch, the first several layers of the substrate had major structural modification, in the form of buckling about 0.6A for the top two layers and 0.05A in the 6^{th} layer. For the case of a mono-layer, the vibrational densities of state of the silver atoms extend substantially beyond the maximum of the bulk density. The atoms in the first copper layer's density of state also show substantial enhancement of the high frequency end. These reflect the strong bonding between the monolayer and the substrate. The vibrational thermodynamic functions for these interface atoms will be presented

K1.00282 Improvements in 3-omega measurement of thermal conductivity for nanostructured materials , CHUANLE ZHOU, M. GRAYSON, Electrical Eng. Comp. Sci., Northwestern University, Evanston IL, USA, G. KOBLMUELLER, Walter Schottky Institut, Tech. Univ. Munich, Germany — Nanostructured materials have reduced thermal conductivity in order to enhance the thermoelectric figure of merit (ZT). The 3ω method is widely used for vertical thermal conductivity measurements in the nanostructure materials, especially layered materials. The challenge for this method is to measure the small 3ω voltage at the third harmonic, above the comparably large ω voltage from the sample at the fundamental frequency, complicated by the nonlinear signal from other components in the measurement circuit. We carefully study the 3ω method [Cahill, Rev. Sci. Instrum. 61 (2), 802 (1990)] and develop a strategy to increase the signal to noise ratio of the data, for more accurate results. We also investigate an alternate sample preparation geometry for the 3ω measurement, so that the heat flow is vertical and linear through the thin film instead of cylindrical as is standard for this method. This results in a direct measurement of the vertical thermal conductivity in such an anisotropic material. New geometries for measuring lateral thermal conductivity will also be proposed and explored.

K1.00283 PHASE TRANSITIONS AND STRONGLY CORRELATED SYSTEMS –

K1.00284 Magnetic Superstructure and Metal-Insulator Transition in Mn-Substituted $Sr_3Ru_2O_7$

M.A. HOSSAIN, UBC and SIMES, Stanford, Z.H. ZHU, UBC, B. BOHNENBUCK, MPI, Stuttgart, Y.-D. CHUANG, Berkeley Lab, Y. YOSHIDA, AIST, Z. HUSSAIN, Berkeley Lab, B. KEIMER, MPI, Stuttgart, I.S. ELFIMOV, G.A. SAWATZKY, A. DAMASCELLI, UBC — We present a temperature-dependent resonant elastic soft x-ray scattering (REXS) study of the metal-insulator transition in $Sr_3(Ru_{1-x}Mn_x)_2O_7$, performed at both Ru and Mn L-edges. Resonant magnetic superstructure reflections together with ab-initio density functional theory calculations identify the ground state as a spin checkerboard with blocks of 4 spins up and 4 spins down. Based on modelling of the REXS intensity from randomly distributed Mn impurities, we establish the inhomogeneous nature of the metal-insulator transition, with an effective percolation threshold corresponding to an anomalously low $x \sim 0.05$ Mn substitution. Perhaps more important, our results suggest that the same checkerboard instability might be present already in the parent compound $Sr_3Ru_2O_7$. In collaboration with: A.G. Cruz Gonzalez, J.D. Denlinger (Berkeley) I. Zegkinoglou, M.W. Haverkort (MPI) J. Geck, D.G. Hawthorn (UBC) R. Mathieu, Y. Tokura, S. Satow, H. Takagi (Tokyo) H.-H. Wu and C. Schussler-Langeheine (Cologne).

K1.00285 Ultrafast quasiparticle dynamics in the hidden order state of URu_2Si_2

MENGKUN LIU, Boston University, DZMITRY YAROTSKI, TOMASZ DURAKIEWICZ, STUART TRUGMAN, Los Alamos National Laboratory, RICHARD AVERITT, Boston University, ANTOINETTE TAYLOR, Los Alamos National Laboratory — The heavy-fermion compound URu_2Si_2 has attracted much interest in the past two decades due to appearance of the 'hidden order' (HO) state in this material below 17.5 K. Despite an extensive effort, the development of the theoretical description of the origin of HO has been hindered by the lack of adequate experimental evidence regarding low-energy electronic structure of this compound. We report on application of ultrafast optical spectroscopy to probe quasiparticle dynamics in the vicinity of E_F in a single crystal URu_2Si_2 undergoing the HO phase transition. The relaxation dynamics of the photoexcited carriers exhibits a strong dependence on temperature and excitation intensity. Data analysis using the Rothwarf-Talyor model demonstrates an opening of a 5 meV energy gap as the temperature decreases below 20 K. This behavior is consistent with recent results obtained from angle-resolved photoemission spectroscopy, scanning tunneling microscopy and neutron scattering experiments.

K1.00286 High Field (H,T) Phase Diagram and Anisotropy of $CeRhIn_5$ single crystals

YOSHIMITSU KOHAMA, MPA-CMMS, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, HUIQIU YUAN, LIN JIAO, Department of Physics, Zhejiang University, Hangzhou 310027, China, MARCELO JAIME, FEDOR BALAKIREV, ERIC BAUER, MPA-CMMS, Los Alamos National Laboratory, Los Alamos, NM 87545, USA — The specific heat (C_p) of a single crystal sample of composition $CeRhIn_5$ was measured as a function of temperature and magnetic field applied perpendicular and parallel to the crystallographic $c-$axis. Our experiments, carried out at temperatures below the AFM ordering temperature $T_N =$ 3.7 K, show a clear anomaly in $C_p(H)$ when the applied field is strong enough to suppress the magnetic order. This anomaly, which reduces the magnitude as the temperature is lowered, was used to map the (H,T) phase diagram for the first time to a magnetic field of 55 T and temperatures as low as 700mK.[1] Extrapolation of the low temperature phase boundary indicates the presence of a magnetic field-induced quantum critical point at $H_c \approx$ 50 T that is weakly dependent of the sample orientation, although intermediate magnetic fields reveal clear anisotropy. Our results will be discussed in the context of field-induced quantum phase transitions in strongly anisotropic correlated matter.

K1.00287 Transport properties in magnetic Griffiths phases

DAVID NOZADZE, THOMAS VOJTA, Department of Physics, Missouri University of Science and Technology, Rolla, MO 65409 — We study the temperature dependence of the electrical resistivity in the quantum Griffiths phases associated with the ferromagnetic and antiferromagnetic quantum phase transitions in itinerate systems. The resistivity is calculated by means of the semi-classical Boltzmann equation. We show that the contribution to the resistivity due to the scattering by spin-fluctuations in rare regions varies as T^λ with the logarithmic correction for both ferromagnetic and antiferromagnetic systems. Here λ is the usual Griffiths exponent which takes the value 0 at the critical point and increases with the distance from the criticality. We also consider other transport properties such as thermal resistivity, thermopower and Peltier coefficient.

K1.00288 Evolution of Power-Law Behavior of Temperature Dependence of Electrical Resistivity in $Pr_{1-x}Nd_xOs_4Sb_{12}$[1]

P.-C. HO, Physics/California State University, Fresno, R.E. BAUMBACH, A.A. DOORAGHI, M.B. MAPLE, Physics/University of California, San Diego, T. YANAGISAWA, Hokkaido University, Japan — The study of the $Pr_{1-x}Nd_xOs_4Sb_{12}$ series has been carried out in order to investigate the effect of ferromagnetism (FM) on the unconventional superconductivity (SC), the high field ordered phase (HFOP), and quantum critical behavior in $PrOs_4Sb_{12}$ [1, 2, 3]. Two critical concentrations $x_{cr,1} \sim 0.58$ and $x_{cr,2} \sim 0.33$ were previously identified in this system [2]: SC disappears near $x_{cr,1}$ and weak FM extends into the SC region for $x_{cr,2} < x < x_{cr,1}$ [3]. In order to further examine the possible quantum critical behavior, a power-law analysis of the temperature dependence of the electrical resistivity data is performed. Upon suppression of SC, for samples of $x_{cr,2} < x < x_{cr,1}$, the power-law exponent decreases from $\sim$ 1.8 toward 1 in the temperature region below 2.5 K, resembling non-Fermi liquid behavior.

K1.00289 Temperature Dependent Investigations on Single Crystal Gallium Ferrite Using X-ray Diffraction and Raman Spectroscopy

S. MUKHERJEE, Dept. of Physics, IIT Kanpur, India, RAJEEV GUPTA, Dept. of Physics and Materials Science Programme, IIT Kanpur, India, ASHISH GARG, Materials Science and Engineering, IIT Kanpur, India — $Ga_{2-x}Fe_xO_3$ ($0.8 \leq x \leq 1.2$) or GFO is a room temperature paramagnetic piezoelectric material with its ferrimagnetic to paramagnetic transition temperature (T_c), varying from 200 K to 300 K. We synthesized GFO ($x \sim$ 1.08-1.10) single crystals using flux growth method. Partial occupancies of the cationic sites obtained using Reitveld refinement of XRD data were used to calculate the lattice magnetic moment. We have also carried out Raman scattering as a function of temperature from 18 K to 450 K. Temperature evolution of the peak positions of most of the modes can be adequately described using an anharmonic model suggesting absence of any lattice anomaly across the phase transitions. This observation is consistent with the XRD data. However, the temperature dependence of the line width of a number of modes exhibits a change in slope across the phase transition boundary. In order to understand and quantify this change in the line width as a function of temperature we calculate the product of electron-phonon coupling strength and the density of states at the Fermi level. The deviation from anharmonicity is qualitatively explained as a consequence of a weak magneto-elastic effect in the low temperature phase.

K1.00290 Power-law Griffiths singularities in a randomly layered Heisenberg magnet , FAWAZ HRAHSHEH, THOMAS VOJTA, Department of Physics, Missouri University of Science and Technology, Rolla MO 65409, USA — We study the ferromagnetic phase transition in a randomly layered Heisenberg model using Monte-Carlo simulations. A recent strong-disorder renormalization group approach [Phys. Rev. B 81, 144407 (2010)] predicted that the critical point in this system is of exotic infinite-randomness type and is accompanied by strong power-law Griffiths singularities. Here, we show the results of simulations that provide numerical evidence in support of these predictions. Specifically, we investigate the finite-size scaling behavior of the magnetic susceptibility which is characterized by a non-universal power-law divergence in the Griffiths phase. In addition, we calculate the spin-wave stiffnesses both parallel and perpendicular to the layers. We find that the perpendicular stiffness decays to zero at lower temperatures than the parallel stiffness which vanishes at the critical point.

K1.00291 Density matrix Loschmidt echo and quantum discord in quantum phase transitions , YANCHAO LI, Beijing Computational Science Research Center (CSRC), STATE KEY LABORATORY FOR SUPERLATTICES AND MICROSTRUCTURES, INSTITUTE OF SEMICONDUCTORS, CAS COLLABORATION, BEIJING COMPUTATIONAL SCIENCE RESEARCH CENTER (CSRC) TEAM — We introduce the concept of the Loschmidt echo (LE) to the space of the reduced density matrix of spin and fermionic systems to study the relationship between the density matrix Loschmidt echos (DMLEs) and quantum phase transitions (QPTs). Our results show that the DMLEs are remarkably influenced by the criticality of the system, and the method is a convenient way to study QPT. Meanwhile, we compare quantum discord and DMLE calculations, aiming to explore the difference and connection between them in identifying QPTs.

K1.00292 Time Reversal Symmetry Breaking in 2D Lattice Model , WEI LIU, ALEXANDER PUNNOOSE, City College of New York — We use magnetic group as a tool to classify the possible spontaneous time-reversal symmetry breaking states in 2D electronic systems. We study the leading order fluctuations of the order parameter with discrete symmetry. The method is applied to the study of Topological Mott insulator phase in Graphene and orbital loop currents in CuO planes.

K1.00293 The Verwey transition in Fe_3O_4: lattice distortions on a fs time-scale , R. KUKREJA, S. DE JONG, M. HOSSAIN, C. BACK, A. SCHERZ, D. ZHU, W. SCHLOTTER, J. TURNER, W. LEE, Y. CHUANG, R. MOORE, O. KRUPIN, M. TRIGO, H. DÜRR, SLAC/ RSXS collaboration, L. PATTHEY, SLAC/ RSXS collaboration and PSI, N. PONTIUS, T. KACHEL, A. FÖHLISCH, M. BEYE, Helmholtz Zentrum Berlin, F. SORGENFREI, Uni. Hamburg and CFEL, W. WURTH, Uni. Hamburg and CFEL, C. CHANG, M. DÖHLER, C. TRABANT, Uni. Cologne, C. SCHÜSSLER-LANGEHEINE, Uni. Cologne and HZB — Magnetite, Fe_3O_4, displays a strong decrease in resistivity upon heating above $T_C = 123$ K: the Verwey transition. This transition is accompanied by a structural change from monoclinic to cubic symmetry. Despite decades of research and indications that charge and orbital ordering play an important role, the mechanism behind the Verwey transition is yet unclear. Using pump-probe soft X-ray scattering at the new LCLS SXR beamline, we have studied the role of the structural transition for the Verwey transition on ultra-fast time-scales. Focusing off-resonance on the high T forbidden (001) lattice reflection, we find a lattice response on time-scales $t < 250$ fs. The response displays a pump fluence threshold indicative of a phase transition. This strongly suggests that the lattice, via coupling to certain low energy phonon modes, plays a crucial role for the Verwey transition in Fe_3O_4.

K1.00294 Metal-insulator transition characteristics of epitaxial and polycrystalline $SmNiO_3$ thin films , SIEU HA, GULGUN AYDOGDU, SHRIRAM RAMANATHAN, Harvard University — $SmNiO_3$ (SNO) is known to exhibit a sharp insulator to metal transition at 130 °C in bulk form and is a candidate material for utilization in advanced electronic devices such as memory and neuromorphic circuits. We present growth and characterization of SNO thin films deposited on $LaAlO_3$ and Si single crystals. Structural properties such as crystallinity, strain, and stoichiometry are examined with x-ray diffraction and x-ray photoelectron spectroscopy. Temperature-dependent resistance measurements are performed, and a metal-insulator transition is observed for films on both substrates. We investigate how resistance changes are affected by thermal cycling and the role of surface oxygen loss on electrical characteristics.

K1.00295 Quantum phase diagram of the half filled Hubbard model with bond-charge interaction , ARIEL DOBRY, Instituto de Física Rosario (Argentine), ARMANDO ALIGIA, Centro Atómico Bariloche and Instituto Balseiro (Argentine) — Using field theoretical bosonization, we determine the quantum phase diagram of the one-dimensional Hubbard model with bond-charge interaction X in addition to the usual Coulomb repulsion U at half-filling, for small values of the interactions. We show that it is essential to take into account formally irrelevant terms of order X. They generate relevant terms proportional to X^2 in the flow of the renormalization group (RG). The model shows three phases separated by a charge transition at $U = U_c$ and a spin transition at $U = U_s > U_c$. For $U < U_c$ singlet superconducting correlations dominate, while for $U > U_s$, the system is in the spin-density wave phase as in the usual Hubbard model. For intermediate values $U_c < U < U_s$, the system is in a spontaneously dimerized bond-ordered wave phase, which is absent in the ordinary Hubbard model with $X = 0$. We provide an analytical expression for $U_s(X)$. The results, with only one adjustable parameter, are in excellent agreement with numerical ones for $X < t/2$ where t is the hopping.

K1.00296 Neutron diffraction study of quasi-one-dimensional lithium purple bronze: possible mechanism for dimensional crossover[1] , JOHN J. NEUMEIER, M.S. DA LUZ, Montana State University, C.A.M. DOS SANTOS, Escola de Engenharia de Lorena - USP, B.D. WHITE, Montana State University, H.J.I. FILHO, Escola de Engenharia de Lorena - USP, J.B. LEÃO, Q. HUANG, NIST Center for Neutron Research — The crystallographic structure of quasi-1D lithium purple bronze was investigated using neutron powder diffraction at temperatures T in the range 5 K $< T <$ 295 K. Lattice parameters, atomic positions, and occupation numbers are reported. At room temperature, it has a monoclinic symmetry with space group $P2_1/m$, lattice parameters $a = 12.750(1)$ Å, $b = 5.524(1)$ Å, $c = 9.491(2)$ Å, and $\beta = 90.593(1)°$. The stoichiometry was determined through chemical analysis *and* refinement of the NPD data to be $Li_{0.924}Mo_6O_{17.6}$. The bond-valence-sum method was applied to calculate the valence of each Mo ion as a function of T, which allows discussion of the mechanism by which charge is transferred between the double 1D conducting chains.

[1]Supported by the DOE-BES (DE-FG-06ER46269), the NSF (DMR-0907036), FAPESP (2009/14524-6), and CNPq (301334/2007-2 and 490182/2009-7).

K1.00297 Study of phase transitions in ternary lead indium niobate-lead magnesium niobate-lead titanate relaxor ferroelectric morphotropic single crystals[1] , PETER FINKEL, HAROLD ROBINSON, AHMED AMIN, NUWC — In this work we report on the elastic hysteretic behavior observed in ferroelectric lead indium niobate-lead magnesium niobate-lead titanate (PIN-PMN-PT) relaxor single crystals under conditions of cooperative stress, temperature, and electric field. Room temperature elastic response displays strong and sharp discontinuity associated with stress induced phase transition. Quasistatic elastic response and ultrasonic wave propagation measurements demonstrated that this strain discontinuity in PIN-PMN-PT single crystal is associated with a ferroelectric rhombohedral (FR)—ferroelectric orthorhombic (FO) phase transition. The temperature dependent elastic response and transition strain were modeled by Devonshire theory. The crystal instability under compression is significantly improved by application of a dc bias electric field.

[1]Authors acknowldge support from the ONR.

K1.00298 ^{1}H NMR Study of Proton Dynamics in the Ferroelastic Transition of $K_4LiH_3(SO_4)_4$ Cystals , MOOHEE LEE, HO HYOUN KIM, B.J. MEAN, KI HYEOK KANG, B. NDIAYE, Konkuk University, Seoul, South Korea, AE RAN LIM, Jeonju University, Jeonju, South Korea — $K_4LiH_3(SO_4)_4$ is known to show a ferroelastic transition at $T_c = 114$ K. We have performed ^{1}H nuclear magnetic resonance(NMR) measurements to investigate proton dynamics in the phase transition of $K_4LiH_3(SO_4)_4$ crystals in the temperature range of 70-300 K at 2.67 T. The ^{1}H NMR spectrum shows a composite structure with dominating broad and weak narrow components. The broad component has an extremely long T_1 whereas the narrow component exhibits a short T_1 at room temperature. The intensity of the narrow peak decreases at low temperature vanishing below 200 K. From this behavior, we find that the narrow component comes from rapidly moving protons whereas the broad component originates from rigid protons. From the temperature dependence of the short T_1 for the narrow component, the activation energy for the proton's rapid motion is deduced to be ∼1900 K. On the other hand, the long T_1 for the broad component decreases at low temperature suggesting that the proton dynamics associated with the ferroelastic transition change abruptly across T_c.

K1.00299 Ion conductivity relaxation and specific heat close to the first-order phase transition of $\gamma-RbAg_4I_5$, RUBEN A. VARGAS, Universidad del Valle, HERNANDO CORREA, Universidad del Quindo, DIEGO PEÑA-LARA, Universidad del Valle — We report on simultaneous measurements of specific heat at normal pressure and ac conductivity in single-crystalline γ-$RbAg_4I_5$ close to and below its γ-to-β first order phase transition at 121 K. We found an accurate proportionality between the specific heat, $\mathbf{c}_P$, and the temperature derivative of the product $\mathbf{nE}_\sigma$, where β **=1- n**, is the Kohlrausch stretching exponent for the conductivity relaxation and $\mathbf{E}_\sigma = \mathbf{d(ln}\sigma\mathbf{)/d(T^{-1})}$ is the dc conductivity activation energy, which is non-Arrhenius. Thus, our results show that the dc conductivity activation energy $\mathbf{E}_\sigma\mathbf{(T)}$ includes, besides the true microscopic energy "barrier" for independent ionic motion, **(1-n)** $\mathbf{E}_\sigma$ (according the coupling model), an additional contribution from the enthalpy of the mobile Ag-ions defects, **h**.

K1.00300 Critical dynamics of randomly layered magnets , HATEM BARGHATHI, THOMAS VOJTA, Missouri University of Science and Technology — We report the results of large-scale Monte-Carlo simulations of the critical dynamics in the randomly layered Heisenberg model. This system has recently been reported to display an exotic phase transition controlled by an infinite-randomness critical point [Phys. Rev. B 81, 144407 (2010)]. In agreement with this, we found the critical dynamics to be ultraslow. At criticality, the time autocorrelation function decays only logarithmically with time while it follows a nonuniversal power-law in the Griffiths phase. We also study the case of XY spin symmetry where the interplay between the randomness and the Kosterlitz-Thouless physics leads to even stronger disorder effects.

K1.00301 A second metastable spin-ordered state on ferrimagnetic single crystal Cu_2OSeO_3 , CHIH CHIEH CHOU, C.L. HUANG, K.F. TSENG, S. MUKHERJEE, J.L. HER, Y.H. MATSUDA, K. KINDO, H. BERGER, H.D. YANG — DC and AC susceptibilities were executed on ferrimagnetic single crystal Cu_2OSeO_3 under magnetic field (H) and hydrostatic pressure (P) circumstance. With increasing H, the ferrimagnetic transition at T_C ∼ 60 K tends to a higher temperature. Furthermore, the T_C rises with a linear slope and magnetization is enhanced with increasing P. Features of the ladder shown in the M vs. H curve or the peak observed in the dM/dH vs. H curve are noted at H_{SF} ∼ 0.5 kOe, exhibiting a competing ordered state in magnetic fields below T_C. Remarkably, another shoulder is observed at ∼ 1 kOe in the dM/dH vs. H curve, revealing a metastable spin ordered state in Cu_2OSeO_3. In addition, the novel state is retained and enhanced by applied pressure. However, at H up to 55 T, there is no more observable slop change in magnetization. These magnetic properties suggest a complex spin orientation in the spin-frustrated system Cu_2OSeO_3.

K1.00302 Current Bearing Electron Shock Wave[1] , MOSTAFA HEMMATI, Arkansas Tech University — For analytical solution of breakdown waves, we use a one-dimensional, steady-state, three-component (electrons, ions, and neutral particles) fluid model. The wave front is considered to be a shock front and the electron gas partial pressure is considered to provide the driving force for the propagation of the wave. The basic set of equations consists of the equation of conservation of mass flux, equation of conservation of momentum, equation of conservation of energy, plus Poison's equation. In this study, the emphasis will be on the waves propagating into a neutral medium and we will investigate breakdown waves for which a large current exist behind the wave front. We apply shock conditions to obtain breakdown wave profile for electric field, electron velocity, electron temperature, electron number density, and ionization rate behind the shock front for breakdown waves propagating in the opposite direction of the electric filed force on electrons.

[1]We would like to express our gratitude for Arkansas Space Grant Consortium's financial support of this project.

Tuesday, March 22, 2011 2:30PM - 4:54PM –
Session L1 DCMP DCP: Recent Advances in Ultrafast Studies of Condensed Matter Ballroom A1

2:30PM L1.00001 Ultrafast and Nonlinear Optical Spectroscopy of Carbon Nanotubes[1] , JUNICHIRO KONO, Department of Electrical and Computer Engineering, Rice University — Single-walled carbon nanotubes (SWNTs) provide a variety of unique opportunities for studying the dynamics and interactions of one-dimensional (1-D) electrons and phonons. We have carried out a series of ultrafast and nonlinear optical experiments on SWNTs, revealing novel properties of high- density 1-D excitons as well as coherent lattice vibrations.[2] We have shown that there exists an upper limit on the density of 1-D excitons in SWNTs, which results in photoluminescence saturation. Using a model based on diffusion-limited exciton-exciton annihilation, we provided realistic estimates for the exciton densities in the saturation regime. We also predicted and demonstrated that there is an optimum temperature at which the exciton density can be maximized, due to the existence of a dark exciton state. Using ultrashort pulses, we have also investigated the dynamics of coherent phonons (CPs) in SWNTs, including both the low frequency radial breathing mode and high frequency G-mode phonons. Pulse shaping techniques allowed us to generate and detect CPs in SWNTs in a chirality-selective manner, which provided insight into the chirality dependence of light absorption, phonon generation, and phonon-induced band- structure modulations. Finally, we observed novel large- amplitude CPs through near-band-edge excitations as well as strongly polarization-dependent CP signals in highly-aligned SWNTs.

[1]This work was performed in collaboration with Y. Murakami, A. Srivastava, T. A. Searles, L. G. Booshehri, E. H. Hároz, D. T. Morris, J.-H. Kim, K.-J. Yee, Y.-S. Lim, G. D. Sanders, C. J. Stanton, and R. Saito.

3:06PM L1.00002 Femtosecond magnetism and spin manipulation on a time-scale of the exchange interaction , ALEXEY KIMEL, Radboud University Nijmegen — The dynamics of phase transformations on the time-scale pertinent to atomic, orbital and spin motion is a rather unexplored field in physics. This is also a particularly interesting problem of modern magnetism, a study of which may have tremendous consequences for future development of magnetic recording technology. However, generation of magnetic field pulses much shorter than 100 ps and strong enough to reverse magnetization (more than 1T) is an extremely challenging technical problem.As a result the dynamics of the magnetic phase transitions at the sub-100 ps time-scale remains to be one of the most intriguing areas of modern magnetism [1,2]. Recently it has been observed that a 40 fs laser pulse influences spins in a magnet as an equally short pulse of effective magnetic field with a strength up to 20 T [3,4]. In my talk I will discuss how these opto-magnetic pulses can be used to excite a magnet on a time-scale of the exchange interaction between the spins [5-7]. Novel insights into the physics of non-equilibrium magnetism will be provided, showing that two exchange-coupled magnetic sublattices of a ferrimagnet may have totally different spin dynamics [8]. As a result, ultrafast spin reversal of two antiferromagnetically coupled magnetic sub-lattices appears to proceed via a novel ferromagnet-like transient state.

3:42PM L1.00003 Theory of ultrafast pump-probe phenomena in high-temperature superconductors[1] , JIAN-XIN ZHU, Los Alamos National Laboratory, Los Alamos, NM 87545 — The physics underlying the pairing mechanism for high-temperature superconductors remains a topic of current interest. The complexity lies with the existence of competing interactions in these strongly correlated electronic materials. The ultra-fast pump-probe technique can make a stride to untangle the competing degrees of freedom (DOF). In this talk, the theoretical underpinning for this technique will be reviewed. In particular, we have developed a three-temperature model [1] to simulate the real time dependence of the electron and phonon temperatures in high-temperature superconductors. The model considers anisotropic electron-phonon coupling [2]. Based on this model, we have calculated the time-resolved spectral function, which exhibits interesting features with time delay. It has been found that the excitation of phononic DOF can provide a defining signature for the evidence of electron-vibration mode coupling [1]. In addition, the time-resolved optical conductivity and Raman spectra will also be discussed within the same model [3]

4:18PM L1.00004 Ultrafast Optical Excitation in $YBa_2Cu_3O_{7-\delta}$: Tracing the Optical Phonons , ALEXEJ PASHKIN, University of Konstanz — The time-resolved spectroscopy of nonequilibrium states proved to be a powerful tool for observation of the electron-phonon scattering dynamics and the recombination of photoexcited quasiparticles (QP), particularly in high-temperature cuprate superconductors. However, most of the reported experiments monitor only the electronic subsystem [1-5]. Thus, a detailed dynamics of the various phonon modes during an initial non-thermal regime has been beyond reach. Here we utilize the field-resolved ultrabroadband THz spectroscopy to resonantly trace ultrafast phonon and QP dynamics of optimally doped single crystals of $YBa_2Cu_3O_{7-\delta}$ [6]. The superconducting state is perturbed by 12-fs optical pump pulses, and the induced changes in the mid-infrared optical conductivity are probed by THz transients. Thus, we simultaneously observe the dynamics of nonequilibrium QPs and two specific phonon modes with a time resolution of 40 fs. A quantitative line shape analysis of the apex oxygen vibration allows us to separately follow its transient occupation and coupling to the Josephson plasma resonance. A strong phonon population and the maximum QP density are reached within the same time scale of 150 fs demonstrating that the lattice absorbs a major portion of the pump energy before the QPs are thermalized. Our results indicate substantial electron-phonon scattering in $YBa_2Cu_3O_{7-\delta}$ and introduce a powerful approach for characterizing transient phonon dynamics in a broad variety of solids.

Session L2 DCMP: Single Molecule Transistors and Graphene Quantum Dots Ballroom A2

2:30PM L2.00001 Spectroscopy and read-out of STM-patterned donor based qubits[1] , MICHELLE SIMMONS, University of New South Wales — We report low temperature transport measurements of few-to single P donor based quantum dots in silicon. Dots with a high donor number (approx. 7) show a surprisingly dense spectrum of excited states with an average energy spacing of 100 micro eV. The energy spacing of these features is much too low to be accounted for by the nm-scale lateral confinement of either the dot or the leads and can be explained by lifting of valley degeneracy of the dot orbital states [1]. The use of all epitaxial in plane P:Si gates allow us to tune both the electron number in the dot and modulate the transparency of the tunnel barriers [2]. We also present transport through a deterministic single donor device, where we observe both the signature of a single donor directly through STM imaging and demonstrate that the charging energy and excited state spectrum is consistent with the orbital states of a single P-donor. Finally we present our latest results of spin read-out in STM-patterned donor based devices.

3:06PM L2.00002 Single-donor transport in silicon: Atomic physics in restricted momentum space[1] , SVEN ROGGE, University of New South Wales — Technology reached a level of miniaturization where we can realize transport through a single dopant atom in a transistor. Such transport spectroscopy can probe the atomic orbitals and the interaction of the atom with the environment. This interaction with the environment in a nano-device leads alters the dopants properties, such as the level spectrum and the charging energy, from those of the bulk. The system discussed here is a gated arsenic donor in a silicon field effect transistor. Electronic control over the wavefunction of dopants is one of the key elements of quantum electronics. This talk focuses on the role of the restricted momentum space which has a severe impact on the charge and spin configuration of a donor atom in a nano-device. The combined experimental and theoretical study of the gated two-electron state of the donor led to the realization of the pseudo spin nature of the valleys. We observe a blocked electronic relaxation due to combined spin and valley selection rules. Time averaged transport measurements put a lower bound of 50 ns on the rate of the blocked transition, 1000 times slower than a bulk transition. For the low lying excited states Hund's rule is violated due to vanishing exchange in orthogonal valleys. Furthermore, we observe reduced charging energies and bound singlet and triplet excited states for this negatively charged donor that can be explained in the self consistent tight binding model. Finally, experiments demonstrating coherent coupling between two donors and between a donor and the leads will be discussed.

3:42PM L2.00003 Orbital Gating of Single Molecule Transistors , MARK REED, Yale University — Electron devices containing molecules as the active region have been an active area of research over the last few years. In molecular-scale devices, a longstanding challenge has been to create a true three-terminal device; e.g., one that operates by modifying the internal energy structure of the molecule, analogous to conventional FETs. Here we report the observation of such a solid-state molecular device, in which transport current is directly modulated by an external gate voltage. We have realized a molecular transistor made from the prototype molecular junction, benzene dithiol, and have used a combination of spectroscopies to determine the internal energetic structure of the molecular junction. Resonance-enhanced coupling to the nearest molecular orbital is revealed by electron tunneling spectroscopy, demonstrating for the first time direct molecular orbital gating in a molecular electronic device.

4:18PM L2.00004 A single-molecule optical transistor , VAHID SANDOGHDAR, ETH Zurich — This abstract not available.

4:54PM L2.00005 Optical, magnetic and electronic properties of graphene quantum dots[1] , A. DEVRIM GUCLU, National Research Council of Canada — We present a theory of optical, magnetic and electronic properties of graphene quantum dots. We demonstrate that there exists a class of triangular graphene quantum dots with zigzag edges [1-8] which combines magnetic, optical and transport properties in a single-material structure. These dots exhibit robust magnetic moment and optical transitions simultaneously in the THz, visible and UV spectral ranges due to the existence of a band of degenerate states lying at the Fermi level in the middle of the energy gap [1-6]. The magnetic and optical properties[5,7] are determined by strong electron-electron and excitonic interactions in the degenerate band, treated exactly using numerical techniques combining tight-binding, DFT, Hartree-Fock and configuration interactions methods. We show that the spin polarized degenerate band leads to quenching of the absorption spectrum at half-filling, while addition of a single electron fully depolarizes all electron spins and turns the absorption on. It is thus possible to design gate and size tunable graphene quantum dots with desired optical and magnetic properties for optoelectronic and photo-voltaic applications. Collaborators: P. Potasz, O. Voznyy, M. Korkusinski, and P. Hawrylak.

Session L3 DCMP: Gap Structure of the Ba-122 Iron Based Superconductors Ballroom A3

2:30PM L3.00001 Electronic structure studies of $Ba/EuFe_2As_2$ based superconductors by angle and time-resolved photoemission spectroscopy , JOERG FINK, Helmholtz-Zentrum Berlin/ IFW Dresden — We report high-resolution ARPES studies on the evolution of the electronic structure of $Ba/EuFe_2As_2$ compounds upon n-type doping by replacing Fe by Co and applying chemical pressure by substituting As by P. In particular, we have investigated the nesting conditions between the hole pockets in the centre and the electron pocket at the corner of the Brillouin zone (BZ) for various wave vectors perpendicular to the FeAs layers. In the case of chemically doped systems we observe a shift of the Fermi level in an almost rigid band system. These changes of the electronic structure upon doping cause a reduction of the nesting conditions, possibly yielding a microscopic explanation of the phase diagrams in which antiferromagnetic (AF) order is destroyed, followed by the appearance and disappearance of superconductivity at higher doping concentration. On the basis of the almost equivalent phase diagram obtained upon chemically pressurizing the compound, one expects a similar change of the electronic structure. However, in this case, with increasing P concentration, we observe a non-rigid-band-like change of the electronic structure in the centre of the BZ. In spite of this difference, also here the nesting conditions decrease with increasing P substitution, possibly providing a microscopic explanation for the phase diagram. Finally, we have performed femtosecond time-resolved ARPES studies on undoped and doped $Ba/EuFe_2As_2$ after optical pumping. Regarding the relaxation processes we obtain information on the complex dynamics of the excited electronic state in these semi metallic systems. Furthermore, we derive a small electron-phonon coupling constant making electron-phonon coupling an unlikely candidate for the mechanism of high-T_c superconductivity in these compounds. This work is performed in collaboration with S. Thirupathaiah, E. Rienks, H. A. Dürr, S. de Jong, E. van Heumen, E. Slooten, Y. Huang, R. Huisman, M. S. Golden, L. Rettig, R. Cortes, U. Bovensiepen, M. Wolf, A. Erb, T. Wolf, H.S. Jeevan, P. Gegenwart.

3:06PM L3.00002 Symmetry of spin excitation spectra in 122-ferropnictides[1] , DMYTRO INOSOV, MPI-FKF Stuttgart — We have studied the symmetry of spin excitation spectra in 122-ferropnictide superconductors by comparing the results of first-principles calculations with inelastic neutron scattering (INS) measurements on Ni- and Co-doped $BaFe_2As_2$ samples close to the optimal doping level, which exhibit neither static magnetic phases nor structural phase transitions. In both the normal and superconducting (SC) states, the spectrum does not follow the $I4/mmm$ space group of the crystal, but instead inherits its symmetry from the unfolded Brillouin zone of the Fe- sublattice. This is manifest both in the in-plane anisotropy of the normal- and SC-state spin dynamics and in the out-of-plane dispersion of the spin-resonance mode and the SC spin gap. The in-plane anisotropy is temperature-independent and can be qualitatively reproduced in normal-state density-functional theory calculations without invoking a symmetry-broken ("nematic") ground state that was previously proposed as an explanation for this effect. Below the SC transition, the energy of the magnetic resonant mode, as well as its intensity and the SC spin gap, inherit the normal-state intensity modulation along the out-of-plane direction. Apparently, it can be traced back to the three-dimensional band structure and the superconducting gap, both of which were reported to disperse along the out-of- plane direction.

3:42PM L3.00003 London penetration depth as a sensitive tool for determining the superconducting gap structure in iron-pnictide superconductors , RYAN GORDON, Department of Physics and Astronomy, Iowa State University and Ames Laboratory, Ames, IA — In the high$-T_c$ cuprates, experiments and theories have relied on a single-band picture that is essentially two- dimensional with a single superconducting gap, which provided a simple way to understand the angular dependence of the superconducting order parameter. In iron-based superconductors, the experimental mapping of the superconducting gap structure is complicated by the doping- dependent, multi-band electronic structure with three- dimensional character and the existence of at least two distinct superconducting gaps. Focusing on precision measurements of the London penetration depth, $\lambda(T)$, in "122" $Ba(Fe_{1-x}T_x)_2As_2$ (T=Co,Ni,Ru,Pt,Pd,Co+Cu) single crystals, I will discuss the systematics of the ubiquitous power law temperature variation of the in-plane penetration depth, $\lambda_{ab}(T) = \lambda_{ab}(0) + \beta T^n$, and of the absolute value, $\lambda_{ab}(0)$, with the doping level, x. To understand the role of disorder and pairbreaking scattering, the effect of heavy ion irradiation has been systematically studied and the results are compared with other systems, most notably stoichiometric LiFeAs. Together with the doping dependence of the out-of- plane London penetration depth, $\lambda_c(T)$, and comparisons to thermal conductivity and specific heat data, these results strongly suggest the development of a significant in-plane anisotropy of the superconducting gap(s) and are also consistent with the appearance of accidental c-axis nodes (not imposed by symmetry) for concentrations moving away from optimal doping. By taking pairbreaking scattering into account, the data for the optimally doped compounds are well described by weak-coupling superconductivity with two nodeless superconducting gaps having amplitudes that differ by about a factor of two. I conclude by emphasizing the significant role of three-dimensionality and scattering in determining the electrodynamics of iron-based superconductors.

4:18PM L3.00004 Phase diagram and superconducting gap structure of the iron-pnictide superconductor $(Ba,K)Fe_2As_2$[1] , XIGANG LUO, Department de Physique, Universite de Sherbrooke, Sherbrook, Quebec J1K2R1, Canada — Measurements of the Nernst and Seebeck coefficients were used to delineate the T-x phase diagram of the iron-pnictide superconductor $Ba_{1-x}K_xFe_2As_2$. The sensitivity of these two coefficients to the reconstruction of the Fermi surface caused by the onset of antiferromagnetic order below a temperature T_N allowed us to track T_N precisely as a function of concentration x, even when the electrical resistivity, for example, shows no anomaly at the magnetic transition. In the region of concentrations where superconductivity appears out of an antiferromagnetic normal state ($T_c < T_N$), we investigate the evolution of the superconducting gap structure of $Ba_{1-x}K_xFe_2As_2$ by measuring the thermal conductivity in the T=0 limit. This is a sensitive and directional probe of nodal quasiparticles. As the concentration x is reduced, we find a sudden change in the gap structure from a full gap without nodes to a gap with nodes. We ascribe this change to the onset of antiferromagnetism below a critical doping x_N inside the superconducting phase, whose effect is most likely to alter both the Fermi surface and the angular dependence of the gap. We compare these results with our earlier study on $Ba(Fe_{1-x}Co_x)_2As_2$ [1,2].

4:54PM L3.00005 Superconductivity in a 3D tight-binding model for Ba-122[1] , SIEGFRIED GRASER, University of Augsburg — Theoretical investigations of the superconducting state in the iron pnictides have shown that weak-coupling approaches based on a tight-binding parametrization of the LDA band structure can be successfully applied to describe both magnetism and superconductivity in these materials. FLEX, RPA, and fRG studies find in most cases a superconducting state with s-wave symmetry that exhibits a π-phase shift between the gap on the electron and the hole Fermi surfaces, often called a sign-changing s-wave state. Besides this general agreement about the symmetry of the superconducting state these studies have also revealed that the momentum dependence of the gap, including the possibility of gap nodes, is highly sensitive to details of the electronic structure, in particular to the orbital composition of the Fermi surface. Since superconductivity in these materials is restricted to the FeAs layers that, at least for the 1111 compounds, are well separated and only weakly coupled most tight-binding models used to study the superconducting state have been limited to two dimensions. On the other hand the 122 compounds as well as the binary compounds show a very pronounced 3D electronic structure with changing orbital weights on the Fermi surfaces along the k_z direction. An RPA based calculation of the spin susceptibility for the Ba-122 material demonstrates that the necessary averaging over the full three dimensional Brillouin zone leads to a broader and more commensurate spin response compared to a corresponding two dimensional calculation in agreement with experimental observations. In addition changes of the orbital character of the Fermi surface lead to a complicated three dimensional gap structure exhibiting V-shaped or near horizontal nodes on the hole sheets near the zone boundary that can in part explain the puzzling transport measurements.

Session L4 GQI: Quantum Information: Featured Experiments Ballroom A4

2:30PM L4.00001 Entanglement of spin waves among four quantum memories[1] , H. JEFF KIMBLE, California Institute of Technology — Quantum networks are composed of quantum nodes that interact coherently by way of quantum channels and open a broad frontier of scientific opportunities [1]. For example, a quantum network can serve as a 'web' for connecting quantum processors for computation and communication as well as a "simulator" for enabling investigations of quantum critical phenomena arising from interactions among the nodes mediated by the channels. The physical realization of quantum networks generically requires dynamical systems capable of generating and storing entangled states among multiple quantum memories, and of efficiently transferring stored entanglement into quantum channels for distribution across the network. While such capabilities have been demonstrated for diverse bipartite systems, entangled states have so far not been achieved for interconnects capable of "mapping" multipartite entanglement stored in quantum memories to quantum channels. In my presentation, I will describe an experiment [2] that demonstrates measurement-induced entanglement stored in four atomic memories; user-controlled, coherent transfer of the atomic entanglement to four photonic channels; and characterization of the full quadripartite entanglement by way of quantum uncertainty relations [3]. Our work thereby provides an important advance for the distribution of multipartite entanglement across quantum networks. Moreover, our entanglement verification method can be applied for the study of entanglement order for condensed matter systems in thermal equilibrium. With regard to quantum measurement, our multipartite entangled state can be applied for sensing an atomic phase shift beyond the limit for any unentangled state.

3:06PM L4.00002 Quantum Networks with Atoms and Photons , CHRISTOPHER MONROE, JQI and University of Maryland — Trapped atomic ions are among the most promising candidates for quantum information processing. All of the fundamental quantum operations have been demonstrated in this system, and the central challenge now is how to scale the system to larger numbers of qubits. By entangling atomic qubits through both deterministic phonon and probabilistic photon interfaces, the trapped ion system can be scaled in various ways for applications in quantum communication, quantum computing, and quantum simulations. I will discuss several options and issues for such atomic quantum networks, along with state-of-the-art experimental progress.

3:42PM L4.00003 Quantum-logic clocks for fundamental physics and geodesy[1] , TILL ROSENBAND, NIST — We have compared the rates of two quantum-logic clocks based on the optical $^1S_0$-$^3P_0$ transition in Al^+. The performance of the newer clock is unmatched, and despite many differences, their rates agree to $1.8 \pm 0.7 \times 10^{-17}$, within the accuracy limit of the older clock. The newer clock has an accuracy of 8.6×10^{-18} and stability near $10^{-15}(\tau/s)^{-1/2}$. Quantum-correlation spectroscopy yields an improved measurement stability of $3.7 \times 10^{-16}(\tau/s)^{-1/2}$. This technique also allows Q-factors beyond 6×10^{15} to be seen. This is the highest observed Q-factor in physics. The talk will discuss the basic operation of quantum-logic clocks based on Al^+, together with recent results that include a first geo-potential difference measurement, and constraints on the temporal variation of the fine-structure constant. Potential uses of entangled states in such clocks are also explored.

[1]Supported by ONR, NIST, AFOSR, and DARPA.

4:18PM L4.00004 Towards Quantum Information Processing with Superconducting Circuits[1] , ROBERT SCHOELKOPF, Yale University — In the dozen years since the initial demonstrations that superconducting circuits based on Josephson junctions could be considered as qubits, there has been remarkable progress in the field. Several different "species" of these artificial atoms have been designed and tested, and coherence times have increased by more than 1,000, or a factor of 10 every three years. While real devices are still far from satisfying all the DiVincenzo criteria with fidelities that would meet the error correction threshold, one can nonetheless perform preparation, control, quantum logic, and measurement on multiple superconducting qubits, all with surprisingly high purity and precision given that these are man-made, solid-state systems. In recent years we have seen the preparation of highly-entangled multi-qubit states that violate the Bell and Mermin inequalities, as well as the demonstration of single quantum algorithms, which all benefit from the strong coupling, addressability, and all-electronic control that is possible with these systems. Many experiments employ the concept of a "quantum bus," where qubits couple via superconducting transmission lines that form high-quality resonant cavities. A spinoff of this work is the advent of quantum optics on a chip: microwaves are photons too! The combination of qubits coupled to cavities has allowed the preparation and detection of single gigahertz photons, as well as other highly non-classical states of microwave light. Great progress has also been made in quantum measurement, and other Josephson circuits are now delivering amplifiers that operate at or beyond the Heisenberg limit. In this talk I will attempt to give an overview of some of the key concepts, some experimental highlights from recent years, and point out some possible directions for the future in this field.

[1]I would like to acknowledge all my collaborators at Yale, and funding from ARO, NSA/LPS, NSF, and IARPA.

4:54PM L4.00005 Quantum Information and the Foundations of Quantum Mechanics: a story of mutual benefit , ANTON ZEILINGER, Faculty oft Physics, University oft Vienna, and Institute oft Quantum Optics and Quantum Information — Fundamental tests, particularly of quantum nonlocality, in the 1970s were crucial for the development of the new field of quantum information science. The consequent development of new technologies has led to novel possibilities to do fundamental tests. A most simple and clear test of noncontextuality, i.e. the existence of joint probability distributions, is due to a proposal by Klyachko et al. [PRL 101, 020403 (2008)]. There, the experimental tests became possible because of technology developed for quantum communication. It turns out that a very simple and intuitive picture of the contradiction with realism can be given. In parallel, an experiment closing the freedom of choice loophole in quantum entanglement [T. Scheidl et al., Proc Natl Acad Sci USA (2010) 19709], together with earlier experiments testing the Leggett-type inequality and objectivity, i.e. the existence of observables without the context of observation, might be challenged. Current micro-optics technology and the exploitation of external states of light like Hermite-Gauss and Laguerre-Gauss allows to extend this kind of experiments into higher-dimensional Hilbert Spaces. There, interesting connections between entanglement and mutually unbiased bases have been found.

Tuesday, March 22, 2011 2:30PM - 5:30PM –

Session L5 COM: Topics in Alternative Energy Ballroom C1

2:30PM L5.00001 Efficient High Surface Area Vertically Aligned Metal Oxide Nanostructures for Dye-Sensitized Photoanodes by Pulsed Laser Deposition[1] , RENE LOPEZ, Department of Physics and Astronomy, University of North Carolina at Chapel Hill, NC, 27599 — Dye Sensitized Solar Cells (DSSCs) differ from conventional semiconductor devices in that they separate the function of light absorption from charge carrier transport. At the heart of a DSSC is a metal oxide nanoparticle film, which provides a large effective surface area for adsorption of light harvesting molecules. The films need to be thick enough to absorb a significant fraction of the incident light but increased thickness results in diminished efficiencies due to augmented recombination. Losses in efficiency are due to the slow trap-limited diffusion process responsible for electron transport. This process limits the effective electron diffusion length to about $\sim$ 10 μm and results in an efficiency-limiting trade-off between light absorption and carrier extraction. Here we introduce a new structural motif for the photoanode in which the traditional random nanoparticle oxide network is replaced by vertically aligned bundles of oxide nanocrystals. This structure improves absorbed photon to current efficiencies (APCE) to values above 90% over most of the dye absorption range. The bundled anode is fabricated by a simple laser deposition process and features a surface area $\sim$ 2 times larger than that of traditional anodes. The direct pathways provided by the vertical structures also appear to provide for an enhanced collection efficiency for carriers generated throughout the device.

[1]This material is based upon work supported as part of the UNC EFRC: Solar Fuels and Next Generation Photovoltaics, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award N

3:06PM L5.00002 Predictive Defect Science for Cost-Effective Photovoltaics , TONIO BUONASSISI, Massachusetts Institute of Technology — Low-cost photovoltaic materials are typically defect-rich, and defects impede electronic transport and photoconversion efficiency. Since efficiency and cost are inversely related, defect-rich materials have until recently resulted in poor-quality, economically uncompetitive solar cells. In this presentation, we review defect physics in low-cost photovoltaic absorbers. Accurate identification of performance-limiting defects requires multiscale characterization, evaluating cm-size devices while probing down to the nanometer scale for defect recognition. We will review recent advances in macroscopic CCD-based PV characterization tools, and elucidate how these can be coupled to synchrotron nanoprobe techniques. Once the nature and underlying physical behavior of these defects are known, we demonstrate how manipulation of defect distribution and state, aided by predictive modeling, can enhance solar cell performance.

3:42PM L5.00003 Nanoscale heat transfer and thermoelectrics for alternative energy[1] , RICHARD ROBINSON, Cornell University — In the area of alternative energy, thermoelectrics have experienced an unprecedented growth in popularity because of their ability to convert waste heat into electricity. Wired in reverse, thermoelectrics can act as refrigeration devices, where they are promising because they are small in size and lightweight, have no moving parts, and have rapid on/off cycles. However, due to their low efficiencies bulk thermoelectrics have historically been a niche market. Only in the last decade has thermoelectric efficiency exceeded $\sim$20% due to fabrication of nanostructured materials. Nanoscale materials have this advantage because electronic and acoustic confinement effects can greatly increase thermoelectric efficiency beyond bulk values. In this talk, I will introduce our work in the area of nanoscale heat transfer with the goal of more efficient thermoelectrics. I will discuss our experiments and methods to study acoustic confinement in nanostructures and present some of our new nanostructured thermoelectric materials. To study acoustic confinement we are building a nanoscale phonon spectrometer. The instrument can excite phonon modes in nanostructures in the $\sim$100s of GHz. Ballistic phonons from the generator are used to probe acoustic confinement and surface scattering effects. Transmission studies using this device will help optimize materials and morphologies for more efficient nanomaterial-based thermoelectrics. For materials, our group has synthesized nano-layer superlattices of Na_xCoO_2. Sodium cobaltate was recently discovered to have a high Seebeck coeficent and is being studied as an oxide thermoelectric material. The thickness of our nano-layers ranges from 5 nm to 300 nm while the lengths can be varied between 10 μm and 4 mm. Typical aspect ratios are 40 nm: 4 mm, or 1:100,000. Thermoelectric characterization of samples with tilted multiple-grains along the measurement axis indicate a thermoelectric efficiency on par with current polycrystalline samples. Due to phonon confinement in nano-structures, it is expected that the thermoelectric efficiency of these sheets will be much higher than that of single crystalline $Na_{0.7}CoO_2$, when the nanosheets have single grains along the heat transport path.

4:18PM L5.00004 Alternative Energy: A New Frontier for Microfluidics , CULLEN BUIE, Massachusetts Institute of Technology — Microfuidics is classified as the physics of fluid manipulation at sub-mm length scales. Typically, microfluidic techniques benefit from small sample volumes, low power consumption, and increased surface-to-volume ratio. Because of their high surface to volume ratio, microfluidic systems often utilize surface phenomena such as wettability (i.e. droplet microfluidics) and surface charge (i.e. electrokinetics) for actuation. To date, most applications of microfluidics are in medicine or biology with the purpose of creating "lab on a chip" devices. However, the scale of microfluidics is favorable for other engineering problems as well. In this talk we will discuss how phenomena typically applied to lab on a chip devices can be used to enhance energy systems. Specifically, we explore electric field driven fluid and particle flows such as electrophoresis, electroosmosis, and dielectrophoresis. We will show how these phenomena can solve a diverse array of problems, from water management in fuel cells to the selection of microorganisms for bio-energy applications.

4:54PM L5.00005 Fusion related physics: Understanding the basic physics of High Energy Density Plasmas (HEDP) using ultra-short pulse laser-matter interactions[1] , RONNIE SHEPHERD, Lawrence LIvermore National Lab — Nuclear fusion is one nature's most fundamental methods of generating energy. In stars, the fusion reactions that occur deep within stellar interiors generate radiation and particles that fill the Universe. For many years, a goal of scientists has been to utilize these processes on earth to generate energy. However, understanding the basic physics of the interacting particles is required to exploit this energy source. We present data and analysis from one technique (ultra-short pulse laser matter interactions) currently being used to understand this physics. High power, short pulse lasers offer the ability of studying matter heated to extremely high temperatures (as high as 700 eV) and near solid density (10^{22} part/cm^3). Two aspects of the basic physics will be presented, namely radiation absorption and particle energy exchange currently under investigation using these lasers.

Session L6 FIAP: Complexity in Invention: The Strongly Coupled Systems that Contribute to Innovation Success Ballroom C2

2:30PM L6.00001 ABSTRACT WITHDRAWN –

3:06PM L6.00002 Value analysis for advanced technology products , MARK SOULLIERE, Corning Incorporated — Technology by itself can be wondrous, but buyers of technology factor in the price they have to pay along with performance in their decisions. As a result, the "best" technology may not always win in the marketplace when "good enough" can be had at a lower price. Technology vendors often set pricing by "cost plus margin," or by competitors' offerings. What if the product is new (or has yet to be invented)? Value pricing is a methodology to price products based on the value generated (e.g. money saved) by using one product vs. the next best technical alternative. Value analysis can often clarify what product attributes generate the most value. It can also assist in identifying market forces outside of the control of the technology vendor that also influence pricing. These principles are illustrated with examples.

3:42PM L6.00003 Innovation, Novel Solutions and New Devices: The Engines that Drive the Magnetic Storage Industry; Choosing the Right Combination , ERNESTO E. MARINERO, Hitachi GST San Jose Research Center, 3404 Yerba Buena Road San Jose, CA 95135, USA — Magnetic storage technology aims to achieve recording densities $> 10^{12}$ bits/in2 in the foreseeable future. The dimensions of the magnetic domains and sensor minimum feature sizes at this density will be $\sim$ 15 – 25 nm. These nanoscale dimensions present major challenges for both the materials utilized for magnetic recording, and to the sensors employed to reliably detect the minute magnetic fluxes emanating from such nanoscale domains. These include fundamental physical limits of material properties on account of the reduced dimensionality, as well as nanofabrication challenges to attain the required nanometer feature sizes with the stringent dimensional tolerances required. Since its invention in 1954, the storage density in magnetic recording has incremented by 10^9 and the cost of storage, measured in \$/MB, has undergone a price reduction of the same order. Impressive as these accomplishments are, is the fact that the fundamental engineering principles of the technology today are essentially the same as when it was invented. This is in spite of numerous efforts to replace it with new alternative technologies or by dire predictions by its own practitioners of its impending death based on perceived limitations. In this talk the state-of-the art and challenges facing the HDD industry in its efforts to continue incrementing the storage density will be discussed. I will illustrate how advances in materials engineering, new physical phenomena and breakthroughs in nanofabrication have facilitated such an impressive technology evolution. Moreover, the key ingredients for said innovations to be implemented as technology solutions will be discussed..

4:18PM L6.00004 Manufacturing physics: using large(r) data sets and physical insight to develop great products , STEVEN ROSENBLUM, Corning Incorporated — Early stage research does a fantastic job providing knowledge and proof-of-feasibility for new product concepts. However, the handful of data points required to validate a concept is typically insufficient to provide insight on the whole range of effects relevant to manufacturing the product. Moving to manufacturing brings larger data sets and variability; opportunistic analysis of these larger sets can yield better product design rules. In the early 2000s Corning developed an optical transmission fiber optimized to suppress stimulated Brillouin scattering (SBS). Analyzing the larger data set provided by the manufacturing environment using the same theoretical framework developed by the original researchers refined our understanding of how to improve SBS in optical fibers beyond what was known from our early efforts. This greater understanding allowed us to design better performing products.

4:54PM L6.00005 Foundational Forces & Hidden Variables in Technology Commercialization , BRANDON BARNETT, Intel Corporation — The science of physics seems vastly different from the process of technology commercialization. Physics strives to understand our world through the experimental deduction of immutable laws and dependent variables and the resulting macro-scale phenomenon. In comparison, the goal of business is to make a profit by addressing the needs, preferences, and whims of individuals in a market. It may seem that this environment is too dynamic to identify all the hidden variables and deduct the foundational forces that impact a business's ability to commercialize innovative technologies. One example of a business "force" is found in the semiconductor industry. In 1965, Intel co-founder Gordon Moore predicted that the number of transistors incorporated in a chip will approximately double every 24 months. Known as Moore's Law, this prediction has become the guiding principle for the semiconductor industry for the last 40 years. Of course, Moore's Law is not really a law of nature; rather it is the result of efforts by Intel and the entire semiconductor industry. A closer examination suggests that there are foundational principles of business that underlie the macro-scale phenomenon of Moore's Law. Principles of profitability, incentive, and strategic alignment have resulted in a coordinated influx of resources that has driven technologies to market, increasing the profitability of the semiconductor industry and optimizing the fitness of its participants. New innovations in technology are subject to these same principles. So, in addition to traditional market forces, these often unrecognized forces and variables create challenges for new technology commercialization. In this talk, I will draw from ethnographic research, complex adaptive theory, and industry data to suggest a framework with which to think about new technology commercialization. Intel's bio-silicon initiative provides a case study.

Session L7 DBP: System Biology I: The Physics of Development Ballroom C3

2:30PM L7.00001 Robustness in multicellular systems , JOAO XAVIER , Memorial Sloan Kettering Cancer Center — Cells and organisms cope with the task of maintaining their phenotypes in the face of numerous challenges. Much attention has recently been paid to questions of how cells control molecular processes to ensure robustness. However, many biological functions are multicellular and depend on interactions, both physical and chemical, between cells. We use a combination of mathematical modeling and molecular biology experiments to investigate the features that convey robustness to multicellular systems. Cell populations must react to external perturbations by sensing environmental cues and acting coordinately in response. At the same time, they face a major challenge: the emergence of conflict from within. Multicellular traits are prone to cells with exploitative phenotypes that do not contribute to shared resources yet benefit from them. This is true in populations of single-cell organisms that have social lifestyles, where conflict can lead to the emergence of social "cheaters," as well as in multicellular organisms, where conflict can lead to the evolution of cancer. I will describe features that diverse multicellular systems can have to eliminate potential conflicts as well as external perturbations.

3:06PM L7.00002 Axis Specification in Hydra , ALBRECHT OTT, Universitaet des Saarlandes — Hydra is an about cm sized polyp of roughly 10^5 cells exhibiting surprising robustness: it can regenerate even from a random cell aggregate made from its own cells. During such a reorganization, hydra first forms a hollow cell sphere. We show that even a weak temperature gradient directs the axis of the regenerating animal – but only if it is applied during the symmetry-breaking moment. We observe that the spatial distribution across the cell sphere of the early expressed, head-specific gene ks1 has become scale-free and fractal at that point. We suggest that in order to break the symmetry and define an axis during the regeneration process, the cell network organizes towards a state, that is characterized by an unusually high sensitivity to external perturbation as well as spatially self-similar gene expression patterns. The observed behavior arises naturally from next-neighbor cell communication, when long-range signaling as required for axis definition is achieved through increased synchronization of expression profiles. Numerical results in progress show that our observations can be robustly reproduced with avalanches of gene expression patterns generated from gene switching above a stimulation threshold.

3:42PM L7.00003 Surface cell differentiation controls tissue surface tension and tissue positioning during zebrafish gastrulation , S.F.G. KRENS[1], Institute of Science and Technology Austria — Differences in tissue surface tension (TST) between different tissue types are thought to guide tissue organization and cell sorting in development. Measurements of TST have been useful to predict the outcome of in vitro cell sorting and envelopment experiments. However, the outcome of cell sorting experiments in vitro often substantially differs from tissue positioning in vivo, raising questions as to the actual contribution of TST to tissue positioning within the developing embryo. Here, we show that surface tension of germ layer tissues during zebrafish gastrulation critically relies on the differentiation of their surface cells. We also show that surface differentiation of the different germ layer tissues varies and is considerably different between the situation in vitro and in vivo, explaining the apparent dissimilar outcome of cell segregation between these two situations. To analyze germ layer TST as a function of surface cell differentiation, we interfere with surface cell properties of germ layer aggregates by misexpressing genes involved in surface cell differentiation specifically within surface cells using the GAL4-UAS system, and measure tissue surface tension using both parallel plate compression and micropipette aspiration techniques. Our data provides evidence in favor of a critical function of surface cell differentiation in modulating TST and subsequently tissue positioning within the developing embryo.

[1]In collaboration with C.P. Heisenberg, Max Planck Institute of Molecular Biology and Genetics.

4:18PM L7.00004 Self-organized cytoskeletal dynamics during fruit fly epithelial morphogenesis , KONSTANTIN DOUBROVINSKI, Princeton University — Epithelial morphogenesis plays a major role in embryonic development. During this process cells within epithelial sheets undergo complex spatial reorganization to form organs with specific shapes and functions. The dynamics of epithelial cell reorganization is driven by forces generated through the cytoskeleton, an active network of protein filaments and motor proteins. In this talk, I will present a novel mesoscopic-scale physical description of force generation by the cytoskeleton, and show that this minimal description can account for a wide range of phenomena associated with fruit fly epithelial morphogenesis.

4:54PM L7.00005 Collective Chemotactic Cell Movement; a Key Mechanism of Development and Morphogenesis , CORNELIS WEIJER, College of Life Sciences University of Dundee — We investigate the molecular mechanisms by which cells produce and detect chemotactic signals and translate this information in directed movement up or down chemical gradients in the social amoebae *Dictyostelium discoideum,* and during gastrulation in the chick embryo. Investigation of Dictyostelium mutants with changes in cAMP cell-cell signalling dynamics and chemotaxis, show how cellular heterogeneity in signalling dynamics and polarised activation of the actin-myosin cytoskeleton drive aggregation, cell sorting, slug formation and migration. Chemotactic cell movement also plays a critical role during gastrulation in the chick embryo a model for amniote development. We suggest that epiblast cell movement during the formation of the primitive streak as well as the movement of the mesoderm cells after their ingression through the streak is controlled by a combination of attractive and repulsive guidance cues. We use computer models explore signalling and cell movement interact to give rise to emergent phenomena at the tissue and organism level such as pattern formation and morphogenesis.

Tuesday, March 22, 2011 2:30PM - 5:30PM –
Session L8 FHP: J. H. Van Vleck: Quantum Theory and Magnetism Ballroom C4

2:30PM L8.00001 Van Vleck from Spectroscopy to Susceptibilities: Kuhn Losses Regained , MICHEL JANSSEN, University of Minnesota — As a young assistant professor in Minneapolis, John H. Van Vleck spent much of his time between 1923 and 1926 writing a book-length Bulletin for the National Research Council. As its title, Quantum Principles and Line Spectra, suggests, the book focuses almost exclusively on spectroscopy, the core pursuit of the old quantum theory. By the time it finally appeared in 1926, the old quantum theory had given way to the new quantum mechanics. Van Vleck soon realized that matrix mechanics reinstated some well-confirmed results of the classical theory of susceptibilities that had been lost in the old quantum theory. In the history and philosophy of science literature, such losses are called 'Kuhn losses'. Using mathematical techniques similar to those presented in his NRC Bulletin, Van Vleck started to work on the theory of susceptibilities. In 1929, now a full professor in Madison, he began writing another book, which appeared in 1932 and has become a classic: The Theory of Electric and Magnetic Susceptibilities. In this talk I follow Van Vleck's trajectory from spectroscopy to susceptibilities and examine how his two books reflect and helped shape research traditions.The talk is based on joint work with Charles Midwinter.

3:06PM L8.00002 J. H. Van Vleck and Magnetism at the University of Wisconsin: 1928 -1934 , DAVID HUBER, Univ. of Wisconsin-Madison — In 1928, John Van Vleck returned to his alma mater to take a position in the Physics Department. Six years later he left to join the faculty of Harvard University. While Van Vleck was at Wisconsin, he began a series of theoretical studies that helped lay the foundation for the modern theory of magnetism in solids. In 1932 Van Vleck published his celebrated monograph, *The Theory of Electric and Magnetic Susceptibilities,* in which he made use of the new theory to explain the results of experimental studies in a variety of magnetic materials. In my talk, I will review the accomplishments of Van Vleck and his students during this period and also comment briefly on his notes for a second edition of the book.

3:42PM L8.00003 My interactions with J.H. Van Vleck as a student and colleague at Harvard , NICOLAAS BLOEMBERGEN, University of Arizona — In the summer of 1947 I participated as a graduate student in discussions with professors J.H. Van Vleck, C.J. Gorter and E.M. Purcell on exchange narrowing of magnetic resonance lines. Subsequent work on exchange broadening and narrowing in nuclear spin systems will be reviewed and interspersed with personal reminiscences.

4:18PM L8.00004 Remembering Van: Three Madison families, and other tales , CHARLES P. SLICHTER, Department of Physics, University of Illinois, Champaign/Urbana, IL61801 — The talk will present some history, in part personal, in part scientific, of Van's influence on other scientists and on magnetic resonance.

4:54PM L8.00005 Van Vleck and the magnetic susceptibilities of gaseous molecules , HORST MEYER, Duke University — In his 1927 Physical Review article and in his 1932 book, *The Theory of Electric and Magnetic Susceptibilities,* Van Vleck used the new quantum theory to derive the magnetic susceptibilities of O_2 and NO in their gaseous form and compared them with experiments. He was therefore very interested in low temperature susceptibility experiments on O_2 at Oxford University in 1954 where individual O_2 molecules were trapped in small, almost spherical cages in organic clathrates. Correspondence between him and this speaker, then at Oxford, led to further measurements of O_2 and also of NO in such clathrates, to theory and to subsequent publications and correspondence. Later communication with Van Vleck on the magnetism in rare earth iron garnets, a subject of long-term interest to him, will be described in connection with experiments carried out at Duke University. Some fond personal recollections of this speaker of his interaction with Van Vleck - both while at Harvard, during visits and through correspondence which extended into the seventies - will be presented.

Tuesday, March 22, 2011 2:30PM - 5:30PM –
Session L9 DFD: Micelles and Vesicles I D220

2:30PM L9.00001 Faceting of multicomponent charged elastic shells , RASTKO SKNEPNEK, CHEUK LEUNG, LIAM C. PALMER, Northwestern University, GRAZIANO VERNIZZI, Siena College, SAMUEL I. STUPP, MICHAEL J. BEDZYK, MONICA OLVERA DE LA CRUZ, Northwestern University — Combining coarse-grained molecular dynamics simulations with continuum elastic theory, we show that electrostatic interactions between charged lipid head groups can lead to the crystallization of the bilayer. Regions with different molecular charge ratios have distinct elastic properties and naturally tend to segregate inducing an effective line tension between neighboring patches. The line tension and local patch-dependent elastic properties, i.e., bending rigidity and Young modulus, have a drastic effect on the shell shape. We explore a wide region of parameter space and find a gallery of faceted structures, closely resembling shapes of shells recently identified experimentally.

2:42PM L9.00002 Modeling co-evolution of defects and curvature in lipid vesicles: coarse-grained simulation studies[1] , ROBIN SELINGER, JUN GENG, JONATHAN SELINGER, Kent State Univ. — To explore interaction between topological defects and curvature in lipid vesicles, we present a coarse-grained simulation approach in which defects and vesicle shape both evolve in time. First we model a vesicle cooled into the tilted gel phase. To represent the tilt field at the mesoscale, we superimpose an XY model onto a coarse-grained liquid membrane [1] where each particle represents a patch of lipid bilayer. The presence of two $+1$ defects drives the vesicle to a prolate equilibrium state as previously predicted; but extra $+1/-1$ defect pairs may induce a highly disordered shape which is deeply metastable. We discuss comparison with relevant experiments. Next we consider a lipid vesicle with nematic order, e.g. composed of lipids with a rod-shaped head group. With weak coupling between defects and curvature, the vesicle is spherical with four $+1/2$ defects. With stronger coupling, the vesicle becomes prolate with two defects clustered at each end. As coupling is further increased, pores nucleate at the defects and coalesce, producing a hollow cylinder. We compare simulation results with theoretical predictions and consider further applications e.g. to study tilt and defects in gel phase lipid rafts.

2:54PM L9.00003 Coarse-grained model for lipid bilayer membranes and vesicles[1] , JUN GENG, JONATHAN SELINGER, ROBIN SELINGER, Kent State Univ. — We present a coarse-grained model for simulation studies of lipid bilayer membranes and vesicles. We separately track the behavior of the leaflets in each bilayer, allowing us to model the mechanics of vesicles and a rich array of other phases, topologies, and defect structures. Each particle in the coarse-grain model represents a patch of lipid molecules and carries a vector degree of freedom, representing the local average lipid chain orientation. Particles interact via a pair potential depending on separation distance and relative chain orientation. Solvent is treated as implicit, and membrane fluctuations are modeled via a Langevin thermostat. Resulting bilayer structures show liquid-like diffusion within each leaflet. We show that bilayer vesicles coalesce spontaneously from a random initial state, even though no spontaneous curvature is imposed by the model. We also explore the transition from vesicles to lamellar phases as a function of increasing density. We discuss potential application to the study of vesicle fission and fusion.

[1]Work supported by NSF-DMR-0605889

3:06PM L9.00004 Molecular dynamics study of shape transitions in aqueous micelle solutions[1] , A. SANGWAI, R. SURESHKUMAR, Syracuse University, Syracuse, NY 13244, USA. — It is well known that surfactant molecules self-assemble in aqueous solutions to form various micellar structures such as spheres, rods or sheets. Although this phenomenon is widely studied experimentally, the molecular mechanisms of shape transitions are not well understood. Atomistic simulations of self-assembled micellar systems are computationally prohibitive to sample several hundred nanoseconds necessary to capture shape transitions. We demonstrate that MARTINI coarse-grained (CG) force field for CTAC is capable of accurately representing micellar assemblies by comparing the CG system to fully atomistic ones. Microsecond molecular dynamic simulations using MARTINI CG models in explicit water are used to predict sphere to rod transitions in micelles. Inter-micelle association free energies are estimated to distinguish between the chemical environments in which the micelle assumes a spherical versus rod-like shape. Presence of hydrophobic salt e.g. Sodium Salicylate, is shown to greatly promote the formation of rodlike structures. CG MARTINI molecular dynamics is benchmarked as a practical approach to study nano-scale micellar structures.

[1]NSF Grant 1049454

3:18PM L9.00005 Ordered bulk aggregates of lipid vesicles , ANA HOCEVAR, Jozef Stefan Institute, PRIMOZ ZIHERL, Faculty of Mathematics and Physics, University of Ljubljana and Jozef Stefan Institute — We study the structure of bulk assemblies of identical lipid vesicles. In our model, each vesicle is represented as a convex polyhedron with flat faces, rounded edges, and rounded vertices. Each vesicle carries an elastic and an adhesion energy and it turns out that in the limit of strong adhesion, the minimal-energy shape of cells minimizes the weighted total edge length. We calculate the shape of the rounded edge exactly and show that it can be well described by a cylindrical surface. We compare several candidate space-filling polyhedra and we find that the oblate shapes are preferred over prolate shapes for all volume-to-surface ratios. We also study aggregates of vesicles whose adhesion strength on lateral faces is different from that on basal/apical faces. We determine the anisotropy needed to stabilize prolate shapes and we show that at any volume-to-surface ratio, the transition between the oblate and the prolate shapes is very sharp. We compare the geometry of the model vesicle aggregates with the shapes of cells in certain simple animal tissues. Predictions of our model are consistent with available experimental data.

3:30PM L9.00006 Understanding crumpling lipid vesicles at the gel phase transition[1] , LINDA HIRST, School of Natural Sciences, University of California, Merced, ADAM OSSOWSKI, MATTHEW FRASER, University of California, Merced — Wrinkling and crumpling transitions in different membrane types have been studied extensively in recent years both theoretically and computationally. There has also been very interesting recent work on defects in liquid crystalline shells. Lipid bilayer vesicles, widely used in biophysical research can be considered as a single layer smectic shell in the liquid crystalline phase. On cooling the lipid vesicle a transition to the gel phase may take place in which the lipid chains tilt and assume a more ordered packing arrangement. We observe large scale morphological changes in vesicles close to this transition point using fluorescence microscopy and investigate the possible mechanisms for this transition. Confocal microscopy is used to map 3D vesicle shape and crumpling length-scales. We also employ the molecular tilt sensitive dye, Laurdan to investigate the role of tilt domain formation on macroscopic structure.

[1]Funded by NSF CAREER award (DMR - BMAT #0852791).

3:42PM L9.00007 Thin shell vesicles composed of hydrophilic plate-like nanoparticles , ANAND SUBRAMANIAM, School of Engineering and Applied Sciences, Harvard University, JIANDI WAN, Department of Mechanical and Aerospace Engineering, Princeton University, ARVIND GOPINATH, Fischer School of Physics, Brandeis University, HOWARD STONE, Department of Mechanical and Aerospace Engineering, Princeton University — Nanopowders of graphene oxide, montmorillonite and laponite spontaneously delaminate into ultrathin nanoscopic plates when dispersed in water. These plates, which are typically $\sim$ 1 nm thick and microns in lateral dimension, have found many uses as precursors to graphene, ceramics, layer-by-layer structures, and as structural modifiers of nanocomposites. Here we show that mechanical forces due to shear in a narrow gap can assemble hydrophilic plate-like particles on air bubbles, forming stable nanoplated armored bubbles. Translucent inorganic vesicles (vesicles defined here as closed thin-shelled structures with the same liquid inside and outside) of these particles are produced when the nanoplated armored bubbles are exposed to common water-miscible organic liquids and surfactants. These inorganic vesicles are mechanically robust, have walls that are about six nanometres thick, and are perforated with pores of submicron dimensions. We characterize the phenomenon and find that a wetting transition at the scale of the nanoparticles is the primary mechanism of formation. The discovery of these novel inorganic structures raises a wealth of questions of fundamental interest in materials and surface science.

3:54PM L9.00008 The effect of interlayer distance of thickness fluctuations in a swollen lamellar phase: A neutron spin echo study , MICHIHIRO NAGAO, NIST Center for Neutron Research and Indiana University — Thickness fluctuations in surfactant membranes have been measured using small-angle neutron scattering (SANS) and neutron spin echo (NSE) techniques as a function of the membrane thickness in a swollen lamellar structure composed of nonionic surfactant, water and oil. An excess dynamics from the bending motion was observed around the length scales of the membrane thickness, which originates from thickness fluctuations of the membranes. The amount of oil in the bilayers controls the interlayer distance (membrane thickness) and the bending motion of the membranes. An enhancement of the thickness fluctuations suppresses the bending motion, which introduces the increase in the bending modulus at low swelling condition. The decrease in the bending modulus with further increase in the thickness indicates the decrease of the synchronization between monolayers. In the high swelling conditions, the monolayer movement dominates the dynamics of the membranes in the measured dynamic range.

4:06PM L9.00009 The effect of interlayer distance on thickness fluctuations in a swollen lamellar phase: A molecular dynamics study , SUKHUM CHAWANG, The Univesity of Oklahoma, TAKUMI HAWA, The University of Oklahoma — Molecular dynamics simulations have been conducted to characterize thickness fluctuations in a swollen lamellar structure, composed of a non-ionic surfactant, water, and oil, to verify the results of the neutron scattering experiments by Nagao. The thickness fluctuations are measured as an excess dynamics from the bending motion around the length scales of the membrane thickness and as a function of the interlayer distance (membrane thickness). The enhancement of the thickness fluctuations is observed in all ranges of thickness we simulated; however, it decays with increase of the membrane thickness. Dependence of directions of sampling wave vectors q on the thickness fluctuation is also investigated. At more normal direction (perpendicular to the membrane surfaces) the excess dynamics is clearly observed, while at more lateral direction (parallel to the membranes) the bending motion is more clearly observed. The present results show the existence of the enhancement of the thickness fluctuations and the importance of the sampling directions.

4:18PM L9.00010 Studies of lipid vesicle mechanics using an optical fiber dual-beam trap[1] , TESSA M. PINON, School of Engineering-University of California, Merced, LINDA S. HIRST, JAY E. SHARPING, School of Natural Sciences-University of California, Merced — Fiber-based optical traps can be used for manipulating micron-sized dielectric particles such as microspheres and biological cells. Here we study the mechanics of giant unilamellar vesicles (GUVs) which are held and stretched by light forces in a fiber-based dual-beam optical trap. Our GUVs are suspended in a buffer solution and encapsulate various concentrations and molecular weights of poly(ethylene glycol) (PEG) polymer yielding a range of refractive index contrasts and trapping conditions. We find that we can trap GUVs in solution with index contrasts of less than 0.01. We explore the mechanical response of the GUV membrane to a range of forces which are proportional to laser power and refractive index contrast. Our trapping system is a compact and inexpensive platform and trapping is viewed in real time under a microscope. We hypothesize that forces within the high-tension regime will induce a linear response in vesicle surface area. This project sets the stage for membrane mechanics and lipid phase change studies.

[1]Grant: NSF award #DMR 0852791, "CAREER: Self-Assembly of Polyunsaturated Lipids and Cholesterol in the Cell Membrane"

4:30PM L9.00011 Thermal Stress of Supported Lipid Bilayer Induces Formation and Collapse of Uniform Radius Tubules , KIMBERLY WEIRICH, DEBORAH FYGENSON, University of California, Santa Barbara — Supported lipid bilayer (SLB) provides a model system in which to quantitatively investigate fluid bilayer transitions from planar to tubular and tubular to spherical morphologies. Following a small increase in temperature, flexible filaments extrude from a fluid SLB. Individual filaments can reach hundreds of microns in length before spontaneously collapsing into discs. We demonstrate that the filaments are tubular and report the effects of lipid composition and flow-induced tension on their properties. At high ionic strength, the sub-resolution tubules are adsorbed to the SLB, enabling the measurement of their radius to within $\pm$5 nm using fluorescence microscopy.

4:42PM L9.00012 A Time-Resolved Study on Nanodisc-to-Vesicle Transformation , MU-PING NIEH, IMS/CMBE, Uinversity of Connecticut, SUANNE MAHABIR, WAN KEI WAN, University of Western Ontario, JOHN KASTARAS, Oak Ridge National Lab/CNBC — Structural phase diagram of a phospholipid mixture composed of dimyristoyl phosphatidylcholine (DMPC), dihexanoyl phosphatidylcholine (DHPC) and dimyristoyl phosphatidylglycerol (DMPG) contains many rich morphologies, e.g., nanodiscs also known as "bicelles", bilayered ribbons, unilamellar vesicles (ULVs), multi-lamellar vesicles (MLVs) and perforated lamellae. In this report, we will present time-resolved small angle neutron scattering and dynamic light scattering measurements of the structural transformation from nanodiscs to ULVs as a function of temperature, lipid concentration and charge density. The result will reveal the growth rate of nanodiscs and all the intermediate structures along the transformation process. Through the understanding of the kinetic pathway, the size and polydispersity of the self-assembled nano-size ULVs can be well-controlled. These ULVs can be used as a carrier for therapeutics or imaging probes.

4:54PM L9.00013 Crystallization Induced by Electrostatic Correlations in Vesicles of Mixed-Valence Ionic Amphiphiles[1] , CHEUK YUI LEUNG, RASTKO SKNEPNEK, LIAM PALMER, GRAZIANO VERNIZZI, MEGAN GREENFIELD, SAMUEL STUPP, MICHAEL BEDZYK, MONICA OLVERA DE LA CRUZ, Northwestern University — Charged amphiphilic molecules, including molecules with biological motifs, have been predicted to organize into elastic membrane or crystalline shells with non-spherical shapes. We demonstrate that pure electrostatic interaction allow (-1) anionic water insoluble amphiphiles and (+3) cationic amphiphiles, which form only micelles in water, to co-assemble into buckled vesicles. The strong interaction between the +3 and -1 head groups increases the cohesive energy of the amphiphiles and favors the formation of crystallized membranes or shells that facet spontaneously into buckled shapes predicted by simulations of vesicles with heterogeneous elastic properties. In situ small-angle and wide-angle X-ray scattering (SAXS-WAXS) experiments conducted at the Advanced Photon Source DND-CAT confirm the presence of crystalline bilayers. Our simulations verify that ionic lateral correlations among the oppositely charged head groups of the co-assembled amphiphiles are responsible for the observed tail crystallization.

5:06PM L9.00014 Endocytic internalization of nanoparticles into polymeric vesicles. , ANJA KROEGER, KARMENA JASKIEWICZ, Max Planck Institute for Polymer Research, ANTJE LARSEN, Department of Materials Science and Technology, University of Crete and F.O.R.T.H., GEORGE FYTAS, Department of Materials Science and Technology, University of Crete and F.O.R.T.H. and Max Planck Institute for Polymer Research — The monitoring of transport through cell membranes is essential for proper functioning of all living organisms. Poorly understood mechanisms of endocytosis have become the focus of intense investigations. Here we present a photon correlation spectroscopy study of the uptake of polystyrene nanoparticles (hydrodynamic radius, R_h=16nm) by poly(dimethylsiloxane)-b-poly(2-methyloxazoline) polymersomes (R_h=150nm) in aqueous solution. The relaxation function C(q,t) for a particle/polymersome mixture with a molar ratio 100:1 at different scattering wave vectors (q) reveal the presence of free and bound particles. Both the experimental form factor P(q) and the effective diffusion coefficient D(q) of the polymersome in the q-range of 0.005-0.033nm^{-1}are consistently described by modeling these q-patterns by a filled polymersome with about 30 particles under the examined conditions. The emerged picture is supported by cryo-TEM imaging.

5:18PM L9.00015 AC-Electrokinetic Characterization and Induced Encapsulation Release of Micelles in Aqueous Suspensions , VICTORIA FROUDE, YINGXI ELAINE ZHU, University of Notre Dame — Micelles and polymers vesicles have been of increasing interest as drug delivery systems for controlled release, specific cell targeting, and medical diagnostics. In addition, AC-electrokinetic techniques have emerged as a viable option for colloidal and biocolloidal manipulation. In this work, we examine the dielectrophoresis (DEP) characteristics of complex micellar nanoparticles under non-uniform AC-electric field of varied ac-field frequencies (5 kHz-20 MHz) and amplitudes (0.1-10 Vpp) by fluorescence correlation spectroscopy (FCS) at a single-molecule resolution. We focus on the AC-field induced transport of sodium tetradecyl sulfate (STS) and sodium dodecyl sulfate (SDS) micelles tagged with various fluorescent and drug encapsulates in aqueous media. We observe a strong AC-frequency dependence of micelle concentration between two microelectrodes, from which the DEP crossover frequency is determined. Surprisingly, we also observe an AC-field induced dissociation of the micelle structure and a resulting release of fluorescent encapsulates at a characteristic low AC-field frequency of approximately 1-10 kHz, where the dissociation has been found to be dependent on the surface charge of the interior encapsulate.

Session L10 DCMP: Nanoclusters and Nanowires on Surfaces D221

2:30PM L10.00001 Structure and dynamics of PtSn/γAl_2O_3[1] , F.D. VILA, J.J. REHR, U. of Washington, S.D. KELLY, EXAFS Analysis, S.R. BARE, UOP LLC — Supported metal clusters have many industrial applications, especially in heterogeneous catalysis. Their activity and durability is determined by their internal atomic and electronic structure, as well as by their interaction with the support. We have previously shown[2] that unusual phenomena such as large structural disorder and negative thermal expansion in supported Pt clusters can be understood by using a combination of MD and x-ray absorption spectroscopy simulations. Here we present results for prototypical $Pt_{10}Sn_{10}$ alloy clusters on γAl_2O_3. Our simulations show that the internal structure and surface location of the clusters varies dynamically on a time scale of a few ps. While the Sn atoms are especially mobile, the clusters have well defined Pt-Pt and Pt-Sn coordination shells at $\sim$2.75Å. Moreover, at any instant there are between 2 and 5 bonds between the Pt/Sn and the O atoms in the surface. Finally, we present simulations of the XANES spectra and their relation to charge transfers between atoms in the cluster and between the cluster and the surface.

2:42PM L10.00002 Polarization dependent Pd deposition structure on $LiNbO_3$ {0001} surface[1] , SEUNGCHUL KIM, ANDREW M. RAPPE, Department of Chemistry, University of Pennsylvania — We investigate effects of polarization orientation on atomic structure of palladium deposited on lithium niobate ($LiNbO_3$) {0001} surface, using density functional theory (DFT) and kinetic Monte Carlo (kMC) simulations. Adsorption, diffusion, aggregation and clustering process – include geometries, paths and energies – of Pd clusters were calculated from DFT simulations. It has been observed that energy barriers of Pd motions on the negatively poled (c^-) surface are much larger than those on the positively poled surface (c^+), which indicates the Pd motions on the c^- surface are much slower than that of c^+ surface. We demonstrate, using kMC with kinetic parameters from DFT, very slow motion of Pd on c^- surface leads dispersed small clusters or atoms while fast motion on c^+ surface leads large clusters, indicating larger Pd-covered area on c^- surface than c^+ after Pd deposition.

[1]This work has been supported by US-DOE (grant DE-FG02-07ER15920), and by AROSR (FA9550-07-1-0397). Computational support was provided by HPCMO of the US-DoD.

2:54PM L10.00003 Cu/CuOx Nanoclusters on ZnO(1010): Electronic, Catalytic, Morphological Structure[1] , ZIYU ZHANG, FEI WANG, Dept. of Physics, Louisiana State University, MAOMIN REN, Dept. of Chemical Engineering, Louisiana State University, FRANK WOMACK, Dept. of Physics, Louisiana State University, MINH LE, Dept. of Chemical Engineering, Louisiana State University, YAROSLAV LOSOVYI, CAMD, Louisiana State University, RICHARD KURTZ, PHIL SPRUNGER, Dept. of Physics, Louisiana State University, JOHN FLAKE, Dept. of Chemical Engineering, Louisiana State University — To develop a high performance catalyst for CO2 reduction, we tried bi-layers based on CuOx (x=0, 1, 2) and ZnO. The highest yield rate is found for Cu(I) on ZnO. The repeatability of the experiment illustrates that the Cu(I) catalytic clusters are stable in the air, due to the interface of the bilayer.STM and ARPUS results reveal that the preparation process are highly dependent on the annealing temperature and cluster size. EELS and UPS data show that CO adsorption is distinctly different between Cu and CuOx clusters on ZnO, which explains the different yield rate. Based on TDS and EELS of adsorption such as CO2, H2O, combined with DFT calculation, the mechanism of methanol synthesis is given by introducing intermediate products.

3:06PM L10.00004 Role of nitrogen dopants in the stabilization of nancrystalline cubic zirconia , RENAT SABIRIANOV, Univesity of Nebraska at Omaha, G. WANG, Y.L. SOO, G. LUO, H.J. LIN, W.N. MEI, F. NAMAVAR, C.L. CHEUNG — The role of the nitrogen doping in the stabilizing the nanocrystalline cubic phase of zirconia films fabricated by nitrogen beam assisted deposition (IBAD) is investigated. The IBAD zirconia films have diameters three times larger than those previously reported in a sol-gel method. Confocal Raman spectroscopy study indicates that the atomic structure of these IBAD zirconia films evolve from cubic to tetragonal and then to monoclinic phase upon annealing at elevated temperatures. The presence of nitrogen in the films is confirmed by secondary ion mass spectroscopy. X-ray absorption near edge structure study of these films infers that the nitrogen atoms are incorporated at the substitutional sites of these films. Ab-initio density functional calculations suggests that the substitutional nitrogen atoms could effectively immobilize native defect including oxygen vacancies and interstitial ions in nanocrystalline cubic zirconia.

3:18PM L10.00005 Preparation dependent neutralization efficiency of Pt/TiO2 nanoparticles

, ALEX ARJAD, YARMOFF JORY, University of California, Riverside — Metal nanoclusters resident on an oxide surface can be produced by sputtering thin films as well as by direct deposition. We previously used the neutralization of scattered low energy alkali ions to demonstrate that Au nanoclusters formed by sputtering a thin gold film on TiO_2 have similar electronic properties as those formed by deposition [1]. In this work, we compare Pt nanoclusters grown on TiO_2 by both sputtering and deposition. It is shown that Pt nanoclusters formed by deposition are more efficient at neutralizing scattered low energy Na+ ions than those formed by sputtering a thin platinum film. We attribute this difference to the strong-metal-support-interaction (SMSI) present in the Pt/TiO_2 system, but not with Au/TiO_2.

3:30PM L10.00006 Nanoparticle shape instability by Coulomb interactions[1]

, NATALYA ZIMBOVSKAYA, University of Puerto Rico-Humacao — Metal atoms adsorbed on few-layer graphenes condense to form nanometer-size droplets whose growth in size is limited by a competition between the surface tension and repulsive electrostatic interactions from charge transfer between the metal droplet and the graphene. Under certain conditions a growing droplet can be unstable to a family of shape instabilities. This phenomenon was observed for Yb deposited and annealed on few-layer graphenes. A theoretical model to describe it is developed. The model describes the onset of shape instabilities for nanoparticles where their growth is limited by a generic repulsive potential and provides a good account of the experimentally observed structures for Yb on graphene [1].

3:42PM L10.00007 Structure and Energy Stability of Metal Nanoparticles[1]

, HECTOR BARRON, University of Texas at San Antonio, JUAN PEDRO PALOMARES-BAEZ, Instituto Potosino de Investigacion Cientifica y Tecnologica, JESUS VELAZQUEZ-SALAZAR, University of Texas at San Antonio, JOSE LUIS RODRIGUEZ-LOPEZ, Instituto Potosino de Investigacion Cientifica y Tecnologica, MIGUEL JOSE-YACAMAN, University of Texas at San Antonio, UNIVERSITY OF TEXAS AT SAN ANTONIO COLLABORATION, INSTITUTO POTOSINO DE INVESTIGACION CIENTUFICA Y TECNOLOGICA COLLABORATION — In this work we present a theoretical model for the structural evolution and energy stability for metal nanoparticles from the small (1-2 nm) to the big ($\sim$50 nm) size ranges. We have found that the appearances of structural lattice defects as well as surface reconstructions are important factors that highly influence the growth process. A simple assembly model for a path transformation for metal nanoparticles is presented and compare with experimental evidence.

4:06PM L10.00009 Attachment of Quantum Dots on Zinc Oxide Nanorods

, JARED SEAY, HUAN LIANG, PARAMESWAR HARIKUMAR, University of Tulsa — ZnO nanorods grown by hydrothermal technique are of great interest for potential applications in photovoltaic and optoelectronic devices. In this study we investigate the optimization of the optical absorption properties by a low temperature, chemical bath deposition technique. Our group fabricated nanorods on indium tin oxide (ITO) substrate with precursor solution of zinc nitrate hexahydrate and hexamethylenetramine (1:1 molar ratio) at 95C for 9 hours. In order to optimize the light absorption characteristics of ZnO nanorods, CdSe/ZnS core-shell quantum dots (QDs) of various diameters were attached to the surface of ZnO nanostructures grown on ITO and gold-coated silicon substrates. Density of quantum dots was varied by controlling the number drops on the surface of the ZnO nanorods. For a 0.1 M concentration of QDs of 10 nm diameter, the PL intensity at 385 nm increased as the density of the quantum dots on ZnO nanostructures was increased. For quantum dots at 1 M concentration, the PL intensity at 385 nm increased at the beginning and then decreased at higher density. We will discuss the observed changes in PL intensity with QD concentration with ZnO-QD band structure and recombination-diffusion processes taking place at the interface.

4:18PM L10.00010 Controlled Deposition of Nanocrystal Quantum Dots on Silicon Surfaces

, OLIVER SEITZ[1], HUE M. NGUYEN[2], DAMIEN AUREAU[3], AMANDEEP SRA[4], ANTON V. MALKO[5], YVES J. CHABAL[6], University of Texas at Dallas — Studying Forster resonant energy transfer (FRET) has constantly been a challenge because of the poor control in transferring nanocrystal quantum dots (NQDs) onto various substrates. This lack of control often resulted in formation of aggregates (3D growth), inhomogeneity, and poor adhesion. In this study, using self assembled monolayers (SAMs), dense monolayer of NQDs have been attached onto silicon substrate, with and without the presence of oxide interlayer, allowing investigating FRET effects via photoluminescence measurements. Such SAMs, directly attached to the silicon, via Si-C bonds, display an interface quality with low interface states. Moreover, the ability to be prepared with tunable thicknesses renders them ideal for FRET investigation. Such hybrid colloidal NQD/Silicon optoelectronic structures could potentially be attractive for both photovoltaic as well as light emitting applications.

4:30PM L10.00011 Synthesis of a long gold atomic strand incorporated with carbon atoms

, YOSHIFUMI OSHIMA, TOMOYA ONO, Osaka University, KUNIO TAKAYANAGI, Tokyo Institute of Technology, NGUYEN DUY HUY, Osaka University — Single metal or carbon atomic strands have attracted much interest because of their unique properties. They have been usually fabricated by stretching or thinning the junction between both electrodes, but limited to be several atoms in length at maximum. We show that a long atomic strand can be synthesized by pulling one-dimensional reconstructed structure formed on the electrode surface. In the transmission electron microscope combined with a scanning tunneling microscope, gold atoms were observed to be pulled out one-by-one from carbon contaminated gold (111) surface layer each 0.5 nm elongation till diminishing the layer. This observation was explained by the first-principle calculation, showing that two carbon atoms are incorporated at each interval (0.5 nm) between two neighboring gold atoms aligned along the [112] direction to form the one-dimensional reconstructed structure, when the gold (111) surface is contaminated with carbon atoms.

4:42PM L10.00012 Scanning Tunneling Microscopy Study of Quantum Cobalt Chains[1] , NADER ZAKI, Columbia University, DANDA ACHARYA, Pacific Northwest National Laboratory, DENIS POTAPENKO, Columbia University, PETER JOHNSON, PERCY ZAHL, PETER SUTTER, Brookhaven National Laboratory, RICHARD OSGOOD, Columbia University — We recently reported [1] on a new surface phase of the Co-vicinal-Cu(111) system, which exhibits self-assembled uniform Co quantum wires that are stable at 300K. STM images show that the wires form along the leading edge of the step rise, differentiating it from previously theoretically predicted atomic-wire phases as well as experimentally observed step-island formation. Our observations allow us to comment on the formation kinetics of the atomic-wire phase and on the fit of our data to a recently developed lattice-gas model. LT-STM measurements, taken on self-assembled Co chains, reveal a charge-density modulation that is dependent on tip bias. These charge-modulations are observed for tip-bias relatively far away from the Fermi level, both at negative and positive bias. We present arguments for the identification of these modulations as due to either charge-density-like waves (CDW) or excited states of this 1-D system.

4:54PM L10.00013 ABSTRACT WITHDRAWN –

5:06PM L10.00014 Characterization of the surface environment of PbSe nanoparticles by correlating calculated and measured x-ray spectra , KEITH GILMORE, AARON HAMMACK, APRIL SAWVEL, EVELYN ROSEN, D. FRANK OGLETREE, JEFFREY URBAN, DELIA MILLIRON, BRETT HELMS, BRUCE COHEN, DAVID PRENDERGAST, Lawrence Berkeley National Lab, NANO-SURFACES TEAM — Given that defining characteristics of nanoparticles are often dictated by their surfaces, it is desirable to be able to control the surface environments. We seek this control through ligand exchange chemistry and investigate PbSe as a model system. We correlate calculated and measured x-ray spectra to quantify the extent of ligand exchange, validate our structural models, and characterize the optical and electronic properties induced by the new surface environment. Chemical shifts in x-ray photoelectron spectra indicate changes in atomic bonding at the surface, whereas x-ray absorption spectra reveal ligand conformation and binding coordination at the surface. The colloidal synthesis of PbSe particles is highly reliable and the resulting particles are technologically useful size-tunable IR absorbers. Such particles have Pb rich surfaces and native oleic acid coats. We replace the oleic acid with alternate ligands of choice, which may change the Pb:Se ratio at the particle surface.

5:18PM L10.00015 Anchoring platinum on graphene using metallic adatoms , F.G. SEN, Department of Mechanical, Automotive and Materials Engineering, University of Windsor, Windsor, ON, Canada, Y. QI, Chemical Sciences and Materials Systems Laboratory, General Motors R&D Center, Warren, MI U.S.A., A.T. ALPAS, Department of Mechanical, Automotive and Materials Engineering, University of Windsor, Windsor, ON, Canada — To anchor Pt on the graphene surface 25 different metallic adatoms were individually inserted into Pt(111)/graphene interface and the work of separation required to break the interface between Pt-adatom and C-adatom bonds were computed using first principles calculations. With the exception of Al, Zn and Au, all metals increased the strength of the Pt/graphene interface, while many transition metals with unfilled d orbitals, such as Sc, Ti, V, Cr, Co, Ni, Zr, Nb, Mo, Ru, Rh, Ta, W, Re, Os, Ir, could increase the Pt/graphene interface strength from 0.009 J/m^2 to above 0.5 J/m^2. The Pt-adatom bond had metallic character and its strength was proportional to the amount of charge transferred from the adatom to the Pt. The strength of carbon-adatom bond was proportional to the ratio of charge transferred to the carbon over charge transferred to the platinum from the adatom. As this ratio was $>$1.0 for Ir, Os, Ru, Rh and Re and these emerged as the most promising adatoms for anchoring Pt on graphene.

2:30PM L13.00001 Relaxation of stresses and dynamical heterogeneities close to jamming in a granular experiment , CORENTIN COULAIS, OLIVIER DAUCHOT, CEA-SPEC-GIT, ROBERT BEHRINGER, Duke U — Dynamical Heterogeneities have been found to exhibit maximal size and scale invariance at Jamming. We address here the question of the link with stresses in the materials. To that end, we use a confined, vibrated layer of 8000 bidisperse grains under uniaxial compression. The vibration is horizontal, transverse to the direction of compaction. First, an intruder is pulled at constant velocity through the assembly and force measurements reveals maximal time correlations at Jamming. Then, the experimental setup is slightly modified to accept photoelastic grains, made of soft or hard materials. By measuring positions and stresses, decorrelation of forces as well as dynamics in structure, spontaneous fluctuations are probed. Both quenches and intruder pulling protocols are performed, and novel behavior at Jamming is seen.

2:42PM L13.00002 Nonlinear elasticity near jamming probed in bidisperse foams , ALEXANDER SIEMENS, MARTIN VAN HECKE — An unusual characteristic of the jamming transition is the difference in scaling of the bulk and shear modulus of frictionless soft particles near jamming. We probe this scaling by compressing a bidisperse foam monolayer sandwiched between a glass plate and a fluid surface. We also determine the weakly nonlinear effective bubble-bubble interactions in a 1D chain of bubbles under compression.

2:54PM L13.00003 Reversible plasticity near Jamming in foams , GIJS KATGERT, WILSON C.K. POON, University of Edinburgh — We study the response of a disordered foam monolayer, confined between a soapy solution and a glass plate to an oscillatory compressive strain brought about by inflating a central bubble. We show that, when driven quasistatically slowly, the foam as a whole can exhibit kinematically reversible plasticity or *anelasticity*: the bubble packing alternates between two reproducible configurations, which are separated by multiple plastic events and global displacements. After establishing that the timescale beyond which the foam behaves quasistatically is set by the scaling of the foam compressive modulus with packing fraction ϕ, we map out the boundary between reversible and irreversible plasticity in the space spanned by ϕ and the compressive strain ε and tentatively find the strain to scale as $\varepsilon \sim (\phi - \phi_c)^{1/4}$, with ϕ_c the jamming point. We finally extract a plasticity lengthscale from our experiment and show it to grow on approach to ϕ_c.

3:06PM L13.00004 Local origins of volume fluctuations in granular materials[1]

, JAMES PUCKETT, North Carolina State University, FREDERIC LECHENAULT, Universite Montpellier II, KAREN DANIELS, North Carolina State University — Recent experiments and simulations have observed that the fluctuations in the local volume fraction, ϕ, decrease as the granular material approaches jamming. We investigate the role of boundary condition and inter-particle friction, μ, on these fluctuations for a dense bidisperse granular monolayer driven at the perimeter. Using a radical Voronoi tessellation, we find a universal linear relationship between the mean variance of ϕ independent of boundary condition and μ. We examine the universality and origins of this trend using the recent granocentric model modified to draw neighbors from an arbitrary distribution $P(s)$, the edge-to-edge distance between neighbors. The mean and variance of the observed particle separation s are described by a single length scale controlled by mean ϕ. We tested diverse functional forms of $P(s)$ and found that each produces the trend of decreasing fluctuations, but only the experimentally-observed $P(s)$ provides quantitative agreement with the measured ϕ fluctuations. In conclusion, we find $P(\phi)$ and $P(s)$ encode similar information about the distribution of free volume in a driven granular system under different boundary conditions and inter-particle friction.

[1]NSF DMR-0644743

3:18PM L13.00005 Intermittent Jamming in Quasi-2D Microfunnels

, CARLOS ORTIZ, KAREN DANIELS, North Carolina State University, ROBERT RIEHN[1] — Both athermal granular jamming and thermal glass transitions have recently received extensive attention. We experimentally investigate the jamming transition in a quasi-2D system of nearly hard-sphere, micron-sized PMMA-PHSA particle suspension in a density and index-matched medium flowing through a microfunnel. We observe a packing fraction driven transition from a gas-like to a liquid-like to a solid-like phase. At sufficiently high packing fractions we observe intermittent jamming under constant pressure. Further increase in the packing fraction forms a stable solid-like jammed phase which is disordered on long-ranges, and susceptible to re-melting by reverse flow, agitation, and diffusion. By displaying properties of both athermal granular jamming and thermal glass transitions, our experiment provides a useful testing ground for understanding the jamming transition as a unifying framework.

[1]North Carolina State University

3:30PM L13.00006 Controllable jamming of amorphous granular materials applied to robotics[1]

, ERIC BROWN, RODENBERG RODENBERG, The University of Chicago, JOHN AMEND, HOD LIPSON, Cornell University, ANNAN MOZEIKA, ERIK STELTZ, iRobot G&I Research, MITCHELL ZAKIN, DARPA, HEINRICH JAEGER, The University of Chicago — We demonstrate the practicality of using a controlled jamming transition in an amorphous mass of granular material for applications to robotic gripping, and how the gripping capabilities depend on the properties of the jammed state. A mass of granular material contained in a flexible membrane in an unjammed state flows and conforms to almost any object it is pressed against. Upon application of a vacuum, the external pressure on the membrane jams the granular mass with a volumetric contraction $< 1\%$, allowing it to pinch the object. By measuring the holding force on a test sphere at different levels of envelopment, we show that three mechanisms contribute to the holding force: friction, suction, and interlocking. We use a solid mechanics model to relate the holding force from each mechanism to the measured stress response of jammed granular materials to compressional, extensional, and bending strains. This opens up new possibilities for the design of simple systems that excel at gripping objects of arbitrary shape.

3:42PM L13.00007 Jamming in Vertical Channels[1]

, G. WILLIAM BAXTER, FIONA STEEL, Penn State Erie, The Behrend College — We study jamming of low aspect-ratio cylindrical Delrin grains in a vertical channel. Grain heights are less than their diameter so the grains resemble antacid tablets, coins, or poker chips. These grains are allowed to fall through a vertical channel with a square cross section where the channel width is greater than the diameter of a grain and constant throughout the length of the channel with no obstructions or constrictions. Grains are sometimes observed to form jams, stable structures supported by the channel walls with no support beneath them. The probability of jam occurrence and the strength or robustness of a jam is effected by grain and channel sizes. We will present experimental measurements of the jamming probability and jam strength in this system and discuss the relationship of these results to other experiments and theories.

[1]Supported by an Undergraduate Research Grant from Penn State Erie, The Behrend College.

3:54PM L13.00008 Geometry Dependence of the Clogging Transition in a Tilted Hopper

, CHARLES THOMAS, DOUGLAS DURIAN, University of Pennsylvania — We report the effect of system geometry on the clogging of granular material flowing out of a flat-bottomed hopper. We vary the hopper tilt angle, aperture shape, and granular media shape, investigating smooth spheres (glass beads), compact angular grains (beach sand), and rod-like grains (rice). We measure the average number of grains discharged before a clog halts the flow. This value grows with hole size as a power law, diverging above a critical hole size. We determine the critical value by performing a least-squares fit to the data. Beyond that critical hole size, the flow does not clog for any given tilt angle. This critical hole size grows with increasing tilt, diverging at $\pi - \theta_r$, where θ_r is the angle of repose. The value of the critical hole size as a function of tilt angle describes a well-defined transition on a clogging phase diagram. For circular apertures, the shape of this transition is similar for all grain types. However, this is not the case for the narrow slit apertures, where the rate of growth of the critical hole size with tilt angle depends on the material. The growth rate is the fastest for angular grains, then smooth spheres, with rod-like grains showing the slowest growth. This suggests a profound link between the aperture geometry and the particle shape.

4:06PM L13.00009 Jamming of Granular Flow in a Two-Dimensional Hopper[1]

, JUNYAO TANG, SEPEHR SADIGHPOUR, ROBERT BEHRINGER — We seek an understanding of the physics of jamming for hopper flow using high speed spatio-temporal video data for photoelastic disks flowing through a two-dimensional hopper. We have found experimental support for the hypothesis that jamming events of granular flow in a hopper is approximately a Poisson process. The mean flow time between two consecutive jams increases rapidly with the hopper opening size, but it is insensitive to changes of the hopper wall angle.Through particle tracking and photoleastic measurements, we measure stress fields, velocity fields and density fields, as well as their fluctuations during the flow. Current work is focusing on understanding how to combine these results to give us further insights of the relation between mean flow properties and jamming and their dependence on hopper configuration.These data are part of an IFPRI-NSF Collaboratory for comparing physical data and simulations.

[1]This work is funded by IFPRI. (International Fine Particle Research Institute)

4:18PM L13.00010 Structural Stability and Jamming of Self-Organized Cluster Conformations in Granular Materials[1] , A. TORDESILLAS, U. of Melbourne, B. BEHRINGER, Duke U, Q. LIN, J. SHI, U. of Melbourne, J. ZHANG, Indiana U-Purdue University-Fort Wayne — We probe emergent self-organized particle cluster conformations in slowly deforming dense granular materials. We invoke structural mechanics to devise a new stability measure for clusters, and use this measure to explore stability of jammed states of cluster conformations consisting of particles in force chains and minimal contact cycles. Knowledge of the spatio-temporal evolution of the (relative) stability of jammed conformations offers valuable clues to granular rheology and self-assembly. We use data from assemblies of bi-/poly-disperse disks subject to 2D deformation in two biaxial strain tests: one computational and one experimental. Self-assembly occurs on multiple length scales with jammed force chains and minimal cycles forming the basic building blocks. Three-cycles are stabilizing agents acting as granular trusses to load-bearing force chain columns. The co-evolution of minimal cycles and force chains form a generic feature of these materials and loading paths.

4:30PM L13.00011 Decoupling of Rotational and Translational Diffusion in Supercooled Colloidal Fluids[1] , KAZEM V. EDMOND, GARY L. HUNTER, Emory University, MARK T. ELSESSER, HYUNJOO PARK, DAVID J. PINE, New York University, ERIC R. WEEKS, Emory University — Using high-speed confocal microscopy, we directly observe the three-dimensional rotational dynamics of rigid clusters of microspheres suspended in dense colloidal suspensions. The clusters are highly ordered packings of fluorescently-labeled PMMA particles, fabricated using a recently developed emulsification technique. Our colloidal suspensions serve as good approximations to hard-sphere fluids, while the clusters probe the system's local rotational and translational dynamics. Far from the colloidal liquid's glass transition, both rotational and translational motion of the clusters are purely Brownian. However, in the liquid's supercooled regime, we observe a decoupling between the two types of motion: as the glass transition is approached, rotational diffusion slows down even more than translational diffusion. Our observation supports the notion that supercooled liquids are not merely liquids with large viscosities but that diffusion takes place by fundamentally changed mechanisms.

[1]Supported by NSF Grant No. CHE-0910707

4:42PM L13.00012 Confinement of Colloidal Suspensions in a Cylindrical Geometry , NABIHA SAKLAYEN, GARY L. HUNTER, KAZEM V. EDMOND, ERIC R. WEEKS, Emory University — We study binary colloidal suspensions confined within a glass microcapillary to model the glass transition in confined cylindrical geometries. We use high speed three-dimensional confocal microscopy to observe particle dynamics. The use of a slightly tapered microcapillary enables us to probe a range of local volumes for a single colloidal sample. We observe that confinement of the sample slows down particles. In addition, the particles form layers against the capillary walls; these layers also influence particle mobility. We see that even though confinement is primarily responsible for slowing down particles, particles within a layer are seen to move even slower. Within each region of the microcapillary, the mobility perpendicular to the confining boundaries is influenced by distance from the confinement boundary, while the parallel component of mobility is not.

4:54PM L13.00013 Shear-induced dynamics of polydisperse jammed emulsions , ERIC R. WEEKS, JOAQUIM CLARA RAHOLA, Physics Dept., Emory University — We study dense and highly polydisperse emulsions at droplet volume fractions ranging from phi = 0.65 to 0.85. We apply oscillatory shear and observe the subsequent droplet motions using confocal microscopy. Both affine and nonaffine droplet motions are observed, with the large droplets typically moving affinely and pushing the smaller droplets around in non-affine ways. Despite the polydispersity of the sample and the complex droplet trajectories, we observe dynamic correlation length scales. These length scales grow from one to four times the mean droplet diameter, with larger length scales corresponding to higher strain amplitudes (up to strains of about 6%).

5:06PM L13.00014 A Jamming Phase Diagram for Pressing Polymers , CHAO TENG, Nanjing University, ZEXIN ZHANG, Soochow University, XIAOLIANG WANG, GI XUE, Nanjing University, NANJING UNIVERSITY TEAM, SOOCHOW UNIVERSITY COLLABORATION — Molecular glasses begin to flow when they are heated. Other glassy systems, such as dense foams, emulsions, colloidal suspensions and granular materials, begin to flow when subjected to sufficiently large stresses. The equivalence of these two routes to flow is a basic tenet of jamming, a conceptual means of unifying glassy behavior in a swath of disordered, dynamical arrested systems. However, a full understanding of jamming transition for polymers remains elusive. By controlling the packing densities of polymer glasses, we found that polymer glasses could once flow under cold-pressing at temperatures well below its calorimetric glass transition temperature (Tg). The thermomechanical analysis (TMA) results confirmed that Tg changed with density as well as the applied stress, which is exactly what to be expected within the jamming picture. We propose a jamming phase diagram for polymers based on our laboratory experiments.

5:18PM L13.00015 Visualization of force networks in a three-dimensional granular system , CHANTAL CARPENTIER, KINGA LORINCZ, PETER SCHALL, DANIEL BONN, FRED BROUWER, University of Amsterdam — Force networks form the skeleton of granular matter. The understanding of the rigidity to flow transition of granular materials requires the study of the three-dimensional distribution of forces between the particles. Here we propose a new method to visualize and measure contact forces in three-dimensional suspensions. We use a rigidochromic dye which we attach chemically to the surfaces of the particles to measure local forces at the contact point. This dye exhibits non-fluorescent transitions, when it is free to relax mechanically, but shows strong fluorescence when confinement blocks mechanical relaxation. Preliminary experiments suggest that the fluorescent intensity is a direct measure of the local contact force. We use confocal microscopy to create spatial intensity maps to reconstruct the entire contact force distribution.

Tuesday, March 22, 2011 2:30PM - 5:18PM –

Session L14 FEd: Physics Education Research D227

2:30PM L14.00001 A Proactive Approach for Improving the Mathematical Foundation of Students Taking College Physics , LEIGH SMITH, JAMES SULLIVAN, HOWARD JACKSON, Department of Physics, University of Cincinnati, Cincinnati, OH 45221 — We report on preliminary results using the mathematics teaching program ALEKS (see aleks.com) along with the use of Just-in- Time-Teaching (JiTT) and Peer Instruction (PI) to improve the performance of students in College Physics, an algebra-based course. ALEKS, an adaptive program based on artificial intelligence and long-used in the mathematics community, was made available to students 5 weeks ahead of the first class session with participation encouraged by the award of a small class credit. Student participation and engagement was remarkable with many students making significant gains in their mathematics performance. Preliminary data suggests that performance on the first midterm was strongly correlated with performance within ALEKS. The use of JiTT and PI in two out of the four classes suggested overall a modest increase over standard lecture sections, but with women performing significantly better in these classes. We acknowledge the financial support of McGraw-Hill and ALEKS and the National Science Foundation through CCLI grant DUE-1022563.

2:42PM L14.00002 Improving Students' Interest and Motivation in Introductory Physics Laboratory: A Comparative Study , YEVGENIYA V. ZASTAVKER, JENNIFER A. SIMONOVICH, EMILY TOWERS, F. W. Olin College of Engineering — Project-based learning (PjBL) has shown to be an effective method to enhance student learning in many disciplines, including science and engineering fields. Due to the complex nature of PjBL, however, the effectiveness of this learning environment has been linked, to a large degree, to the specifics of its implementation. This talk will present a comparative study of two technical PjBL courses required for engineering majors at a small technical school, *Introductory Mechanics Laboratory* and *Introductory Engineering Design*. Twelve semi-structured in-depth interviews are analyzed using grounded theory approach. The results indicate that despite similarity in the course goals of these PjBL environments, students' interest and motivation varies dramatically based on the relative levels of student autonomy and scaffolding provided in each course. We propose a framework for creating appropriate PjBL environments in *Introductory Physics Laboratories* with an emphasis on improving engineering and physics students' interest and motivation in the relevant coursework and improving student retention.

2:54PM L14.00003 Integrating pre-, in- and post-lecture activities to improve students' learning in a large introductory physics course[1] , KWAN CHENG, MEHMET CAGLAR, AMY PIETAN, HANI DULLI, Texas Tech University — Monitoring and assessing the students' learning activities before, during and after lecture teaching in a large (more than 150 students) introductory physics class setting are important to evaluate the efficacies of various teaching pedagogies and methods. At Texas Tech, an online and integrative computer-based approach of using an interactive pre-lecture tutorial, an in-class concept test using a wireless student response system and a homework/tutorial system has been implemented in Fall 2010. The strategy of implementation of this integrative approach and the assessment results from various in-house and standard Mechanics tests will be presented. In addition, how this approach may create synergism of lab and lecture teaching efforts will also be addressed.

[1]This project is supported by the NIH grant 5RC1GM090897-02.

3:06PM L14.00004 Design and development of physics simulations in the field of oscillations and waves suitable for k-12 and undergraduate instruction using video game technology , TREVOR TOMESH, University of Wisconsin - River Falls, COLIN PRICE, University of Worcester, England — Using the scripting language for the Unreal Tournament 2004 Engine, Unreal Script, demonstrations in the field of oscillations and waves were designed and developed. Variations on Euler's method and the Runge-Kutta method were used to numerically solve the equations of motion for seven different physical systems which were visually represented in the immersive environment of Unreal Tournament 2004. Data from each system was written to an output file, plotted and analyzed. The over-arching goal of this research is to successfully design and develop useful teaching tools for the k-12 and undergraduate classroom which, presented in the form of a video game, is immersive, engaging and educational.

3:18PM L14.00005 A Physics of Semiconductors Concept Inventory , EMANUELA ENE, Oklahoma State University, BRUCE J. ACKERSON COLLABORATION[1], ALAN CHEVILLE COLLABORATION[2] — Following the trend in science and engineering education generated by the visible impact that the Force Concept Inventory (FCI) has created, a Physics of Semiconductors Concept Inventory (PSCI) has been developed. Whereas most classroom tests measure *how many* facts students can remember, or if they *can manipulate* equations, PSCI measures *how well* students interpret concepts and *how well* they can infer new knowledge from already learned knowledge. Operationalized in accordance with the revised Bloom's taxonomy, the multiple–choice items of the PSCI address the "understand", "apply", "analyze" and "evaluate" levels of cognition. Once standardized, PSCI may be used as a predictor for students' academic performance in the field of semiconductors and as an assessment instrument for instructional strategies.

3:30PM L14.00006 A semantic space mapping of introductory physics concepts , NIC RADY — We know that physics students and their professors organize knowledge differently, but exactly how do they organize knowledge. The Physics Perception Assessment (PPA) has been designed to create a map of the semantic space of 15 commonly encountered concepts in a first-semester physics course. Preliminary data taken with the PPA will be presented and from this data, an "expert" semantic space configuration will be presented.

3:42PM L14.00007 A student's guide to searching the literature using online databases[1] , CASEY W. MILLER, DUSTIN BELYEA, MICHELLE CHABOT, University of South Florida, Department of Physics, TROY MESSINA, Centenary College of Louisiana, Department of Physics — A method is described to empower students to efficiently perform general and specific literature searches using online resources [Miller et al., Am. J. Phys. **77**, 1112 (2009)]. The method was tested on undergraduate and graduate students with varying backgrounds in scientific literature. Students involved in this study showed marked improvement in their awareness of how and where to find scientific information. Repeated exposure to literature searching methods appears worthwhile, starting early in the undergraduate career, and even in graduate school orientation.

[1]Supported by NSF-CAREER, and the Mattie Allen Broyles and Gus S. Wortham Endowments.

3:54PM L14.00008 Mutual Mentoring Makes Better Mentors , CINDY BLAHA, Carleton College, AMY BUG, Swarthmore College, ANNE COX, Eckerd College, LINDA FRITZ, Franklin & Marshall College, BARBARA WHITTEN, Colorado College — In this talk we discuss one of the impacts of an NSF ADVANCE sponsored horizontal, mutual mentoring alliance. Our cohort of five women physicists at liberal arts colleges has found that mutual mentoring has had a profound impact on many aspects of our professional lives. In this talk we will describe how our peer-to-peer mentoring has enabled us to become better mentors for our undergraduate students, for recent graduates beginning their careers and for colleagues at local and neighboring institutions.

4:06PM L14.00009 Impact of Mutual Mentoring on Research , BARBARA WHITTEN, Colorado College, CYNTHIA BLAHA, Carleton College, AMY BUG, Swarthmore College, ANNE COX, Eckerd College, LINDA FRITZ, Franklin and Marshall College — In this talk we discuss one of the impacts of an NSF ADVANCE sponsored horizontal, mutual mentoring alliance. Our cohort of five women physicists at liberal arts colleges has found that mutual mentoring has had a profound impact on many aspects of our professional lives. In this talk we will give some specific ways that we have supported and helped to expand each other's research. For some new areas of research were opened, for others new focus was brought to existing areas, and still others found acceptance for where they were.

4:18PM L14.00010 Developing Effective Undergraduate Research Experience , MICHAEL EVANS, CAROLINA C. ILIE, Dept. of Physics, SUNY Oswego — Undergraduate research is a valuable educational tool for students pursuing a degree in physics, but these experiences can become problematic and ineffective if not handled properly. Undergraduate research should be planned as an immersive learning experience in which the student has the opportunity to develop his/her skills in accordance with their interests. Effective undergraduate research experiences are marked by clear, measurable objectives and frequent student-professor collaboration. These objectives should reflect the long and short-term goals of the individual undergraduates, with a heightened focus on developing research skills for future use. 1. Seymour, E., Hunter, A.-B., Laursen, S. L. and DeAntoni, T. (2004), "Establishing the benefits of research experiences for undergraduates in the sciences: First findings from a three-year study". *Science Education*, 88: 493–534. 2. Behar-Horenstein, Linda S., Johnson, Melissa L. "Enticing Students to Enter Into Undergraduate Research: The Instrumentality of an Undergraduate Course." *Journal of College Science Teaching* 39.3 (2010): 62-70.

4:30PM L14.00011 Seriously? Freshmen In A Physics Research Lab?[1] , ROSA ELIA CÁRDENAS, ISAAC MANZANERA ESTEVE, JOHN T. MARKERT, The University of Texas at Austin, Department of Physics, SARAH SIMMONS, The University of Texas at Austin, Office of Honors, Research, and International Studies — We report on the University of Texas College of Natural Sciences Freshman Research Initiative (FRI) program as a whole and more specifically, its physics stream. The FRI program was developed in an effort to improve retention in the College of Natural Sciences (CNS). The general goal of the program is to bring students at the freshman level into a research laboratory. The reasoning is that as students become part of a research laboratory he or she will feel more involved with science, both academically and socially, and will be more likely to continue on a research science route. We will present the college wide statistical tracking data which shows that the FRI program has indeed improved retention in the CNS, has improved GPA and has improved graduate school matriculation. We will also discuss the tracking of three generations of physics stream participants. We describe the curriculum, training, precautions and techniques used as we bring freshmen into a physics research laboratory.

4:42PM L14.00012 Mentoring undergraduates for experimental research in physics[1] , JEREMY LEVY, U. Pittsburgh — Undergraduate research experiences are pivotal in shaping careers in physics. I will support this thesis—the implicit focus of this session—with anecdotes highlighting research performed by undergraduates in my group at the University of Pittsburgh, as well as my own recollections as an undergraduate researcher.

[1]This work was supported by NSF DMR-0704022.

4:54PM L14.00013 Modular Curriculum Approach (MCA) for teaching of introductory physics: Tablet PCs and flexible instructional space to stimulate active learning , TIKHON BYKOV, McMurry University, Department of Physics, YELENA KOSHELEVA, McMurry University, Departments of Psychology, Curriculum and Instruction — Modular Curriculum Approach is an innovative model designed at McMurry University and adopted for teaching of introductory physics courses. In MCA, traditional lab/lecture structure is converted into a system of flexible instructional modules, with lecture, lab, and discussion being merged into one technologically and collaboratively rich experience. Different elements are integrated with Tablet PCs as a single unifying platform to improve continuity among module components. A technology suite incorporated with tablets includes: Physlets, tablet-adapted personal response systems, data acquisition systems, and tablet-based note-taking tools. The MCA has been further reinforced by creating a new instructional space with movable partitions, allowing for easy transformation between lecture and lab modes. The space is supportive of small peer- group activities with easy-to-reconfigure table clusters, multiple white and black board surfaces, multiple TVs and projection screens.

5:06PM L14.00014 Impact E-Learning Platform Moodle on the Physic's Learning Process in the High School's Students , JONAS TORRES-MONTEALBAN, GREGORIO RUIZ-CHAVARRIA, ENRIQUE ARMANDO GOMEZ-LOZOYA, Universidad Autonoma Chapingo — As a didactic proposal, moodle e-learning platform was implemented in one of two Physics High School's group at UACH, in order to show how the use of new technologies can improve the learning progress linked to physics concepts. As a result, the first group worked at the same time with inside class activities as well as outside resources from the moodle e-platform. The second group only worked with inside class activities. This teaching application was developed in six sections. Section I defines the educational framework. Section II identifies the key physic's concepts to be studied in each proposed activity. Section III describes the didactic model. Section IV displays the compared results between similarities and differences in both groups. Section VI shows the gathered information in order to be discussed as a topic related on how new technologies improve the Physic's learning process in the high school' students.

Tuesday, March 22, 2011 2:30PM - 5:30PM –

Session L15 DMP GMAG FIAP: Focus Session: Spins in Semiconductors - Spin Torque and Spin Injection D171

2:30PM L15.00001 Spin Torque Switching in GaMnAs Magnetic Tunnel Junctions[1] , LIN XUE, R. A. BUHRMAN, D.C. RALPH, Cornell University, D.W. RENCH, M.J. WILSON, P. SCHIFFER, N. SAMARTH, Physics Dept., Penn State University — We have fabricated and measured submicron magnetic tunnel junctions made from GaMnAs multilayers: GaMnAs/GaAs/GaMnAs/MnAs, where GaMnAs is a ferromagnetic semiconductor, GaAs serves as the tunneling barrier, and MnAs is a ferromagnet that provides an exchange bias to the upper GaMnAs (reference) layer. The devices have magnetoresistances of order 50% at 4.2 K and exhibit clear spin-torque switching of the lower GaMnAs layer between parallel and antiparallel orientations relative to the reference layer. We report the switching phase diagram as a function of current and magnetic field. We also describe efforts to probe the high-speed magnetic dynamics in GaMnAs driven by spin torque from ns-scale current pulses and microwave-frequency currents that can drive ferromagnetic resonance.

[1]This work is supported by ONR MURI.

2:42PM L15.00002 Theory of current-induced torque in uniform ferromagnets , KAREL VYBORNY, LIVIU ZARBO, Institute of Physics, Academy of Sciences of the Czech Rep, T. JUNGWIRTH, Institute of Physics, Academy of Sciences of the Czech Rep; School of Physics and Astronomy, University of Nottingham — In a model ferromagnetic semiconductor (Ga,Mn)As with strong spin-orbit interaction, it has been experimentally shown that magnetization can be manipulated by injection of unpolarized currents [Chernyshov et al., Nat. Phys. 5, 656 (2009)]. We critically review the existing theoretical approaches to this phenomenon and present a model whose results are compared to more recent measurements of the current-induced torque driven by ferromagnetic resonance in (Ga,Mn)As. The results entail the dependence of the effect on carrier concentration, various types of strain, and temperature.

2:54PM L15.00003 Intrinsic spin-orbit coupling effects on spin and charge pumping in magnetic tunnel junctions with microwave-driven precessing magnetization , FARZAD MAHFOUZI, BRANISLAV NIKOLIC, Department of Physics and Astronomy, University of Delaware, Newark, DE 19711, USA, NAOTO NAGAOSA, Department of Applied Physics, University of Tokyo, Tokyo 113-8656, Japan — We develop a microscopic quantum transport approach to the problem of spin pumping by precessing magnetization in one of the ferromagnetic layers within FIF or FIN (F-ferromagnet; N-normal metal; I-insulating barrier) magnetic tunnel junctions (MTJs) in the presence of intrinsic spin-orbit couplings (SOC) at the FI interface. Our approach evaluates the nonequilibrium Green functions (NEGFs) by starting from the time-dependent Hamiltonian of these junctions. To express the time-averaged charge current, or the corresponding dc pumping voltage in open circuits that was measured in recent experiments on MTJs [T. Moriyama *et al.*, Phys. Rev. Lett. **100**, 067602 (2008)], we construct a novel solution for the double-time-Fourier-transformed NEGFs where their two energy arguments are connected by the Floquet theorem describing emission and absorption of finite number of photons. Within this fully quantum-mechanical treatment of the conduction electrons, we find that only in the presence of the interfacial Rashba SOC non-zero dc pumping voltage in F|I|N junctions emerges at the adiabatic level (i.e., proportional to microwave frequency).

3:06PM L15.00004 Manipulation of ferromagnetic state by means of spin-orbit interactions , LEONID ROKHINSON, Purdue University — The current state of information technology accentuates the dichotomy between processing and storage of information, with logical operations performed by charge-based devices and non-volatile memory based on magnetic materials. The major obstacle for a wider use of magnetic materials for information processing is the lack of efficient control of magnetization. Reorientation of magnetic domains is conventionally performed by non-local external magnetic fields or by externally polarized currents. Efficiency of the latter approach is greatly enhanced in materials where ferromagnetism is carrier-mediated. In such materials control of carriers' polarization provides an alternative mean to manipulate orientation of magnetic domains. In some crystalline conductors the charge current couples to spin via intrinsic spin-orbit (SO) interactions and generates electron spin polarization. Unlike the Oersted field, the SO-induced polarization is spatially localized and can be controlled by local electric fields. This non-equilibrium electron spin polarization couples to magnetic moments of magnetic ions and is capable of controlling magnetization of the ferromagnet. We show that magnetization can be reversibly manipulated by SO-induced polarization of carrier spins generated by the injection of unpolarized currents. We demonstrate domain rotation and hysteretic switching of magnetization between two orthogonal easy axes in a model ferromagnetic semiconductor GaMnAs.

3:42PM L15.00005 Ferromagnetic resonance driven by current-induced torque in uniform ferromagnetic micro-structures , H. KUREBAYASHI, D. FANG, University of Cambridge, J. WUNDERLICH, Hitachi Cambridge Laboratory, K. VYBORNY, L.P. ZARBO, Institute of Physics, ASCR, R.P. CAMPION, A. CASIRAGHI, B.L. GALLAGHER, University of Nottingham, T. JUNGWIRTH, Institute of Physics, ASCR, A.J. FERGUSON, University of Cambridge, EU GRANTS FP7-214499 NAMASTE COLLABORATION — We show that the recently demonstrated current induced torque (CIT) [A. Chernyshov, et al. Nat. Phys. 5, 656 (2009)] can excite magnetisation dynamics in micro-bars of uniform ferromagnetic semiconductors. Due to the combined effects of the spin-orbit and exchange interactions, a microwave current injected into (Ga,Mn)As (or (Ga,Mn)(As,P)) micro-bars generates an oscillating effective magnetic field. By using a sensitive electrical detection technique, we accurately measure the magnitude and direction of driving fields for samples under different strain. We confirm the observation of a field with the symmetry of the Dresselhaus spin-orbit interaction and observe an additional field with the symmetry of the Rashba spin-orbit interaction. Our work demonstrates a new scalable FMR technique which provides a sensitive method to study the nature of current-induced torques and to perform magnetic characterisation of uniform ferromagnetic micro-structures.

3:54PM L15.00006 Non-local spin transport devices with a tunable channel[1] , J. MISURACA, J.-I. KIM, P. XIONG, S. VON MOLNAR, Department of Physics, Florida State University, K.K. MENG, J. LU, J.H. ZHAO, Institute of Semiconductors, Chinese Academy of Sciences — The spin lifetime in GaAs is known to vary strongly with carrier density near the metal to insulator transition [1]. However, a detailed study to optimize this lifetime is complicated because many replica samples need to be made and measured. This difficulty can be circumvented by employing Si:$Al_{0.3}Ga_{0.7}As$, a persistent photoconductor, as the spin transport medium. This material, which is structurally similar to GaAs, has been characterized and shown to have an effective carrier density which can be tuned *in situ* via photo-excitation from 10^{14} to 10^{18} cm^{-3}[2]. Heterostructures (2-μm Si:$Al_{0.3}Ga_{0.7}As$, a thin epitxial Fe layer, and a GaAs graded junction to create linear contacts between them) have been grown by MBE and non-local spin devices have been patterned by photolithography and wet etching. Magnetic measurements on Fe micro-patterns demonstrated the possibility of controlling the coercivity of the Fe electrodes [3]. Electrical characterization of the devices will be presented. [1] J. Kikkawa et al., Phys. Rev. Lett. 80, 4313 (1998) [2] J. Misuraca et al., Phys. Rev. B. 82, 125202 (2010) [3] K. K. Meng et al., Appl. Phys. Lett. 97, 072503 (2010).

[1]This work is supported by NSF DMR-0908625 and NSFC 10920101071.

4:06PM L15.00007 Electron Charge and Spin Transport in Ferromagnet/Semiconductor Schottky Barrier Heterostructures , QI HU, CHRIS PALMSTROM, University of California at Santa Barbara, ERIC GARLID, CHAD GEPPERT, PAUL CROWELL, University of Minnesota — Previous studies of Fe/n^+-GaAs/n-GaAs heterostructures in the lateral non-local geometry have shown that spin accumulation is observed only when tunneling current across ferromagnet/semiconductor Schottky barrier is sufficiently large. The tunneling mechanism is modeled by band diagram simulations and transport calculation using the WKB approximation for the barrier. These suggest that tunneling from localized states in the quantum well (QW) which forms just inside the Schottky interface dominates over tunneling directly from the semiconductor bulk. Electron tunneling spectroscopy is utilized to probe the predicted localized states in the QW. Valleys in the derivative of tunneling conductance spectra were observed at discrete forward bias voltages which are attributed to localized 2-dimensional energy states. The spin escape time of the 2D energy states in the QW is calculated using a spin-dependent WKB approximation. The results are compared with the spin lifetime and escape time extracted from three-terminal spin Hanle measurements. This work was supported by the NSF MRSEC and ONR MURI programs, and NSF DMR-0804244.

4:18PM L15.00008 Dependence of spin-injection spectra of CoFe/GaAs contacts on temperature and annealing conditions , GIAN SALIS, IBM Research - Zurich, ANDREAS FUHRER, SANTOS F. ALVARADO — Spin injection from CoFe contacts into bulk GaAs epilayers is studied experimentally. Close to the metal/semiconductor interface the GaAs epilayer is highly n-doped, allowing efficient spin injection through the Schottky tunnel barrier. Spin polarization in the GaAs channel is measured as a non-local voltage at CoFe detection contacts. Similar to spin injection from Fe contacts, an inversion of the sign of injected spin polarization is found at a finite forward bias U_c applied to the injection contact. We investigate the dependence of the nonlocal signal on U_c. From the data, the spin polarization of the differential interface conductance is obtained, providing spectral information on the spin-polarized density of states. The dependence of these spectra on measurement temperature as well as on annealing and growth conditions is discussed and compared to samples with Fe injection contacts.

4:30PM L15.00009 Electrical Measurements of the Extrinsic Spin Hall Effect in $Fe/In_xGa_{1-x}As$ Heterostructures[1] , CHAD GEPPERT, ERIC GARLID, MUN CHAN, PAUL CROWELL, University of Minnesota, QI HU, CHRIS PALMSTRØM, University of California at Santa Barbara — We report on all-electrical measurements of the extrinsic spin Hall effect in $Fe/In_xGa_{1-x}As$ heterostructures with n-type channel doping (Si) and highly doped Schottky tunnel barriers. The spin Hall effect refers to the transverse spin current generated by application of a longitudinal unpolarized charge current. Complementary spin accumulation at opposing edges of the channel is detected via a Hanle effect in the voltage measured by pairs of ferromagnetic Hall contacts. The spin Hall conductivity is extracted by fitting the data to a drift-diffusion model incorporating spin precession and relaxation. Tuning the channel conductivity with applied bias allows the skew and side-jump contributions to be determined independently. The resulting magnitude is in agreement with models based on ionized impurity scattering. Further quantitative comparison to theoretical models is achieved by increasing the In concentration beyond previously reported values.

[1]Supported by ONR and NSF.

4:42PM L15.00010 Ab initio Investigation of the Failure of Efficient Spin-Injection in Fe/GaAs Superlattices , SINEAD GRIFFIN, NICOLA SPALDIN, ETH Zürich — Magnetic metal-semiconductor systems have been widely studied for use as spintronic devices. The injection of elemental ferromagnetic Fe into GaAs shows great device potential because of the relativity high Curie temperature of Fe compared to other possible injection materials. However, spin-injection in Fe/GaAs has not been successful with several phases such as FeAs and Fe_2As forming at the interface. We perform Density Functional Theory calculations on bulk FeAs and Fe_2As to elucidate the structural and magnetic ground states. We then incorporate these Fe-As layers into GaAs/FeAs superlattices and investigate the resulting structures. Both the effects of Fe content and the number of layers in the heterostructure on the magnetic and electronic properties are considered. Our results show that the magnetic ground state of the FeAs compounds helps to explains the failure of spin-injection in these superlattices.

4:54PM L15.00011 Lateral spin injection and detection through electrodeposited Fe/GaAs interfaces[1] , SARMITA MAJUMDER, ANTHONY ARROTT, KAREN KAVANAGH, SFU, ANTHONY SPRING THORPE, CMC, SFU TEAM, CMC COLLABORATION — We report results on spin injection and detection through epitaxial, electrodeposited Fe/GaAs tunnel barriers formed ex-situ on epitaxially grown GaAs (001). The BCC-Fe ?lms are predominantly single crystalline with large mosaic spread [1]. Tunnel junctions, fabricated with bulk GaAs wafers, and epitaxially grown MBE or MOCVD GaAs (001), showed the expected increase in tunneling current with increasing surface Si dopant concentration. Spin transport through in situ coherently strain, MBE Fe/GaAs interfaces have been reported at spin polarization levels as high as 42% at 50K.[3]. In our experiments the design of the epitaxially grown GaAs substrates followed those used successfully for in situ MBE Fe spin contacts. [2]. A spin voltage (4 mV) has been detected for $2x10^{18}$/cm3 doped tunnel junctions at liquid nitrogen temperatures (77 K) using an injection current of 20 A/cm2 while varying the applied in-plane magnetic ?eld ($\pm$ 300 Gauss) along a <100> easyaxis of the Fe contacts. 1. Z. L. Bao, S. Majumder, A. A. Talin, A. S. Arrott, K. L. Kavanagh, JES 155 (2008) H841. 2. X. Lou, C. Adelmann, A. S. Crooker, E. S. Garlidi, J. Zhang, K. S. Reddy, S. D. Flexner, C. J. Palmstrøm, and P.A. Crowell, Nature Phys. 3 (2007) 197.

[1]Acknowledgments: NSERC

5:06PM L15.00012 All-electrical spin injection and detection in an AlGaN/GaN two-dimensional electron gas[1] , D.R. HOY, Department of Physics, The Ohio State University, Columbus, OH, Y. PU, Department of Physics and Center for Emergent Materials, The Ohio State University, Columbus, OH, S.D. CARNEVALE, Department of Materials Science and Engineering, The Ohio State University, Columbus, OH, E. JOHNSTON-HALPERIN, Department of Physics and Center for Emergent Materials, The Ohio State University, Columbus, OH, R.C. MYERS, Department of Physics and Department of Materials Science and Engineering, The Ohio State University, Columbus, OH — Materials with low spin-orbit coupling, including wide band gap semiconductors, may allow practical semiconductor spintronics. Here we investigate all-electronic spin injection and detection using ferromagnetic Fe electrodes on a polarization doped AlGaN/GaN two-dimensional electron gas (2DEG) grown by molecular beam epitaxy. The ultrathin AlGaN cap provides polarization doped electrons and serves as a thin tunnel barrier for spins. The surface morphology is characterized by atomic force microscopy and the electron density, resistivity, and mobility are characterized by Hall measurements. Through the Hanle effect, we investigate the dependence of the spin injection efficiency and spin lifetime with temperature and bias.

[1]This work was supported by the Center for Emergent Materials at the Ohio State University, an NSF MRSEC.

5:18PM L15.00013 Studies of spin injection into thin film InSb from CoFe , YONG-JAE KIM, R.L. KALLAHER, J.J. HEREMANS, Virginia Tech — Spin-based electronics requires manipulation of spin-polarized carriers in materials. The narrow gap semiconductor InSb is a promising material for spin-based devices due to its strong spin-orbit interaction, allowing spin manipulation using electric fields. Yet, spin injection from spin-polarized electrodes into InSb has not yet been demonstrated. In order to electrically characterize spin injection and detection in InSb, we use InSb/CoFe lateral spin valve geometries studied at low temperatures and in tilted magnetic fields. The geometries are fabricated by depositing two non-epitaxial CoFe electrodes at mesoscopic separations on high-mobility InSb thin films through an insulator window. The anisotropy of the ferromagnetic electrodes provides parallel and anti-parallel configurations. We have observed two-state non-local output voltages, which are consistent with a spin injection signal. Interestingly, the switching signal is very sensitive to temperature in the range studied. The switching signal appears at low external fields due to CoFe magnetic anisotropy effects. The results are discussed in the light of the CoFe anisotropy and expected spin-coherence properties of InSb (partial support from DOE DE-FG02-08ER46532).

Tuesday, March 22, 2011 2:30PM - 5:30PM –

Session L16 DMP GMAG: Focus Session: Magnetic Nanostructures: Probing Using Advanced Methods D173

2:30PM L16.00001 Soft X-ray Spectroscopy of Magnetic Nanostructures: New Phenomena and Applications[1]

, ELKE ARENHOLZ, Advanced Light Source, Lawrence Berkeley National Laboratory, 1 Cyclotron Rd, Berkeley, CA 94720 — The delicate balance between charge, spin, orbital, and lattice degrees of freedom in transition metal oxides leads to unique phenomena such as colossal magnetoresistance, high temperature superconductivity, as well as a remarkable diversity of charge, spin, and orbital ordered phases. The rich phase diagrams are determined by the strong local interaction of electrons in transition metal d orbitals. Subtle changes in d occupancy and overlap—and thereby phase transitions—can be induced by variations in temperature, by external fields, through doping and lattice distortions. In particular, interfaces can hold surprising electronic and magnetic properties that differ remarkably from the adjacent layers. Soft x-ray based techniques are ideal tools to study these systems as they are inherently element-specific, allow characterizing the valence state and the symmetry of lattice sites and provide detailed information about the electronic and magnetic structure with nanometer spatial resolution and on ultrafast time scales. Here we show that the to-date little explored angular dependence of the x-ray magnetic dichroism provides unique insights in the correlation between atomic, magnetic and electronic structure in these systems [1-4]. Taking advantage of this approach will prove invaluable for the engineering of novel nanoarchitectures to be used in low cost and energy efficient devices with improved performance and multiple functionalities.

3:06PM L16.00002 Investigation of ferromagnetic/antiferromagnetic nanostructures using X-ray magnetic dichroism

, J. WU, National High Magnetic Field Laboratory, Florida State University, Tallahassee, Florida 32310, USA, J.S. PARK, Department of Physics, University of California at Berkeley, Berkeley, California 94720, USA, W. KIM, Korea Research Institute of Standards and Science, Yuseong, Daejeon 305-340, Koera, E. ARENHOLZ, M. LIBERATI, A. SCHOLL, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, California 94720, USA, CHANYONG HWANG, Korea Research Institute of Standards and Science, Yuseong, Daejeon 305-340, Koera, Z.Q. QIU, Department of Physics, University of California at Berkeley, Berkeley, California 94720, USA — The spin structure of epitaxially grown antiferromagnetic/ferromagnetic bilayer was investigated using X-ray Magnetic Circular Dichroism (XMCD) and X-ray Magnetic Linear Dichroism (XMLD) techniques. The XMLD measurement on the antiferomagnetic film (NiO or CoO) gives a direct probe of the spin orientation of the compensated antiferromagnetic spins. This capability enables us to give a clear clue to the mechanism of the exchange bias in the bilayer and to give a direct observation of the antiferromagnetic vortex.

3:18PM L16.00003 XPCS Study of Antiferromagnetic Domain Fluctuation[1]

, KEOKI SEU, SUJOY ROY, Lawrence Berkeley National Laboratory, SAN-WEN CHEN, XIANGSHUN LU, HONGYU GUO, SUNIL SINHA, Dept. of Physics, University of California, San Diego, KARINE DUMESNIL, Univeristy of Nancy, France — We have studied magnetic domain fluctuations in Yttrium-Dysprosium-Yttrium trilayer films using X-ray Photon Correlation Spectroscopy (XPCS) in conjunction with resonant soft X-ray magnetic scattering. Dysprosium thin film possesses a helical antiferromagnetic phase below Tn = 180 K and a ferromagnetic phase below Tc = 64 K. With coherent soft x-rays we observed magnetic speckle in the scattering from the antiferromagnetic domains. We determined critical points and found a shift of Curie temperature from the bulk value. Hysteresis associated with a first order phase transition was also observed. We observed magnetic speckle around the magnetic satellite peak at (0,0,q_m) due to static disorder as well as magnetic domains. At temperatures above Tn the system showed static behavior on times scales up to $\sim$ 300 sec which is indicative of non-fluctuating static disorder that persists above Tn. Close to Tc, there appears to be time-dependent fluctuations due to slow domain wall motion and these will be discussed.
