, PETER GREENE, University of California, Davis, BRIAN J. KIRBY, JULIE A. BORCHERS, JUNE W. LAU, NIST, Gaithersburg, KAI LIU, University of California, Davis — We report deposition-order-dependent, and depth-dependent, magnetization reversal in Co/Pd with graded anisotropy, which are technologically important as they address both writability and thermal stability challenges. Multilayers of $[Co(0.4nm)/Pd(0.6nm)]_{60}$ have been deposited by sputtering, where the Ar pressure has been varied from 5 to 12 and 20 mtorr in type A samples and in the reverse order in type B samples. An extensive set of structural and magnetization reversal studies with depth-resolution has been performed using XRD, cross-sectional TEM, magnetometry, PNR and XMCD. In type A samples, due to the larger grain size, lower interfacial roughness and less disorder in the magnetically softer layer, magnetization reversal proceeds via domain nucleation, propagation, and annihilation. Type B samples show a more localized reversal. Layers grown at higher pressure contain more disorder and rougher interfaces, which is carried into the magnetically softer layers deposited on top, thus impeding domain movement.

3:42PM L16.00005 ABSTRACT WITHDRAWN –

3:54PM L16.00006 Magnetization reversal and magnetic imprinting in a giant exchange bias system

, M.R. FITZSIMMONS, LANL, J.A. BORCHERS, NIST, M. LAVER, PSI, K.L. KRYCKA, W.C. CHEN, S. WATSON, NIST, C. DUFOUR, K. DUMESNIL, Laboratoire de Physique des Matériaux, Université H. Poincaré Nancy — We present compelling experimental evidence, obtained with small angle neutron scattering (SANS) that magnetization reversal of an exchange biased $DyFe_2/YFe_2$ superlattice occurs via reversal of magnetic domains with at least two different length scales. Our SANS studies used both unpolarized neutron beams (with a high field magnet) and polarized neutron beams using ^{3}He filter polarization analysis. Magnetic length scales ranging from tens of nanometers to greater than several hundreds of nanometers were observed. The magnetization contained within nanometer large domains constituted a significant fraction of the total magnetization at the exchange bias field. During magnetization reversal some of the domains were arranged in a quasi-periodic manner. Because the ferromagnetic domains are so small, they exchange couple to relatively small portions of the pinned magnetic layer (i.e., $DyFe_2$), which at the nm length scale may appear relatively perfect. This reasoning may explain why the $DyFe_2/YFe_2$ system is a system that exhibits among the largest exchange bias observed to date. This work was supported by the Office of Basic Energy Science, U.S. Department of Energy and the National Science Foundation. ML acknowledges support from DanScatt.

4:06PM L16.00007 Polarized Neutron Reflectivity and Electron Microscopy Analysis of the Magnetic Microstructure in Antiparallel-Coupled Co Multilayers , JOHN UNGURIS, BENJAMIN MCMORRAN, Center for Nanoscale Science and Technology, JULIE BORCHERS, BRIAN MARANVILLE, BRIAN KIRBY, THERESA GINLEY, Center for Neutron Research, National Institute of Standards and Technology — Antiparallel exchange-coupled thin films are a convenient way to provide a ferromagnetic surface in situations where zero net magnetization is required, for example, when studying superconducting-ferromagnetic proximity effects with spin-triplet superconducting correlations.[1] We use the complementary techniques of polarized neutron reflectivity (PNR) and scanning electron microscopy with polarization analysis (SEMPA) to characterize the magnetic structure of such an antiferromagnetically coupled Co/Ru/Co multilayer. We find that, although the average macroscopic magnetization follows the simple antiparallel coupling picture, at the nanoscale the 3-dimensional magnetic structure is much more complex. The films are mostly antiparallel, but the magnetization directions fluctuate by as much as $\pm$ 40° over lengths as small as 100 nm. This structure has significant implications when trying to understand the local spin-dependent transport properties at the ferromagnetic interface. Applying magnetic fields further complicates the structures, leading to spin-flop related magnetic arrangements.

4:18PM L16.00008 Distinguishing the ultrafast dynamics of orbital and spin magnetic moments in solids , CHRISTINE BOEGLIN, CNRS-IPCMS-UMR7504 — Ultrafast magnetization dynamics is an important issue for both fundamental science and for applications in order to optimize spin manipulation on a microscopic level. Since the first observation of laser induced spin dynamics,[1] the mechanisms of angular momentum dissipation at picosecond timescales have been widely debated. In order to progress in the understanding of such microscopic ultrafast mechanisms, it is now possible to probe absolute values of magnetization with a high temporal resolution (100 fs). In this context, we have used ultrashort optical laser pulses (60 fs duration) to induce changes of the magnetization in a ferromagnetic CoPd alloy film with perpendicular anisotropy. The dynamics was probed with ultrashort circularly polarized femtosecond X-ray pulses, measuring the X-ray magnetic circular dichroism (XMCD) at Co $L_{2,3}$ edges.[2,3] We observe that the two components of the magnetic moments (L and S) show different ultrafast dynamics and that the spin-orbit coupling related to the magneto-crystalline anisotropy in solids is strongly affected by fs laser pulses in the ultrashort time scales. These dynamics can be compared to the purely electronic effect at the CoL_3 edge. Electronic excitations and their response to the laser pump pulse will be discussed and related to the modifications in the spin-orbit coupling. We will compare our results with time resolved MOKE experiments recently performed on CoPd alloys.

4:54PM L16.00009 Neutron Reflectivity Study in Py/CoO Exchange Bias System , SAN-WEN CHEN, XIANGSHUN LU, SUNIL SINHA, Dept. of Physics, University of California, San Diego, AMI BERKOWITZ, ERIC FULLERTON, KEITH CHAN, Center of Magnetic Recording Research, University of California, San Diego, VALARIA LAUTER, HAILEMARIAM AMBAYE, Neutron Science Divn., Oak Ridge National Laboratory, ELIZABETH BLACKBURN, University of Birmingham, UK — We have studied the permalloy-cobalt monoxide exchange bias system using polarized neutron reflectivity. Both polycrystalline and epitaxial single crystalline (with the (111) and (100) CoO planes at the interface) CoO films were studied. By fitting the reflectivity for both directions of the applied field relative to the cooling field, we are able to obtain both the nuclear and spin depth profiles, as well as locating the pinned spins which are responsible for the exchange bias effect. The pinned spins at the interface can be resolved in the polycrystalline sample, which is consistent with our previous study with resonant soft x-ray reflectivity. One could reasonably have expected a stronger exchange bias effect in the (111) single crystal CoO film, because it has more uncompensated spins at the interface. The neutron reflectivity, however, shows lesser pinned spins. In the presentation, we will show the difference between the magnetic density profiles of the samples involving polycrystalline, (111) and (100) single crystalline CoO films respectively.

5:06PM L16.00010 Effects of hydrogen/deuterium absorption on the magnetic properties of Co/Pd multilayers , KINESHMA MUNBODH, FELIO PEREZ, CAMERON KEENAN, DAVID LEDERMAN, West Virginia University, MIKHAIL ZHERNENKOV, MICHAEL FITZSIMMONS, Los Alamos National Laboratory — The effects of hydrogen and deuterium absorption were studied in two Co/Pd multilayers with perpendicular magnetic anisotropy using Polarized Neutron Reflectivity (PNR). PNR measurements were performed with the field in the plane of the sample with the magnetization M saturated at H = 6.0 T and unsaturated at 0.65 T. The nominal thicknesses of the Co/Pd layers were 2.5 Å/21 Å. Therefore, the actual layer chemical composition, thickness, and interface width parameters were defined from the nuclear scattering length density (SLD) profile obtained from both x-ray reflectivity (XRR) and PNR and their derivatives. The nuclear PNR SLD profile showed that although deuterium absorption occurred throughout the sample, the multilayer stack did not expand. The magnetic SLD showed that M in both the Pd and Co layers was affected. At saturation, M decreased, while at H = 0.65 T M increased upon deuterium exposure. Magnetization measurements confirmed hydrogen absorption decreased the total M at saturation and increased the component of M parallel to the field when not at saturation. These results indicate that hydrogen or deuterium absorption decreases both the perpendicular anisotropy and total magnetization of the samples.

5:18PM L16.00011 Revisit of Magnetism of Fe overlayers on Cu(001) , CHANYONG HWANG, Korea Research Institute of Standards and Science, YONG ROK OH, Pukyung National University, Y.S. PARK, WONDONG KIM, Korea Research Institute of Standards and Science, LEELA POORNIMA, Chungnam National University, Z.Q. QIU, University of california at Berkeley — Fe films on Cu(001) have drawn a great attention due to the complicated structural and magnetic properties. It is known from the previous investigations that depending on the Fe thickness, Fe/Cu system has three distinguishable regions in terms of the structural and magnetic properties. Especially the spin structure in region II, where the film thickness ranges from 5 ML to 11 ML, has been controversial for the last two decades. We have studied the spin structure of Fe films on Cu(001) in region II via x-ray magnetic circular dichroism (XMCD) and surface magneto-optic Kerr effect (SMOKE) measurements. Wedge-shaped Fe films, which ranged from 6 ML to 10 ML, have been grown on Cu(001) at room temperature by an e-beam evaporator. Our results suggest a new model, which is totally different from the previous models, based on the incommensurate spin density wave.

Session L17 GMAG DMP: Focus Session: Magnetic Oxide Thin Films - Ferroic and Oxide Tunnel Junctions D174

2:30PM L17.00001 All-Manganite Tunnel Junctions with Interface-Induced Barrier Magnetism[1]

, ZOUHAIR SEFRIOUI, Grupo de Física de Materiales Complejos, Universidad Complutense de Madrid, 28040 Madrid (Spain) — The recent discovery of several unexpected phases at complex oxide interfaces is providing new insights into the physics of strongly correlated electron systems. The possibility of tailoring the electronic structure of such interfaces has triggered a great technological drive to functionalize them into devices. In this communication, we describe an alternative strategy to produce spin filtering by inducing a ferromagnetic insulating state in an ultrathin antiferromagnetic layer in contact with a ferromagnetic layer. This artificially induced spin filtering persists up to relatively high temperatures and operates at high applied bias voltages. The results suggest that after playing a key role in exchange-bias for spin-valves, uncompensated moments at engineered antiferromagnetic interfaces represent a novel route for generating highly spin-polarized currents with antiferromagnets.

Work done in collaboration with M. Bibes, C. Carrétéro, A. Barthélémy (Unité Mixte de Physique CNRS/Thales, Campus de Polytechnique, 1, Avenue A. 3:06PM L17.00002 Nanostructured $CoFe_2O_4$ Films for Magnetic Logic Applications

, RYAN COMES, MAN GU, University of Virginia, MIKHAIL KHOKHLOV, Guilford College, JIWEI LU, STUART WOLF, University of Virginia — $CoFe_2O_4$ (CFO) offers unique properties as a magnetoelectric material due to its large magnetoelastic response when strained. Previous work has shown that when CFO is co-deposited with $BiFeO_3$ (BFO) nanostructured phase segregation occurs and electrical control of the magnetic anisotropy is possible [1]. Such a system offers unique possibilities for an electrically-controlled spintronic logic scheme. To that end, CFO films were grown on MgO and $SrTiO_3$ (STO) substrates using pulsed electron deposition. Films grown on MgO substrates exhibit large perpendicular anisotropy due to epitaxial strain, while films on STO exhibit mixed anisotropy. Using electron-beam lithography, nanopillars were etched into the film in dense arrays and characterized using magnetic force microscopy. Pillar arrays were produced with diameters between 30 and 75 nm with pitch ranging from 90 to 200 nm. The dipole interactions in these pillars were examined and their potential applications for spintronic logic were evaluated. Thinner $CoFe_2O_4$ islands were also patterned on STO with EBL and then used as a template for a co-deposited BFO/CFO film. Results of this work will also be presented.

3:18PM L17.00003 Spin-polarized tunnelling across single or double ferrite-based spin-filters

, SYLVIA MATZEN, JEAN-BAPTISTE MOUSSY, CEA-Saclay, RICHARD MATTANA, KARIM BOUZEHOUANE, CYRILE DERANLOT, FREDERIC PETROFF, UMP CNRS/Thales, JAGADEESH MOODERA, GUOXING MIAO, Francis Bitter Magnet Laboratory, CEA-SACLAY, FRANCE TEAM, UMP CNRS/THALES, FRANCE TEAM, FRANCIS BITTER MAGNET LABORATORY, MIT, USA TEAM — The generation of highly spin-polarized electron currents at room temperature is the basis of most spin-based device technologies. One approach known as spin filtering, has the potential of generating 100% spin-polarized currents by the spin selective transport of electrons across a ferromagnetic tunnel barrier. In this work, we investigate the spin-polarized tunnelling characteristics of ferrites (CoFe2O4, NiFe2O4 and MnFe2O4), which are exciting candidates for spin filtering at room temperature. Tunnel junctions containing epitaxial ferrite tunnel barriers have been grown by oxygen plasma-assisted molecular beam epitaxy. Their structural, chemical and magnetic properties having previously been optimized by a number of in situ and ex situ methods, we focus on the spin-polarized tunnelling in the ferrite-based systems using different measurement techniques and we propose an unconventional device combining two ferrite magnetic tunnel barriers in order to get large tunnelling magnetoresistance without the necessity of magnetic electrodes.

3:30PM L17.00004 Effect of Strain on Electronic and Magnetic Structure of Fe-doped $CoFe_2O_4$[1]

, JARRETT MOYER, CARLOS VAZ, Dept. of Applied Physics and Center for Research on Interface Structures and Phenomena, Yale University, EZANA NEGUSSE, Dept. of Physics, Montana State University, DARIO ARENA, National Synchrotron Light Source, Brookhaven National Laboratory, VICTOR HENRICH, Dept. of Applied Physics and CRISP, Yale University — The development of new materials with large room temperature spin polarizations and small conductivity mismatches with semiconductors is key for more complex spintronics devices. $CoFe_2O_4$ has a high Curie temperature (T_C = 793 K), a large predicted spin polarization, and, when doped with iron, a conductivity similar to semiconductors; however, the magnetic properties of thin films are different from the bulk. To investigate the effect of strain, $Co_{1-x}Fe_{2+x}O_4$ thin films ($0 \leq x \leq 0.65$) are grown epitaxially on MgO (001) and $SrTiO_3$ (001) by MBE. UPS probes filled valence band states, while X-ray Linear Dichroism (XLD) determines d-orbital occupations. SQUID magnetometry and XMCD are used to determine bulk and site-specific magnetic moments, respectively. These measurements allow us to understand how strain affects the electronic and magnetic structure of $Co_{1-x}Fe_{2+x}O_4$ thin films.

[1]This research is primarily supported by NSF Grant MRSEC DMR-0520495.

3:42PM L17.00005 Fabrication and properties of LuFe2O4 thin film[1]

, WENBIN WANG, University of Tennessee & Oak Ridge National Lab, XIAOSHAN XU, ZHENG GAI, PAUL C. SNIJDERS, THOMAS Z. WARD, Oak Ridge National Lab, JIAN SHEN, University of Tennessee & Fudan University — We have succeed in growing the LuFe2O4 polycrystalline thin film on the MgO(111) substrate with the Pulsed laser deposition(PLD) method. The surface structures, crystallographic and magnetic properties of the sample were characterized by XRD, AFM, SEM and SQUID. XRD pattern shows the sample crystallized in both (001) and (110) directions, which is also reflected in their morphological appearance in both AFM and SEM images. SQUID measurements reveal strong ferromagnetic signal in the thin film.

[1]Research sponsored by the Division of Materials Sciences and Engineering, Office of Basic Energy Sciences, U.S. Department of Energy.

3:54PM L17.00006 Magnetic Force Microscopy of Magnetite Thin Films with Transition Metal Buffer Layers[1]

, ALFRED KH. LEE, MARK C. MONTI, JOHN T. MARKERT, ALEX DE LOZANNE, Department of Physics, The University of Texas at Austin, PRIYANGA B. JAYATHILAKA, CHRIS A. BAUER, CASEY W. MILLER, Physics Department, University of South Florida — Magnetite (Fe_3O_4) has been the subject of interest as a material for use in spin devices. Its ideal properties for this application break down in thin film morphologies due to the occurrence of antiphase boundaries (APBs). The density of APBs can be adjusted to some degree via film strain. This is accomplished in this work by including a variety of transition metal buffer layers between Fe_3O_4 and its MgO substrate. We investigate the microscale magnetic domain structure via magnetic force microscopy of Fe_3O_4 films on MgO with no, a Mo, or an Fe buffer layer across a temperature range surrounding the Verwey temperature ($T_V \sim$ 120K) and compare to bulk measurements from a SQUID magnetometer.

4:06PM L17.00007 A structural, electronic and magnetic study of ultrathin iron oxides , M. MONTI, B. SANTOS, J. MARCO, J. DE LA FIGUERA, CSIC-Rocasolano Madrid-SPAIN, M.A. NIÑO, T.O. MENTEŞ, A. LOCATELLI, ELETTRA Trieste-ITALY, K.F. MCCARTY, Sandia Nat Labs Livermore-USA, A. MASCARAQUE, O. RODRÍGUEZ DE LA FUENTE, Complutense Univ Madrid-SPAIN — Iron oxides continue to fascinate us after nearly a century of "modern" science devoted to their growth, properties and structure. Recently, a revival of research has been spurred by the multiferroic character of magnetite, and by its predicted half-metal character, both interesting for spintronic applications. Maghemite is, on the other hand, an interesting counterpart to magnetite. They both present the same inverse spinel structure but maghemite is a ferrimagnetic insulator. In this work we individually characterize flat triangular islands, less than 10 atomic layers thick, of magnetite and maghemite on Ru(0001) by means of selected-area X-ray photoemission and absorption, X-ray circular dichroism and low-energy electron diffraction and reflectivity. We grow magnetite islands in-situ, with well-defined magnetic domains inside, surrounded by a wüstite wetting layer by depositing iron in a molecular oxygen background pressure. Further exposure to NO_2 transforms the magnetite islands into maghemite, while changing the wüstite wetting layer into hematite.

4:18PM L17.00008 Giant tunnel electroresistance and electrical control of spin polarization with ferroelectric tunnel barriers , VINCENT GARCIA, Unité Mixte de Physique CNRS/Thales, Palaiseau, France — At room temperature, we use piezoresponse force microscopy to show robust ferroelectricity in $BaTiO_3$ ultrathin films, and conductive-tip atomic force microscopy to demonstrate the resistive readout of the polarization state via its influence on the tunnel current [1]. This giant electroresistance nondestructive readout paves the way for ferroelectric memories with simplified architectures, higher densities and faster operation. Additionally, ferroelectric tunnel junctions with ferromagnetic electrodes were engineered to demonstrate local, large and non-volatile control of carrier spin polarization by switching ferroelectric polarization [2]. Our results represent a giant interfacial type of magnetoelectric coupling and suggest a new low-power approach for spin-based information control.

4:54PM L17.00009 Electrically Controlled Spin Valve at a Complex Oxide Interface , EVGENY TSYMBAL, J.D. BURTON, University of Nebraska - Lincoln — Since the discovery of giant magnetoresistance exploration of spin-dependent electronic transport has proved promising for applications. To avoid the costly generation of magnetic fields in these devices there have been recent efforts toward manipulating magnetization by *electric* fields. Such magnetoelectric effects can be induced at the surfaces and interfaces of many ferromagnetic metals. Ferroelectric materials are especially helpful in this because their spontaneous electrical polarization can induce a large response at the interface with a magnetic metal. One example is the ferroelectric control of magnetic order at the interface between $La_{1-x}A_xMnO_3$ (where A is a divalent cation), and the ferroelectric $BaTiO_3$ [1]. Importantly, ferroelectric films can now be made thin enough (less than a few nm) to allow measurable electron tunneling while still maintaining a stable and switchable polarization [2]. Here we show that those few atomic layers near the interface sensitive to the ferroelectric polarization can act as an atomic scale spin-valve in series with the ferroelectric tunnel barrier. Switching the ferroelectric barrier induces more than an order of magnitude change in the conductance due to the interfacial spin-valve, constituting a substantial spin-dependent transport phenomenon controlled by an electric field alone.

5:06PM L17.00010 Magnetic state switching controlled by a voltage in $La_{0.7}Ca_{0.3}MnO_3$/(Ba, Sr)TiO_3/$La_{0.7}Ca_{0.3}MnO_3$ tunneling junctions , WEIJIN HU, Department of Physics, Pennsylvania State University, University Park, PA 16802, KE CHEN, XIAOXING XI, Department of Physics, Pennsylvania State University, University Park, PA 16802 and Department of Physics, Temple University, Philadelphia, PA 19122, QI LI, Department of Physics, Pennsylvania State University, University Park, PA 16802, ZHIDONG ZHANG, Shenyang National Laboratory for Materials Science, Institute of Metal Research, CAS, Shenyang 110016, China — We report the switching of the two magnetic states (parallel and antiparallel states) in $La_{0.7}Ca_{0.3}MnO_3$/(Ba, Sr)TiO_3/$La_{0.7}Ca_{0.3}MnO_3$ magnetic tunneling junctions by measuring the tunneling magnetoresistance after applying a voltage pulse. The junction size ranges between 5x5 to 20x20 μm^2 with the barrier thickness in the range of 1-3 nm. We have found that magnetic state of the junction can be switched both from the antiparallel to parallel state and from the parallel to antiparallel state in certain and different field ranges, respectively. The switching does not depend on the polarity of the electrical field direction and the magnetic field direction. The critical voltage for the switching depends on the magnetic field with higher voltage needed for lower magnetic field. The critical voltage depends almost linearly on the bias magnetic field when the switch occurs.

5:18PM L17.00011 Four resistance states in $La_{0.7}Sr_{0.3}MnO_3$/(Ba, Sr)TiO_3/$La_{0.7}Sr_{0.3}MnO_3$ multiferroic tunnel junction at room temperature , PENG XU, YUEWEI YIN, WEIJIN HU, MURALIKRISHNA RAJU, QI LI, Department of physics, The Pennsylvania State University, University Park, PA 16802, USA, XIAOGUANG LI, Hefei National Laboratory for Physical Sciences at Microscale, Department of Physics, University of Science and Technology of China, 230026, China — Multiferroic tunnel junction (MFTJ), composed of two ferromagnetic electrodes separated by a thin ferroelectric barrier, has been predicted to serve as a four-state device as a result of the coexistence of tunneling magnetoresistance and tunneling electroresistance effects. Our previous results have demonstrated such devices, but only at low temperatures. Here, we report a MFTJ composed of $La_{0.7}Sr_{0.3}MnO_3$/(Ba, Sr)TiO_3/$La_{0.7}Sr_{0.3}MnO_3$ fabricated by pulsed-laser deposition. A typical R-H loop with a sharp-switched resistance states (magnetic parallel and antiparallel) similar to that of magnetic tunnel junctions has been observed up to room temperature. Upon polarization reversal of the barrier, both the parallel and antiparallel resistances will switch to a different value. Clear tunneling magnetoresistance and tunneling electroresistance, hence the four-resistance states, have been observed at room temperature. The resistance states can be switched between them by electric and magnetic fields and the manipulation of the states will be discussed.

Tuesday, March 22, 2011 2:30PM - 5:30PM –
Session L18 GMAG DMP: Focus Session: Low D/Frustrated Magnetism - 2D Lattices D172

2:30PM L18.00001 Exotic quantum phases in a frustrated quantum spin model on a honeycomb lattice[1] , CHRISTOPHER VARNEY, University of Maryland / Georgetown University, KAI SUN, VICTOR GALITSKI, University of Maryland, MARCOS RIGOL, Georgetown University — A quantum spin liquid is a phase that defies the usual conventions, i.e. quantum fluctuations prevent long range order even at $T = 0$. The search for models that exhibit this type of behavior has intensified in recent years. In this work, we utilize the Lanczos algorithm to study hard-core bosons on a frustrated honeycomb lattice with nearest-neighbor (t) and next-nearest-neighbor hoppings (t'). The two limits of this model, $t'/t = 0$ and $t'/t = \infty$, favor two different superfluid phases. In between, we find that an anomalous phase is stabilized by the strong frustration in this system and compare its properties with a quantum spin liquid and a fragmented Bose-Einstein condensate.

[1]This research is supported by by US-ARO, JQI-NSF-PFC, and the Office of Naval Research.

2:42PM L18.00002 Protecting the Kitaev honeycomb model from external fields[1] , HAITAN XU, JACOB TAYLOR, Joint Quantum Institute, University of Maryland, College Park, MD 20742, and National Institute of Standards and Technology, Gaithersburg, MD 20899 — We propose an approach to generate many-body interactions from two-body interactions with stable cat states. Applied to the celebrated Kitaev honeycomb model, our approach opens a spectral gap in the gapless phase of the model without any external magnetic field. We confirm the non-Abelian topological properties of a generalized Kitaev model and demonstrate our approach's robustness to sources of error. Our work provides a complete framework for experimentally realizing and manipulating non-Abelian anyons, with direct application in topological quantum computation.

2:54PM L18.00003 Paramagnetic ground states and field-driven Néel order in S=3/2 Heisenberg antiferromagnets on a honeycomb lattice , GANESH RAMACHANDRAN, Department of Physics, University of Toronto, D.N. SHENG, Department of Physics and Astronomy, California State Univ., Northridge, Y.J. KIM, A. PARAMEKANTI, Department of Physics, University of Toronto — We study the spin-3/2 Heisenberg antiferromagnet on a honeycomb lattice with exchange interactions which frustrate Néel order. Our motivation stems from the recent synthesis of $Bi_3Mn_4O_{12}(NO_3)$, a spin-3/2 bilayer honeycomb lattice antiferromagnet which remains paramagnetic to the lowest temperature, but shows a field-induced Néel transition. We use a combination of spin wave theory, exact diagonalization, and bond operator theory to study the effects of quantum and thermal fluctuations, second-neighbor exchange, biquadratic exchange and bilayer coupling. Biquadratic terms give rise an AKLT valence bond solid ground state, and bilayer coupling leads to an interlayer dimer solid. Upon applying a magnetic field, both these states undergo a phase transition into a Néel long range ordered state. We comment on experimental consequences and disorder effects.

3:06PM L18.00004 Gapped Z_2 spin liquid and chiral antiferromagnetic phase in Hubbard model on the honeycomb lattice , YUAN-MING LU, YING RAN, Boston College — In Schwinger-fermion representation we identify a Z_2 spin liquid called the sublattice-pairing state (SPS) as the gapped spin liquid phase discovered in recent Quantum Monte study of Hubbard model on a honeycomb lattice. We show that SPS is identical to the zero-flux Z_2 spin liquid state in Schwinger-boson representation by an explicit duality transformation. SPS is connected to an *unusual* antiferromagnetic ordered phase, which we term as chiral-antiferromagnetic (CAF) phase, through an $O(4)$ critical point. CAF phase breaks $SU(2)$ spin rotation symmetry completely and has three Goldstone modes. Our results indicate that there is likely a hidden phase transition between CAF phase and the usual antiferromagnetic (Neel) phase at large U/t. We also propose numerical measurements to reveal the CAF phase and the hidden phase transition.

3:18PM L18.00005 Exotic phases in Mott insulating Iridates with strong spin-orbit coupling: Phase diagram of the Kitaev-Heisenberg model in a magnetic field , HONG-CHEN JIANG, Microsoft Research, Station Q, UCSB, ZHENG-CHENG GU, Kavli Institute for Theoretical Physics, UCSB, XIAO-LIANG QI, SIMON TREBST, Microsoft Research, Station Q, UCSB — Motivated by the recent proposal of a Mott insulating state with strong spin-orbit coupling for the Iridate Na_2IrO_3[1], we discuss the collective ground states of the effective Iridium moments in the presence of Heisenberg-Kitaev exchange interactions and a time-reversal symmetry breaking magnetic field. For a field pointing in the (111) direction we find a rich phase diagram with both symmetry breaking magnetically ordered phases as well as an unconventional topological phase which is stable over a small range of coupling parameters. Our numerical simulations further indicate two exotic multicritical points at the boundaries between these ordered phases, which we will discuss.

[1] J. Chaloupka, G. Jackeli, and G. Khaliullin, Phys. Rev. Lett. 105, 027204 (2010).

3:30PM L18.00006 Schwinger boson spin liquid states on honeycomb lattice: projective symmetry group analysis and critical field theory , FA WANG, Department of Physics, MIT — Motivated by the numerical evidence of a gapped spin liquid in the honeycomb Hubbard model [Meng et al. Nature 464, 847 (2010)], we analyse possible Z_2 spin liquids with gapped bosonic spinons coupled to Z_2 gauge field on honeycomb lattice within the Schwinger boson formalism. By the projective symmetry group method we find that there are only two relevant Z_2 spin liquids on honeycomb lattice with different (zero or π) gauge flux in the elemental hexagon. The zero-flux state seems to be a good candidate for the numerically observed spin liquid. It can acquire collinear AFM Neel order via a continuous O(4) transition. In the critical field theory of this transition the coupling of bosonic spinons to the Higgs field contains cubic powers of spatial derivatives, therefore does not break honeycomb lattice symmetry and allows for a continuous transition to a commensurate collinear Neel order. We will also discuss several observable features of this spin liquid.

3:42PM L18.00007 Nature of the spin liquid state of the Hubbard model on the honeycomb lattice , BRYAN CLARK, DMITRY ABANIN, PCTS, Department of Physics, Princeton University, SHIVAJI SONDHI, Department of Physics, Princeton University — Recent numerical work (Nature 464, 847 (2010)) indicates the existence of a spin liquid phase (SL) that intervenes between the antiferromagnetic and semimetallic phases of the half filled Hubbard model on a honeycomb lattice. To better understand the nature of this exotic phase, we study the quantum $J_1 - J_2$ spin model on the honeycomb lattice, which provides an effective description of the Mott insulating region of the Hubbard model. Employing the variational Monte Carlo approach, we analyze the phase diagram of the model, finding a phase transition between antiferromagnet and an unusual Z_2 SL state which we identify as the SL phase of the Hubbard model. At higher $J_2/J_1 > 0.3$ we find a transition to a dimerized state with spontaneously broken rotational symmetry.

3:54PM L18.00008 Finite-temperature phase transition to $m = 1/2$ plateau phase in a S=1/2 XXZ model on Shastry-Sutherland Lattices , TAKAFUMI SUZUKI, Institute for Solid StatePhysics — We study the finite-temperature transition to the $m = 1/2$ magnetization plateau in a model of interacting $S = 1/2$ spins with longer range interactions and strong exchange anisotropy on the geometrically frustrated Shastry-Sutherland lattice. This model was shown to capture the qualitative features of the field-induced magnetization plateaus in the rare-earth tetraboride, $\mathrm{TmB_4}$. Our results show that the transition to the plateau state occurs via two successive transitions with the two-dimensional Ising universality class, when the quantum exchange interactions are finite, whereas a single phase transition takes place in the purely Ising limit. To better understand these behaviors, we perform Monte Carlo simulations of the classical generalized four-state chiral clock model and compare the phase diagrams of the two models. The magnetic properties and critical behavior of the finite-temperature transition to the $m = 1/2$ plateau state are also discussed.

4:06PM L18.00009 Study of spin-lattice coupling in the Shastry-Sutherland compound $SrCu_2(BO_3)_2$, RAMZY DAOU, MPI-CPfS, MARCELO JAIME, SCOTT CROOKER, NHMFL-Los Alamos, FRANZISKA WEICKERT, MICHAEL NICKLAS, FRANK STEGLICH, MPI-CPfS, HANNAH DABKOWSKA, BRUCE GAULIN, McMaster University — $SrCu_2(BO_3)_2$ supports a network of orthogonally coupled spin-dimers whose ground state consists of localized spin-singlets which can be described by the exactly solvable Shastry-Sutherland Hamiltonian. On applying strong magnetic fields (>20T), however, the spin gap in $SrCu_2(BO_3)_2$ is closed and triplet excitations are generated. As a consequence of the strong geometric frustration, the triplet band is nearly dispersionless and a sequence of steps and plateaux in the magnetisation at integer fractions of the saturation magnetisation are observed, corresponding to static magnetic textures that are commensurate with the lattice. Here we present high resolution measurements in pulsed magnetic fields up to 65T of the magnetostriction and magnetocaloric effect which 1) shed light on the coupling between spin and lattice degrees of freedom and 2) are aimed to address discrepancies between existing data and theoretical predictions for the sequence of field-induced plateaus. Experiments were carried out at the Dresden High Magnetic Field Laboratory and the pulsed field facility of the National High Magnetic Field Laboratory.

4:18PM L18.00010 Phase Transitions in the $J_1 - J_2$ Ising Model on the Square Lattice[1] , SONGBO JIN, ARNAB SEN, ANDERS SANDVIK, Boston University — The $J_1 - J_2$ Ising model on the square lattice is one of the simplest classical models to study the effects of competing interactions and the resulting phase transitions. In spite of previous studies, there remains a controversy regarding the nature of the transition into the "stripe" phase in this model for $J_2/J_1 > 0.5$. In this study, we use the Binder cumulant of the order parameter to address this question. We use the Wang-Landau and Metropolis algorithms to simulate the model in the relevant parameter space. From our numerics, we determine that the transition is first-order for $0.5 < J_2/J_1 < g_{tri}$ ($g_{tri} \approx 0.8$) and becomes continuous in nature for larger values of J_2/J_1. We also discuss the order parameter distribution and correlation lengths at the first-order transition.

4:30PM L18.00011 Low Temperature ^{31}P-NMR Study of the Frustrated Square-Lattice Compound $BaCdVO(PO_4)_2$[1] , B. ROY, R. NATH, D.C. JOHNSTON, Y. FURUKAWA, Ames Laboratory, Dept. of Phys. and Astro., Iowa State Univ., C. GEIBEL, MPI CPfS, Dresden — $BaCdVO(PO_4)_2$ is known to be a S = 1/2 frustrated square-lattice (FSL) system with a ferromagnetic nearest neighbor exchange coupling $J_1 \sim$ -3.36 K and an antiferromagnetic next nearest neighbor exchange coupling $J_2 \sim$ 3.53 K. We have carried out ^{31}P-NMR measurements at low temperatures down to 0.1 K to investigate magnetic properties of this compound from a microscopic point of view. ^{31}P spin-lattice relaxation rates ($1/T_1$) measured at H = 0.8 T are almost independent of temperature above 2 K, show a peak at 1.05 K and become constant below 0.4 K. The temperature dependence of $1/T_1$ indicates the existence of antiferromagnetic ordering at $T_N \sim$ 1.05 K which is also evidenced by the broadening of the NMR spectrum below that temperature. We will compare our NMR results with those of a similar FSL system, $Pb_2VO(PO_4)_2$ and discuss the similarities and differences in the magnetic properties of these two systems.

4:42PM L18.00012 Magnetic phase diagram of spatially anisotropic, frustrated spin-1/2 Heisenberg antiferromagnet on square and stacked square lattices , KINGSHUK MAJUMDAR, Department of Physics, Grand Valley State University, Allendale, MI 49401 — Magnetic phase diagram of a spatially anisotropic, frustrated spin-1/2 Heisenberg antiferromagnet on a square and a stacked square lattice is investigated using second-order spin-wave expansion. It is shown that with increase in next nearest neighbor frustration the second-order corrections play a significant role in stabilizing the magnetization. We obtain two ordered magnetic phases (Neél and stripe) separated by a paramagnetic disordered phase. Within second-order spin-wave expansion we find that the width of the disordered phase diminishes with increase in the interlayer coupling (for the 3D case) or with decrease in spatial anisotropy but it does not disappear. Our obtained phase diagram differs significantly from the phase diagram obtained using linear spin-wave theory.

4:54PM L18.00013 Study of Orbital Degenerate System in Frustrated Checkerboard Lattice , JOJI NASU, Tohoku University, SUMIO ISHIHARA — Orbital degree of freedom is one of the recent attractive themes in transition-metal oxides. In contrast to the spin degree of freedom, the orbital interaction explicitly depends on the bond direction, and a certain kind of frustration exists. In the geometrical frustrated lattice, cooperating and competing effects between the orbital frustration and the geometrical frustration provide new features in the static and dynamical properties of orbital. The present purpose is to study the intrinsic orbital frustration effect in a geometrical frustrated lattice. We introduce the spin-less Hubbard-type model with the doubly degenerate d_{yz} and d_{zx} orbitals in the checkerboard lattice. The effective Hamiltonian for the strong correlation limit is derived. We have the $J_z S_i^z S_j^z$ type Ising interaction for the nearest-neighbor bonds and the $J_x S_i^x S_j^x$ type Ising one for the next nearest-neighbor bonds. Here **S** is the orbital pseudo-spin operator. In the mean-field approximation, there is a macroscopic number of degeneracy at the frustration point J_x/J_z=2. In the classical Monte-Carlo simulation, we have a staggered orbital order and the reentrant phase-boundary. In the analyses by the spin-wave approximation and the exact diagonalization method, a large damping of the high-energy orbital dynamics due to the frustration is observed.

5:06PM L18.00014 Thermodynamics of the AF Heisenberg Model on the Checkerboard Lattice; a Numerical Linked-Cluster Expansion Study[1] , EHSAN KHATAMI, MARCOS RIGOL, Georgetown University — Employing numerical linked-cluster expansions (NLCEs) along with exact diagonalizations of finite clusters with periodic boundary condition, we study the energy, specific heat, entropy, and various susceptibilities of the antiferromagnetic (AF) Heisenberg model on the checkerboard lattice. NLCEs, combined with extrapolation techniques, allow us to access temperatures much lower than those accessible to exact diagonalization and other series expansions. We find that the high-temperature peak in specific heat decreases as the frustration increases, consistent with the large amount of unquenched entropy in the region around maximum classical frustration, where the nearest-neighbor and next-nearest-neighbor exchange interactions (J and J', respectively) have the same strength, and with the formation of a second peak at lower temperatures. The staggered susceptibility shows a change of character when J' increases beyond $0.75J$, implying the disappearance of the long-range AF order at zero temperature. For $J' = 4J$, in the limit of weakly-coupled crossed chains, we find large susceptibilities for stripe and Néel order with $\mathbf{Q} = (\pi/2, \pi/2)$ at low temperatures with AF correlations along the chains. Other magnetic and bond orderings, such as a plaquette valence-bond solid and a crossed-dimer order suggested by previous studies, have also been investigated.

5:18PM L18.00015 Quantum Phases of the Cairo Pentagonal Lattice , IOANNIS ROUSOCHATZAKIS, ANDREAS M. LAEUCHLI, RODERICH MOESSNER, Max Planck Institute for the Physics of Complex Systems, NEW STATES OF QUANTUM MATTER TEAM — We present an analytical and numerical study of the spin S=1/2 antiferromagnetic Heisenberg model on the Cairo pentagonal lattice. This is the dual of the Shastry-Sutherland lattice and has been discussed as a possible new candidate for having a spin liquid ground state [1]. More recently a S=5/2 version of this model has been realized in the Bi2Fe4O9 system [2]. Here we use a model with two different types of exchange couplings and investigate the nature of the ground state as a function of their ratio. This strategy allows us to understand the nature of a number of phases and derive effective models for their description with and without a magnetic field. Of particular interest is a surprising interplay between a collinear and a four-sublattice orthogonal phase due to an underlying order-by-disorder mechanism. Furthermore we address the issue of possible nonmagnetic ground states such as singlet and spin nematic phases.

Session L19 GMAG DMP: Focus Session: Spin Transport & Magnetization Dynamics in Metals V D170

2:30PM L19.00001 Thermal spin fluctuations in itinerant ferromagnets: Aspects of magnetic thermodynamics and transport properties , KIRILL BELASHCHENKO, University of Nebraska-Lincoln — The character of thermal spin fluctuations in itinerant ferromagnets is a long-standing problem. Our recent theoretical results offer new insights in this issue. First, I will discuss a classical effective spin model with both rotational and longitudinal spin fluctuations, which allows for a variable degree of itinerancy. Magnetic thermodynamics in this model was analyzed for fcc and bcc lattices using Monte Carlo simulations compared (favorably) with mean-field and generalized Onsager approximations. It was found that magnetic short-range order is relatively weak and almost independent on the degree of itinerancy. The ambiguity of the phase space measure will be emphasized. Next, I will discuss our first-principles calculations of spin-disorder resistivity (SDR) of Fe, Ni, and heavy rare-earth metals (Gd-Tm series), in which the Landauer conductance is explicitly averaged over spin disorder configurations. For Fe the SDR agrees very well with experiment. For Ni, comparison with experiment suggests that the average local moment in the paramagnetic state is reduced to $\sim$0.35 μ_B. The effect of magnetic short-range order on SDR is found to be weak in both Fe and Ni. Overall, the results suggest that thermal spin fluctuations in Fe and Ni have an effectively classical character. While the crystallographically averaged paramagnetic SDR for rare earth metals agrees quite well with experiments, its anisotropy systematically and significantly exceeds the available measurements. This discrepancy is critically evaluated, suggesting the need for additional experiments.

3:06PM L19.00002 Theory of the Kondo Temperature in Multilevel Quantum Dots[1] , ION GARATE, IAN AFFLECK, University of British Columbia and Canadian Institute for Advanced Research — We develop a simple but general method to evaluate the Kondo temperature in a multilevel quantum dot that is weakly coupled to conducting leads. Our analysis reveals that the Kondo temperature is strongly enhanced when the intradot energy-level spacing is smaller than the charging energy.

[1]We acknowledge financial support from NSERC and CIFAR.

3:18PM L19.00003 Role of initial quantum correlation in transient linear response , CHIKAKO UCHIYAMA, Univ. of Yamanashi, Japan, MASAKI AIHARA, Nara Institute of Science and Technology, Japan — We study the transient linear response of a two-level system coupled with an environmental system for correlated and factorized initial conditions. We find the significant differences between the transient linear response in these cases, especially for strong system-environment interaction at intermediate temperatures. This means that we need to pay attention to the initial conditions when we analyze experiments on transient linear response. This is because the conventional factorized initial condition, in which the system-environment correlation is disregarded, results in an incorrect response.

3:30PM L19.00004 Even-odd parity effects of a spin-1 Heisenberg chain on long-range interaction and entanglement[1] , SANGCHUL OH, University at Buffalo, SUNY, MARK FRIESEN, University of Wisconsin-Madison, XUEDONG HU, University at Buffalo, SUNY — A strongly coupled spin chain can be used as a quantum data bus, to mediate long-range interactions and entanglement between remote qubits.By obtaining numerical solutions for finite size systems, we investigate even-odd parity effects in a spin-1 chain and their consequences for long-range interactions and entanglement. We observes some similarities with a spin-1/2 chain [1]. For example, we find that an even-size chain mediates an RKKY (Ruderman-Kittel-Kasuya-Yosida)-like interaction between weakly coupled attached spins, while an odd-size chain acts as a central spin to the attached spins. On the other hand, we find that the RKKY-like interactions have a different character. For a spin-1/2 chain, the interactions decay with qubit separation as they oscillate between ferro and antiferromagnetic couplings. For a spin-1 chain, the interactions also oscillate, but they decay very little as a function of qubit separation. We believe this behavior is a manifestation of the finite Haldane gap of an integer spin chain in the thermodynamic limit.

3:42PM L19.00005 Theory of Magnetization of Interacting Bloch Electrons , PRASANTA MISRA, University of Houston, GOURI TRIPATHI, Berhampur University, India — We derive a theory of magnetization of interacting Bloch electrons in the paramagnetic limits. We start with a thermodynamic potential, which includes both the quasi-particle and correlation contributions. The startling result obtained by us is that the modifications brought about by the electron-electron interactions for the magnetization in the quasi-particle interaction is precisely cancelled by the contributions due to electron correlations and thus the magnetization is devoid of explicit many-body corrections. In contrast, it is well known that both the spin susceptibility and the spin Knight-shift are exchange enhanced by electron-electron interactions. This is due to second order effects in the sense that while both the spin vertices are renormalized, the renormalization of only one of the vertices is cancelled by the contribution due to electron correlations. However, there is only one spin-vertex in the expression for magnetization which is renormalized in the quasi-particle approximation. We discuss the importance of self-energy corrections on the single-particle spectrum and we have shown as how to predict that the interacting electron system is magnetic or not by considering a variant of the Hubbard Hamiltonian in the momentum space.

3:54PM L19.00006 Exact solution for permeability of a ferromagnet under parametric bichromatic irradiation , ADIL-GERAI KUSSOW, University of Massachusetts, Lowell, Department of Physics, ALKIM AKYURTLU, University of Massachusetts, Lowell, Department of Electrical and Computer Engineering — If two parametrically coupled electromagnetic fields are applied to a ferromagnet, a non-linearity of the equation of precession of magnetic moment strongly affects the permeability. If the coupling constant $|\beta| < 1$ between the probe (p) wave and the support (s) wave is small, the permeability $\hat{\mu}(\omega)$, at the frequency of the probe wave $\omega = \omega_p = 2\omega_s$, is still monochromatic-like, with the re-normalized resonance spin waves frequency $\Omega_r \to \Omega(1+\beta)$. If a coupling is strong, $\beta \leq -1$, unusual response effects are possible (the magnetic transparency and profoundly non-monochromatic permeability $\hat{\mu}(\omega)$. Possible optical applications to the homogeneous negative refractive index materials are discussed.

4:06PM L19.00007 Element specific analysis of magnetic anisotropy in practical Mn-based antiferromagnetic alloys from first principles , KHMELEVSKYI SERGII, Institute of Applied Physics, Vienna University of Technology, Austria, ALEXANDR B. SHICK[1], Institute of Physics ASCR, v.v.i., Na Slovance 2, 182 21 Praha 8, Czech Republic, PETER MOHN, Institute of Applied Physics, Vienna University of Technology, Austria — Magnetic Anisotropy Energy (MAE) and element specific contribution to MAE has been studied for practical Mn-based antiferromagnetic alloys with layered $L1_0$ structure in the framework of the Local Spin Density Approximation and fully relativistic torque method. It is found that the contribution to the total MAE from non-magnetic 3d and 4d-elements in MnNi and MnPd alloys is comparable to the contribution of the magnetic Mn atoms. In the 3d-5d MnIr alloy the Ir contribution is found to be dominating. The origin of this contribution from the elements with total zero atomic spin moment is linked to the calculated non-trivial spin density distributions on the corresponding atom, which gives a zero moment only on average. We have also found and discuss a strong dependence of the total and element specific contribution to MAE on the state of the magnetic order.

4:18PM L19.00008 Theoretical search for new permanent magnets with no rare earth atoms , LIQIN KE, VLADIMIR ANTROPOV, Ames Laboratory — We performed the extensive computational search for better permanent magnets containing no rare earth atoms. Our initial studies are concentrated on the intrinsic properties of magnetic materials such as magnetization, the Curie temperature and magnetic anisotropy. A computational tool based on the electronic structure methods has been developed to describe these physical properties as a function of electronic concentration. The application of this technique allowed us to provide several possible directions to perform a search for new materials. We discuss some physical limitations of required properties in iron based materials using the analysis of their electronic structure and simplified magnetic models. The issues of chemical substitutions, modification of geometry and changing the dimensionality of systems will be discussed as well. The specific results will be shown for Fe and Co based systems with the additions of N, C, W, Al and other atoms.

4:30PM L19.00009 Ab initio study of $d^{\bigcirc}$ magnetism in CaC , HADI AKBARZADEH, ZAHRA NOURBAKHSH, S. JAVAD HASHEMIFAR, Isfahan University of Technology — The half-metallic ferromagnetism in d^0 ionic compounds has attracted considerable attention in the spintronics community [Phys. Rev. B 73 024404, 2006]. In this work we employ density functional theory to study electronic, magnetic, and mechanical properties of the high ionic CaC compound in the Zinc Blend (ZB), Rock Salt (RS), B_2, Wurtzite (WZ), NiAs, and tetragonal structures.The observed ferromagnetic equilibrium state in the RS, NiAs, WZ, tetragonal and ZB structures is attributed to the partially filled sharp p band of carbon around the Fermi level. Half-metallicity has been found in the equilibrium ZB and expanded WZ structures with a magnetic moment of 2 μ_B/formula units. Comparing the Gibbs free energy of various structures indicates favorability of the half metallic phases in negative pressures. Topological analysis of the electronic charge density reveals topological character of the paramagnetic-ferromagnetic phase transition of the revised NiAs and B_2 structures as well as the geometrical character of the magnetic phase transitions of the RS and ZB structures.

4:42PM L19.00010 Greigite and Spinorbitronics[1] , BAOMIN ZHANG, GILLES DE WIJS, Institute for Molecules and Materials, Radboud University Nijmegen, ROB DE GROOT, Institute for Molecules and Materials, Radboud University Nijmegen; Institute for Advanced Materials, University of Groningen, ELECTRONIC STRUCTURE OF MATERIALS TEAM, SOLID STATE MATERIALS FOR ELECTRONICS TEAM — Greigite(Fe_3S_4) and magnetite(Fe_3O_4) are isoelectronic and isostructural ferrimagnets. In biology, the motility of magnetotactic bacteria is based on any or both of them. Not much work is known on greigite. Unlike half-metallic magnetite, greigite is a normal metal. Although the constituent elements are light, the complex Fermi-surface of greigite is remarkably sensitive to relativistic effects. The existence of several Fermi-surface sheets is dependent on the direction of the magnetization. This implies spintronics based on a homogeneous material rather than a device. Since this effect is intrinsically relativistic, spin-contamination is irrelevant here.

[1]Thanks to FOM and NWO for support.

4:54PM L19.00011 Experimental and theoretical investigations into the twinning energy of an FSMA system , P.K. MUKHOPADHYAY, MADHUPARNA KARMAKAR, RAJINI KANTH B., LCMP, S.N.B.N.C.B.S., Kolkata 98, India, S.N. KAUL, SoP, Central University, Hyderabad 46, India — Ferromagnetic shape memory alloys (FSMA) are smart materials with largest magnetic field induced strain below austenite - martensite transformations. The lower temperature martensitic state is characterized by the presence of structural twins that have this exceptional magnetoelastic coupling. To understand this behavior, we carried out sound velocity and attenuation measurements on a typical FSMA material, NiFeAl system, and determined the Young's moduli under various stresses and associated strains. We found that the effect of stress is to alter the martensite temperature. We also studied a theoretical thermodynamic constitutive model and Clausius-Duhem inequality, to determine the stress resulting from an applied strain for an isothermal system. In the absence of an applied magnetic field the free energy of the system consists of only the mechanical energy contribution which in turn is dependent upon the elastic moduli pertaining to the elastic and twinning strains. The paper describes the details of measurements and the model chosen, along with the discussions on the correspondence between the experimental observations and various theoretically determined quantities.

5:06PM L19.00012 Influence of Goldstone modes on the electronic properties of helical magnets , YAN SANG, DIETRICH BELITZ, University of Oregon, KWAN-YUET HO, TED KIRKPATRICK, University of Maryland — We have investigated the influence of Goldstone modes on the electronic properties of helical magnets, such as MnSi, in which a Dzyaloshinsky-Moriya term in the action leads to helical order with a pitch wave number q [1]. In the presence of a homogeneous external magnetic field H the helix is superimposed by a homogeneous magnetization, which leads to a conical phase [2]. The Goldstone mode in this conical phase has the form $\Omega^2 \propto c_z k_z^2 + c_\perp k_\perp^4/q^2 + c_H k_\perp^2$, where k_z and $k_\perp$ denote the components of the wave vector parallel and perpendicular to H, respectively. The elastic constants c_z and $c_\perp$ are independent of H for small H, whereas $c_H \propto H^2$. This Goldstone mode couples to the conduction electrons and leads to nonanalytic temperature dependences of various observables. In the conical phase, the strongest effect is on the thermal conductivity and the single-particle relaxation rate, which both are proportional to $T^{3/2}$. We also report results for the specific heat and the electrical resisitivity, both in the conical phase and in other phases of MnSi [3]. [1] P. Bak and M.H. Jensen, J. Phys. C 13, L881 (1980). [2] Y. Ishikawa, G. Shirane, J.A. Tarvin, and M. Kohgi, Phys. Rev. B 16, 4956 (1977). [3] Kwan-yuet Ho, T.R. Kirkpatrick, Yan Sang, D. Belitz, Phys. Rev. B 82, 134427 (2010)

5:18PM L19.00013 Is CrO_2 Fully Spin Polarized? Analysis of Andreev Spectra and Excess Current , TOMAS LOFWANDER, Department of Microtechnology and Nanoscience - MC2, Chalmers University of Technology, SE-412 96 Goteborg, Sweden, ROLAND GREIN, MATTHIAS ESCHRIG[1], Institut fuer Theoretische Festkoerperphysik and DFG-Center for Functional Nanostructures, Karlsruhe Institute of Technology, 76128 Karlsruhe, Germany — We report an extensive theoretical analysis of point-contact Andreev reflection data available in the literature on ferromagnetic CrO_2. We find that the spectra can be well understood within a model of fully spin-polarized bands in CrO_2 together with spin active scattering at the contact. This is in contrast to analyses of the data within extended Blonder-Tinkham-Klapwijk models, which lead to a spin polarization varying between 50% and 100% depending on the transparency of the interface. We propose to utilize both the temperature dependence of the spectra and the excess current at voltages above the gap to resolve the spin-polarization in CrO_2 in a new generation of experiments.

Session L20 DMP GERA FIAP: Focus Session: Thermoelectric Materials: Skutterudites, Novel and Nanostructured Materials D168

2:30PM L20.00001 Synthesis and thermoelectric property of Ca-doped n-type $Bi_{85}Sb_{15}$ alloy , KAMAL KADEL, WENZHI LI, Florida International University, GIRI JOSHI, GMZ, ZHIFENG REN, Boston College — $Bi_{1-x}Sb_x$ (0.09<x<0.20) alloys are n-type semiconducting materials that exhibit a good thermoelectric property at low temperature, around 80 K. In the present work we investigated the thermoelectric properties of undoped $Bi_{85}Sb_{15}$ and different Ca-doped $Bi_{85}Sb_{15}Ca_x$ alloys (x=0.5, 2, and 5) synthesized via arc-melting first and followed by ball milling and hot pressing. Effect of different Ca doping levels on transport properties of $Bi_{85}Sb_{15}$ alloys has been investigated. It is found that thermal conductivity decreases with increasing Ca. Electrical transport measurements show that power factor increases with doping level of Ca up to $Bi_{85}Sb_{15}Ca_2$ and then decreases, yielding the maximum value of power factor of 3.8×10^{-3} $Wm^{-1}K^{-2}$ and ZT of 0.39 at room temperature for $Bi_{85}Sb_{15}Ca_2$. Properties at below room temperature will also be presented.

2:42PM L20.00002 Exploration of Electron Poor Materials and their thermoelectric properties , DARYN BENSON, ULRICH HAUSSERMANN, OTTO SANKEY, Arizona State University — The Electron Poor Materials (EPM); ZnSb, ZnAs which have an average 3.5 valence electrons are explored via ab initio calculations. These materials are of interest for thermoelectric research. The EPM are then compared to valence balanced zinc-blende materials; InSb, GaSb, ZnSe, and ZnTe. Analysis of binding to assess the interesting electronic properties such as the role of nonclassical four-center bonds and the thermoelectric Seebeck coefficient are discussed. Bandstructure comparisons to a simple tight-binding model (Linear Combination of Atomic Orbitals (LCAO)) are preformed in order to test the effects of the atomic orbitals on the electronic structure.

2:54PM L20.00003 Chemical Doping Effect on the Thermoelectric Properties of $T$$Ga_3$($T$ = Fe, Ru, Os) , NEEL HALDOLAARACHCHIGE, AMAR KARKI, ADAM PHELAN, YIMIN XIONG, RONGYING JIN, JULIA CHAN, SHANE STADLER, DAVID YOUNG, Louisiana State University, USA — Thermoelectric properties of chemically-doped intermetallic narrow-band semiconductors: $T$$Ga_3$($T$ = Fe, Ru, Os) are reported. The parent compounds show semiconductor-like behavior (E_g $\sim$ 0.2 eV, n_{290K} $\sim$ $10^{18}$$cm^3$) with large $n-$type Seebeck coefficients at room temperature (S_{290K} $\sim$ -300 μV/K). The semiconductor-like $FeGa_3$ becomes metallic upon chemical doping (adding electron carriers), but $RuGa_3$ and $OsGa_3$ remain semiconducting. While the electrical resistivity and the Seebeck coefficients of all the compounds decrease with electron doping, the Seebeck coefficients remain fairly large and $n-$type, which leads to larger power factors than those of the pure samples. The thermal conductivity (κ_{290K}= 1.6 W/m K) of electron-doped $FeGa_3$ decreases, which increases the room temperature power factor by a large percentage (S^2/ρ_{290K} = 60 μW/m K^2) over that of pure $FeGa_3$. This improvement in the power factor leads to a corresponding enhancement in the thermoelectric figure of merit (ZT) – a factor of 5 increases above undoped polycrystalline $FeGa_3$ and two orders of magnitude improvement over that of pure single crystalline $FeGa_3$.

3:06PM L20.00004 Doping dependence of thermoelectric performance in Mo_3Sb_7: first principles calculations[1] , DAVID PARKER, MAO-HUA DU, DAVID SINGH, Oak Ridge National Laboratory — Experimental studies have indicated the substantial thermoelectric promise of doped Mo_3Sb_7, with a figure-of-merit ZT of 0.9 (H. Xu *et al*, J. Appl. Phys. **105**, 053703 (2009)) already achieved at high temperature. However, optimal doping levels have not yet been achieved. We study doping of Mo_3Sb_7 with transition metals (Ni,Fe,Co,Ru) via first principles calculations, including electronic structure, lattice dynamics and Boltzmann transport. We discuss the selection of dopant and the potential thermoelectric performance of optimally doped Mo_3Sb_7.

3:18PM L20.00005 Giant Seebeck Coefficient in V-TCNE thin films[1] , AUDREY CHAMOIRE, CHRISTOPHER JAWORSKI, Department of Mechanical Engineering, OSU, CHI-YUEH KAO, Department of Chemistry, OSU, JOSEPH HEREMANS, Department of Mechanical Engineering and Department of Physics, OSU, ARTHUR EPSTEIN, Department of Physics and Department of Chemistry, OSU — The disordered structure of organic conductors results in a naturally low thermal conductivity (κ) but their ZT is known to be low because of their low thermopower (S) and electrical conductivity (σ). Here we report an exception, with results obtained from 220 to 320K for the thermopower of V-$TCNE_x$ (V-$(C_2(CN)_4)_x$) thin films deposited on a Si wafer (111). At room temperature S=+21.8 mV/K and increases with decreasing temperature. Those values are matched only by very pure semiconductors such as Si at low temperature, Bi nanowires, or strongly correlated electron systems like $FeSb_2$. The valence band of V-TCNE has a very high density of states over a very narrow energy range, ascribed mostly to vanadium 3d(t_{2g}) orbitals,[2] which is consistent with the exceptionally large value of S. The dependence of S and σ upon illumination will also be shown, alongside preliminary estimates for the ZT.

3:30PM L20.00006 Einstein Modes in the Phonon Density of States of the Single-Filled Skutterudite $Yb_{0.2}Co_4Sb_{12}$

, IVO K. DIMITROV, Brookhaven National Laboratory, MICHAEL E. MANLEY, Lawrence Livermore National Laboratory, STEVEN M. SHAPIRO, Brookhaven National Laboratory, JIONG YANG, WENQING ZHANG, LIDONG CHEN, Shanghai Institute of Ceramics, Chinese Academy of Sciences, QING JIE, Brookhaven National Laboratory, GEORG EHLERS, ANDREY PODLESNYAK, Spallation Neutron Source, Oak Ridge National Laboratory, JORGE CAMACHO, QIANG LI, Brookhaven National Laboratory — Measurements of the phonon density of states by inelastic neutron scattering and specific heat measurements along with first principles calculations, provide compelling evidence for the existence of an Einstein oscillator (*rattler*) at $\omega_{E1} \approx$ 5.0 meV in the filled skutterudite $Yb_{0.2}Co_4Sb_{12}$. Multiple dispersionless modes in the measured density of states of $Yb_{0.2}Co_4Sb_{12}$ at intermediate transfer energies (14 meV $\leq \omega \leq$ 20 meV) are exhibited in both the experimental and theoretical *density of states* of the Yb-filled specimen. A peak at 12.4 meV is shown to coincide with a second Einstein mode at $\omega_{E2} \approx$ 12.8 meV obtained from heat-capacity data. The emergence of local modes at intermediate transfer energies is attributed to altered properties of the host $CoSb_3$ cage as a result of Yb filling. It is suggested that these modes are owed to a complementary mechanism for the scattering of heat-carrying phonons in addition to the mode observed at $\omega_{E1} \approx$ 5.0 meV.

3:42PM L20.00007 On the role of nanostructure on the thermal conductivity of skutterudite thermoelectrics[1]

, MARCO FORNARI, Central Michigan University, DMITRI VOLJA, JIVTESH GARG, Massachusetts Institute of Technology, DAEHYUN WEE, Ewha Womans University, BORIS KOZINSKY, Robert Bosch LLC, NICOLA MARZARI, University of Oxford — One of the most effective strategies to improve the thermoelectric figure of merit in skutterudites is to reduce thermal conductivity via alloying, filling, or nanostructuring. The latter is most effective when the dimension of the domains is comparable in size to the mean free path of the dominant heat-conducting phonons. In bulk, pristine semiconductors and insulators thermal conductivity and phonons' mean-free paths can nowadays be calculated fully from first-principles from the anharmonic terms in the ionic displacements. We show here our results for the lattice thermal conductivity of several compounds with the skutterudite structure, obtained from the Boltzmann transport equation using phonon lifetimes determined from density functional calculations. We will also discuss the effect of fourth-order terms, albeit as obtained using phenomenological approaches. Last, we comment on the interplay between the different length scales for the nanostructured domains and the relevant heat-carrying phonons.

3:54PM L20.00008 Thermoelectric Properties of p-type Yb Filled Skutterudite $Yb_yFe_xCo_{4-x}Sb_{12}$[1]

, CHEN ZHOU, DONALD MORELLI, Michigan State University, XIAOYUAN ZHOU, GUOYU WANG, University of Michigan, CTIRAD UHER, University of Michgan — Since the discovery in 1995 of high thermoelectric figure of merit in skutterudite compounds, much work has been done to optimize the thermoelectric properties of these materials. As a result of this effort, n-type skutterudites are available today with figure of merit ZT approaching 1.8. By contrast, p-type skutterudites have lagged behind, with the best materials having figure of merit less than unity. In this study, we report the thermoelectric and magnetic properties of p-type Yb-filled skutterudites of nominal composition $Yb_yFe_xCo_{4-x}Sb_{12}$ with the aims of extending our knowledge of the filled skutterudite family and enhancing the thermoelectric properties of these p-type materials.

4:06PM L20.00009 First principles calculations of the interactions of a filling atom with its neighboring atoms in a skutterudite (LaFe4Sb12)[1]

, JOSEPH FELDMAN, NRL, DAVID SINGH, ORNL, NOAM BERNSTEIN, NRL — The room temperature lattice thermal conductivity of filled skutterudites is about a factor of 5 smaller than that of unfilled skutterudites which has caused a great deal of attention to be focused on these materials from a scientific standpoint, as well as a technological one, i.e., thermoelectric applications. In an effort to gain a microscopic understanding of this we have previously used a central force model and Green-Kubo techniques with force parameters heavily based on first principles results [Bernstein et al., Phys Rev. B **81**, 134301 (2010)]. However, as we had no first principles information on the La-Fe cubic anharmonic parameters in LaFe4Sb12 we have performed new direct method calculations for a larger supercell than the Bravais cell used previously to compute not only the six independent La-Fe cubic anharmonic parameters but numerous other parameters. Atomic forces were computed in various structural configurations differing only by the coordinates of one of the two La positions in the simple cubic supercell. DFT results are compared for LAPW, PAW, and plane-wave pseudopotential methods.

4:18PM L20.00010 Thermoelectric Technology for Automotive Waste Heat Recovery[1]

, GREGORY MEISNER, GM Global Research and Development — Essential to the long term success of advanced thermoelectric (TE) technology for practical waste heat recovery is fundamental physics and materials research aimed at discovering and understanding new high performance TE materials. Applications of such new materials require their development into efficient and robust TE modules for incorporation into real devices such as a TE generator (TEG) for automotive exhaust gas waste heat recovery. Our work at GM Global R&D includes a continuing investigation of Skutterudite-based material systems and new classes of compounds that have potential for TE applications. To assess and demonstrate the viability of a TEG using state-of-the-art materials and modules, we have designed, fabricated, installed, and integrated a working prototype TEG to recover exhaust gas waste heat from a production test vehicle. Preliminary results provide important data for the operation and validation of the mechanical, thermal, and electrical systems of the TEG in combination with the various vehicle systems (e.g., exhaust bypass valve and controls, thermocouples, gas and coolant flow and pressure sensors, TE voltage and output power). Recent results from our materials research work and our functioning automotive TEG will be presented.

4:30PM L20.00011 Bottom-Up Strategy for Thermoelectric Nanocomposites[1]

, ANUJA DATTA, Department of Physics, University of South Florida — Thermoelectric (TE) materials that incorporate nano-scale domains offer potential control over electrical and thermal properties simultaneously. A bottom-up strategy may provide cost-effective, scalable, and reproducible processing of TE materials with improved TE properties above existing materials. The strategy involves composition and size controlled syntheses of TE materials as nanocrystals by employing facile solution based processes followed by densification into bulk nanocomposite pellets using Spark Plasma Sintering. In this talk an overview of the various solution phase synthesis processes for preparing nanocrystals of different TE materials will be presented. In addition the TE properties after SPS densification will be discussed in relation to composition and grain size within the nanocomposites. Experimental results will be assessed together with theoretical modeling in describing the effect of the nano-scale domains on the TE properties.

5:06PM L20.00012 Formation Mechanisms of Embedded Zincblende and Wurtzite Nitride Nanocrystals , ADAM WOOD, University of Michigan, X. WENG, Penn State University, Y.Q. WANG, Materials Science & Tech. Division, LANL, R.S. GOLDMAN, University of Michigan — Semiconductor nanocomposites have been proposed for high figure of merit thermoelectrics. A promising approach to nanocomposite synthesis is matrix-seeded growth, which involves ion-beam-amorphization of a semiconductor film, followed by nanoscale re-crystallization via rapid thermal annealing (RTA) [1]. In this work, we are studying the formation and evolution of N ion-implanted InAs and GaAs. Low temperature (77K) N ion implantation into InAs leads to the formation of an amorphous layer with crystalline InAs remnants. RTA at up to 550 $^\circ$C leads to the nucleation of zincblende (ZB) InN nanocrystals (NC). RTA at 600 $^\circ$C leads to nucleation of both ZB and wurtzite (WZ) InN, with an increase in average NC size. These results are consistent with the predictions of a thermodynamic model for the nanoscale-size-dependence for nucleation of ZB and WZ InN. We are also developing a novel approach to *direct* the seeding of nanostructure arrays, using a combination of focused-ion-beam (FIB) implantation and conventional ion implantation. To date, we have demonstrated the selective positioning of WZ and ZB GaN NCs using 75keV and 100keV N implantation, followed by FIB patterning and 800 $^\circ$C RTA. [1] X. Weng, et al, *J. Appl. Phys.* **97,** 64301 (2005).

5:18PM L20.00013 Thin film thermocouples for thermoelectric characterization of nanostructured materials , MATTHEW GRAYSON, CHUANLE ZHOU, ANDREW VARRENTI, SEUNG HYE CHYUNG, JIEYI LONG, SEDA MEMIK, Electrical Eng. Comp. Sci, Northwestern University — The increased use of nanostructured materials as thermoelectrics requires reliable and accurate characterization of the anisotropic thermal coefficients of small structures, such as superlattices and quantum wire networks. Thin evaporated metal films can be used to create thermocouples with a very small thermal mass and low thermal conductivity, in order to measure thermal gradients on nanostructures and thereby measure the thermal conductivity and the Seebeck coefficient of the nanostructure. In this work we confirm the known result that thin metal films have lower Seebeck coefficients than bulk metals, and we also calibrate the Seebeck coefficient of a thin-film Ni/Cr thermocouple with 50 nm thickness, showing it to have about 1/4 the bulk value. We demonstrate reproducibility of this thin-filmSeebeck coefficient on multiple substrates, and we show that this coefficient does, in fact, change as a function of film thickness. We will discuss prototype measurement designs and preliminary work as to how these thin films can be used to study both Seebeck coefficients and thermal conductivities of superlattices in various geometries. The same technology can in principle be used on integrated circuits for thermal mapping, under the name "Integrated On-Chip Thermocouple Array" (IOTA).

Tuesday, March 22, 2011 2:30PM - 5:30PM –

Session L21 DMP GIMS DCP: Focus Session: Imaging and Modifying Materials at the Limits of Space and Time Resolution II D161

2:30PM L21.00001 Nanoscale phase transitions within single ion tracks. , WILLIAM WEBER, University of Tennessee, RAM DEVANATHAN, Pacific Northwest National Laboratory, PEDRO MOREIRA, Universidade Estadual de Campinas — The dynamics of track development due to the passage of energetic ions through solids is a long-standing issue relevant to nuclear materials, age-dating of minerals, space exploration, and nanoscale fabrication of novel devices. We have integrated computer simulation and experimental approaches to investigate nanoscale phase transitions under the extreme conditions created within single tracks of energetic ions in the $Gd_2Zr_{2-x}Ti_xO_7$ system and $ZrSiO_4$. Based on the inelastic thermal spike model, we have used molecular dynamics simulations to follow the time evolution of the structure of individual tracks and to reveal the phase transition pathways to experimentally observed concentric track structures. The molecular dynamics simulations clearly demonstrate the dependence of track evolution on composition, deposited energy density, and the complex competition among melting, disordering and recrystallization processes.

2:42PM L21.00002 Exploring electron beam induced heat and mass transport at the atomic scale[1] , CHRISTIAN KISIELOWSKI, Lawrence Berkeley National Laboratory — In recent years the performance of mid-voltage electron microscopes was significantly boosted to reach deep sub-Ångstrom resolution around 0.5 Å at 300 kV in broad beam (TEM) and focused probe (STEM) modes. Atomic resolution microscopy at voltages as low as 50 kV (and possibly below) was fostered. As a result the detection of single atoms across the Periodic Table of Elements is now possible even if light atoms are considered. After decades of striving for resolution enhancement, electron microscopy has now reached a limit that is given at a fundamental level by the Coulomb scattering process itself and by beam-sample interactions, which set a maximum dose limit that can be easily reached for soft and hard materials with the developed high-brightness electron guns. Consequently, new frontiers for electron microscopy emerge and this contribution addresses dynamic processes at the single atom level that can now be captured in time series of images at frequencies below 1 Hz reaching towards kHz. In this frequency range much of the observed atom dynamics is electron beam induced and the control of beam-sample interaction imposes constraints as well as opportunities. In this contribution it is shown that it seems feasible to exploit beam sample interactions to gain better insight into heat and mass transport in soft and hard matter at atomic resolution.

2:54PM L21.00003 Gold nanoislands for sensitivity enhancement in organic and imaging mass spectrometries (LDIMS, keV- and MeV-SIMS) , ARNAUD DELCORTE, OSCAR RESTREPO, ANEESH PRABHAKARAN, Institute of Condensed Matter and Nanosciences, Université catholique de Louvain, Belgium — Gold nanoparticles condensed on the surface of organic materials induce large ion yield enhancements in secondary ion mass spectrometry, using atomic projectiles. Here, we first show that the interest of surface metallization extends to MeV-SIMS and to UV laser desorption/ionization, in which the energy of the primary beam is deposited through the electronic subsystems (but not to keV-cluster-SIMS). For the three methods, gold nanoislands induce at least a ten-fold increase of the characteristic fragment and molecular ion yields, making surface metallization an interesting approach for imaging MS of organic surfaces. In the second part of this report, we discuss the underlying physics. For instance, using molecular dynamics simulations, we explain why 10 keV atomic projectiles interacting with metallized organic surfaces desorb more molecules, and why it is not the case with cluster projectiles such as C_{60} and Au_{400}. For the other regimes of irradiation, arguments involving photon absorption and electronic effects are proposed.

3:06PM L21.00004 Surface characterization at the spatial resolution limit with Individual Cluster Impacts[1] , FRANCISCO FERNANDEZ-LIMA, MICHAEL J. ELLER, JOHN D. DEBORD, STANISLAV V. VERKHOTUROV, Texas A&M University, SERGE DELLA-NEGRA, IPN, Orsay, EMILE A. SCHWEIKERT, Texas A&M University — The use of cluster bombardment (e.g. C_{60} and Au_{400}) for surface analysis and characterization has shown significant advantages due to enhanced emission of molecular ions, low damage cross section, and reduced molecular fragmentation. At temporally and spatially discrete cluster impacts, the small impacted volume (10^3 nm^3) and ionized ejecta are ideal candidates for surface molecule interrogation. In the present talk, recent measurements of co-emitted photons, electrons and secondary ions from individual cluster impacts for several projectile-target combinations will be presented. Inspection of the photon and electron emissions show that the emission profiles are correlated with the target structure/composition at the nanometer level, with the particularity that co-emitted photons, electrons and secondary ion pairs can be used as indicators of the surface content and homogeneity. Examples of surface mapping of intact molecules via electron emission microscopy combined with secondary ion detection will be shown.

3:18PM L21.00005 Electronic response of dielectric covered metal surfaces to highly charged ions[1]

, R.E. LAKE, Clemson University, J.M. POMEROY, National Institute of Standards and Technology, C.E. SOSOLIK, Clemson University — The strong Coulombic perturbation on a solid target from a highly charged ion (HCI) initiates a complex many-body response from target electrons that can produce novel effects such as potential energy sputtering, nanofeature formation and huge secondary electron yields. Far above the surface, HCIs reach a critical electron capture distance and neutralization proceeds via resonant charge transfer over the vacuum barrier [1]. Motivated by recent experiments [2], we detail the onset of charge transfer between a HCI and a metal covered with a dielectric thin film (Co with 1.5 nm Al_2O_3) to determine the film's effect on the critical distance. Surprisingly, we find that the first captured electrons are pulled through the exposed dielectric and come from the underlying metal. Additionally, the Al_2O_3 film lowers the effective work function of the target and extends the critical distance compared to a clean metal. I will discuss how the experimental parameters (thin film material/thickness and ion charge state/velocity) can be tuned to allow the ion to interact with electrons in either the metal or thin film.

3:30PM L21.00006 Extraordinary sensitivity of nanoscale infrared spectroscopy demonstrated on Graphene and thin SiO_2

, GREG ANDREEV, Z. FEI, UCSD, W. BAO, Z. ZHAO, C.N. LAU, UC Riverside, L.M. ZHANG, Boston U, M. FOGLER, G. DOMINGUEZ, M. THIEMENS, UCSD, F. KEILMANN, Max Planck, Garching, D. BASOV, UCSD — Infrared Spectroscopy is a powerful tool for characterizing materials by their vibrational mode fingerprint and/or electron conductivity. Its application to nanoscale resolved studies is highly desirable but remained challenging mainly for two reasons: a suitable source of intense, broadband infrared illumination was not widely available and the spatial resolution of conventional microscopes was limited by diffraction. We have resolved both issues by utilizing tunable External Cavity Quantum Cascade Lasers (EC-QCLs) as an intense illumination source for a scattering Scanning Near Field Optical Microscope (s-SNOM), capable of <10nm spatial resolution. With this combination of EC-QCLs + s-SNOM we demonstrate <10nm resolution imaging and spectroscopy of extremely thin materials: Silicon oxide layers (SiO_2) as thin as 2nm and even single atomic layers of Carbon (Graphene). The spectra register contrasts for volumes as small as 20x20x1nm^3 = 400 yoktoliters of SiO_2, and about 70 yl of Graphene over a broad spectral range: 1065-2250cm^{-1}. We explain the origins of this extraordinary sensitivity with an improved theoretical framework for calculating the near field response of a multilayer system.

3:42PM L21.00007 Mesoscopic metal-insulator transitions at twin domain walls in improper ferroelastic VO_2[1]

, ALEXANDER TSELEV, Oak Ridge National Laboratory — Appearance of unusual phenomena at interfaces of different materials due to symmetry breaking and atomic, electronic, or spin reconstructions is well established area of intensive research. Domain walls in ferroic materials also can show unusual behavior due to symmetry discontinuities. VO_2 is a strongly-correlated-electron material, which exhibits a metal-insulator phase transition with a structural, lattice symmetry-lowering transformation making this material an improper ferroelastic. We observe mesoscopic metal-insulator transitions at the ferroelastic domain walls in the lower-symmetry phase of VO_2 that occur at temperatures as much as 10-12 °C below the bulk transition, resulting in the formation of metallic channels in the semiconducting material. The experiments are made using AFM-based scanning near-field microwave microscopy, which allows simultaneous accurate imaging of topography and the low-frequency dielectric function with a special resolution as high as 50 nm. The latter is possible due to a relatively high frequency used (in a few GHz range), when the sample-probe capacitive coupling becomes sufficiently strong and the electric current path is complete by displacement currents between the sample, probe tip, and the probe shield electrode. Density functional calculations indicate that ferroelastic domain walls of this type possess metallic character at low temperatures, which can be ascribed to elevated structural symmetry at the domain walls. The observed behavior, linked as well to the strain inhomogeneity inherent to ferroelastic materials, is generally relevant to symmetry-lowering phase transitions in other material systems.

4:18PM L21.00008 Simulation of Non-contact Atomic Force Microscopy for Structural Analysis

, JAMES CHELIKOWSKY, TZU-LIANG CHAN, University of Texas at Austin, C.Z. WANG, KAI-MING HO, Ames Laboratory of US DOE, Iowa State University — A powerful probe of materials centers on the use of atomic force microscopy (AFM). However, an analysis of AFM images can be complex and problematic. We will present an efficient scheme to simulate non-contact AFM images by employing a first-principles self-consistent potential from the sample as the essential input. This scheme does not require an explicit modeling of the AFM tip. Our method will be illustrated by applying it to various types of semiconductor surfaces including Si(111) (7x7), TiO2 (110) (1x1), Ag/Si(111)- ($\sqrt{3} \times \sqrt{3}$) R30^o and Ge/Si(105) (1x2) surfaces. We obtain good agreement with experimental results and previous theoretical studies by using this scheme. The method can quickly and efficiently aid in identifying different models for surface structures.

4:30PM L21.00009 Synchrotron X-ray Enhanced Scanning Tunneling Microscopy[1]

, VOLKER ROSE, JOHN FREELAND, Argonne National Laboratory — Proper understanding of complex phenomena occurring in nanostructures requires tools with both the ability to resolve the nanometer scale as well as provide detailed information about chemical, electronic, and magnetic structure. Scanning tunneling microscopy (STM) achieves the requisite high spatial resolution; however, direct elemental determination is not easily accomplished. X-ray microscopies, on the other hand, provide elemental selectivity, but currently have spatial resolution only of tens of nanometers. We present a novel and radically different concept that employs detection of local synchrotron x-ray interactions utilizing a STM that provides spatial resolution, and x-ray absorption directly yields chemical, electronic, and magnetic sensitivity. If during tunneling the sample is simultaneously illuminated with monochromatic x-rays, characteristic absorption will arise. Electrons that are excited into unoccupied levels close to the Fermi level modulate the tunneling current giving rise to elemental contrast.

4:42PM L21.00010 Frequency comb generation in a tunneling junction by intermode mixing of ultrafast laser pulses

, MARK HAGMANN, NewPath Research L.L.C., DZMITRY YAROTSKI, ANATOLY EFIMOV, ANTOINETTE TAYLOR, Los Alamos National Laboratory — Nonlinear interaction of electromagnetic radiation with tunneling electrons results in a number of peculiar physical phenomena, such as frequency mixing and imaging of insulating surfaces with scanning tunneling microscopy (STM). Arguably, the most promising among them is coupling of femtosecond laser pulses to the STM for material dynamics observation at nm/ps scales. However, the underlying physics is still poorly understood and the majority of existing studies of nonlinear mixing have been restricted to the use of CW lasers in a narrow range. Here, we present a new method for the hyper-spectral characterization of the nonlinear effects in tunneling junction. We use a 10-fs laser pulses at a nominal repetition rate of 74.25 MHz to generate a frequency comb in the tunneling current with frequencies up to 1 GHz. The typical output power at the fundamental (repetition) frequency is -120 dBm, and decreases for higher harmonics. The observed magnitude and square-law dependence of the signal power on the tunneling current and incident laser power are in good agreement with theoretical predictions.

4:54PM L21.00011 First principles computation of dynamical structure factor in real and momentum space in cuprates , YUNG JUI WANG, B. BARBIELLINI, HSIN LIN, TANMOY DAS, SUSMITA BASAK, Northeastern Univ. (NU), P. E. MIJNARENDS, Delft Univ. of Tech. and NU, S. KAPRZYK, NU and AGH (Poland), R. S. MARKIEWICZ, A. BANSIL, NU — We present a method for efficient, accurate first-principles calculations of the dynamical structure factor $S(\mathbf{q},\omega)$ in periodic systems, using products of real space Green functions and fast Fourier transforms (FFT). We further invert $S(\mathbf{q},\omega)$ via Fourier transformation [1] to reconstruct the propagator of electron density $X(\mathbf{x},t)$ in real space and time domain, thereby visualising spatially the dynamics of an electron doped cuprate system in real time. The present method is useful for many-body perturbation theories of excitations based on Density Function Theory (DFT) and modeling of various highly resolved spectroscopies going beyond the standard LDA [2-5]. Some illustrative examples will be presented. Work supported by the US DOE.

5:06PM L21.00012 Beam self-focusing in the near field emission scanning electron microscopy , FUXIANG LI, ARTEM ABANOV — Recent experiment on the near field emission scanning electron microscopy shows an unexpectedly high lateral and vertical resolution. We show that these effects can be explained by the beams self-focusing. We derive the equations for the beam propagation and solve them numerically. Our results are in a very good agreement with the experiment.

5:18PM L21.00013 Enhancing the spatial resolution in PEEM beyond 30nm using diamondoid surface coating , HITOSHI ISHIWATA, Stanford University, HENDRIK OHLDAG, Stanford Synchrotron Radiation Lightsource, ZHI-XUN SHEN, NICK MELOSH, Stanford University, ANDREAS SCHOLL, Advanced Light Source — The spatial resolution in Photoemission Electron Microscopy typically does not allow imaging features smaller than 30nm. PEEM resolution is limited by chromatic and spherical aberrations of the electrostatic lenses in the microscope column in combination with a wide angular and energy distribution of the secondary electrons to make these aberrations significant. Diamondoids have recently been shown to act as a monochromator for secondary electrons, thus reducing chromatic aberration in PEEM. In addition to improving the resolution of the microscope the diamondoid coating will also enhance the image intensity since now more secondary electrons will be accepted by the aperture. At 10kV the spatial resolution of PEEM3 is of the order of 150-200nm so that the magnetic domains can hardly be recognized anymore without the diamondoid coating. However, they become visible on the sample that was coated with diamondoids, indicating that the coating improved the spatial resolution by monochromatizing the secondary electrons. We also find that the image intensity is enhanced by a factor of 2-3 with the diamondoid coating. These initial findings on samples with relatively large domains of 150nm are very encouraging and we are therefore convinced that we can push the resolution limit below 30nm studying samples with smaller domains at higher acceleration voltages of 20kV.

Tuesday, March 22, 2011 2:30PM - 5:18PM –
Session L22 DCMP GMAG: URu2Si2 D163

2:30PM L22.00001 Quantification of U f-valence in URu_2Si_2 from 3D Bulk Fermi Surface Topology[1] , JONATHAN DENLINGER, O. KRUPIN, Lawrence Berkeley Natl Lab, J.W. ALLEN, U. of Michigan, B.J. KIM, Argonne Natl Lab, K. HAULE, KYOO KIM, G. KOTLIAR, Rutgers U., J.L. SARRAO, Los Alamos Natl Lab, N.P. BUTCH, U. of Maryland, M.B. MAPLE, UC San Diego — The three-dimensional bulk Fermi surface (FS) topology of paramagnetic-phase URu_2Si_2, as measured by photon-dependent angle-resolved photoemission spectroscopy of UHV-cleaved surfaces, is presented and discussed. Complete characterization of silicon-terminated surface states using spatial dependence, surface adsorption and theoretical surface slab calculations, allows identification of the bulk electronic band structure. The bulk FS topology is shown to be distinctly different from those of both localized $ThRu_2Si_2$-like f-core LDA calculations (U^{4+}) and fully itinerant LDA calculations. Key experimental FS topologies can be matched to itinerant LDA contours with suitable Fermi energy shifts that may mimic strong correlation effects not well treated in LDA. The intermediate-sized FS band topologies point to a mixed valent f-occupation between those of the two LDA calculations, $n_f \approx 2.2$ (f-core) and $n_f \approx 2.6$ (f-itinerant).

[1]Supported by U.S. DOE at the Advanced Light Source (DE-AC02-05CH11231), at UM (DE-FG02-07ER46379) and UCSD (FG02-04ER46105 & FG02-04ER46178), and by NSF at UCSD (DMR08-02478).

2:42PM L22.00002 Band renormalization at the hidden order transition in URu_2Si_2 , T. DURAKIEWICZ, G. DAKOVSKI, Y. LI , G. RODRIGUEZ, J.J. JOYCE, E.D. BAUER, P.H. TOBASH, Los Alamos National Laboratory, P.M. OPPENEER, Uppsala University, P.S. RISEBOROUGH, Temple University — The temperature-dependent evolution of the band structure in the hidden order (HO) system URu_2Si_2 was investigated by angle-resolved photoemission(ARPES) and time-resolved photoemission (trARPES) methods. The band structure changes with temperature, and the two dominant effects set the scale for the observed variations near the Fermi level. A hybridization gap is opening at around 70K, and the smaller gap forms below the HO transition temperature. The quasiparticle dynamics across the transition is measured with trARPES. The 3D nature of the electronic structure results in differences obtained by ARPES performed at different photon energies. We show how three different experiments, performed at 7eV, 21.2eV and 34eV can be reconciled with one model when the 3D electronic structure is taken into account.

2:54PM L22.00003 Complete mapping of dynamic spin correlations in the Hidden Order phase of URu_2Si_2[1] , H. BARATH, Johns Hopkins University, Z. YAMANI, W.J.L. BUYERS, CNBC, National Research Council, Canada, T. WILLIAMS, G. LUKE, McMaster University, Canada, J. RODRIGUEZ, J. LEAO, NIST Center for Neutron Research, D. GARRETT, McMaster University, Canada, K.J. MCCLELLAN, E.D. BAUER, J.L. SARRAO, LANL, USA, C. BROHOLM, Johns Hopkins University — URu_2Si_2 is a heavy fermion compound which undergoes a phase transition at 17.5 K to a "Hidden Order (HO) phase". We use inelastic neutron scattering to investigate spin correlations in the HO and paramagnetic phases and find them to be qualitatively different. While the normal state response has sharp features in Q but not in energy, consistent with an itinerant magnet, a distinct spectral gap develops in the HO phase. These results are consistent with previous measurements [1]. Here we present a full measurement of the scattering function, $S(\mathbf{Q},\omega)$, for energy transfers, $\hbar\omega < 11$ meV throughout the [H 0 L] plane. The data shows qualitatively different dispersion within, and perpendicular to, the tetragonal basal plane and provides information about the Fermi surface and its reconstruction upon entering the HO phase.

3:06PM L22.00004 Broken Rotational Symmetry in the Hidden Order Phase of URu_2Si_2 , T. SHIBAUCHI, R. OKAZAKI, H.J. SHI, Department of Physics, Kyoto University, Y. HAGA, T.D. MATSUDA, E. YAMAMOTO, JAEA, Y. ONUKI, JAEA and Osaka University, H. IKEDA, Y. MATSUDA, Department of Physics, Kyoto University — The nature of the so-called 'hidden order' phase transition at $T_h = 17.5$ K in the heavy fermion compound URu_2Si_2 has posed a long-standing mystery, because despite 25 years of study it remains unidentified what symmetry is broken in this ordered phase. We report the emergence of an in-plane anisotropy of the magnetic susceptibility below T_h, which breaks four-fold rotational symmetry in tetragonal URu_2Si_2. Two-fold oscillations in the magnetic torque, which is measured in magnetic ?elds rotating precisely within the ab plane, are sensitively detected in small pure crystals for the first time. The amplitude of the two-fold oscillations onsets precisely at T_h, indicating its close link to an order parameter of the hidden order phase. Our findings uncover that the hidden order phase is an electronic 'nematic' phase, a translationally invariant metallic phase with spontaneous breaking of rotational symmetry.

3:18PM L22.00005 Optical evidence of Fermi liquid scattering in URu_2Si_2 , THOMAS TIMUSK, JESSE HALL, SARAH PURDY, TRAVIS WILLIAMS, GRAEME LUKE, McMaster University, TOOMAS RÕÕM, TAANIEL ULEKSIN, URMAS NAGEL, Natl-. Inst. of Chem Phys, & Biophys., Tallinn, Estonia, RICARDO LOBO, ESPCI-Paris-Tech, Paris France, P. LEJAY, Inst. Neel, Grenoble, France, CHRISTOPHER HOMES, Brookhaven Natl. Lab. Upton, N.Y. — We present new high resolution, low noise, data that demonstrates that in the coherent heavy Fermion state of URu_2Si_2 the conductivity is due to heavy ($m \approx 50m_e$) quasiparticles with a self energy that is dominated by Fermi liquid scattering according to $1/\tau(T,\omega) = A(\omega^2 + (\pi T)^2)$ where the coefficient $A = 0.23\ \mu\Omega\text{cmK}^{-2}$. We use this property to develop a new method of reducing the noise in the low frequency reflectance spectra of this material. In the hidden order state the spectra show evidence of anisotropy of the hidden order gap parameter with $2\Delta_{max} = 6.0$ meV and $2\Delta_{min} = 4.6$ meV.

3:30PM L22.00006 Signature of Hidden Order in URu_2Si_2 in the c-axis Optical Conductivity , JESSE HALL, SARAH PURDY, TRAVIS WILLIAMS, GRAEME LUKE, THOMAS TIMUSK, McMaster University, TOOMAS RÕÕM, TAANIEL ULEKSIN, URMAS NAGEL, Natl-. Inst. of Chem Phys & Biophys., Tallinn, Estonia, RICARDO LOBO, ESPCI-Paris-Tech, Paris France — We present high quality c-axis far infrared optical data for the heavy fermion compound URu_2Si_2. In particular, we compare the signature of the as yet poorly understood 'hidden order' state along the a- and c-axes of the tetragonal structure. The results presented here demonstrate the presence of the hidden order in the ac plane along the c- direction, although there is a very pronounced difference from the absorption at 5 meV seen along the a-axis. We present an assessment of the nature and significance of the a-c anisotropy of the hidden order signature.

3:42PM L22.00007 Cyclotron resonance of ultra-clean URu_2Si_2 single crystals in the hidden order and superconducting states , SHO TONEGAWA, KEN-ICHIRO HASHIMOTO, YAO-HAN LIN, RYO KATSUMATA, KOUSUKE IKADA, Department of Physics, Kyoto University, YOSHINORI HAGA, TATSUMA MATSUDA, ETSUJI YAMAMOTO, Advanced Science Research Center, Japan Atomic Energy Agency, YOSHICHIKA ONUKI, Graduate School of Science, Osaka University, TAKASADA SHIBAUCHI, YUJI MATSUDA, Department of Physics, Kyoto University — The cyclotron resonance is a powerful probe to detect the effective mass and scattering time of the electron, but there is few example of the report in the heavy fermion compounds. We succeeded in observing cyclotron resonance in the heavy fermion superconductor URu_2Si_2 not only in the hidden ordered state, but also in the superconducting state. In the hidden ordered state, we observe the missing heavy band which has not been detected by de Haas van Alphen (dHvA) measurements. In the superconducting state, the resonance lines exhibit an unexpected sharpening below the transition temperature, suggesting the realization of quasiparticle Bloch state in the vortex lattice state. We will compare our data to the dHvA measuments and discuss the possible electronic structure of the hidden order state.

3:54PM L22.00008 Neutron Scattering Study of $URu_{1.9}Re_{0.1}Si_2$: Driving Hidden Order Towards Quantum Criticality , TRAVIS WILLIAMS, McMaster University, N.P. BUTCH, University of Maryland, G.M. LUKE, McMaster University, M.B. MAPLE, University of California San Diego, Z. YAMANI, W.J.L. BUYERS, Chalk River Laboratories — We report inelastic neutron scattering measurements in the hidden order state of $URu_{1.9}Re_{0.1}Si_2$. We have fit the data to a resolution convolved simple harmonic oscillator model, plus a continuum extending to 10meV. We observe that towards the Quantum Critical Point (QCP) induced by Re-doping, the gapped incommensurate fluctuations are fairly robust, being nearly identical to the parent material. The gap at the commensurate point (1 0 0) is driven down as the doped system approaches the QCP. The response of this commensurate spin fluctuation associated with the hidden order acquires substantial damping. The particle-hole spectrum of nested fermions [1] can be fitted to the energy and damping of the excitations, but there is no evidence for the static charge density wave that the model implies [2], in agreement with STM [3]. We conclude that Re-doping weakens, but does not destroy, the hidden order on approaching the QCP transition to ferromagnetism.

4:06PM L22.00009 Fano resonance and the hidden order in URu_2Si_2 probed by quasiparticle scattering spectroscopy* , W. K. PARK, L. H. GREENE, Univ. of Ill. at Urbana-Champaign, E. D. BAUER, P. H. TOBASH, F. RONNING, X. LU, J. L. SARRAO, J. D. THOMPSON, Los Alamos Nat. Lab. — The nature of the hidden order transition occurring at 17.5 K in URu_2Si_2remains puzzling despite intensive investigations over the past two and half decades. Recent experimental and theoretical developments render it a timely subject to probe the hidden order state using quasiparticle tunneling and scattering techniques. We report on the Fano resonance in pure and Rh-doped URu_2Si_2 single crystals using point-contact spectroscopy. The conductance spectra reproducibly reveal asymmetric double peak structures slightly off-centered around zero bias with the two peaks merging well above the hidden order transition temperature. An analysis using the Fano resonance model in a Kondo lattice [1] shows that the conductance peaks arise from the hybridization gap opening. Our estimated gap size agrees well with those reported from other measurements. We will present experimental results over a wide parameter space including temperature and doping dependences and discuss their underlying physics. [1] M. Maltseva, M. Dzero, and P. Coleman, Phys. Rev. Lett. **103**, 206402 (2009). *The work at UIUC is supported by the U.S. DOE under Award Nos. DE-FG02-07ER46453 and DE-AC02-98CH10886, and the work at LANL is carried out under the auspices of the U.S. DOE, Office of Science.

4:18PM L22.00010 Tunneling into clean Heavy Fermion Compounds: Origin of the Fano Lineshape[1] , PETER WOLFLE, Institute for Theory of Condensed Matter and Center for Functional Nanostructures, Karlsruhe Institute of Technology, D-76128 Karlsruhe, Germany, YONATAN DUBI, ALEXANDER BALATSKY, Los Alamos National Lab — Recently observed tunneling spectra on clean heavy fermion compounds show a lattice periodic Fano lineshape similar to what is observed in the case of tunneling to a Kondo ion adsorbed at the surface. We show that the translation symmetry of a clean surface in the case of *weakly correlated* metals leads to a tunneling spectrum given by the superposition of the local weighted density of states of all energy bands involved, which does not have a Fano lineshape. In particular the spectrum will show any hybridization gap present in the band structure. By contrast, in a *strongly correlated* heavy fermion metal the heavy quasiparticle states will be broadened by interaction effects. The broadening grows as one moves away from the Fermi surface, up to a value of the order of T_K , the Kondo scale. We show that the hybridization gap is completely filled in this way, and an ideal Fano lineshape of width T_K results, similar to the impurity case. We also discuss the possible influence of the tunneling tip on the surface, in (i) leading to additional broadening of the Fano line, and (ii) enhancing the hybridization locally, hence adding to the impurity type behavior. The latter effects depend on the tip-surface distance.

4:30PM L22.00011 A Γ_5 composite density wave model for the hidden order of URu_2Si_2[1] , PIERS COLEMAN, PREMALA CHANDRA, Rutgers University, REBECCA FLINT, Massachusetts Institute of Technology — Motivated by recent experiments on URu_2Si_2[1-4], we propose a theory for the hidden order in this material in which the hidden order parameter is a composite density wave formed formed between conduction electrons and a Γ_5 $5f^2$ doublet. In this theory, two-channel quadrupole fluctuations in the $Gamma_5$ proceed via virtual fluctuations into a $5f^1$ Kramer's doublet with Γ_7 symmetry. Hybridization in these two channels is described by a Schwinger boson which condenses in both the hidden order and the magnetic phase. In the magnetic phase, the hybridization develops in the up or down channels, whereas in the hidden order phase, it develops with equal amplitude in both channels. Our theory can account for the development of an anomalous $\Delta\chi_{xy}$ as a consequence of the composite order. It also predicts the formation of a tiny orbital moment aligned along the xy axis in the basal plane of the crystal that should be observable in neutron scattering experiments.

4:42PM L22.00012 Hybridization wave as the "Hidden Order" in URu_2Si_2[1] , JONATAN DUBI, ALEXANDER BALATSKY, Los Alamos National Lab — A phenomenological model for the hidden order transition in the heavy Fermion material URu_2Si_2 is introduced. The model assumes an incommensurate, momentum-carrying hybridization between the light hole band and the heavy electron band, appearing after a Fano hybridization takes place. The hybridization wave is identified as the "Hidden Order" order parameter. The model, simplified to one dimension, qualitatively reproduces numerous experimental results obtained from e.g. neutron scattering and scanning tunneling microscopy, and mainly the gap-like features in the density of states and the appearance of features at an incommensurate vector $Q^* \sim 0.6\pi/a_0$. Finally, the model allows us to make various predictions which are amenable to current experiments.

4:54PM L22.00013 Hexadecapolar Kondo effect in URu_2Si_2? , ANNA TOTH, GABRIEL KOTLIAR — Motivated by recent findings on the electronic structure of URu_2Si_2 , we derive the coupling of a localized hexadecapolar mode to itinerant fermionic quasiparticles in tetragonal crystal field, and show how it maps onto the two-channel Kondo (2CK) model. Channel symmetry is a consequence of time-reversal symmetry, and a 2CK regime can be observed if the crystal field splitting is less than the Kondo temperature. Corollary to the derivation, for an f^2-configuration in tetragonal environment, a relevant crystal field splitting is always present in addition to the 2CK interaction–even if the local degrees of freedom are a Γ_5 doublet. Solving the coupling by the numerical renormalization group, we are able to fit the susceptibility and the specific heat of the dilute system, $Th_{1-x}U_xRu_2Si_2$, in magnetic field and place the measurements on the verge of the local moment and the 2CK regimes.

5:06PM L22.00014 Electronic structure and multipolar fluctuations in URu2Si2 , HIROAKI IKEDA, Department of Physics, Kyoto University, RYOTARO ARITA, Department of Applied Physics, University of Tokyo, TETSUYA TAKIMOTO, Asia Pacific Center for Theoretical Physics, POSTECH — The intriguing phase transition at 17.5K in URu_2Si_2 was discovered by Palstra in 1985. In spite of intensive research studies over a quarter century, the order parameter remains still unknown; so-called "hidden order" phase. Many recent experimental data indicate that the magnetic and electronic properties can be easy to understand from the viewpoint of the itinerant picture rather than the localized picture. Thus, to elucidate the complicated electronic structure will be our important first step to comprehend the nature. Recently, by using a state-of-the-art *ab initio* downfolding, we have succeeded to construct the Wannier orbitals and to obtain the tight-binding Hamiltonian in terms of these basis set. Adding on-site Coulomb interactions between f orbitals, we obtain a multi-band Anderson lattice model, including full f orbitals. We here analyze the model Hamiltonian within the random phase approximation, and investigate magnetic fluctuations and multipolar fluctuations in URu_2Si_2. From these results, we discuss possible order parameters in the "hidden order" phase.

Session L23 DMP: Focus Session: Search for New Superconductors II: Towards Theoretical Design D165

2:30PM L23.00001 Spectral Weight Transfer in a Multi-Orbital Mott System , WEI-CHENG LEE, PHILIP PHILLIPS, Department of Physics, University of Illinois at Urbana-Champaign — One of the unique properties in a single band Hubbard model is the spectral weight transfer upon doping. Unlike in a Fermi liquid the redistribution of the spectral weights occurs predominantly near the chemical potential, a significant amount of spectral weights can be transferred from the high energy scales (upper Hubbard band) down to the chemical potential as a Mott insulator is doped. In this talk, we analyze the spectral weight transfer in a multi-orbital Mott system. We find that the spectral weights transferred from the high energy scales are greatly increased due to the multi-orbital structure, leading to a reduction of the critical doping level exhibiting zero thermopower. We argue that this indicates a suppression of the pseudogap phase and also predict the existence of new branches of charge 2e bosons carrying spin 1 at low energy in a multi-orbital Mott system. Relevant experimental consequences will be discussed.

2:42PM L23.00002 Electron-electron interaction in superconducting Lithium under pressure[1] , AMANDEEP KAUR, ERIK YLVISAKER, University of California, Davis, DEYU LU, YAN LI, Brookhaven National Laboratory, GIULIA GALLI, WARREN PICKETT, University of California, Davis — Lithium is known to exist in different phases and to uperconduct under pressure (P). We investigate the screened electron-electron interaction in Li as a function of P by analyzing the dielectric band structures of several phases. These band structures are obtained by iterative diagonalization[2] of the dielectric matrix as a function of wave vector and frequency. Even though the superconductivity in lithium is electron-phonon mediated, lithium is a good test system to study the screened e-e interaction more generally, which might be a primary mechanism for the superconductivity in high T_c nitrides of the form MNCl (M=Ti,Zr,Hf).

[2]H.Wilson, F.Gygi and G.Galli, Phys. Rev. B, 78,113303 (2008); Hugh F. Wilson, Deyu Lu, Francois Gygi Phys. Rev. B. 79, 245106 (2009).

2:54PM L23.00003 An investigation of non-superconducting PuPt2In7 , HAHNBIDT RHEE, WARREN PICKETT, UC Davis, Dept of Physics, FILIP RONNING, Los Alamos National Lab, MPA-CMMS, JIAN-XIN ZHU, Los Alamos National Lab, Theoretical Division, ERIC BAUER, Los Alamos National Lab, MPA-CMMS — $PuPt_2In_7$, like the heavy-fermion 115s, is member of a family of systems that are made up of RM_3 (R=Ce, Pu, ...; M=In, Ga, ...) building blocks. Superconductivity is observed in many of these materials, and it is understood to arise from an unconventional pairing mechanism due to antiferromagnetic spin fluctuations. Experiments discover that $PuPt_2In_7$, however, is an enhanced Pauli paramagnet with a Sommerfeld coefficient of $\sim$250 mJ/mol K^2. Here we present a DFT (Density Functional Theory) study of its electronic structure, with direct comparisons made to superconducting $PuCoGa_5$ and $PuCoIn_5$. Fermi surfaces, orbital decomposition of density of states, and band structures reveal many similarities between the two compounds. Our goal is to understand why we observe superconductivity in one but not the other.

3:06PM L23.00004 Why positive hole carriers and negatively charged planes are conducive to high temperature superconductivity , J.E. HIRSCH, University of California San Diego — The vast majority of superconducting materials have positive Hall coefficient in the normal state, indicating that hole carriers dominate the normal state transport. This was noticed even before BCS theory, and has been amply confirmed by materials found since then: the sign of the Hall coefficient is the strongest normal state predictor of superconductivity. In the superconducting state instead, superfluid carriers are always electron-like, i.e. negative, as indicated by the fact that the magnetic field generated by rotating superconductors is always parallel, never antiparallel, to the body's angular momentum ("London moment"). BCS theory ignores these facts. In contrast, the theory of hole superconductivity, developed over the past 20 years (papers listed in http://physics.ucsd.edu/∼jorge/hole.html) makes charge asymmetry the centerpiece of the action. The Coulomb repulsion between holes is shown to be smaller than that between electrons, thus favoring pairing of holes, and this fundamental electron-hole asymmetry is largest in materials where the conducting structures have *excess negative charge*, as is the case in the cuprates, arsenides and MgB_2. Charge asymmetry implies that superconductivity is driven by lowering of kinetic energy, associated with expansion of the carrier wavefunction and with *expulsion of negative charge* from the interior to the surface of the material, where it carries the Meissner current. This results in a macroscopic electric field (pointing outward) in the interior of superconductors, and a macroscopic spin current flowing near the surface in the absence of external fields, a kind of macroscopic zero point motion of the superfluid (spin Meissner effect). London's electrodynamic equations are modified in a natural way to describe this physics. It is pointed out that a dynamical explanation of the Meissner effect *requires* radial outflow of charge in the transition to superconductivity, as predicted by this theory and not predicted by BCS. The theory provides clear guidelines regarding where new higher T_c superconductors will and will not be found.

3:42PM L23.00005 The Possibility of Phonon-Mediated Superconductivity in an Iron-Based Material , SHEENA SHAH, ELENA ROXANA MARGINE, ALEKSEY KOLMOGOROV, University of Oxford — We have identified a synthesizable candidate FeB4 material with a potential for conventional superconductivity at 15-20 K [1,2]. The strong electron-phonon coupling in the proposed material is unexpected as the recently discovered iron-based superconductors are considered to display an unconventional pairing mechanism. The new nonmagnetic ground state crystal structure has been predicted with an ab initio evolutionary search [3] and shown to be marginally stable at ambient pressures.

3:54PM L23.00006 A DFT (LDA+U) study of the electronic properties of layered, square-planar coordinated, copper monoxide structures , PAUL M. GRANT, IBM Research Staff Member Emeritus, San Jose, CA 95120 USA — It is now 25 years and two months since Georg Bednorz observed the onset of high temperature superconductivity in copper oxide perovskites, and yet today its origin remains still largely unresolved. However, it quickly became evident the phenomenon was restricted to those structures possessing a common feature – square planar coordinated "sheets," or "layers" of copper monoxide, and thus now thought to be essential to effect superconductivity in this family of materials. We examine the structural stability and electronic properties of these 2D approximations to the layered CuO compounds as a function of Hubbard U within the DFT (LDA+U) framework, especially for those particular values yielding metallic band formation, and their subsequent fermiology and electron/hole-phonon coupling properties. Although such particular 2D embodiments do not, as yet, exist, we consider their study via DFT as valuable proxies[1] to aid eventual understanding of that flavor of superconductivity revealed by the Bednorz-Mueller breakthrough.

[1]P. M. Grant, Journal of Physics: Conference Series **129** (2008) 012042.

4:06PM L23.00007 Design Algorithms for Novel High Temperature Superconductors[1] , O. PAUL ISIKAKU-IRONKWE, The Center for Superconductivity Technologies(TCST), EMEKA OGUZIE, UKO OFE, TCST — A grand challenge in superconductivity is to develop a "materials specific" theory that enables us to design superconductors from the Periodic Table. Using the Periodic Table properties of electronegativity, valence electrons, formula weight and atomic number, we have been able to quantitatively describe all superconductors in terms of those parameters. We have observed specific correlations with various families of superconductors that enable us to reverse engineer those superconductors. We have developed simple equations, maps and algorithms that facilitate the design of superconductors and predict their approximate transition temperatures. Our design method does not employ density functional theory, even though DFT can be used to verify it. In this paper, we provide many examples of predicted "materials specific" novel high temperature superconductors that should test the authenticity of our design algorithms. We also propose a design for possible room temperature superconductivity.

4:18PM L23.00008 Ionic Plasma Screening and Long-Range Electron Correlations in Quasi-One-Dimensional Conductors[1] , YURI GARTSTEIN, ANVAR ZAKHIDOV, University of Texas at Dallas — In quasi-one-dimensional systems with the intercalation-type doping, the dynamical response of dopant ions can substantially affect the interplay of density-wave and superconducting instabilities. We study a generic model of the system of Coulombically coupled Luttinger-liquid chains modified by the Coulomb interaction with displacements of dopant ions. Our interest is in the macroscopic, long wave-length, effects of the ionic response. This three-dimensional electron-ion model system is exactly solvable in the forward-scattering channel allowing us to find the resulting system excitations and electron correlations. For a jellium-like ion response, the effect of the bare electron-electron repulsion on the long- range correlations is essentially canceled by the ions with the effective electron-electron interactions now exhibiting regions of shorter-range repulsion and longer-range attraction. This picture is clarified and reproduced within the macroscopic dielectric function framework. If the system also features a non-polarizational interaction with another optical phonon mode, superconducting correlations are developed already due to the forward-scattering only.

4:30PM L23.00009 Phase transitions in a three dimensional $U(1) \times U(1)$ lattice London superconductor: Metallic superfluid and charge-4e superconducting states[1] , EGIL HERLAND, Norwegian University of Science and Technology, EGOR BABAEV, Amherst University, ASLE SUDBO, Norwegian University of Science and Technology — We consider a three-dimensional lattice $U(1)\times U(1)$ and $[U(1)]^N$ superconductors in the London limit, with individually conserved condensates. The $U(1)\times U(1)$ problem, generically, has two types of intercomponent interactions of different characters. First, the condensates are interacting via a minimal coupling to the same fluctuating gauge field. A second type of coupling is the direct dissipationless drag represented by a local intercomponent current-current coupling. We study phase transitions and two types of competing paired phases which occur: (i) a metallic superfluid phase, (ii) a composite superconducting phase where there is order in the phase sum of the order parameters which has many properties of a single-component superconductor but with a doubled value of electric charge.

4:42PM L23.00010 Exact calculations of phase separation instabilities and pairing in two-dimensional Betts nanoclusters , ARMEN KOCHARIAN, Department of Physics, California State University, Los Angeles, GAYANATH FERNANDO, KUN FANG, Department of Physics, University of Connecticut, Storrs — The energy eigenvalues and eigenstates of the Hubbard model with nearest and next nearest neighbor hoppings are calculated by exact diagonalization and Lanczos (algorithm) techniques in isotropic Betts nanoclusters with the square symmetry and periodic boundary conditions. The electron pairing instabilities and quantum critical points for one hole off half filling are evaluated by monitoring the charge and spin pairing gaps and level crossings instabilities in the ground state and at finite temperatures. The calculated spin and charge energy gaps and quantum critical points in optimized 8 and 10 site Betts clusters of square symmetry pertain universal critical behavior and are fully consistent with the exact results obtained for an "elementary" bipartite square geometry [Kocharian et al., Phys. Rev. B 78, 075431 (2008)]. We found the strong particle-hole assymetry effect in the electron pairing instability due to the presence of the next nearest neighbor hopping term. Correlated lectrons in various contrasting bipartite and non-bipartite two- and three- dimensional cluster topologies display a number of inhomogeneous, coherent and non-coherent nanoscale phases seen by scanning tunneling microscopy in high Tc cuprates, iron pnictides, manganites, etc.

4:54PM L23.00011 Electromagnetic Interactions between Electrons moving in the Layered Conductors with a Dielectric Interlayer , KENJI TANAHASHI, Hokkaido Institute of Technology — Electromagnetic interactions between two electrons moving in the two layered conductors separated with a dielectric interlayer have been estimated. We assume a simple situation in which the two electrons in the layered conductors move with the constant velocity in the same direction. The electric and magnetic fields of a moving electron are derived from the scalar and the vector potentials in the non-relativistic frame. The total electromagnetic force exerted between two electrons is obtained by the Lorentz expression, and the force depends on the velocity of the moving electrons. With increasing the velocity of the electrons, the magnetic force increases and the magnetic attractive force exceeds the electric repulsive force, when $v/c \geq 1/\sqrt{\varepsilon_r \mu_r}$, where v is the velocity of the two electrons moving parallel in the same direction, c is the speed of light, andε_r is the relative dielectric constant in the direction of the perpendicular to the plane of the layers, andμ_r is the in-plane permittivity of the conduction layers. In vacuum the magnetic interaction between moving electrons never surpasses the electric interaction. However, in the highly anisotropic structures in conductivity, the magnetic interaction between moving electrons should be taken into consideration to investigate the behavior of the electrons.

5:06PM L23.00012 Electrodynamics of Nearly Ferroelectric Superconductors in the non-local Pippard limit[1] , UPALI APARAJITA, City College, CUNY and Queensborough Community College, CUNY, JOSEPH BIRMAN, City College, CUNY — We report the structure of the magnetic field and secular current in a Nearly Ferroelectric Superconducting (NFE-SC) thin film. It was shown that unlike in conventional superconducting films, the external radiation causes alternating pattern of current strips. The strength of the innermost current torrents is governed by the laser field intensity as well as resonance with the ferroelectric component. The latter is modeled by secular reflection and random scattering in the Pippard non-local limit. Our calculations suggest that corresponding magnetic field pattern affects vortex formation in such material.

[1]We acknowlege support from FRAP-PSC-CUNY.

5:18PM L23.00013 Planar-coordinated nickelates, isoelectronic to overdoped cuprates: an LDA+DMFT comparison , CHUCK-HOU YEE, GABRIEL KOTLIAR, KRISTJAN HAULE, Rutgers University — We show the Ni-O planes in the bilayer and trilayer T'-type nickelates, recently synthesized by Poltavets, *et al.* [1], are electronically analogous to the Cu-O planes in overdoped superconducting cuprates. The density of states, Fermi surface, nickel valence and mass renormalization, computed using LDA+DMFT, are in good agreement with available experiment, and indicate that the compounds are well-described by multilayer Hubbard physics. Significant interlayer coupling generates bonding-antibonding Fermi surfaces, similar to those seen in the cuprates. We investigate the possibility that interlayer coupling can explain the presence of a phase transition with $R \log 2$ entropy in the trilayer, and the absence of such a transition in the bilayer.

Session L24 DCOMP: Focus Session: Quantum Transport Simulations and Computational Electronics – GNRs and QDs D167

2:30PM L24.00001 Numerical simulation of time-dependent transport in graphene , DHARMENDAR REDDY, PRIYAMVADA JADAUN, LEONARD F. REGISTER, SANJAY K. BANERJEE, The University of Texas at Austin — We present a numerical method for modeling time-dependent quantum transport in graphene. The time-dependent Schrodinger equation is solved with a pi-orbital-based atomistic tight-binding Hamiltonian. A novel variation of an alternating-direction semi-implicit scheme is employed on the hexagonal tight-binding lattice to maintain stability and conserve probability while achieving computational efficiency. Open boundaries including source terms to allow time-dependent non-equilibrium Green's function (NEGF) calculation of graphene devices will be discussed.

2:42PM L24.00002 ABSTRACT WITHDRAWN –

2:54PM L24.00003 Current-Voltage Characteristics of Graphane Nanoribbon Transistors[1] , JUN-QIANG LU, DANIEL VALENCIA, University of Puerto Rico at Mayaguez — Using first-principles transport calculations, we investigate current-voltage characteristics of transistors made by graphane nanoribbons (or hydrogenated graphene nanoribbons). Our results show that transistors made by graphane nanoribbons can achieve better performance than those made by graphene nanoribbons because of the intrinsic large band gap presented in graphane.

[1]JQL acknowledges start-up support from the Institute for Functional Nanomaterials, University of Puerto Rico.

3:06PM L24.00004 Switching Behavior of Carbon Chains Bridging Graphene Nanoribbons: Effects of Uniaxial Strain , BRAHIM AKDIM, RUTH PACHTER, Air Force Research Lab — Recently, several experiments [1,2] demonstrated the stability of chain-like carbon nanowires bridged between graphene nanoribbons, paving the way for potential applications in nano-devices. On the basis of density functional tight-binding calculations, we demonstrated switching for chains terminated with a five-membered ring under an applied strain, serving as a model for morphological changes in realistic materials. Electron transport calculations showed an increase of up to 100% in the output current, achieved at a reverse bias-voltage of 2V and an applied strain of just 1.5%. Structural analysis suggested that the switching is driven by conformational changes, in our case triggered by the formation and annihilation of a five-membered ring at the interface of the chain-graphene edge. In addition, we showed that a five-membered ring can easily be formed at the interface under a source-drain bias or through a gate voltage. This mechanism can serve as an explanation of experimentally observed conductance for the materials.

3:18PM L24.00005 Giant Mechanoelectrical Switching in Ferromagnetic Graphene Nanoribbons , HONG LI, RUI QIN, JING ZHOU, QIHANG LIU, ZHENGXIANG GAO, JING LU, State Key Laboratory of Mesoscopic Physics and Department of Physics, Peking University, Beijing 100871, P. R. China, WAI-NING MEI, R.F. SABIRIANOV, Department of Physics, University of Nebraska at Omaha, Omaha, Nebraska 68182-0266, USA — Giant mechanoelectrical effect is observed when twisting a ferromagnetic zigzag-edged graphene nanoribbon (ZGNR) with collinear spin configuration from ab initio quantum transport calculations. The resulting switch ratio is up to 10^{10}% when the ZGNRs are overturned once and can be even enhanced to over 10^{14}% via multiply overturnings. We find such a switch equivalent to a spin valve without resort to an external magnetic field. Furthermore, consideration under Noncollinear situation is aslo in progress.

3:30PM L24.00006 Transport in Carbon Nanotubes: 2LSU(2) regime reveals subtle competition between Kondo and Intermediate Valence states , G. MARTINS, C. BUSSER, E. VERNEK, P. ORELLANA, G. LARA, E. KIM, A. FEIGUIN, E. ANDA — Three different numerical techniques are used to study the two-level SU(2) regime, obtained from an SU(4) Hamiltonian by orbital mixing via coupling to the leads. SU(4) Kondo physics has been experimentally observed, and studied in detail, in Carbon Nanotube Quantum Dots. Adopting a two molecular orbital basis, the Hamiltonian is rewritten, such that one of the molecular orbitals decouples from the charge reservoir, although still interacting capacitively with the other molecular orbital. This basis transformation explains in a clear way how the charge transport in this system turns from double- to single-channel when it transitions from the SU(4) to the 2LSU2 regime. The charge occupancy of these molecular orbitals displays gate-potential-dependent occupancy oscillations that arise from a competition between the Kondo and Intermediate Valence (IV) states. The determination of whether the Kondo or the IV state is more favorable, for a specific value of gate potential, is assessed by the definition of an energy scale T_0, which is calculated through DMRG. We speculate that the calculation of T_0 may provide experimentalists with a useful tool to analyze correlated charge transport in many other systems. For that, a current work is underway to improve the numerical accuracy of its DRMG calculation and explore different definitions.

3:42PM L24.00007 Scattering matrix approaches for dissipative quantum transport , DAVID FERRY, Arizona State University — The Usuki method, which is closely related to both the scattering matrix approach and recursive Green's functions provides a stable numberical method for the simulation of quantum transport in semiconductors. It has major advantage over the Green's function method for self-consistent simlations in that the electron density involves integrals in the contacts where the distribution is near equilibrium, rather than throughout the active area. Various applications of this approach have been studied, and we discuss primarily ballistic transport in quantum dots and dissipative transport in gated quantum wire transistors. Dissipation is introduced via a proper self-energy determined in the mode representation, which is then transformed to the site representation used in the recursive approach.

4:18PM L24.00008 Electron hopping between Wurtzite CdSe Quantum Dots Linked by Molecules[1] , IEK-HENG CHU, Dept of Physics and QTP, Univ of Florida, MARINA RADULASKI, Dept of Physics, Univ of Belgrade, Serbia, NENAD VUKMIROVIC, Lawrence Berkeley National Lab, HAI-PING CHENG, Dept of Physics and QTP, Univ of Florida, LIN-WANG WANG, Lawrence Berkeley National Lab — Recent experimental results show that the transport properties of quantum dot (QD) arrays will be tremendously improved after attached by cross-linking molecules. Here, we present an *ab initio* study on the electron hopping rates between wurtzite CdSe QDs connected by Sn_2S_6 molecules. The conduction band minima (CBM) transports among connected QDs are calculated. The charge patching method (CPM) is used to construct the charge density of the QDs and the connected systems. The folded spectrum method (FSM) was applied to find the band edge states and the electronic coupling between the neighboring QDs. Electron-phonon couplings are calculated to yield the reorganization energy. The electron hopping rate is then calculated by Marcus theory and its corresponding quantum treatments. Hopping rates for three different sizes of QDs, and two different types of molecular attachments are also presented here for comparison.

[1]Supported by DOE/BES-DE-FG02-02ER45995, DOE/BES-DE-AC02-05CH11231 and NSF/DMR-0804407, and computers from NERSC.

4:30PM L24.00009 Coulomb Drag in Open Quantum Dots[1] , CANRAN XU, MAXIM VAVILOV, University of Wisconsin - Madison — We investigate the Coulomb drag effect in a system of two open quantum dots, in the presence of interdot and intradot Coulomb interactions. We present an analytical expression for the drag current at the low temperature limit obtained in the random-phase approximation. We show that the non-zero current arises from the asymmetry of electronic states with respect to the Fermi level. This asymmetry originates due to fluctuations of the transmission amplitudes in the chaotic quantum dots described by a random-matrix theory, and therefore the drag current exhibits interesting sample-to-sample mesoscopic fluctuations.

[1]Supported by NSF Grant No. DMR-0955500 and Petroleum Research Fund

4:42PM L24.00010 Nonequilibrium quantum many-body transport in multiple lead quantum dot devices[1] , JONG HAN, SUNY at Buffalo — Recently proposed imaginary-time formalism of steady-state nonequilibrium is extended to three reservoir systems and discuss their interference effects. We first consider a quantum dot coupled to three non-interacting leads in the context of the Anderson impurity model driven by source-drain bias. We discuss the difference between the two and three reservoir systems. We then consider the system of interacting leads, used as a prototype for two-channel Kondo model in quantum dot device.[2] We rewrite the charging interaction on the large dot via a gauge transformation to a correlated tunneling and perform quantum Monte Carlo simulation for equilibrium and nonequilibrium using the Matsubara-voltage formalism. We discuss the cross-over from local Fermi liquid to non-Fermi liquid as a function of the Coulomb parameter in the large dot in the electron self-energy and the magnetic susceptibility. We discuss the nonequilibrium spectral evolution of local Fermi liquid.

4:54PM L24.00011 Continuous measurements of electron tunneling through a quantum dot by a quantum point contact , HSI-SHENG GOAN, National Taiwan University — The time-resolved charge detection through a quantum dot (QD) by a nearby quantum point contact (QPC) detector, each coupled to its own independent electrodes and gates, has been demonstrated. The conditional counting statistics of electron transport in this QD-OPC system has also been measured [1]. The conditional counting statistics that is the statistical current fluctuations of one system given the observation of a particular current in the other system could be substantially different from their unconditional counterparts. We provide a thorough analysis on the QD-QPC system. We use the stochastic master equation (or quantum trajectory) approach to describe the conditional dynamics of the QD under continuous measurements by a QPC. We simulate in each single experimental realization the observed QPC current which reveals the real time information of single-electron tunneling events through the QD. We then use the n-resolved master equation approach to calculate the conditional counting statistics through the QD (QPC) conditioned on the observed current in QPC (QD). Our investigation goes beyond the analysis presented in Ref.[1] in which they neglected, in the noise power(second cumulant) of the QPC, the QPC shot noise as compared to the telegraph noise contribution induced by the single-electron tunneling events through the QD.

5:06PM L24.00012 Designer switches: Effect of contact geometry on the transient current of a strongly correlated quantum dot[1] , ALI IHSAN GOKER, Bilecik University, ZHIYONG ZHU, UDO SCHWINGENSCHLOGL, AURELIEN MANCHON, King Abdullah University of Science and Technology — The time-dependent non-crossing approximation is utilized to investigate the influence of the geometry of contacts made of gold on time dependent current through a quantum dot suddenly shifted into the Kondo regime via a gate voltage. For an asymmetrically coupled system, instantaneous conductance exhibits complex fluctuations. We identify the frequencies participating in these fluctuations and they turn out to be proportional to the separation between the sharp features in the density of states and the Fermi level. Increasing ambient temperature or bias quenches the amplitude of these fluctuations. This suggests that the interference between the emerging Kondo resonance and the van Hove singularities in the density of states is the underlying microscopic mechanism for these fluctuations. Based on these observations, we predict that using different electrode geometries would give rise to drastically different transient currents which can be accessed with state-of-the-art ultrafast pump-probe techniques.

Tuesday, March 22, 2011 2:30PM - 4:54PM –
Session L25 DCMP: Superconductivity: Vortex Phenomena II D166

2:30PM L25.00001 Vortex Pinning in MoGe Thin Films Containing Periodic Hole Arrays , MICHAEL LATIMER, Northern Illinois University, ZHILI XIAO, WAI-KWONG KWOK, ALEXANDRA JOSHI-IMRE, Argonne National Laboratory, CASTRO ABUGHAYADA, Northern Illinois University — Resistivity measurements on MoGe thin films containing periodic hole arrays were carried out to study the effects of the lattice symmetry and the size of the pinning centers. Thin films of MoGe were prepared with holes drilled using focused-ion-beam milling to create pinning sites for the vortex lattice. We investigate periodic arrays with hexagonal, square and triangular geometry to determine the change in transport properties with varying magnetic fields. Hole sizes from 50nm to 100nm were tested determine the effects of single and multiple vortices in a single pinning site.

2:42PM L25.00002 Flux dynamics across MoGe bridges in the parallel field orientation[1] , MILIND KUNCHUR, MANLAI LIANG, University of South Carolina, ALEXANDER GUREVICH, Florida State University — We have investigated flux motion in amorphous molybdenum-germanium (MoGe) film bridges with the magnetic field B parallel to the film plane but perpendicular to the current direction. In a temperature range close to the transition temperature Tc we observe an exponential dependence of the Ohmic resistance R on B at low values of the current I, and a nonlinear R(I) at higher currents. In this regime, the diameter of the vortex is approximately equal to the film thickness and the applied magnetic field is comparable to the lower critical field for the parallel field orientation. Dissipation presumably occurs by thermally activated flux jumps over the thickness of the film involving nucleation and expansion of vortex kinks.

[1]This work was supported by the U. S. Department of Energy under Grant No. DE-FG02-99ER45763.

2:54PM L25.00003 Vortex instability in molybdenum-germanium superconducting film[1] , MANLAI LIANG, MILIND KUNCHUR, University of South Carolina — We studied the high driving force regime of the current-voltage transport response in the mixed state of amorphous molybdenum-germanium (MoGe) superconducting films to the point where the flux flow becomes unstable. The observed nonlinear response conforms with the classic Larkin-Ovchinikov picture with a quasiparticle energy-relaxation rate dominated by the quasiparticle recombination process. The measured energy relaxation rate was found to have a magnitude and temperature dependence in agreement with theory.

[1]This work was supported by the U. S. Department of Energy under Grant No. DE-FG02-99ER45763.

3:06PM L25.00004 Small Angle Neutron Scattering Studies of the Vortex Lattice in $CeCoIn_5$ with $H \perp c$, M.R. ESKILDSEN, P. DAS, University of Notre Dame, IN, USA, A.T. HOLMES, E.M. FORGAN, University of Birmingham, UK, A.D. BIANCHI, Universite de Montreal, Canada, J.S. WHITE, S. GERBER, M. KENZELMANN, J.L. GAVILANO, M. ZOLLIKER, Paul Scherrer Institute, Switzerland, C. WANG, E.D. BAUER, J.L. SARRAO, Los Alamos Natl. Lab., NM, USA, C. PETROVIC, Brookhaven Natl. Lab., NY, USA — We report on small-angle neutron scattering measurements on the vortex lattice (VL) in the mixed state of $CeCoIn_5$ with the magnetic field (H) along [100] and [110]. For both field orientations a distorted hexagonal VL is observed, reflecting the penetration depth anisotropy of the screening current plane. With $H \parallel [100]$ the VL is oriented with Bragg reflections along the [001]-axis at all fields. For $H \parallel [110]$ the same VL orientation is observed at low fields, followed by a 90° first-order reorientation transition as H is increased. We attribute this behavior to Fermi surface anisotropy coupled with non-local effects. For $H \parallel [100]$ we obtain the field dependence of the form factor ($|F|^2$) both within (50 mK) and outside (350 mK) the magnetic Q-phase. At both temperatures $|F|^2$ varies with H in a manner similar to $H \parallel [001]$ [J.S. White *et al.*. New J. Phys. **12**, 023026 (2010)], due to the competition between Pauli paramagnetism and the antiparallel spin alignment of d-wave pairing giving rise to "magnetized" VL cores.

3:18PM L25.00005 Low temperature enhancement of the remanent magnetization in $CeCoIn_5$, C.F. MICLEA, Los Alamos National Laboratory, Los Almos, USA, M. NICKLAS, A.C. MOTA, F. STEGLICH, Max-Planck-Inst. for Chemical Physics of Solids, Dresden, Germany, M.M. ALTARAWNEH, N. HARRISON, Los Alamos National Laboratory, Los Almos, USA, I. VEKHTER, Louisiana State Univ., Baton Rouge, USA, J.D. THOMPSON, R. MOVSHOVICH, Los Alamos National Laboratory, Los Alamos, USA — We investigated the vortex dynamics together with RF penetration depth measurements in the heavy fermions compound $CeCoIn_5$ down to 50 mK. No strong pining is observed and the relaxation curves are logarithmic as expected from Kim-Anderson theory. The temperature dependence of the relaxation rate, S, with a small but finite residual value indicate that quantum tunneling plays a role in the vortex creep only at very low temperatures. Remarkably, a new phase transition marked by a strong increase in the remnant magnetization, M_{rem} is observed around $T = 0.3$ K in very low magnetic fields. M_{rem} increases roughly by a factor of two at 50 mK and we discuss if this can be caused solely by the change in the vortex lattice symmetry or underling magnetism has to play a role. Moreover, this anomaly is corroborated by the RF measurements at very low fields. We extended the vortex dynamics investigation to Pb irradiated $CeCoIn_5$. While the defects created by irradiation have a clear effect on the relaxation rates the enhancement of M_{rem} still takes place at the same temperature.

3:30PM L25.00006 Vortex Core Size Measurements in YNi_2B_2C and $TmNi_2B_2C$, P. DAS, C. RASTOVSKI, K. SCHLESINGER, M.R. ESKILDSEN, University of Notre Dame, IN, USA, J.M. DENSMORE, Army Research Laboratory, Aberdeen, MD, USA, S.L. BUD'KO, P.C. CANFIELD, Ames Laboratory and Iowa State University, IA, USA — The vortex core size in type-II superconductors is typically determined from measurements of a related quantity combined with a theoretical model, with the best known example being the upper critical field and the GL-result: $\xi = \sqrt{\phi_0/2\pi H_{c2}}$. However, for many non-conventional superconductors such an approach is problematic, as for example in the case of $TmNi_2B_2C$ and $CeCoIn_5$ where H_{c2} is suppressed by coexistence with magnetism. In such instances a direct, model independent determination of the vortex core is desirable, and can be obtained by small-angle neutron scattering (SANS) measurements of the vortex lattice (VL) if a sufficient number of reflections are recorded [J. M. Densmore *et al.*, Phys. Rev. B **79**, 174522 (2009)]. Here we report on VL SANS studies on two members of the borocarbide superconductors, YNi_2B_2C and $TmNi_2B_2C$. Non-magnetic Y1221 measurements at 0.2 and 0.5 T show clear evidence of a vortex squeezing effect. In magnetic Tm1221 the vortex core size was found to be $\xi = 10.8$ nm, roughly a factor of two smaller than the value estimated by the measured H_{c2} (21 nm). Supported by NSF award no. DMR-0804887 (Notre Dame) and DOE BES contract No. DE-AC02-07CH11358 (Ames).

3:42PM L25.00007 ABSTRACT WITHDRAWN –

3:54PM L25.00008 Revealing the effect of edge contamination on vortex matter structure in a Nb single crystal with neutron diffraction techniques[1] , HELEN HANSON, XI WANG, MICHAEL LUK, JING SHI[2], XINSHENG LING, Brown University, BRIAN MARANVILLE, CHARLES MAJKRZAK, NIST Center for Neutron Research — The vortex matter of type II superconductors provides a model system to study the effect of quenched random disorder on an elastic lattice, particularly in the framework of Bragg glass theory. Neutron scattering techniques are used to examine the structure of the vortex matter and to quantify the phase diagram. After measuring various thermal-magnetic histories, our data provided evidence for the edge contamination model in a Nb single crystal. Since surface oxidation is known to suppress the Bean-Livingston Surface barrier and the inhomogeneous distribution of surface impurities in Nb, we oxidize our sample surface and repeat our measurements. By comparing the data, we are able isolate the dynamic impact of the edge disorder from the static influence of bulk pinning. We discuss the various experimental obstacles in measuring the predicted Bragg glass state. We also report on Reverse Monte Carlo Refinement simulations modeling possible structures of our vortex matter.

[1]This research was supported by the U.S. DOE under grant DE-FG02 – 07ER46458.
[2]Permenant Address: Wuhan University

4:06PM L25.00009 Exploring the vertical variation of the flux line lattice angular orientation using a novel neutron diffraction technique[1] , XI WANG, HELEN HANSON, JING SHI[2], XINSHENG LING, Brown University, BRIAN MARANVILLE, CHARLES MAJKRZAK, NIST, MARK LAVER, PSI, UWE KEIDERLING, MARGARITA RUSSINA, HZB — We use a slicing neutron diffraction technique, employing neutron reflectometry collimation, to study the orientational order of the flux line lattice in a Nb single crystal. We are able to reveal the spatial variation of the different orientation distributions along the length of the flux lines. The results are strongly dependent on the magnetic history of the vortex matter, suggesting various interactions with the disorder in the system. After thermally annealing the different initial states, memory of the growth procedure is removed from the data and a possible ground state is reached. In this final state, the novel vertical slicing reveals the persistence of a domain splitting. We suggest that this domain splitting is due to the quenched disorder in the underlying Nb atomic lattice. We believe that this new insight will be instrumental in growing a true Bragg glass, the theoretically predicted ground state with topological order.

[1]This research is supported by the US DOE under the grant DE-FG02 - 07ER46458.
[2]Permanent address:Wuhan University, Wuhan 430072, PRC

4:18PM L25.00010 Vortex activation energy in high-Tc superconductors from transport measurements: new systematics[1] , YURI L. ZUEV, JOHN SINCLAIR, JAMES R. THOMPSON, University of Tennessee, SUNG HUN WEE, CLAUDIA CANTONI, DAVID K. CHRISTEN, Oak Ridge National Laboratory — From electrical transport measurements on thin films of YBCO with and without nano-precipitate "columnar defects," we extract information about the activation energy for vortex creep. We also obtain new scaling between temperature, critical current density J_C, and the power law index n describing the voltage-current relation $V \propto I^n$. This scaling occurs in the range of field and temperature where J_C decays as a power-law of magnetic field. In this regime the n-value can unexpectedly increase as applied field increases. We will discuss implications of these observations and compare systems with and without such scaling.

[1]Work at ORNL supported by the US DOE.

4:30PM L25.00011 Comparison of free flux flow in two single crystals of V_3Si with slightly different pinning strengths[1] , OZARFAR GAFAROV, ALBERT A. GAPUD, SUNHEE MORAES, University of South Alabama, JAMES R. THOMPSON, University of Tennessee Knoxville and Oak Ridge National Laboratory, DAVID K. CHRISTEN, Oak Ridge National Laboratory, ARNEIL P. REYES, National High Magnetic Field Laboratory — Results of recent measurements on two very clean, single-crystal samples of the A15 superconductor V_3Si are presented. Magnetization and transport data confirm the "clean" quality of both samples, as manifested by: (i) high residual resistivity ratio, (ii) low critical current densities, and (iii) a "peak" effect in the field dependence of critical current. The (H,T) phase line for this peak effect is shifted in the slightly "dirtier" sample, which also has higher critical current density J_c(H). High-current Lorentz forces are applied on mixed-state vortices in order to induce the highly ordered free flux flow (FFF) phase, using the same methods as in previous work. A traditional model by Bardeen and Stephen (BS) predicts a simple field dependence of flux flow resistivity ρ_f(H), presuming a field-independent flux core size. A model by Kogan and Zelezhina (KZ) takes core size into account, and predicts a deviation from BS. In this study, ρ_f(H) is confirmed to be consistent with predictions of KZ, as will be discussed.

4:42PM L25.00012 Magnetic-field-induced stripe order and a 2D vortex glass phase in $La_{1.905}Ba_{0.095}CuO_4$[1] , JOHN TRANQUADA, JINSHENG WEN, QING JIE, SU JUNG HAN, QIANG LI, MARKUS HUECKER, ZHIJUN XU, LIYUAN ZHANG, GENDA GU, Brookhaven Natl Lab, M.V. ZIMMERMANN, HASYLAB, D.K. SINGH, NCNR — We have measured the resistivity parallel and perpendicular to the CuO_2 planes in $La_{1.905}Ba_{0.095}CuO_4$ ($T_c = 32$ K) as a function of perpendicular magnetic field. We have discovered a significant regime of field and temperature where the perpendicular resistivity is finite (and large) but the parallel resistivity is zero. This regime appears to correspond to a quasi-two-dimensional vortex glass phase, a state that theory predicts cannot exist at finite temperature. It seems to be stabilized by field-induced charge and spin stripe order, which we have detected with x-ray and neutron diffraction, respectively.

Tuesday, March 22, 2011 2:30PM - 5:30PM –
Session L26 DMP DCOMP: Focus Session: Iron Based Superconductors – ARPES D162/164

2:30PM L26.00001 ABSTRACT WITHDRAWN –

2:42PM L26.00002 Angle-resolved photoemission spectroscopy study of $Ba(Fe_{1-x}Ru_x)_2As_2$, TIAN QIAN, NAN XU, PIERRE RICHARD, YINGBO SHI, GUANGHAN CAO, ZU'AN XU, HONG DING, INSTITUTE OF PHYSICS, CHINESE ACADEMY OF SCIENCES COLLABORATION, ZHEJIANG UNIVERSITY COLLABORATION — Ru-doped $BaFe_2As_2$ compounds were discovered recently to show superconductivity at a relatively wide doping range. We will present angle-resolved photoemission spectroscopy results of electronic structure and Fermi surface of $Ba(Fe_{1-x}Ru_x)_2As_2$, and discuss implications to its superconductivity.

2:54PM L26.00003 Chiral orbital angular momentum and warping effect in topological insulator Bi2Te3 , WON SIG JUNG, Y.K. KWAN, B.Y. KIM, Yonsei University, Seoul, Korea, J.Y. KIM, B.K. CHO, Dept of Materials Science and Engineering, GIST, Korea, C. KIM, Yonsei University, Seoul, Korea — The spin of a topologically protected metallic surface state on topological insulators has a chiral state. The Spin chiral state is aligned with orbital angular momentum of the electron in the surface states. We observe orbital angular momentum direction by using angle resolved photoemission (ARPES) with circularly polarized lights.

3:06PM L26.00004 Pseudogap in non-superconducting pnictides, $CaFe_2As_2$ and $EuFe_2As_2$, K. MAITI, G. ADHIKARY, N. SAHADEV, D.N. BISWAS, R. BINDU, N. KUMAR, A. THAMIZHAVEL, S.K. DHAR, Dept of Condensed Matter Physics and Materials Science, Tata Institute of Fundamental Research, Homi Bhabha Road, Colaba, Mumbai - 400 005, India — Superconductivity in Fe-pnictides are studied extensively recently as they provide a non-cuprate domain to study unconventional superconductivity via doping induced suppression of magnetism. In order to study the role of magnetic interactions in the electronic structure and its implication in superconductivity, we probed the electronic structure of the parent compounds $CaFe_2As_2$ and $EuFe_2As_2$ using high resolution photoemission spectroscopy. Single crystalline samples were prepared by flux method. Photoemission measurements were carried out using a Gammadata Scienta analyzer R4000 and monochromatic photon sources. The high resolution spectra exhibit signature of a pseudogap above the spin density wave (SDW) transition temperature in both $CaFe_2As_2$ and $EuFe_2As_2$. The intensity at the Fermi level show a sudden decrease across the SDW transition indicating more prominent pseudogap. An additional gap opens up in $EuFe_2As_2$ across the antiferromagnetic transition temperature as expected. Interestingly, $CaFe_2As_2$ also exhibit signature of another gap opening at low temperatures although no phase transitions observed in this temperature range.

3:18PM L26.00005 Unconventional superconducting gap in $NaFe_{0.95}Co_{0.05}As$ observed by ARPES , PIERRE RICHARD, Institute of Physics, Chinese Academy of Sciences, Z.-H. LIU, Renmin University, K. NAKAYAMA, Tohoku University, G.-F. CHEN, Renmin University, S. DONG, J.-B. HE, D.-M. WANG, T.-L. XIA, Renmin University, K. UMEZAWA, T. KAWAHARA, S. SOUMA, T. SATO, T. TAKAHASHI, Tohoku University, T. QIAN, Y. HUANG, N. XU, Y. SHI, H. DING, Institute of Physics, Chinese Academy of Sciences, S.-C. WANG, Renmin University — The size, the symmetry and the temperature evolution of the superconducting (SC) gap in a given material are directly related to the SC pairing mechanism. The momentum-resolution capability of angle-resolved photoemission spectroscopy (ARPES) allows precise determination of these key parameters, even for complex multi-band systems such as the iron-based superconductors. We performed an ARPES study of $NaFe_{0.95}Co_{0.05}As$. The fermiology of this electron-doped 111-pnictide is similar to that of other pnictides. Similarly, the measured SC gaps are nearly isotropic and their size indicates that the system is in the strong coupling regime. Surprisingly, the SC gaps show little change upon increasing temperature towards T_c, while coherence vanishes.

3:30PM L26.00006 Studies on the orbital characters and quasi-particle dynamics of LiFeAs , YEONGKWAN KIM, B.Y. KIM, CHUL KIM, D.J. SONG, W.S. KYUNG, C. KIM, Institute of Physics and Applied Physics, Yonsei University, Seoul 120-749, Korea, B.S. LEE, K.H. KIM, FPRD, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea — Since the discovery, iron-based superconductors have been intensively and extensively studied by using various techniques including angle resolved photoelectron spectroscopy (ARPES). So far, most of ARPES studies have been performed on 122-compounds and 1111-compounds. However, 122-phase materials do not have neutral cleavage surfaces and have 3-dimensional band structures. These traits of 122- and 1111-phase make the spectral shape generally broad and do not allow investigation of the intrinsic electronic structures in detail. In that respect, LiFeAs is an ideal material with neutral cleavage surfaces and quasi-2 dimensional band structures. In this presentation, our recent ARPES work on the electronic structure of LiFeAs will be presented. We investigated the orbital character of each band by ARPES with various polarizations of the photon. Since the main valence band of LiFeAs comes from iron d-orbitals, pin-pointing the characters of bands should be an important starting point. In addition, we analyzed details of the spectral function in regard to the quasi-particle dynamics..

4:18PM L26.00008 Nodeless superconductivity in the stoichiometric superconductor LiFeAs , HYUNSOO KIM, MAKARIY A. TANATAR, RUSLAN PROZOROV, Ames Laboratory, Ames, IA 50011, USA, YOO JANG SONG, YONG SEUNG KWON, Department of Physics, Sungkyunkwan University, Suwon, Gyeonggi-Do 440-746, Republic of Korea — The in- and out-of-plane London penetration depths were measured in single crystals of the intrinsic LiFeAs superconductor using a tunnel diode resonator (TDR) down to $0.03T_c$. This compound appears to be in the clean limit with a residual resistivity of $\rho_0 \approx 5$ $\mu\Omega$·cm and $RRR = 65$; it can be placed at a slightly overdoped value when compared to the charge-doped pnictides. The low-temperature region of the penetration depth, which is sensitive to the superconducting gap symmetry, is exponentially flat implying a nodeless gap. The superfluid density is well described by the self-consistent two-gap γ-model, where the larger gap is $\Delta_1/T_c \sim 2$ and the smaller gap is $\Delta_2/T_c \sim 1$. Together with the previous data, our results support the $s_\pm$ symmetry that evolves from nodeless to a nodal gap structure upon departure from optimal doping in Fe-based superconductors. We also conclude that pairbreaking scattering plays an important role in the deviations of the low-temperature behavior from exponential in $\lambda(T)$ of Fe-based compounds.

4:30PM L26.00009 Superfluid Density in the 111 Fe Pnictide Superconductors , C. J. ARGUELLO, T. GOKO, J.P. CARLO, Y.J. UEMURA, Columbia University, A.A. ACZEL, T.J. WILLIAMS, G.M. LUKE, McMaster University, C.Q. JIN, Beijing IoP — We performed muon spin relaxation studies in two kinds of '111' iron pnictides, $Li_{1.1}FeAs$ and $Li_{0.9}FeP$. The zero field spectra of the latter show a fast relaxation in a small volume fraction (approximately 13%) due probably to magnetism. In the case of the arsenide, the zero field spectra show a completely paramagnetic state. Below Tc, an applied transverse field allowed us to measure the superfluid density (via relaxation rate σ) for both compounds. We found that both of them have very high superfluid density and low Tc: $\sigma(T = 2K) \simeq 1.8\mu s^{-1}$ with Tc$\simeq$18K for $Li_{1.1}FeAs$, and $\sigma(T = 2K) \simeq 2.0\mu s^{-1}$ with Tc$\simeq$4K for $Li_{0.9}FeP$.

4:42PM L26.00010 Spin lattice relaxation rate measurements in $Ba_{0.69}K_{0.31}Fe_2As_2$ by nuclear magnetic resonance[1] , SANGWON OH, ANDREW MOUNCE, WILLIAM HALPERIN, Northwestern University, CHENGLIN ZHANG, PENGCHENG DAI, University of Tennessee, ARNEIL REYES, PHILIL KUHNS, National High Magnetic Field Lab — Magnetic impurities have been a problem with NMR measurements of single crystals in the K doped Ba-122 system because of extremely wide linewidth that can be more than 1MHz at low temperature [1]. We have a high quality single crystal of $Ba_{0.69}K_{0.31}Fe_2As_2$ (T_c = 34K) for which the NMR linewidth does not significantly increase at low temperatures and at very large external magnetic fields. In this sample we measure the spin-lattice relaxation rate, $1/T_1$, from 300 K to 4 K at various magnetic fields 6.4 T, 13 T, and 16 T. The rapid increase of $1/T_1T$ down to T_c on cooling can be attributed to spin fluctuations above T_c. In the superconducting state, $1/T_1$ has a kink around 20 K, and below this temperature in a field of 13 T it exhibits a power law dependence, \varpropto T^3. This behavior can be explained by an impurity effect in a superconductor with extended s-wave symmetry [2].

4:54PM L26.00011 Frustrated proximity effects between s and $s_\pm$ superconductors , VALENTIN STANEV, ALEXEI E. KOSHELEV, Materials Science Division, Argonne National Laboratory — The nature of the superconducting order parameter (OP) in iron pnictides and chalcogenides is a hotly debated issue. It was theoretically proposed that the OP has opposite signs on the hole and the electron bands, i.e., it belongs to the unconventional class of $s_\pm$ (or extended s)-wave. There are, however, very few experiments that can directly distinguish this state from the ordinary s-wave OP. One way to address this problem is to study the proximity effects in a sandwich composed of conventional and iron pnictide superconductors (SC). If the pnictides indeed have the $s_\pm$ OP this system is intrinsically frustrated. In the case of strong frustration, a time-reversal symmetry-breaking (TRSB) SC state emerges, in which the OP phases in different bands are tilted at an angle, different from π, and controlled by the coupling strength. Observation of such state in the iron-based SC materials would give definite evidence for the $s_\pm$ OP. We present a microscopic, fully self-consistent approach to this problem, based on Usadel equations. We have studied the conditions for existence of the TRSB state and its experimental signatures.

5:06PM L26.00012 Doping dependence of $Ba(Fe_{1-x}Co_x)_2As_2$ thin films by the THz conductivity measurement , D. NAKAMURA, F. NABESHIMA, Y. IMAI, A. MAEDA, Dept. of Basic Science, the University of Tokyo, T. KATASE, Materials and Structures Laboratory, Tokyo Institute of Technology, H. HIRAMATSU, ERATO-SORST, Japan Science and Technology Agency, H. HOSONO, Materials and Structures Laboratory, Tokyo Institute of Technology — We investigated the THz conductivity for thin films of Fe-based superconductor, $Ba(Fe_{1-x}Co_x)_2As_2$ with different Co concentrations. For the optimally doped sample, we found a structure corresponding to superconductivity gap, 2 Δ, whose magnitude is 2.8 meV at lowtemperatures, leading to 2 Δ/k_BT_c = 4.1[1]. This value is in good agreement with the smaller gap found in an ARPES measurement[2]. For the underdoped sample in which the coexistence of antiferromagnetic ordering with superconductivity was observed, we found the strong suppression of the carrier lifetime around the antiferromagnetic phase transition temperature ($T \sim$ 40 K). However, the real part of the complex conductivity did not be clearly suppressed in this temparature regigon. This behavior may be related to the responce of carriers at the Dirac cone, which observed in $BaFe_2As_2$[3]. Details will be discussed in the presentation.

5:18PM L26.00013 Pair breaking in iron-based superconductors , KEVIN KIRSHENBAUM, SHANTA SAHA, TYLER DRYE, STEVEN ZIEMAK, JOHNPIERRE PAGLIONE, University of Maryland at College Park — The relative ease of crystal growth combined with the range of elements available for chemical substitution, especially on the transition metal site, has allowed for numerous studies of different iron-based superconductors. There are, however, remaining questions about the pairing symmetry in this system. We present transport scattering rate data for optimally-doped single crystals from several superconducting 122 materials and discuss the relationship between superconducting transition temperature and transport scattering rate in the context of pair breaking.

Tuesday, March 22, 2011 2:30PM - 5:30PM –

Session L28 DCOMP DMP: Focus Session: Computational Materials Design - Property Optimization C156

2:30PM L28.00001 Computational Design of Microstructures , LONG-QING CHEN, Penn State University — Many important engineering materials are designed by controlling their phase transformations and microstructure evolution. Examples include the improvement of mechanical properties through solid state precipitation reactions in alloys such as Ni-based superalloys and age-hardened Al-alloys, the useful dielectric properties and electro-mechanical coupling effects by manipulating the phase transitions in ferroelectric crystals, the memory effect of shape-memory alloys by utilizing martensitic transformations. In this presentation, recent effort on integrating the phase-field approach with other computational methods such as first-principles calculations and CALPHAD will be discussed. A number of examples of coupling phase-field simulations and experimental measurements will be presented. It will be demonstrated that one can use the phase-field method to not only help interpreting experimental observations but also provide guidance to achieve desirable transition temperatures and specific domain/microstructure structures. The possibility to directly obtain the effective responses of a microstructure under an applied field from phase-field simulations, and thus the evolution of effective mechanical and transport properties will also be discussed.

3:06PM L28.00002 Phase-field model and its numerical solution for coring and microstructure evolution studies in alloys[1] , PATRICE E. A. TURCHI, JEAN-LUC FATTEBERT, MILO R. DORR, MICHAEL E. WICKETT, JAMES F. BELAK, Lawrence Livermore National Laboratory — We describe an algorithm for the numerical solution of a phase-field model (PFM) of microstructure evolution in alloys using physical parameters from thermodynamic (CALPHAD) and kinetic databases. The coupled system of PFM equations includes a local order parameter, a quaternion representation of local crystal orientation and a species composition parameter. Time evolution of microstructures and alloy composition is obtained using an implicit time integration of the system. Physical parameters in databases can be obtained either through experiment or first-principles calculations. Application to coring studies and microstructure evolution of Au-Ni will be presented.

3:18PM L28.00003 High Temperature Thermal Conductivity from First Principles , CHRISTIAN CARBOGNO, Materials Department, University of California Santa Barbara / Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, RAMAMURTHY RAMPRASAD, University of Connecticut, Storrs / Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin — In spite of significant research efforts, little is yet known about the atomistic details and mechanisms that underlie peculiarly low (or high) thermal conductivities, especially at elevated pressures and temperatures. Under such extreme conditions, systematic experimental measurements are hard to perform; conventional theoretical approaches typically fail to capture significant physical aspects of the problem, since these methods are either inherently limited to (a) low temperatures and/or (b) to perfect crystals. A recently developed *ab initio* simulation strategy [1] allows to overcome the latter limitation, but the assessment of the high temperature regime remains an unsolved challenge. Within this work, we present efficient strategies to overcome this serious restriction and show their applicability for zirconia based ceramics - a material typically used in high temperature applications, for instance in thermal barrier coatings [2].

3:30PM L28.00004 First Principles Studies of the Thermoelectric Figure of Merit of Zintl Compounds $Ca_{14}AlSb_{11-x}As_x$, TRINH VO, PAUL VON ALLMEN, JEAN-PIERRE FLEURIAL, Jet Propulsion Lab, CalTech — We present predictions for the thermoelectric Figure of merit (ZT) of zintl compounds $Ca_{14}AlSb_{1-x}As_x$ obtained from Density Functional Theory calculations. The Seebeck coefficient, S, was obtained using the Boltzmann transport equation in the relaxation time approximation and first principles electronic structure calculations. We found that the Seebeck coefficient changes dramatically when one or more Sb atoms in the zintl compound $Ca_{14}AlSb_{11}$ are replaced with one or more As atoms, and that the difference in S between the original $Ca_{14}AlSb_{11}$ and the substituted one, $Ca_{14}AlSb_{11-x}As_x$, depends strongly on the positions of substituting As atoms.

3:42PM L28.00005 First-principles model of absolute band shifts induced by (001) biaxial strain in group IIIA-VA semiconductors , EUGENE KADANTSEV, PAWEL HAWRYLAK, IMS NRC — A new model for the evolution of conduction and valence bands of IIIA-VA (InAs, GaAs, InP) semiconductors under (001) biaxial strain is developed. The model is based on ab initio calculations which take into account finite strain dependent relaxation of the reference levels. It is shown that in type I heterostructures subjected to (001) compressive biaxial strain, the confinement of holes can be reduced as compared to some existing models of biaxial strain.

3:54PM L28.00006 Possible calcium centers for hydrogen storage applications: An accurate many-body study by AFQMC calculations with large basis sets[1] , WIRAWAN PURWANTO, HENRY KRAKAUER, SHIWEI ZHANG, YUDISTIRA VIRGUS, College of William and Mary — Weak H_2 physisorption energies present a significant challenge to first-principle theoretical modeling and prediction of materials for H storage. There has been controversy regarding the accuracy of DFT on systems involving Ca cations. We use the auxiliary-field quantum Monte Carlo (AFQMC) method[2] to accurately predict the binding energy of Ca^+-$4H_2$. AFQMC scales as $N^3_{\rm basis}$ and has demonstrated accuracy similar to or better than the gold-standard coupled cluster CCSD(T) method. We apply a modified Cholesky decomposition to achieve efficient Hubbard-Stratonovich transformation in AFQMC at large basis sizes. We employ the largest correlation consistent basis sets available, up to Ca/cc-pCV5Z, to extrapolate to the complete basis limit. The calculated potential energy curve exhibits binding with a double-well structure.

[1]Supported by DOE and NSF. Calculations were performed at OLCF Jaguar and CPD.

4:06PM L28.00007 Theoretical modification of WO_3 for water splitting , PREDRAG LAZIC, MARIA K. CHAN, RICKARD ARMIENTO, YABI WU, GERBRAND CEDER, Massachusetts Institute Of Technology — Using the sun's energy to produce hydrogen from water through photocatalytic process has been a dream since its first demonstration by Fujishima and Honda 40 years ago. Since then significant effort has been made to find a suitable material for this purpose but so far efficiency of the available materials is too low to be commercially interesting. However there are some promising candidates that have some very desirable properties for solar water splitting and their other properties are believed to be improvable by some changes in the material. One of such candidates is WO_3 which shows a very good light absorption and very high stability in aqueous environment. Unfortunately it also has a position of conduction band minimum slightly too low to support H^+/H_2 reaction of hydrogen evolution and also has a relatively large gap which prevents it from using a large part of solar spectrum and thus yielding a low efficiency for water splitting. We have tried to remedy those two problems by substitutions and codoping in the pure WO_3 material within the density functional theory. For some of the modifications we see improved material properties.

4:18PM L28.00008 Ab initio investigations of complex oxides , ALTYNBEK MURAT, JULIA E. MEDVEDEVA, Missouri University of Science & Technology — We employ *ab-initio* density functional approach to investigate the structural, optical and electronic properties of twelve complex oxides with layered structure $RAMO_4$, R=In or Sc, A=Al, Ga, M=Ca, Cd, Mg, and/or Zn. We find that presence of the light metal (e.g., Al, Ca, Mg and Sc) oxides significantly affects the optical band gap which varies from 0.64 eV ($InGaCdO_4$) to 4.35 eV ($ScAlMgO_4$). At the same time, the electron effective mass remains nearly isotropic in all oxides, and both structurally and chemically distinct layers are expected to participate in charge transport once the materials are degenerately doped. Further, for a comparative systematic investigation of carrier generation mechanisms in complex oxides, we calculated the electronic properties of fluorine doped (F_O) and oxygen-reduced $RAMO_4$ materials as well as their single-cation constituents in various phases. We determine most preferable spatial distribution of the F impurity and the oxygen defect in the layered structure of each material and find that the dopant/vacancy site locations correlate with the formation energy of the single-cation oxides. The results allow us to draw conclusions on the role played by each constituent oxide and to predict how the properties of multicomponent materials can be controlled via chemical composition, crystal structure and carrier generation.

4:30PM L28.00009 Tuning of Metal-Metal Bonding by Counterion Size in Hypothetical AETiO2 Compounds , XIAODONG WEN, ROALD HOFFMANN, Department of Chemistry and Chemical Biology, Cornell University, Ithaca, NY — The structures and electronic properties of a number of real and hypothetical ABX2 compounds sharing (or evolving from) a single P4/mmm structural type are examined utilizing first principle calculations. These include the known CaCuO2 and SrFeO2 phases. A number of variations of this P4/mmm ABX2 framework, some obvious, some exotic, all with a chemical motivation, were investigated: A=alkali metal, alkaline earth metal or La, B= Ti, Fe, Cu or Pt, and X=C, O, S, C2, H2 or F. Careful attention was given to the d-orbital splitting patterns and magnetic states (ferromagnetic or antiferromagnetic) of these compounds, as well as their stability gauged by phonon dispersions and energetics. The most interesting as yet unmade compounds that emerged was an AETiO2 (AE = alkaline earth metal, Be, Mg, Ca, Sr and Ba) series, with Ti-Ti bonding, part σ, part π, tuned by the AE2+ cation size. The Ti-Ti bonding in 3D AETiO2 structures has a unique electronic feature of 1D metal chain. These AETiO2 (M=Ca, Sr and Ba) structures are calculated to be thermodynamically and dynamically stable. Experimentally, the high temperature method fails so far. Perhaps a low temperature method offer a better pathway to synthesize the AETiO2 (M=Ca, Sr and Ba) structures.

4:42PM L28.00010 Rational Band Structure Engineering of TiO_2 for Photoelectrochemical Water Splitting , SU-HUAI WEI, WAN-JIAN YIN, YANFA YAN, National Renewable Energy Lab — The search for new semiconducting materials or the engineering of existing semiconductors for commercially viable photoelectrochemical (PEC) water splitting has been extremely challenging. Meeting that challenge requires the discovery of a semiconductor with several tightly coupled material property criteria such as appropriate band gap (1.6 – 2.2 eV), efficient visible light absorption, high carrier mobility, and correct band edge positions that straddle the water redox potentials. However, previous searches/modifications of semiconducting materials for PEC water splitting application have often focused on a particular individual criterion such as band gap, neglecting the possible detrimental consequence to other important criteria. In this talk, general strategies for the rational design of semiconductors such as TiO_2 to simultaneously meet all of the requirements for a high efficiency solar-driven PEC water splitting device are discussed. Density-functional theory calculations reveal that with appropriate donor-acceptor co-incorporation, heavily doped anatase TiO_2 hold great potential to satisfy all of the criteria for a viable PEC device. Other approaches to modify the band structure of TiO_2, such as the application of strain, will also be discussed.

4:54PM L28.00011 Structural and Electronic Properties of $LaTiO_2N$ with O/N Disorder[1] , WEI KANG, MARK S. HYBERTSEN, Center for Functional Nanomaterials, Brookhaven National Lab — $LaTiO_2N$ is an attractive candidate photo-catalyst for water-splitting, showing strong absorption in the visible range with an optical gap about 2.1 eV and catalytic activity for hydrogen and oxygen evolution in the presence of auxiliary co-catalysts. It is also a good prototype suitable for theoretical study. It has a small unit cell while exhibiting several key characteristics found in the more complex oxides and oxynitrides synthesized in the search for improved photo-catalysts. This includes the reduced band gap and the disorder in one of the components, the O/N anion sublattice. We study the structural properties using a first-principles cluster expansion method. Our results reveal that at the temperatures characteristic of synthesis and annealing conditions, the occupation of O/N in $LaTiO_2N$ is intrinsically disordered. However the structure retains residual long-range order, in agreement with anion site occupancies measured in powder neutron diffraction. Short-range order in the O/N occupation is also observed. We use many-body perturbation theory to study the electronic and optical properties for some low-energy structures. The fundamental gap is found about 0.5 eV lower than the apparent absorption edge observed in experiments.

5:06PM L28.00012 The Se effect on the oxygen reduction reaction on the Se/Ru electrocatalysts. Insight from first principles. , SERGEY STOLBOV, University of Central Florida — Rational search for new efficient low-cost electrocatalysts for oxygen reduction reaction (ORR) on the hydrogen fuel cell cathodes focuses on varying the material composition to modify the local densities of electronic states (LDOS) of the surface atoms, in order to tune the surface-adsorbate electronic state hybridization and hence binding energies of the ORR intermediates. My calculation results for the Se/Ru electrocatalysts suggest an alternative way of tuning the binding energies. The Se atoms deposited on the Ru surface are found not to change Ru LDOS noticeably, however, Se atoms are negatively charged due to ionic Se-Ru bonding. As a result, they repeal electrostatically the adsorbed negatively charged O and OH intermediates, and this way reduce their binding energies. Since for the Ru case, reduction of the O and OH binding energies makes ORR energetically favorable, Se deposition dramatically improve the ORR rate on Ru. The ORR rate can thus be enhanced by changing coverage of the deposited halchogen atoms or by tuning the charge transfer to those by modifying the substrate composition.

5:18PM L28.00013 First principles studies of the oxygen reduction reaction on Se-Ru nanostructures , SEBASTIAN ZULUAGA, SERGEY STOLBOV, University of Central Florida — Experiments show an enhanced rate of the oxygen reduction reaction (ORR) on Se-Ru nanostructures (NS) in hydrogen fuel cell cathodes. We use first principles methods to study Ru and Se-Ru NS of approximate 1.2 nm size and shine some light on how the Se affects the O and OH adsorption, which is the bottle neck of the power delivered by the fuel cell. Experiments shows that the Se-Ru NS have a Ru core but is not clear how the Se is distributed on the surface. Our calculation shows that the Se atom adsorbs on the Ru surface with a binding energies in the range 5.7 to 7.1 eV with electronic charge transfer from the Ru atoms. Due to repulsion between negatively charged Se atoms, they tend to spread uniformly over the the Ru NS rather than form islands on its surface. We have also found that, in contrast to the flat Ru surface, the Se bond to the low coordinated Ru atoms have significant covalent component. Our calculation shows how the presence of Se atoms affects the adsorption of the ORR intermediates on the NS. In particular, we show that the electrostatic repulsion between charged Se and O or OH reduces the binding energy of the latters.

Tuesday, March 22, 2011 2:30PM - 5:30PM –
Session L29 GQI: Quantum Entanglement C148

2:30PM L29.00001 Entanglement entropy between two coupled Tomonaga-Luttinger liquids , SHUNSUKE FURUKAWA, YONG BAEK KIM, Dept. of Physics, University of Toronto — We consider a system of two coupled Tomonaga-Luttinger liquids (TLL) on parallel chains and study the Rényi entanglement entropy S_n between the two chains. The limit $n \to 1$ corresponds to the von Neumann entanglement entropy. The system is effectively described by two-component bosonic field theory with different TLL parameters in the symmetric/antisymmetric channels. We argue that in this system, S_n is a linear function of the length of the chains followed by a universal subleading constant γ_n determined by the ratio of the two TLL parameters. We derive the formulae of γ_n for integer $n \geq 2$ using (a) ground-state wave functionals of TLLs and (b) conformal boundary states, which lead to the same result. These predictions are checked in a numerical diagonalization analysis of a hard-core bosonic model on a ladder. Although our formulae of γ_n are not analytic in the limit $n \to 1$, our numerical result suggests that the subleading constant in the von Neumann entropy is also universal.

2:42PM L29.00002 Entanglement from Charge Statistics: Exact Relations for Many-Body Systems , FRANCIS SONG, Yale University, CHRISTIAN FLINDT, Universite de Geneve, STEPHAN RACHEL, Yale University, ISRAEL KLICH, University of Virginia, KARYN LE HUR, Yale University — We present exact formulas for the entanglement and Rényi entropies generated at a quantum point contact (QPC) in terms of the statistics of charge fluctuations, which we illustrate with examples from both equilibrium and non-equilibrium transport. The formulas are also applicable to groundstate entanglement in systems described by non-interacting fermions in any dimension, which in one dimension includes the critical spin-1/2 XX and Ising models where conformal field theory predictions for the entanglement and Rényi entropies are reproduced from the full counting statistics. These results may play a crucial role in the experimental detection of many-body entanglement in mesoscopic structures and cold atoms in optical lattices.

2:54PM L29.00003 Quantum Monte Carlo Calculation of the Topological Entanglement Entropy in a Kagome Spin Liquid , ROGER MELKO, Waterloo, SERGEI ISAKOV, ETH Zurich, ANN KALLIN, Waterloo, MATTHEW HASTINGS, Microsoft Research and Duke — We develop a quantum Monte Carlo procedure to compute the Renyi entanglement entropy of interacting quantum many-body systems at nonzero temperature. We illustrate the method by calculating the topological entanglement entropy in a featureless Mott Insulating phase of a Bose-Hubbard model on the kagome lattice. The topological entanglement entropy displays a characteristic finite-temperature crossover behavior discussed previously in the context of the toric code. At zero-temperature it becomes the log of the quantum dimension of the topological order, confirming the existence of a Z2 spin liquid phase in the groundstate of this model.

3:06PM L29.00004 Entanglement entropy and boundary operators in quantum impurity systems , ERIK ERIKSSON, HENRIK JOHANNESSON, University of Gothenburg — Entanglement in quantum impurity systems can be studied analytically using boundary conformal field theory (BCFT). In particular, the effect from an impurity on the entanglement entropy of a surrounding region is governed by the boundary operator content of the model. We present general results for the corrections to scaling of the Rényi entanglement entropies when perturbing the BCFT with boundary operators [arXiv:1011.0448]. These results are then used to predict the asymptotic large-block behavior of the impurity contribution to the entanglement entropy in various Kondo systems.

3:18PM L29.00005 Global quantum correlations in the spin-1 bilinear-biquadratic chain , ROMAN ORUS, University of Queensland and Max Planck Institute of Quantum Optics, TZU-CHIEH WEI, University of British Columbia — We investigate global properties of the ground state of the spin-1 bilinear-biquadratic quantum spin chain in the thermodynamic limit, focusing on the geometric entanglement and fidelity diagram. The two quantities are computed via iTEBD and they appear to be capable of detecting the various well-known phase transitions in the system, including a Kosterlitz-Thouless one. The two quantities also behave distinctively at other points in the phase diagram. In particular, this is the case for the fidelity diagram at $\theta \approx 1.34\pi$ (around a possible transition to a spin nematic phase), and also for the geometric entanglement at the integrable gapped point $\theta = 3\pi/2$, where we conjecture an infinite entanglement length in the system.

3:30PM L29.00006 Definitions of entanglement entropy of spin systems in the valence-bond basis[1] , YU-CHENG LIN, Applied Physics, National Chengchi University, ANDERS SANDVIK, Physics, Boston University — The valence-bond structure of spin-1/2 Heisenberg antiferromagnets is closely related to quantum entanglement. We investigate definitions of entanglement entropy based on individual valence bonds connecting two subsystems, as well as shared loops of the transposition graph (overlap) of two valence-bond states [1]. We reformulate a previously used definition based on valance bonds in the wave function as a true ground state expectation value, and find that its scaling for the Heisenberg chain agrees with an exact result. The loop-based entanglement entropy of the two-dimensional Heisenberg model is shown to satisfy the area law (with an additive logarithmic correction), unlike single-bond definitions (which exhibit multiplicative logarithmic corrections).

3:42PM L29.00007 ABSTRACT WITHDRAWN –

3:54PM L29.00008 General relation between energy spectrum and entanglement spectrum , XIAOLIANG QI, Stanford University, HOSHO KATSURA, Gakushuin Univeristy, Tokyo, Japan, ANDREAS LUDWIG, University of California, Santa Barbara — We demonstrate that the bipartite density matrix, arising from a spatial bipartitioning of a gapped topological state which possesses gapless edge modes in the form of a conformal field theory (CFT) (when terminated against a topologically trivial state/vacuum), such as e.g. a general quantum Hall state, is the density matrix of a the chiral edge state CFT at a finite temperature. We obtain this result by applying a physical instantaneous cut of the gapped system, and by viewing the cutting process as a sudden "quantum quench" into a CFT, using the tools of boundary conformal field theory. In particular, we obtain a general relation between the Hamiltonian spectrum of gapless theories and the entanglement spectrum of the gapped theory obtained from coupling two gapless theories.

4:06PM L29.00009 The entanglement spectrum of perturbed Chern-Simons theories[1] , THOMAS JACKSON, ISRAEL KLICH, University of Virginia — Topological field theories — theories insensitive to the metric of the space they live on — have been shown to be applicable to a remarkable variety of condensed matter systems. A natural and important question is how perturbations relevant for real systems (interactions, etc.) deform these topological structures. In this work, we consider perturbations of Chern-Simons theory by a small Yang-Mills term, which breaks topological symmetry by introducing local bulk degrees of freedom in the form of massive gluons. We consider the behavior of the entanglement spectrum (the eigenvalues of the reduced density matrix) of this theory under this perturbation. We argue that the act of taking the partial trace may be viewed as adding a chemical potential gradient for the gluons near the boundary of the space, with a length scale determined by the gluon mass — or, colloquially, a "hot edge."

4:18PM L29.00010 Entanglement, Dissipation and the Casimir effect , ISRAEL KLICH, University of Virginia — The role of dissipation in the Casimir force between metals or dielectric has a been discussed in many works and is an important part of the Casimir theory, where puzzles about the finite temperature corrections to the effect are still being worked out. Here, we study the contribution of dissipation in creating distance dependent entanglement between materials, and on the meaning of the corresponding entropy.

4:30PM L29.00011 Entanglement Entropy Scaling of 2D Critical Wave Functions , MICHAEL ZALETEL, JENS BARDARSON, JOEL MOORE, UC Berkeley — While CFT calculations have revealed a variety of universal predictions for the entanglement spectrum of critical 1+1D field theories, much less is known about higher-dimensional systems. CFT methods can be extended to a class of 2+1D theories characterized by a $z = 2$ critical point, the so-called Rokhsar-Kivelson wave functions. The entanglement entropy of RK-type critical wave functions contains a universal logarithmic contribution $\gamma \log(L)$ for some geometries arising from a trace anomaly in the corresponding CFT. We first re-examine the free boson, where the existence of order-unity contributions that depend on the boson compactification radius has been discussed in several recent papers (Hsu et al., Stéphan et al., Oshikawa). We find analytically and numerically that the logarithmic contribution exists with the coefficient predicted by Fradkin and Moore and is independent of the compactification. However, it appears that their conjecture that general CFTs show the same dependence of γ on central charge as the free boson is incorrect. We present arguments and numerical evidence for this conclusion in $c = 1/2$ and $c = 1$ lattice models.

4:42PM L29.00012 Entanglement spectra of Hofstadter and related models , ZHOUSHEN HUANG, DANIEL AROVAS, University of California, San Diego — We compute the bipartite entanglement spectra for the Hofstadter model on various two-dimensional lattices. The behavior of the entanglement eigenstates in the vicinity of a partition boundary is investigated in detail. We also investigate the formation of entanglement edge states as one tunes through a topological phase transition in Haldane's honeycomb lattice model and other related systems.

4:54PM L29.00013 Entanglement Spectrum In Condensed Matter[1] , B. ANDREI BERNEVIG, Princeton University — I will review the information that entanglement spectra give for a wide range of systems in condensed matter physics, such as fractional quantum hall effect, quantum spin chains, topological insulators, and disordered systems. (the results are based on a series of works performed in collaboration with N. Regnault, R. Thomale, A. Chandran, A Sterdyniak, M. Hermanns, Z. Papic, T.L. Hughes, E. Prodan, D.P. Arovas)

5:06PM L29.00014 Simultaneous generation of multiple quadripartite continuous-variable cluster states in the optical frequency comb of a single optical parametric oscillator , MATTHEW PYSHER, University of Virginia, YOSHICHIKA MIWA, University of Tokyo, REIHANEH SHAHROKHSHAHI, RUSSELL BLOOMER, OLIVIER PFISTER, University of Virginia — We report the experimental generation of multiple, four-mode, continuous-variable cluster states from a single optical parametric oscillator (OPO) operating below threshold. We use a PPKTP crystal phasematching two concurrent nonlinear interactions to entangle the optical frequency comb formed by the OPO cavity. Four independent entanglement witnesses (a.k.a. infinitesimal operators of stabilizers, or "nullifiers") display squeezing in each cluster state, and we utilize the large phase-matching bandwidth of the nonlinear interactions to display the simultaneous creation of several such cluster states using only a single pump frequency. A slightly more sophisticated version of this experimental method, using a crystal with three nonlinear interactions and 15 pump frequencies, has theoretically shown the ability to produce arbitrarily large square-grid cluster states suitable for universal one-way quantum computing.

5:18PM L29.00015 Multipartite entanglement in the optical frequency comb of a depleted-pump optical parametric oscillator , REIHANEH SHAHROKHSHAHI, OLIVIER PFISTER — The optical frequency comb (OFC) of a single optical parametric oscillator (OPO) has been shown to be a very interesting candidate for scaling the size of quantum entangled states. In sophisticated OPOs below threshold, square-grid cluster states of very large size can in principle be generated. Here, we study a very simple OPO well above threshold, in the linearized fluctuation approximation, and investigate the effect of pump depletion on multiple, simultaneously resonant, signal-mode pairs. We find that the depleted quantum pump mediates quantum correlations between the signal fields. These correlations lead in turn to inseparability of these fields, as evidenced by the well-known van Look-Furusawa entanglement criteria. Due to its simplicity and its scalability, this fully inseparable multipartite entangled state could used as a resource in quantum information protocols.

Session L30 DCMP: Graphene: Thermal Conduction and Phonons C147/154

2:30PM L30.00001 Thermal transport in suspended and supported monolayer graphene grown by chemical vapor deposition , WEIWEI CAI, Xiamen University, ARDEN MOORE, SHANSHAN CHEN, YANWU ZHO, Univ. of Texas at Austin, LI SHI, RODNEY S. RUOFF, Univ. of Texas at Austin — Although electron transport in graphene has been studied extensively and graphene is predicted to have very high thermal conductivity near room temperature, there is only limited experimental data in the literature on phonon transport in graphene because of experimental challenges. We report results based on micro-Raman spectroscopy for the measurement of the thermal conductivity of large-area, monolayer graphene grown by CVD on copper and subsequently suspended over a circular hole. The obtained optical absorption is measured directly by measuring the transmission through the graphene covered hole. Based on the thermal interface conductance of (28+2.8/-3.8) MW/m^2 K, the contact thermal resistance is determined to be considerably smaller than the measured thermal resistance of the suspended graphene. The obtained thermal conductivity of the supported graphene is (370 +490/-300) W/m K, which is considerably smaller than that of suspended graphene in agreement with recent measurements of mechanically exfoliated graphene supported on SiO_2.

2:42PM L30.00002 Surprising Effects of Substrate on Thermal Transport in Supported Graphene , ZHUN-YONG ONG, Physics Department, University of Illinois at Urbana-Champaign, ERIC POP, ECE Department, University of Illinois at Urbana-Champaign — We study thermal transport in graphene "supported" on SiO2 using molecular dynamics (MD) simulations. We find that coupling to the substrate leads to an order of magnitude decrease in the apparent thermal conductivity (TC), explaining recent experiments [1]. This reduction is due to the substrate damping of flexural acoustic (ZA) phonons, which implies that the high TC of isolated graphene is due to the large mean free path of long-wavelength ZA modes [2]. However, we find that by increasing the strength of the interfacial interaction, the apparent TC is enhanced by up to a factor of four. Using a continuum model [3], we relate the apparent TC enhancement to the ZA modes coupling with the substrate Rayleigh waves. In the weak coupling limit, the ZA modes have a quadratic dispersion and small group velocities at long wavelengths; in the strong coupling limit, the hybridized interfacial modes have a linear dispersion and larger group velocities. This finding suggests that the TC of supported graphene may be tunable through interfacial interaction.

2:54PM L30.00003 Two Dimensional Phonon Transport in Graphene , INSUN JO, Department of Physics, The University of Texas at Austin, JAE HUN SEOL, ARDEN L. MOORE, MICHAEL T. PETTES, Department of Mechanical Engineering, The University of Texas at Austin, LUCAS LINDSAY, Department of Physics - Boston College, NATALIO MINGO, Laboratoire d'Innovation pour les Technologies des Energies Nouvelles et les Nanomatériaux, Commissariat à l'Énergie Atomique Grenoble, DAVID BROIDO, Department of Physics - Boston College, ZHEN YAO, Department of Physics, The University of Texas at Austin, LI SHI, Department of Mechanical Engineering, The University of Texas at Austin — We present thermal conductivity measurements of monolayer graphene exfoliated on a silicon dioxide substrate at different temperatures. A nanofabricated resistance thermometer device is developed to measure the thermal conductance of graphene and supporting 300nm thick SiO_2 layer, which allows us to extract the thermal conductivity of graphene while supported on this layer. The measured value is as high as 600 W/mK near room temperature, which is lower than that of suspended graphene, 1500-5800 W/mK, but still higher than those of metal interconnects. Theoretical calculations show that the strong interface-scattering of flexural modes across the graphene-oxide interface is responsible for the decreased value.

3:06PM L30.00004 Influence of Polymeric Residue on the Thermal Conductivity of Suspended Bi-Layer Graphene[1] , MICHAEL PETTES[2], Department of Mechanical Engineering, The University of Texas at Austin, Austin, Tx, INSUN JO[3], ZHEN YAO, Department of Physics, The University of Texas at Austin, Austin, Tx, LI SHI[4], Department of Mechanical Engineering, The University of Texas at Austin, Austin, Tx — The thermal conductivity (κ) of two bi-layer graphene samples suspended between two micro-resistance thermometers was measured to be close to 600 W m^{-1} K^{-1} at room-temperature and exhibits a $\kappa \propto T^{1.5}$ behavior at temperature (T) between 50 – 125 K. The lower thermal conductivity than the basal plane values of graphite and the temperature dependence are attributed to scattering of phonons in the bi-layer graphene by a residual polymeric layer that was clearly observed by transmission electron microscopy.

3:18PM L30.00005 Phonon thermal conductivities of multi-layered graphene , LUCAS LINDSAY, Department of Physics, Computer Science, and Engineering, Christopher Newport University, Newport News, VA 23606, USA, DAVID BROIDO, Department of Physics, Boston College, Chestnut Hill, MA 02467, USA — Using an exact numerical solution of the phonon Boltzmann equation, we show that the intrinsic lattice thermal conductivities, κ, of N-layer graphene (N=1-5) are dominated by contributions from out-of-plane, flexural (ZA) phonon modes contrary to previous theories based on the relaxation time approximation, which assumed this contribution to be negligible [1, 2]. We find a reduction of κ with increasing N due to interlayer coupling, which: 1) lifts the degeneracy of the flexural acoustic mode frequencies, 2) makes the ZA phonon branch become linear near the zone-center, and 3) breaks a selection rule for anharmonic phonon-phonon scattering in two-dimensional systems.

3:30PM L30.00006 Thermal properties of novel 2D hybrid graphene-BN nanostructures , NIKHIL MEDHEKAR, Monash University, JUN SONG, Brown University — Graphene, a 2D honeycomb carbon crystal of one-atom thickness, has been widely recognized as a very promising material for next generation optoelectronic and NEMS applications. Recent developments have shown that it is possible to obtain hybrid 2D structures by combining sp2-graphene lattice with sp2-lattice of non-carbon materials such as hexagonal Boron Nitrides. The atomically thin sheets containing both hexagonal-Boron Nitride and graphene can result in new materials with properties complementary to their individual properties and further enrich the potential applications. Here, using molecular dynamics simulations, we elucidate the characteristics of thermal transport in 2D hybride h-BN and graphene materials. We find the thermal conductivity of the hybrid material is a strong function of the relative domain widths, interface type (e.g., zigzag and armchair) as well as the interface quality. Our results provide crucial insights on the role of the interfaces and defects in phonon scattering in the hybrid material and can potentially provide means to tailor its thermal properties.

3:42PM L30.00007 Thermal Expansion in Graphene and Graphane: Role of Anharmonic and Harmonic Effects , ARUNIMA SINGH, RICHARD G. HENNIG, Department of Materials Science and Engineering, Cornell University — As the practical application of graphene nears realization, knowledge of effects of temperature on mechanical properties of graphene becomes important. In this study we use empirical potentials and density-functional perturbation theory (DFPT) to determine the thermal expansion of free-standing graphene, graphene on substrates, and its hydrogenated derivative graphane. Comparisons of MD simulations with calculations using the quasi- harmonic approximation using an empirical potential show that anharmonic effects are negligible at temperatures below 2200K. In contrast to the DFPT calculations using the quasi-harmonic approximation, MD results show that free-standing graphene has a positive thermal expansion coefficient above 600K. For graphene on a substrate our DFPT results agree with those of Jiang et. al [1] and show that the substrate suppresses the negative thermal expansion coefficient with increasing strength of the substrate- graphene interaction. We also investigate the thermal expansion of the thermodynamically stable conformers of graphane using DFPT.

3:54PM L30.00008 Observation of coherent G-mode phonon oscillations in graphene films , J.-H. KIM, Chungnam National University, M.H. JUNG, B.H. HONG, Sungkyunkwan University, E.H. HAROZ, J. KONO, Rice University, K.J. YEE, Chungnam National University — We have observed coherent G-mode lattice vibrations in three stacked-mono layer and multi-layer graphene films by using ultrashort pulses from a Ti:Sapphire laser. The degenerated E_{2g}modes were excited through the impulsive stimulated Raman scattering process, and detected through induced reflectivity modulations. The G-mode frequency from the stacked-mono layer graphene is shifted toward higher energy compared with that of the multi-layer graphene. A dephasing time of abound 0.6 ps for the stacked-mono layer graphene was found to be shorter than that of semiconducting single-walled carbon nanotubes (1.48 ps) and slower than that of metallic single-walled carbon nanotubes, due to stronger electron-phonon interactions, where the phonon energy can be dissipated by exciting electrons between a linear bands of graphene. Through the strong polarization dependence of coherent G-mode lattice vibrations, we confirmed that the $E_{2g}^{(2)}$ symmetry is dominant.

4:06PM L30.00009 Theory of coherent phonons in graphene[1] , G.D. SANDERS, Universiy of Florida, C.J. STANTON, University of Florida, J.-H. KIM, K.-J. YEE, Chungnam National University, M.H. JUNG, B.H. HONG, Sungkyunkwan University, E.H. HAROZ, J. KONO, Rice University — We develop a theory for the generation and detection of coherent phonons in graphene. Coherent phonons are generated via the deformation potential electron-phonon interaction with photogenerated carriers. In our theory the electronic states are treated in a third nearest neighbor extended tight binding formalism which gives a good description of the states over the entire graphene Brillouin zone while the phonon states are treated in a valence force field model. The equations of motion for the coherent phonon amplitudes are obtained in a density matrix formalism and we find that the coherent phonon amplitudes satisfy driven oscillator equations for each value of the phonon wavevector. Comparison is made with recent experimental measurements.

4:18PM L30.00010 Coherent phonon spectroscopy of the shearing mode in bilayer and few-layer graphene , DAVIDE BOSCHETTO, Department of Physics, Columbia University and Laboratoire d'Optique Appliquée, ENSTA/Ecole Polytechnique, Palaiseau, LENADRO MALARD, CHUN HUNG LUI, KIN FAI MAK, HUGEN YAN, Department of Physics, Columbia University, ZHIQIANG LI, TONY F. HEINZ, Department of Physics and Electrical Engineering, Columbia University — The interlayer shearing vibration in graphite, a low-energy optical phonon, is known to consist of adjacent atomic planes moving laterally in opposite directions with respect to one another. We have applied coherent phonon spectroscopy, based on a sensitive femtosecond pump-probe measurement, to investigate the corresponding mode in few-layer graphene samples down to bilayer thickness. Here we report on the evolution of the frequency and lifetime of this mode with thickness. To model the expected behavior, we have analyzed a model of identical nearest-neighbour couplings. We find that this model predicts most of the observed reduction in frequency with decreasing layer thickness. We consider to the remaining deviations between the model and our experimental data in terms of a slight increase in the interlayer spacing, leading to a reduced restoring force, with decreasing graphene layer thickness. This decrease in lattice spacing with thickness is expected for layered materials governed by van der Waals forces. We also show experimentally that the shearing mode frequency is robust against external perturbations, such as different substrates and the presence of adlayers.

4:30PM L30.00011 Tuning the Kohn Anomaly in the Phonon Dispersion of Graphene by Interaction with the Substrate and by Doping , LUDGER WIRTZ, CNRS - IEMN, Lille, France, ADRIEN ALLARD, CNRS - IEMN, Lille, CLAUDIO ATTACCALITE, CNRS, Institut Neel, Grenoble, MICHELE LAZZERI, CNRS - IMPMC, Paris, FRANCESCO MAURI, ANGEL RUBIO, ETSF/Univ. Basque Country, San Sebastian, Spain — The phonon dispersion of graphene displays two strong Kohn Anomalies (kinks) in the highest optical branch (HOB) at the high-symmetry points G and K. The slope of the HOB around K is a measure of the electron-phonon coupling (EPC) and determines the dispersion of the Raman D and 2D lines as a function of the laser energy. We show that the EPC can be strongly modified both due to interaction with a metallic substrate and due to doping. For graphene grown on a Ni(111) surface, a total suppression of the Kohn anomaly occurs: the HOB around K becomes completely flat. This is due to the strong hybridization of the graphene p-bands with the Nickel d-bands which lifts the linear crossing of the p-bands at K. From experimental phonon dispersions one can therefore draw conclusions about the interaction strength between graphene and its different substrates. Furthermore, we present a new way to tune the EPC in graphene through electron/hole doping. We show that for the highest optical branch at K, the EPC is strongly dependent on the doping level. This dependency influences the dispersion of the Raman D and 2D lines and makes it possible to measure the charge state of graphene via resonant Raman spectroscopy.

4:42PM L30.00012 Thermoelectric effect in high mobility single layer epitaxial graphene[1] , XIAOSONG WU, YIKE HU, MING RUAN, NERASOA K. MADIOMANANA, CLAIRE BERGER, WALT A. DE HEER, School of Physics, Georgia Tech — The thermoelectric response of high mobility single layer epitaxial graphene on silicon carbide substrates as a function of temperature and magnetic field have been investigated. For the thermopower, a strong deviation from the Mott relation, i.e. a quardratic correction to the linear temperature dependence, has been observed even when the carrier density is high. In the quantum Hall regime, the amplitude of the TEP peaks is lower than a quantum value predicted by theories, despite the high mobility of the sample. A systematic reduction of the amplitude with decreasing temperature suggests that the suppression of the TEP is intrinsic to Dirac electrons in graphene.

[1]This work was supported by NSF grant DMR-0820382 and the W. M. Keck Foundation.

4:54PM L30.00013 Thermoelectric transport in graphene with tunable mobility[1] , XINFEI LIU, Physics Deaprtment, UC Riverside, DEQI WANG, JING SHI, Physics Department, UC Riverside — Thermoelectric transport properties of single layer graphene have recently been studied both experimentally and theoretically. The unique band structure of graphene leads to unusual thermoelectric properties which are very sensitive to the carrier mobility. However, all previous experiments were carried out in graphene devices with different mobility values and comparisons were drawn among different devices. Recently, we have shown that by controlling the charge state of the ligand-bound nanoparticles on graphene it is possible to tune the mobility of the same graphene device over a wide range, e.g. 5000-19000cm^2/Vs. In this work, we adopted this method and successfully tuned the mobility of graphene while systematically studied the Seebeck and Nernst effects in a magnetic field up to 14 Tesla for each fixed mobility value. Our results show that at zero magnetic field, the width of the transition region near the Dirac point decreases sharply and the diverging behavior in the Seebeck coefficient becomes more pronounced as the mobility is tuned from low to high. At high magnetic fields, the Seebeck coefficient in the high mobility state clearly reveals additional features that are related to the splitting of the zeroth Landau level near the Dirac point. Moreover, we demonstrate that the Nernst peak height at the Dirac point depends linearly on the carrier mobility in graphene.

5:06PM L30.00014 Thermoelectric Properties of Graphene Ribbons[1] , ENRIQUE MUNOZ, Instituto de Fisica, Pontificia Universidad Catolica de Valparaiso, Chile — Several theoretical and experimental studies have been recently concerned with electric and thermal transport in graphene layers and ribbons, where propagation of electrons [1] and phonons [2] seems to be dominated by a ballistic mechanism. Of particular interest in this context is the identification and characterization of thermoelectric effects [3], which represent a promising alternative for energy recovery in technological applications. In the present work, the effect of the electron- phonon interaction over a predominantly ballistic transport mechanism in graphene ribbons is studied in the context of thermoelectricity. Theoretical estimations of the thermopower S, and the corresponding figure of merit ZT, are presented for this system as a function of temperature.

5:18PM L30.00015 Theromelectricity in Graphene: Effects of a gap and magnetic fields[1] , SUBROTO MUKERJEE, Indian Institute of Science, Bangalore India, AAVISHKAR PATEL, Indian Institute of Technology, Kanpur India — We calculate the thermopower of monolayer graphene in various circumstances. First we show that experiments on the thermopower of graphene can be understood quantitatively with a very simple model of screening in the semiclassical limit. We can calculate the energy dependent scattering time for this model exactly. We then consider acoustic phonon scattering which might be the operative scattering mechanism in free standing films, and predict that the thermopower will be linear in any induced gap in the system. Further, the thermopower peaks at the same value of chemical potential (tunable by gate voltage) independent of the gap. Finally, we show that in the semiclassical approximation, the thermopower in a magnetic field saturates at high field to a value which can be calculated exactly and is independent of the details of the scattering. This effect might be observable experimentally.

Session L31 DMP GSCCM DCOMP: Focus Session: Materials at High Pressure III: Electronic Transitions C145

2:30PM L31.00001 Pressure Induced Metal Insulator Phase Transition in $Eu_2Ir_2O_7$, FAZEL FALLAH TAFTI, JUN ISHIKAWA, YO MACHIDA, ALIX MCCOLLAM, SATORU NAKATSUJI, STEPHEN JULIAN — The metal to insulator phase transition of the pyrochlore iridate $Eu_2Ir_2O_7$ has been studied by means of resistivity measurements under pressure in the range 2 to 12 GPa. At ambient pressure, the system is a "metal" at high temperatures with a non-metallic rise of resistivity with decreasing temperature followed by a metal-insulator phase transition at T_{MI} below which it becomes insulating. With increasing pressure, a cross-over from non-metallic to metallic appears in the resistivity curves at a temperature $T^* > T_{MI}$. As the pressure is further increased T^* rises, T_{MI} drops and the low temperature insulating phase melts into a metallic phase through a continuous transition at P $\sim$ 7.8 GPa. The high pressure metallic phase is rather curious and exhibits two characteristic features of Kondo metals: a minimum resistivity and a logarithmic rise of resistivity at low temperatures. We will show that there is a remarkable correspondence between the resistivity curves measured at various pressures and those obtained by successively replacing the R site of the $R_2Ir_2O_7$ family by larger rare earth atoms.

2:42PM L31.00002 Pressure-induced Metallization of Carbon Disulfide[1] , RANGANATH DIAS, Institute for Shock Physic, Dept. of Physics, Washington State University, Pullman, WA 99164 , MATHEW DEBESSAI , Institute for Shock Physic, Washington State University, Pullman, WA 99164 , CHOONG-SHIK YOO, Institute for Shock Physics, Dept. of Chemistry, Washington State University, Pullman, WA 99164 — We will report high pressure electrical resistivity measurements on solid CS_2 in diamond anvil cell to 60GPa. The result shows a steady decrease in resistivity to that of metal at around 55GPa. Its visual appearance of CS_2 also supports its insulator-metal transition: the initially transparent CS_2 becomes opaque and eventually reflective with increasing pressure. We will also present a plausible mechanism for the observed metallization.

[1]The work has been supported by NSF (DMR-0854618) and DTRA (HDTRA1-09-1-0041).

2:54PM L31.00003 Electrical resistance measurement of optimal doped YBCO under pressure , TAKAKI MURAMATSU, TcSUH, University of Houston, DUC PHAM TEAM, CHING-WU CHU TEAM — High pressure effect on nearly optimal doped high T_C cuprate superconductor $YBa_2Cu_3O_{7-x}$ was studied by the electrical resistance measurements up to about 30 GPa. Superconducting phase of $YBa_2Cu_3O_{7-x}$ in pressure-temperature phase diagram was confirmed. T_C has the broad maximum at about 8 GPa and then decreases with pressure and disappears at the pressure between 23 GPa and 25 GPa. In higher pressure region, the resistance shows upturn below about 60 K, indicating the possibility of crossover on $YBa_2Cu_3O_{7-x}$ from superconductor to semiconductor at about 24 GPa

3:06PM L31.00004 Pressure induced phase transition in FeGa alloys , CHRISTOPHER DEVREUGD, Virginia Tech University, MUHTAR AHART, Carnegie Institution of Washington, PETER GEHRING, NIST Center for Neutron Research, DWIGHT VIEHLAND, Virginia Tech University, RUSSELL HEMLEY, Carnegie Institution of Washington — Giant magnetostriction in Fe– x Ga alloys (15 – x - 27) offers potential for future generations of sensors and actuators. A maximum in the magnetostrictive strain is found at Ga content of about 19 percent, which is ten times higher than that of pure alpha-Fe. To investigate the behavior of FeGa alloys under pressure, we chose a slow cooled alloy of FeGa-19 as our sample and performed x-ray diffraction experiments in a diamond anvil cell up to 45 GPa. Diffraction pattern shows powder rings associated with (110), (200), and (211) Bragg reflections from expected bcc structure of iron below 24 GPa. We also observed the intensity increases along the powder rings associated with the crystal structure of Galfenol. Considering the (110) Bragg peak splits into three peaks above 24 GPa, our results indicate that FeGa alloy undergoes a bcc cubic to a hexagonal transition around 24 GPa. When the pressure is decreased, the hcp phase transforms back to the bcc phase. The transition mechanism can be understood by using the analogy to the bcc-hcp phase transition in pure iron under pressure. The transition in iron is a martensitic or displacive one. The hcp structure can be derived from the bcc structure through a relatively minor distortion of the bcc structure.

3:18PM L31.00005 High Pressure Studies of UO_3[1] , ZSOLT JENEI, MAGNUS LIPP, JAE-HYUN KLEPEIS, BRUCE BAER, HYUNCHAE CYNN, WILLIAM EVANS, Lawrence Livermore National Laboratory, CHANGYONG PARK, DIMITRI POPOV, HPCAT, Advanced Photon Source, Argonne National Laboratory — It has been reported that upon compression t ambient temperature δ-UO3 becomes amorphous at 2.2 GPa. (Journal of Alloys and Compounds 315 p59–61). We studied the properties of γ-UO3 in diamond anvil cell up to 75 GPa. Powder diffraction experiments performed at HPCAT/Advanced Photon Source show the crystalline uranium trioxide transforms to an amorphous solid between 12 and 14 GPa and remains amorphous up to 75 GPa. The transition has been confirmed by Raman spectroscopy as well. In this paper we'll present our findings on the amorphous transition together with the equation of state of both the crystalline phase and the amorphous phase.

[1]This work performed under the auspices of the US DOE by LLNL under Contract DE-AC52-07NA27344 HPCAT is supported by CIW, CDAC, UNLV and LLNL through funding from DOE-NNSA, DOE-BES and NSF. APS is supported by DOE-BES, under Contract No. DE-AC02-06CH11357.

3:30PM L31.00006 High-pressure equation of state of U_3O_8[1] , JAE-HYUN KLEPEIS, ZSOLT JENEI, MAGNUS LIPP, WILLIAM EVANS, Lawrence Livermore National Laboratory, DMITRY POPOV, HPCAT, APS, Argonne National Laboratory, CHANGYONG PARK, HPCAT APS Argonne National Laboratory — We will present experimental studies at high pressures of the equation of state of U_3O_8. Isothermal pressure-volume measurements of U_3O_8 were made at ambient/elevated (600 K) temperatures in the pressure range of 1 atm $\sim$ 80 GPa (10 $\sim$ 70 GPa). Angle dispersive X-ray diffraction patterns at ambient temperature indicate that the A-centered orthorhombic structure of U_3O_8 transforms to the face centered cubic (fcc) structure above 9 GPa. Both the orthorhombic and cubic phases co-exist between 9 GPa and 30 GPa. As the temperature is increased at 10 GPa, we find that U_3O_8 also transforms to the fcc structure. As the pressure is increased at 600 K, the fcc structure undergoes a phase transition to the body centered tetragonal structure. Since the uranium in U_3O_8 is the dominant x-ray scatterer, the behavior of the oxygen at the phase transitions was measured using Raman spectroscopy.

[1]This work was performed under the auspices of the US DOE by LLNL under Contract DE-AC52-07NA27344. HPCAT is supported by CIW, CDAC, UNLV and LLNL through DOE-NNSA, DOE-BES and NSF. APS is supported by DOE-BES, under Contract DE-AC02-06CH11357.

3:42PM L31.00007 High pressure x-ray diffraction of uranium oxide formed by natural oxidation of uranium[1] , HYUNCHAE CYNN, WILLIAM J. EVANS, BRUCE J. BAER, Lawrence Livermore National Laboratory, SIMON MACLEOD, Atomic Weapons Establishment, MAGNUS J. LIPP, ZSOLT JENEI, J.H. PARK KLEPEIS, Lawrence Livermore National Laboratory, YUE MENG, STANISLAV SINOGEIKIN, HP-CAT, APS — Naturally oxidized uranium has been compressed using a diamond anvil cell. Although X-ray diffraction shows the anisotropic nature in the pressure dependent changes to the lattice parameters of pure uranium as previously recorded, uranium oxide appears stable at high pressure in the fluorite structure with no clear evidence of a phase transition observed above the transition pressure previously measured for bulk uranium oxide. The lattice parameters of uranium oxide formed by natural surface oxidation have been determined along with those of the underlying pure uranium employing Rietveld refinement. We will discuss the seemingly unexpected findings about uranium oxide.

[1]Work performed under the auspices of the US DOE by LLNL under Contract DE-AC52-07NA27344. Diffraction studies were performed at HPCAT (Sector 16), APS/ANL. HPCAT is supported by CIW, CDAC, UNLV and LLNL through funding from DOE-NNSA, DOE-BES and NSF. APS

3:54PM L31.00008 Uranium hydride (UH_3) and deuteride (UD_3) under conditions of high pressure and temperature , MAGNUS LIPP, ZSOLT JENEI, JAE HYUN PARK KLEPEIS, BRUCE BAER, HYUNCHAE CYNN, WILLIAM EVANS, DON FUJINO, Lawrence Livermore National Laboratory, BLAKE NOLAN, JOE WERMER, Los Alamos National Laboratory, CHANGYONG PARK, DMITRY POPOV, HPCAT, Advanced Photon Source, Argonne National Laboratory — Uranium hydrides are currently being evaluated as fuels in new reactor designs. They also serve as sources for very clean hydrogen by decomposing when heated at ambient pressure. We have examined their behavior over a large pressure and temperature range by placing small quantities and a pressure marker in a diamond anvil cell for angle dispersive x-ray diffraction. Neon was chosen as pressure transmitting medium to ensure the best possible hydrostatic conditions. We'll discuss crystal structures, the equation of state, the bulk modulus and the phase diagram. Work performed under the auspices of the US DOE by LLNL under Contract DE-AC52-07NA27344. Diffraction studies were performed at HPCAT (Sector 16), APS/ANL. HPCAT is supported by CIW, CDAC, UNLV and LLNL through funding from DOE-NNSA, DOE-BES and NSF. APS is supported by DOE-BES, under Contract No. DE-AC02-06CH11357.

4:06PM L31.00009 Structural Stabilities and Electronic Properties of Cobalt Hydrides , YASUYUKI MATSUURA, TATSUYA SHISHIDOU, ADSM, Hiroshima University, TAMIO OGUCHI, ISIR, Osaka University, ADSM, Hiroshima University — Cobalt forms ferromagnetic hydrides CoH_x at high pressures of hydrogen [1]. As the hydrogen pressure increases at temperatures 250-350°C, the concentration of hydrogen in the hcp phase monotonically increases, and reaches $x \sim 0.6$ at 7 GPa. At higher pressures, an fcc-based hydride with $x \sim 1.0$ is formed. At ambient pressure and 120 K, hydrogen atoms in the solution with $x \leq 0.26$ are randomly distributed over octahedral interstitial sites [2]. In the solution with $x = 0.34$ ($x \geq 0.38$), hydrogen atoms occupy every third (second) layer. The magnetic moments of the hcp-based hydrides are oriented to the c-axis, and are decreased with increasing hydrogen concentration at a rate of about 0.36 μ_B per hydrogen atom. In this study, we optimize the structural parameters for several structures, and investigate the structural stabilities and related electronic properties by using first-principles calculations. The full-potential linearized augmented plane wave method with the generalized gradient approximation is adopted.

4:18PM L31.00010 Formation of collapsed tetragonal phase in $EuCo_2As_2$ under high pressure[1] , MATTHEW BISHOP, University of West Georgia (UWG), Carrollton, GA 30118, USA, WALTER UHOYA, GEORGIY TSOI, YOGESH VOHRA, University of Alabama at Birmingham (UAB), Birmingham, AL 35294, USA, ATHENA SEFAT, BRIAN SALES, Oak Ridge National Laboratory (ORNL), Oak Ridge, TN 37831, USA — The structural properties of $EuCo_2As_2$ have been studied up to 35 GPa, through the use of x-ray diffraction in a diamond anvil cell at a synchrotron source. At ambient conditions, $EuCo_2As_2$ ($I4/mmm$) has a tetragonal lattice structure with a bulk modulus of 48 $\pm$ 4 GPa. With the application of pressure, the $a$axis exhibits negative compressibility with a concurrent sharp decrease in c-axis length. The anomalous compressibility of the $a$axis continues until 4.7 GPa, at which point the structure undergoes a second-order phase transition to a collapsed tetragonal (CT) state with a bulk modulus of 111 $\pm$ 2 GPa. We found a strong correlation between the ambient pressure volume of 122 parents of superconductors and the corresponding tetragonal to collapsed tetragonal phase transition pressures.

4:30PM L31.00011 The behavior of semi-metal Bi_4Te_3 under pressure , JASON JEFFRIES, Lawrence Livermore National Laboratory, A.L. LIMA SHARMA, Sandia National Laboratory and San Jose State University, P.A. SHARMA, C.D. SPATARU, Sandia National Laboratory, S.K. MCCALL, Lawrence Livermore National Laboratory, J.D. SUGAR, Sandia National Laboratory, S.T. WEIR, Lawrence Livermore National Laboratory, Y.K. VOHRA, University of Alabama, Birmingham — As a member of the $(Bi_2)_m(Bi_2Te_3)_n$ adaptive series, Bi_4Te_3 exhibits identical crystallographic symmetry and similar electronic properties to the archetypal thermoelectric material Bi_2Te_3. The extra Bi atoms in Bi_4Te_3 serve to increase the electronic density of states, making Bi_4Te_3 a semi-metal, as opposed to semiconducting Bi_2Te_3, at ambient pressure. We will report the results of high-pressure structural and magnetotransport characterization of Bi_4Te_3, focusing on the interplay between structural parameters and the underlying electronic properties. Lawrence Livermore National Laboratory is operated by Lawrence Livermore National Security, LLC, for the U.S. Department of Energy, National Nuclear Security Administration under Contract DE-AC52-07NA27344.

4:42PM L31.00012 Theoretical X-ray Spectroscopy for Strongly Correlated Materials at High Pressure[1] , ADAM P. SORINI, CHENG-CHIEN CHEN, SHIBING WANG, WENDY L. MAO, THOMAS P. DEVEREAUX, Stanford Institute for Materials and Energy Science, CHI-CHANG KAO, SSRL, SLAC National Acclererator Laboratory — We present theoretical x-ray spectra for correlated d- and f-electron materials under extreme conditions. We use exact-diagonalization to study small clusters of atoms including ligand charge-transfer and atomic-multiplet effects. These techniques allow us to extract information from spectroscopic measurements regarding phase transitions in strongly correlated materials as a function of pressure. We show recent results for hematite (Fe2O3) which undergoes a variety of phase transitions (structural, spin, metal/insulator) near 50 GPa, which have been observed using hard x-ray quadrupolar absorption. We also apply our models to the correlated f-electron "volume collapse" systems which show complex behavior under pressure.

4:54PM L31.00013 Fermi surface of SnO under pressure , NIELS CHRISTENSEN, AXEL SVANE, Aarhus University — Tin monoxide undergoes a pressure induced insulator-metal transition around 5 GPa. The pressure effects on the electronic band structure, the Fermi surface (FS) and its nesting properties of SnO in the metallic phase have been derived from ab initio calculations within the local density (LDA) and quasiparticle selfconsistent GW (QSGW) approximations. It is found that the topologies of the FS determined by the two approaches are very similar. Nesting occurs between two different sheets of the FS, most pronounced via (1,1,0) Q- vectors connecting the outer electron surface with the hole surface The present study was motivated by recent observation of superconductivity in SnO under pressure [1].

5:06PM L31.00014 Dynamic response of Cu46Zr54 metallic glass to high-strain-rate shock loading: Plasticity, spall, and atomic-level structures , BEDRI ARMAN, Texas A&M, SHENG-NIAN LUO, TIMOTHY GERMANN, Los Alamos National Laboratory, TAHIR CAGIN, Texas A&M — Dynamic response of Cu46Zr54 metallic glass under adiabatic planar shock wave loading with molecular dynamics simulations was investigated. We analyzed the Hugoniot (shock) states up to 60 GPa, shock-induced plasticity and dynamic spall strengths. Especially, the spall strengths likely represent the limiting values achievable in experiments such as laser ablation. To characterize local deformation and structure at various stages of shock, release, tension and spallation, the local von Mises shear strain and Voronoi tessellation analyses were used. Modeled glass showed plasticity as localized shear transformation zones rather than thermal origin. Nucleation of voids occurred preferentially at the highly shear-deformed regions. Our simulations through the Voronoi and shear strain analyses suggest that the atoms having different local structures are of different shear resistances that lead to shear localization.

5:18PM L31.00015 Single Crystal X-ray Diffraction at Megabar Pressures and Temperatures of Thousands Degrees , LEONID DUBROVINSKY, NATALIA DUBROVINSKAIA, MARCO MERLINI, MICHAEL HANFLAND — The most reliable information about crystal structures and their response to changes in pressure and temperature is obtained from single crystal diffraction experiments. We have developed a methodology to perform single crystal X-ray diffraction experiments in laser-heated diamond anvil cells and demonstrate that structural refinements and accurate measurements of the thermal equation of state of metals, oxides, silicates from single crystal intensity data are possible in a pressures ranging up to megabars and temperatures of thousands degrees. New methodology was applied to solve *in situ* high-pressure high-temperature structure of iron oxide and study structural variations of iron and aluminum bearing silicate perovskite at conditions of the Earth lower mantle.

Session L32 DMP: Focus Session: Nano-Optics, Semiconductor and Metal Nanostructures C144

2:30PM L32.00001 Linear Optical and SERS Study on Metallic Membranes with Subwavelength Complementary Patterns , QINGZHEN HAO, YONG ZENG, LASSE JENSEN, DOUGLAS WERNER, VINCENT CRESPI, TONY JUN HUANG, Pennsylvania State University, INTERDEPARTMENTAL COLLABORATION — An efficient technique is developed to fabricate optically thin metallic films with subwavelength patterns and their complements simultaneously. By comparing the spectra of the complementary films, we show that Babinet's principle nearly holds in the optical domain. A discrete-dipole approximation can qualitatively describe their spectral dependence on the geometry of the constituent particles and the illuminating polarization. Using pyridine as probe molecules, we studied surface-enhanced Raman spectroscopy (SERS) from the complementary structure. Although the complementary structure posses closely related linear spectra, they have quite different near-field behaviors. For hole arrays, their averaged local field gains as well as the SERS enhancements are strongly correlated to their transmission spectra. We therefore can use $\cos^4\theta$ to approximately describe the dependence of the Raman intensity on the excitation polarization angle θ, while the complementary particle arrays present maximal local field gains at wavelengths generally much bigger than their localized surface plasmonic resonant wavelengths.

2:42PM L32.00002 Optically controlled patchy modification of metal nanoparticles , STEFAN STOIANOV, JASON RIDLEY, BRANDON THORPE, WEBSTER SANTOS, HANS ROBINSON, Virginia Polytechnic Institute and State Univeristy — It is well known that that metal nanostructures strongly concentrate light intensity at hot spots located at sharp corners or in narrow gaps, either due to plasmonic resonances or the lightning-rod effect. This is exploited a several important applications, such as surface enhanced Raman spectroscopy (SERS) and apertureless NSOM. We propose using this phenomenon to induce photochemical reaction on the surface of metal nanoparticles, leading to differential, or patchy, functionalization of the particles. We have functionalized gold and silver nanoparticles fabricated using nanosphere lithography with ligands that contain o-nitrobenzyl functional groups. Upon absorption of a photon, these compounds cleave off, leaving behind a modified surface. Differential functionalization will be demonstrated by comparing the rate of photoreactions at the hotspots (measured with SERS) to the average cleavage rate (measured with FTIR).

2:54PM L32.00003 ABSTRACT WITHDRAWN –

3:06PM L32.00004 TDDFT studies of plasmonic excitations in small transition metal-doped gold chains[1] , NEHA NAYYAR, ALAMGIR KABIR, Department of Physics Univ. of Central Florida, VOLODYMYR TURKOWSKI, TALAT S. RAHMAN, Department of Physics and NSTC Univ. of Central Florida — We apply a TDDFT approach to study the absorption spectra of pure Au chains and those doped with transition metal (TM) atoms (Ni, Rh, Fe) up to 24 atoms. We find that for gold chains with more than 10 atoms a collective plasmon mode is formed whose intensity grows with the number of atoms. The plasmon energy approaches asymptotically a value of 0.6eV when the number of atoms is about 20. However, in the chains with odd number of atoms, an additional low-energy excited state close to the plasmonic peak is found which can be related to an excitation at the chain edge. Doping with TM atoms also leads to the formation of additional plasmon peaks close in energy to the main one, especially pronounced in the case of Ni- doped chains. We compare the results for the optical absorption spectrum of the system in the case of doping by different TM atoms and the role of the d-electron states of these atoms in formation of the additional plasmon peaks.

3:18PM L32.00005 ABSTRACT WITHDRAWN –

3:30PM L32.00006 Ultrafast photoconductive response of $LaAlO_3/SrTiO_3$ nanoscale photodetectors[1] , YANJUN MA, CHENG CEN, University of Pittsburgh, CHUNG WUNG BARK, CHAD M. FOLKMAN, CHANG-BEOM EOM, University of Wisconsin-Madison, JEREMY LEVY, University of Pittsburgh — Conducting AFM lithography can be used to create nanoscale field effect transistors at the $LaAlO_3/SrTiO_3$ interface.[2,3] Such devices exhibit gatable photoconductive response, which spans from visible to near-infrared regime.[4] By implementing the pump-probe measurement with a home-built femtosecond laser, we observe an ultrafast nonlinear optical response of these nanoscale photodetectors. We explore the feasibility of these devices for molecular-scale THz spectroscopy applications.

3:42PM L32.00007 Infrared and Terahertz Nanoscopy , RAINER HILLENBRAND, CIC nanoGUNE Consolider — During the last years, near-field microscopy based on elastic light scattering from atomic force microscope tips (scattering-type scanning near-field optical microscopy, s-SNOM [1]) has become a powerful tool for nanoimaging of local dielectric material properties [2-5] and optical near fields of photonic nanostructures [6-8]. After an introduction of s-SNOM, I will discuss recently developed applications in materials sciences and nanophotonics. I will focus particularly on IR and THz imaging at wavelengths λ around 10 and 118 μm, where we typically achieve a wavelength-independent resolution better than 40 nm, corresponding to $\lambda/250$ and $\lambda/3000$, respectively [3]. Using metal-coated tips, the strong field enhancement at the tip apex probes the local dielectric properties of a sample, allowing for the simultaneous recognition of materials and free-carrier concentration in semiconductor nanodevices [3] and nanowires [5]. Quantitative free-carrier mapping is enabled by near-field plasmon-polariton spectroscopy, which can be also applied to study strain-induced changes of carrier concentration and mobility [4]. Nanoscale imaging of strain and nanocracks in ceramics can be achieved by near-field infrared phonon-polariton spectroscopy [4]. I will also discuss the capability of s-SNOM to image the vectorial near-field distribution of photonic nanostructures. In this application, a dielectric tip scatters the near fields at the sample surface. I will discuss how the amplitude and phase-resolved measurement of different near-field components allows for mapping of the polarization state in nanoscale antenna gaps [8], of near-field modes in loaded infrared gap antennas [7] and of mid-infrared energy transport in nanoscale transmission lines.

4:18PM L32.00008 Single GaN nanowire polariton luminescence , AYAN DAS, MARC JANKOWSKI, WEI GUO, PALLAB BHATTACHARYA, University of Michigan, Ann Arbor — Polariton emission from a single GaN nanowire in the strong coupling regime has been investigated in the temperature range of 200-300 K. GaN nanowires grow in the wurtzite structure with the c-axis along the growth direction. The polariton dispersion characteristics are determined from angle-resolved reflectivity measurements. The light emission characteristics measured as a function of incident optical power density reveal a distinct non-linear behavior and threshold, accompanied by a sharp decrease in linewidth over an order of magnitude and a small blue-shift that is ascribed to polariton-polariton interactions. Angle-resolved photoluminescence measurements above threshold indicate polariton cooling to the bottom of the lower polariton branch, triggered by the onset of stimulated scattering which is characterized by a fast relaxation time as obtained from time resolved photoluminescence measurements. Emission above threshold is linearly polarized. Second order correlation measurements and interferomtery indicate significant bunching below threshold and a coherent emission above threshold. These measurements indicate a coherent emission. Photon lasing due to carrier population inversion is observed at higher pump power densities.

4:30PM L32.00009 Photoreflectance spectroscopy of single GaAs/GaP Core-shell Nanowires[1] , A. WADE, M. MONTAZERI, M.A. FICKENSCHER, H.E. JACKSON, L.M. SMITH, University of Cincinnati, J.M. YARRISON-RICE, Miami University, J.H. KANG, Q. GAO, H.H. TAN, C. JAGADISH, Australian National University — We present a direct observation of the light hole (lh) and heavy hole (hh) valence band splitting in highly strained GaAs/GaP core/shell nanowires obtained by photoreflectance (PR) from a single nanowire. The NWs were prepared by Au nanoparticle (100 nm) catalyst-assisted MOCVD growth with two different shell thicknesses, where the induced strain is controlled varying the core/shell ratio. They were then dispersed on silicon for the PR measurement. The spectra show a $\sim$140eV splitting of the lh and hh bands for two different wires. Raman spectroscopy was carried out on the same growths in order to measure the hydrostatic and shear strain [1]. From the measured strain we calculate the hh and lh splitting and find them to be in reasonable agreement with PR.

4:42PM L32.00010 Photoreflectance measurements of single wurtzite InP nanowires , M. MONTAZERI, A. WADE, S. PERERA, K. PEMASIRI, L.M. SMITH, H.E. JACKSON, University of Cincinnati, J.M. YARRISON-RICE, Miami University, S. PAIMAN, Q. GAO, H.H. TAN, C. JAGADISH, Australian National University — We have carried out photoreflectance measurements from a single semiconductor nanowire for the first time to our knowledge. We show that photoreflectance is an easy, quick and nondestructive technique which could be used to study the electronic band structure of a single semiconductor nanowire at both room and low temperatures. We have used photoreflectance to study electronic band structure of single wurtzite InP nanowires at room and low temperatures. Nanowires were grown by MOCVD using 100nm Au-nanoparticle catalysts. Derivative like features in the photoreflectance spectrum around the fundamental gaps allow us to extract energies of 1.50eV, 1.53eV and 1.70eV for A, B and C excitons of wurtzite an InP nanowire at low temperature. These values are compared to values obtained by photoluminescence-excitation and photocurrent measurements. Supported by the NSF (#0701703, #0806700 and #0806572) and the Australian Research Council.

4:54PM L32.00011 Investigation of Electronic Structure in Wurtzite InP Nanowires , SARANGA PERERA, K. PEMASIRI, M. FICKENSCHER, A. WADE, L.M. SMITH, H.E. JACKSON, University of Cincinnati, J.M. YARRISON-RICE, University of Miami, Oxford OH, S. PAIMAN, Q. GAO, H. TAN, C. JAGADISH, Australian National University — We use photoluminescence excitation (PLE), time-resolved photoluminescence (PL), and CW photoluminescence to investigate the electronic structure of wurtzite InP nanowires (NWs) as a function of diameter (30, 50, 100 nm) at 10 K. The NWs were prepared by Au catalyst-assisted MOCVD growth with a 420°C growth temperature and a V/III ratio of 700. A tunable Titanium-Sapphire laser was used to excite the nanowire sample. PL from the NWs show a dominant defect line near 840nm (1.475eV) that obstructs the view of the free exciton line which should be around 824nm (1.504eV). PLE was performed by measuring the intensity of the defect emission as a function of the excitation laser. The laser was polarized parallel and perpendicular to the nanowire and the PL was collected with circular polarization. PLE spectra show three peaks for the A, B and C hole bands (*APL* **97**, 023106-2010). Polarization measurements may probe optical selection rules. Support for this work was provided by the NSF (0701703, 0806700 and 0806572) and the Australian Research Council.

5:06PM L32.00012 Photoluminescence in Strain-Engineered Si/SiGe Three Dimensional Nanostructures , NIKHIL MODI, New Jersey Institute of Technology, ECE Department, Newark NJ 07102 USA, LEONID TSYBESKOV, New Jersey Institute of Technology, ECE Department, Newark NJ 07102, USA, DAVID LOCKWOOD, XIAO WU, JEAN-MARC BARIBEAU, National Research Council, Institute for Microstructural Sciences, Ottawa ON, Canada — The effect of strain on the degeneracy of energy band minima in composition-controlled Si/SiGe nanostructures with high germanium content ($\sim$ 50%) is studied by low temperature photoluminescence (PL) spectroscopy, ultra-high resolution transmission electron microscopy and energy dispersive X-ray spectroscopy measurements. PL spectra obtained from selective excitation of the multilayered nanostructures show a reduction in the strained-silicon fundamental energy bandgap and a splitting of energy levels presumably associated with partial removal of two-fold degeneracy of the SiGe valence band. PL kinetics recorded using different excitation wavelengths show dramatically different PL lifetimes, ranging from $\sim$ 2 μs to $<$ 10 ns. We show that it is possible to obtain high quantum efficiency luminescence at 1.3-1.6 μm.

5:18PM L32.00013 State filling dependent tunneling in hybrid InAs/GaAs-InGaAs/GaAs dot-well structures , VITALIY DOROGAN, YURIY MAZUR, EUCLYDES MAREGA JR., MOURAD BENAMARA, GEORGIY TARASOV, Department of Physics, University of Arkansas, Fayetteville, AR 72701, USA, CHRISTOPH LIENAU, Institute of Physics, Carl von Ossietzky University, 26129 Oldenburg, Germany, GREGORY SALAMO, Department of Physics, University of Arkansas, Fayetteville, AR 72701, USA — A strong dependence of quantum dot (QD) - quantum well (QW) tunnel coupling on the energy band alignment is established in hybrid InAs/GaAs - $In_xGa_{1-x}As$/GaAs dot-well structures by changing the QW composition to shift the QW energy through the QD wetting layer (WL) energy. Due to this coupling a rapid carrier transport from the QW to the QD excited states takes place. As a result, the QW photoluminescence (PL) completely quenches at low excitation intensities. The threshold intensities for the appearance of the QW PL strongly depend on the relative position of the QW excitonic energy with respect to the WL ground state and the QD ground state energies. These intensities increase by orders of magnitude as the energy of the QW increases to approach that of the WL due to the increased efficiency for carrier tunneling into the WL states as compared to the less dense QD states below the QW energy.

Session L33 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides: Lattice Dynamics, Polarons, and Structure C143/149

2:30PM L33.00001 Ultrafast Polaron Dynamics in Multiferroic $LuFe_2O_4$* , R.P. PRASANKUMAR, J. LEE, D. TALBAYEV, A.J. TAYLOR, CINT, Los Alamos National Laboratory, C.L. ZHANG, S.-W. CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, X.S. XU, Department of Chemistry, University of Tennessee — The multiferroic material $LuFe_2O_4$ has attracted much recent attention due to its strong magnetoelectric coupling. We used ultrafast optical spectroscopy to examine $LuFe_2O_4$ by employing a 1.55 eV probe pulse to examine the $Fe^{2+} - > Fe^{3+}$ polaronic excitation as a function of temperature and pump photon energy. After 1.55 eV excitation, the photoinduced reflectivity change $\Delta R/R$ decreases within $\sim$1 picosecond (ps), after which a $\sim$30 ps acoustic phonon oscillation is observed. The initial fast drop in $\Delta R/R$ can be explained by $Fe^{2+} - > Fe^{3+}$ polaron hopping, and the subsequent rapid recovery is due to polaron redressing; this is observed at all temperatures. Pumping the Fe^{2+} on-site excitation at 3.1 eV revealed different dynamics. Notably, coupling between the on-site and charge transfer excitations was strongly suppressed above the antiferromagnetic ordering temperature, demonstrating the strong influence of charge and spin order on polaron dynamics.

2:42PM L33.00002 Amplitude and phase gratings based on spatially modulated densities of optically generated polarons in thermally reduced $LiNbO_3$[1] , HAUKE BRUENING, MIRCO IMLAU, University of Osnabrueck, Germany — In thermally reduced, nominally pure $LiNbO_3$ a variety of small polarons can be observed, being responsible for the distinct photochromic properties of this material. In this contribution we use a spatially modulated excitation of polarons for the recording of holographic gratings. These gratings inherit some of the pronounced features of the polarons like a stretched-exponential relaxation behavior with a lifetime in the ms-range. Beside amplitude gratings we also find phase gratings leading to a high diffraction efficiency in some recording and readout geometries. The origin of these phase gratings can't be explained by the classic photorefractive effect due to Fe_{Li} or other photorefractive dopants. In contrast, our findings are discussed in the frame of a model taking into account a local change of the refractive index by the polaronic distortion of the crystal lattice. Measurements of activation energies also indicate that these gratings can be attributed to the small bound (Nb_{Li}^{4+})-polaron.

2:54PM L33.00003 Hamiltonian approach to Feynman's path-integral polaron treatment[1] , J.T. DEVREESE, S.N. KLIMIN, Theorie van Quantum en Complexe Systemen (TQC), Universiteit Antwerpen, Antwerpen, Belgium — The Feynman path-integral based all-coupling variational approach for the Fröhlich-polaron is re-formulated and extended using the Hamiltonian formalism with time-ordered operator calculus. Special attention is devoted to the excited polaron states. The energy levels and the inverse lifetimes of the excited polaron states are, for the first time, explicitly calculated within this all-coupling approach. The resulting transition energies are compared with the peak positions of the polaron optical conductivity, as recently calculated numerically using diagrammatic quantum Monte Carlo.

[1]This work was supported by FWO-V projects G.0356.06, G.0370.09N, G.0180.09N, G.0365.08, and the WOG WO.035.04N (Belgium).

3:06PM L33.00004 Comparison of the Raman low frequency spectra of NBT and KLT[1] , DANIEL JACKSON, RADHA PATTNAIK, Physics Dept., Lehigh University, HAOSU LUO, Shanghai Institute of Ceramics, Chinese Academy of Sciences, DWIGHT VIEHLAND, Materials Science Dept., Virginia Tech, JEAN TOULOUSE, Physics Dept., Lehigh University — We present the results of a detailed comparative study of the low frequency central peak in sodium bismuth titanate ($Na_{0.5}Bi_{0.5}TiO_3$ or NBT) and potassium lithium tantalate (K_{1-x} Li_xTaO_3 or KLT) from 90 degree angle Raman scattering with a resolution of 1 cm^{-1}. The Raman spectra of NBT were obtained over a wide temperature range from 78 to 950 K, spanning the two transitions, from cubic to tetragonal at ∼820 K and tetragonal to rhombohedral in the range 480-600 K. In an effort to better understand the nature of these phase transitions in NBT, we performed a detailed analysis of the central peak and soft mode combined, using different models. In particular, we compare the model in which these two features are uncoupled with the model in which they are coupled with a strength parameter, δ^2. These models are also discussed in the more general context of A-site substituted ABO_3 perovskites. The effects of an external electric field and mechanical pressure on the transitions will also be discussed.

3:18PM L33.00005 Phonon structures and IR intensities in strained BaTiO3 , ALDO RAELIARIJAONA, University of Arkansas, HUXIANG FU — While soft modes and structural instability in cubic ferroelectrics have been well studied, the vibration properties in structurally stable phases are relatively less understood, however. Here we have carried out first-principle calculations, using density-functional perturbation theory, to determine the phonon structures and IR intensities at gamma point for tetragonal Barium titanate under different in-plane strains, in which lattice parameter ranges from 3.93 Å to 3.80 Å. We find that some modes shift strongly with the inplane strain, while other modes show surprisingly little change. The response of IR intensity is also revealed to be mode-dependent. The microscopic insight for these behaviors is examined.

3:30PM L33.00006 Neutron Diffuse Scattering Measurements of PZT , D. PHELAN, P.M. GEHRING, J. RODRIGUEZ, C. STOCK, NIST Center for Neutron Research, X. LONG, Y. XIE, Z.-G. YE, Simon Fraser University — Neutron diffuse scattering measurements were performed on a single crystal of $PbZr_{0.675}Ti_{0.325}O_3$. The data is compared and contrasted with other Pb-based piezoelectrics, such as the relaxor $PbMg_{1/3}Nb_{2/3}O_3$, and is discussed within the context of random fields.

3:42PM L33.00007 A Neutron Study of the Structure and Lattice Dynamics of Single Crystal PZT , PETER GEHRING, National Institute of Standards and Technology — The outstanding piezoelectric properties of $PbZr_{1-x}Ti_xO_3$ (PZT) perovskite ceramics have long been exploited in numerous device applications, making PZT arguably the most technologically important ferroelectric material in use today. Efforts to understand the piezoelectric mechanism have inspired a plethora of structural studies spanning decades, but solving the PZT phase diagram has proven to be famously problematic because single crystals have not been available save for Zr- and Ti-rich compositions that lie very near the end members $PbZrO_3$ and $PbTiO_3$, where the piezoelectricity is weakest. Thus, whereas PZT has been the subject of thousands of powder and ceramic investigations, no consensus regarding the crystal structures of PZT exists. We report the first neutron diffraction study of single-crystal PZT with compositions x = 0.325 and 0.460 [1]. Our data refute the thesis that the ferroelectric phases of PZT within this composition range, all of which are highly piezoelectric, are purely monoclinic (Cc or Cm). The broadening of certain Bragg peaks can be interpreted in terms of coexisting rhombohedral and monoclinic domains, whereby monoclinic order is enhanced by Ti-doping. This is consistent with the theoretical proposal that the tendency to form macroscopic monoclinic phases facilitates the mechanism of polarization rotation by reducing the energy required to reorient the electric polarization. Dispersions of the lowest energy TO and TA phonon modes were measured on a single crystal of PZT with x = 0.325 in the paraelectric phase at 650 K [2]. The TO mode energy drops at small wave-vectors suggesting that it is a soft mode associated with the ferroelectric phase transition at 590 K. Evidence of a second soft-mode, corresponding to a phase transition at 370 K at the R-point, is provided based on the redistribution of spectral weight as a function of temperature.

4:18PM L33.00008 Correlations between tetragonality, polarization, and ionic displacement in lead titanate-derived ferroelectric perovskite solid solutions[1] , ANDREW RAPPE, TINGTING QI, ILYA GRINBERG, University of Pennsylvania — We use first-principles density functional theory calculations to investigate the dependence of tetragonality on local structure in a variety of ferroelectric solid solutions. We demonstrate that tetragonality is strongly coupled to the B-cation displacement and weakly coupled to the A-cation displacement. Examination of various $BiM^{3+}O_3$ additives to $PbTiO_3$ for different M^{3+} ionic sizes reveals that substitution of either small B-cations or low doping of large B-cations gives rise to large spontaneous polarization and tetragonality. Understanding how the phase transition temperature (T_c) and tetragonality are affected by Pb- and Bi-based perovskite additives provides a rational path for designing new high-temperature piezoelectric materials.

[1]We acknowledge support from ONR, DOE and DOD

4:30PM L33.00009 First principles prediction of a morphotropic phase boundary in the $Bi(Zn_{1/2}Ti_{1/2})O_3$-$(Bi_{1/2}Sr_{1/2})(Zn_{1/2}Nb_{1/2})O_3$ alloy[1] , VALENTINO R. COOPER, Oak Ridge National Laboratory, ASEGUN S. HENRY, Georgia Institute of Technology, SHIGEYUKI TAKAGI, University of Tennessee, DAVID J. SINGH, Oak Ridge National Laboratory — We present a density functional theory study on alloys of the tetragonally distorted $Bi(Zn_{1/2}Ti_{1/2})O_3$ (BZT) and the rhombohedrally oriented $(Bi_{1/2}Sr_{1/2})(Zn_{1/2}Nb_{1/2})O_3$ (BSZN). We find that compositions with $\geq$ 50% BZT are tetragonally distorted with the polarization pointing mainly along the [001] direction. Conversely, for low concentrations of BZT the polarization is rhombohedrally oriented. Based on these results we propose a phase diagram with a possible monoclinc phase between 25% and 50% BZT where this material may have a useful piezoelectric response.

4:42PM L33.00010 Probing Ferroelectricity in Thin-film Perovskite $SnTiO_3$ with First-principles Structural Instability Analysis[1] , WILLIAM PARKER, JAMES RONDINELLI, SERGE NAKHMANSON, Argonne National Laboratory — Perovskite $SnTiO_3$ has been recently identified in a number of computational studies as an attractive, environmentally-friendly material with potential to replace ferroelectric $PbTiO_3$. However, additional computational evidence suggests that bulk perovskite $SnTiO_3$ may be metastable. Using density-functional theory and phonon-band instability analysis, we investigate avenues for epitaxial stabilization of ferroelectric perovskite $SnTiO_3$ thin films with applied strains of up to ± 2%.

[1]The U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences supports this project under contract No. DE-AC02- 06CH11357.

4:54PM L33.00011 Room temperature metastable monoclinic phase in $BaTiO_3$ crystals , TOM LUMMEN, JIANJUN WANG, Pennsylvania State University, University Park, Pennsylvania 16802, USA, MARTIN HOLT, Center for Nanoscale Materials, Argonne National Laboratory, Argonne, Illinois 60439, USA, AMIT KUMAR, EFTIHIA VLAHOS, SAVA DENEV, LONG-QING CHEN, VENKATRAMAN GOPALAN, Pennsylvania State University, University Park, Pennsylvania 16802, USA — Low-symmetry monoclinic phases in ferroelectric materials are of considerable interest, due to their associated enhanced electromechanical coupling. Such phases have been found in Pb-based perovskite solid solutions such as lead zirconate titanate (PZT), where they form structural bridges between the rhombohedral and tetragonal ground states in compositional space. In this work, we directly image such a monoclinic phase in $BaTiO_3$ crystals at room-temperature, using optical second harmonic generation, Raman, and X-ray microscopic imaging techniques. Phase-field modeling indicates that ferroelectric domain microstructures in $BaTiO_3$ induce local inhomogeneous stresses in the crystals, which can effectively trap the transient intermediate monoclinic structure that occurs across the thermal orthorhombic-tetragonal phase boundary. The induced metastable monoclinic domains are ferroelectrically soft, being easily moved by electric fields as low as 0.5 kV cm^{-1}. Stabilizing such intermediate low-symmetry phases could very well lead to Pb-free materials with enhanced piezoelectric properties.

5:06PM L33.00012 Infrared spectroscopy of KDP under high pressure[1] , ANA AKRAP, CHRISTOPHER C. HOMES, Condensed Matter Physics and Materials Science Dept., Brookhaven National Laboratory, Upton, New York, RICARDO P.S.M. LOBO, Laboratoire de Physique et d'Étude des Matèriaux, ESPCI-ParisTech, CNRS-UPMC, 10 rue Vauquelin, F-75231 Paris Cedex 5, France, PATRICK SIMON, CRMHT, CNRS UPR 4212, Université d'Orléans, 1D Av. de la Recherche Scientifique, 45071 Orléans Cedex 02, France — We have determined infrared reflectivity of potassium dihydrogen phosphate (KDP) in the paraelectric ($T > T_c$ =135 K) and ferroelectric phase ($T < T_c$), at pressures ranging from ambient up to 10 kbar, for polarizations parallel and perpendicular to the ferroelectric axis. As the T_c is lowered and the paraelectric phase is suppressed by pressure, we track the behavior of several relevant phonon modes. Under pressure there is a significant increase in the oscillator strength of the 150 cm^{-1} mode, accompanied by its shift to lower energies. The ferroelectric soft mode is critically damped below 6.5 kbar, but becomes underdamped at higher pressures.[2] The coupling of the ν_4 mode at 500 cm^{-1} to the ferroelectric soft mode is investigated.

5:18PM L33.00013 Elastic Anizotropy and Domain Stability in Ferroelectric Thin Films and Problem of Critical Thickness for Memory , ALEXANDER BRATKOVSKY, Hewlett-Packard Laboratories, A.P. LEVANYUK, UA Madrid — The most important effect of the depolarizing field in thin ferroelectric (FE) capacitors is the emergence of domains in place of monodomain state desirable for memory applications, and it depends on the parameters of system Ferroelectric- Electrode. We have studied FE films of BaTiO3, PbTiO3, and Pb (Zr)0.5(Ti)0.5O3 with SrRuO3 electrodes on SrTiO3 (100) substrate. Due to lattice misfit, the FE film becomes tetragonal with the polar axis perpendicular to the film. We have studied rarely addressed topic of relation between the equilibrium domain structure and limits of absolute stability of the monodomain state. We have found that in films with thickness close to the minimal one compatible with FE the stripe domains form with domain walls along the cubic axes in BTO and PTO films, while in PZT it is at 45 degrees to the axes. The orientational dependence of their energy is actually very weak, less than 1% is all above systems. The threshold of absolute instability of the monodomain state is shifted by electrostriction most significantly in BTO and PTO, where it gets close to the (formal) "critical thickness" for FE in monodomain films. In PZT, on the other hand, electrostriction hardly affects it [1].

Session L34 DMP: Focus Session: Interfaces in Complex Oxides - Heterointerfaces C141

2:30PM L34.00001 Electronic instabilities at paraelectric and superconducting interface: A mean field approach[1] , J.T. HARALDSEN, A.V. BALATSKY, Theoretical Division, Los Alamos National Laboratory and Center for Integrated Nanotechnologies, Los Alamos, NM 87545 — We examine the modified electronic states at the interface between superconducting and ferro(para)-electric films. We find that the coupling of a classical fluctuating paraelectric P and superconducting ψ order parameters can significantly modify these orders at the interface. Using a Ginzburg-Landau formalism, we show that linear and quadratic terms of the electric polarization produce instabilities in ψ at the interface, where the linear interaction produces a modulation of the order parameters and create an interface-induced ferroelectric polarization within the paraelectric bulk state. We will discuss implications of this work for the experiments on the epitaxial oxide films.

3:06PM L34.00004 Unconventional proximity effect and inverse spin-switch behavior in a model manganite/cuprate/manganite trilayer system , JUAN SALAFRANCA, Universidad Complutense de Madrid, Spain., SATOSHI OKAMOTO, Oak Ridge National Laboratory — The proximity effect in a model manganite/cuprate system is investigated theoretically. We consider a situation in which spin-polarized electrons in manganite layers antiferromagnetically couple with electrons in cuprate layers as observed experimentally. The effect of the interfacial magnetic coupling is found to be much stronger than the injection of spin-polarized electrons into the cuprate region. As a result, the superconducting transition temperature depends on the thickness of cuprate layer significantly. Since the magnetic coupling creates *anti*-spin-polarization, an applied magnetic field and the *anti*-polarization compete resulting in the inverse spin-switch behavior where superconducting transition temperature is increased by applying a magnetic field. This work was supported by the NSF Grant DMR-0706020 (J.S.) and by the Materials Sciences and Engineering Division, Office of Basic Energy Sciences, the US DOE (S.O.).

3:18PM L34.00005 Magnetoelectric Coupling in P(VDF-TRFE)/LCMO Heterojunctions[1] , ANIL KUMAR, University of Nebraska-Lincoln, USA, EVGENY KIRIANOV, Lincoln South-West High School, NE, USA, VASILY MOSHNYAGA, I. Physikalisches Institut, Universität Göttingen, Germany, PANKAJ SHARMA, ALEXEI GRUVERMAN, ANDREI SOKOLOV, University of Nebraska-Lincoln, USA — Engineered magnetoelectric heterojunctions have recently attracted significant interest due to the possibility to control magnetic properties by external electric fields. Doped lanthanum manganites are attractive candidates to use as a part of such junctions because of their strong coupling between charge, spin and lattice effects. On the other side the use of a ferroelectric (FE) as a gate electrode has dual benefits: it offers the possibility to design a non-volatile data storage device and provide large charge density change at the interface. The ferroelectric polymer, polyvinylidene fluoride (PVDF), is an interesting candidate due to its outstanding electromechanical, dielectric, and mechanical properties. Here we present results of our transport studies of $La_{.67}Ca_{.33}MnO_3$ /P(VDF-TrFE) heterojunction. Manganite thin films were grown by MAD technique, followed by Langmuir-Blodgett deposition of ferroelectric polymer. Results are explained by electron accumulation induced metal-insulator transition in the LCMO layer.

3:42PM L34.00007 Emergent phenomena at the heterointerface of multiferroic $BiFeO_3$ and ferromagnetic $La_{0.7}Sr_{0.3}MnO_3$[1] , PU YU, Department of Physics, University of California, Berkeley — Novel phenomena and functionalities at the heteroepitaxial complex oxide heterostructures have been attracting much scientific attention from the fundamental physics as well as the technological applications. Essentially, the charge and spin reconstruction at the interface could lead to exotic, totally unexpected state of matters at the interface, such as conductive interface between insulating materials and interfacial ferromagnetism at the proximity of antiferromagnet. In this talk, I will present a systematic study of the electronic (charge) and magnetic (spin) interactions in an all-oxide model heterostructure system consisting of the ferromagnet (FM) $La_{0.7}Sr_{0.3}MnO_3$ (LSMO) and the multiferroic (ferroelectric (FE) and antiferromagnetic (AFM)) $BiFeO_3$(BFO). The study has demonstrated the existence of magnetic coupling at this interface, manifested in the form of an enhanced coercive field as well as an exchange bias. Using x-ray magnetic circular dichroism, the origin of the significant exchange bias has been attributed to a novel ferromagnetic state in the antiferromagnetic BFO sublattice at the interface with LSMO. Based on this finding, the electrical control of magnetic coupling has been explored in the field effect geometry. The magneto-transport measurement clearly demonstrates a reversible switch/control between two distinct exchange bias states by isothermally switching the FE polarization of BFO. This is an important step towards controlling magnetization with electric fields, which may enable a new class of electrically controllable spintronic devices and provide a new basis for producing electrically controllable spin polarized currents. Finally, at the end of the talk, a generic interpretation will be proposed for the understanding of magnetoelectric coupling in the current model system.

4:18PM L34.00008 Modified Magnetotransport in Digital Manganite Superlattices[1] , BRITTANY NELSON-CHEESEMAN, Materials Science Division, Argonne National Laboratory, TIFFANY SANTOS, Center for Nanoscale Materials, Argonne National Laboratory, SAM BADER, ANAND BHATTACHARYA, Materials Science Division and Center for Nanoscale Materials, Argonne National Laboratory — We investigate how the series of manganite superlattices, $(LaMnO_3)_{2n}(SrMnO_3)_n$, responds to an out-of-plane magnetic field in order to better understand how the magnetism and magnetotransport are modified in a short period superlattice. The n=1 superlattice shows magnetotransport and magnetic hysteresis similar to the random alloy with positive low field magnetoresistance (MR) due to anisotropic magnetoresistance (AMR) and negative MR at high fields due to colossal magnetoresistance (CMR). However, the n=2 superlattice behaves differently with large negative MR at high fields, and no positive low field MR for T<100K. The lack of positive low field MR has also been seen in $La_{2/3}Sr_{1/3}MnO_3$ films with perpendicular magnetic anisotropy, suggesting that the n=2 sample moments contain an out-of-plane, canted or frustrated component at low fields. The reemergence of positive low field MR for the n=2 sample above 100K indicates that the driving force for the different moment orientation is strongly temperature dependent.

4:30PM L34.00009 $La_{0.7}Sr_{0.3}MnO_3$ Epitaxial Films on $SrTiO_3$(001): Interface Effects & Electronic Distribution , J.-S. LEE, D.A. ARENA, National Synchrtron Light Source, Brookhaven National Lab, C.-C. KAO, Stanford Synchrotron Radiation Light Source, SLAC, P. YU, Dept. of Physics, UC-Berkeley, R. RAMESH, Dept. of Physics, UC-Berkeley and Mater. Sci. Div., LBNL — $La_{1-x}Sr_xMnO_3$ is an attractive material for incorporation into spin-dependent electronic devices and optimally doped $La_{0.7}Sr_{0.3}MnO_3$ (LSMO) is among the most widely studied colossal magneto-resistance materials. Using a combination of soft x-ray absorption spectroscopy and hard x-ray reflectivity, we found that epitaxial films of LSMO grown on STO(001) substrates exhibit an inhomogeneous 3d electron-distribution along surface normal direction, divided between an intermediate layer (enriched in Mn^{3+}) and a nominal mixed-valence layer (Mn^{3+} & Mn^{4+}) of LSMO. This electronic redistribution near the interface is in turn correlated with an unusual remanent magnetic state.

4:42PM L34.00010 $La_{0.7}Sr_{0.3}MnO_3$ Epitaxial Films on $SrTiO_3$(001): Interface Effects & Magnetic Configuration , D.A. ARENA, J.-S. LEE, C.S. NELSON, National Synchrotron Light Source, Brookhaven National Lab, C.-C. KAO, Stanford Synchrotron Radiation Light Source, SLAC, P. YU, Dept. of Physics, UC-Berkeley, R. RAMESH, Dept. of Physics, UC-Berkeley and Mater. Sci. Div., LBNL, R. FAN, C.J. KINANE, S. LANGRIDGE, ISIS, Harwell Campus, STFC, UK — Mixed valence manganites, in which a delicate interaction between electronic, orbital, magnetic and structural degrees of freedom produces rich phase diagrams reflecting the competing, nearly-degenerate ground states, have been under intense investigation for decades. We present evidence for an unusual magnetic configuration in $La_{0.7}Sr_{0.3}MnO_3$ (LSMO) epitaxial films grown on $SrTiO_3$(001) substrates. At low temperatures, the remanent state of the near-surface region in thick LSMO films is aligned anti-parallel to the the applied magnetic field. This unusual magnetic configuration is also correlated with an in-plane structural fluctuation, as measured by x-ray diffraction. We suggest that the unexpected magnetic ordering in these films may also be associated with an orbital reconstruction of the Mn e_g orbitals.

4:54PM L34.00011 Magnetoelectric coupling at the interface of $BiFeO_3/La_{0.7}Sr_{0.3}MnO_3$ multilayers , MARIA J. CALDERON, Inst. Ciencia de Materiales de Madrid-CSIC, R. YU, Rice University, S. LIANG, University of Tennessee, Oak Ridge National Lab, J. SALAFRANCA, Universidad Complutense de Madrid, S. DONG, Southeast University and Nanjing University, S. YUNOKI, RIKEN and Japan Science and Technology Agency, A. MOREO, E. DAGOTTO, University of Tennessee, Oak Ridge National Lab, L. BREY, Inst. Ciencia de Materiales de Madrid-CSIC — Magnetoelectric coupling has recently been demonstrated in a system composed of the ferromagnetic manganite $La_{0.7}Sr_{0.3}MnO_3$ (LSMO) and the ferroelectric antiferromagnetic $BiFeO_3$ (BFO) [1,2]. Using a realistic microscopic model we study the effects of the charge redistribution and orbital reconstruction on the LSMO/BFO interface ground state. We find that the BFO interface (ferro)magnetism is affected by the charge density at the interface which, in turn, can be modified by the ferroelectric polarization on BFO. This interface induced magnetoelectric coupling leads to the recently observed electric field controlled exchange bias.

5:06PM L34.00012 Modulation doping of double-exchange ferromagnetism in an antiferromagnetic manganite: Theory and Synthesis[1] , ANAND BHATTACHARYA, T.S. SANTOS, Argonne National Laboratory, B.J. KIRBY, NIST, Gaithersburg, SANJEEV KUMAR, IFW, Dresden, S.J. MAY, Argonne National Laboratory; Drexel University, J.A. BORCHERS, B.B. MARANVILLE, NIST, Gaithersburg., J. ZARESTKY, Oak Ridge National Laboratory, S.G.E. TE VELTHUIS, Argonne National Laboratory, JEROEN VAN DEN BRINK, IFW, Dresden — In this talk we shall discuss the concepts that underlie modulation doping in the context of manganites, particularly the high bandwidth $La_{1-x}Sr_xMnO_3$, and how modulation doped structures are realized using oxide-MBE based techniques. The transport and magnetic properties of modulation doped antiferromagnetic digital superlattices of $(LaMnO_3)_1/(SrMnO_3)_1$ will be discussed in the context of theoretical ideas about exchange interactions in these materials going back to the seminal work of de Gennes, and compared to similar structures in other parts of the $La_{1-x}Sr_xMnO_3$ phase diagram.

[1]U. S. Department of Energy, BES, Contract No. DE-AC02-06CH11357; NIST, U.S. Department of Commerce.

5:18PM L34.00013 Modulation doping of double-exchange ferromagnetism in an antiferromagnetic manganite: Magnetic Structure , T.S. SANTOS, A. BHATTACHARYA, S.G.E. TE VELTHUIS, Argonne National Lab, B.J. KIRBY, J.A. BORCHERS, B.B. MARANVILLE, NIST NCNR, S.J. MAY, Drexel U., S. KUMAR, J. VAN DEN BRINK, IFW Dresden, J. ZARESTKY, Ames Lab — In his pioneering work, de Gennes described a canted antiferromagnetic (AF) state that arises when mobile carriers are added to an insulating AF manganite. However, attempts to realize this canted AF state have been impeded by phase segregation into mixed F and AF phases for x=0.1-0.2. Using a digital synthesis technique to carry out modulation doping of charge carriers into an AF host near x=0.5, we exploit the competing double-exchange and superexchange interactions to realize the canted AF state predicted by de Gennes. We observed the canted AF state using polarized neutron reflectometry and neutron diffraction using polarized neutrons and polarization analysis. Theoretical consideration using the two-orbital model shows that these additional carriers cause a local enhancement of F double-exchange with respect to AF superexchange, resulting in local canting of the AF spins, where the canting angle depends on the doping level. We observe that the canting angle varies with the spreading of charge near the delta-doped layer. 2:30PM L35.00001 First Principles Stability and Coherency Strain in Mg3RE (RE=rare earth) D019 Metastable Precipitates in Mg , A. ISSA, J. SAAL, C. WOLVERTON, Northwestern University — As the need for strong yet lightweight materials intensifies, magnesium alloys have become increasingly important. Although lightweight, these alloys exhibit low strength, particularly in comparison to aluminum alloys. The potential to greatly strengthen magnesium alloys has driven current research, with a recent focus on strengthening precipitates, particularly involving rare earth (RE) dopants. The morphology of these precipitates dictates their effect on the strength of the alloy, and quantifying the coherency strain between the precipitates and the Mg matrix is key to determining the morphology of the precipitate. The large size of the potential composition space makes a systematic experimental study costly and time consuming. Therefore, we apply density functional theory (DFT) to systematically predict the formation energies and coherency strains of D019 precipitates in Mg-RE systems along several crystallographic directions. In particular, we look for D019 precipitates that favorably form plate-shaped morphologies along non-basal planes, as this morphology should be effective obstacles to plastic deformation. These Mg-RE systems also provide an interesting testing ground for the accuracy of DFT methods for intermetallic compounds containing f-electrons.

2:42PM L35.00002 Chemical Correlations in Atomic Size-Mismatch Disordered Alloys Predicted from KKR-DCA[1] , D.A. BIAVA, Dept. of Physics, University of Illinois, Urbana, IL 61801, D.D. JOHNSON, Ames Laboratory/US DoE and the Dept. of Materials Science & Engineering, Iowa State University, Ames, Iowa 50011 — The dynamical cluster approximation (DCA) has been implemented in a Korringa-Kohn-Rostoker (KKR) electronic-structure method to predict electronic and structural properties of disordered alloys, in particular, chemical short-range order (SRO). We adapted an optimal-basis method[2] to the KKR-DCA to account for variations in atomic size due to different configurations present in size-mismatch alloys. In comparison to experiment, we find excellent agreement for predicted lattice constants and SRO, with origins identified in the electronic structure and affecting mechanical properties at finite temperatures. We also show how coarse-grained symmetry of the DCA can be exploited to reduce memory and computation time, allowing us to perform for the first time self-consistent KKR-DCA calculations with 2^{16} or more configurations (and atoms) on a single compute node.

2:54PM L35.00003 Modified Embedded Atom Method potential for Fe-C system , LAALITHA LIYANAGE, Mississippi State University, JEFF HOUZE, SEONG-GON KIM, MARK TSCHOPP, SUNGHO KIM, Mississippi State University, MIKE BASKES, Los Alamos National Laboratory, MARK HORSTEMEYER, Mississippi State University — A Modified Embedded Atom Method potential for the Fe-C alloy system was developed. Pair parameters were constructed based on the structural and elastic properties of element pairs in the L12 reference structure from ab-initio simulations and then adjusted to reproduce heat of formation and elastic constants of cementite, and the interstitial energies for iron. The single element potential of carbon correctly predicts graphite and diamond as the two minimum energy structures.The potential parameters were optimized using an optimization method combining Latin hypercube sampling of the N-dimensional parameter space and multi-objective optimization. The potential was tested for stability of cementite by molecular dynamic simulation at room temperature.

3:06PM L35.00004 The unified mechanism of aging effects in both martensite and parent phase for shape-memory alloys: atomic-level simulations , J. DENG, X. DING, State Key Laboratory for Mechanical Behavior of Materials, Xi'an Jiaotong University, Xi'an 710049, China, T. SUZUKI, K. OTSUKA, Ferroic physics Group, National Institute for Materials Science, Tsukuba 305-0047, Ibaraki, Japan, T. LOOKMAN, A. SAXENA, Theoretical Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA, J. SUN, State Key Laboratory for Mechanical Behavior of Materials, Xi'an Jiaotong University, Xi'an 710049, China, X. REN, Ferroic physics Group, National Institute for Materials Science, Tsukuba 305-0047, Ibaraki, Japan — Most shape-memory alloys (SMAs) subject to the aging effects not only in the martensite phase but also in the parent phase. These aging effects have been attracted much attention as they strongly affect the practical applications of SMAs. So far, the intrinsic mechanism of them has remained controversial due to the difficulty in visualization of what happens in atomic scale. In the present study, by using a combination of molecular dynamics method and Monte-Carlo method [1], we investigate the aging effects in both martensite and parent phase. We successfully reproduced the thermal behaviors of aging effects for SMAs, i.e., the A_f temperature increase with aging time in martensite and the M_s temperature decrease with aging time in parent phase, which keep good agreement with the experimental observations [2]. In addition, quantitative analysis of the atomic configurations during aging reveals that the aging effects are not associated with a change in the average structure.

3:18PM L35.00005 Enhanced High Temperature Mechanical Behavior of FeCo-Based Alloys , ROBERT CAMMARATA, Johns Hopkins University, DEZHI ZHANG, Chinese Academy of Sciences, CHIA-LING CHIEN, Johns Hopkins University — FeCo alloys have been used for a variety of soft magnetic material applications, including for use in high temperature engine applications. However, inferior mechanical properties, in particular relatively low creep resistance, can limit their use at elevated temperatures. We have investigated a variety of microstructural engineering approaches to improve the creep resistance without significantly degrading the magnetic properties. Two such approached will be discussed: oxide dispersion strengthening and annealing treatments leading to grain growth and precipitation hardening. We have shown that both of these methods allow for sensitive control of the resulting microstructural evolution. This control in turn allows for substantial improvement in both the room temperature yield strength as well as the high temperature creep resistance. Detailed microstructural characterization as well as tensile and testing results will be presented.

3:30PM L35.00006 Fermi surface of an important nano-sized metastable phase: Al_3Li , STEPHEN DUGDALE, University of Bristol, UK, JUDE LAVEROCK, Boston University, USA, ASHRAF ALAM, MINA ROUSSENOVA, University of Bristol, UK, JOANNE WENSLEY, University of Cambridge, UK, JADWIGA KWIATKOWSKA, Polish Academy of Sciences, NOBU SHIOTANI, KEK-PF, Japan — Nanoscale particles embedded in a metallic matrix are of considerable interest as a route towards identifying and tailoring material properties. In particular, Al-Li alloys, which form ordered nanoscale precipitates of $L1_2$ Al_3Li for a range of Li concentrations, have been deployed successfully in the aerospace industry owing principally to their superior strength-to-weight ratio. These precipitates, however, are metastable and only form within the surrounding Al matrix, meaning their electronic structure, thought to be important in contributing to the enhanced material properties through its Young's modulus, has so far been inaccessible through conventional techniques. Here, we take advantage of the strong positron affinity of Li to directly probe the Fermi surface of metastable Al_3Li nanoscale precipitates of Al-Li.

3:42PM L35.00007 Metastable states along the Bain path in AgZr with AFLOW[1] , MICHAEL MEHL, Naval Research Laboratory, GUS HART, Brigham Young University, MICHAL JAHNATEK, STEFANO CURTAROLO, Duke University — AgZr crystallizes in the B11 structure, which is bcc-like with stacking AABB along [001]. Using AFLOW[2] we find another low energy structure, "Z2" ,[3] an fcc-like variant of B11. The B11 to Z2 transition follows the Bain path, with c/a changing from 1.9 (B11) to 2.6 (Z2). This seems similar to results for elemental bcc solids,[4] where we find a secondary Bain path minimum which is elastically unstable. Here there is no simple path from the Z2 structure back to the B11 structure, and the Z2 structure is metastable. Using first- principles DFT we demonstrate the possibility of a pressure induced phase transition from B11 to Z2 at 35 GPa. We also examine the $L1_0$ structure, which is higher in energy than Z2 at zero pressure. We find that a transition from B11 to $L1_0$ at 32 GPa, so that $L1_0$ is the true high-pressure phase of AgZr. We discuss the stability of all three of these phases at both zero and high pressure, and the possibility of similar transitions in more useful materials.

3:54PM L35.00008 Localized Rattling of Al atoms in $VAl_{10+\delta}$, DOUGLAS SAFARIK, Los Alamos National Laboratory, TOMASZ KLIMCZUK, Institute for Transuranium Elements, Karlsruhe, ANNA LLOBET, DARRIN BYLER, Los Alamos National Laboratory, EKHARD SALJE, Cambridge University — We have studied the localized rattling mode in the 'Einstein solid' $VAl_{10+\delta}$ using a suite of thermodynamic, transport, and neutron diffraction measurements. The rattling originates from Al atoms that occupy the large void within Z_{16} Friaf polyhedra, of which there are eight per unit cell in the $VAl_{10+\delta}$ structure. Our heat capacity, thermal expansion, and electrical resistivity data are all qualitatively consistent with a low-frequency harmonic vibration of the atom. However, our neutron diffraction data show that the rattling atom potential is better described as sixth-order, rather than harmonic. Using a single-site, sixth-order effective potential for the rattling atom, we can explain our thermodynamic, transport, and structural data, including the unusual temperature dependence of the elastic constants.

4:06PM L35.00009 High-energy diffraction measurements of deeply undercooled Co-Pd liquids using electrostatic levitation[1] , G.E. RUSTAN, Iowa State University, N.A. MAURO, J.C. BENDERT, K.F. KELTON, Washington University, A. KREYSSIG, A.I. GOLDMAN, Iowa State University — Co-Pd liquids in their deeply undercooled state have attracted a great deal of interest because of the potential for magnetically triggered nucleation of the solid phase. We report on the results of high-energy x-ray diffraction measurements, using 129 keV x-rays at the Advanced Photon source, on a series of liquid Co-Pd alloys in a containerless environment employing electrostatic levitation. Diffraction data were collected using a flat-plate two-dimensional detector during free cooling from temperatures well above the liquidus, to as much as 200 degrees C of undercooling for compositions ranging from 50:50 to 80:20 (Co:Pd). The composition dependence and temperature dependence of differences in structure will be discussed.

[1]This work was supported by the National Science Foundation under grant DMR-08-01757, DMR-06-06065, DMR-08-56199 and NASA under grants NNX07AK27G and NNX09AJ19H.

4:18PM L35.00010 Ab initio studies of the effect of nanoclusters on magnetostriction of Fe1-xGax alloys[1] , HUI WANG, YANNING ZHANG, University of California, Irvine, TENG YANG, Z.D. ZHANG, Institute of Metal Research and International Centre of Materials Physics, Chinese Academy of Sciences, LIZHI SUN, RUQIAN WU, University of California, Irvine — We investigated the effects of B2-like and D0-like nanoclusters on the magnetostriction of Fe-xGax alloys, through systematic density functional calculations. While the B2-like Fe-Ga clusters still undergo slightly tetragonal distortion, D03-like Fe-Ga clusters remain to be cubic in the Fe matrix. Moreover, we found that B2-like nanostructures produce negative magnetostriction whereas D03- like nanostructures give small positive magnetostriction in Fe-xGax alloys. The formation of nanoscale precipitates cannot be the reason for the extraordinary enhancement of magnetostriction of Fe1-xGax alloys.

4:30PM L35.00011 The lost heat capacity and entropy in the helical magnet MnSi , SERGEI STISHOV, ALLA PETROVA, Institute for High Pressure Physics of Russian Academy of Sciences, Troitsk, Moscow Region, Russia, ANATOLY SHIKOV, Russian Research Center Kurchatov Institute, Moscow 123182, Russia, THOMAS LOGRASSO, Ames Laboratory, Iowa State University, Ames, IA, EYVAZ ISAEV, Department of Physics, Chemistry and Biology, SE-581 83, Linkoping University, Sweden, BORIE JOHANSSON, Applied Materials Physics, Materials Science Department, The Royal Technological University, SE-100 44 Stockholm, Sweden, LUKE DAEMEN, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA — We report results of measurements and analysis of the heat capacity of MnSi. The measurements included data collection at a magnetic field of 4T, which suppresses strongly the longitudinal spin fluctuations and the phase transition. To analyze the experimental data, calculations of the phonon spectrum and phonon density of states in MnSi were performed. Inelastic neutron scattering with a polycrystalline sample of MnSi was used to validate the computational results. The combination of the experimental and theoretical data turned out to be decisive in revealing some hidden features of the thermal excitations in MnSi. In particular, the analysis of the available data led conclusively to the existence of a negative contribution to the heat capacity and entropy in MnSi at $T > T_c$, implying that a specific spin ordering process did occur in the paramagnet phase of MnSi.

4:42PM L35.00012 A common magnetic origin for the Invar effects in fcc iron-based ferromagnets , CHRIS HOOLEY, University of St Andrews, U.K., FRANCOIS LIOT, Max Planck Institut fur Eisenforschung, Germany — Using first-principles calculations, in conjunction with Ising magnetism, we undertake a theoretical study to elucidate the origin of the experimentally observed Invar effects in disordered fcc iron-based ferromagnets. First, we show that our theory can account for the Invar effects in iron-nickel alloys, the anomalies being driven by the magnetic contributions to the average free energies. Second, we present evidence indicating that the relationship between thermal expansion and magnetism is essentially the same in all the studied alloys, including those which display the Invar effect and those which do not. Hence we propose that magnetism plays a crucial role in determining whether a system exhibits normal thermal expansion, the Invar effect, or something else. The crucial determining factor is the rate at which the relative orientation of the local magnetic moments of nearest-neighbor iron atoms fluctuates as the system is heated.

4:54PM L35.00013 Electronic Origin of Fast Sulfur Diffusion in 3d Transition Metals , DMITRI NOVIKOV, UTRC, United Technologies Corporation, 411 Silver Lane, 129-21 East Hartford, CT 06108, ALAN CETEL, MICHAEL MALONEY, KEVIN SCHLICHTING, BRAD COWLES, Pratt & Whitney, 400 Main Street, East Hartford, CT 06108, SERGEY OKATOV, ILIYA LOMAYEV, YURI GORNOSTYREV, CJSC Institute of Quantum Materials Science, Ekaterinburg, Russia, SEGEI BURLATSKY, United Technology Research Center — The microscopic origins of abnormally fast diffusion of sulfur in nickel have been investigated. Transition state theory of vacancy mediated diffusion of substitutional impurities with parameters calculated from first-principle density-functional theory (DFT) was used to determinate of the diffusion coefficients of S and Al impurities in fcc Ni. Sulfur diffusion coefficient was found to be two orders of magnitude higher than for aluminum in good agreement with experimental data. We found that sulfur has a very low barrier for jump toward vacancy and also significantly decreases migration barriers for neighboring nickel atoms. We discuss the microscopic factors contributing to the dramatic difference in S and Al diffusion coefficients and show that electronic structure and chemical bonding play crucial role in enhanced diffusion of S. We also found that S considerably increases Ni self-diffusion rate. The implications of S effect on the stability of thermally grown oxides in superalloys are discussed.

5:06PM L35.00014 Nitrogen Adsorption, Solubility and Transport within Group V Metals , PANITHITA ROCHANA, EKIN OZDOGAN, JENNIFER WILCOX, Department of Energy Resources Engineering, Stanford University — It is well known that Group V metals have strong-binding characteristics to diatomic molecule, e.g. N_2, O_2, H_2, and CO. Within this study, N_2 has been investigated to determine the mechanism of surface adsorption, dissociation and subsequent atomic diffusion into the bulk crystal structure of vanadium(V). Alloys of ruthenium(Ru)-V have been examined indicating that Ru can be used to tune the electronic structure of the bulk to enhance atomic diffusion. Electronic structure calculations based on density functional theory have been studied on the investigation of N_2 adsorption on 3 low-index surfaces, (110), (100) and (111). Preliminary investigations indicate that the V(111) surface binds N_2 the strongest at fcc site (E_{ads} = 1.4eV). To determine bulk solubility, binding energy calculations are carried out as a function of N concentration. N was found to be stable primarily at O-sites within the bulk V lattice. Bader charge and density of states analyses are analyzed to investigate the mechanism of bulk absorption and solubility phenomena. Results will be presented on the adsorption, bulk solubility, and transport of N in V and V-based alloys. The application to this study is toward the design of an N_2-selective dense membrane in which atomic N may be produced on the permeate side with hydrogen as a sweep gas for the ammonia synthesis process.

5:18PM L35.00015 The wake of H in V, Nb and Ta at elevated temperatures: Irreversibility and non-central forces revisited , FRANZ REIDINGER — At elevated temperatures U and Do of the Arrhenius equation for diffusion describe the amplitude and relaxation rate, respectively, of the stern wave wake of H in V, Nb and Ta. The key evidence for this hypothesis is the close correlation between the isotope dependence of U derived from the Gorsky measurements[1] and the shear distortion of the orthorhombic phases of NbH(D) and TaH(D). The isotope dependence of U can be expressed in closed form: U=a$\sqrt{M}$ + b$\sqrt{m}$ where M and m are the atomic numbers of the host metal and H isotope and a and b are 7.4 and 37 for Nb and Ta, and 0 and 55 for V, respectively, in units of meV. I explain this correlation in two steps: a) the cubic symmetry of the nearest neighbor strain field[2] of the interstitial H is the result of a dynamic superposition, possibly caused by a JT resonance[3], of the two orthorhombic variants of β-NbH0.75 and b) the successful characterization of the diffusion process as jump diffusion[4] eliminates the transition state from consideration. Instead it is the relaxation of the just emptied site from its residual orthorhombic distortion towards the cubic symmetry of the bcc metal which is being measured. 1)Z Qi, J Voelkl, R Laesser and H Wenzl: J. Session L36 DMP: Focus Session: Graphene Structure, Dopants and Defects: Adsorbates C142

2:30PM L36.00001 First-principles calculations of gated adatoms on graphene[1] , KEVIN T. CHAN, HOONKYUNG LEE[2], MARVIN L. COHEN, Dept. of Physics, University of California, Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory — The two-dimensional surface of graphene is well-suited for adsorption of adatoms or molecules. The application of a gate voltage can be used to precisely control the electron concentration of the adsorbate-graphene system. Such control over electronic properties of adsorbates on graphene might have useful applications in areas such as catalysis and hydrogen storage. In this work, the gating of a variety of adatoms adsorbed on graphene is studied using first-principles calculations. We compute the projected density of states, local electrostatic potential, and charge density of the adatom-graphene system as a function of gate voltage. We demonstrate that adatoms on graphene can be ionized by gating, and that the ionization causes a sharp change in the electrostatic potential. Additional interesting features of our results are also discussed.

2:42PM L36.00002 High-resolution measurement of SiO2 surface potential using scanning Kelvin-probe microscopy[1] , WILLIAM CULLEN, KRISTEN BURSON, MAHITO YAMAMOTO, MICHAEL FUHRER, University of Maryland — It is now widely recognized that the dominant contribution to disorder in SiO_2-supported graphene is due to scattering from charged impurities. These charged impurities give rise to a conductivity which is linear in carrier density, and create electron-hole puddles in graphene. The screened potential variation produced in graphene has been imaged using scanning tunneling microscopy/spectroscopy (STM/STS) by spatially mapping the variation in the Dirac point, revealing a length scale of 20 nm for the charge puddles. However, there is a substantial gap in resolution between the STM measurements and previous measurements with much greater potential sensitivity but limited spatial resolution. Here we attempt to bridge this gap using scanning Kelvin-probe microscopy (SKPM) of SiO_2 in ultrahigh vacuum. Our measurement takes advantage of the high spatial resolution allowed by UHV non-contact AFM while maintaining UHV control of the sample environment.

2:54PM L36.00003 Revealing the dominant scatterer in Graphene on SiO_2[1] , MASA ISHIGAMI, Department of Physics and Nanoscience Technology Center, University of Central Florida — Freely suspended graphene sheets display high-field effect mobility, reaching 2×10^5 cm^2 /V s. Yet, suspended graphene sheets are fragile and impractical for most experiments and applications. Graphene sheets on SiO_2 are easier to handle but possess low-carrier mobilities, which can even vary by an order of magnitude from sample to sample. Poor and unpredictable transport properties reduce the utility of SiO_2-bound graphene sheets for both fundamental and applied sciences. Therefore, understanding the impact of substrates is crucial for graphene science and technology. We [1] have measured the impact of atomic hydrogen adsorption on the electronic transport properties of graphene sheets as a function of hydrogen coverage and initial, pre-hydrogenation field-effect mobility. The saturation coverages of atomic hydrogen for different devices are found to be proportional to their initial mobility, indicating that the number of native scatterers is proportional to the saturation coverage of hydrogen. By extrapolating this proportionality, we show that the field-effect mobility can reach 1.5×10^4 cm^2 /V s in the absence of the hydrogen-adsorbing sites. The affinity to atomic hydrogen is the signature of the most dominant type of native scatterers in graphene-based field-effect transistors on SiO_2. The dominant scatterer is identified by comparing the reactivity of charge puddles, ripples and resonant scatterers to atomic hydrogen.

3:30PM L36.00004 Magnetic field effects on the local electronic structure near a single impurity in Graphene[1] , LING YANG, Department of Physics and Astronomy, University of California, Riverside, California, 92521, JIAN-XIN ZHU, Theoretical Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, SHAN-WEN TSAI, Department of Physics and Astronomy, University of California, Riverside, California 92521 — Impurities in graphene can have a significant effect on the local electronic structure of graphene when the Fermi level is near the Dirac point. We study the problem of an isolated impurity in a single layer graphene in the presence of a perpendicular magnetic field. We use a linearization approximation for the energy dispersion and employ a T-matrix formalism to calculate the Green's function. We investigate the effect of an external magnetic field on the Friedel oscillations and impurity-induced resonant states. Different types of impurities, such as vacancies, substitutional impurities, and adatoms, are also considered.

3:42PM L36.00005 Tunable magnetoresistance behavior in suspended graphitic multilayers through ion implantation , CARLOS DIAZ-PINTO, XUEMEI WANG, SUNGBAE LEE, Department of Physics, Texas Center for Superconductivity, University of Houston, VIKTOR HADJIEV, Texas Center for Superconductivity, University of Houston, DEBTANU DE, WEI-KAN CHU, HAIBING PENG, Department of Physics, Texas Center for Superconductivity, University of Houston — A linear positive magnetoresistance (MR) is often observed in graphitic multilayers, yet its origin remains inconclusive. Recently, a non-Markovian transport theory predicts a strong positive MR in two dimensional systems under the influence of both short- and long-range disorders, while a negative MR is expected with only one type of disorder. Here, we address the role of disorders on the MR behavior of suspended graphitic multilayers through ion implantation. Boron implantation is found to drastically change the MR behavior: the linear positive MR transforms into a negative MR after the introduction of short-range disorders (boron), in consistence with the non-Markovian theory. This suggests that the origin of the unexplained linear positive MR in graphitic structures is the non-Markovian transport under the interplay between long-range disorders (charged surface adsorbents) and short-range disorders (defects inside the lattice). After ion implantation, short-range disorders dominate, leading to a distinct negative MR behavior.

3:54PM L36.00006 Raman spectroscopic study of chemically-doped few layer graphenes , PINGHENG TAN, WEIJIE ZHAO, JUN ZHANG, JIAN LIU — Graphene, the latest carbon allotrope discovered at 2004, has attracted intensively scientific interest owing to its distinctive properties. Chemical doping is expected to substantially increase the density of free charge carriers by charge transfer and to modify the Fermi level of doped materials. Here, we investigated charge transfer and optical phonon mixing in few layer graphenes in detail by utilizing sulfuric acid as an electron-acceptor dopant. Sulfuric acid molecules are found to be only physically adsorbed on the surface layers of graphenes and no intercalation happens. The top and bottom layers of bilayer graphenes can be intentionally doped differently by concentrated sulfuric acid. The difference of hole doping between the top and bottom layers results in phonon mixing of symmetric and antisymmetric modes in bilayer graphenes. The Raman frequency evolution with the doping level qualitatively agrees with recent ab initio theoretical calculations. Sulfuric acid molecules can be expected as a stable electron-acceptor dopant for graphenes to study the physical properties of few layer graphenes at different doping levels.

4:06PM L36.00007 The doping mechanism in graphene , RAZVAN A. NISTOR, DENNIS M. NEWNS, GLENN J. MARTYNA, IBM T. J. Watson Research Center — Doping graphene by adsorbing chemical species on its surface is one way to control the carrier concentration of this novel material. Using large-scale *ab initio* simulations and electronic structure calculations, we show the carbon layer acts as a metal catalyst facilitating the disproportionation reaction of adsorbed chemical species on its surface. This reaction leads to the formation of charge transfer complexes which thereby dope the graphene. We also investigate the charge transfer in graphene-silicon and defected graphene-silicon-oxide interfaces. Our microscopic understanding of the doping mechanism in graphene, which brings to light the catalytic power of the material, is important in the development of carbon-based electronics.

4:18PM L36.00008 Understanding Graphene Coatings: Characterization of Solvent Exfoliated Few-Layer Graphene by Raman Scattering , JORGE CAMACHO[1], LESTER LAMPERT, WILLSON ARIFIN, ROBBY FLAIG, TIMOTHY RUE, TYLER KRISKO, JAMES HAMILTON, University of Wisconsin-Platteville — Graphene has unique properties like its ballistic transport at room temperature combined with chemical and mechanical stability and these properties can be extended to few-layer of graphene. Potential large-area applications that include transparent conductive coatings and fuel cell electrodes require dispersing graphene in a fluid phase. Graphene nano-platelets can be synthesized by dispersion and exfoliation of graphite in organic solvents such N-methyl-pyrrolidine (NMP) and cyclohexylpyrrolidone (CHP). However, liquid-phase exfoliation produces graphene with defects that can disrupt the electronic properties. One of the remaining questions is whether the defects created during synthesis can be minimized. We report a Raman spectroscopic study showing that defects in few-layer graphene produced by liquid-phase exfoliation of graphite can be controlled by the type or mixture of solvents used.

4:30PM L36.00009 First Principles Study of Interactions between Dopant Atoms in Graphene[1] , NABIL AL-AQTASH, IGOR VASILIEV, New Mexico State University — We study the interactions between the boron (B) and nitrogen (N) dopant atoms in graphene. Our calculations are carried out using density functional theory combined with the generalized gradient approximation for the exchange-correlation functional. The total energies, equilibrium geometries, electronic charge distributions, and densities of states of doped graphene sheets are examined in cases of B-B, N-N, and B-N co-doped graphene. The interaction energy between the two dopant atoms is found to be inversely proportional to the square of the separation distance. We find the B-B and N-N interactions to be repulsive and the B-N interaction to be attractive. The changes in the density of states observed in B- and N-doped graphene are explained in terms of electronic charge transfer.

[1]Supported by DOE DE-FG36-08GO88008.

4:42PM L36.00010 Bonding and charge transfer induced by metal adatom adsorption on graphene , XIAOJIE LIU, C.Z. WANG, M. HUPALO, Y.X. YAO, M.C. TRINGIDES, Ames Laboratory - USDOE, Iowa State University, WEN-CAI LU, Institute of Theoretical Chemistry, Jilin University, Changchun, China, K.M. HO, Ames Laboratory - USDOE, Iowa State University — Structures and adsorption energies of alkali, simple, transition as well as rare earth metal adatoms on graphene were studied systematically by first-principles calculations. Bonding character and charge transfer between the metal adatoms and the graphene were also analyzed using the quasi-atomic minimal basis set orbitals (QUAMBOs) approach. We showed that the interaction between the alkali metal adatoms and graphene can be characterized as ionic with minimal effects on the lattice and electronic states of the graphene layer. On the other hand, transition metal adsorption exhibits strong covalent bonding and induces large distortion in the lattice and electronic states of the graphene. For trivalent simple metal adatom adsorption, mixed covalent and ionic bonding is observed. Interaction of rare earth adatoms with graphene can be either ionic or covalent depending on the specific elements. Charge redistributions upon the metal adsorptions also induce significant electric dipole moments and changes in the magnetic moments of the adatoms. These results are confirmed by STM studies of the nucleated island density in epitaxial growth experiments.

4:54PM L36.00011 Transport properties of metalo-organic functionalized graphene[1] , STEFAN C. BADESCU[2], VICTOR M. BERMUDEZ, THOMAS L. REINECKE, NRL, Washington, DC — Transition metal atoms can act as strong covalent anchors for organic molecules on graphene. The hybridization between the metallic d orbitals and the p orbitals of graphene provides a doping method without breaking C-C bonds. Using first-principle calculations for a range of adsorbed transition metals we identify the induced impurity levels and we reveal a dependence of the spin states on adsorbate coverage. We construct sets of maximally localized Wannier functions that interpolate accurately the calculated bandstructures. These sets are used then to describe the electronic transport from the dilute regime to finite coverages.

5:06PM L36.00012 The electronic structure and chemical bonding of graphene doped with Group IA and Group VIIA elements: A density functional theory study , YIMING MI, Graduate Department, Shanghai University of Engineering Science, SHUICHI IWATA, Graduate School of Frontier Sciences, The University of Tokyo — The ground state geometry and the electronic structure of graphene doped with group IA and VIIA elements were calculated with the first principles plane wave pseudopotential approaches within the density functional theory formalism in this paper. In terms of the generalized gradient approximation(GGA), GW approximation and optimizing atomic positions, a reliable geometry of the structure was acquired. The calculated formation energies for different configurations under ambient temperature implied that a new kind of material will produce. The results acquired here allow one to suggest new material with semiconductor or semimetallic behavior by adjusting the relative concentration of the doped atoms carefully.

Session L37 DMP: Focus Session: Graphene Structure, Dopants, and Defects: Magnetism C146

2:30PM L37.00001 Missing atom as a source of carbon magnetism , IVAN BRIHUEGA, Dept. Fisica de la Materia Condensada. Universidad Autonoma de Madrid — Introducing vacancies in graphene-like systems by irradiation has been shown to be an efficient method to vary its mechanical behavior, tune its electronic properties and even to induce magnetism in otherwise non-magnetic samples [1-2]. While the role played by these vacancies as single entities has been extensively addressed by theory [3-6], experimental data available refer to statistical properties of the whole heterogeneous collection of vacancies generated in the irradiation process. Here, by artificially generating isolated vacancies on a graphite surface and measuring their local density of states on the atomic scale, we have shown how single vacancies modify the electronic properties of this graphene-like system [7]. Our scanning tunneling microscopy experiments, complemented by tight binding calculations, reveal the presence of a sharp electronic resonance at the Fermi energy around each single graphite vacancy, which implies a dramatic reduction of the charge carriers' mobility and can be associated with the formation of local magnetic moments. Finally, we have extended our investigations to other graphene systems.

3:06PM L37.00002 Kondo quantum criticality in graphene , BRUNO UCHOA, University of Illinois at Urbana-Champaign, T.G. RAPPOPORT, Universidade Federal do Rio de Janeiro, A.H. CASTRO NETO, Boston University — Graphene fits in a large class of "pseudogap" materials which are allowed to exhibit quantum criticality as a result of the interplay of strong correlations and a vanishing density of states near the Fermi points. In the presence of magnetic impurities, we show there is a symmetry class of localized orbitals which, in combination with quantum interference effects inbuilt in the honeycomb lattice, can lead to a novel class of Kondo quantum criticality in graphene [1]. In this class, graphene effectively screens the local spin as a super-ohmic dissipative environment and the RKKY interaction decays spatially with a fast power-law $\sim 1/R^7$, rather than the standard $1/R^3$ decay expected for Dirac fermions. We also show that unlike metals, the exchange coupling between the localized and itinerant spins can be controlled across the quantum critical region with the application of an external gate voltage. This effect may permit the first experimental observation of quantum criticality in graphene at zero magnetic field, directly with scanning tunneling probes and gating.

3:18PM L37.00003 Kondo effect in graphene in the presence of Rashba spin-orbit interaction , MAHDI ZAREA, Ohio/Northwestern University, NANCY SANDLER, SERGIO ULLOA, Ohio University — We present an exact solution for the Anderson model of a single-orbital magnetic impurity on graphene in the Kondo regime. Different positions for the impurity are considered: on top of a carbon atom, substitutional or interstitial (middle of the hexagon cell). We show that regardless of the impurity position, the effective exchange Hamiltonian always describes a single- channel Kondo problem. The inclusion of the Rashba spin-orbit interaction changes the linear energy dispersion to a quadratic one near the Dirac points with the corresponding change in the density of states. This in turn, modifies the value of the critical Kondo coupling as compared to the case where the spin-orbit is absent. Moreover, spin-orbit interactions, introduce a Dzyaloshinsky-Moriya (DM) term in the Kondo Hamiltonian away from particle-hole symmetry. Although still in the single channel region, the effective exchange coupling is augmented by the DM term and the Kondo temperature shows an exponential increase. Supported by NSF-PIRE and MWN/CIAM

3:30PM L37.00004 Transport in irradiated graphene: Kondo and charge fluctuation effects , VIVEK AJI, SUNG-PO CHAO, University of California at Riverside — Observation of an upturn in resistance at low temperatures in irradiated graphene has renewed the interest in the nature of the Kondo effect in systems with linear density of states. The vanishing density of states near the Dirac point leads to a much wider local moment regime but a cross over to the charge fluctuation at very low carrier densities indeed occurs. In this talk I will show how the Kondo scale and the resistance versus temperatures evolves from one regime to the other, and compare our results with experimental data. Our chief conclusion is that a good agreement with data can be achieved only if one posits that the energy of the impurity level varies linearly with the chemical potential.

3:42PM L37.00005 Spin and Transport Properties of Doped Graphene , KATHLEEN MCCREARY, WEI HAN, ROLAND KAWAKAMI, University of California, Riverside — Graphene is an ideal system to investigate the interplay of magnetic moments and conduction electrons. Electrostatic gates are able to tune the electron and holes concentrations substantially, and localized magnetic moments can form, in principle, through a variety of methods including vacancies, edges, and adsorbed impurities. Theory predicts a coupling of the localized moments and the conduction electrons, leading to gate tunable indirect coupling between moments which can be ferromagnetic or antiferromagnetic. In this study, we perform magnetotransport measurements on graphene devices where the graphene surface is modified inside an ultrahigh vacuum chamber through a variety of methods including hydrogen adsorption, Ar sputtering, and molecular beam deposition of transition metals [1]. Both /in situ/ and /ex situ/ magnetotransport measurements are performed, where the latter involves the air-free transfer to a low temperature (1.6 - 300 K), high field (7 T) cryostat. We will report results on the temperature-dependent, high-field magnetotransport characteristics of doped graphene.

3:54PM L37.00006 ABSTRACT WITHDRAWN —

4:06PM L37.00007 Can Carbon Be Ferromagnetic? , HENDRIK OHLDAG, SLAC National Accelerator Center, PABLO ESQUINAZI, University Leipzig, ELKE ARENOHOLZ, Lawrence Berkeley National Laboratory, DANIEL SPEMANN, MARTIN ROTHERMEL, ANNETTE SETZER, TILMAN BUTZ, University Leipzig — The existence of long range magnetic order at room temperature in carbon based structures without magnetic elements is very unexpected. Theoretical results from different groups suggest that the existence of long range magnetic order in a graphite structure is possible, if one takes the effects of defects and/or the incorporation of hydrogen atoms into account. SQUID results provided first systematic hints for the existence of magnetic order at room temperature in virgin as well as irradiated highly oriented pyrolytic graphite (HOPG) samples. We present a x-ray dichroism study of graphite surfaces [1] that addresses the origin and magnitude of ferromagnetism in metal-free carbon. Using element specific x-ray microscopy we can show that metallic impurities do not play a role in the ferromagnetism of carbon and that carbon can be ferromagnetic without ferromagnetic impurities. A detailed spectroscopic study shows that in addition to carbon *pi*-states, also hydrogen-mediated electronic states exhibit a net magnetization with magnetic remanence at room temperature. The observed magnetism is restricted to the top $\sim$10 nm of the sample where the actual magnetization reaches a value similar to classic ferromagnetic materials like e.g. Nickel. [1] H. Ohldag et al., Phys. Rev. Lett. **98,** 187204 (2007) and submitted to NJP (2010)

4:18PM L37.00008 Extinction of ferromagnetism in HOPG by thermal annealing[1] , XIAOCHANG MIAO, ARTHUR HEBARD, Department of Physics, University of Florida, Gainesville, FL 32611, SEFAATTIN TONGAY, BILL APPLETON, Nanoscience Institute for Medical and Engineering Technologies, University of Florida, Gainesville, FL 32611 — Observations of ferromagnetism (FM) in highly ordered pyrolytic graphite (HOPG) have generated vigorous research activity to clarify its origin, especially when transition metals are known to be absent. We report that the ferromagnetism of pristine HOPG samples as measured by hysteretic magnetization loops can be diminished and eventually extinguished with sufficiently long high vacuum anneals at temperatures greater than 2000°C. Concomitant with the extinction of ferromagnetism, we observe an anneal-induced increase in grain size (accompanied by possible edge reconstruction) confirmed by XRD measurement and improved transport properties, including lower in-plane and out-of-plane resistance, higher electron and hole mobility and improved charge compensation. The implied anneal-induced reduction of defects and vacancies suggests that the FM of pristine HOPG is correlated with localized states located at zigzag edges, vacancies and related defects.

4:30PM L37.00009 Local Moment Formation of an Anderson Impurity on Graphene , CHUNHUA LI, Department of Physics and Texas Center for Superconductivity, University of Houston, Houston, Texas, 77204, USA, JIAN-XIN ZHU, Theoretical Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA, C. S. TING, Department of Physics and Texas Center for Superconductivity, University of Houston, Houston, Texas, 77204, USA — We study the effect of a magnetic impurity on a single layer of graphene within an Anderson impurity model. Due to the vanishing local density of state at the Fermi level in graphene, the impurity spin cannot be effectively screened out. Treating the problem within the Gutzwiller approximation, we found a region in the parameter space of U-E^f where the impurity electron is in the local moment state, which is characterized by a zero effective hybridization between the bath electron and magnetic impurity. Here U is the onsite Coulomb repulsion of the impurity and E^f is its energy level with respect to the Fermi energy. The competition between U and E^f is also discussed. While larger U reduces double occupation and favors local moment formation, a deeper impurity level prefers double occupation and a nonzero hybridization and thus a Kondo screened state. For a fixed U, by continuously lowering the impurity level, the impurity first enters from a Kondo screened state to a local moment state and then departs from this state and re-enters into the Kondo screened state.

4:42PM L37.00010 Spin-dependent scattering from gated potential obstacles in graphene systems[1] , MAHMOUD ASMAR, SERGIO ULLOA, Ohio University — We study the scattering of Dirac fermions in a sheet of graphene from potential obstacles created by external gates in the presence of both intrinsic and extrinsic Spin-Orbit(SO) interactions [1]. Obtaining an analytical solution in real-space representation for the eigenvectors allows us to calculate the phase shifts generated by a finite-size obstacle in the presence of SO interactions [2]. These states take into account the total angular momentum of the Hamiltonian, which includes spin, pseudo-spin and orbital angular momentum. We find an interesting interplay of both SO interactions, which results in oscillations of the spin-flip cross sections with energy; this also generates a difference between both cross sections for different interaction ranges. These results may open a possibility of obtaining spin-polarized currents that are of importance in the field of spintronics.

5:06PM L37.00012 Ferromagnetically coupled local moments along an extended line defect in graphene[1] , CARTER T. WHITE, NRL, SMITHA VASUDEVAN, GWU, DANIEL GUNLYCKE, NRL — Recently an extended line defect was observed composed of octagonal and pentagonal carbon rings embedded in a graphene sheet [Nat. Nanotech. 5, 326 (2010)]. We report results of studies we have made of this defect using both first-principles and semi-empirical methods. Two types of boundary-localized states arising from the defect are identified. The first (second) type has eigenstates with wavefunctions that are anti- symmetric (symmetric) with respect to a mirror plane that is perpendicular to the graphene sheet and passes through the line defect center line. The boundary-localized anti-symmetric states are shown to be intimately connected to the zigzag edge states of semi-infinite graphene. They exhibit little dispersion along the defect line and lie close to the Fermi level giving rise to a spontaneous spin polarization along the defect once electron-electron interactions are included at the level of a mean field approximation to a Hubbard Model. Within this approach, symmetry requires that the principal moments couple ferromagnetically both along and across the line defect leading to approximately 2/3 more up than down spin electrons per defect repeat unit.

[1]This work was supported by ONR, directly and through NRL.

5:18PM L37.00013 Correlating Magnetotransport and Diamagnetism of sp2-Bonded Carbon Networks Through the Metal-Insulator Transition , P.M. VORA, J.M. KIKKAWA, Department of Physics and Astronomy, University of Pennsylvania, P. GOPU, M. ROSARIO-CANALES, J.J. SANTIAGO-AVILES, Department of Electrical Engineering, University of Pennsylvania, C.R. PEREZ, Y. GOGOTSI, Department of Materials Science and Engineering, Drexel University — Titanium carbide-derived carbons (TiC-CDCs) are porous sp2-bonded networks synthesized by exposing TiC to chlorine gas at an elevated temperature. The latter "chlorination temperature" adjusts the size of graphitic domains within this material. We perform magnetoresistance, temperature dependent resistance, and SQUID magnetization measurements on TiC-CDC samples prepared at different chlorination temperatures. Transport reveals a metal-insulator transition where high (low) chlorination temperature samples are on the metallic (insulating) side of the transition. Magnetoresistance measurements are consistent with electronic transport in the weak and strong localization regimes for metallic and insulating samples, respectively. The diamagnetic contribution to the total magnetization increases with chlorination temperature, suggesting that the metal-insulator transition is associated with the expansion of graphitic domains. We also discuss a magnetoresistance anomaly observed in insulating samples. This work supported by NSF DMR-0907266 and NSF MRSEC DMR-05-20020.

Session L38 DCP DBP: Focus Session: Quantum Coherence in Biology II A130/131

2:30PM L38.00001 The role of quantum coherence in excitonic energy transfer: quantum process tomography, molecular dynamics and efficiency measures[1] , ALAN ASPURU-GUZIK, Department of Chemistry and Chemical Biology, Harvard University — Long-lived electronic coherences in various photosynthetic complexes at cryogenic and room temperature have generated vigorous efforts both in theory and experiment to understand their origins and explore their potential role to biological function. The ultrafast signals resulting from the experiments that show evidence for these coherences result from many contributions to the molecular polarization. Quantum process tomography (QPT) is a technique whose goal is that of obtaining the time-evolution of all the density matrix elements based on a designed set of experiments with different preparation and measurements. The QPT procedure was conceived in the context of quantum information processing to characterize and understand general quantum evolution of controllable quantum systems, for example while carrying out quantum computational tasks. We introduce our QPT method for ultrafast experiments, and as an illustrative example, apply it to a simulation of a two-chromophore subsystem of the FMO photosynthetic complex, which was recently shown to have long-lived quantum coherences. Our FMO model is constructed using an atomistic approach to extract relevant parameters for the simulation of photosynthetic complexes that consists of a quantum mechanics/molecular mechanics approach combined with molecular dynamics and the use of state-of-the-art quantum master equation approaches. We provide a set of methods that allow for quantifying the role of quantum coherence, dephasing, relaxation and other elementary processes in energy transfer efficiency in photosynthetic complexes, based on the information obtained from the atomistic simulations, or, using QPT, directly from the experiment. The possible presence or absence of effects due to correlated protein motion is discussed. The role of non-Markovianity will be discussed. The ultimate goal of the combination of this diverse set of methodologies is to provide a reliable way of quantifying the role of long-lived quantum coherences and obtain atomistic insight of their causes.

[1]Supported by DARPA Quantum Effects in BIological Environments and MIT/Harvard/BNL DOE Center for Excitonics.

3:06PM L38.00002 Multidimensional electronic spectroscopy of phycobiliproteins from cryptophyte algae , DANIEL TURNER, University of Toronto — We describe new spectroscopic measurements which reveal additional information regarding the observed quantum coherences in proteins extracted from photosynthetic algae. The proteins we investigate are the phycobiliproteins phycoerythrin 545 and phycocyanin 645. Two new avenues have been explored. We describe how changes to the chemical and biological environment impact the quantum coherence present in the 2D electronic correlation spectrum. We also use new multidimensional spectroscopic techniques to reveal insights into the nature of the quantum coherence and the nature of the participating states.

3:42PM L38.00003 Simulation study of 2D spectrum of molecular aggregates coupled to correlated vibrations[1] , DARIUS ABRAMAVICIUS, VYTAUTAS BUTKUS, LEONAS VALKUNAS, Physics Dept. Vilnius University, SHAUL MUKAMEL, Chemistry Dept. University of California Irvine — Oscillatory dynamics of two-dimensional (2D) spectra of photosynthetic pigment-protein complexes raise the questions of how to disentangle various origins of these oscillations, which may include quantum beats, quantum transport, or molecular vibrations. We study the effects of correlated overdamped fluctuations and under-damped vibrations on the 2D spectra of Fenna-Matthews-Olson (FMO) aggregate, which has well-resolved exciton resonances, and a circular porphyrin aggregate (P6), whose absorption shows vibrational progression. We use a generic exciton Hamiltonian coupled to a bath, characterized by a spectral density. Fluctuations have smooth, while vibtations have δ-type spectral densities. We show how various scenarios of correlated molecular fluctuations lead to some highly oscillatory crosspeaks. Molecular vibrations cause progression of diagonal peaks in the 2D spectrum and make their corresponding cross-peaks highly oscillatory. We, thus, demonstrate that bath fluctuations and molecular vibrations of realistic molecular aggregates are highly entangled in 2D spectroscopy.

3:54PM L38.00004 Coherent Control of Single Molecules at Room Temp , NIEK VAN HULST, DAAN BRINKS, RICHARD HILDNER, ICFO - the Institute of Photonic Sciences (Barcelona) Spain — Electronic coherence plays a key role in natural processes like ultrafast energy transfer and charge separation. Coherent control has proven powerful, however in complex biosystems with different conformations and environments, the intrinsic inhomogeneity of the synchronized subset severely limits the achievable degree of control. The ultimate solution to overcome intrinsic inhomogeneities is the investigation of the behavior of one molecule at a time. Here we report the observation and manipulation of vibrational wave-packet interference and electronic coherence in *individual molecules* at ambient conditions. Adapting time and phase distribution of the optical excitation field to the dynamics of each molecule we achieve a superior degree of control. The time-phase maps show distinct diversity between different, yet chemically identical, molecules. We induce Rabi-oscillations and control the coherent superposition state in a single molecule. Broadly distributed coherence decay times are found for different individual molecules giving direct insight into the structural heterogeneity of the local surroundings. Our approach allows single-molecule coherent control in a variety of complex inhomogeneous systems and thus to study the role of coherence in energy transfer of single biocomplexes under natural conditions. D.Brinks *et al. Nature* **465**, 905 (2010); R.Hildner *et al. Nat.Physics* doi:10.1038/nphys1858 (2010).

4:06PM L38.00005 Shaped ultrafast pulses for coherent control of energy flow in light harvesting complexes[1] , MOHAN SAROVAR, K. BIRGITTA WHALEY, University of California, Berkeley — We report on preliminary investigations of the use of evolutionary algorithms for the design of shaped femtosecond laser pulses to control energy flow in the Fenna-Matthews-Olson (FMO) light harvesting complex. We shape the experimentally accessible phase degrees of freedom of pulses of various duration and assess the ability to control (i) the exciton population on distinct chromophores, and (ii) the purity of the FMO complex state at short times. We assess the experimental feasibility of the designed pulses and sketch directions for future improvement of the pulse design technique.

[1]We acknowledge support from DARPA under the QuEST program

4:18PM L38.00006 Towards experimental verifications of the transport mechanisms in light-harvesting dynamics[1] , F. CARUSO, S. MONTANGERO, T. CALARCO, S.F. HUELGA, M.B. PLENIO, Ulm Univ. — Recently, we identified the key mechanisms explaining the very- high efficiency and robustness of excitation energy transfer in bacterial photosynthesis, finding that dephasing noise may remarkably enhance the capability of transmitting energy (classical/quantum information) in light-harvesting systems (in communication complex networks [Caruso et al., PRL 2010]), by opening up additional transport pathways and suppressing the ineffective ones. To verify the relevance of such mechanisms in the actual bio-molecular systems, we propose how to gain control over the light-harvesting dynamics by using quantum optimal control tools. In this way, by means of optimally shaped and 'robust' laser pulses, we can: i) faithfully prepare the photosystem in some specific initial state (local site or coherent superposition, e.g. quasi-dark and -bright states), and ii) probe efficiently the dynamics, under realistic experimental conditions, i.e. sample of randomly oriented light-harvesting complexes and extra laser constraints related to an experiment in progress. These results could allow us to more easily discriminate the different transport pathways, to characterize the environmental properties, and so enhance our comprehension of coherent processes in biological complexes.

[1]EU Marie-Curie Fellowship

4:30PM L38.00007 Photobiomodulation (PBM) Applications in Ophthalmology , ROBERT DOTSON, Private Medical Practice — In a very real sense, we are all creatures of light. This fact is just now beginning to impact medicine, as quantum theory begins to spread outside the confines of physics and into the life sciences. No longer can living organisms simply be viewed as retorts for biochemical reactions. They also demonstrate an energy component that will prove to be the unifying force of life in all its varied forms. With the advent of this shift in the life sciences, light is becoming an increasingly important diagnostic and therapeutic tool within medicine. Ophthalmologists have long been concerned with light and its application and, consequently, have an interest in the coming scientific revolution, photomedicine. A brief history of the use of low energy light for healing, a review of known mechanisms by which photons interact with living cells, and a review of some of the established cellular effects will be presented. Finally, brief clinical studies will be presented illustrating the benefits of PBM - specifically regarding: corneal healing, glaucoma, and dry age-related macular degeneration. The purpose of this talk is to introduce the emerging field of PBM to the physics community at large.

Tuesday, March 22, 2011 2:30PM - 5:18PM –

Session L39 DBP DPOLY DCP: Focus Session: Single Molecule Biophysics III: Novel Single Molecule Approaches to Biology A124/127

2:30PM L39.00001 High-resolution laser-based detection for magnetic tweezers , KEIR NEUMAN, National Institutes of Health — Magnetic tweezers are a versatile and powerful single-molecule manipulation technique capable of applying force and torque on single bio-molecules. They afford several unique advantages over other single-molecule manipulation techniques such as optical tweezers or atomic force microscopy. The hallmark of magnetic tweezers is the ability to twist bio-molecules without the need for complex optical instrumentation. Perhaps less known but of equal significance, magnetic tweezers rely on a slowly decaying magnetic field gradient (1 mm) to impose force so they are intrinsically configured in a passive force clamp mode. These features make magnetic tweezers particularly well suited for the study of nucleic acid structure, DNA topology, and protein-nucleic acid interactions. The one downside to most magnetic tweezers to date is that they rely on video tracking methods to determine the position of the particle. Despite recent progress, the spatial and temporal resolution and accuracy are fundamentally limited by image tracking techniques. I will describe recent improvements utilizing laser-based detection to overcome these limitations. We implemented back-scattered laser-based detection combined with video image tracking to achieve high-resolution, high-bandwidth, three-dimensional position tracking.

3:06PM L39.00002 Massively Parallel Single-Molecule Manipulation Using Centrifugal Force , WESLEY WONG, KEN HALVORSEN, Harvard University — Precise manipulation of single molecules has led to remarkable insights in physics, chemistry, biology, and medicine. However, two issues that have impeded the widespread adoption of these techniques are equipment cost and the laborious nature of making measurements one molecule at a time. To meet these challenges, we have developed an approach that enables massively parallel single- molecule force measurements using centrifugal force [1]. This approach is realized in the centrifuge force microscope, an instrument in which objects in an orbiting sample are subjected to a calibration-free, macroscopically uniform force- field while their micro-to-nanoscopic motions are observed. We demonstrate high- throughput single-molecule force spectroscopy with this technique by performing thousands of rupture experiments in parallel, characterizing force-dependent unbinding kinetics of an antibody-antigen pair in minutes rather than days. Currently, we are taking steps to integrate high-resolution detection, fluorescence, temperature control and a greater dynamic range in force. With significant benefits in efficiency, cost, simplicity, and versatility, single-molecule centrifugation has the potential to expand single-molecule experimentation to a wider range of researchers and experimental systems.

[1] K. Halvorsen, W.P. Wong, Biophysical Journal - Letters 98 (11), (2010).

3:18PM L39.00003 Horizontal Magnetic Tweezers for Micromanipulation of Single DNA-Protein Complexes , C. MCANDREW, Catholic University, A. SARKAR, P. MEHL, CUA — We report on the development of a new magnetic force transducer or "tweezer" that can apply pico-Newton forces on single DNA molecules in the focus plane. Since the changes in DNA's end-to-end extension are coplanar with the pulling force, there is no need to continually refocus. The DNA constructs (λ-DNA end labeled with a 3μm polystyrene bead and a 2.8μm paramagnetic sphere) and appropriate buffer are introduced to a custom built 400μL to 650μL closed cell. This closed cell isolates our sample and produces low-noise force and extension measurements. This chamber rests on a stage fixed to a three axis micromanipulator. Entering the flat chamber are two micropipettes, a 2.5μm id pipette for aspirating the polystyrene bead and a 20μm id pipette for injecting proteins of interest. The suction and the injection pipettes are rigidly mounted to a hydraulic, three-axis micromanipulator. DNA-bead constructs, once introduced to the chamber, can be located by moving the stage over the objective. We have shown that we can easily and reputably find, capture, and manipulate single molecules of DNA within a force range of 0.1pN to 100pN.

3:30PM L39.00004 Modeling the effects of internal and external fluctuations on lifetimes of proteins measured by an AFM , ERIC CORWIN, University of Oregon, MAXIME CLUSEL, Institut Laue-Langevin & CNRS Montpellier — Measurements of the distribution of the time to unfold a single- molecule of a given protein under an externally applied force have emerged as an important tool with which to study the mechanical stability and energy landscape of a protein. In such an experiment the protein is potentially subject both to internal fluctuations in structure as well as external fluctuations in temperature and applied force. We report on a theoretical exploration of the effects that each kind of fluctuation may have on the measured lifetime distribution. We show that it is extremely difficult to distinguish internal fluctuations from external fluctuations in the lifetime distribution. We find that the rate distribution has higher sensitivity to the origins of fluctuations. Therefore, we propose an experimental protocol to estimate the approximate magnitude of internal fluctuations by intentionally adding increasing amounts of external fluctuations and measuring the skewness of the resulting rate distribution.

3:42PM L39.00005 Onset of excluded volume in poly(ethylene oxide) elasticity measurements , ANDREW DITTMORE, Materials Dept., UCSB, DUSTIN B. MCINTOSH, Physics, UCSB, OMAR A. SALEH, Materials Dept., UCSB — We use magnetic tweezers to control tension in an 80 kDa poly(ethylene oxide) (PEG) chain. In good solvent, force effectively transforms the swollen coil into a series of smaller polymers ("tension blobs") and progressively diminishes self-avoidance interactions between distant parts of the chain. Excluded volume effects dominate the low-strain elasticity, where the extension follows a 2/3 power law in force in accordance with scaling predictions. These effects disappear as the polymer first enters a linear power-law regime, and then a high-force asymptotic regime well described by the Marko-Siggia wormlike chain model. All told, we observe two transitions between three elastic regimes. We show that the transition forces can be used to determine the polymer's Kuhn length, excluded volume, and thermal blob size, and find that PEG requires roughly 30 Kuhn lengths before self-avoidance becomes significant. Thus, we show that single-molecule elasticity can quantify the onset of a polymer's excluded volume, a problem that has eluded bulk measurement techniques.

3:54PM L39.00006 Peptide Nucleic Acids as Tools for Single-Molecule Sequence Detection and Manipulation , HAGAR ZOHAR, CRAIG HETHERINGTON, CARLOS BUSTAMANTE, SUSAN MULLER, University of California, Berkeley — The ability to strongly and sequence-specifically attach modifications such as fluorophores and haptens to individual double-stranded (ds) DNA molecules is critical to a variety of single-molecule experiments. We propose using modified peptide nucleic acids (PNAs) for this purpose and implement them in two model single-molecule experiments where individual DNA molecules are manipulated via microfluidic flow and optical tweezers, respectively. We demonstrate that PNAs are versatile and robust sequence-specific tethers.

4:06PM L39.00007 Resolving Single Molecule Lysozyme Dynamics with a Carbon Nanotube Electronic Circuit , YONGKI CHOI, ISSA S. MOODY, ISRAEL PEREZ, TATYANA SHEPS, GREGORY A. WEISS, PHILIP G. COLLINS, Depts. of Physics and Astronomy, Chemistry, and Molecular Biology, Univ. of California at Irvine, Irvine, CA 92697 — High resolution, real-time monitoring of a single lysozyme molecule is demonstrated by fabricating nanoscale electronic devices based on single-walled carbon nanotubes (SWCNT). In this sensor platform, a biomolecule of interest is attached to a single SWCNT device. The electrical conductance transduces chemical events with single molecule sensitivity and 10 microsecond resolution. In this work, enzymatic turnover by lysozyme is investigated, because the mechanistic details for its processivity and dynamics remain incompletely understood. Stochastically distributed binding events between a lysozyme and its binding substrate, peptidoglycan, are monitored via the sensor conductance. Furthermore, the magnitude and repetition rate of these events varies with pH and the presence of inhibitors or denaturation agents. Changes in the conductance signal are analyzed in terms of lysozyme's internal hinge motion, binding events, and enzymatic processing.

4:18PM L39.00008 Mechanical properties of NRR domain from human Notch 1 studied by single molecule AFM force spectroscopy , ROBERT SZOSZKIEWICZ, ASHIM DEY, Dept. of Physics, Kansas State University — For proteins in living cells, forces are present from macroscopic to single molecule levels. Single molecule atomic force microscopy in force extension (FX-AFM) mode measures forces at which proteins undergo major conformational transitions with $\sim$10 pN force sensitivity (FX-AFM). Here, we present the results of the FX-AFM experiments on a construct comprising the NRR domain from human Notch 1. It is believed that understanding the mechanical properties of Notch at the single molecule level can help to understand its role in triggering some breast cancers. The experimental results on the Notch construct and further analysis revealed several conformational transitions of this molecule under force. These results opened a path for further investigations of Notch constructs at various physiologically relevant conditions.

4:30PM L39.00009 Non-Perturbative Tracking of Processive DNA Synthesis with Single-Molecule Fluorescence , EVERETT LIPMAN, CHARLES WICKERSHAM[1], Department of Physics, University of California, Santa Barbara — We have demonstrated recently that double-stranded DNA labeled with a periodic series of fluorescent dyes can be used to track a single helicase. Here we describe how this technique can be modified to follow DNA synthesis. By means of a stepwise loss of fluorescence during strand displacement, we monitor processive motion of a single $\phi 29$ DNA polymerase without labeling or altering the enzyme or the template strand, and without applying any force. We observe a wide range of speeds, with the highest exceeding by several times that observed in other single-molecule experiments. Because this method enables repeated observations of the same polymerase traversing identical segments of DNA, it should prove useful for studying sequence-specific effects in DNA replication and transcription.

[1]Present address: California Institute for Quantitative Biomedical Research, UC Berkeley

4:42PM L39.00010 Single molecule studies reveal new mechanisms for microtubule severing[1] , JENNIFER ROSS, JUAN DANIEL DIAZ-VALENCIA, MARGARET MORELLI, UMass Amherst, DONG ZHANG, DAVID SHARP, AECOM — Microtubule-severing enzymes are hexameric complexes made from monomeric enzyme subunits that remove tubulin dimers from the microtubule lattice. Severing proteins are known to remodel the cytoskeleton during interphase and mitosis, and are required in proper axon morphology and mammalian bone and cartilage development. We have performed the first single molecule imaging to determine where and how severing enzymes act to cut microtubules. We have focused on the original member of the group, katanin, and the newest member, fidgetin to compare their biophysical activities in vitro. We find that, as expected, severing proteins localize to areas of activity. Interestingly, the association is very brief: they do not stay bound nor do they bind cooperatively at active sites. The association duration changes with the nucleotide content, implying that the state in the catalytic cycle dictates binding affinity with the microtubule. We also discovered that, at lower concentrations, both katanin and fidgetin can depolymerize taxol-stabilized microtubules by removing terminal dimers. These studies reveal the physical regulation schemes to control severing activity in cells, and ultimately regulate cytoskeletal architecture.

4:54PM L39.00011 Polymer Nanocomposites as a Facile Method for Engineering Acto-Myosin Networks at the Interface , MATTHEW CAPORIZZO, University of Pennsylvania Department of Materials Science and Engineering, YUJIE SUN, YALE GOLDMAN, University of Pennsylvania Department of Physiology, RUSSELL COMPOSTO, University of Pennsylvania Department of Materials Science and Engineering, NANO-BIO INTERFACE CENTER COLLABORATION — Filamentous actin acts as the rails for the molecular motor myosin in muscle contraction and intercellular mass transport. Consequently, understanding the process by which actin organizes, polymerizes, and binds is fundamental for the design of myosin based actuators capable of responding to external stimuli. Starting with atomically smooth, freshly cleaved mica optically coupled to glass slides, a random copolymer nanoparticle composite is engineered for *in situ* single molecule TIRF/AFM studies with controlled roughness, electrostatic binding strength, and binding site density. Four distinct regimes of actin binding are observed; no attachment, end-on attachment, weak side-on attachment, and side-on immobilization. Transitions between regimes are likely to mark competition between the affinity to charged nanoparticles and the inherent resistance of the semi-rigid filaments to bending. Surface conditions optimal for actin immobilization are identified, and Myosin V stepping kinetics are studied on the artificially immobilized filaments, confirming filament support of motility. Supported by NSF grant DMR-0425780.

5:06PM L39.00012 Electrostatic Effects on the Elasticity of Single ssDNA Molecules , DUSTIN B. MCINTOSH, OMAR A. SALEH, University of California Santa Barbara — Nucleic acids are highly-charged polyelectrolytes whose structure and function strongly depend on the concentration and type of salt ions in solution. We have created a simple experimental system for studying nucleic acid/ ion interactions, based on magnetic-tweezer measurements of the elasticity of single denatured ssDNA molecules in solutions with a known salt concentration. Using this system, we were able to reconcile single-molecule force-extension data with scaling theories of self-avoiding polymers, and we found that the Kuhn length of ssDNA scales with the Debye length in NaCl solutions. (Saleh et al., PRL 102, 068301 (2009)). Here, we use the system to investigate interactions of ssDNA with multivalent salts. We find that, in divalent salt, ssDNA elasticity is qualitatively similar to that in monovalent salt, but with significant quantitative differences. Notably, at low ionic strength, ssDNA in divalent salt maintains the same low-force scaling behavior ("Pincus blob" regime) as seen in monovalent salts. However, there are differences in the elastic behavior at high forces ($>$ a few pN). In addition, analysis of the low-force scaling behavior indicates it requires $\sim$100 fold smaller concentrations of divalent salt to condense ssDNA. We discuss the data in the context of electrostatic theories, including Debye-Huckel, as well as bulk experiments on similar systems.

Session L40 DBP: Focus Session: Noisy Dynamics as Survival Strategies and Nanopores A122/123

2:30PM L40.00001 TBA , MATTHEW R. BENNETT, Rice University — This abstract not available.

3:06PM L40.00002 Evolution and Biophysics of the *Escherichia coli lac* Operon , J. CHRISTIAN RAY, The University of Texas M. D. Anderson Cancer Center, OLEG IGOSHIN, Rice University, SELWYN QUAN, RUSSELL MONDS, Stanford University, TIM COOPER, The University of Houston, GÁBOR BALÁZSI, The University of Texas M. D. Anderson Cancer Center — To understand, predict, and control the evolution of living organisms, we consider biophysical effects and molecular network architectures. The lactose utilization system of *E. coli* is among the most well-studied molecular networks in biology, making it an ideal candidate for such studies. Simulations show how the genetic architecture of the wild-type operon attenuates large metabolic intermediate fluctuations that are predicted to occur in an equivalent system with the component genes on separate operons. Quantification of gene expression in the *lac* operon evolved in growth conditions containing constant lactose, alternating with glucose, or constant glucose, shows characteristic gene expression patterns depending on conditions. We are simulating these conditions to show context-dependent biophysical sources and costs of different lac operon architectures.

3:18PM L40.00003 The effects of nongenetic memory on population level sensitivity to stress[1] , RHYS ADAMS, DMITRY NEVOZHAY, The University of Texas MD Anderson Cancer Center, ELIZABETH VAN ITALLIE, MATTHEW BENNETT, Rice University, GABOR BALAZSI, The University of Texas MD Anderson Cancer Center — While gene expression is often thought of as a unidirectional determinant of cellular fitness, recent studies have shown how growth retardation due to protein expression can affect gene expression levels in single cells. We developed two yeast strains carrying a drug resistance protein under the control of different synthetic gene constructs, one of which was monostable, while the other was bistable. The gene expression of these cell populations was tuned using a molecular inducer so that their respective means and noises were identical, while their nongenetic memory properties were different. We tested the sensitivity of these two cell population distributions to the antibiotic zeocin. We found that the gene expression distributions of bistable cell populations were sensitive to stressful environments, while the gene expression distribution of monostable cells were nearly unchanged by stress. We conclude that cell populations with high nongenetic memory are more adaptable to their environment.

3:30PM L40.00004 Interplay of Noisy Gene Expression and Dynamics Explains Patterns of Bacterial Operon Organization[1] , OLEG IGOSHIN, Rice University — Bacterial chromosomes are organized into operons – sets of genes co-transcribed into polycistronic messenger RNA. Hypotheses explaining the emergence and maintenance of operons include proportional co-regulation, horizontal transfer of intact "selfish" operons, emergence via gene duplication, and co-production of physically interacting proteins to speed their association. We hypothesized an alternative: operons can reduce or increase intrinsic gene expression noise in a manner dependent on the post-translational interactions, thereby resulting in selection for or against operons in depending on the network architecture. We devised five classes of two-gene network modules and show that the effects of operons on intrinsic noise depend on class membership. Two classes exhibit decreased noise with co-transcription, two others reveal increased noise, and the remaining one does not show a significant difference. To test our modeling predictions we employed bioinformatic analysis to determine the relationship gene expression noise and operon organization. The results confirm the overrepresentation of noise-minimizing operon architectures and provide evidence against other hypotheses. Our results thereby suggest a central role for gene expression noise in selecting for or maintaining operons in bacterial chromosomes. This demonstrates how post-translational network dynamics may provide selective pressure for organizing bacterial chromosomes, and has practical consequences for designing synthetic gene networks.

4:06PM L40.00005 Population-level control of gene expression[1] , DMITRY NEVOZHAY, RHYS ADAMS, Department of Systems Biology, UT M. D. Anderson Cancer Center, ELIZABETH VAN ITALLIE, MATTHEW BENNETT, Department of Biochemistry and Cell Biology and Institute of Biosciences and Bioengineering, Rice University, GABOR BALAZSI, Department of Systems Biology, UT M. D. Anderson Cancer Center — Gene expression is the process that translates genetic information into proteins, that determine the way cells live, function and even die. It was demonstrated that cells with identical genomes exposed to the same environment can differ in their protein composition and therefore phenotypes. Protein levels can vary between cells due to the stochastic nature of intracellular biochemical events, indicating that the genotype-phenotype connection is not deterministic at the cellular level. We asked whether genomes could encode isogenic cell populations more reliably than single cells. To address this question, we built two gene circuits to control three cell population-level characteristics: gene expression mean, coefficient of variation and non-genetic memory of previous expression states. Indeed, we found that these population-level characteristics were more predictable than the gene expression of single cells in a well-controlled environment.

4:18PM L40.00006 Functional Differentiation in EVS modeling , IRINA TROFIMOVA, CI Laboratory, WILLIAM SULIS, McMaster University — Ensembles with Variable Structures (EVS) were introduced in mid-1990s as stochastic milti-agent models in which agents possessed either formal diversity (described in a multi-dimensional vector space of abstract characteristics) or resource-oriented diversity (Trofimova, 2000). The process of functional differentiation (i.e. appearance of functional roles) is modelled as constraints on the flow of resources which pass through agents of the model. These constraints are: 1) the maximum amount of resource that an individual can accept from outside, 2) the maximum amount of resource that an individual can give back to the population or other environment, 3) distribution of the exchange of the resource over time (frequency and amount of the resource per step), and 4) the maximum amount of contacts that an individual can hold with such environment (sociability). Sociability appears to have a major impact on clustering dynamics within the population and to be an order parameter in phase transition in clustering behaviour, therefore it interfered with functional differentiation. Two patterns of functional differentiation were observed, before and after the phase transition in clustering, corresponding to sociability values below and after the critical points.

4:30PM L40.00007 Fitness in fluctuating environments , SORIN TANASE NICOLA, ILYA NEMENMAN, Emory University — Often environments change faster than the time needed to evolve optimal phenotypes through cycles of mutation and selection. We focus on this case, but assume that environmental oscillations are slower than an individual's lifetime. This is relevant, for example, for bacterial populations confronted with daily environmental changes. We analyze a resource-limited competition between a mutant phenotype and the ancestor. Environmental dynamics is represented by periodically varying, off-phase parameters of the corresponding Lotka-Volterra model. For the very slow dynamics (but still faster than the fixation time scale) the strength and the sign of selection are functions of the birth/death rates averaged over all of the environmental states and independent of the period of the fluctuations. For faster fluctuations, selection depends on the particular sequence of the successive environmental states. In particular, a time reversal of the environmental dynamics can change the sign of the selection. We conclude that the fittest phenotype in a changing environment can be very different from both the optimal phenotype in the average environment, and the phenotype with the largest average fitness.

4:42PM L40.00008 Development of an electrical nanopore device towards the control of the translocation of DNA with single base resolution[1] , HONGBO PENG, BINQUAN LUAN, STANISLAV POLONSKY, STEPHEN ROSSNAGEL, GUSTAVO STOLOVITZKY, IBM Research at Thomas J. Watson Research Center — Recently, application of nanopores to low-cost DNA sequencing has attracted great interest as there is great need to reduce the cost of sequencing a whole human genome to $1000. A key issue in the field of nanopore DNA sequencing is to control the DNA translocation. Here we will report the development of what we call a "DNA transistor": a nanopore-based electrical device for controlling the translocation of DNA with single base resolution. The key part of this device is a free standing membrane, within which multiple layers of electrically addressable metal electrodes separated by dielectric layers are embedded. A 1-5 nanometer size pore is made through the membrane. We demonstrated that such a device is electrically viable for the electrode layer or the spacing dielectric layer as thin as 3 nm in 1 mM KCl solution. Induced electrical signals on the nano-electrodes by the translocating DNA, as well as the modulation of DNA translocation speed by the voltage bias applied on the nanoelectrodes are also observed. Our ongoing experiments test if the modulated electrical field can trap or translocate DNA at a single base resolution.

5:06PM L40.00010 Polymerization of nanopores for controlled surface charges[1] , WASEEM ASGHAR, AZHAR ILYAS, RICHARD TIMMONS, SAMIR IQBAL, The University of Texas at Arlington — The solid-state nanopores have emerged as a novel candidate for DNA sequencing and protein analysis. Traditional approaches for nanopore diameter shrinking use electron microscopy induced shrinking and deposition processes. These approaches are limited due to less control on surface composition of the deposited film, slow deposition rate and initial membrane thickness dependant shrinking processes. We report a novel approach of pulsed plasma polymer deposition which addresses all of the above described issues. The surface chemical composition and geometry of solid-state nanopores are controlled by plasma deposition of highly conformal thin polymeric films. Surface energy and pore-wall surface charges are controlled using appropriate monomer during plasma deposition process.

Session L41 DCP: Condensed Phase Dynamics and Structure A115/117

2:30PM L41.00001 Temperature and Lengthscale Dependence of Solvophobic Solvation in a Water-like Liquid , JOHN DOWDLE, PETER ROSSKY, University of Texas at Austin — Temperature and lengthscale dependence of the solvation of cavity solutes is investigated along the saturation curve of the Jagla liquid, a simple liquid consisting of particles that interact via a spherically symmetric potential combining hard and soft core interactions. The results are compared with an identical calculation for a model of a typical atomic liquid, the Lennard-Jones potential, and with predictions for cavity solubilities in water made by the recently developed cavity equation of state. We find that the Jagla liquid captures the qualitative thermodynamic behavior of hydrophobic hydration as a function of temperature for both small and large lengthscale solutes. The results suggest that a competition between two lengthscales that favors low- density, open structures as temperature is decreased is an essential interaction of a liquid that models hydrophobic hydration.

2:42PM L41.00002 Effects of Physical Confinement on the Hysteresis between Melting and Freezing Temperatures of Decanol[1] , SAMUEL AMANUEL, JARGALSAIKHAN DULMAA, AMER KHRAISAT, Department of Physics and Astronomy, Union College, Schenectady, NY 12308 — There is substantial evidence that physical confinement alters melting and freezing temperatures of materials. These have been qualitatively explained using free energy considerations. However, it is not clear how physical confinement influences melting and freezing when the bulk material itself exhibits substantial supercooling. Bulk 2-decanol, for instance, exhibits substantial hysteresis between its melting (approximately -23°C) and freezing (-3°C) temperatures. Evidently, both its melting and freezing temperatures are influenced by physical size. However, the hysteresis between the freezing and melting temperatures seems less sensitive to physical size. This may be the result of differences in homogeneous versus heterogeneous nucleation in physically confined 2-decanol.

2:54PM L41.00003 Evaluating the Liquid Liquid Phase Transition Hypothesis of Supercoooled Water , DAVID LIMMER, DAVID CHANDLER, University of California, Berkeley — To explain the anomalous behavior of supercooled water it has been conjectured that buried within an experimentally inaccessible region of liquid water's phase diagram there exists a second critical point, which is the terminus of a first order transition line between two distinct liquid phases. The so-called liquid-liquid phase transition (LLPT) has since generated much study, though to date there is no consensus on its existence. In this talk, we will discuss our efforts to systematically study the metastable phase diagram of supercooled water through computer simulation. By employing importance-sampling techniques, we have calculated free energies as a function of the density and long-range order to determine unambiguously if two distinct liquid phases exist. We will argue that, contrary to the LLPT hypothesis, the observed phenomenology can be understood as a consequence of the limit of stability of the liquid far away from coexistence. Our results suggest that homogeneous nucleation is the cause of the increased fluctuations present upon supercooling. Further we will show how this understanding can be extended to explain experimental observations of hysteresis in confined supercooled water systems.

3:06PM L41.00004 Anomalous lattice parameter isotope-shift in hexagonal ice Ih from first principle calculations[1] , BETÜL PAMUK, MARIVI FERNANDEZ-SERRA, PHILIP ALLEN, Stony Brook University — The lattice parameters of light (H_2O) and heavy (D_2O) Ih ice differ by 0.09% [1]. The larger lattice constant is that of the heavier isotope, contrary to normal expectations. This isotope shift of the lattice constant is linked to the zero point energy of phonons in ice. In particular, it can be linked to the anti-correlation of the O-H stretch frequency and the O-O distance in H-bonded materials. In order to determine which phonons give the anomaly, we calculate Grüneisen parameters of H_2O and D_2O ice using first principles density functional theory, within the frozen phonon approximation. Our results show a strong dependence on the density functional chosen. We analyze these differences and make connections to experiment. These results indicate that not only H-bond effects but also van der Waals interactions are necessary to reproduce the correct lattice constant zero-point shifts in ice.

3:18PM L41.00005 Local effects in the X-ray absorption spectrum of salt water , ERIC SCHWEGLER, Lawrence Livermore National Laboratory, HEATHER KULIK, Stanford University, NICOLA MARZARI, University of Oxford, ALFREDO CORREA, Lawrence Livermore National Laboratory, DAVID PRENDERGAST, Lawrence Berkeley National Laboratory, GIULIA GALLI, UC Davis — We have used first principles molecular dynamics and theoretical X-ray absorption spectroscopy (XAS) to investigate the aqueous solvation of cations in $MgCl_2$, $CaCl_2$, and NaCl solutions. We focus our discussion on the species-specific effects that Mg^{2+}, Ca^{2+}, and Na^+ have on the X-ray absorption spectrum of the respective solutions. For the divalent cations, we find that the water molecules that form a rigid first solvation shell around Mg^{2+} and a more flexible solvation shell around Ca^{2+} also exhibit differing hydrogen bonding characteristics. Acceptor hydrogen bonds present in the water surrounding Ca^{2+} enhance a post-edge peak near 540 eV in the XAS spectrum, while the absence of such hydrogen bonding features for the first shell surrounding Mg^{2+} corresponds to a diminished intensity at the post-edge peak. For Na^+, we find that a broad tilt angle distribution results in broadened post-edge features, despite donor-and-acceptor populations comparable to Ca^{2+}. We present re-averaged spectra of the $MgCl_2$, $CaCl_2$, and NaCl solutions that provide an explanation of concentration-dependent features that have been found in corresponding experimental measurements.

3:30PM L41.00006 Nuclear momentum distribution and potential energy surface in hexagonal ice[1] , LIN LIN, Princeton University, JOSEPH MORRONE, Columbia University, ROBERTO CAR, Princeton University, MICHELE PARRINELLO, ETH Zurich — The proton momentum distribution in ice Ih has been recently measured by deep inelastic neutron scattering and calculated from open path integral Car-Parrinello simulation. Here we report a detailed investigation of the relation between momentum distribution and potential energy surface based on both experiment and simulation results. The potential experienced by the proton is largely harmonic and characterized by 3 principal frequencies, which can be associated to weighted averages of phonon frequencies via lattice dynamics calculations. This approach also allows us to examine the importance of quantum effects on the dynamics of the oxygen nuclei close to the melting temperature. Finally we quantify the anharmonicity that is present in the potential acting on the protons.

3:42PM L41.00007 The quantum nature of the hydrogen bond: insight from path-integral molecular dynamics , BRENT WALKER, XIN-ZHENG LI, ANGELOS MICHAELIDES, London Centre for Nanotechnology and Department of Chemistry, University College London, London WC1E 6BT, U.K — Hydrogen (H) bonds are weak, generally intermolecular bonds, that hold together much of soft matter, the condensed phases of water, network liquids, and many ferroelectric crystals. The small mass of H means H-bonds are inherently quantum mechanical; effects such as zero point motion and tunneling should be considered, although often are not. In particular, a consistent picture of quantum nuclear effects on the strength of H-bonds and consequently the structure of H-bonded systems is still absent. Here, we report *ab initio* path-integral molecular dynamics studies on the quantum nature of the H-bond. Systematic examination of a range of H-bonded systems shows that quantum nuclei weaken weak H-bonds but strengthen relatively strong ones. This correlation arises from a competition between anharmonic intermolecular bond bending and intramolecular bond stretching. A simple rule of thumb enables predictions to be made for H-bonded bonded materials in general with merely classical knowledge (e.g. H-bond strength or H-bond length). Our work rationalizes the contrasting influence of quantum nuclear dynamics on a wide variety of materials, including liquid water and HF, and highlights the need for flexible molecules in force-field based studies of quantum nuclear dynamics.

3:54PM L41.00008 Hydration phase diagram for BaO terminated $BaTiO_3$[1] , JOHN MARK MARTIREZ, Department of Chemistry, University of Pennsylvania, WISSAM AL-SAIDI, Department of Chemical and Petroleum Engineering, University of Pittsburgh, ANDREW RAPPE, Department of Chemistry, University of Pennsylvania — This study reveals geometries H_2O adopts upon adsorption on BaO terminated $BaTiO_3$(BTO) at low to high saturation. A hydration phase diagram for the aforementioned termination is presented, for moderate temperatures, and moderate to ultra high vacuum H_2O pressures. Calculations suggest a very stable H_2O adsorption for wide range of pressures, including high vacuum conditions (p_{H_2O} 10^{-12} bar). This opens venues for mechanistic studies and hopefully will serve as a guide to condition that might suppress H_2O adsorption on BTO for applications where it is undesired.

4:06PM L41.00009 ABSTRACT WITHDRAWN –

4:18PM L41.00010 Topological reaction coordinates to explore the structure of atomic clusters and organic molecule isomers from first principles , FABIO PIETRUCCI, CECAM EPF Lausanne (CH), WANDA ANDREONI, CECAM and Institut de Théorie des Phénomènes Physique EPF Lausanne (CH) — We introduce a simple reaction coordinate based on spectral graph theory which describes the topology of the network of chemical bonds around a given atom. We employ the reaction coordinate in combination with DFT-based first-principles metadynamics to systematically explore the possible structures of silicon and carbon clusters (including fullerene-like cages) for sizes of tens of atoms. From our extensive exploration we are able to estimate the fractal dimension of the configuration space, which both for silicon and carbon clusters turns out to be quite low. Using the same approach we simulate the interconversion among a large number of chemically relevant organic molecules which are isomers of the C_4H_5N formula unit, and we demonstrate the possibility of automatically exploring isomerisation, association, and decomposition reactions without prior knowledge of the products involved.

4:30PM L41.00011 Transport through a quantum dot with excitonic dot-lead coupling[1] , FLORIAN ELSTE, DAVID R. REICHMAN, ANDREW J. MILLIS, Columbia University — We study the effect of a Coulombic dot-lead interaction on transport through a quantum dot hybridized to two Luttinger-liquid leads.[2] A bosonization approach is applied to treat the interaction between charge fluctuations on the dot and the dynamically generated image charge in the leads.[3] The nonequilibrium distribution function of the dot and the tunneling current are computed within a master-equation approach. Particular attention is paid to two situations: (i) a quantum dot placed between two leads such that it cuts the Luttinger liquid into two semi-infinite quantum wires; (ii) a quantum dot side-hybridized to two parallel infinite quantum wires. The presence of the excitonic dot-lead coupling is found to enhance transport in the vicinity of the Coulomb-blockade threshold. This behavior is in contrast to the usual power-law suppression of electronic tunneling which is found if this interaction is ignored.

4:42PM L41.00012 Spectroscopic and Theoretical Investigations of the Potential Energy Surfaces of Molecules with Intramolecular π-type Hydrogen Bonding[1] , ESTHER OCOLA, HEE-WON SHIN, ABDULAZIZ AL-SAADI, JAAN LAANE, Texas A&M University — Spectroscopic methods and theoretical calculations have been utilized to investigate the conformations of several cyclic organic molecules. The laser induced fluorescence (LIF) spectra of 2-indanol show the presence of four conformations. The one with intramolecular hydrogen bonding between the –OH group and the benzene ring is of lowest energy. The potential energy surface (PES) in terms of the ring puckering and internal rotational vibrations, which govern the conformational changes, was determined. 3-Cyclopenten-1-ol possesses a similar PES as established from its infrared and Raman spectra and theoretical calculations. This PES also shows the presence of four conformations. The π-bonding conformer lies at lowest energy. LIF has been used to study the conformational energies of 2-hydroxytetralin, and 2-cyclohexenol has been investigated by infrared and Raman techniques. The analyses of the hydrogen bonding in these molecules as well as in a dozen others were supported by both *ab initio* and DFT calculations.

4:54PM L41.00013 Raman Spectra and the Potential Energy Function for the Internal Rotation of 1,3-Butadiene and its Isotopomers[1] , JAAN LAANE, PRAVEENKUMAR BOOPALACHANDRAN, Texas A&M University, NORMAN CRAIG, Oberlin College — The gas-phase Raman spectra of 1,3-butadiene-d_0, 2,3-d_2, 1,1,4,4-d_4, and –d_6 have been collected with CCD detection with numerous scans of ten hours or more. For each isotopomer eight Raman transitions in the 240-330 cm^{-1} region corresponding to double quantum jumps of the A_u internal rotation (ν_{13}) were observed for the *trans* conformer. Weaker bands in the 170-260 cm^{-1} region were assigned to the *gauche* conformation, which lies at higher electronic energy. A periodic potential function for the internal rotation, which fits the data for all the isotopomers, was determined. This function shows the *gauche* form to be 966 cm^{-1} higher in energy and the barrier between the *trans* and *gauche* structures to be 2055 cm^{-1}. The *cis* structure has an energy 408 cm^{-1} higher than the *gauche*. Fourteen combination band or hot band series involving ν_{13} for the *trans* conformer were also observed, and these allow the internal rotation levels in various excited vibrational states to be determined.

[1]Supported by R.A. Welch grant A-0396.

5:06PM L41.00014 Transition and Excited States of 1,1'-azo-bis-1,2,3-triazole , VLADIMIR GONCHAROV, Vanderbilt University, OLGA GONCHAROVA, Vertex Pharmaceuticals Inc., KALMAN VARGA, Vanderbilt University — A novel photochromic molecule has been recently synthesized[1]. The photo-isomerization of this nitrogen-rich small molecule is efficiently controlled by a xenon flash lamp suggesting a potential in photonic and molecular mechanics applications. We perform a synergistic quantum molecular dynamics (QMD), real-time time dependent density functional theory (TDDFT) and TDDFT- perturbation theory study to capture and elucidate the transition state, excitation energies and optical properties of the molecule. We also use it to test performance of recently developed real-time TDDFT method[2] to calculate hyperpolarizabilities and compare results with the Sternheimer method.

5:18PM L41.00015 Importance of Electronic Relaxation for Inter-Coulombic Decay in Aqueous Systems[1] , DAVID PRENDERGAST, Molecular Foundry, Lawrence Berkeley National Laboratory (LBNL), CRAIG P. SCHWARTZ, RICHARD J. SAYKALLY, Chemistry Dept., University of California, Berkeley and Chemical Sciences, LBNL, SHERVIN FATEHI, Kenneth S. Pitzer Center for Theoretical Chemistry, University of California, KEITH V. LAWLER, Chemical Sciences, LBNL, C. WILLIAM MCCURDY, Chemical Sciences, LBNL and Departments of Applied Science and Chemistry, University of California, Davis — Inspired by recent photoelectron spectroscopy experiments on hydroxide solutions, we have examined the conditions necessary for enhanced (and, in the case of solutions, detectable) intermolecular Coulombic decay (ICD) – Auger emission from an atomic site other than that originally excited. We present general guidelines, based on energetic and spatial overlap of molecular orbitals, for this enhancement of ICD-based energy transfer in solutions. These guidelines indicate that this decay process should be exhibited by broad classes of biomolecules and suggest a design criterion for targeted radiooncology protocols. Our findings indicate that ICD processes in hydroxide solutions are not dependent on hydroxide hydrogen bond donation.

Session L42 DPOLY: Dillon Medal Symposium A302/303

2:30PM L42.00001 John H. Dillon Medal Talk: Protein Fibrils, Polymer Physics: Encounter at the Nanoscale , RAFFAELE MEZZENGA, ETH - Zurich — Aggregation of proteins is central to many aspects of daily life, ranging from blood coagulation, to eye cataract formation disease, food processing, or neurodegenerative infections. In particular, the physical mechanisms responsible for amyloidosis, the irreversible fibril formation of various proteins implicated in protein misfolding disorders such as Alzheimer, Creutzfeldt-Jakob or Huntington's diseases, have not yet been fully elucidated. In this talk I will discuss how polymer physics and colloidal science concepts can be used to reveal very useful information on the formation, structure and properties of amyloid protein fibrils. I will discuss their physical properties at various length scales, from their collective liquid crystalline behavior in solution to their structural features at the single molecule length scale and show how polymer science notions can shed a new light on these interesting systems. 1) "Understanding amyloid aggregation by statistical analysis of atomic force microscopy images" J. Adamcik, J.-M. Jung, J. Flakowski, P. De Los Rios, G. Dietler and R. Mezzenga, Nature nanotechnology, 5, 423 (2010)

3:06PM L42.00002 Interdiffusion in bilayers of PCBM fullerene and poly(3-hexyl thiophene) P3HT , EDWARD J. KRAMER, NEAL D. TREAT, MICHAEL A. BRADY, UCSB, MICHAEL F. TONEY, SSRL, MICHAEL L. CHABINYC, CRAIG J. HAWKER, UCSB — Bulk heterojunction (BHJ) photovoltaic materials, typified by blends of PCBM and P3HT, are often regarded as immiscible in the absence of casting solvent. We use dynamic secondary ion mass spectrometry and grazing incidence wide angle X-ray scattering to probe the interdiffusion of bilayers of P3HT and deuterated dPCBM. We find that the as cast P3HT film is semicrystalline, while the dPCBM film is amorphous, and that there is complete interdiffusion between dPCBM and P3HT after annealing for 300 s at T = 150°C, a typical treatment to improve device efficiency. This interdiffusion occurs without disrupting the ordered lamellar stacking in the P3HT crystallites, showing that PCBM is miscible with amorphous P3HT at this temperature (the size and/or perfection of the P3HT crystallites actually increases during the annealing). At T < 150°C rapid diffusion of dPCBM into P3HT still occurs but the dPCBM concentration reaches an apparent solubility limit after long anneals, a limit that decreases with decreasing temperature. This result suggests that dPCBM will phase separate from amorphous P3HT in the BHJ on cooling from 150°C to room temperature.

3:18PM L42.00003 , GEROGES HADZIIOANNOU, —

3:30PM L42.00004 Coarse grained polystyrene simulations: Static and dynamic properties[1] , KURT KREMER, Max Planck Institute for Polymer Research, Mainz, Germany — By combining input from short simulation runs of rather small systems with all atomistic details together with properly adapted coarse grained models we are able quantitatively predict static and especially dynamical properties of both pure polymer melts of long entangled chains but also of systems with low molecular weight additives. Comparisons to rather different experiments such as diffusion constant measurements, NMR relaxation experiments and dielectric spectroscopy show a remarkable quantitative agreement without any adjustable parameter. The model is also able to distinguish different tacticities and to study the consequences for static and dynamic properties. Reintroduction of chemical details into the coarse grained trajectories allows the study of long time trajectories in all atomistic detail providing the opportunity for rather different means of data analysis.

[1]Work done in collaboration with D. Fritz, V. Harmandaris and N. van der Vegt.

3:42PM L42.00005 Effects of Side Chains on the Self-Assembly and Photovoltaic Properties of Conjugated Polymer Semiconductors , SAMSON JENEKHE, University of Washington — Conjugated polymer semiconductors are of growing interest in electronics and optoelectronics. Although it is now well established that the electronic band structure, charge transport, and electronic properties of conjugated polymers can be varied over a wide range through manipulation of the molecular backbone structure, little is known about the effects of alkyl side chains on the solid state morphology and properties of these materials. We have investigated homologous series of conjugated homopolymers, block copolymers, and random copolymers with controlled variation of their alkyl sides towards understanding the effects the size and typology of the side chains on self-assembly, morphology, and photovoltaic properties. We found that diblock copoly(3-alkylthiophenes) exhibit highly crystalline and phase-separated nanostructures in blend films with fullerene derivatives, resulting in superior photovoltaic properties compared to the corresponding homopolymers. The solid state morphology and photovoltaic efficiency of a series of donor-acceptor copolymer semiconductors that have the same optical band gap but different alkyl side chains were found to vary dramatically. Self-assembled block copolymer nanowires with widths of 10-30 nm and aspect ratios of up to 900 have been found to be promising building blocks for constructing efficient bulk heterojunction solar cells.

3:54PM L42.00006 Nacre-Mimetic Composites via Single-Step Self-Assemblies of Polymer-Coated Colloids , OLLI IKKALA, Helsinki University of Technology/Aalto University School of Science and Technology, MOLECULAR MATERIALS TEAM — We demonstrate a scalable single-step self-assembly of polymer-modified plate-like colloidal platelets for nacre-mimetic materials, which overcomes the problem of sequential deposition to prepare hard and soft nacre-mimetic assemblies, which is inherently slow and not scalable. The materials have low density and show good mechanical properties, i.e., modulus of 45 GPa and strength 250 MPa, i.e. partly surpassing those of nacre (Walther et al, Nano Letters 2010, Angew Chem 2010). We expect that the concepts open a route for biomimetic materials from the lab to technology.

4:06PM L42.00007 On the Crystallinity and Chain Conformation in PEO / Layered Silicate Nanocomposites , SPIROS H. ANASTASIADIS[1], K. CHRISSOPOULOU, S. BOLLAS, Foundation for Research and Technology - Hellas, Heraklion Crete, Greece, K. ANDRIKOPOULOS, S. FOTIADOU, D. CHRISTOFILOS, Aristotle University of Thessaloniki, Thessaloniki, Greece, G.A. VOYIATZIS, Institute of Chemical Engineering and High Temperature Chemical Processes, Patras, Greece — The structure of nanohybrid materials as well as the chain conformation under confinement is investigated in hydrophilic polymer / layered silicate nanocomposites. A series of PEO / sodium montmorilonite hybrids was synthesized utilizing melt intercalation with compositions covering the whole range from pure polymer to pure clay. Intercalated nanocomposites with mono- and bi-layers of PEO chains are obtained in all cases. The intercalated chains as well as the ones adsorbed on the outer surface of the clay particles remain purely amorphous; nevertheless, their conformations exhibit different characteristics from those of the amorphous bulk material with the intercalated PEO chains adopting preferably gauche conformations. It is only for compositions where a large amount of excess polymer exists outside the completely full galleries that the polymer crystallinity is recovered. Sponsored by NATO's Scientific Affairs Division, by the Greek GSRT and by the EU.

4:18PM L42.00008 Formation and application of functional coatings on synthetic fibers , KIRAN GOLI, ALI OZCAM, KRISTEN ROSKOV, RICHARD SPONTAK, ORLANDO ROJAS, JAN GENZER, NC State University — We present two simple methods for modifying synthetic fibers made of polypropylene (PP) and poly(ethylene terephthalate) (PET). Specifically, we alter the inert PP fiber mats by physisorbing denatured proteins, and cross-linking the protein layers using glutaraldehyde. The amino- and hydroxyl-functionalities present in the protein coatings serve as attachment points for polymerization initiators. In addition, PET fibers are modified chemically by amidation with 3-aminopropyltriethoxysilane (APTES), followed by hydrolysis, which yields silanol groups that permit surface attachment of the initiator molecules. "Grafting from" polymerization from such modified PP and PET surfaces is employed following the atom transfer radical polymerization protocol to form functional and responsive polymer coatings. These include arrays of poly(2-hydroxyethyl methacrylate) (PHEMA) as well as chemically-modified PHEMA layers. Selected applications of these functional fibers will be outlined briefly, including, capture of metals or other contaminants from waters, prevention of protein adsorption, and attachment of metallic nanoparticles.

4:30PM L42.00009 Peptide assembly for nanoscale control of materials , DARRIN POCHAN, University of Delaware — Self-assembly of molecules is an attractive materials construction strategy due to its simplicity in application. By considering peptidic, charged synthetic molecules in the bottom-up materials self-assembly design process, one can take advantage of inherently biomolecular attributes; intramolecular folding events, secondary structure, and electrostatic interactions; in addition to more traditional self-assembling molecular attributes such as amphiphilicty, to define hierarchical material structure and consequent properties. Design strategies for materials self-assembly based on small (less than 24 amino acids) beta-hairpin peptides will be discussed. Self-assembly of the peptides is predicated on an intramolecular folding event caused by desired solution properties. Importantly, kinetics of self-assembly can be tuned in order to control gelation time. The final gel behaves as a shear thinning, but immediately rehealing, solid that is potentially useful for cell injection therapies. The morphological, and viscoelastic properties of these peptide hydrogels will be discussed. In addition, slight changes in peptide primary sequence can have drastic effects on the self-assembled morphology. Additional sequences will be discussed that do not form hydrogels but rather form nanoscale templates for inorganic material assembly.

4:42PM L42.00010 Food Materials - a natural playground for soft matter physics , ADAM BURBIDGE, Nestec SA — Traditional food science has its origins in chemistry, and has therefore tended to focus on trying to link molecular formulation and functional performance. Nevertheless, foods are almost always complex hierarchically structured materials of biological origin, far from thermodynamic equilibrium. These kinds of systems provide a challenge of relating structure to function, which is a natural playground for many ideas and concepts of soft matter physics. In this talk I will briefly outline the incredibly rich structural complexity of food products and highlight some areas which are appear to be amenable to physically based reasoning. Despite some notable contributions, food materials physics is a field very much in it's infancy, and I will highlight some outstanding (in both senses of the word) problems!

4:54PM L42.00011 Assembly of conjugated-polymer-based nanostructures driven by solution-state crystallization , RYAN HAYWARD, FELICIA BOKEL, EUNJI LEE, BRENT HAMMER, P.K. SUDEEP, EMILY PENTZER, TODD EMRICK, University of Massachusetts Amherst — Conjugated polymers such as regioregular poly(3-alkyl thiophenes), are well known to crystallize into extended one-dimensional nanowires or fibrils. This behavior is not only important for the efficiency of charge transport in device layers, but can also provide a driving force to assemble different optoelectronic components into well- defined nanostructures. We have investigated the assembly of two systems that rely on solution-state crystallization of poly(3-hexyl thiophene) (P3HT). In the first case, co- crystallization of freely dissolved and particle-bound P3HT provides hybrid fibrils of polymers flanked with n-type inorganic nanoparticles. In the second case, crystallization of P3HT-poly(3-triethylene glycol thiophene) diblock copolymers yields fibrils that can form supramolecular helical assemblies in the presence of salt. We seek to elucidate the mechanisms of self-assembly and the optoelectronic properties of the resulting nanostructures.

5:06PM L42.00012 Temperature responsive hydrogel nanofibers and nanoparticles , JANNE RUOKO-LAINEN, Aalto University/Department of Applied Physics — Poly(N-isopropylacrylamide) (PNIPAM) is one of the most extensively investigated synthetic temperature-responsive polymers. In this work temperature-responsive PNIPAM based triblock copolymer hydrogels, their self-assembly and phase behavior in bulk, are described. Additionally, recent results from responsive hydrogel nanofibers and hydrogel nanoparticles are shown. It is known that block copolymers form well-organized nano structures in bulk or thin films when annealed thermally or in solvent vapours. However, in the case of nanofibers or nanoparticles, the annealing leads in most cases to aggregation and particle sintering. This work utilizes aerosol-based gas phase method where the preparation and annealing of hydrogel nanoparticles with well-organized, hierarchical inner structures are performed without any particle coagulation or sintering. In the method, the block copolymers assemble within aerosol nanoparticles to form, for instance, lamellar onion-like or gyroid inner structures.

5:18PM L42.00013 Orientation and Order in High-Efficiency Polymer Solar Cell Active Layers , M.R. HAMMOND, R.J. KLINE, L.J. RICHTER, C.L. SOLES, D.M. DELONGCHAMP, NIST, T. XU, L. YU, Univ. Chicago, M.F. TONEY, SSRL — Using a combination of scattering and spectroscopy techniques, we have characterized molecular orientation and order in bulk heterojunction (BHJ) organic photovoltaic cells based upon thieno[3,4-*b*]thiophene-*alt*-benzodithiophene copolymers (PTB) and fullerene derivatives. The various techniques probe complimentary aspects of the full distribution of (e.g.) polymer chain orientations, so analysis of the data in tandem allows us to evaluate the relative likelihood of several model distributions. Specifically, X-ray diffraction data yielded a full orientation distribution for the polymer pi-stacking direction within well-ordered regions, with the nominal result of a strong preference for pi-stacking in the vertical direction. This structural characteristic may enhance vertical charge mobility and thus be one factor leading to the outstanding performance of PTB based devices. However, the most plausible model distribution would suggest that those ordered (diffracting) regions of the PTB BHJ films comprise only a small percentage of the total polymer volume within the film.

3:06PM L43.00002 Block copolymers exhibiting simultaneous electronic and ionic conduction for use in lithium battery electrodes , ANNA JAVIER, Lawrence Berkeley National Laboratory, SHRAYESH PATEL, University of California, Berkeley, DANIEL HALLINAN, Lawrence Berkeley National Laboratory, NITASH BALSARA, University of California, Berkeley — A block copolymer system that can demonstrate both electronic and ionic conductivity is analyzed for its performance in rechargeable lithium batteries. Here, the electrically active polymer is poly(3-hexylthiophene), while poly(ethylene oxide) is used as the lithium ion conductor. This block copolymer is then mixed with $LiFePO_4$ and used as the cathode material. Other components in the battery include a lithium metal anode and poly(styrene)-*block*-poly(ethylene oxide) (SEO) as the solid electrolyte. Lithium bis(trifluoromethane)sulfonimide (LiTFSI) is utilized to facilitate ionic conductivity in both the electrolyte and the cathode. The synthesis of the block copolymer and its device performance in rechargeable lithium metal batteries will be presented.

3:18PM L43.00003 All Solid State Rechargeable Lithium Batteries using Block Copolymers , DANIEL HALLINAN, NITASH BALSARA, U.C. Berkeley — The growing need for alternative energy and increased demand for mobile technology require higher density energy storage. Existing battery technologies, such as lithium ion, are limited by theoretical energy density as well as safety issues. Other battery chemistries are promising options for dramatically increasing energy density. Safety can be improved by replacing the flammable, reactive liquids used in existing lithium-ion battery electrolytes with polymer electrolytes. Block copolymers are uniquely suited for this task because ionic conductivity and mechanical strength, both important properties in battery formulation, can be independently controlled. In this study, lithium batteries were assembled using lithium metal as negative electrode, polystyrene-b-poly(ethylene oxide) copolymer with lithium salt as electrolyte, and a positive electrode. The positive electrode consisted of polymer electrolyte for ion conduction, carbon for electron conduction, and an active material. Batteries were charged and discharged over many cycles. The battery cycling results were compared to a conventional battery chemistry.

3:30PM L43.00004 Solubility of Lithium Polysulfides in a Block Copolymer Electrolyte for Lithium/Sulfur Batteries , ALEXANDER TERAN, NITASH BALSARA, University of California, Berkeley and Lawrence Berkeley National Laboratory — The primary challenges to commercialization of the high-energy-density lithium sulfur battery are dendrite growth of the lithium metal at the anode and capacity fade due to loss of active mass through dissolution at the cathode. Nanostructured solid polymer electrolytes offer one potential solution to reduce the amount of capacity fade seen in lithium metal/sulfur batteries by keeping the active material localized at the cathode and to prevent the growth of dendrites at the anode due to their high shear moduli. The block copolymer electrolyte poly(styrene)-*block*-poly(ethylene oxide) (SEO) has shown acceptable ionic conductivity and sufficient shear modulus to retard lithium dendrite growth. The solubility of the lithium polysulfide reaction intermediates Li_2S_x, where $1 \leq x \leq 8$, was studied in SEO copolymers with a range of molecular weights and salt concentrations using small angle X-ray scattering, X-ray diffraction, and differential scanning calorimetery.

3:42PM L43.00005 Solution Processable Hybrid Polymer-Inorganic Thermoelectric Materials , SHANNON YEE, University of California, Berkeley, NELSON COATES, KEVIN SEE, JEFFREY URBAN, Lawrence Berkeley National Laboratory, RACHEL SEGALMAN, University of California, Berkeley — In the last decade thermoelectric material improvements have largely been attributed to a reduction in thermal conductivity due to nanostructuring. An alternative approach is to decouple and optimize the power factor using the unique properties of organic-inorganic interfaces. One method to do this could rely on the electrical properties of a conducting polymer in combination with the thermoelectrical proprieties of an inorganic semiconductors. It is expected that the thermal conductivity of this hybrid material would be low due to the inherent phonon mismatch between polymers and inorganics. Recently we have developed a method for producing a solution processable bulk thermoelectric material ($ZT>0.1$) using a hybrid polymer-inorganic systems consisting of crystalline tellurium nanowires coated in a thin layer of PEDOT:PSS. The interface properties of these materials scale and bulk films demonstrate enhanced transport properties beyond those of either component. Here, we present our methodology, theoretical explanation, and experimental transport properties of this new class of materials where the thermal conductivity, electrical conductivity, and thermopower predictably vary as a function of polymer loading in the hybrid composite.

3:54PM L43.00006 Microscopic mechanism of energy storage in PVDF-CTFE from ab-initio calculations , V. RANJAN, NC State University, Raleigh, NC, MARCO BUONGIORNO NARDELLI, J. BERNHOLC, NC State University, Raleigh, NC and CSMD, ORNL, TN — Polypropelene is most used capacitor dielectric for high energy density storage. However, exotic materials such as copolymerized Polyvinylidene fluoride (PVDF) could potentially lead to an order of magnitude increase in the stored energy density [1,2]. In contrast to linear dielectric properties of polypropelene, several polymers in the PVDF family display nonlinear dielectric properties under electric field. The nonlinearity was postulated to be due to a phase transition from non-polar to a polar structure, whose energy is lowered by an electric field [2]. Our calculations map out the atomistic details of phase transformations for both pure PVDF and PVDF-CTFE. Interestingly, admixture of a small amount of copolymer lowers both the polarization and the energy barriers for the transformation. The barrier lowering facilitates the transformation and may result in reduced loss in the charge-discharge cycle, enabling tuning of material properties for energy storage applications.

4:06PM L43.00007 Nanotube Forests for Electrochemical Energy Storage from Electrostatic Assembly[1] , LIN SHAO, WOO-SIK JANG, Yale University, JODIE LUTKENHAUS, Texas A&M University — With increasing global energy consumption, efficient energy storage sytems are urgently needed. Currently, lithium-ion batteries are prevalent in many of these applications because of their established reliability and superior performance relative to older technologies; however, Li-ion batteries can be limited by mass transfer and safety concerns. Here, we present nanostructured polymer-based electrodes that potentially address these limitations. We apply layer-by-layer (LbL) assembly and nanotemplating to realize LbL-nanotube cathode arrays containing vanadium pentoxide and polyaniline. Both polyaniline and V2O5 store charge via doping/undoping and intercalation/deintercalation, respectively. The aim is to create high surface area electrodes that minimize the diffusion resistance of reactants, which could boost power density. The (LbL) growth profile was monitored using UV-Vis spectroscopy and profilometery. Electrochemical properties were characterized using cyclic voltammetery. Scanning electron microscopy images confirm that large areas of LbL nanotubes can be made. Future work will assess how nanostructured cathodes will behave electrochemically as nanotube aspect ratio is varied.

4:18PM L43.00008 Block-Copolymer Lithium Battery Electrolytes , HANY EITOUNI, Seeo, Inc — With high energy density at low cost, Li ion has become the most prevalent portable rechargeable battery chemistry in the world. As demand for smaller and lighter batteries grows, the energy density limitation of Li ion batteries presents a significant hurdle. Pushing the existing Li ion platform to higher energy densities compromises lifetime and safety, and these have emerged as the most pressing challenges in today's industry. The weakest link in terms of safety and stability of Li ion batteries is the organic liquid electrolyte that facilitates ionic transport between the electrodes. The continuous electrochemical degradation of the electrolyte at the electrodes causes poor cycle life of the batteries, and in some cases, runaway reactions that lead to explosions. Dry polymer electrolytes coupled to Li metal anodes had been considered a high energy alternative to liquid-based systems, as the solid-solid interface promised to alleviate the stability problems of the liquid electrolyte. However, repeated cycling of Li metal anodes leads to dendrite formation, reducing battery life and compromising safety. Recent theoretical work indicates that dendrite growth can be stopped if the shear modulus of current polymer electrolytes can be increased by three orders of magnitude without a significant decrease in ionic conductivity. Thus, the mechanical properties of polymer electrolytes are particularly important in rechargeable solid-state lithium batteries. Because ion transport in polymers is coupled to the motion of the molecules that are solvating the ions, the presence of mobile molecules is essential to allow for a conductive medium. However, the same mobility of molecules is detrimental to the polymer's structural integrity. There is, thus, a clear need to develop methodologies for decoupling the conductive and mechanical properties of polymer electrolytes. Electrolytes comprised of self-assembled block-copolymer nanostructures overcome this principal constraint.

4:54PM L43.00009 Effect of Nanoscale Morphology on Selective Ethanol Transport through Block Copolymer Membranes , ASHISH JHA, NITASH BALSARA, UC Berkeley — We have examined the possibility of using A-B block copolymers for selective separation of alcohols from aqueous mixtures. The A block is not soluble in the liquids of interest and serves as the structural block while B serves as the transporting block. The size of the transporting channels has been controlled by varying the molecular weight, and the geometry has been controlled by varying the composition of the copolymer. Experimental results that reveal the dependence of membrane transport on the size and geometry of the transporting domains will be presented.

5:06PM L43.00010 Simulation study of charge distribution near an ionomer-electrode interface[1] , ELSHAD ALLAHYAROV[2], PHILIP TAYLOR, Physics Department, Case Western Reserve University, Cleveland OH, USA — Molecular dynamics simulations have been used to investigate the nature of the electrostatic field and of the proton density distribution in a Nafion-like ionomer in contact with an electrode. We compare our results for a heterogeneous ionomer, in which a partial phase separation has resulted in separate nanoscopic regions of hydrophobic and hydrophilic material, with those predicted by one-dimensional theoretical models in which Poisson-Boltzmann techniques are used to derive self-consistent potentials and concentration distributions. We further examine the effects of the strong inhomogeneous electrostatic fields in changing the morphology of the ionomer in the vicinity of the electrode from its original form in the bulk material.

2:30PM L44.00001 Dillon Medal Break –

3:06PM L44.00002 Confinement and elastic modulus in polymer nanofibers , EYAL ZUSSMAN, MICHAEL BURMAN, ARKADII ARINSTEIN, Technion — Size-dependant behavior is considered in electrospun polymer nanofibers. Experimental results unambiguously show that the abrupt increase in the elastic modulus of polymer nanofibers, below a cross-over diameter, relative to the bulk could not be attributed to surface energy effect. Polyamide (*Nylon-6.6*) nanofibers were tested by using either bending or tensile deformation modes (the surface energy affects the effective modulus only in the case of bending, and has no effect in the case of tensile deformation). It turns out that the obtained experimental data cannot be explained by the influence of surface energy upon the elastic modulus either qualitatively or quantitatively. This fact supports the explanation which is based on the geometrical confinement of the supermolecular structures of nano-objects.

3:18PM L44.00003 Size-dependent behavior of electrospun polymer nanofibers under small deformation , ARKADII ARINSTEIN, EYAL ZUSSMAN, Technion — A model describing a mechanism resulting in size-dependent behavior of electrospun polymer nanofibers under small deformation is proposed. According this model, the polymer matrix of the nanofibers consists of correlated groups of chains/subchains, partially orientated along the fiber. These supermolecular structures which were formed during electrospinning are confined by the fiber boundary. Thus, when the fiber elongates under external force the relative rotations of these correlated regions are hindered. As a result the elastic modulus depends on the diameter of the deformed fiber. In case of small fiber diameters this restriction is dominant while this effect decreases with increase of fiber diameter, and tends to zero for large fiber diameters according to square-law which was verified by experimental observations.

3:30PM L44.00004 ABSTRACT WITHDRAWN –

3:42PM L44.00005 Ionic conduction at liquid-liquid interfaces[1] , FRANCISCO SOLIS, Arizona State University, MONICA OLVERA DE LA CRUZ, Northwestern University — In coexisting liquid phases with different dielectric constants, ionic species do not have, in general, uniform concentrations. Salt ions accumulate predominately in the liquid with higher dielectric constant. Furthermore, excess accumulation and depletion of ions appears at the interface between the liquids, In this presentation we explore the effects of these non-uniform ionic distributions in the AC conductivity of the liquid mixture. We describe in detail the frequency dependence of of the conductivity for each of the ionic components.

[1]We acknowledge the support of the NERC, which is a EFRC funded DOE Office of Science under Award DE-SC0000989

3:54PM L44.00006 Vapor-Phase Free Radical Polymerization in the Presence of Ionic Liquids , MALANCHA GUPTA — Ionic liquids (ILs) have recently attracted significant interest as an environmentally-friendly alternative to traditional volatile organic solvents because ILs are non-volatile, non-flammable, and can be easily recycled. ILs can be exploited in many ways to improve the selectivity and kinetics of chemical reactions, including polymer synthesis. Ionic liquids have negligible vapor pressure and are therefore stable under vacuum. A few studies have investigated ILs as substrates in inorganic vacuum deposition processes, but to our knowledge ILs have not been used in vapor phase polymerization systems. We have recently introduced ionic liquids into the initiated chemical vapor deposition (iCVD) process for the first time. The iCVD polymerization process occurs via a free-radical mechanism, and the deposited polymeric films are compositionally analogous to solution-phase polymers. Despite the wide range of polymers that have been synthesized using iCVD, it has proven difficult to polymerize monomers with low surface concentrations such as styrene and low propagation rates such as methyl methacrylate and it is difficult to produce block copolymers. In this talk, we will show that our novel ILiCVD system can address some of these shortcomings. We will explain the effects of deposition time, temperature, and monomer solubility on the morphology of the polymer and the molecular weight of the polymer chains.

4:06PM L44.00007 Molecular orientation and photo-degradation of PTCDA films on TiO_2(110) , ORHAN KIZILKAYA, EIZI MORIKAWA, CAMD, Louisiana State University, PHILLIP SPRUNGER, Louisiana State University — The molecular orientation and photo-degradation process of 3,4,9,10-perylene-tetracarboxylic-dianhydride (PTCDA) films on TiO_2(110) were investigated by near edge X-ray absorption spectroscopy (NEXAFS). As the incidence angle of p-polarized synchrotron light with respect to the substrate surface normal increases, the intensity of the σ* resonances diminishes and the π* resonances is greatly enhanced. This finding indicates that the molecular orientation of the PTCDA film is flat on the TiO_2(110) surface. NEXAFS results of pristine and photo-degraded PTCDA films exposed to synchrotron white light at the VLSPGM beamline of CAMD revealed the photo-degradation mechanism. We found that the intensity of σ* states diminishes and the intensity of π* states of increases upon the PTCDA film exposed to white light for 30 minutes.

4:18PM L44.00008 Functionalization dependence of the electron beam sensitivity of bridged calix[6]arenes[1] , GREGORY SPENCER, Texas State University-San Marcos, DANIEL RALLS, ANUP BANDYOPADHYAY, MICHAEL BLANDA, Texas State University-San Marcos — Calixarenes have long been studied as a class of high resolution, negative electron beam resists. Previous work has shown the sensitivity can be improved by adding functional groups to the monomer's molecular rim to allow for a more efficient cross-linking mechanism. However, all previous studies dealt with either unfunctionalized resists or monomers that were fully functionalized. In this study, the number of attached functional groups was deliberately varied to directly observe its effect on sensitivity. A bridged calix[6]arene monomer was used as the basic structure. The number of these attached allyl groups ranged from 0 to 8 in steps of 2 per separate synthesis. The bridging units were xylenyl groups which produced both a cone conformer and a 1-2-3-alternate conformer. Resists were formed using all nine different calix[6]arenes and each was subjected to testing. Contrast curves for the cone and alternate conformers were measured by AFM. Resist sensitivities were found as a function of the number of attached groups. The sensitivity was found to be a strong function of the number of attached groups. These results will be discussed.

4:30PM L44.00009 Surface Segregation of Small Macrocyclic , SHIH-FAN WANG, The University of Akron, Department of Polymer Science, XIAOPENG LI, The University of Akron, Department of Chemistry, RENFENG HU, Colorado School of Mines, Department of Chemical Engineering, BULENT AKGUN, National Institute of Standards and Technology, REBECCA AGAPOV, CHRYS WESDEMIOTIS, The University of Akron, Department of Polymer Science, DAVID T. WU, Colorado School of Mines, Department of Chemical Engineering, MARK D. FOSTER, The University of Akron, Department of Polymer Science — Surface segregation of the thin film blends containing 20wt% 2k macrocyclic polystyrene were studied using surface MALDI-ToF mass spectrometry (MS), time of flight secondary ion mass spectrometry (ToF-SIMS), and neutron reflectometry (NR). To provide contrast between the species for these techniques, the linear polymer in the blend was deuterated. MALDI-ToF MS results show that the 2k macrocyclic chains are depleted from the surface after a film of an isotopic macrocylic/linear blend (h-CPS2K/ d-LPS2K) is annealed at 125°C for 12hrs. The surface concentration of CPS is less than 1wt%, while the surface concentration of the hydrogenous component in an analogous h-LPS2K/ d-LPS2K film is 20wt% after annealing. The isotopic effect is not significant for the 2k blends and the architecture effect determines the surface segregation. ToF-SIMS and NR results corroborate this view.

4:42PM L44.00010 Structure Formation and Transition Mechanism in Two-Dimensional Molecular Chiral Phases[1] , YE-LIANG WANG, BING YANG, NAN JIANG, HUAN-YAO CUN, SHI-XUAN DU, Institute of Physics, Chinese Academy of Sciences, Beijing100190, China, YUE WANG, Jilin University, Changchun 130023, China, KARL-HEINZ ENRST, Empa, CH-8600 Dubendorf, Switzerland, HONG-JUN GAO, Institute of Physics, Chinese Academy of Sciences, Beijing100190, China — The self-assemble behavior of prochiral species, QA16C molecules, on a Au(111) surface and the induced chirality by 2D confinement on solid surfaces as well as its chiral transferring process will be presented in this presentation. Initial stages of a chiral phase transition in the monolayer of QA16C molecules on the Au(111) surface were investigated by scanning tunneling microscopy (STM) at submolecular resolution. The prochiral molecules form a homochiral lamella phase at low coverages upon adsorption. A transition to a racemate lattice is observed with increasing coverage. Enantiomers of a homochiral lamella line become specifically substituted by opposite enantiomers such that a heterochiral structure evolves. To explain this phenomenon, we propose a "chiral replacement" model: enantiomers replace QA molecules in enantiopure phase, leading to racemic one. Our findings are significant for the understanding and control of chiral phase transitions in related molecular systems like liquid crystals.

4:54PM L44.00011 Formation and Collapse of Biodegradable Polymer Monolayers at the Air-Water Interface , HAE-WOONG PARK, KIMBERLY OHN, YOU-YEON WON, Purdue University — Poly(lactide-*ran*-glycolide) (PLGA) is widely used as an excipient in formulations of aerosol drugs. It has recently been reported that the surface pressure-area isotherm of PLGA at the air-water interface shows a plateau at intermediate compression levels and a sharp rise in pressure upon further compression. In order to investigate the molecular origin of this behavior, we have conducted an extensive set of surface pressure and AFM imaging measurements with PLGA materials having a range of different molecular weights. The results suggest that (1) the plateau occurs due to the formation (and collapse) of a continuous water-free monolayer of the polymer under continuous compression, and (2) the monolayer becomes significantly resistant to compression at high compression because at that condition the collapsed domains become large enough to become glassy. We will also demonstrate that this property of PLGA allows the polymer to be used as an anchoring block to form a smooth biodegradable monolayer of block copolymers at the air-water interface.

5:06PM L44.00012 8CB-Langmuir Layer at air/water interface: Line Tension vs. Dipolar Repulsion , PRITAM MANDAL, Department of Physics, Kent State University, ANDREW BERNOFF, Dept. of Mathematics, Harvey Mudd College, Claremont, CA 91711, ADIN MANN, Dept.of Chemical Engineering, Case Western Reserve University, Cleveland, OH 44106, JAMES ALEXANDER, Dept. of Mathematics, Case Western Reserve University, Cleveland, OH 44106, ELIZABETH MANN, Department of Physics, Kent State University, ANDREW BERNOFF COLLABORATION, ADIN MANN AND JAMES ALEXANDER COLLABORATION — Langmuir ¯lms of 8CB, a smectic liquid crystal at room temperature, exhibits coexistence of phases with di®erent thicknesses. With decompression of a 8CB-liquid-monolayer gaseous holes appear in liquid monolayer. Molecular interactions controlling the phase separation include short-range van der Waals attraction and long range dipolar repulsion. At small distances where attraction dominates gaseous domains return to energy-minimizing circular shapes. But with size of the holes increasing beyond a critical value, dipolar repulsion becomes strong enough to deform the domains; forming even labyrinth patterns. We use Brewster angle microscopy to study the ¯lm. Our objective is to obtain a critical diameter of the domains beyond which they are non-circular. Experimental value will be compared with that from theory.

5:18PM L44.00013 Origins of the Failure of Classical Nucleation Theory for Nanocellular Polymer Foams[1] , RUSSELL THOMPSON, YEONGYOON KIM, University of Waterloo — The behavior of nanocellular polymer foams, in which nanometer-sized bubbles of fluid are dispersed in a polymer matrix, is dominated by its internal surfaces. In particular, nucleation of a nanocellular foam can involve fundamentally different physics from microcellular or regular foams due to properties of the surfaces. Nucleation rates for nano-bubbles in polymer have been calculated using both classical nucleation theory and self-consistent field theory. An identical model is used for both calculations showing that classical nucleation theory predictions are off by many orders of magnitude. The cause of the failure of classical nucleation theory can be traced primarily to its representation of a bubble surface as an infinite planar interface. For nanoscopic bubbles, the curvature of the bubble surface is comparable to the size of the polymer molecules. Polymers on the outside of a curved bubble surface can explore more conformations than can polymers next to a flat interface. This results in a lower free energy for the curved interface system with respect to a flat interface system, which gives a significantly smaller barrier energy to nucleation and thus a much higher nucleation rate.

Tuesday, March 22, 2011 2:30PM - 5:30PM –

Session L45 DAMOP: Strongly Correlated Physics with Atoms and Molecules A310

2:30PM L45.00001 Quantum phase transitions in a polarized gas of dipolar molecules forming flexible chain[1] , BARBARA CAPOGROSSO-SANSONE, ITAMP, Harvard-Smithsonian center for Astrophysics, Cambridge, MA, 02138, ANATOLY KUKLOV, Department of Engineering Science and Physics, CSI, CUNY, Staten Island, NY 10314, USA — We numerically demonstrate the formation of quantum flexible chains in a gas of polar molecules confined into a stack of N 1d or 2d optical lattice layers, and with dipole moment aligned perpendicularly to the layers. Molecules interact via dipole-dipole interaction. Ab initio simulations of a single chain pinned at one end reveal quantum roughening transition. Multi-chain ensemble is studied in the J-current model approximation and chain superfluidity (CSF) is found. Increasing density of the chains leads to quantum phase transition from CSF to N-layered molecular superfluid (N-SF). We discuss the nature of this transition and its dependence on density, and the conditions for experimental realization and detection of the chain soup.

[1]We acknowledge support by NSF, grant PHY0653135, and by ITAMP.

2:42PM L45.00002 The Hyperfine Molecular Hubbard Hamiltonian[1] , LINCOLN D. CARR, MICHAEL L. WALL, Colorado School of Mines — An ultracold gas of heteronuclear alkali-metal dimer molecules with hyperfine structure loaded into a one-dimensional optical lattice is investigated. The hyperfine molecular Hubbard Hamiltonian (HMHH), an effective low-energy lattice Hamiltonian, is derived from first principles [1]. The large permanent electric dipole moment of these molecules gives rise to long-range dipole-dipole forces in a dc electric field and allows for transitions between rotational states in an ac microwave field. Additionally, a strong magnetic field can be used to control the hyperfine degrees of freedom independently of the rotational degrees of freedom. By tuning the angle between the dc electric and magnetic fields and the strength of the ac field, it is possible to control the number of internal states involved in the dynamics as well as the degree of correlation between the spatial and internal degrees of freedom. The HMHH's unique features have direct experimental consequences such as quantum dephasing, tunable complexity, and the dependence of the phase diagram on the molecular state.

2:54PM L45.00003 The Prediction of a Gapless Topological "Haldane Liquid" Phase in a One-Dimensional Cold Polar Molecular Lattice[1] , JASON KESTNER, BIN WANG, JAY SAU, SANKAR DAS SARMA, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, MD — We show that ultracold two-component fermionic dipolar gases in an optical lattice with strong two-body on-site loss can be used to realize a tunable effective spin-one model. Fermion number conservation provides an unusual constraint that $\sum_i \left(S_i^z\right)^2$ is conserved, leading to a novel topological liquid phase in one dimension which can be thought of as the gapless analog of the Haldane gapped phase of a spin- one Heisenberg chain. The properties of this phase are calculated numerically via the infinite time-evolving block decimation method and analytically via a mapping to a one-mode Luttinger liquid with hidden spin information.

3:06PM L45.00004 Density wave patterns for fermionic dipolar molecules on a square optical lattice: mean field theory analysis , KARLIS MIKELSONS, JIM FREERICKS, Georgetown University — We model a system of ultra cold fermionic dipolar molecules on a two dimensional square lattice. Assuming that the molecules are in their nondegenerate hyperfine ground state, and that the dipole moment is polarized perpendicular to the planes, we approximate these molecules as spinless fermions with long range repulsive dipolar interactions. We use mean field theory to obtain the phase diagram as a function of the filling, the strength of interaction and the temperature. We find a number of ordered density wave phases in the system, as well as phase separation between these phases.

3:18PM L45.00005 Quantum Phases of Atom-Molecule Mixtures of Fermionic Atoms , NICOLAS LOPEZ, UCR — Nicolas Lopez (University of California, Riverside, USA) Chi-Yong Lin (National Dong Hwa University, Taiwan) Shan-Wen Tsai (University of California, Riverside, USA) Cold atom experiments have realized a variety of multicomponent quantum mixtures, including Bose-Fermi atomic mixtures. Mixtures of fermionic atoms and diatomic molecules, which are boson, have also been obtained by tuning of the interactions with external fields [1]. We study many-body correlations in such a system where the molecules are weakly bound and therefore pairs of fermionic atoms easily convert into and dissociate from the bound molecule state and this exchange mediates a long-range interaction between the fermions. We consider a simple many-body Hamiltonian that includes the destruction of fermionic atom pairs to form single bosonic molecules and vice versa [2]. We employ a functional renomalization-group approach and calculate the renormalized frequency-dependent interaction vertices and fermion self-energies. We find an instability from the disordered quantum liquid phase to a BCS phase and calculate the energy scale for the transition. The unusual frequency-dependence of this mediated interaction leads to strong renormalization of the self-energy, and also affects the couplings in the BCS channel. [1] M. Greiner, C. A. Regal, J. T. Stewart, and D. S. Jin, Phys. Rev. Lett. **94**, 110401 (2005) [2] E. Timmermans, K. Furuya, P. W. Milonni, and A. K. Kerman, Phys. Lett. A **285**, 228 (2001)

3:30PM L45.00006 Stability and Properties of the Polaron Condensate in a Strongly Interacting Boson-Fermion Mixture , ZENG-QIANG YU, SHIZHONG ZHANG, HUI ZHAI, Institute for Advanced Study, Tsinghua University, China — In this work we study dilute bosons embedded in a single component Fermi sea across a boson-fermion wide Feshbach resonance using a single channel model. The ground state is a condensation of bosonic polarons, and its stability requires that the interaction strength between bosons exceeds a critical value, which is a universal number at boson-fermion resonance and exhibits a maximum in unitary regime. We calculate the condensate fraction and sound velocity across resonance. The transition from polaron condensate to molecular Fermi gas is also discussed.

3:42PM L45.00007 Colliding clouds of strongly interacting fermions and out-of-phase spin modes[1] , EDWARD TAYLOR, WILLIAM SCHNEIDER, SHIZHONG ZHANG, MOHIT RANDERIA, The Ohio State University — Motivated by recent experiments at MIT, we consider the problem of what happens when two Fermi clouds prepared in different hyperfine states collide with each other at low velocities close to a Feshbach scattering resonance. Upon coming into contact with each other, we show that the two clouds evolve preferentially into a metastable upper branch (with amplitude given by the coherent quasiparticle residue Z) where interactions are repulsive, and not the ground state lower branch. As a result, even though the underlying interaction between the fermions is attractive, for sufficiently strong interactions in the unitary region, the clouds will "bounce" off each other. Using Boltzmann, sum rule and hydrodynamic approaches, we make predictions for the frequency of the bounce mode on the BEC side of resonance, including unitarity, where the scattering length is positive.

3:54PM L45.00008 Ferromagnetic ordering in two-component Fermi gas: four particle problem , SHENGQUAN ZHOU, DAVID CEPERLEY, University of Illinois at Urbana-Champaign, SHIWEI ZHANG, College of William and Mary — To interpret the experiment of Jo et al. on implementing the Stoner model of itinerant ferromagnetism, we investigate the energy spectrum of a system of four interacting spin-half fermions using exact diagonalization on a finite grid. The formation of molecular bound states and the ferromagnetic transition of the excited scattering states are examined systematically as a function of the interaction coupling constant. If the interaction is modeled by an effective positive scattering length, the transition density to ferromagnetism changes significantly.

4:06PM L45.00009 Atom-dimer and dimer-dimer scattering in fermionic mixtures near a narrow Feshbach resonance , JESPER LEVINSEN, University of Cambridge, DMITRY PETROV, LPTMS, Universite Paris-Sud XI, France — We develop a diagrammatic approach for solving few-body problems in heteronuclear fermionic mixtures near a narrow interspecies Feshbach resonance. We calculate s-, p-, and d-wave phaseshifts for the scattering of an atom by a weakly-bound dimer. The fermionic statistics of atoms and the composite nature of the dimer lead to a strong angular momentum dependence of the atom-dimer interaction, which manifests itself in a peculiar interference of the scattered s- and p-waves. This effect strengthens with the mass ratio and is remarkably pronounced in 40K-(40K-6Li) atom-dimer collisions. We discuss the collisional relaxation of the dimers to deeply bound states and evaluate the corresponding rate constant as a function of the detuning and collision energy. Finally, we calculate the scattering length for two dimers formed near a narrow interspecies resonance.

4:18PM L45.00010 Phases of the attractive Hubbard model in a trap , ELIAS ASSMANN, TU Graz, GEORGE BATROUNI, Institut Non-Lineaire de Nice, SIMONE CHIESA, UT knoxville, HANS GERD EVERTZ, TU graz, RICHARD SCALETTAR, UC Davis — We present a quantum Monte Carlo study of the fermion attractive Hubbard model in a quadratic trap. A rather dramatic failure of the local density approximation occurs in the half-filled region where coupling to nearby superfluid domains induces a strong suppression of charge fluctuations. By monitoring the behavior of the equal-time pairing correlations, we show the existence of a low temperature phase consistent with quasi-long-range order.

4:30PM L45.00011 Thermodynamics of the 3D Hubbard model on approach to the Neel transition , LODE POLLET, ETH Zurich, SEBASTIAN FUCHS, University of Goettingen, EMANUEL GULL, Columbia University, EVGENY BUROVKSI, Lancaster University, EVGENY KOZIK, ETH Zurich, THOMAS PRUSCHKE, University of Goettingen, MATTHIAS TROYER, ETH Zurich — We study the thermodynamic properties of the 3D Hubbard model for temperatures down to the Néel temperature using cluster dynamical mean-field theory. In particular we calculate the energy, entropy, density, double occupancy and nearest-neighbor spin correlations as a function of chemical potential, temperature and repulsion strength. To make contact with cold-gas experiments, we also compute properties of the system subject to an external trap in the local density approximation. We find that an entropy per particle $S/N \approx 0.65(6)$ at $U/t = 8$ is sufficient to achieve a Néel state in the center of the trap, substantially higher than the entropy required in a homogeneous system. Precursors to antiferromagnetism can clearly be observed in nearest-neighbor spin correlators.

4:42PM L45.00012 Superconductivity in strongly repulsive fermions: the role of kinetic-energy frustration[1] , LEONID ISAEV, GERARDO ORTIZ, Indiana University Bloomington, CRISTIAN BATISTA, T-4, LANL — We discuss a physical mechanism of a non-BCS nature which can stabilize a superconducting state in a *strongly repulsive* electronic system. By considering the 2D Hubbard model with spatially modulated electron hoppings, we demonstrate how kinetic-energy frustration can lead to robust d-wave superconductivity at *arbitrarily* large on-site repulsion. This phenomenon should be observable in experiments using fermionic atoms, e.g. ^{40}K, in specially prepared optical lattices.

[1]PRL 105, 187002 (2010)

4:54PM L45.00013 Non-perturbative predictions for cold atom Bose gases with tunable interactions , BOGDAN MIHAILA, Los Alamos National Laboratory, FRED COOPER, Santa Fe Institute, CHIH-CHUN CHIEN, Los Alamos National Laboratory, JOHN F. DAWSON, University of New Hampshire, EDDY TIMMERMANS, Los Alamos National Laboratory — We discuss a theoretical description for dilute Bose gases as a loop expansion in terms of composite-field propagators by rewriting the Lagrangian in terms of auxiliary fields related to the normal and anomalous densities. We demonstrate that already in leading order this non-perturbative approach describes a large interval of coupling-constant values, satisfies Goldstone's theorem, yields a Bose-Einstein transition that is second-order, and is consistent with the critical temperature predicted in the weak-coupling limit by the next-to-leading order large-N expansion.

5:06PM L45.00014 Density functional theory for fermionic atom gases , MATTHIAS TROYER, PING NANG MA, SEBASTIANO PILATI, ETH Zurich, XI DAI, Chinese Academy of Sciences — We will show how Kohn-Sham density-functional theory (DFT), which forms the basis of most electronic structure calculations in material science, can be applied to ultracold atomic gases in optical lattices. We present the derivation of an exchange correlation functional for atomic gases and show first applications within a local spin density approximation. In particular we will show that the local density approximation in DFT is much more accurate than what is commonly referred to as "local density approximation" in the atomic gases community. As an outlook we will discuss how the development of DFT for ultracold atomic gases can form a strong link between materials science and atomic physics.

5:18PM L45.00015 Using off-diagonal confinement as a cooling method[1] , VALERY ROUSSEAU, Louisiana State University, KALANI HETTIARACHCHILAGE, JUANA MORENO, MARK JARRELL, DAN SHEEHY — We show that the recently proposed "off-diagonal confining" (ODC) method (Phys. Rev. Lett. 104, 167201 (2010)) can lead to temperatures that are smaller than with the conventional "diagonal confining" (DC) method, depending on the control parameters of the system. We determine these parameters using exact diagonalizations for the hard-core case, then we extend our results to the soft-core case by performing quantum Monte Carlo simulations for both DC and ODC systems at fixed temperatures, and analysing the corresponding entropies.

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P1 DCMP: Magnetism and Localization in f Electron Systems Ballroom A1

8:00AM P1.00001 Ce115's and beyond[1] , J. D. THOMPSON, Los Alamos National Laboratory — Recent studies of members of the Ce115 ($CeMIn_5$ (M=Co, Rh)) family of heavy-fermion materials have allowed a new perspective on the relationship between magnetism and unconventional superconductivity in strongly correlated electron systems. The antiferromagnet $CeRhIn_5$ under pressure, superconducting $CeCoIn_5$in a magnetic field, and Cd-doped $CeCoIn_{5-x}Cd_x$ reveal a phase of long-range antiferromagnetic order that coexists microscopically with bulk, nodal superconductivity. Though the detailed relationship between these orders differs in each, evidence suggests that the order parameters are coupled irrespective of these differences and that similar conclusions may hold in structurally related $CePt_2In_7$ and the recently discovered 5f-electron compound $PuCoIn_5$. Characteristics of magnetism and superconductivity in theses 4f- and 5f-electron systems bear similarities to those in cuprate and iron-pnictide superconductors.

[1]In collaboration with E. D. Bauer, A. Bianchi, Z. Fisk, M. Kenzelmann, H. O. Lee, R. Movshovich, M. Nicklas, T. Park, F. Ronning, V. A. Sidorov and O. Stockert. Work at Los Alamos was performed under the auspices of the US DOE, OBES.

8:36AM P1.00002 How spins become pairs: Composite pairing and magnetism in the 115 heavy fermion superconductors , REBECCA FLINT, Massachusetts Institute of Technology — The highest temperature heavy fermion superconductors are found in the 115 family: $CeMIn_5$ (M=Co,Ir,Rh) and $PuMGa_5$ (M=Co,Rh) [1], where the heavy quasiparticles are only partially formed by the time they pair. The internal structure of the pair is thus just as important as the forces holding it together. We show that the heavy fermion condensate necessarily contains two d-wave components condensed in tandem: pairs of heavy quasiparticles on neighboring sites and composite pairs consisting of two electrons bound to a single local moment. These two components draw upon the antiferromagnetic and two-channel Kondo interactions, respectively, to cooperatively enhance the superconducting transition temperature, as we demonstrate within a symplectic-N solution [2,3] of the two-channel Kondo-Heisenberg model [4]. Additionally, the tandem condensate is electrostatically active, which we predict will result in a superconducting shift in the electronic quadrupolar frequency, as measured in Mossbauer spectroscopy.

9:12AM P1.00003 Imaging the "Hidden Order" Transition in URu_2Si_2 , ANDREW SCHMIDT, University of California, Berkeley — In URu_2Si_2, bulk measurements indicating the formation of heavy bands begin at temperatures around 55 K but are interrupted by an unidentified electronic phase transition, the "hidden order," at $T_o = 17.5$ K. Heavy bands in a Kondo lattice are expected to form due to strong hybridization between electrons localized in real space on magnetic ions and those delocalized in momentum space. Why the "hidden order" appears has been an outstanding question in heavy fermion physics. We use spectroscopic imaging scanning tunneling microscopy (SI-STM) to image the electronic structure of URu_2Si_2 though T_o. Above T_o we find the Fano spectra expected for Kondo screening of a magnetic lattice, while below T_o a partial energy gap opens. Heavy-quasiparticle interference imaging shows that the gap forms due to a light momentum-space band splitting below T_o into two heavy fermion bands. Our observations of the "hidden order" transition are thus consistent with a sudden alteration in both the hybridization at each U atom and the associated heavy bands.

9:48AM P1.00004 Scanning Tunneling Microscopy and Spectroscopy of the Heavy Fermion Compounds URu_2Si_2 and $CeCoIn_5$[1] , PEGOR AYNAJIAN, Princeton University — Heavy electronic states originating from the f atomic orbitals underlie a rich variety of quantum phases of matter. We use atomic scale imaging and spectroscopy with the scanning tunneling microscope (STM) to examine the novel electronic states that emerge from the uranium f states in URu_2Si_2 [1]. We find that as the temperature is lowered, partial screening of the f electrons' spins gives rise to a spatially modulated Kondo-Fano resonance that is maximal between the surface U atoms. At T=17.5 K, URu_2Si_2 is known to undergo a 2^{nd} order phase transition from the Kondo lattice state into a phase with a hidden order parameter. From tunneling spectroscopy, we identify a spatially modulated, bias-asymmetric energy gap with a mean-field temperature dependence that develops in the hidden order state. Spectroscopic imaging further reveals a spatial correlation between the hidden order gap and the Kondo resonance, suggesting that the two phenomena involve the same electronic states. We further study the behavior of the Kondo lattice in a model heavy fermion compound $CeCoIn_5$ as a function of temperature and establish a direct comparison between the two heavy fermion compounds.

10:24AM P1.00005 "Hidden order," heavy electron ferromagnetism, and non-Fermi liquid behavior in the pseudoternary system $URu_{2-x}Re_xSi_2$[1] , M. BRIAN MAPLE, Univeristy of California, San Diego — The identity of the ordered phase that occurs at temperatures below $T_o = 17$ K in the heavy fermion compound URu_2Si_2 has eluded researchers for two and a half decades. Features in various physical properties associated with this so-called "hidden order" (HO) phase are reminiscent of a charge or spin density wave that forms a gap over about 40% of the Fermi surface below T_o, while the remainder of the Fermi surface is gapped by the superconductivity below $T_c = 1.5$ K. In order to attain a better understanding of these phenomena, the physical properties of URu_2Si_2 have been studied as a function of applied pressure, chemical substitution, and magnetic field. Whereas the application of pressure suppresses the superconductivity and induces a phase transition from the HO phase to an antiferromagnetic phase, the substitution of Re for Ru results in the suppression of the superconductivity and the HO transition, the nearby emergence of ferromagnetic (FM) order, and unique critical behavior associated with the FM phase. Magnetization measurements on the $URu_{2-x}Re_xSi_2$ pseudoternary system as a function of x reveal the onset of ferromagnetism at a concentration $x_{cr} \approx 0.15$, which apparently represents a FM quantum critical point. Non-Fermi liquid (NFL) behavior in the physical properties such as the electrical resistivity and specific heat at low temperatures is found to extend deep into the FM region of the T - x phase diagram. Experiments conducted on $URu_{2-x}Re_xSi_2$ single crystals to investigate the superconducting, HO, and FM phases, characterize the NFL behavior, and establish the T - x phase diagram are described. The experimental results are compared to theoretical models for ferromagnetism in a Kondo lattice. Research performed in collaboration with N. P. Butch, J. R. Jeffries, B. T. Yukich, and D. A. Zocco

Wednesday, March 23, 2011 8:00AM - 11:00AM –
Session P2 DCMP: The Kondo Ground State in Graphene Ballroom A2

8:00AM P2.00001 Topological Kondo Ground State in Graphene[1] , HARI C. MANOHARAN, Stanford University — Dirac electrons in graphene comprise two-component wavefunctions and quantum symmetries intertwining pseudospin, chirality, and Berry's phase, all ultimately stemming from a node or topological degeneracy in the spectrum known as the Dirac point. Graphene represents one prototype example of a larger class of nodal metals in which a relativistic spectrum causes the density of states to vanish linearly. Based on the unique electronic structure of such systems, a large body of theoretical work has highlighted the propensity for Dirac electrons to condense in strongly correlated ground states when additionally coupled to the real spin degree of freedom. We report the observation of one of these elusive ground states, realized in graphene via unconventional Kondo screening of individual atomic spins by massless Dirac fermions. Low-temperature scanning tunneling microscopy reveals the emergence of a new energy scale and a striking bimodal Kondo resonance localized around magnetic atoms placed on a clean graphene monolayer. Quasiparticle interference maps and concomitant spectroscopy in a high magnetic field demonstrate the spin origin of the associated ground states, and their direct link to local conservation or breaking of effective time-reversal symmetry in the underlying Dirac Hamiltonian. We find these novel spin states to be topologically controlled by Berry phase interference; in the most exotic manifestation, we show experimental evidence for two electron flavors—decoupled in momentum space by a π Berry phase shift cancellation—participating in a chiral two-channel Kondo effect. We link these results to a new platform we have developed for the study of topological phases, artificial graphene assembled by atomic manipulation.

[1]This work performed in collaboration with L. S. Mattos, C. R. Moon, M. W. Sprinkle, C. Berger, K. Sengupta, A. V. Balatsky, W. A. de Heer, K. K. Gomes, W. Ko, W. Mar. We acknowledge support from DOE and NSF.

8:36AM P2.00002 Orbitally controlled Kondo effect in graphene[1] , TIM WEHLING, University of Hamburg — Graphene differs from usual metals or semiconductors in being a truly two-dimensional material with the charge carriers resembling massless Dirac fermions and the chemical potential being highly tunable by gate voltages. Recently, scanning tunneling spectroscopy experiments opened the exciting possibility to address the interaction of graphene with magnetic adatoms and to investigate the Kondo effect in a material that is simple, of immediate technological importance and offers unprecedented high tunability. Here, we develop a realistic description of the interaction of magnetic adatoms with graphene and explain the role of orbital symmetries: General symmetry arguments show that the Kondo effect in graphene is controlled not only by the spin but also by the orbital degree of freedom and spin-orbit coupling. For the example of Co adatoms, commonly used in experiments, we identify possible scenarios for the Kondo effect based on ab initio calculations. For a Co atom absorbed on top of a carbon atom, the Kondo effect is quenched by spin-orbit coupling below an energy scale of 15K. For Co with spin S=1/2 located in the center of a hexagon, a crossover from SU(4) Kondo physics at higher energies to an SU(2) Kondo effect on the scale of the Co spin-orbit coupling strength is encountered. The interplay of the orbital adatom physics and the peculiar band structure of graphene is directly accessible in Fourier transform tunneling spectroscopy or in the gate-voltage dependence of the Kondo temperature which is predicted to display a very strong, characteristic particle-hole asymmetry. The particular high symmetry situation provided by adatoms on graphene can pave the way for a deeper understanding of Kondo screening in general nanomagnetic structures.

[1]Support from SFB 668 and SPP 1459 are acknowledged.

9:12AM P2.00003 Kondo effect and STM spectroscopy of Dirac electrons in graphene[1] , KRISHNENDU SENGUPTA[2], Indian Association for the Cultivation of Science — We show that graphene, whose low-energy quasiparticles display Dirac like behavior, may exhibit a two-channel Kondo effect in the presence of magnetic impurities. We present a large Nanalysis for a generic spin Slocal moment coupled to Dirac electrons in graphene and demonstrate that the corresponding Kondo temperature can be tuned by an experimentally controllable applied gate voltage. We also study the STM spectra of these Dirac electrons in the presence of such impurities and demonstrate that such spectra depend qualitatively on the position of the impurity atom in the graphene matrix. More specifically, for impurity atoms atop the hexagon center, the zero-bias tunneling conductance, as measured by a STM, shows a peak; for those atop a graphene site, it shows a dip. We provide a qualitative theoretical explanation of this phenomenon and show that this unconventional behavior is a consequence of conservation/breaking of pseudospin symmetry of the Dirac quasiparticles by the impurity. We also predict that tuning the Fermi energy to zero by a gate voltage would not lead to qualitative change in the shape of the conductance spectra when the impurity is atop the hexagon center. A similar tuning of the Fermi energy for the impurity atop a site, however, would lead to a change in the tunneling conductance from a dip to a peak via an antiresonance. We discuss some recent experiments on a doped graphene sample that seem to have qualitative agreement with our theory and suggest further experiments to test our predictions.

9:48AM P2.00004 Quantum critical Kondo screening in graphene , MATTHIAS VOJTA, Technische Universitaet Dresden — Magnetic impurities in neutral graphene provide a realization of the pseudogap Kondo model, which displays a quantum phase transition between phases with screened and unscreened impurity moment. In this talk, I discuss the physics of the pseudogap Kondo model with finite chemical potential μ. While carrier doping restores conventional Kondo screening at lowest energies, properties of the quantum critical fixed point turn out to influence the behavior over a large parameter range. Most importantly, the Kondo temperature T_K shows an extreme asymmetry between electron and hole doping. At criticality, depending on the sign of μ, T_K follows either the scaling prediction $T_K \propto |\mu|$ with a universal prefactor, or $T_K \propto |\mu|^x$ with $x \approx 2.6$. This asymmetry between electron and hole doping extends well outside the quantum critical regime and also implies a qualitative difference in the shape of the tunneling spectra for both signs of μ. Finally, the considerations are extended to the two-channel Kondo model where non-Fermi liquid behavior emerges at lowest energies.

10:24AM P2.00005 Gate-Controlled Ionization and Screening of Cobalt Adatoms on a Graphene Surface , VICTOR BRAR, U.C. Berkeley — Graphene impurities provide both a source of mobility-limiting disorder as well as a means to alter the graphene electronic structure in a desirable way. While these effects have thus far been primarily studied with spatially averaged techniques, understanding the microscopic physics of such behaviour requires local-probe exploration of the subnanometre-scale electronic and structural properties of impurities on graphene. In this talk I will describe scanning tunnelling microscopy and spectroscopy measurements made on individual Co atoms deposited onto back-gated graphene devices. We observe features in the tunneling local density of states (LDOS) of the Co adatoms related to both atomic resonances and phonon excitations. We also find that the electronic structure of Co adatoms can be tuned by application of the device gate voltage, and that the Co atoms can be reversibly ionized. Large screening clouds are observed to form around Co adatoms ionized in this way, and we observe that some intrinsic graphene defects also show charging behaviour. Our results provide new insight into charged-impurity scattering in graphene, as well as the possibility of using graphene devices as chemical sensors. The relationship between our measurements and recent transport experiments will also be discussed.

Wednesday, March 23, 2011 8:00AM - 10:24AM –

Session P3 DCMP FIAP DMP: FIAP/DCMP/DMP Prize Session: Pake, Adler, IAP Ballroom A3

8:00AM P3.00001 George E. Pake Prize Talk: Silicon:Germanium's Road to Market; A Sceptic's Guide From Surface Science to WiFi , BERNARD MEYERSON[1], IBM — There is an adage that goes, "Believe none of what you hear and only half of what you see." Though this overstates matters just a bit, it is nonetheless a valuable insight, as much of the success in developing and commercializing silicon;germanium(Si:Ge) technology was derived from the suspension of core scientific "truths" in favor of rigorous examination of their origins. In this talk I will review a series of foundational discoveries regarding the inception of growth for Si:Ge alloys that ultimately led to the pervasive deployment of this technology. Inextricably linked to the success of this work was a diverse team of extraordinarily talented individuals who each contributed remarkable insights at critical junctures, a valuable reminder of the potential of collaborative innovation to produce seminal discontinuities in science and technology. I will trace the evolution of collaborative innovation from this nucleus to a foundational business model by which much of current silicon technology is derived.

[1]Invited Pake Prize presentation

8:36AM P3.00002 David Adler Lectureship Award in the Field of Materials Physics Talk: Novel Nitride and Oxide Electronics[1] , STEPHEN PEARTON, University of Florida — Recent progress in development of GaN-based transistors for gas and bio-sensing applications and amorphous IGZO layers for use thin film transistors (TFTs)on flexible substrates, including paper,will be presented. For the detection of gases such as hydrogen, the gateless GaN transistors are typically coated with a catalyst metal such as Pd or Pt to increase the detection sensitivity at room temperature. Functionalizing the surface with oxides, polymers and nitrides is also useful in enhancing the detection sensitivity for gases and ionic solutions.The use of enzymes or adsorbed antibody layers on the semiconductor surface leads to highly specific detection of a broad range of antigens of interest in the medical and security fields. We give examples of recent work showing sensitive detection of glucose, lactic acid, prostate cancer and breast cancer markers and the integration of the sensors with wireless data transmission systems to achieve robust, portable sensors. The amorphous transparent conducting oxide InZnGaO4 (IGZO) is attracting attention because of its high electron mobility (10-50 cm2.V-1.sec-1), high transparency in the visible region of the spectrum and its ability to be deposited with a wide range of conductivities.This raises the possibility of making low-cost electronics on a very wide range of arbitrary surfaces, including paper and plastics. N-type oxides such as zinc oxide, zinc tin oxide, indium gallium oxide, and indium gallium zinc tin oxide (IGZO) exhibit surprisingly high carrier mobilities even for amorphous films deposited at 300K. This has been explained by the fact that the conduction in these materials is predominantly through non-directional s orbitals which are less affected by disorder than the directional sp3 orbitals which control electron transport in Si. Examples of progress and discussion of remaining obstacles to use of IGZO TFTs will be presented

[1]Work performed in collaboration with Fan Ren.

9:12AM P3.00003 Prize for Industrial Applications of Physics Talk: Low energy spread Ion source for focused ion beam systems-Search for the holy grail , BILL WARD — In this talk I will cover my personal experiences as a serial entrepreneur and founder of a succession of focused ion beam companies (1). Ion Beam Technology, which developed a 200kv (FIB) direct ion implanter (2). Micrion, where the FIB found a market in circuit edit and mask repair, which eventually merged with FEI corporation. and (3). ALIS Corporation which develop the Orion system, the first commercially successful sub-nanometer helium ion microscope, that was ultimately acquired by Carl Zeiss corporation. I will share this adventure beginning with my experiences in the early days of ion beam implantation and e-beam lithography which lead up to the final breakthrough understanding of the mechanisms that govern the successful creation and operation of a single atom ion source.

9:48AM P3.00004 Prize for Industrial Applications of Physics Talk: Start-up Company (Ad)Ventures – the Highs & Lows , NICHOLAS ECONOMOU, PointSpectrum,LLC — Each start-up company is a unique enterprise, with its own strengths, weaknesses, challenges and eventual outcome. However, there are many aspects common to all new technology companies, including the need for: 1. An innovative technology edge. 2. A solid product idea. 3. A team with experienced people in at least some of the key jobs. 4. Adequate initial funding to achieve some significant milestones. 5. Patient investors who can persevere through the inevitable hard times. 6. A liquidity/exit strategy clearly articulated from day one. The case studies of how other companies were started and developed can provide useful insights into what may lie ahead for the founders of a new company. Several examples from my own experience will be discussed. While they are all clearly different, there are common threads running through all of these stories. Some thoughts on what went right or wrong, and what could have been done better will be presented.

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P4 DPOLY: Kinetic Pathways to Assembly of Polymers, Particles and Biomolecules Ballroom A4

8:00AM P4.00001 Equilibration and metastability in block copolymer micelles , TIMOTHY LODGE, University of Minnesota — The strong incompatibility between a solvophobic block and the surrounding medium leads naturally to extremely slow chain exchange kinetics between micelles. The steric barrier between well-solvated coronas similarly inhibits micelle fusion/fission processes. Consequently, equilibration of block copolymer micelles is typically prohibitively slow. As a result, it is possible for one system to adopt quite different micellar shapes and sizes, depending on preparation method. However, by using low volatility solvents such as ionic liquids or paraffinic oils, combined with weakly solvophobic blocks, it is possible to design model systems with accessible critical micelle temperatures. This enables the study of both the mechanisms of chain exchange, by time-resolved small-angle neutron scattering, and the evolution of non-equilibrium structures, by dynamic light scattering. Examples of both approaches will be discussed.

8:36AM P4.00002 Uncovering the Biological Identity at the NanoScale; Fundamantal principles governing interactions between nanoparticles and living organisms , KENNETH DAWSON, University College Dublin — This abstract not available.

9:12AM P4.00003 Nanoparticle formation by block copolymer directed rapid precipitations—Flash NanoPrecipitaiton , ROBERT PRUD'HOMME, Princeton University — With widespread interest in the generic "nano" attention has been focused on strategies of making small particles. High-value applications that drive new process innovation include very hydrophobic pharmaceutical actives, dyes and pigments for ink jet printing, or the dispersal of highly toxic insecticides on carriers. While it is relatively easy to make inorganic nano-particles, for example CdS particles, it is much more challenging to make nanoparticles from low surface energy organic solids. Strategies for forming nano particles vary from supercritical spraying, supercritical freezing, milling, solvent exchange precipitation, and imbibing into polymeric micelles. The solute and process combine to give differences in crystalline/amorphous products, individual particles/agglomerates, and uniformity/polydispersity of sizes. We will give an overview of the techniques and the classes of products that each addresses. We have developed a new technology that has two components: (1) rapid and tailored micromxing in an impinging jet, and (2) novel block copolymer stabilizers. The impinging jet process allows the production of nano-particles by: 1) elimination of mass transfer limitations and compositional gradients within 10 ms as determined by independent measurements with competitive-parallel reactions, 2) production of high supersaturations and solute concentrations so that high production rates can be obtained, and 3) control of particle size by stabilization of the particle using block copolymer self-assembly. The process depends critically on control of three time scales: particle nucleation and growth, block copolymer micellization, and polymer adsorption on the particle to produce steric stabilization. We present data on characterization of the mixing times using competitive reactions, data on polymer micellization kinetics, and results on the successful production of β-carotene and taxol particles with control of the particle size between 40 nm to 600 nm. A range of block copolymers have been used : PS-b_PEO, PBA-b-PAA, and PCL-b-PEO. Homogeneous rapid nucleation and growth produces particle size distributions that are much narrower than those obtained by alternate size-reduction or precipitation routes, and results in a decreased tendency to Ostwalt ripen.

9:48AM P4.00004 ABSTRACT WITHDRAWN –

10:24AM P4.00005 Soft matter self-assembly driven by specific and nonspecific attractions: dynamic pathways and the Ostwald rule of stages[1] , STEPHEN WHITELAM, Lawrence Berkeley National Lab — Ostwald's rule of stages is one of the few rules-of-thumb we possess that suggests the dynamical pathway a material will take when crystallizing. It states that bulk phases intermediate in free energy between the parent phase and the stable solid will emerge before establishment of the stable solid. Although widely applicable, this rule is frequently seen to break down in experiments and computer simulations, showing it to be without theoretical foundation. A first step in going beyond this rule is to understand why it breaks down. Here we test Ostwald's rule of stages in a statistical mechanical model of crystallization. Our model describes particles that are prototypical of a class of materials (such as proteins and patchy nanoparticles) able to form solid phases stabilized by directional attractions, as well as sparse and dense fluidlike phases. We find that the rule holds in certain regimes of parameter space and breaks down in others. Importantly, its breakdown can be anticipated using simple arguments. We show that the qualitative crystallization pathway of the model depends in general on both the thermodynamic landscape prescribed by inter-particle interactions and on the relative rate of particle rotations and translations. This observation emphasizes that any general rule of crystallization must account for both thermodynamic and dynamic factors.

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P5 FEd FPS: Broader Impact: Partnerships and Resources to Achieve Successful Public and K-12 Outreach and Engagement Ballroom C1

8:00AM P5.00001 Science Museum Resources and Partnerships for Public and K-12 Outreach and Engagement , LARRY BELL, Museum of Science, Boston — Science museums engage in a wide range of activities not apparent to exhibit hall visitors. Many of them can support research outreach to public and K-12 teachers and students. In addition to exhibits in science centers, and demonstrations on topics like electricity or cryogenics, science museums offer courses for children and adults, out-of-school programs for students, teacher professional development; some do K-12 curriculum development and some run science magnet schools. In recent years science museums have increased their capacity to communicate with the public about current research. The Museum of Science, for instance, created a Current Science and Technology Center in 2001 dedicated to science in the news and current research developments. Through this Center, the Museum partnered with Harvard University to provide a wide range of public engagement activities as part of Harvard's Nanoscale Science and Engineering Center focused on the Science of Nanoscale Systems and their Device Applications. In the past five years a number of new collaborations among science museums have developed, many in partnership with researchers and research centers. Perhaps the largest or these, the Nanoscale Informal Science Education Network (NISE Net) was launched in 2005 with funding from the National Science Foundation. The NISE Net links informal science education organizations together and to university research centers to raise the capacity of all the participant organizations to increase public awareness, understanding, and engagement with nanoscale science, engineering, and technology. Nearly 300 informal educational organizations in every state nationwide make use of NISE Net's educational materials, professional development, national and regional meetings, and online resources. NISE Net is an open source network with all of its materials freely available to everyone.

8:36AM P5.00002 Professional Society Resources and Partnerships for Public and K-12 Outreach and Engagement[1] , PHILIP W. HAMMER, American Institute of Physics — Outreach and public engagement lower the barriers that inhibit broader public appreciation of and participation in physics, and are important for inspiring the next generation of scientists and science-literate citizens. The APS and many other professional societies have made significant and sustained investments in public engagement because of the importance of these activities - APS, for example, has an entire department dedicated to outreach. In addition, professional societies have responded to members who desire resources for enabling and enhancing their own outreach efforts. A key question is always, "What works?" Professional societies can help provide the answers. In this talk, I will explore the critical interface played by professional societies as a bridge to the public, as a resource to members, and as a broker of partnerships. I will also feature numerous examples of creative and compelling ways to engage the public, including physicscentral.org, LaserFest, NISE Net, Comic Con, SOCKs, citizen science, and many more. A more important question is, "Is it fun?" I will show that the answer is an unqualified, "Yes!"

[1]The author gratefully acknowledges Rebecca Thompson, Head of APS Public Outreach, for her contributions to this work.

9:12AM P5.00003 National Laboratory Resources and Partnerships for Public and K-12 Outreach and Engagement , ADITI RISBUD, Lawrence Berkeley National Laboratory — Nanoscale science and engineering draws upon aspects of chemistry, physics, biology and engineering to address scientific problems in energy, healthcare, security and technology. Scientists in this field often work in a multidisciplinary setting, which suggests a need for educational content unlike that currently offered in single-discipline high school and college science courses. Instructors are faced with the daunting task of accurately describing nanoscience in the context of their discipline, while inspiring students to explore careers in nanoscale science and engineering. The Molecular Foundry, a Department of Energy nanoscience user facility located at Lawrence Berkeley National Laboratory, offers opportunities for high school and college students, along with science and engineering educators interested in learning basic concepts and research developments in nanoscience. Successful partnering with the Nanoscale Informal Science Education Network also provides opportunities for scientists to interact informally with the general public. These interactions convey the role of national laboratories in helping lay audiences understand the breakthroughs, potential issues and societal impact of nanoscience.

9:48AM P5.00004 Marshalling Corporate Resources for Public and K-12 Technical Education Outreach and Engagement , JAMES WYNNE, IBM TJ Watson Research Center — In 1988, the Education Task Force of the Business Roundtable recommended that American corporations invest in pre-college education. Prior to that date, corporate investment was targeted at higher education. IBM and other corporations responded by encouraging their employees and their corporate philanthropic organizations to develop programs aimed at enhancing pre-college education. The IBM TJ Watson Research Center initiated a Local Education Outreach program, active for these past 23 years, that marshals the resources of our science-rich institution to enhance STEM education in our local schools. We have broad and deep partnerships between the Research Center and local school districts, including New York City. We have just completed our 19th consecutive year of Family Science Saturdays, which brings 4th and 5th grade children, along with their parents, to our Research Center for hands-on workshops in topics like States of Matter, Polymer Science, Kitchen Chemistry, and Sound and Light. The workshops are staffed by IBM volunteers, assisted by local high school student "Peer Teachers." Since 1990, the IBM Corporation has joined with a coalition of other companies, professional engineering societies, and government agencies to sponsor the annual Engineers Week (EWeek) campaign of technical education outreach, serving as Corporate Chair in 1992, 2001, and 2008. In recent years, we have annually recruited around 5000 IBM volunteers to reach out to more than 200,000 K-12 students in order to increase their awareness and appreciation of technical careers and encourage them to continue their studies of STEM (science, technology, engineering, and mathematics). The speaker, who helped found the APS Forum on Education (FED) and served as FED Councillor for 8 years, will review these and other programs for Public and K-12 Technical Education Outreach and Engagement.

10:24AM P5.00005 University Research Center Resources and Partnerships for Public and K-12 Outreach and Engagement[1] , GRETA M. ZENNER PETERSEN, University of Wisconsin-Madison — Collaboration and partnerships are essential to successful outreach and engagement in science. Through working together across disciplines and institutions, we can take advantage of a broad range of skills and expertise to strengthen a project and its outcomes. Additionally, building upon outreach and engagement resources developed by others is equally important to efficiently increasing impact and reducing redundancy. Research centers based at universities and other institutions of higher education commonly serve as both partners and resources for those active in education and outreach. This talk will share successful examples of public and K-12 outreach and engagement efforts that partner with a research center and/or use resources developed by a research center. A thorough discussion of strategies and recommendations for fostering such collaborations, as well as a broad survey of partnership models that exist, will help those at all levels of outreach and engagement experience pursue their science education ideas and goals.

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P6 DAMOP: Creating and Probing Exotic Optical Lattices Ballroom C2

8:00AM P6.00001 Quantum Gas Microscope - Simulating the Bose-Hubbard model and beyond[1] , MARKUS GREINER, Harvard University — The Quantum Gas Microscope enables high fidelity detection of single atoms in a Hubbard-regime optical lattice, bringing ultracold atom research to a new, microscopic level. I will report on investigating the Bose-Hubbard model by directly measuring number statistics and correlations across the superfluid - Mott insulator quantum phase transition. I will then give an outlook on how this enables creating novel phases in optical lattices and realizing quantum magnetism.

[1]This work was supported by ARO DARPA, AFOSR MURI, and NSF.

8:36AM P6.00002 Probing Mott insulators with single atom resolution , STEFAN KUHR, MPI Garching — This abstract not available.

9:12AM P6.00003 The Dicke quantum phase transition with a superfluid gas in an optical cavity , KRISTIAN BAUMANN, ETH Zurich — A phase transition describes the sudden change of state in a physical system, such as the transition between fluid and solid. Quantum gases provide the opportunity to establish a direct link between experiment and generic models which capture the underlying physics. A fundamental concept to describe the collective matter-light interaction is the Dicke model which has been predicted to show an intriguing quantum phase transition. We have realized the Dicke quantum phase transition in an open system formed by a Bose-Einstein condensate coupled to an optical cavity, and have observed the emergence of a self-organized supersolid phase. The phase transition is driven by infinitely long-ranged interactions between the condensed atoms, which are induced by two-photon processes involving the cavity mode and a pump field. We have shown that the phase transition is described by the Dicke Hamiltonian, including counter-rotating coupling terms, and that the supersolid phase is associated with a spontaneously broken spatial symmetry. The boundary of the phase transition is mapped out in quantitative agreement with the Dicke model.

9:48AM P6.00004 Strongly Correlated Quantum Gases Trapped in 3D Spin-Dependent Optical Lattices , BRIAN DEMARCO, University of Illinois — Optical lattices have emerged as ideal systems for exploring Hubbard model physics, since the equivalent of material parameters such as the ratio of tunneling to interaction energy are easily and widely tunable. In this talk I will discuss our recent measurements using novel lattice potentials to realize more complex Hubbard models for bosonic ^{87}Rb atoms. In these experiments, we adjust the polarization of the lattice laser beams to realize fully three-dimensional, spin-dependent cubic optical lattices. We demonstrate that atoms can be trapped in combinations of spin states for which superfluid and Mott-insulator phases exist simultaneously in the lattice. We also co-trap states that experience a strong lattice potential and no lattice potential whatsoever. I will discuss recent measurements revealing a mechanism similar to Kapitza resistance that leads to thermal decoupling in this latter combination. The implications for sympathetic cooling and thermometry using species-dependent lattices will be outlined.

10:24AM P6.00005 Excitons and Polaritons for Optical Lattice Ultracold Atoms in Cavity QED[1] , HASHEM ZOUBI, Institute for Theoretical Physics, Innsbruck University, Technikerstrasse 25, A-6020 Innsbruck, Austria — The quantum phase transition from the superfluid to the Mott insulator phase is predicted by the Bose-Hubbard model and realized for optical lattice ultracold atoms. We extend the model to include excited atoms and their coupling to cavity photons. In applying a mean field theory we calculate the phase diagram, where the Mott insulator reappears for deeper optical lattices [1]. In the Mott insulator we consider the system as an artificial crystal similar to molecular crystals with advantages due to the controllability of the system parameters. In such a system electronic excitations are delocalized due to resonance dipole-dipole interactions and in exploiting the lattice symmetry they form collective electronic excitations termed excitons [2]. We show that excitons in low dimensional systems include dark and bright modes, and in free space they can be metastable or superradiant, which deviates from the case of a single atom, the fact that implies the use of resonators [3]. We suggest optical lattice ultracold atoms as new frontiers of matter for cavity QED. In the strong coupling regime excitons and cavity photons are coherently mixed to form new quasiparticles called polaritons [4]. We suggest polariotons as a nondestructive observation tool for the different phases and properties of the system. We present different set-ups that have the potential to realize optical lattice ultracold atoms within a cavity. We emphasize the recent experiment in using tapered nanofibers, which are simultaneously used to trap and optically interface cold atoms through evanescent fields [5]. This system constitutes a hybrid quantum system combining both atomic and solid state devices.

Wednesday, March 23, 2011 8:00AM - 11:00AM –
Session P7 DBP GSNP: System Biology II: The Physics of Morphogenesis Ballroom C3

8:00AM P7.00001 Contractile forces driving embryonic development , MATTHIAS KASCHUBE, Princeton University — Proper development of an organism requires an orchestrated interplay of large sets of components. Recent developments in live fluorescent imaging methods allow the visualization of many key proteins in cells and tissues. Developing quantitative image analysis methods to measure the dynamics of shape changes in individual cells is central for understanding how a tissue gets sculpted, what molecular machineries are driving this process, and what interactions between cells are regulating it. In this talk, I will present recent advances in our understanding of the dynamical processes during morphogenesis, focusing on the example of tissue folding and invagination at the beginning of gastrulation in Drosophila. I show that this process is driven by a contractile multicellular actomyosin meshwork that dynamically forms within a few minutes at the cell surfaces. In individual cells, contraction is pulsed, with phases of contraction interrupted by pauses in which the cell size is maintained, i.e. a ratchet type dynamics that reduces the surface area of cells incrementally. Measuring the dynamics of whole cell shape changes in 2-photon live imaging data reveals that contraction pulses drive cell lengthening and relocation of cell nuclei, two transformations that are essential for successful invagination of tissue. This analysis further shows that over subsequent stages of invagination, during which cells undergo an elaborate sequence of shape changes, the volume of individual cells is a preserved quantity. These results shed new light on the forces and cellular dynamics driving tissue morphogenesis and are a step towards a quantitative understanding of how an organism's shape and internal structure arises in development.

8:36AM P7.00002 From Global Stresses to Local Cell Packing During Development[1] , DAVID LUBENSKY, University of Michigan — To perform their functions, cells in epithelial tissues must often adopt highly regular packings. It is still not fully understood how these ordered arrangements of cells arise from disordered, proliferative epithelia during development. I will use experimental and theoretical studies on an attractive model system, the cone cell mosaic in fish retina, to illustrate some ways that mechanical forces and cell signaling can interact to produce this transformation. Experiments examining the response to surgical lesions suggest that the correct mechanical environment at the tissue scale is essential to induce cone cells to rearrange into a rectangular lattice. Starting from this observation, I will argue that large-scale mechanical stresses naturally couple to and orient cell polarization and that this coupling can lead cells to line up in regular rows, as observed in the fish retina. This model predicts that cells in the rows will adopt characteristic trapezoidal shapes and that fragments of rows will persist even in tissue where the mosaic pattern is disrupted by lesions; these predictions are borne out by an analysis of cell packings at the level of the zonula occludens in wildtype and lesioned retinas.

[1]Supported by NSF grant IOS-0952873

9:12AM P7.00003 Emergence and Dynamics of Polar Order in Developing Epithelia , REZA FARHADIFAR, Harvard University — Planar Cell Polarity (PCP) is a conserved process in many vertebrate and invertebrate tissues, and is fundamental for the coordination of cell behavior and patterning. A well-studied example is the orientational pattern of hairs in the wing of the adult fruit fly Drosophila, which is an important model organism in biology. The Drosophila wing is an epithelium, i.e., a two-dimensional sheet of cells, which grows from a few cells to thousands of cells during the course of development. In the wing epithelium, planar polarity is established by an anisotropic distribution of PCP proteins within cells. The distribution of these proteins in a given cell affects the polarity of neighboring cells, such that at the end of wing development a large-scale PCP orientational order emerges. Here we present a theoretical study of planar polarity in developing epithelia based on a vertex model, which takes into account cell mechanics, cell adhesion, and cell division, combined with experimental results obtained from time-lapse imaging of the wing development. We show that in experiment, polarity order does not develop de novo at the end of wing development, but rather cells are initially polarized at an angle with respect to their final polarity axis. During wing development, the polarity axes of cells reorient towards their final direction. We identify a basic mechanism to generate such a large-scale initial polarization, based on the growth of a small number of cells with an initially random PCP distribution. Finally, we study the effect of shear and oriented cell division on dynamics of PCP order, showing that these two processes can robustly reorient the polarity axes of cells.

9:48AM P7.00004 Simple Physics in Diseases and Embryonic Development of the Eye[1] , ABBAS SHIRINIFARD, Biocomplexity Institute, Indiana University — While molecular-level regulation within cells during embryonic development is highly complex, the physical mechanisms which translate this intracellular information into multicellular physical structure at the tissue level are often surprisingly simple. I will discuss an example where regulation of cell-cell contact energies is primarily responsible for robust and evolvable regular patterns, the organization of the ommatidia and supporting cells into the regular tiling characteristic of the Drosophila eye and another example where adhesion failures in the human retina result in choroidal neovascularization leading to blindness. In both cases, simulations based on materials-science techniques can help us understand the patterning mechanisms and the reasons for their robustness and failures. Such simulations are easy to extend to other developmental phenomena and to development-related diseases like cancer.

[1]EPA grant "The Texas-Indiana Virtual STAR Center" and NIH grants R01 GM76692 and R01 GM077138.

10:24AM P7.00005 Morphogenesis of walled cells , OTGER CAMPAS, Harvard University — Walled cells have the ability to remodel their shape while sustaining an internal turgor pressure that can reach values up to 10 atmospheres. This requires a tight and simultaneous regulation of cell wall assembly and mechanochemistry, but the underlying mechanisms by which this is achieved remain unclear. In this talk I will discuss the interplay between growth and mechanics in shaping a walled cell, in the particularly simple geometry of tip-growing cells, which elongate via the assembly and expansion of cell wall in the apical region of the cell. Using only conservation laws and describing the observed irreversible expansion of the cell wall during growth as the extension of an inhomogeneous viscous fluid shell under the action of turgor pressure, we determine theoretically the radius of the cell and its growth velocity in terms of the turgor pressure and the secretion rate and rheology of the cell wall material. Moreover, we derive simple scaling laws for the geometry of the cell and find that a single dimensionless parameter, which characterizes the relative roles of cell wall assembly and expansion, is sufficient to explain the observed variation in shapes of tip-growing cells. Our work shows that the physics of cell wall expansion tightly constrains cell shape, providing a unified explanation of the characteristic morphologies of tip-growing cells across species that span several kingdoms, even though their underlying molecular mechanisms of cell morphogenesis are very different. More generally, our description provides a general framework to understand cell growth and remodeling in plants (pollen tubes, root hairs, etc.), fungi (hyphal growth and fission and budding yeast) and some bacteria.

Wednesday, March 23, 2011 8:00AM - 10:24AM –

Session P8 FPS FIAP: The Physics, Technology and Future of Robotics Ballroom C4

8:00AM P8.00001 Finding Fun and Fame in Physics with Robots , RANDY DUMSE, University of Northern Iowa — Physicist are often sought outside their immediate field for difficult solutions. Perhaps this is not surprising. However it might be unexpected how great the needs for physicists in the broadly cross discipline fields as robotics truly are. In this talk the author will describe being lured to Hollywood, by the need to uncover one of those principles, to find the deeper physical issues behind Panavision's needs for motion control. Then later describe using robotics as a tool to introduce students to physical concepts. Robots are excellent tools to focus student interest, both in General Ed courses, and graduate level electronics courses. In this vein, the author will try to highlight, "Where's the Physics in Robotics?"

8:36AM P8.00002 Recent Advances in Robotics and Career Opportunities for Physicists[1] , PAUL BOUCHIER, Dallas Personal Robotics Group — Some of the most significant advances in robotic systems over the last year are shown in this talk, which covers both autonomous and partly autonomous robots. A few robotic employers, both in Texas and elsewhere are profiled, with an emphasis on opportunities of interest to physicists.

[1]The presenter is president of the Dallas Personal Robotics Group

9:12AM P8.00003 Physics and Robotic Sensing – the good, the bad, and approaches to making it work , BRIAN HUFF, The University of Texas at Arlington — All of the technological advances that have benefited consumer electronics have direct application to robotics. Technological advances have resulted in the dramatic reduction in size, cost, and weight of computing systems, while simultaneously doubling computational speed every eighteen months. The same manufacturing advancements that have enabled this rapid increase in computational power are now being leveraged to produce small, powerful and cost-effective sensing technologies applicable for use in mobile robotics applications. Despite the increase in computing and sensing resources available to today's robotic systems developers, there are sensing problems typically found in unstructured environments that continue to frustrate the widespread use of robotics and unmanned systems. This talk presents how physics has contributed to the creation of the technologies that are making modern robotics possible. The talk discusses theoretical approaches to robotic sensing that appear to suffer when they are deployed in the real world. Finally the author presents methods being used to make robotic sensing more robust.

9:48AM P8.00004 Robot Competitions Around the World , STEVE RAINWATER, Network Cybernetics Corp. — This abstract not available.

Wednesday, March 23, 2011 8:00AM - 11:00AM –
Session P9 DFD: Liquid Crystals: Smectics, Nano-mixtures D220

8:00AM P9.00001 Achiral structure of B4 phase in a Bent-Core Liquid Crystal[1] , DONG CHEN, MICHAEL-SCOTT HEBERLING, JOSEPH MACLENNAN, MATTHEW GLASER, NOEL CLARK, Liquid Crystal Materials Research Center, University of Colorado at Boulder, HIDEO TAKEZOE, Department of Organic and Polymeric Materials, Tokyo Institute of Technology — Bent-core smectic layers have a tendency to exhibit spontaneous saddle-splay curvature, driven by the intra-layer structural mismatch. In the chiral B4 phase, the tendency for twist in the orientation of neighboring molecules coupled with the saddle-splay curvature lead to the formation of helical nanofilaments with either clockwise or anticlockwise twist. In addition to the helical nanofilament structure, we observe another microscopic structure in P12OPIMB, which is achiral, with no helical twist. This coffee-bean-like microstructure is dominated by saddle-splay curvature, like the dark conglomerate phase, but appears to have three dimensional order. The origin of these structures will be discussed.

[1]This work is supported by NSF MRSEC Grant DMR0820579 and NSF Grant DMR0606528.

8:12AM P9.00002 Two ferroelectric phases in a bent-core liquid crystal , C. ZHANG, N. DIORIO, B.K. SADASHIVA, A. JÁKLI — We report electro-optical, polarization current, dielectric and SAXS studies on novel bent-core materials that contain four ester groups; three in one arm and only one in the other. These materials differ from each other only by the number of carbons (n) in the alkyloxy chain terminating the one ester containing arm: in Ar 35 n=14, while in Ar 39 n=18. The phase sequences of Ar 35 and 39 are very similar to each other. Both have two mesophases, M1 and M2, with M1 in the 115°C-140°C temperature range, and M2 in between about 100°C and 115°C. Polarization current measurements indicate polarization current and optical switching in the M_1 phase with spontaneous polarization and switching time in the Ps$\sim$2.5-3mC/m^2 and τ $\sim$200μs range, respectively. While in Ar 35 the M2 phase cannot be switched, in the AR 39 we could detect polarization switching with a polarization value of about 5-6 mC/m^2 and switching time over a millisecond. Dielectric and X-ray scattering studies were employed to reveal the fine structure of the M_1 and M_2 phases.

8:24AM P9.00003 Surface Induced Reduction of Twisting Power in Liquid Crystal Films , LIDONG PAN, University of Minnesota, CHENG-CHER HUANG — Null transmission ellipsometry was employed to study the temperature evolution of the helical structure in smectic liquid crystal films. Free standing films with thickness ranging from 31 to more than 400 layers were prepared and studied. The experimental results show a reduced twisting power in thin films. A simple model was constructed to explain the results. Surface effect was found to be the reason for this phenomenon. Our findings are consistent with the studies of helically ordered magnetic films.

8:36AM P9.00004 Evolution of the isotropic to smectic-A phase transition in liquid crystal and acetone binary mixtures , KRISHNA SIGDEL, GERMANO IANNACCHIONE, Worcester Polytechnic Institute — The first-order transition from the isotropic (I) to smectic- A(SmA) phase in the liquid crystal 4-cyano-4'-decylbiphenyl (10CB) doped with the polar solvent acetone (ace) has been studied as a function of solvent concentration by high- resolution ac-calorimetry. Heating and cooling scans were performed for miscible 10CB+ace samples having acetone mole fractions from $x_{ace} = 0.05(1$ wt.%) to $0.36(10\%)$ over a wide temperature range from 310 to $327K$. Two distinct first-order phase transition features are observed in the mixture whereas there is only one transition (I-SmA) in the pure 10CB for that particular temperature range. Both calorimetric features reproduce on repeated heating and cooling scans and evolve with increasing x_{ace} with the high temperature feature relatively stable in temperature but reduced in size while the low temperature feature shifts dramatically to lower temperature and exhibits increased dispersion. Polarizing optical microscopy supports the identification of a smectic phase below the high-temperature heat capacity signature indicating that the low-temperature feature represents an injected smectic-smectic phase transition. These effects may be the consequence of screening the intermolecular potential of the liquid crystals by the solvent that stabilizes a weak smectic phase intermediate of the isotropic and pure smectic-A.

8:48AM P9.00005 The Power of Poincaré: Elucidating the Hidden Symmetries in Focal Conic Domains , ELISABETTA A. MATSUMOTO, GARETH P. ALEXANDER, BRYAN GIN-GE CHEN, RANDALL D. KAMIEN, Department of Physics and Astronomy, University of Pennsylvania — Focal conic domains are typically the "smoking gun" by which smectic liquid crystalline phases are identified. The geometry of the equally spaced smectic layers is highly generic but, at the same time, difficult to work with. We develop an approach to the study of focal sets in smectics which exploits a hidden Poincaré symmetry revealed only by viewing the smectic layers as projections from one-higher dimension. We use this perspective to shed light upon the concentric cyclides of Dupin and several classic focal conic textures which exhibit a more widespread level of geometric organization as in Friedel's law of corresponding cones, the networks and trellises expounded by Bouligand, or Apollonian packings.

9:00AM P9.00006 Phase behavior of platelets at different aspect ratios , ANDRES MEJIA, YA-WEN CHANG, Artie McFerrin Department of Chemical Engineering, Texas A&M University, College Station, TX 77843, DAZHI SUN, Department of Mechanical Engineering, Texas A&M University, College Station, TX 77843, AGUSTIN DIAZ, ABRAHAM CLEARFIELD, Department of Chemistry, Texas A&M University, College Station, TX 77843, HUNG-JUE SUN, Department of Mechanical Engineering, Texas A&M University, College Station, TX 77843, ZHENGDONG CHENG, Artie McFerrin Department of Chemical Engineering, Texas A&M University, College Station, TX 77843 — Suspensions of α -ZrP monolayer plates have recently been found to exhibit an isotropic to nematic (I-N) and nematic to smectic (N-S) phase transition. In the past, computer simulations have been developed to study the phase diagrams of platelets. In order to experimentally investigate the phase transitions and rheological behaviors of these particles, it is necessary to be able to manipulate their size, thickness and reduce their size distribution. We demonstrate here the strong dependency of the I-N transition on the aspect ratio (diameter/thickness) via the control of pristine α -ZrP platelets. We confirmed that the I-N transition volume fraction decrease monotonically with the aspect ratio as shown in previous simulations by J.A.C. Veerman and D. Frenkel. Furthermore, we found additional isotropic and gel phases by increasing the polydispersity of platelet sizes.

9:12AM P9.00007 Liquid Crystal-ZnO Nanoparticle Potential Photovoltaics: Role of LC Order and ZnO Particle Size and Concentration[1] , LUZ J. MARTINEZ-MIRANDA, JANELLE BRANCH[2], ROBERT THOMPSON, JEFFERSON W. TAYLOR, LOURDES SALAMANCA-RIBA, University of Maryland — We investigate the role order plays in the transfer of charges in ZnO nanoparticle - 8CB liquid crystal system for photovoltaic applications as well as the role the nominally 5x7nm^2 ZnO nanoparticles play in improving that order. Our results for the 5nm nanoparticles show an improvement in the alignment of the liquid crystal with increasing weight percentage of ZnO nanoparticles, up to a concentration of 30% wt for the 5nm particles accompanied by an increase by three orders of magnitude in the current generated.[3] Our results for the 5 x 7 nm^2 sample show that the current is larger than the current obtained for the 5 nm samples. The photocurrent can be expressed as the conductivity as a function dependent in the order in the sample times the portion of the electric field that is absorbed and transformed into the current.

9:24AM P9.00008 Interaction of a Bi-molecular Liquid Crystal Film With Functionalized Nanoparticles[1] , JEFFERSON W. TAYLOR, LUZ J. MARTINEZ-MIRANDA, University of Maryland, LYNN K. KURIHARA, Naval Research Labs — We investigate the properties of a nominally bi-molecular film of liquid crystal mixed with a magnetic nanoparticle (CoFe) that was functionalized with an organic compound (MHDA or APTS) with the atomic force microscope (AFM). We seek to investigate if the functionalization compound has an effect on the ordering of the liquid crystal in the vicinity of the nanoparticle. Studies in bulk liquid crystals have shown that the functionalization compound influences how the liquid crystal will reorganize.[2] The results of this investigation are compared to the results of work done on phospholipids in close contact with uncovered silica nanoparticles.[3] There seems to be a relation between the way that the two functionalizations behave in the bulk 8CB. The two functionalizations studied behave differently for particles larger than 22 nm, and apparently for the smaller particles.

9:36AM P9.00009 Directed assembly of CdSe/ZnS quantum dots in cholesteric liquid crystal matrix , ANDREA RODARTE, LINDA S. HIRST, SAYANTANI GHOSH, University of California, Merced — Controlled self assembly of quantum dots (QDs) over macroscopic scales is important to realizing the potential for new applications such as photovoltaic devices and sensors. Here, we suspend CdSe/ZnS core/shell QDs in a cholesteric liquid crystal (LC) and investigate the dispersion and collective emission of the QDs when loaded into a Grandjean-Cano wedge cell. We use polarized optical microscopy and scanning photoluminescence microscopy to generate spatial and spectral maps of the QD-liquid crystal samples. We find that the LC forms Grandjean steps approximately 200um in width and the spectral effects of the QD emission correlate to the stripe formation. We also find that the cholesteric LC modulates the spectral emission of the QDs, creating a wavelength gradient dependant on the orientation of the collection polarizer with the director axis of the liquid crystal molecules.

9:48AM P9.00010 ABSTRACT WITHDRAWN –

10:00AM P9.00011 Diffusion-controlled Aggregation of Bucky Balls on Freely Suspended Smectic Liquid Crystal Films , ZOOM NGUYEN, TATYANA MALININA, CHEOL PARK, JOSEPH MACLENNAN, MATTHEW GLASER, NOEL CLARK, University of Colorado-Boulder, LIQUID CRYSTAL MATERIALS RESEARCH CENTER TEAM — Bucky balls (BB) have the tendency to clump together, making it hard to have them suspended in a solvent. We find that in highly viscous bulk 8CB, a smectic liquid crystal at room temperature, the aggregation happens more slowly. As the result, a freely suspended film made from the 8CB-BB mixture contains mostly small BB clumps. The diffusion coefficients of the clumps in thin films are much bigger than in the bulk, however, accelerating the aggregation process. We measure, via video microscopy, the decrease of the clumps' diffusion coefficients over time, indicating that their sizes increase towards a terminal size determined from the rate of diffusion. The terminal-sized clumps still diffuse around and stick to each other when they meet, forming the classic fractal pattern.

10:12AM P9.00012 Investigation of the lyotropic liquid crystal phase of Graphene Oxide solution[1] , YUE SHI, RIZWAN MAHMOOD, DONG CHEN, NOEL CLARK — Graphite Oxide spontaneously exfoliates into single-layer Graphene Oxide flakes in water. As the concentration becomes higher, Graphene Oxide solution shows a phase transition from the isotropic to the lyotropic liquid crystal phase. In the liquid crystal phase, the Graphene Oxide flakes can be ordered spontaneously by flow and shearing forces. We will report the investigation of the liquid crystal phase of the Graphene Oxide solution. In addition, the light scattering studies give dynamic information of the Graphene Oxide solution. Both the translational and rotational diffusion properties are investigated corresponding to different phases formed by Graphene Oxide at different concentrations.

[1]Supported by NSF MRSEC Grant DMR0820579.

10:24AM P9.00013 Defect dynamics in monodomain formation of a lyotropic chromonic liquid crystal under confinement , XUXIA YAO, Georgia Tech, ALEJANDRO REY, McGill University, JUNG PARK, MOHAN SRINIVASARAO, Georgia Tech — Lyotropic chromonic liquid crystals are a relatively new class of liquid crystals. We have studied the process of monodomain formation and the associated defect dynmaics of an anionic dye, Sunset Yellow FCF(SSY), under confinement in a flat capillary. SSY solutions were filled into a flat capillary by capillary action in isotropic phase and subsequently cooled to nematic state. Defect coarsening processes due to confinemnet include growth of small uniform domains, splitting of a center disclination line (+1) into two lines (+1/2), merging of uniform domains, and relaxation of defect curvature after pinch-off. Previously we studied the kinematics of a branch point involving a +1 and two +1/2 intersecting lines. Here we report on the collision of two such branch points and the subsequent emergence of two curved +1/2 lines that eventually coarsen into two paralell lines close to the edge of the capillary. A model that includes bending and tension line elasticity describes the branch point post collision and provides the means to asses viscoleatic moduli.

10:36AM P9.00014 Thermotropic Gold Nanorod Liquid Crystal Phases[1] , PAUL LUCHETTE, PETER PALFFY-MUHORAY, Liquid Crystal Institute - KSU — Large scale, oriented arrays of gold nanorods (Au NR) are of interest for a variety of applications, such as negative index materials and hyperbolic dispersion lenses. We report a method for preparing lyotropic, nematic LC phases of Au NR by combining polymer coated Au NR with a low molecular weight ($<$ 3200) polymers solvent. The solvent system was prepared by reacting hydroxymethyl siloxane and styrene via a hydrosilylation reaction. At appropriate ratios, these mixtures exhibit liquid crystalline phase behavior. Lyotropic LC phases of Au NR were observed for Au NR with aspect ratio above 4, diameter $\sim$15nm, using either linear or cyclic siloxane-styrene polymers as the solvent. Compared with other preparation methods such as lithography or evaporative deposition that produce static films, these self-assembled thermotropic LC phases of Au NR may be re-oriented in response to thermal or electric stimulus.

10:48AM P9.00015 Organic-Inorganic Liquid Crystalline Composites , PETR SHIBAEV, Department of Physics, Fordham University, New York — Design of novel liquid crystalline composites consisting of organic liquid crystals, metal oxides (titanium oxide, zinc oxide, etc.) and "interface" layer covering inorganic materials is presented and discussed. The composites respond to light irradiation by changing orientation of liquid crystalline molecules, resulting in the changes of transmission and reflection properties of cells made of composite materials. The interaction of composite materials with light results from a complex chain of physico-chemical processes inside both the inorganic component and the "interface" layer. The processes that play the major role in the re-orientation of liquid crystalline molecules in the surface layer include: i. light-induced formation of electron-donor pairs inside metal oxides, ii. energy transfer of electron excitations to molecules inside the "interface" layer, iii. breaking of hydrogen bonds and conformational changes of molecules inside the "interface" layer. The experimental study of the processes resulting in re-orientation of liquid crystals by light is accompanied by theoretical calculations of conformational changes inside the "interface" layer and molecular re-orientation on the surface of inorganic materials.

Session P10 DMP: Focus Session: Growth, Structure, Dynamics, and Function of Nanostructured Surfaces and Interfaces – Metals D221

8:00AM P10.00001 Interplay between Quantum Size Effect and Strain Effect on Growth of Nanoscale Metal Thin Film[1] , MIAO LIU, University of Utah, YONG HAN, Iowa State University, FENG LIU, University of Utah — Quantum Size Effect (QSE) has been shown to be a dominant factor in the growth of metal nanofilms on semiconductor substrates in the so-called electronic growth regime. On the other hand, the strain effect is ubiquitous in heteroepitaxial growth of semiconductor and metal thin films. Most time, however, these two important effects have been studied separately focusing on one while neglecting the other. Here, we develop a theoretical framework to investigate the interplay between QSE and strain effect on the stability of metal nanofilms. The QSE and strain effect are shown to be coupled through the concept of "quantum stress". First-principles calculations reveal large quantum oscillations in the surface stress of metal nanofilms as a function of film thickness, which adds extrinsically additional strain-coupled quantum oscillations to surface energy of strained metal nanofilms. Our theory enables a quantitative estimation of the amount of strain in experimental samples from the measured stability patterns, explaining a possible origin for some outstanding discrepancies between the existing theories and experiments.

8:12AM P10.00002 Contrasting growth modes of Ru thin film nano-structures on Si and Pd[1] , XIANGSHI YIN, AO TENG, The University of Tennessee, MUSTAFA ÖZER, Oak Ridge National Laboratory, HANNO WEITERING, The University of Tennessee, PAUL SNIJDERS, Oak Ridge National Laboratory — We have studied Ruthenium thin film growth on both Si (111) and Pd (111) surfaces. The films were deposited at low (LN2) temperature and at room temperature, and subsequently annealed at elevated temperatures, up to 600C. The surface structure, morphology, and chemical composition were investigated by LEED, STM, AES and XPS. Upon deposition at low temperature, nanoclusters are formed on both Si and Pd. Remarkably, the nanoclusters are approximately 3 nm in diameter and exhibit narrow size distributions on both substrates. In the case of Ru on Si, XPS spectra indicate silicide formation at the interface above 300C, but the nanocluster surface morphology survives up to 600C. On the other hand, nanoclusters on Pd smoothen into atomically flat films above 200C. The striking difference in adatom mobilities on these substrates is surprising in light of the very high melting temperature of Ru (2400C).

8:24AM P10.00003 Temperature-dependence of Ni+Al co-deposition on NiAl(110): Atomistic-level modeling of deviations from perfect alloy ordering , YONG HAN, DAPENG JING, BARIS UNAL, P.A. THIEL, J.W. EVANS, Institute for Physical Research and Technology; Departments of Chemistry, MSE, Mathematics, Physics and Astronomy; Ames Lab, ISU, Ames, Iowa 50011 — Stoichiometric co-deposition of Ni and Al on NiAl(110) for high enough temperatures (below the order-disorder transition for NiAl) must produce near-perfect alloy islands and overlayers. However, at 300K, island structure is far from perfectly ordered and depends strongly on the deposition protocol (e.g., simultaneous vs. sequential). Realistic atomistic-level modeling of this non-equilibrium behavior must provide an accurate description of not just alloy thermodynamics (through adatom adsorption and interaction energies), but also of diffusion kinetics (for adatom attachment-detachment at and transport along island edges). This is achieved by multi-site lattice gas modeling with DFT input for adsorption and interaction energies for adatoms both at adsorption sites and at transition states for hopping [T. Duguet, Y. Han et al., Proc. Nat. Acad. Sci. 107 (2010) Special Issue on Surface Chemistry; Y. Han et al., submitted (2010)]. Model analysis by KMC simulation shows a transition from poor alloy order at 300K to almost perfect order at 600K.

8:36AM P10.00004 Electronic origin of kinetic and dynamic processes at atomic steps on vicinal metal substrates[1]

, WENGUANG ZHU, University of Tennessee & Oak Ridge National Laboratory — Single-atomic-layer steps play an important role in the kinetics and dynamics of morphological evolution and structural formation at surfaces. In this talk, we will attempt to elucidate the importance of the electronic nature in determining the bonding of adatoms and the activation barriers for adatom descent at step edges. The insights gained through first-principles case studies have timely and important impacts in understanding the evolution of many nanostructured surfaces and prevention of electrical breakdown in nanodevices. In the first case [1], we establish a clear correlation between the preferred diffusion mechanism and step-edge barrier and the relative degree of electronic shell filling of the adatom and the substrate. We also find an approximate linear relation between the adatom step-edge hopping barrier and the adatom-surface bonding strength with a slope roughly proportional to the number of the nearest neighbors of the adatom in the initial state. These results can serve as simple guiding rules for predicting precise atomic surface morphologies and designing desirable surface nanostructures, such as atom wires [2]. In the second case [3], we discover an optimal surface electromigration inhibitor on the technologically important Cu(111) surface, characterized by energetically favoring and binding strongly at the kink of step edges. Finally, we will briefly discuss how the electronic bonding strengths influence the nucleation and growth behavior of carbon atoms at the step edges of various transition-metal surfaces, a crucial insight in designing optimal kinetic pathways for mass production of quality epitaxial graphene [4].

9:12AM P10.00005 Bilayer islands in heteroepitaxy of transition metals: insights from first principles[1]

, TALAT S. RAHMAN, MARISOL ALCANTARA ORTIGOZA, SERGEY STOLBOV, Department of Physics, University of Central Florida, Orlando, FL32816 — Although not in equilibrium configuration, bilayer islands have been observed in the heteroepitaxy of some transition metals for four decades. Its physical origin, however, was investigated experimentally recently for Ru on Pt(111) [1]. By introducing an energy-gain criterion (upon adlayer formation) and by analyzing the density of electronic states of 1 to 3 Ru adlayers on Pt(111), we show that, even though no bonding stronger than that of atoms in bulk Ru is involved, the energy gain for the formation of the second layer is the largest. We find that the effect of the lattice mismatch is not trivial to elucidate from experiment since the electronic structure of a clean substrate changes in the presence of strain and/or chemical bonding with other species. The lattice mismatch, however, is the key factor for the instability in the formation of a third-layer. We extend the model to explain the well-known case of Co/Cu(111) and to predict other possible bilayer systems.

9:24AM P10.00006 Collective Super-Diffusive Motion of the Pb Wetting Layer on Si(111)

, MICHAEL ALTMAN, K.L. MAN, M.M.T. LOY, Hong Kong University of Science and Technology, M.C. TRINGIDES, Iowa State University — An unusual mass transport behavior has been discovered in the Pb/Si(111) wetting layer. Mass transport is studied by observing non-equilibrium coverage profile evolution with low energy electron microscopy (LEEM). Equilibration of an initial coverage step profile does not exhibit the profile broadening and gradual, $x \sim t^{1/2}$, time-dependent evolution that is expected from classical considerations. Instead, the profile edge is displaced linearly in time, $x \sim t$, much faster than expected for thermally activated hopping and without dispersal. LEEM also reveals a wave-like disturbance in the wetting layer that propagates in the direction opposite the step profile motion. The Pb coverage that is left in the wake of this disturbance can be determined accurately and with high lateral resolution using selected-area LEED due to the Devil's Staircase (DS) phases in this system. The expanding wave converts an initial homogeneous DS phase with coverage $\theta > \theta_c$ to a final phase with $\theta_c = 1.25$ ML, thereby conserving mass across the initial step profile position. This identifies a collective super-diffusive motion of the Pb layer that can extend rapidly over macroscopic distances. Such motion may facilitate the remarkably efficient self-organization of uniform height, quantum size effect-induced Pb islands on Si(111).

9:36AM P10.00007 Crossover from concerted motion to periphery diffusion for Cu clusters on Cu(111): Application of Fine Grid On-Lattice SLKMC[1]

, SYED ISLAMUDDIN SHAH, GIRIDHAR NANDIPATI, University of Central Florida, ALTAF KARIM, Lawrence Berkeley National Laboratory, ABDELKADER KARA, TALAT S. RAHMAN, University of Central Florida — The "fine grid on-Lattice" Self-Learning Kinetic Monte Carlo (SLKMC) technique combines the ideas embedded in the SLKMC [1] method with a new pattern recognition scheme which incorporates both fcc and hcp sites to characterize and store configurations. Application of methods for saddle point searches have revealed several new mechanisms involving multiple atoms which contribute to cluster migration. We present results for the diffusion of 2D Cu islands on Cu(111), using semi-empirical interatomic potentials [2], at three temperatures (300K, 500K and 700K). Long time simulations show a trend in crossover from concerted motion to periphery diffusion for clusters containing more than 14 atoms. The calculated trends in effective energy barriers and diffusion constants are compared with those obtained earlier from the SLKMC Method [1] which allowed only surface fcc site occupancy.

9:48AM P10.00008 Shape transitions in strained islands: kinetics versus energetics[1]

, YUNSIC SHIM, YEVGEN KRYUKOV, JACQUES AMAR, University of Toledo — Recently, it has been argued that the shape transition from compact to ramified islands observed experimentally in submonolayer Cu/Ni(100) growth is not due to kinetics but can be understood in terms of energetic arguments. In order to determine the responsible mechanisms we have carried out temperature-accelerated dynamics (TAD) simulations as well as energetics calculations. Surprisingly, our results indicate that the strain-energy contribution to the dependence of island-energy on shape is relatively weak. In contrast, our TAD simulations indicate that unexpected concerted motions occurring at step edges may be responsible. The energy barriers for these concerted motions are significantly lower than for Cu/Cu(100) and Ni/Ni(100), decrease with increasing island size, and appear to saturate for islands larger than 300 - 400 atoms. These results suggest that the shape transition is of kinetic origin but is strongly mediated by strain.

[1]Supported by NSF-DMR 0907399

10:00AM P10.00009 Temperature-induced crossovers in the static roughness of a one-dimensional interface[1] , ELISABETH AGORITSAS, DPMC-MaNEP - University of Geneva (Switzerland), VIVIEN LECOMTE, Laboratoire de Probabilite et Modeles Aleatoires, University Paris Diderot (France), THIERRY GIAMARCHI, DPMC-MaNEP - University of Geneva (Switzerland) — At finite temperature and in presence of disorder, a one-dimensional elastic interface displays different scaling regimes at small and large lengthscales. Using a replica approach and a Gaussian variational method (GVM), we explore the consequences of a finite interface width ξ on its small-lengthscale geometrical fluctuations. We compute analytically the static roughness $B(r)$ of the interface as a function of the distance r between two points on the interface, in the specific case of short-range elasticity and random-bond disorder. We find that for a finite ξ two temperature regimes exist, and we determine the corresponding different roughness regimes and their crossover lengthscales. In addition, using a directed polymer description, we study via a second GVM procedure and generic scaling arguments, a modified toy model that provides further insight on those results, which apply to experimental interfaces such as e.g. ferromagnetic domain walls in thin films, subjected to a quenched uncorrelated disorder.

10:12AM P10.00010 Mean field approach to fluctuations of surface line defects[1] , DIONISIOS MARGETIS, Department of Mathematics, University of Maryland — Below the roughening transition temperature, the dynamics of crystal surfaces are driven by the motion of line defects (steps) of atomic size. According to the celebrated Burton Cabrera-Frank (BCF) model, the steps move by mass conservation, as adsorbed atoms (adatoms) diffuse on terraces and attach/detach at step edges. The resulting deterministic equations of motion incorporate nonlinear couplings due to entropic and elastic-dipole step-step interactions. In this talk, I will discuss a formal theory for stochastic aspects of step motion by adding noise to the BCF model in 1+1 dimensions. I will define systematically a "mean field" that enables the conversion of the coupled, nonlinear stochastic equations for the distance between neighboring steps (terrace widths) to a single Langevin-type equation for an effective terrace width. In the course of my study, I invoke the Bogoliubov-Born-Green Kirkwood-Yvon (BBGKY) hierarchy for joint terrace-width probability densities and a decorrelation ansatz for terrace widths. By using an example drawn from epitaxial growth (with material deposition from above), I will compare the mean field approach to an exact result from a linearized growth model. [D. Margetis, J. Phys A: Math. Theor. 43, 065003 (2010).]

10:24AM P10.00011 Spacing distribution functions for 1D point island model with irreversible attachment[1] , DIEGO GONZALEZ, THEODORE EINSTEIN, University of Maryland, ALBERTO PIMPINELLI, University of Maryland and Science Attache, French Consulate, Houston — We study the configurational structure of the point island model for epitaxial growth in one dimension. In particular, we calculate the island gap and capture zone distributions. Our model is based on an approximate description of nucleation inside the gaps. Nucleation is described by the joint probability density p_n^{xy} (x,y), which represents the probability density to have nucleation at position x within a gap of size y. Our proposed functional form for p_n^{xy} (x,y) describes excellently the statistical behavior of the system. We compare our analytical model with extensive numerical simulations. Our model retains the most relevant physical properties of the system.

10:36AM P10.00012 Capture zone area distributions for homogeneous nucleation and growth of islands during deposition[1] , JIM EVANS, YONG HAN, Iowa State University, MAOZHI LI, Renmin University — The size distribution of islands formed by homogeneous nucleation and growth during deposition is known to encode information about the nucleation mechanism. The same was recently proposed for the distribution, g(A), of areas, A, of capture zones (CZ) surrounding islands [1], where most atoms landing within a CZ aggregate with the associated island. We have developed a precise theory for g(A) whose evolution is driven by the nucleation of new islands [2]. g(A) has a complicated form controlled by details of the spatial aspects of nucleation. However, it is reasonably approximated by a Generalized Gamma distribution, $g(A) \sim A^{\beta} \exp[-cA^{n}]$. For compact 2D islands, one has n $\sim$ 1.5, and $\beta \sim 3(i+2)/2$ for critical size i. Here, β follows from analysis of the creation of new small capture zones between nearby pairs of islands, and n from analysis of the likelihood that a new CZ overlaps an existing large CZ.

10:48AM P10.00013 Modeling Island-Growth Capture Zone Distributions (CZD) with the Generalized Wigner Distribution (GWD): New Developments in Theory and Experiment[1] , ALBERTO PIMPINELLI[2], T.L. EINSTEIN, DIEGO LUIS GONZÁLEZ, RAJESH SATHIYANARAYANAN[3], AJMI BH. HAMOUDA[4], U. Maryland — Earlier we showed [PRL 99, 226102 (2007)] that the CZD in growth could be well described by $P(s) = as^{\beta}\exp(-bs^2)$, where s is the CZ area divided by its average value. Painstaking simulations by Amar's [PRE 79, 011602 (2009)] and Evans's [PRL 104, 149601 (2010)] groups showed inadequacies in our mean field Fokker-Planck argument relating β to the critical nucleus size. We refine our derivation to retrieve their $\beta \approx i+2$ [PRL 104, 149602 (2010)]. We discuss applications of this formula and methodology to experiments on Ge/Si(001) and on various organics on SiO_2, as well as to kinetic Monte Carlo studies homoepitaxial growth on Cu(100) with codeposited impurities of different sorts. In contrast to theory, there can be significant changes to β with coverage. Some experiments also show temperature dependence.

Session P11 FIAP: Electronic Structure: Theory and Spectra I D222

8:00AM P11.00001 Hybrid functional calculations for defects in TiO_2[1] , CHRIS VAN DE WALLE, Materials Department, University of California, Santa Barbara, JOEL VARLEY, Department of Physics, University of California, Santa Barbara, ANDERSON JANOTTI, Materials Department, University of California, Santa Barbara — Density functional theory (DFT) has proven its value as an immensely powerful tool for assessing structural properties of defects in semiconductors or insulators. Frequently, however, information about electronic structure is required, i.e., the position of defect levels in the band gap. Since DFT in the LDA or GGA severely underestimates the band gap, the position of defect levels is subject to large error bars. Here we show that the use of hybrid functionals allows us to overcome this problem. We illustrate the power of the approach with the example of point defects in TiO_2, a material of high interest for electronics, optoelectronics, and photocatalysis. Unintentional n-type conductivity in TiO_2 has often been attributed to oxygen vacancies (V_O). We find that V_O is indeed a shallow donor [1]. Our calculated formation energies allow us to assess whether vacancy concentrations are consistent with experimental observations of unintentional conductivity.

8:12AM P11.00002 Bandgap properties of amorphous TiO2 (aTiO2) , M. KYLEE UNDERWOOD, West Virginia University, BINAY PRASAI, BIN CAI, DAVID A. DRABOLD, Ohio University, JAMES P. LEWIS, West Virginia University — In photocatalytic and photovoltaic applications, TiO_2 is a convenient material due to its stability, abundance, and functionality. The natural bandgap of TiO_2 is very wide thus limits its usability to the UV region of the solar spectrum. Previous research has indicated that these limitations may be overcome by doping with anionic nonmetal elements such as carbon or nitrogen. However, both experimental and theoretical research suggests that these dopants tend to act more as recombination centers rather than truly enhance the functionality of TiO_2. Although naturally occurring in crystalline form, the initial processing of TiO_2 for the production of thin films and powders results in mostly amorphous materials and further processing locks the material into a particular crystalline or poly-crystalline form. The properties of anatase and rutile crystalline structures of bulk and nanophase TiO_2 have been studied in detail; however, amorphous TiO_2 ($aTiO_2$) lacks a similar depth of study. We show, through ab initio density functional theory calculations, that $aTiO_2$ exhibits a bandgap almost identical to crystalline TiO_2. We will further discuss our results for anionic nonmetal dopants in $aTiO_2$.

8:24AM P11.00003 Evidences for Ti-N anchoring in organic dyes on TiO2 and its influence on photovoltaic performance[1] , YANG JIAO, SHENG MENG, Inst. Physics, Chinese Academy of Sciences, SEEC LAB TEAM — New metal-free organic dyes with a novel donor-pi-acceptor design produce efficiencies exceeding 10% for dye-sensitized solar cells (DSSC) applications since 2010. Based on state-of- the-art electronic structure calculations and real time time- dependent density functional theory (TDDFT) simulations, we present consolidated evidences for novel Ti-N anchoring at the interface for such a broad group of new dyes, inferred from energetics, vibrational recognition, and electronic and optical data. This fact is contrary to what people usually believed and assumed in previous experiments and was largely ignored. We further demonstrate that the presence of interface Ti-N bonds largely benefit the electronic level alignment and photoelectron injection dynamics, greatly contributing to the improved efficiencies of DSSC based on cost-effective, environment-friendly organic dyes.

8:36AM P11.00004 First Principles Study on Ta_2O_5 Polymorphs[1] , YUNING WU, HAI-PING CHENG, Department of Physics, University of Florida, USA, LAN LI, College of Arts and Sciences, Kent State University, USA — Using density functional theory (DFT) with generalized gradient approximations (GGA) and the projector-augmented wave method, we have investigated structure, energetics, elastic tensors and mechanical properties of four crystalline forms of Ta_2O_5 with exact stoichiometry and a model amorphous structure. A virtual crystal potential has also been constructed to address partial oxygen occupancy and compared to models of explicit oxygen vacancies and the oxygen-rich system. Calculations show that mechanical properties of these polymorphs are highly anisotropic. By comparison with experimental data, we find that all crystalline phases and the simulated amorphous phase have Young's modulus higher than the amorphous thin film that is measured experimentally, but the variation among crystalline structures is as high a factor of 2. Electronic properties of three Ta_2O_5 polymorphs have been calculated using a hybrid DFT and Hartree-Fock functional method that improves gap size obtained by GGA. We suggest that further experimental measurements on tantala crystals are needed to understand physical properties of this import material.

8:48AM P11.00005 What is the G^0W^0 band gap of ZnO? , M. STANKOVSKI, G. ANTONIUS, D. WAROQUIERS, A. MIGLIO, H. DIXIT, P. RINKE, H. JIANG, M. GIANTOMASSI, X. GONZE, M. CÔTÉ, G.-M. RIGNANESE — Recently, there has been considerable attention on ZnO as a candidate material for low-cost transparent conducting oxides. Even in its natural wurtzite bulk phase, it is numerically difficult to evaluate G^0W^0 quasiparticle (QP) corrections for ZnO. Therefore we have a wide range of theoretical QP gaps quoted in the literature (from $\sim$1.6 eV to $\sim$3.6 eV to be compared with 3.44 eV experimentally). Typically, many approximations are used *en route*. To find the correct theoretical gap, we have performed calculations of unprecedented accuracy. First, we study the G^0W^0 band gap given different ground-state DFT starting point approximations (LDA and GGA) and the effect of including scalar-relativistic corrections. Second, we present a study of results for norm-conserving pseudopotentials vs. all-electron techniques (both PAW and FP-LAPW). Four different plasmon-pole models are compared with the more accurate contour-deformation approach. Finally, a Hubbard U parameter for the 3d-states of Zn is shown to depend on the exact details of application. This work shows that the band-gap of ZnO is indeed underestimated in the G^0W^0 approach.

9:00AM P11.00006 Energies of formation and electronic band structure of Zn-IV-N_2 semiconductors , ATCHARA PUNYA, WALTER R.L. LAMBRECHT, Case Western Reserve University — The II-IV-N_2 semiconductors are expected to have properties closely related to those of the III-N semiconductors. We focus on Zn-IV-N_2 semiconductors with the group IV-element Si, Ge and Sn. The formation energies of the compounds in this series were calculated by the full-potential linearized muffin-tin orbital method with LDA and GGA. Zero point motion corrections were included. Furthermore, the energies of formation of competing Zn_3N_2, Si_3N_4, Ge_3N_4, Sn_3N_4 compounds were also calculated to determine the allowed ranges of the chemical potentials of the elements where the compounds are stable at zero temperature. For comparison, we also calculated the energy of formation of GaN, which is found to be in good agreement with experimental values. All compounds in the series are found to have a large region of stability. The electronic band structures are calculated using the QSGW method. The band gaps span the region from 1.65 - 5.30 eV, increasing from $ZnSnN_2$ to $ZnSiN_2$, with the bandgap of $ZnGeN_2$ close to that of GaN. While $ZnGeN_2$ and $ZnSnN_2$ are direct band gaps semiconductors, $ZnSiN_2$ is found to have an indirect gap slightly smaller than its lowest direct gap. The states near the valence band maximum at Gamma are symmetry labeled and their splittings analyzed in terms of two crystal field parameters. Spin-orbit coupling is found to have negligible effect on these states.

9:12AM P11.00007 Structural and Electronic properties of β-In_2X_3 (X = O, S, Se, Te) using *ab initio* calculations[1] , S.V. KHARE, S. MARSILLAC, N.S. MANGALE, V. GADE, University of Toledo — Several III-VI body-centered tetragonal layered compounds belonging to space group $I4_1/amd$ have been a subject of interest recently because of their potential applications in high efficiency and environmentally friendly copper-indium-gallium-selenide (CIGS) solar cells and molecules. Here we have studied the structural, energetic, and electronic properties of four compounds β-In_2X_3 (X = O, S, Se, Te), in this space group. Using first principles computations, we have fully determined the lattice constants *a* and *c*, as well as 10 internal parameters that define this unique structure of primitive unit cells of 40 atoms. For β-In_2S_3 our computed values are found to be consistent with experimental measurements. The bulk modulus B, local electronic density of states (LDOS), total density of states (DOS), and band gap E_f of these phases have been investigated.

9:24AM P11.00008 ABSTRACT WITHDRAWN –

9:36AM P11.00009 The surface passivation effects on the optical response of small CdTe quantum dots , OSMAN BARIS MALCIOGLU, JEAN-YVES RATY, University of Liege — In this work, the optical properties of various small-sized CdTe based quantum dots are investigated using time dependent density functional formalism. `turboTDDFT`, an implementation of the Lanczos-Liouville approach to linearized time-dependent density-functional theory, designed to simulate the optical spectra of molecular systems made of up to several hundreds atoms and distrubuted as a part of the open source QUANTUM ESPRESSO project is used. The response of the clusters at ambient temperature is estimated by performing averages of the optical spectra along the molecular dynamics trajectories. Different types of surface passivation schemes are considered in forming the quantum dot structures. Solvent effects on the surfaces that result from different passivation schemes are considered in detail using an explicit solvent approach.

9:48AM P11.00010 First-principles study of the electronic structure of NiS and NiO[1] , JOAQUIN NOYOLA, MENG TAO, QIMING ZHANG, University of Texas at Arlington — First-principles calculations of the electronic structure of NiS and NiO are performed. The exchange-correlation schemes of GGA, DFT+U and hybrid functional have been applied. The resulting band structures for each scheme are compared and analyzed to assess the reliability of the GGA, DFT+U, and hybrid functional.

10:00AM P11.00011 Tight-binding based alloy scattering calculations in $Si_{1-x}Ge_x$, SAUMITRA MEHROTRA, ABHIJEET PAUL, GERHARD KLIMECK — Role of alloy scattering in SiGe device performance has been up for debate since long time. The main source of confusion stems from the choice of alloy scattering potential parameter ΔU_{fit}. We present a theoretical model within tight-binding representation for treating alloy scattering in SiGe devices. The approach is shown to inherently capture the alloy scattering potential parameter(s) which otherwise are experimentally fitted or determined from first principles calculations for different band edges. It is shown that both onsite (variation in atom type) and off-diagonal (variation in bond type) blocks are important in estimating the potential value. The extracted scattering potential is then used to estimate bulk alloy scattering limited mobility in atomistic SiGe representation. The results show good agreement for both n-type and p-type experimental bulk mobility values.

10:12AM P11.00012 Predicting the Direct to Indirect Transition in III-V Alloys , JEREMY NICKLAS, JOHN WILKINS, The Ohio State University — The screened hybrid functional, HSE, used in density functional theory (DFT) has been gaining traction recently for its predictive powers of the band structure in bulk semiconductors. It is natural to assume that these accurate results would carry over to alloy semiconductors, but little work has been done to confirm this. We recently investigated the compositional dependence on the electronic band structure for a range of III-V semiconducting alloys (AlGaAs, InAlAs, AlInP, InGaP, and GaAsP) [1]. These alloys have a critical composition where the band gap crosses over from a direct band gap (having optoelectronic uses) to an indirect band gap (window layers in solar cells). A direct comparison of this critical composition is made between HSE and the standard density functional, PBE, revealing crossover compositions within 12% atomic composition when compared to experiment while PBE overestimates by as much as 39% atomic composition. Such results give merit that HSE is a reliable functional for tuning the electronic properties of semiconducting alloys.

10:24AM P11.00013 Hybrid DFT computes accurate band offsets of semiconductor alloy heterostructures[1] , AMITA WADEHRA, JEREMY NICKLAS, JOHN WILKINS, The Ohio State University — Semiconductor alloy heterostructures are the backbone of optoelectronic devices. Among the most important parameters that determine the utility of heterostructure devices are the valence and conduction band offsets. Although DFT with standard functionals such as LDA or PBE does an acceptable job for valence band offsets, it fails to predict accurate conduction band offsets on its own due to the well-known band gap problem. We demonstrate the accuracy of HSE (Heyd-Scuseria-Ernzerhof) hybrid functional for computing the band gaps and band offsets of a broad selection of technologically important semiconductor alloys and their heterostructures, e.g., AlInAs/GaInAs, GaInP/AlGaAs, AlInP/GaInP [1]. The highlight of this study is the computation of conduction band offsets with a reliability that has eluded standard density functional theory. These results demonstrate predictive power of HSE for band engineering of relevant devices.

10:36AM P11.00014 Electronic Structure of Random Alloys , CHAD WAXLER, BYOUNGHAK LEE, Department of Physics, Texas State University at San Marcos, XAVIER CARTOIXÁ, Departament d'Enginyeria Electrónica, Universitat Autónoma de Barcelona — We present a theoretical investigation of the evolution of the electronic properties of the random alloys as they undergo a transition from one pure crystal to another. For random substitutional alloys the Bloch wavevector is not a good quantum number due to the lack of translational invariance. In spite of this obvious fact the conventional methods used for random alloys calculations, e.g., Virtual Crystal Approximation and Coherent Potential Approximation, assume a medium that pertains the same symmetries of the parent compounds. The question we ask is how well the band structures from such effective medium theories agree with the real electronic structures. We address this issue using direct simulations of randomly distributed (Al,Ga)As and (In,Ga)P atom structures.

10:48AM P11.00015 Atomic-scale evolution of interfacial electronic band alignment in epitaxial Gd_2O_3 on GaAs (100) , B.C. HUANG, Y.P. CHIU, M.C. SHIH, Department of Physics, National Sun Yat-Sen University, Kaohsiung, 80424, Taiwan, J.Y. SHEN, P. CHANG, T.H. CHIANG, Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, 30013, Taiwan, C.S. CHANG, Institute of Physics, Academia Sinica, Taipei, 10617, Taiwan, M.L. HUANG, National Taiwan University, and National Tsing Hua University, Taiwan, M. HONG, Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, 30013, Taiwan, J. KWO, National Taiwan University, and National Tsing Hua University, Taiwan — Direct imaging of the atomic-scale configuration and interfacial electronic band alignment in epitaxial Gd_2O_3 high κ oxides grown on GaAs (100) has been demonstrated using cross sectional scanning tunneling microscopy and spectroscopy. Measurements of the local density of states characteristics with atomic precision enabled us to determine the evolution of electronic properties in passivating the Gd_2O_3/GaAs hetero-interface. Close examinations suggested excellent electrical passivation at this interface, with low interfacial states and low leakage current density. In addition, from the local electronic states across the gate oxides, the spatial extent of the GaAs wavefunctions extended into the gate dielectric situates a minimum thickness of 0.8 nm for the Gd_2O_3 gate capacitance.

Session P12 DMP: Focus Session: Dopants and Defects in Semiconductors: Hyper Doping D223/224

8:00AM P12.00001 Limits of doping $In_{0.53}Ga_{0.47}As$ with Si and Be , SANGEETHA VIJEYARAGUNATHAN, TETSUYA D. MISHIMA, MICHAEL B. SANTOS, University of Oklahoma — We report on a study of doping efficiency in $In_{0.53}Ga_{0.47}As$ layers grown on InP (001) substrates by molecular beam epitaxy. Si and Be effusion cells were used to provide n- and p-type dopants, respectively. In epilayers grown at 0.63 monolayers per second with a substrate temperature of 500°C, doping cell temperatures below T_{Si}=1260°C (T_{Be}=907°C) resulted in electron (hole) concentrations that followed an Arrhenius relation with an activation energy of 5.0 eV (4.0 eV). At higher cell temperatures, the carrier concentration saturated at approximately n=3.1×10^{19}cm^3 (p=2.6×10^{19}cm^3). For T_{Si}=1300°C (T_{Be}=928°C), the carrier concentration was increased to n=4.2×10^{19}cm^3 (p=3.3×10^{19}cm^3) through use of a lower substrate temperature of 400°C (470°C). The maximum carrier concentration achieved through lowering the substrate temperature was n=4.8×10^{19}cm^3 (p=9.1×10^{19}cm^3). For Be doping, the maximum hole concentration was increased to 1.3×10^{20}cm^3 by using a lower growth rate. We will compare our results with the doping of GaSb and InAs, and discuss attempts to increase the maximum concentration through delta-doping and migration enhanced epitaxy.

8:12AM P12.00002 Se-precipitation in ZnSe under moderate-power laser-irradiation at high-pressure , G.P. LINDBERG, R.E. TALLMAN, Dep. of Physics, Univ. at Buffalo, Buffalo, NY, USA, R. LAUCK, M. CARDONA, Max Planck Institut für Festkórperforschung, Stuttgart, Germany, B.A. WEINSTEIN, Dep. of Physics, Univ. at Buffalo, Buffalo, NY, USA — We report evidence for the formation of Se inclusions in ZnSe under laser-irradiation during pressure-Raman experiments. Spectra of high-quality $^{68}Zn^{76}Se$ crystals are recorded at 300K for pressures of 0-13GPa using 647nm excitation at powers of 10 and 100 mW (focal spot $\sim$ 50μm.) For runs at the higher power a new Raman peak appears at 1.8 GPa, and shifts to lower energy at the rate –3.5 cm^{-1}/GPa with further increase of pressure. Its frequency, 228cm^{-1} at 1.8GPa, is within 7 cm^{-1} of the A1 and E$''$ Raman peaks in trigonal Se, which both exhibit negative, strongly non-linear, pressure shifts.[1] In particular, the pressure-shift of the new ZnSe peak gives a reasonable fit to the average dependence of the Se A1 peak over the range 2-8 GPa. No assignment to any of the ZnSe acoustic modes (one- or two- phonon) that also soften with pressure is feasible for the new peak. It is most likely related to the Se A1-mode in Se-inclusions, whose tendency to precipitate appears to increase with pressure.

8:24AM P12.00003 Band Renormalization in Mn Doped TiS_2 , TIMOTHY KIDD, PAUL SHAND, LAURA STRAUSS, University of Northern Iowa, JON RAMEAU, TONICA VALLA, PETER JOHNSON, Brookhaven National Laboratory — Titanium disulphide is a narrow gap semiconductor with a highly 2D layered structure. Mn dopants can be used to transform the band structure into being truly metallic via a rigid band shift of the electronic states. The system also begins to exhibit a variety of low temperature magnetic phases at Mn concentrations above 5%. We have performed angle resolved photoemission measurements of this system that clearly the transformation of the band structure from semiconducting to metallic. Furthermore, it can be seen that states near the valence band maxima become strongly modified beyond the rigid band shift approximation. The degeneracy of these states is lifted and they show behavior much like the spin splitting classically seen in surface states of gold and more recently in those of topological insulators. This behavior was quite unexpected as the states probed should be essentially bulk bands for this inert material. While no signs of temperature dependence were found to correlate these changes in electronic structure with any magnetic phase transition, it seems likely that this novel behavior arises from magnetic interactions with the Mn dopants.

8:36AM P12.00004 Persistent Photoconductivity and Magnetotransport in Dilute Nitride Semiconductor Alloys , R.L. FIELD III, Y. JIN, C. KURDAK, Physics Department, R.S. GOLDMAN, Department of Material Science and Physics Department, University of Michigan, Ann Arbor, MI 48109 — Nitrogen related defects, such as N interstitials and Si-N complexes, are known to dominate electrical and optical properties of dilute nitride semiconductor alloys [1,2]. We investigate the dependence of these defects on N incorporation for MBE grown Si and Te-doped dilute $GaAs_{1-x}N_x$ (x = 0.75-1.9) alloys. Persistent photoconductivity was observed for these heterostructures as high as 160 K, with photo-capture barriers from 216-350 meV. Also, carrier concentrations extracted from Hall measurements reveal a T-independent regime above 150 K and a strong thermally-activated regime below 150 K. These two phenomena are reminiscent of the behavior of n- type AlGaAs, suggesting the presence of similar N-induced DX- center-like states in GaAsN. We will discuss the dependence of these energies on both N composition and annealing temperature.

8:48AM P12.00005 ABSTRACT WITHDRAWN –

9:00AM P12.00006 Magnetic properties of Mn doped zinc selenide clusters: First principles calculations[1]

, SACHIN NANAVATI, Department of Electronic Science, University of Pune, Pune 411007 India, SUNDARARAJAN V., Centre for Development of Advanced Computing (C-DAC), Pune University campus, Pune 411007, India, SHAILAJA MAHAMUNI, Department of Physics, University of Pune, Pune 411007, India, SUBHASH GHAISAS, Department of Electronic Science, University of Pune, Pune 411007, India, VIJAY KUMAR, Dr. Vijay Kumar Foundation, 1969, Sector 4, Gurgaon 122001, India — We report the result of our study on magnetic properties of Mn doped ZnSe clusters within the pseudopotential based density functional theory (DFT). In the present work, we substituted one or two Mn atoms at different cationic sites of small ZnSe clusters and the corresponding stable geometrical configurations are obtained. In general, we find a large magnetic moment of 5 μ_B magnetic moment when one Mn atom is substituted. For the case of doping of two Mn atoms, calculations were performed for both parallel and anti-parallel spin-configurations. The variations in the density of state (DOS), the gap between the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO), the binding energy, and the magnetic moment have been analyzed as a function of the cluster size. This paper will discuss the preferred sites of the dopants, type of magnetization and their bonding characteristics for the above mentioned clusters.

[1]The authors would like to thank C-DAC for the funding and the computing time on its PARAM supercomputers.

9:12AM P12.00007 Sub-bandgap absorptance in chalcogen-hyperdoped silicon[1]

, BONNA NEWMAN, Massachusetts Institute of Technology — It has been shown that optical doping with pulsed lasers can achieve non-equilibrium concentrations up to one atomic % of heavy chalcogens in silicon. Compared to intrinsic silicon, this material exhibits near-unity absorption of sub-bandgap photons and has potential use in silicon infrared photodetectors and high-efficiency photovoltaics. Successful application of this material, however, requires better understanding of the exact mechanism responsible for sub-bandgap absorptance. Using a variety of techniques, we probe the chemical structure of this material system. We find that the short range structure of the dopant atom is correlated to the amount of sub-bandgap absorptance. We also compare the structure of different dopant species (S and Se) as well as different hyperdoping mechanisms (fs-laser doping vs. ion implantation followed by pulsed laser melting). In conjunction with theoretical modeling of expected chalcogen defect states, we identify dominant structural characteristics related to the observation of sub-bandgap absorptance. Expanding on previous results, we demonstrate control of sub-bandgap absorptance through thermal processing. In addition to suggesting a method to engineer the optical properties of the material, this result provides further insight into the thermodynamics of formation of a possible dopant-related defect state. We compare the thermodynamics measurements to the dopant structural measurements and posit a model of sub-bandgap absorptance and defect dynamics. These results provide a better understanding of the phenomena of sub-bandgap absorptance in chalcogen-hyperdoped silicon and a pathway to explore other hyperdoped semiconductors.

[1]We acknowledge the support of the Clare B. Luce Foundation and the Chesonis Family Foundation.

9:48AM P12.00008 Supersaturated Silicon-Chalcogen Alloys for Thin-film Photodetectors

, DANIEL RECHT, AURORE SAID, SI HUI PAN, MICHAEL AZIZ, Harvard School of Engineering and Applied Sciences, JEFFERY WARRENDER, US Army ARDEC - Benet Laboratories, THOMAS CRUSON, DAVID HUTCHINSON, PETER PERSANS, Rensselaer Polytechnic Institute, JOSEPH SULLIVAN, MARK WINKLER, TONIO BUONASSISI, Massachusetts Institute of Technology — Supersatured silicon-chalcogen alloys are known to have strong infrared optical absorption and the ability to detect light with energy less than silicon's bandgap. The range of infrared wavelengths these alloys absorb is much broader than the range over which photodiodes made from these alloys respond. We have recently performed several experiments to understand the disconnect between optical absorption and photodetection in thin, monocrystalline films of these alloys fabricated by ion implantation followed by nanosecond laser melting. When subjected to sensitive tests of photoconductivity, these alloys show no optoelectronic response at several absorbed sub-bandgap wavelengths. Furthermore, measurements on photodiodes made from silicon chalcogen alloys suggest that these materials are in fact a potent low-voltage photodetection gain medium. These results, along with temperature dependent transport measurements and sensitive optical spectroscopy, indicate that the mechanism of sub-bandgap response could be substantially more complex than is commonly thought.

10:00AM P12.00009 Non-radiative Recombination in Intermediate Band Photovoltaics[1]

, JACOB KRICH, ALÁN ASPURU-GUZIK, Harvard University — Intermediate band photovoltaics (IBPV) promise to absorb low energy photons while maintaining large open circuit voltages, breaking the Shockley-Queisser efficiency limit. Proposals for IBPV include hyperdoping semiconductors with impurities forming mid-gap states, creating a band entirely contained inside the larger semiconductor bandgap. For such devices to function, the electronic states in the middle of the band gap must be extended and thus not contribute to multiphonon recombination. Since the intermediate band is produced by randomly placed impurities, however, there is an inherent disorder in the electronic structure, which produces localized states inside the band gap due to Anderson localization, even at high impurity concentrations. We use a finite size scaling analysis to find the localization properties of a non-interacting intermediate band and its resultant contribution to non-radiative recombination.

[1]We acknowledge support from the Harvard University Center for the Environment.

10:12AM P12.00010 A Metal-Insulator Transition in Silicon Hyperdoped with Chalcogens

, ELIF ERTEKIN, MARK WINKLER, MIT, AURORE SAID, MICHAEL AZIZ, Harvard, TONIO BUONASSISI, JEFFREY GROSSMAN, MIT — Hyperdoped Silicon, the material resulting from the laser doping of Silicon to impurity concentrations orders of magnitude beyond the room temperature solubility limit, can exhibit unique properties. For example, "Black Silicon", formed from laser doping with chalcogens S, Se, or Te, exhibits anomalous sub band gap optical absorption at photon energies as low as 0.5 eV and a flat absorption spectrum. While this has piqued interest in the use of Black Silicon for optoelectronics and photovoltaics, there has not yet been a clear explanation for the enhanced optical properties. Focusing on the Se doped systems, we use Density Functional Theory to show that the optical absorption results from an impurity induced insulator to metal transition. Our calculations indicate that an isolated Se impurity introduces a localized electronic state in the band gap. At higher defect concentrations, the transition to the metallic state is demonstrated by an increase in the defect level bandwidth and the eventual merging of the defect state with the conduction bands. The concentration at which this occurs corresponds very well with experimental low temperature Hall effect measurements.

10:24AM P12.00011 Dopant effects on dislocation width of dislocations in Si

, YUTAKA OHNO, Institute for Materials Research, Tohoku University, TOSHINORI TAISHI, Institute for Materials Research, Tohoku Unviersity, YUKI TOKUMOTO, ICHIRO YONENAGA, Institute for Materials Research, Tohoku University — Impurities interact with dislocations in semiconductor crystals, resulting in variations of dynamical activities of dislocations such as mobility and immobilization, and also in leading to inhomogeneity of electrical and optical properties of microelectronic and PV devices. Especially in Si in demanded trend of heavily doping for miniaturized transistors, basic knowledge of dislocation-dopant impurity interaction increases the importance. In CZ-Si doped with n-type impurities of P, As, and Sb, dislocations freshly induced at 1173 K extended their dissociation width with increasing duration of subsequent annealing at the same temperature. The width increased by annealing when the concentration of n-type impurities was high. On the other hand, the dissociation width was unchanged during annealing in Si undoped and doped with p-type impurities of B and Ga. These results suggest that the energy of stacking fault bound to partial dislocations is strongly affected by the number of n-dopant impurities segregated nearby them via their thermal migration, irrespective of atomic size of the dopant impurities; i.e., n-dopant impurities segregate nearby a stacking fault so as to reduce the stacking fault energy.

10:36AM P12.00012 Entropic Influence on the Aggregation Physics of Interstitial Point Defects in Silicon , TALID SINNO, SUMEET KAPUR, ALEX NIEVES, University of Pennsylvania — The evolution of self-interstitials and their aggregates during the annealing of ion-implanted silicon has received a tremendous amount of attention because of their strong, non-linear effects on the diffusion of dopants. The implantation process leads to extensive lattice damage, which must be healed by thermal annealing. Also generated by the implantation process is a large number of self-interstitials which lead to enhanced dopant diffusion during annealing known as Transient Enhanced Diffusion, or TED. A major obstacle to understanding and quantitatively predicting TED is the formation of a variety of self-interstitial aggregates, which range from small amorphous three-dimensional clusters, to planar stacking-faults with various crystallographic orientations. In the present study, we use large-scale constant-stress MD simulations to dynamically simulate the evolution of an ensemble of highly supersaturated self-interstitials at various temperatures and pressures. We show that the simulated interstitial clustering into various types of planar structures exhibits a complex thermodynamic-kinetic phase diagram that is sensitively controlled by entropic factors. The observations are studied with a recently developed approach that maps out the potential energy landscape in the vicinity of the defect cluster and allows for the total (classical) free energy to be analyzed.

10:48AM P12.00013 The chemical trends of a new defect cluster: DDX centers , JIE MA, SU-HUAI WEI, National Renewable Energy Laboratory, Golden, Colorado 80401, USA — DX center is a major "killer" defect limiting n-type doping in group II-VI and III-V semiconductors. It converts a shallow donor to deep one, which is a major reason for the saturation of free-electron carriers in the doping process. Several structure models of isolated DX centers have been proposed in the literatures, such as the broken-bond model (BB-DX), and the α and β cation-cation bond model (CCB-DX). All these DX centers can be stabilized with hydrostatic pressure or reduced dimensionality and size. In group III-V and II-VI semiconductors, it has been common believe that cation-site induced DX centers are easier to form than anion-site induced ones. Because DX centers trap an extra electron, therefore, another defect in the system must donate the electron and form a positive charged defect. We show, using GaAs as an example, that in heavily doped semiconductor, the negative charged DX center and positive charged donor can couple strongly through the Coulomb interaction, forming the dominant DDX center. The DDX centers are still deep level defects. However, unlike the DX center, the DDX centers have different chemical trends, i.e., anion-site DDX center is easier to form than cation-site DDX centers. A simple model is proposed to explain the new trends.

Session P13 APS: Tutorial for Authors and Referees D225/226

8:00AM P13.00001 Tutorial for Authors and Referees —Editors from Physical Review Letters and Physical Review will provide information and tips for our less experienced referees and authors. This session is aimed at anyone looking to submit to or review for any of the APS journals, as well as anyone who would like to learn more about the authoring and refereeing processes. Topics for discussion will include advice on how to write good manuscripts, similarities and differences in writing referee reports for PRL and PR, and other ways in which authors, referees, and editors can work together productively. Following a short presentation from the editors, there will be a moderated discussion. Refreshments will be served.

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P14 DMP GSNP DCOMP: Focus Session: Friction, Fracture and Deformation Across Length Scales II: Plasticity and Rupture D227

8:00AM P14.00001 Scaling theory of continuum dislocation dynamics in two and three dimensions , YONG S. CHEN, WOOSONG CHOI, STEFANOS PAPANIKOLAOU, JAMES P. SETHNA, Cornell University — When crystalline materials deform plastically, complex dislocation structures have been observed experimentally.[1] We provide a continuum plasticity theory to study the emergent self-similar morphologies.[2] We analyze the self-similarity in terms of critical exponents for correlation functions of dislocation density, crystalline orientation and plastic distortion, and explore the connection to the power spectrum of the total free energy. In two and three dimensions, we apply anisotropic loadings, and observe little anisotropy in the critical properties. We explore the addition of quenched disorders to our continuum theory, to investigate the relation between dynamics (plasticity avalanches) and static dislocation morphologies.

8:12AM P14.00002 Saddle node scaling on approach to dislocation nucleation , AKANKSHA GARG, ASAD HASAN, CRAIG MALONEY, Carnegie Mellon University — We study the process of dislocation nucleation in a perfect 2D hexagonal crystal under nano-indentation loading in a numerical model using energy minimization techniques and analysis of the energy eigenmodes. The nucleation event takes the form of a saddle-node catastrophe and is governed by associated scaling laws. In particular, on approach to nucleation, a single energy eigenmode descends through the spectrum and its eigenvalue vanishes as the square root of the distance to the nucleation point. The velocity of the system shows the same scaling behavior, and its normal mode decomposition demonstrates that it is dominated by the critical mode responsible for nucleation.

8:24AM P14.00003 Dislocation dynamics at zero temperature and at finite temperature: analytics and simulations[1] , KARIN DAHMEN, GEORGIOS TSEKENIS, Department of Physics, University of Illinois at Urbana Champaign, PAK YUEN CHAN, THOMAS FEHM, JONATHAN DANTZIG, NIGEL GOLDENFELD, JONATHAN UHL — Crystalline materials are known to deform in an intermittent way with avalanches. Power laws govern the statistics of the avalanches. In this work we are studying plasticity as a member of the universality class of depinning phase transition. Results from our Discrete Dislocation Dynamics simulations agree with analytical mean field predictions for distributions of avalanche sizes, durations, power spectra, and avalanche shapes. Results from phase field crystal simulations agree with analytical predictions for the depinning phase transition at finite temperature. Both numerics and analytics indicate that the dynamics of edge dislocations in sheared crystals belong to the mean field universality class of depinning transitions, both at zero temperature and at finite temperature.

8:36AM P14.00004 Size Matters: size-dependent strength and nucleation-governed deformation mechanisms in nano-scale Cu pillars , JULIA GREER, Caltech — Uniaxial compression and tension tests on single crystalline micro and nanopillars have revealed a strong size effect. For face-centered cubic metals, this size effect is characterized by a power-law: where n is between .5 - .7. The majority of these micro-mechanical tests have been performed on pillars produced by the focused-ion-beam (FIB), a process known to introduce surface damage into the material and to limit the smallest attained pillar diameter to $\sim$150nm while maintaining its shape integrity. In order to overcome these detriments, we developed a new technique combining electroplating and electron beam lithography to create single crystalline Cu nano-pillars with diameters down to 50 nm. We find the mechanical response of these samples to exhibit the same power-law strengthening behavior as other fcc metals down to the diameter of 100nm, as revealed by *in-situ* uniaxial compression and tension tests conducted in a custom-built in-situ mechanical deformation instrument, SEMentor. TEM investigations of the microstructure of pillars produced by the FIB and by electroplating show similar initial dislocation densities of $\sim 10^{14}$ m^{-2} implying that size-dependent strength at the nano-scale is a strong function of initial microstructure and not of fabrication method. We examine the limits of this power-law trend down to diameters of 50nm, as at these small sizes, deformation behavior has been theoretically predicted to change due to the activation of surface dislocation sources and the increasing influence of the surface stress. Furthermore, we find that these single crystalline Cu nano-pillars show a remarkable strain-rate dependence that increases with decreasing diameter further revealing the thermally activated nature of dislocation sources and corresponding changes in activation volume. HRTEM investigations of post-mortem structures will be presented in the context of dislocation-based phenomenological modeling.

9:12AM P14.00005 Effect of Inertia and Damping on Avalanche Distributions in Sheared Amorphous Solids[1] , K. MICHAEL SALERNO, Johns Hopkins University, CRAIG MALONEY, Carnegie Mellon University, MARK O. ROBBINS, Johns Hopkins University — Avalanches occur in a variety of contexts from magnets to granular materials. Molecular dynamics simulations of a sheared binary Lennard-Jones glass are used to explore the effect of inertia and damping on avalanche distributions. We find that the energy dissipation rate is one of the key factors in determining the size of an individual avalanche as well as the distribution of avalanche energies. There are three distinct regimes: an overdamped regime where the distribution has an exponential cutoff that varies with dissipation rate, a critical regime where avalanches follow power-law statistics and large events are limited by simulation size, and a run-away regime where inertia leads to a peak at large energies. The same regimes are found for Langevin type viscous damping and Galilean-invariant Kelvin damping. While inertia determines how an avalanche evolves, some properties of the avalanche are predetermined. Weakening of the average shear modulus prior to an avalanche is a good indicator that a large, system-spanning event may occur.

9:24AM P14.00006 Nonclassical Nucleation and Growth of Cohesive Tensile Cracks , JOSEPH GRAN, UC Davis, JOHN RUNDLE, UC Davis, Santa Fe Institute, WILLIAM KLEIN, Boston University — We analyze the nucleation and growth of cohesive tensile cracks using a Hamiltonian which is written as a functional of the crack separation (offset field). We simulate the nucleation events on a square lattice using a Metropolis Monte Carlo algorithm. Several modes of crack propagation are seen in the simulations. Our results indicate that for certain materials, crack nucleation and growth proceed through the formation and extension of a diffuse "halo" surrounding the classical portion of the crack. This is similar to nonclassical nucleation near the spinodal in magnetic systems. Theoretical considerations and numerical calculations strongly suggest that the diffuse halo can be identified with the fracture "process zone" seen in laboratory studies of advancing cracks. We are investigating scaling exponents associated with this apparent phase transition.

9:36AM P14.00007 Enhanced Strength via crack friction and Pressure[1] , DONALD WIEGAND, ARDEC Picatinny USA, KEVIN ELLIS, CLAIRE LEPPARD, AWE Aldermaston — The effect of pressure on the mechanical response of particulate polymer composites is being studied. Between about 0.1 and 7 MPa for one composite the results indicate that slow crack growth is the dominant failure mode. With continuously creasing strain at low pressures the stress initially increases to a maximum, the compressive strength, then decreases indicating work softening and them becomes approximately constant at a plateau value. Both the compressive strength and the plateau stress increases linearly with pressure but the plateau stress increases with a steeper slope such that at higher pressures work softening is not observed. The results are analyzed in terms of shear cracks with friction between the crack surfaces. The model predicts a threshold stress for crack growth which increases linearly with pressure and further predicts that the compressive strength increases linearly with pressure as observed and with the same slope as the threshold stress. These results clearly indicate that the pressure dependence of the compressive strength is due to the pressure dependence of the threshold stress for crack growth. The changes in the plateau region can also be attributed to frictional effects.

9:48AM P14.00008 Irreversible Damage in Amorphous Silica , CINDY ROUNTREE, CEA,DSM,IRAMIS,SPCSI, DAMIEN VANDEMBROUCQ, Laboratoire PMMH, ESPCI, STEPHANE ROUX, LMT, ENS-Cachan, ELISABETH BOUCHAUD, CEA,DSM,IRAMIS,SPEC — Glass touches every aspect of our lives including the glass dishes which we cook with to the storage of nuclear waste. The extensive use of oxide glasses can be attributed to optical transparency, electrical and heat insulation, and large hardness. However, oxide glasses have a major drawback: brittleness. Even small flaws in the structure can lead to the ultimate failure of the material. Recent Atomic Force Microscope experiments and Molecular Dynamics simulations revealed a process zone ahead of the crack tip where damage nucleates, augments, and finally merges with the advancing crack front. Furthermore, when a-SiO_2 samples are nanoindented, one finds permanent damage under the indenter in the form of densified silica. To shed light on the origin of irreversible deformation in amorphous media, we have expanded our studies to examine what happens to an oxide glass when subjected to shear. MD simulations have been performed in a-SiO_2 systems which are subject to a shearing force at room temperature. The system was initially isotropic and as long the maximum shear deformation remains under 5% the system remains isotropic upon unloading. However if the system is sheared to a point greater than 5% permanent plastic deformation sets in and the system is no longer isotropic upon unloading.

10:00AM P14.00009 Molecular dynamics study of the contact strengths between clean metallic surfaces with nanoscale asperities , HOJIN KIM, ALEJANDRO STRACHAN, School of Materials Engineering, Purdue University, West Lafayette, Indiana, USA — A fundamental understanding of the mechanical behavior of contacting surfaces with nanoscale asperities including their adhesion and friction is critical for MEMS and other applications. We characterize the tensile strength of contacts formed between various clean Pt surfaces such as commensurate contacts between (001) and (111) surfaces and incommensurate (001) ones by using MD simulations over wide range of asperity size. In cyclic closing and opening, the first contact shows significant plastic deformation, leading to a considerable reduction in the contact area. After few cycles, steady state is achieved both contact size and the pullout force. The strength of bridges in both commensurate and incommensurate contacts exhibits strong size effects. Their strength increases with decreasing size until a length of approximately 5 nm below which weakening is observed. Commensurate contacts are stronger than incommensurate ones but only during the initial contacts, after steady state is achieved commensurate and incommensurate (001) surfaces lead to similar strengths.

10:12AM P14.00010 Friction and Sliding of Polystyrene Micro Spheres in the Presence and Absence of Capillary Adhesion[1] , IYAM LYNCH, JACQUELINE KRIM, North Carolina State University — Quartz crystal microbalance (QCM) response to varying load geometries, particularly micro particles, is a rapidly growing field of research.[2,3] This no doubt is due to its varied applications involving the study of textiles, DNA and viruses[3], micro adhesion[2,3], micro sorting[3], and friction. There are many challenges that must be overcome in this field. One major difficulty is capillary adhesion, which is difficult to quantify. We have created an experiment to greatly reduce the impact of capillary adhesion by employing the shaking motion of a 5MHz QCM to eject micro spheres (15μm) from its surface, which subsequently land on the surface of a nearby 8 MHz QCM. The experiment is performed in a vacuum chamber to include different environments such as air, vacuum, and dry nitrogen. During the experiment we monitor the behavior of the unloaded QCM by measuring the change in frequency and quality factor as a result of the newly landed spheres. Particle motion and dynamics are observed using a microscope with a camera attached.

10:24AM P14.00011 Cooperative adhesion and friction of compliant nanohairs[1] , ALI DHINOJWALA, LIEHUI GE, The University of Akron, LIJIE CI, ANUBHA GOYAL, PULICKEL AJAYAN, Rice University, L. MAHADEVAN, Harvard University — The adhesion and friction behavior of soft materials, including compliant brushes and hairs, depends on the temporal and spatial evolution of the interfaces in contact. For compliant nanofibrous materials, the actual contact area of individual fibers make with surfaces depends on the preload applied upon contact. Using in-situ microscopy observations of preloaded nanotube hairs, we show how nanotubes make cooperative contact with a surface by buckling and conforming to the surface topography. The overall adhesion of compliant nanohairs increases with increasing preload as nanotubes deform and continuously add new side-wall contacts with the surface. Electrical resistance measurements indicate significant hysteresis in the relative contact area. Contact area increases with preload (or stress) and decreases suddenly during unloading, consistent with strong adhesion observed for these complaint nanohairs.

10:36AM P14.00012 The effect of Coulombic friction on spatial displacement statistics[1] , ANDREAS MENZEL, NIGEL GOLDENFELD, University of Illinois at Urbana-Champaign — We study the effect of Coulombic (dry) friction on the spatial displacement statistics of one-dimensional stochastic motions. In other words, one of the simplest forms of nonlinear friction is added to the Fokker-Planck equation for conventional viscous Brownian motion, and its consequences are investigated. First, we find the eigenfunctions to the problem that includes the velocity component only. This problem can be mapped on the case of a quantum mechanical harmonic oscillator in the presence of a delta potential. Then we show numerically that a crossover from exponential to Gaussian displacement statistics results from the Coulombic frictional contribution. A transient regime of multiscaling is identified for the spatial distribution function. Our results are important for the interpretation of recent experiments in the field of soft matter physics: it turns out that, for practical purposes, higher order moments of the spatial distribution function must be determined to identify the presence of effective Coulombic frictional forces.

10:48AM P14.00013 Understanding frictional duality and bi-duality: Sb-nanoparticles on HOPG[1] , JAN BRNDIAR, ROBERT TURANSKY, IVAN STICH, Inst. of Physics, Slovak Academy of Sciences, Bratislava, Slovakia — We have simulated [1] the behavior of motion of Sb_n nanoparticles on HOPG with the quest to elucidate the experimentally observed frictional bi-duality [2]. The first duality was observed for clean Sb-nanoparticles deposited under UHV conditions. Both frictionless and "normal" behavior was observed. Another dual behavior was found for Sb-nanoparticles exposed to ambient conditions, both scaling linearly with contact area. The vanishing friction branch is due to incommensurability of the Sb-HOPG. The non-vanishing friction branch can be accounted for by contaminants due to imperfect UHV, such as water, hydrocarbons, oxygen, etc., including small Sb_n clusters. The large friction forces after exposition to ambient conditions result from presence of mobile oxidized multiasperities. The simulations allow for quantitative estimates of impurity concentrations and understanding of the molecular mobility.

Session P15 DMP GMAG FIAP: Focus Session: Spins in Semiconductors - Quantum Computing with Defects D171

8:00AM P15.00001 Quantum computing with defects[1] , JOEL VARLEY, Department of Physics, University of California, Santa Barbara — The development of a quantum computer is contingent upon the identification and design of systems for use as qubits, the basic units of quantum information. One of the most promising candidates consists of a defect in diamond known as the nitrogen-vacancy (NV^{-1}) center, since it is an individually-addressable quantum system that can be initialized, manipulated, and measured with high fidelity at room temperature. While the success of the NV^{-1} stems from its nature as a localized "deep-center" point defect, no systematic effort has been made to identify other defects that might behave in a similar way. We provide guidelines for identifying other defect centers with similar properties. We present a list of physical criteria that these centers and their hosts should meet and explain how these requirements can be used in conjunction with electronic structure theory to intelligently sort through candidate systems. To elucidate these points, we compare electronic structure calculations of the NV^{-1} center in diamond with those of several deep centers in 4H silicon carbide (SiC). Using hybrid functionals, we report formation energies, configuration-coordinate diagrams, and defect-level diagrams to compare and contrast the properties of these defects. We find that the $N_C V_{Si}^{-1}$ center in SiC, a structural analog of the NV^{-1} center in diamond, may be a suitable center with very different optical transition energies. We also discuss how the proposed criteria can be translated into guidelines to discover NV analogs in other tetrahedrally coordinated materials.

8:36AM P15.00002 ABSTRACT WITHDRAWN –

8:48AM P15.00003 Optical Control of Spatial Patterning of Nuclear Polarization in GaAs

, JONATHAN KING, University of California, Berkeley, YUNPU LI, LE PENG, MARIA TAMARGO, CARLOS MERILES, City College of New York, JEFFREY REIMER, University of California, Berkeley — We present new results on the optical polarization of nuclear spins in gallium arsenide. Previous work has identified the contact hyperfine interaction at shallow donors as the mechanism for helicity dependent nuclear polarization. We show a new regime, where donors are only partially occupied, where nuclear quadrupolar relaxation at shallow donors is the dominant mechanism. Since quadrupolar relaxation is helicity independent, the incident light polarization may be tuned such that the two relaxation mechanisms drive the nuclear spins to opposite signs of polarization. We show that incident light wavelength and power may be tuned to create spatial patterns of varying donor occupation in a single sample, which in turn creates a pattern of positive and negative nuclear polarization. We have developed an analytical mode which accurately describes the bulk NMR signal in terms of irradiation power and wavelength. We also present stray-field NMR imaging experiments showing direct observation of the patterned nuclear polarization.

9:00AM P15.00004 Spin Orbit Interaction in Inversion-Symmetric Semiconductors: SrTiO3 and group IV

, CUNEYT SAHIN, Optical Science and Technology Center and Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa 52242, USA, GIOVANNI VIGNALE, Department of Physics, University of Missouri, Columbia, Missouri 65211, MICHAEL E. FLATTÉ, Optical Science and Technology Center and Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa 52242, USA — Low-energy effective spin-orbit Hamiltonians have proved effective at describing the effect of spin-orbit interactions on populations of polarized carriers in direct-gap semiconductors such as gallium arsenide. No similar low-energy Hamiltonians are available for materials with inversion symmetry, such as cubic oxides or group-IV semiconductors. In order to construct such low-energy Hamiltonians we have calculated the electronic band structure of strontium titanate, a perovskite material which has recently been used to make high-density two-dimensional electron gases, using a tight-binding electronic structure with atomic spin-orbit interactions. We have also calculated the band structures of several group-IV semiconductors, including germanium, silicon, and diamond. An expression for the effective spin-orbit interaction in the conduction band of these materials has been derived, and calculated for these materials. The symmetry properties of this effective spin-orbit interaction tensor will also be discussed. This work was supported by an ARO MURI.

9:12AM P15.00005 Excited-State Spin Manipulation and Intrinsic Nuclear Spin Memory using Single Nitrogen-Vacancy Centers in Diamond[1]

, GREGORY FUCHS[2], Center for Spintronics and Quantum Computation, University of California, Santa Barbara — Nitrogen vacancy (NV) center spins in diamond have emerged as a promising solid-state system for quantum information processing and precision metrology at room temperature. Understanding and developing the built-in resources of this defect center for quantum logic and memory is critical to achieving these goals. In the first case, we use nanosecond duration microwave manipulation to study the electronic spin of single NV centers in their orbital excited-state (ES) [1]. We demonstrate ES Rabi oscillations and use multi-pulse resonant control to differentiate between phonon-induced dephasing, orbital relaxation, and coherent electron-nuclear interactions. A second resource, the nuclear spin of the intrinsic nitrogen atom, may be an ideal candidate for a quantum memory due to both the long coherence of nuclear spins and their deterministic presence. We investigate coherent swaps between the NV center electronic spin state and the nuclear spin state of nitrogen using Landau-Zener transitions performed outside the asymptotic regime [2]. The swap gates are generated using lithographically fabricated waveguides that form a high-bandwidth, two-axis vector magnet on the diamond substrate. These experiments provide tools for coherently manipulating and storing quantum information in a scalable solid-state system at room temperature.

9:48AM P15.00006 Dynamic Jahn-Teller Effect in Negatively Charged Nitrogen-Vacancy Center in Diamond[1]

, TESFAYE ABTEW, PEIHONG ZHANG — The negatively charged nitrogen-vacancy (NV) center in diamond has attracted much research interest recently owing to its desirable optical properties and long spin coherent lifetime. The ground state of NV^- center has a $^3A_2$ symmetry, which can be optically excited, to a ^3E state. The excited state is orbitally degenerate therefore should experience either static or dynamic Jahn-Teller (JT) effects. We use accurate first-principles methods to study structural and electronic properties of the NV^- center in diamond both in the ground and excited states. Our results indicate that the excited state of the NV^- center is indeed a dynamic JT system.

10:00AM P15.00007 Using Adiabatic Pulses for the Control of Nitrogen Impurities in Diamond

, ZHI-HUI WANG, Ames Laboratory, USDOE, G. DE LANGE, R. HANSON, Kavli Institute of Nanoscience Delft, Delft University of Technology, Delft, The Netherlands, V.V. DOBROVITSKI, Ames Laboratory, USDOE — High-fidelity quantum control and dynamical decoupling of the NV center in diamond has been recently demonstrated [1]. Efficiently manipulating the spin bath of nitrogen atoms (P1 centers) can add new freedom to the control of NV centers, and can map out the properties of the bath. However, the electron spins of P1 centers have a broad spectrum, and it is difficult to implement accurate rotations uniformly over the whole spectrum. We show that the adiabatic pulses (AP) provide an efficient tool for the bath control. The internal bath dynamics imposes very moderate limitations on the AP parameters so that P1 centers can be controlled with good ($> 90\%$) fidelities. The shape of AP can be tailored to the spectral density of the bath for optimized performance. We show how, by manipulating P1 centers, spin echo and dynamical decoupling of the NV center can be achieved in efficient manner.

10:12AM P15.00008 Nanofabrication of single spins and spin arrays in diamond[1]

, D.M. TOYLI, G.D. FUCHS, D.J. CHRISTLE, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA, C.D. WEIS, T. SCHENKEL, Lawrence Berkeley National Laboratory, Berkeley, CA — The properties of isolated nitrogen vacancy (NV) centers in diamond make them a promising solid-state qubit candidate for spin-based quantum information processing. However, scaling this system to multi-qubit NV center devices requires methods to accurately place single NV centers in pure diamond substrates. To address this challenge we have developed a method for fabricating single NV centers on 50 nm length scales based on ion implantation and electron beam lithography.[2] Secondary ion mass spectroscopy measurements facilitate depth profiling of the implanted nitrogen to provide three-dimensional characterization of the NV center spatial distribution. Finally, electron spin resonance measurements of single NV centers, including temperature-dependent spin coherence measurements, suggest a pathway for optimizing single spin coherence in future devices.

10:24AM P15.00009 Nuclear spin diffusion in semiconductor quantum wells[1] , IONEL TIFREA, TOM D. KIM, Cal State Fullerton — We analyze the nuclear spin diffusion effect in semiconductor quantum wells in connection with dynamical nuclear polarization under optical pumping. The natural confinement provided by the particular geometry of quantum well structures is responsible for a position dependent nuclear spin relaxation time and a reduced nuclear spin diffusion. In particular, we consider the case of GaAs quantum wells within GaAlAs barriers and analyze the nuclear spin diffusion for As nuclei. Our results, obtained for different nuclear spin diffusion constants, show that nuclear spin diffusion has a relatively small effect on the overall polarization of As nuclei in these structures.

[1]The authors would like to acknowledge finacial support from Research Corporation.

10:36AM P15.00010 Single-shot electrical readout of an ensemble nuclear spin memory in silicon , DANE R. MCCAMEY, School of Physics, University of Sydney, J. VAN TOL, National High Magnetic Field Laboratory, Florida State University, G. W. MORLEY, London Centre for Nanotechnology and Department of Physics and Astronomy, University College London, C. BOEHME, Department of Physics and Astronomy, University of Utah — Storing information in spin is widely recognized as a promising technological driver. However, the ability to interact with, and thus control electron spin implies a reasonable coupling to the environment, and thus a limited spin lifetime. This problem can be overcome by using nuclear spins for long term information storage even though mapping nuclear spin information onto device currents has remained challenging. Here, we report on an electrically readable nuclear spin memory implemented using phosphorus donors in silicon [1]. Donor electron spins can be used to encode logical information, which is then transferred to the nuclei. The state can be stored in the nuclear spin and then read out electrically via the hyperfine coupling with the electron. We show that information can be stored in the nuclear spin for longer than 100 seconds, that the information can be read back single shot, and that repetitive measurement does not degrade the stored information. Other nuclei, such as the spin 1/2 ^{29}Si, can also be used, pointing to the possibility of a nuclear spin memory register. [1] D. R. McCamey, J. van Tol, G. W. Morley and C. Boehme. Science, in press (2010)

10:48AM P15.00011 Nuclear spin phase transition in the presence of interacting two-dimensional electrons , ROBERT ŻAK, University of Basel, DMITRII MASLOV, University of Florida, DANIEL LOSS, University of Basel — The recent study of the RKKY interaction between localized moments, e.g., nuclear spins of Ga and As atoms in a GaAs heterostructure, mediated by interacting two-dimensional electrons, has shown a possibility of polarizing nuclear spins at currently accessible temperatures [1]. This ferromagnetic phase transition is governed by: (i) anisotropy of the electron spin susceptibility, χ, in the presence of Rashba spin-orbit interaction (RSOI) and (ii) nonanalyticity in momentum dependence of χ. In this talk I will argue that on top of the anisotropy in χ caused by the RSOI at zero momentum [2], the momentum dependence of χ is anisotropic itself: while the linear scaling of χ_{zz} with momentum saturates at the energy scale set by the RSOI, that of the $\chi_{xx} = \chi_{yy}$ continues through this energy scale (in this way it resembles the temperature and magnetic field dependence of χ in the presence of the RSOI [2]). The effect of the renormalization of the backscattering amplitude in the Cooper channel will be taken into account as well. In the end I will elaborate on possible implications of our results for the stability and nature of the nuclear spin ordered phase. References: [1] P. Simon and D. Loss, PRL **98**, 156401 (2007), P. Session P16 DMP GMAG: Focus Session: Magnetic Nanostructures, Vortices & Domain Walls

D173

8:00AM P16.00001 Tuneable remote pinning of domain walls in magnetic nanowires , L. O'BRIEN, University of Cambridge, D.E. READ, J. SAMPAIO, Imperial College London, D. PETIT, University of Cambridge, E.R. LEWIS, Imperial College London, A.-V. JAUSOVEC, H.T. ZENG, Imperial College London, R.P. COWBURN, University of Cambridge — Domain wall (DW) motion in ferromagnetic nanowires has received much attention for its potential technological applications and for probing fundamental physics. The role of DW pinning in nanowires is crucial for these investigations however it is in general a complex process. Distortions of the DW shape make quantitative agreement between modelling and experiment difficult. Here we demonstrate pinning using nanometre scale localised stray fields. This type of interaction gives well characterised, tailorable potential landscapes that do not appreciably distort the DW. Our experimental results are in excellent quantitative agreement with an Arrhenius-Néel model of depinning - a result only possible when the modelled potential profile agrees fully with that experienced by the DW.

8:12AM P16.00002 Measurements of nanoscale domain wall flexing in a ferromagnetic thin film , A.L. BALK, Physics Dept., Penn State University, University Park PA 16802, M.E. NOWAKOWSKI, Physics Dept., University of California, Santa Barbara CA 93106, M.J. WILSON, D.S. RENCH, P. SCHIFFER, Physics Dept., Penn State University, University Park PA 16802, D.D. AWSCHALOM, Physics Dept., University of California, Santa Barbara CA 93106, N. SAMARTH, Physics Dept., Penn State University, University Park PA 16802 — We use the anomalous Hall effect to probe the nanoscale behavior of a single magnetic domain wall (DW) in (Ga,Mn)As thin film devices with out-of-plane magnetic anisotropy. Video-rate magneto-optical Kerr microscopy is also used to confirm the variation of the AHE with DW position. Our all-electrical technique allows us to observe a low field flexing regime of DW motion, distinct from the stochastic creep regime that occurs at higher fields. This flexing regime is characterized by a larger DW mobility, linear response to applied field, and non-hysteretic motion which is repeatable within our ~ 5 nm experimental resolution. We then analyze the flexing and depinning behavior of the DW to estimate the density and strength of pinning sites. Supported by the ONR MURI program.

8:24AM P16.00003 Observation of two step magnetization reversal in $Fe_0.25TaS_2$, S. PARK, Department of Physics, Chung-Ang University-Seoul, South Korea, S.B. KIM, Laboratory of Pohang Emergent Materials and Department of Physics, Pohang University of Science and Technology - Pohang, South Korea, Y.J. CHOI, Y. HORIBE, S-W. CHEONG, WEIDA WU, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, Piscataway, NJ, 08854, USA — Understanding magnetic coercivity mechanisms in strong ferromagnets is crucial for new technologies. We studied domain wall pinning in a highly anisotropic ferromagnet of single crystalline $Fe_0.25TaS_2$ by utilizing variable temperature magnetic force microscopy (VT-MFM). Magnetic domain structure and the magnetization reversal were investigated in magnetic fields up to 8 tesla at several temperature. Our results revealed the existence of two step magnetization reversal in $Fe_0.25TaS_2$. The real space images of magnetic domains, showing this intriguing phenomenon, will be presented.

8:36AM P16.00004 Measurement of Annihilation Barriers for Magnetic Vortices[1] , JACOB BURGESS, University of Alberta and National Institute for Nanotechnology, DAVID FORTIN, University of Alberta, JOE LOSBY, University of Alberta and National Institute for Nanotechnology, DENYS GROMBACHER, JOHN DAVIS, University of Alberta, MARK FREEMAN, University of Alberta and National Institute for Nanotechnology — Measurements of the susceptibility of an array of 2 micrometer diameter Permalloy discs are made using the AC magneto-optical Kerr effect. Employing an extended version of the rigid vortex model, saturation magnetization as a function of temperature is extracted from the data. The model also allows extraction of the switching distribution of the array as the discs transition from the vortex state to the quasi single-domain state. Tuning of temperature or sweep rate shows shifts in the distribution peak that confirm vortex annihilation is governed by a thermally activated mechanism. Using the measured saturation magnetization data in conjunction with the measured peak shifts, quantitative extraction of energetic parameters used in semi-empirical models of the annihilation energy barrier is possible. Several models are considered in the context of qualitative observations made in the experiment.

8:48AM P16.00005 Pinning Mechanisms for Vortices in Ferromagnetic Films , TE-YU CHEN, MICHAEL ERICKSON, CHRIS LEIGHTON, PAUL CROWELL, University of Minnesota — In ferromagnetic materials, domain wall motion is generally discontinuous and stochastic in the presence of pinning sites. The pinning energy is typically quantified via a single experimental parameter - the coercivity of the hysteresis loop. We show here that in magnetic structures supporting a vortex, the vortex dynamics provide quantitative information about both the strength and range of the interaction between the vortex and individual pinning sites. Using time-resolved Kerr microscopy, we have measured the defect-induced pinning energy and length scales for magnetic vortices in micron-sized NiFe disks. We find that the pinning length scale matches the size of vortex core, and is insensitive to film thickness and growth conditions. This suggests that the dominant mechanism of vortex pinning is directly associated with the core region. The pinning energy however, is strongly dependent on microstructure. Specifically, we observe large pinning energies in NiFe films that have large roughness on lateral length scales commensurate with the core size (10 nm). The dependence of pinning energy on thickness provides further insight into the relative role of surface roughness versus bulk disorder. The strength as well as the spatial distribution of pinning sites suggest that roughness at this length scale is the dominant source of pinning in these films.

9:00AM P16.00006 Enhanced current-induced domain wall motion by tuning perpendicular magnetic anisotropy , SATORU EMORI, GEOFFREY BEACH, Department of Materials Science and Engineering, Massachusetts Institute of Technology — The effect of perpendicular magnetic anisotropy (PMA) on current-induced domain wall (DW) motion is investigated by micromagnetic simulations. The critical current density Jc to drive DWs into periodic transformation and continuous motion by adiabatic spin transfer torque decreases with increasing PMA. Also, with optimized PMA that almost exactly compensates the demagnetizing field, the adiabatic displacement of DWs driven by currents less than Jc is strongly enhanced. Since PMA can be controlled easily in multilayer films (e.g. Co/Pt), this technique of enhancing current-induced DW motion may be practical for device applications.

9:12AM P16.00007 Geometrically Confined Spin Vortices: from Fundamental Physics to Biomedical Applications , VALENTYN NOVOSAD, Argonne National Laboratory — The magnetic ground state of magnetically soft thin film ferromagnets in confined geometries (on the micrometer scale) consists of a curling spin configuration, known as a magnetic vortex state. We have recently demonstrated that the magnetic vortex microdisks can be successfully used as multifunctional magnetic carriers for biomedicine [1]. In particular, we will report on successful interfacing of ferromagnetic nanomaterials with a spin vortex ground state and biomaterials (antibody, whole cell). Namely, the gold-coated lithographically defined microdisks with an Fe-Ni magnetic core were biofunctionalized with anti-human-IL13a2R antibody for specifically targeting human glioblastoma cells. When an alternating magnetic field is applied the vortices shift, leading to the microdisks oscillation that causes a mechanical force to be transmitted to the cell. Cytotoxicity assays, along with optical and atomic force microscopy studies, show that the spin vortex-mediated stimulus creates two dramatic effects: (a) membrane disturbance and compromising, and (b) cellular signal transduction and amplification, leading to robust DNA fragmentation and, finally, programmed cell death [2]. The experiments reveals that by employing biofunctionalized magnetic vortex microdisks the magnetic fields of low frequency of a few tens of Hz and of small amplitude of < 100 Oe applied during only 10 minutes was sufficient to achieve $\sim$90% cancer cells destruction.

9:48AM P16.00008 Fast transport of superparamagnetic beads by field-driven magnetic domain walls , ELIZABETH RAPOPORT, GEOFFREY BEACH, Massachusetts Institute of Technology — The manipulation of superparamagnetic (SPM) beads with magnetic domain walls (DWs) is of interest for biomedical applications [1, 2]. We present data supporting fast, continuous transport of SPM beads by field-driven DWs along straight magnetic nanowires. If the magnetostatic binding force (F_b) between a DW and an SPM bead exceeds the Zeeman force (F_Z) from a driving field, DW velocity is limited by the hydrodynamic drag force on the bead [3], and a wall-bead pair can be propelled at high speeds. We have combined micromagnetic simulations and numerical calculations to determine F_b, covering the parameter space of bead radius, wire width and thickness, and domain wall type. Comparing F_b and F_Z for different applied fields, we find that the field, H_{crit}, at which the Zeeman force separates the wall from the bead, is maximized by the same wire width, independent of bead size. Optimal conditions for continuous bead transport are achieved with 150 nm wide wires, which can transport 500 nm radius beads in driving fields up to 90 Oe, corresponding to transport velocities of up to 8 mm/s. These results suggest that fast, long-distance transport of SPM beads is possible using simple linear magnetic guide-wire structures. [1] M. Donolato, et al., Nanotechnology 20 (2009) [2] G. Vieira et al., Phys. Rev. Lett. 103, 128101 (2009) [3] M.T. Bryan et al., Appl. Phys. Lett. 96,192503 (2010)

10:00AM P16.00009 Domain wall pinning in magnetic structures with perpendicular magnetic anisotropy[1] , DANIEL GOPMAN, DANIEL BEDAU, New York University, S. PARK, DAFINE RAVELOSONA, Institut d'Electronique Fondamentale, Université Paris Sud, Orsay, France, ANDREW KENT, New York University — An experimental technique has been designed to trap domain walls in ferromagnetic nanostructures. Spin valve nanowires and nanopillars with perpendicularly magnetized free and reference layers were engineered with lithographically defined notches of varying depths and lengths. The influence of notch geometry in domain wall pinning has been compared with intrinsic domain wall pinning sites. Thermally activated jumping between metastable states has been observed under rf excitation along with telegraph noise. Coercive fields have been determined to vary linearly with applied direct currents.

10:12AM P16.00010 Breather states in magnetic domain wall racetrack memory samples , JOHN EVES, REMO HUGLI, NAOISE GRISEWOOD, BENI BRAUN, UCD — Proposed magnetic domain wall(DW) racetrack memory [1] exploits controlled motion of magnetic DWs along magnetic nanowires, and the sequence of DWs encodes the bit states. Here we investigate the possibility of the existence of dynamically bound states of pairs of DWs. We show that by the choice of suitable initial conditions for two DWs in a racetrack geometry, such dynamical states can be prepared by a suitable applied field. The breather states correspond to two DWs which have the same chirality and which oscillate around their common center of mass.

10:24AM P16.00011 Reversible helicity and higher harmonics in spin textures: stripes and skyrmions , XIUZHEN YU, Japan Science and Technology Agency(JST), YUSUKE TOKUNAGA, YOSHIO KANEKO, JST, YOSHIO MATSUI, National Institute for Materials Science, YOSHINORI TOKURA, Tokyo Univ., JST and RIKEN — The magnetic bubbles viewed as skyrmions have long been attracting attention because of possible application to spintronics. The bubble configuration has been revealed by versatile microscopic techniques such as magnetic-force microscopy, scanning Hall microscopy, and Lorentz transmission electron microscopy (TEM). However, their topological properties, such as topological spin texture and helicity, have not been sufficiently unraveled in spite of possibly important implication in the novel magneto-transport phenomena. In this study, we have scrutinized the spin texture of the thin films of Sc-doped hexagonal barium ferrite with controlled magnetic anisotropy; we have demonstrated the generation of the bubble lattice under external magnetic fields which are applied perpendicular to the film plane. The magnetic component distributions in strips, bubbles and Bloch lines have been successfully achieved by means of high-resolution Lorentz TEM observations and quantitative analyses of the local magnetizations. The results indicate the reversible helicity and higher harmonics in spin textures of stripy and bubble domains.

10:36AM P16.00012 Domain Growth Behavior in the Compressible Ising Model[1] , MENG MENG, DAVID LANDAU, Center for Simulational Physics, University of Georgia — We perform large scale Monte Carlo simulations to study long-time domain growth behavior in a compressible, spin-exchange, two-dimensional triangular-lattice Ising model with continuous particle positions and zero total magnetization. To investigate the effects of compressibility on domain growth behavior, we include an elastic energy term in the Hamiltonian of our model to adjust the rigidity. The system is quenched below the critical temperature from a homogenous disordered state to an ordered phase where multiple domains coexist. Theory expects the domain size $R(t)$ grow as a power law $R(t) = A + Bt^n$, where t is the time after quench, and n is the domain growth exponent. Lifshitz and Slyozov have predicted n to be $\frac{1}{3}$ at late-time, but earlier studies[2] suggested that n could be affected by compressibility. We observe the domain growth exponent to be significantly smaller than the Lifshitz-Slyozov value of $n = \frac{1}{3}$.

Session P17 DMP GMAG: Focus Session: Bulk Properties of Complex Oxides - 3d Oxides D174

8:00AM P17.00001 Surprises in low dimensional spin 1/2 magnets - from crystal chemistry to microscopic magnetic models of complex oxides , HELGE ROSNER, MPI CPfS Dresden — A microscopic understanding of the structure-properties relation in crystalline materials is a main goal of modern solid state chemistry and physics. Due to their peculiar magnetism, low dimensional spin 1/2 systems are often highly sensitive to structural details. Seemingly unimportant structural details can be crucial for the magnetic ground state of a compound, especially in the case of competing interactions, frustration and near-degeneracy. Here, we present for selected, complex Cu^{2+} systems that a first principles based approach can reliably provide the correct magnetic model, especially in cases where the interpretation of experimental data meets serious difficulties or fails. We demonstrate that the magnetism of low dimensional insulators crucially depends on the magnetically active orbitals which are determined by details of the ligand field of the magnetic cation. Our theoretical results are in very good agreement with thermodynamic and spectroscopic data and provide deep microscopic insight into topical low dimensional magnets.

8:36AM P17.00002 Spin Waves and Magnetic Interaction in the Multiferroic Antiferromagnet MnWO4 , J.A. FERNANDEZ-BACA, FENG YE, ORNL, R.S. FISHMAN, A. PODLESNYAK, G. EHLERS, H.A. MOOK, ORNL, Y.Q. WANG, B. LORENZ, C.W. CHU, Univ of Houston — The spin wave excitations of the multiferroic MnWO4 have been measured in the low-temperature collinear commensurate phase using high-resolution inelastic scattering. The spin excitations can be well described by a Heisenberg model with competing exchange interactions up to 11th nearest neighbors. We find the magnetic exchange couplings are highly frustrated within each zigzag spin chain along c-axis and between chains along the a-axis. However, the magnetic interactions are much weaker between chains along the b-axis. Our measurements suggest that the delicate balance of long range magnetic couplings is subject to small perturbations that can lead to a complex magnetic configuration exhibiting magnetoelectric behavior.

8:48AM P17.00003 Field-induced slow spin relaxation in monoclinic $Nd_2Ti_2O_7$ single crystals[1] , HUI XING, Department of Physics, Zhejiang University, GEN LONG, Department of Physics, SUNY at Buffalo, HANJIE GUO, CHUNMU FENG, GUANGHAN CAO, Zhejiang University, HAO ZENG, SUNY at Buffalo, ZHUAN XU, Zhejiang University — We report the ac susceptibility measurement in the paramagnetic state of the monoclinic $Nd_2Ti_2O_7$ single crystals. An unexpected slow spin relaxation is observed in the presence of a nonzero magnetic field. Such behavior is absent in zero field. Distinct features of the relaxation, including the intrinsic frequency on the order of 1 Hz, the field-, temperature- and spin dilution dependence, and its evolution under positive and negative pressures, indicate that the relaxation is associated with an unusual cooperative behavior involving spin correlations.

9:00AM P17.00004 The d-band manifold in $SrTiO_3$: high mobility Shubnikov–de Haas effect in magnetic fields to the quantum limit. , S. JAMES ALLEN, Physics Dept., BHARAT JALAN, Materials Dept., UCSB, GURU KHALSA, ALLAN MACDONALD, Physics Dept., UT Austin, JAN JAROSZYNSKI, National High Magnetic Field Lab, FSU, SUSANNE STEMMER, Materials Dept., UCSB — The molecular beam epitaxial growth of high mobility ($>$ 30,000 cm^2/volt.sec), low electron density ($\sim 10^{17}$ - $10^{18} cm^{-3}$) La doped $SrTiO_3$ has provided an opportunity to explore the lowest conduction band states, which are derived from the Ti d-band. Despite the long history of experiments on these d-band states, including magneto transport, we are left without a firm quantitative model of the manifold at the conduction band minimum. But, these states form the basis of quantum confined 2D electron systems at oxide interfaces with $SrTiO_3$ and delta doped layers, both the subject of current interest. To remedy this, we have performed magneto transport at temperatures down to $\sim$ 0.4 K, in magnetic fields to 31 Tesla, which is sufficient to reach the quantum limit, in high mobility samples and with carrier densities that tune the Fermi energy through the energy splitting caused by the low temperature tetragonal distortion. In close analogy to hole states in conventional semiconductors, we use 5 "Luttinger" parameters and the splitting energy, to describe these results and compare with the current understanding of the $SrTiO_3$ d-band structure.

9:12AM P17.00005 Low Energy Conduction Band Structure of SrTiO3 , GURU KHALSA, Department of Physics - University of Texas at Austin, BHARAT JALAN, Materials Department, UCSB, S. JAMES ALLEN, Department of Physics - UCSB, SUSANNE STEMMER, Materials Department, UCSB, ALLAN MACDONALD, Department of Physics - University of Texas at Austin — The recent observation of a high mobility 2DEG, and truly two-dimensional superconductor, at oxide interfaces with SrTiO3 (STO) and in delta-doped layers of STO have thus far gone without a clear theoretical description. The starting point for any quantitative theory of these systems is a reliable low energy parameterization of the Ti d-band in the bulk parent compound. Here we present a five parameter symmetry constrained model of the t2g band in STO near the conduction band minimum. We use this model to describe a recent high field (up to 31 Tesla), low temperature, angular magneto-transport study of lightly La doped STO and compare our results with other available experimental data. We will also discuss the relation between orbital density and matrix element effects in photoemission experiments of d0 Perovskites.

9:24AM P17.00006 ABSTRACT WITHDRAWN –

9:36AM P17.00007 Unconventional Electronic Transport in Doped $SrTiO_3$, C. LEIGHTON, A. SPINELLI, M.A. TORIJA, C. LIU, C. JAN, University of Minnesota — Resistivity, Hall effect, and magnetoresistance are reported on a large set of semiconducting $SrTiO_{3-\delta}$ single crystals doped n-type (by reduction or Nb substitution) over a broad range of carrier density (10^{15} to $>10^{20}$ cm^{-3}). Temperature-independent densities, strongly temperature-dependent mobilities (up to 22,000 $cm^2V^{-1}s^{-1}$ at 4.2 K), and a remarkably low critical carrier density for the metal-insulator transition are observed, and interpreted in terms of the quantum paraelectricity of the host. We argue that an unusual, high mobility, low density, metallic state is thus established at carrier densities at least as low as 8.5 x 10^{15} cm^{-3}. At low temperatures the temperature dependence of the mobility and resistivity exhibit a non-monotonic carrier density dependence and an abrupt change in character near 2 x 10^{16} cm^{-3}, indicating a distinct crossover in conduction mechanism, perhaps associated with a transition from impurity band to conduction band transport. The results provide a simple framework for the understanding of the global transport behavior, and suggest some potential applications. Work supported by NSF.

9:48AM P17.00008 Pseudogap in metallic layered nickelate $R_{2-x}Sr_xNiO_4$, MASAKI UCHIDA, K. ISHIZAKA, Y. ISHIDA, Y. ONOSE, R. ARITA, S. SHIN, Y. TOKURA, University of Tokyo, P. HANSMANN, A. TOSCHI, K. HELD, Vienna University of Technology, Y. KANEKO, ERATO-MF, X. YANG, O.K. ANDERSEN, Max-Planck-Institut, R. KUMAI, AIST — We have investigated charge dynamics and electronic structures for single crystals of metallic layered nickelates $R_{2-x}Sr_xNiO_4$. Angle-resolved photoemission spectroscopy (ARPES) on the barely-metallic $Eu_{0.9}Sr_{1.1}NiO_4$ has revealed a large hole surface of x^2-y^2 character with a high-energy pseudogap of the same symmetry and comparable magnitude with those of underdoped cuprates, although the antiferromagnetic interactions are one order of magnitude smaller. Our findings strongly indicate that the high-energy momentum-dependent pseudogap (or Fermi arc) is not unique to the high-T_c cuprates but commonly develops in the anomalous quasi-two-dimensional metallic state near the Mott transition reflecting the real-space charge correlation.

10:00AM P17.00009 Density wave driven metal-insulator transition in nickelates , SUNGBIN LEE, RU CHEN, University of California, Santa Barbara, LEON BALENTS, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, BALENTS GROUP TEAM — The Mott transition in nickelates, RNiO3, shows unusual magnetic ordering and charge ordering in the insulating phase. For the more itinerant nickelates, one may argue that these unusual density waves are actually driven by Fermi-surface nesting, originated from the large flat regions of Fermi surfaces. Using a tight-binding model of the band derived from doubly degenerate eg orbitals, we obtain the density wave induced metal- insulator transition phase diagram in the presence of on-site Coulomb interaction and Hund's coupling, treated in Hartree-Fock approximation. Furthermore, motivated by recent success in layer by layer growth of nickelates, the thin film effects in nickelates are also studied. Finally we calculate the optical conductivity for the various states in our phase diagram, suggesting experimental measurements to check the theory.

10:12AM P17.00010 Molecular correlated insulating state in low-valence layered nickelates , VICTOR PARDO, WARREN E. PICKETT, University of California Davis — In recent years, there has been an effort on artificially creating Fermi surfaces that resemble those of the superconducting cuprates. A Ni^{3+}:d^7 (one e_g electron) configuration can be made into the electron-like analog of the d^9 (one e_g hole) cuprate electronic structure.[1] Another cleaner alternative would be to grow low-valence Ni^{+}:d^9 compounds, which have recently become available through synthesis[2] of members of the series $La_{n+1}Ni_nO_{2n+2}$. We present LDA+U calculations on the layered compounds $La_4Ni_3O_8$ [3] and $La_3Ni_2O_6$, with three and two NiO_2 layers, respectively. Electron count implies very low Ni formal valencies: 1.33+ and 1.5+, respectively. If charge order is present, Ni^{+}:d^9 could occur in a geometry similar to that of the cuprates. However, this is not the case. Both compounds are insulators, which we can attribute to quantum confinement in the NiO_2 tri/bi-layers. The only states close to the Fermi level are Ni $d_{3z^2-r^2}$, which couple along the c-axis (Ni trimers or dimers). The insulating behavior must be viewed from a molecular orbital viewpoint, after AFM order within layers has narrowed the bands. Insulating behavior is that of a "molecular" Mott insulator rather than a charge-ordered insulator.

10:24AM P17.00011 Search for structural fluctuations in the disordered stripe state of $Nd_{1:67}Sr_{0:33}NiO_4$[1] , A.M. MILINDA ABEYKOON, EMIL BOZIN, GENDA GU, JOHN HILL, JOHN TRANQUADA, SIMON BILLINGE, Brookhaven National Laboratory — We present a temperature series PDF and a Rietveld analysis of $Nd_{1:67}Sr_{0:33}NiO_4$ system to study the local structural response in the state above the charge-ordered state that has not been characterized in detail to date. We observed NiO_6 octahedral tilting patterns of different magnitude for short and long-range structure of the system. A sequential Rietveld refinement, and a T-series PDF analysis on the length scale (5-20)Å were carried out to characterize the long-range order of the system. A PDF analysis on the length scale (0-4.2) Å revealed a different magnitude local octahedral tilt pattern as a function of temperature. The correlation length of short-range ordered charge stripes existing above T_{co} was estimated using a Box-Car type PDF model. Combining this information with the refined isothermal atomic displacement parameters (ADPs) yields a much more complete picture of the nature of both atomic displacements and how they are correlated with each other in the system.

10:36AM P17.00012 Lattice normal modes and electronic properties of the correlated metal $LaNiO_3$, GAOYANG GOU, The Makineni Theoretical Laboratories, Department of Chemistry, University of Pennsylvania, Philadelphia, PA 19104, USA, JAMES RONDINELLI, X-Ray Science Division, Argonne National Laboratory, Argonne, IL 60439, USA, ILYA GRINBERG, ANDREW RAPPE, The Makineni Theoretical Laboratories, Department of Chemistry, University of Pennsylvania, Philadelphia, PA 19104, USA — We present results from density functional calculations of lattice vibrations and electronic properties of the correlated metal $LaNiO_3$. Using the landau theory of phase transitions and *ab initio* derived phenomenological coefficients obtained from local-spin density approximation (LSDA) calculation, we examine the evolution of the Raman-active phonon modes with temperature and find that the LSDA results give excellent agreement with experiments. To study the electronic structure of $LaNiO_3$, we extend to the post-LSDA functional methods, including the local spin density+Hubbard U (LSDA+U) method, and two hybrid exchange-correlation functionals, PBE0 and HSE. By comparing the results obtained from the various functionals with the experimental photoelectron spectroscopy (PES) and X-ray photoelectron spectroscopy (XPS) data, we argue that the screening effect coming from the delocalized O-2p and Ni-t_{2g} electrons will be strong enough to reduce the electron correlation of $LaNiO_3$.

10:48AM P17.00013 Time-Dependent Recovery of Charge and Spin Order in Stripe-Ordered Nickelates[1] , Y.F. KUNG, A.F. KEMPER, W.-S. LEE, B. MORITZ, A.P. SORINI, Z.-X. SHEN, T.P. DEVEREAUX, Stanford Institute for Materials and Energy Science, SLAC National Accelerator Laboratory and Stanford University — Using time-dependent Ginzburg-Landau theory, we study the melting and recovery of charge and spin order in striped nickelates ($La_{2-x}Sr_xNiO_4$) in response to an ultrashort pump pulse that destroys the order. We find that the critical temperature for onset of spin order varies with increasing coupling between charge and spin order. Solving the Gross-Pitaevskii equations to model the time evolution, we explore the temporal dynamics of charge and spin order parameters, to be compared to experimental observations at LCLS.

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P18 GMAG DMP: Focus Session: Low D/Frustrated Magnetism - Triangular Lattices

D172

8:00AM P18.00001 Neutron Scattering Studies of the S=1/2 Triangular Lattice Magnets $NaNiO_2$ and $LiNiO_2$, J. PATRICK CLANCY, McMaster University — $NaNiO_2$ and $LiNiO_2$ are isostructural quantum magnets based on a stacked triangular lattice in which magnetism arises from S=1/2 magnetic moments carried by Ni^{3+} ions. Surprisingly, while these compounds are structurally and electronically very similar, the magnetic properties they exhibit are dramatically different. $NaNiO_2$ undergoes a cooperative Jahn-Teller phase transition at 480K and magnetically orders below $T_N \sim 23$K, adopting a structure which consists of ferromagnetic sheets of S=1/2 moments stacked in an antiferromagnetic fashion. In contrast, $LiNiO_2$ undergoes a spin glass transition at $T_g \sim 9$K and remains disordered down to the lowest measured temperatures. Understanding the absence of long-range magnetic order in $LiNiO_2$ is a problem which has attracted considerable interest for more than twenty five years. Among many potential explanations, the answer has most notably been attributed to geometric frustration caused by inherent mixing of the Li and Ni sublattices, or orbital degeneracy resulting from the lack of a coherent Jahn-Teller distortion. In this talk I will describe time-of-flight neutron scattering measurements performed on polycrystalline samples of $NaNiO_2$ and $LiNiO_2$ using the wide Angular-Range Chopper Spectrometer (ARCS) at ORNL and the Disk Chopper Spectrometer (DCS) at NIST. These measurements provide a thorough characterization of the excitation spectra for these two compounds, probing the inelastic scattering over energy scales ranging from $\sim$ 0.1 meV to 1.5 eV. In $NaNiO_2$, our measurements reveal two sets of well-defined spin excitations, which we associate with ferromagnetic spin waves mediated by in-plane interactions and antiferromagnetic spin waves mediated by out-of-plane interactions. In $LiNiO_2$, we observe similar, albeit much broader, excitations consistent with short-range two-dimensional magnetic correlations. In the case of $NaNiO_2$, we have developed a simple linear spin wave theory model to describe these excitations and extract the relevant magnetic exchange couplings for this system.

8:36AM P18.00002 Magnetic order and glassiness in distorted triangular lattice materials, $Cu_{2(1-x)}Zn_{2x}(OH)_3NO_3/(C_7H_{15}COO)$, JIAN WU, FLETCHER WERNER, JULIA S. WILDEBOER, ALEXANDER SEIDEL, ZOHAR NUSSINOV, S.A. SOLIN, Washington University in St. Louis — We have synthesized two series of distorted triangular lattice materials $Cu_{2(1-x)}Zn_{2x}(OH)_3M$, where M = NO_3^- or $C_7H_{15}COO^-$, by hydrothermal reaction. The powder X-ray diffraction measurements show that the substitution of Zn for Cu leads to a series of isostructural doped compounds [1]. The $C_7H_{15}COO^-$ long chain intercalated samples display a series of intense (00*l*) reflections, which signals their enhanced 2D structures with an almost doping-independent interlayer distance 24.2Å. In the DC magnetic susceptibility data for all NO_3^- samples, we observe clear evidence of transitions from a paramagnetic to antiferromagnet phase. The onset of long-range order is further proven by the prominent features in specific heat data. However, all the long chain intercalated samples were found to display several spin-glass-like behaviors. A clear bifurcation between the ZFC and FC data was observed at T $<$ 15K. The time evolution of isothermal remnant magnetization M_{ZFC}(t) has a linear dependence on $\ln(t)$. No peak features or broad maximum have been discovered in the specific heat measurements. Further analysis of the above results suggest that the long chain intercalated samples are cluster spin glasses at low temperature.

8:48AM P18.00003 Spin glassiness and power law scaling in anisotropic triangular spin-1/2 antiferromagnets , ALEXANDER SEIDEL, JIAN WU, JULIA S. WILDEBOER, FLETCHER WERNER, ZOHAR NUSSINOV, S.A. SOLIN, Washington University in St. Louis — We discuss the magnetic properties of a class of spin $S = 1/2$ antiferromagnetic quasi-triangular lattice materials, both in the clean limit and in the presence of non-magnetic Zn impurities. These systems are long organic chain intercalated derivatives of copper hydroxy nitrate, with a very large c-axis separation of 24Å. In these compounds, we find that a spin glass phase is universally preceded by two different power law regimes in the temperature dependence of the DC magnetic susceptibility, separated by a sharp crossover. This is seen both in the presence as well as in the absence of non-magnetic Zn impurities, where the power law exponents are surprisingly unperturbed by the compositional disorder. We argue that these findings may be consistent with a picture based on a self-generated spin glass in the clean undoped compound, where frustration is the driving mechanism of the glassiness rather than disorder. While AC measurements and time dependent magnetization follow traditional spin glass paradigms, the power law structure found in the DC susceptibility is argued to deviate in various ways from scenarios expected based on Griffiths type physics, and may call for new explanations. [1] J. Wu et al., J. Phys. Condens. Matter, 22, 334211 (2010). [2] J. Wu et al., arXiv:1007.0442

9:00AM P18.00004 Competing interactions and continuum excitations in the spin-1 triangular lattice antiferromagnet $NiGa_2S_4$[1] , J. WEN, IQM, Johns Hopkins Univ, USA, Y. NAMBU, ISSP, Univ. of Tokyo, Japan, J. RODRIGUEZ, C. STOCK, NCNR, NIST, USA, S. NAKATSUJI, ISSP, Univ. of Tokyo, Japan, S. ONODA, RIKEN, Japan, Y. MAENO, Kyoto Univ., Japan, C. BROHOLM, IQM, Johns Hopkins Univ, USA — In some geometrically frustrated magnets, conventional long range order is replaced by static or dynamic short range order. Quasi-2D $NiGa_2S_4$ is the only known S=1 antiferromagnet with an exact triangular lattice. Recent neutron scattering experiment on high quality $NiGa_2S_4$single crystals revealed short range quasi-2D incommensurate spin correlation with a critical wavevector close to (1/6, 1/6, 0) [1]. Here we report a measurement of the dynamic spin correlation function through a volume of **Q**-E space for T<<J. A gapless spectrum was observed at the incommensurate critical wavevector while a softened but still gapped response was found at (1/3, 1/3, 0). This indicates dominant third nearest neighbor interaction and competing weaker near neighbor interactions. The excitation spectrum takes the form of a bounded continuum throughout the 2D Brillouin zone. The temperature dependence dynamic correlation length shows that short range correlation persist up to Θ_{cw}=-80(2)K.

9:12AM P18.00005 Quantum Antiferromagnet on an Anisotropic Triangular Lattice , SEDIGH GHAMARI, CATHERINE KALLIN, SUNG-SIK LEE, McMaster University — The effects of quantum fluctuations on the spin 1/2 Heisenberg antiferromagnet on a triangular lattice, with diagonal interchain exchange J' weaker than the intrachain exchange J, are studied. This model is of considerable interest because of its relevance to Cs2CuCl4, where experiments have been interpreted as evidence for a nearby two-dimensional spin liquid and because numerous theoretical studies have proposed that the incommensurate spiral spin density wave order is destroyed by quantum fluctuations well before the one-dimensional limit (J'=0) is reached.

9:24AM P18.00006 ESR as a probe of spinon excitations of the spin-1/2 antiferromagnet Cs_2CuCl_4 , K. POVAROV, A. SMIRNOV, Kapitza Institute for Physical Problems RAS, O. STARYKH, University of Utah, S. PETROV, Kapitza Institute for Physical Problems RAS, A. SHAPIRO, Shubnikov Institute for Crystallography RAS — We report dramatic manifestation of the uniform Dzyaloshinskii-Moriya (DM) interaction in the ESR response of quasi-one-dimensional spin-1/2 antiferromagnet Cs_2CuCl_4. We find the ESR response in the range 10-90 GHz to be strongly sensitive to the relative orientation of the magnetic field and DM axes. Most importantly, we observe splitting of the ESR line into two lines in the paramagnetic phase, upon lowering the temperature from 10 K to 1.3 K. The latter temperature is about twice the ordering temperature $T_N = 0.62$ K, and yet far below the Curie-Weiss temperature 4 K . The splitting occurs when the static magnetic field H is aligned with one of the DM axes of the material and is absent when H is oriented perpendicular to the axes. This novel phenomenon is a consequence of the critical nature of fractionalized spinon excitations of the individual antiferromagnetic chains in the paramagnetic phase. A uniform (along the spin chain direction) DM interaction provides an effective magnetic field, the sign of which is opposite for the right- and left-moving spinons. In the presence of external magnetic field this difference translates into a pair of ESR frequencies, making the experiment a novel probe of spinon excitations.

9:36AM P18.00007 Metallic magnetization plateau on triangular lattice[1] , ZHIHAO HAO, Department of Physics and Astronomy, Johns Hopkins University, OLEG STARYKH, Department of Physics and Astronomy, University of Utah — The $1/3$ magnetization plateau is well established for spin $1/2$ Heisenberg antiferromagnetic model on triangular lattice. The state is stable against a large range of spatial anisotropies and is observed in the triangular compound Cs_2CuBr_4. A natural question to ask is whether the plateau state remains stable if the on-site repulsion U is lowered for the underlying Hubbard model. In our work, we studied the one-band Hubbard model on triangular lattice. Through mean-field calculations, it is discovered that an up-up-down spin density wave state with $1/3$ of saturation magnetization is stablized for a range of U and magnetic field h. For $4.44t \leq U \leq 4.55t$, the state is a half metal: the spin up bands remain metallic while the spin down bands are insulating. For $U > 4.55t$, the spin up bands become gapped and the system is an insulator. It is speculated the plateau state remains stable for the entire range of $U \geq 4.44t$.

9:48AM P18.00008 Phase Diagram of a Geometrically-Frustrated Triangular-Lattice Antiferromagnet in a Magnetic Field[1] , RANDY FISHMAN, Oak Ridge National Laboratory — The magnetic phase diagram of a geometrically-frustrated triangular-lattice antiferromagnet is evaluated as a function of magnetic field and anisotropy using a trial spin state built from harmonics of a fundamental ordering wavevector. A non-collinear incommensurate state, observed to be chiral and ferroelectric in $CuFeO_2$, appears above a collinear state with 4 sublattices (SLs). A previously unobserved collinear 5-SL phase may be accessible in a magnetic field for a non-stoichiometric compound with excess or deficient oxygen. The apparent absence of multiferroic behavior for predicted chiral, non-collinear 5-SL states poses a challenge to theories of the ferroelectric coupling in $CuFeO_2$.

10:00AM P18.00009 ABSTRACT WITHDRAWN —

10:12AM P18.00010 Phases of spatially anisotropic triangular antiferromagnet in high magnetic field , OLEG STARYKH, University of Utah, ANDREY CHUBUKOV, University of Wisconsin — We investigate phases of the Heisenberg spin model on a spatially anisotropic triangular lattice as a function of $J'/J < 1$ and a magnetic field H (J is the exchange along the horizontal bonds, and J' is the exchange along the diagonal bonds). The anisotropy of J's competes with quantum fluctuations and this competition leads to a rich phase diagram. Immediately below the saturation field H_s we find three phases: three-sublattice commensurate phase, incommensurate co-planar "fan" phase, and incommensurate non-coplanar "cone" phase. The former two are supersolids while the latter is a superfluid in the terminology of strongly interacting bosons. At a finite boson density ($H < H_s$) and on approach to the fan-cone phase boundary from within the cone phase with ordering momentum Q, we observe softening of the "roton" minima at momentum Q' different from $-Q$, which one would expect for a direct cone-fan transition. This points on the existence of the intermediate double-spiral state in which boson density exhibits incommensurate modulations with momenta Q and Q'. The extrapolation of our results to $H \sim H_s/3$ predicts that $Q' = Q$, and the intermediate state becomes similar to the "distorted umbrella" state that emerges out of up-up-down phase. We discuss the implications of our findings for the global phase diagram of the anisotropic triangular Heisenberg antiferromagnet.

10:24AM P18.00011 Theory of SU(2) invariant spin liquids on the triangular lattice with spinful Majorana excitations , RUDRO BISWAS, LIANG FU, CHRIS LAUMANN, SUBIR SACHDEV, Harvard — We present a theory of SU(2) invariant spin liquids on the 2D spin 1/2 triangular lattice described by a parton representation of the spin in terms of spin-1 Majorana particles. These spin liquids break time reversal symmetry and generically possess a novel Fermi surface consisting of three lines intersecting at $k = 0$ as well as an unconventional dynamic critical exponent $z = 3$. We also present calculations for observable quantities and discuss possible connections to recent experiments involving spin 1/2 Heisenberg triangular lattices.

10:36AM P18.00012 Phase Diagram of Classical Heisenberg Antiferromagnets with Four-Spin Interactions on Stacked Triangular Lattice under Magnetic field[1] , SHINTARO TAKAYOSHI, Institute for Solid State Physics, University of Tokyo, MASAHIRO SATO, Department of Physics, Aoyama-Gakuin University — Classical Heisenberg antiferromagnet (HAF) on stacked triangular lattice is a simple and important model of frustrated systems. Although there are some candidate materials for triangular HAF, they are not ideal ones and various kinds of perturbations should be present. While it is well known that the ground state of triangular HAF is 120-degree structure, how perturbations destabilize the structure has not been well studied. In this study, we consider effects of four-spin interactions on magnetic phase diagram of triangular HAF. In fact, some real mechanisms of generating four-spin interactions have been known: higher-order electron hopping processes in Mott insulators, spin-phonon couplings, etc. We complete the magnetic phase diagrams by using Monte Carlo simulation. We will report new phases induced by four-spin interactions.

[1]Grant-in-Aid for JSPS Fellows (Grant No. 09J08714)

10:48AM P18.00013 Magnetic ground state and excitation of SrV10O_{15} , JOOSEOP LEE, KAZUKI IIDA, University of Virginia, MATTHEW STONE, SNS, ORNL, MASAAKI MATSUDA, HFIR, ORNL, TOMOMASA KAZITA, TAKURO KATSUFUJI, Waseda University, SEUNGHUN LEE, University of Virginia, UNIVERSITY OF VIRGINIA TEAM, WASEDA UNIVERSITY COLLABORATION, SNS, OAK RIDGE NATIONAL LABORATORY COLLABORATION, HFIR, OAK RIDGE NATIONAL LABORATORY COLLABORATION — $SrV_{10}O_{15}$ has magnetic bilayers composed of triangular lattices with periodical missing, which can be an interesting playground for the study of frustration. In this new type of magnetic structure, using neutron powder diffraction, we find a magnetic ground state below 45K with ordering vector Q=(0 1/2 1), and study detailed spin configuration. Magnetic excitations have also been investigated using a single crystal at ARCS, a time-of-flight neutron chopper spectrometer at SNS. Our results show quite interesting highly dispersive dispersion relations: a gapless Goldstone mode is strongly dispersive along the a and c axis, and is less-strongly dispersive along the b axis. Another mode is dispersionless along the a and b axis, and is strongly dispersive along the c axis. We determine the spin hamiltonian that sheds light in understanding the interplay between orbital, spin, charge, and lattice degrees of freedom in this compound.

Session P19 GMAG: Focus Session: Spin Transport & Magnetization Dynamics in Metals VI

D170

8:00AM P19.00001 Quantum Dynamics of Spin-torqued Nanomagnet , YONG WANG, YAOJUN ZHANG, L.J. SHAM, Department of Physics, University of California, San Diego — Nanomagnet is the key ingredient of many spintronics devices, such as hard disk read head, magnetoresistive random access memory(MRAM),etc. The underlying mechanisms in these structures are due to the interplay between the nanomagnet and spin-polarized electrons. Usually, the nanomagnet is characterized by the classical magnetization vector with its intrinsic quantum fluctuation neglected. By treating the nanomagnet as a huge atom with millions of energy levels, we are able to take account into the magnetization fluctuation, and study the interactions between nanomagnet and spin-polarized electrons on the same footing as quantum objects. We will show that the well-known giant magnetoresistance(GMR) effect and spin transfer torque(STT) effect are the consequences of continuous quantum measurements on the nanomagnet by spin-polarized electrons. We found that the quantum dynamics of nanomagnet is governed by a Fokker-Planck(FP) type equation in the atomic coherent state representation(P- representation). We will also discuss the correlation between the magnetization fluctuation and the electric current fluctuation.

8:12AM P19.00002 Minimum action paths for single domain ferromagnetic nanostructures under the influence of spin transfer torque , GABRIEL CHAVES-O'FLYNN, DANIEL STEIN, ANDREW KENT, ERIC VANDEN-EIJNDEN, New York University — Thermally induced magnetization reversal is an important issue for the design of magnetic storage devices. The problem is usually studied using Kramers' theory of reaction rates, which is applicable when the dynamics can be described as gradient forces. Spin Transfer Torque (STT) is an effect of technological importance which does not fall in this category. For Spin Transfer Torque an action minimization is required to find the most probable paths and transition states between metastable states. We calculate these most probable paths for ferromagnetic nanostructures under the influence of STT in the low noise limit for a variety of current strengths and magnetic fields. Previous action minimization were done in the absence of STT and provide a good basis for comparison [1]. We study thin films with an in-plane easy magnetization axis using the geometrical Minimum Action Method (gMAM) [2]. The action obtained using gMAM is in qualitative agreement with activation energy barriers on previous work by Li-Zhang [3].

8:24AM P19.00003 Giant enhancement of microwave emission in magnetic tunnel junction oscillators by orientating in-plane field[1] , Z.M. ZENG, K.H. CHEUNG, H.W. JIANG, Department of Physics & Astronomy, UCLA, CA 90095, P. UPADHYAYA, P. KHALILI AMIRI, K.L. WANG, Department of Electrical Engineering, UCLA, CA 90095, J.A. KATINE, Hitachi Global Storage Technologies, San Jose, California 95135 — Recently spin-transfer nano-oscillators (STNOs) have attracted considerable attention because they are tunable over a wide frequency rang by varying the applied DC current or magnetic field. One main challenge for practical applications is to boost the relative low emitted power. MgO-based STNOs have exhibited a capability to deliver much larger power. However, they often show multiple emission peaks or broad linewidths. It is necessary to suppress the additional peaks and to reduce the central peak linewidth. In this talk, we present our microwave measurements in MgO-based STNOs as a function of in-plane field orientation. At an optimal orientation, emitted power of a single peak is largely enhanced, together with a significantly narrowed linewidth. The experiment shows that the understanding of intrinsic features of the oscillators as a function of in-plane orientation is important for optimizing the performances of MgO-based nano-oscillators.

8:48AM P19.00005 Spin-transfer oscillators in the effective planar approximation[1] , YA. B. BAZALIY[2], University of South Carolina — Spintronic devices with dominating easy plane anisotropy can be described in an effective planar approximation of the LLG equation. In particular, the effective equation can be used to study the spin-transfer oscillators. We use this approach to study the transitions of the oscillator excited by a combination of an AC and a DC electric currents between the small and large amplitude regimes.

9:00AM P19.00006 High Speed Spin Torque Memory with Combined Perpendicular and In-Plane Polarizers , GRAHAM ROWLANDS, TOFIZUR RAHMAN, JORDAN KATINE, JUAN ALZATE, ALEXEY KOVALEV, YAROSLAV TSERKOVNYAK, KOSMAS GALATSIS, PEDRAM KHALILI AMIRI, KANG WANG, JIAN-PING WANG, ILYA KRIVOROTOV — The use of a perpendicular polarizing layer in combination with an in-plane free layer has been proposed [1] as a means of reducing the switching time and write energy of spin-torque MRAM cells. While these structures have been realized in nanopillars with metallic spacers [2-4], memory applications demand the use of magnetic tunnel junctions (MTJs) due to their higher magnetoresistance and better impedance matching to a write transistor. We augment standard in-plane CoFeB/ MgO/ CoFeB MTJs to include an additional fixed layer pulled out-of-plane by coupling to the adjacent [Co/Pd] multilayer designed to possess a strong perpendicular magnetic anisotropy. This additional polarizer generates spin torque with an out-of-plane component, resulting in a fast precessional switching with no incubation time or pre-switching oscillations. For a variety of sample sizes we observe switching times approaching 100 ps. References: [1] A. D. Kent et al. Appl. Phys. Lett. 84, 3897 (2004). [2] C. Papusoi et al. Appl. Phys. Lett. 95, 072506 (2009) [3] O. J. Lee et al. 95, 012506 (2009) [4] R. Sbiaa et al. J. Appl. Phys. 105, 013910 (2009)

9:12AM P19.00007 Noise in Spin Torque Oscillators , MARK KELLER — In a spin torque oscillator _(STO)_, a direct current passing through a reference magnetic layer becomes spin polarized and transfers angular momentum to a second magnetic layer that is excited into steady-state oscillation. The oscillating magnetization causes an oscillating device resistance, through either the giant magnetoresistance effect or the tunneling magnetoresistance effect, which in combination with the bias current generates an oscillating voltage as the output signal. Interest in potential applications of STOs in integrated microwave circuits is driven by their rapid frequency tunability, small size __(<100 nm)_, and compatibility with standard semiconductor processing techniques. For any oscillator, noise is both an important figure of merit for applications and a useful probe of internal physical processes. I will summarize the theoretical and experimental state of our understanding of frequency and phase noise in a variety of oscillators, considering both time domain and frequency domain measurements. Some aspects can be explained by the effects of thermal fluctuations. Others, such as frequency noise that varies as 1/f at low frequencies, are not yet understood.

9:48AM P19.00008 Optimal spin current pattern for fast domain wall propagation in nanowires[1] , PENG YAN, Physics Department, The Hong Kong University of Science and Technology, Hong Kong, ZHOUZHOU SUN, JOHN SCHLIEMANN, Institute for Theoretical Physics, University of Regensburg, D-93040 Regensburg, Germany, XIANGRONG WANG, Physics Department, The Hong Kong University of Science and Technology, Hong Kong — One of the important issues in nanomagnetism is to lower the current needed for a technologically useful domain wall (DW) propagation speed. Based on the modified Landau-Lifshitz-Gilbert (LLG) equation with both Slonczewski spin-transfer torque and the field-like torque, we derive an optimal temporally and spatially varying spin current pattern for fast DW propagation along nanowires. Under such conditions, the DW velocity in biaxial wires can be enhanced as much as tens of times higher than that achieved in experiments so far. Moreover, the fast variation of spin polarization can efficiently help DW depinning. Possible experimental realizations are discussed.

10:00AM P19.00009 Effects of Spin transfer torques on domain wall nucleation and propagation in perpendicular spinvalve nanopillars , STEPHANE MANGIN, JULIEN CUCCHIARA, THOMAS HAUET, Nancy Unversite, DAVID P. BERNSTEIN, SLAC - Stanford, ERIC E. FULLERTON, UCSD, ANDREW D. KENT, New York Univ, JORDAN KATINE, Hitachi-GST, JONATHAN Z. SUN, IBM — Controlled manipulation of magnetic domain wall (DW) propagation has spurred intensive research in recent years because of its fundamental interest and the potential impact in spintronic device technology such as racetrack memories. Both magnetic fields and electric currents may be used to control domain walls. Most of the studies have been performed on magnetic nanowires with in plane anisotropy. Here we study domain wall creation and propagation in spinvalve nanopillar composed of magnetic materials with perpendicular anisotropy such Co/Ni multilayers [1]. It is shown that DWs can nucleate and propagate in perpendicularly magnetized nanopillar spin valves as small as 50 $\times$ 100 nm^2 [2]. The study of the dynamics of DW nucleation and propagation driven by applied fields and injected currents is presented [3]. High domain wall velocities of about 100m/s are found.

10:12AM P19.00010 Domain Wall Pumping with Spin-Transfer Torque , CARL BOONE[1], Hitachi Global Storage Technologies, ILYA KRIVOROTOV, University of California, Irvine — We numerically investigate the effects of current-perpendicular-to-the-plane (CPP), angularly asymmetric Slonczewski spin-transfer torque (ST) on transverse domain walls (DW) in nanowires. The CPP ST excites long-range domain wall motion in a direction independent of the current polarity and proportional to the square of the current amplitude. This symmetry with respect to current polarity creates the possibility of DW pumping – long range DW motion driven by an alternating current. The DW velocity becomes resonantly enhanced near a frequency that depends on the nanowire dimensions, corresponding to the eigenfrequency of a localized, spatially antisymmetric spin-wave mode that exists within the DW.

[1]The submitted work was done while at University of California, Irvine.

10:24AM P19.00011 Current-Perpendicular-to-Plane (CPP) Magnetoresistance at 4.2K of spin-valves with the half-metal Co(2)Fe(Al(0.5)Si(0.5)) and Permalloy[1] , RAKHI ACHARYYA, REZA LOLOEE, WILLIAM PRATT, JACK BASS, Physics Department, Michigan State University, East Lansing, MI 48824 — There is interest in current-perpendicular-to-plane (CPP) magnetoresistance (MR) in spin-valves containing half-metallic Heusler alloys such as Co(2)FeAl((0.5)Si(0.5)) (CFAS) [1]. Onto [001] oriented MgO substrates, we sputter epitaxially [001] oriented layers of 150-nm-thick Nb, 10-nm-thick Cu, and chosen thickness CFAS. We complete a spin-valve with 25 nm of Cu, 24 nm of Py = Ni(84)Fe(16), 10 nm of Cu, 25 nm of Nb, and 15 nm of a Au capping layer. With optical lithography and Ar-ion milling, we make 25 micron radius pillars insulated with in-situ deposited SiO. Finally, we lightly ion mill the Au surface and deposit a 150 nm thick Nb cross-strip, then covered by 5 nm of Au. The Nb strips superconduct at our measuring temperature of 4.2K, giving uniform current flow. We will describe how the CPP-MR varies with thicknesses of CFAS ranging from 2 nm to 20 nm. We hope to describe additional studies with Ag instead of Cu and with pinned Py layers.

10:36AM P19.00012 Modulation of spin torque from spin transport through two nearby domain walls , ELIZABETH GOLOVATSKI, MICHAEL FLATTÉ, OSTC and Dept. of Physics and Astronomy, University of Iowa — The motion of domain walls due to the spin torque generated by coherent coherent carrier transport [1] is of considerable interest for the development of spintronic devices [2]. We model two π Néel walls [3] separated by a variable distance, and calculate transport characteristics and spin torque through the system [4]. We find that for large separations, the domain walls show the resonant transmission behavior of a spin-dependent double barrier; for small separations, the transmission spectrum resembles that of a 2π wall. We also find that the spin torque across the system initially increases as the separation between the walls increases from zero, then decreases slightly before reaching a saturation value that is larger than both the spin torque of a 2π wall and that of two individual π walls. This work is supported by an ARO MURI.

10:48AM P19.00013 Current-Induced Torques in the Presence of Spin-Orbit Coupling , M.D. STILES, PAUL M. HANEY, Center for Nanoscale Science and Technology, National Institute of Standards and Technology — In systems without spin-orbit coupling, the simple connection between spin transfer torque and the divergence of the spin current has provided a simple description of current induced torques. Here, we generalize this relationship for systems with strong spin-orbit coupling to a relationship between spin transfer torques, total angular momentum current, and mechanical torques. In such systems, the spin-orbit coupling modifies the behavior of the spin transfer torques. For example, the it can give rise to a persistent spin transfer torque in a spin valve: the spin transfer torque density approaches a constant value rather than decaying away from the interface. This approach also provides a formal expression for the mechanical torque at a single ferromagnetic-nonmagnetic interface.

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P20 FIAP/DMP GERA/DCOMP: Focus Session: Physics of Energy Storage Materials IV – Complex Hydrides and Methane D168

8:00AM P20.00001 $NaAlH_4$ – Carbon Aerogel: Kinetic Enhancement of a Complex Hydride by Nanoporous Carbon , FREDERICK PINKERTON, General Motors R&D Center — Complex hydrides promise high gravimetric and volumetric hydrogen storage densities, but considerable modification of their thermodynamic and kinetic properties will be required in order to make them feasible for on-vehicle applications. Catalyst additions to achieve fast hydrogen cycling kinetics have been studied for more than a decade. More recently, the concept of nanoconfinement has been explored as a means to improve kinetics, using melt infusion or solvent infusion to embed the hydride into nanoscale pores within a solid. We have achieved enhanced kinetic performance and reversibility of $NaAlH_4$ incorporated into nanoporous carbon aerogel by melt infusion, even in the absence of a catalyst. In fact, hydrogen cycling of uncatalyzed $NaAlH_4$ in aerogel is almost as good as unconfined $NaAlH_4$ catalyzed by addition of $TiCl_3$. It remains challenging, however, to obtain $NaAlH_4$-carbon aerogel infusions with high hydride loading and/or co-incorporated catalyst. We have therefore investigated combining $NaAlH_4$ with carbon aerogel and nanoporous activated carbon by ball milling. The kinetic performance is similar to that of melt-infused $NaAlH_4$ at the same loading, and importantly, higher $NaAlH_4$ loading can be easily achieved with only modest loss of kinetics. Furthermore, $TiCl_3$ catalyst can be easily co-incorporated. In the latter case, a small but significant improvement over $TiCl_3$-catalyzed $NaAlH_4$ without carbon is observed.

8:36AM P20.00002 Hydrogen release reactions in the {H,Li,B,Na,Al} system , ERIC DHALL, Graduate Student, VIDVUDS OZOLINS, Professor — A thermodynamic investigation of the {H,Li,B,Na,Al} system for new solid state hydrogen storage reactions is performed using first-principles DFT calculations and the the grand-canonical linear programming approach (Akbarzadeh, et al. Adv. Mater. 2007, 19, 3233). We report the static, zero-point, and T $>$ 0 K vibrational energies of all known compounds in this system. Enthalpies, entropies, and hydrogen release temperatures are calculated for all thermodynamically reversible dehydrogenation reactions occurring from 0-1000K. Several novel mixtures of reactants with high gravimetric hydrogen storage densities are found using the calculated {H,Li,B,Na,Al} phase diagrams.

8:48AM P20.00003 First-principles investigations of the quaternary Li-Zn-B-H hydrogen storage system , YONGLI WANG, CHRIS WOLVERTON, Northwestern University — Mixed metal borohydride hydrogen storage materials are a new class of materials which may possess better thermodynamic and kinetic properties than their separate phases. $LiBH_4$ has an undesirably high H_2 desorption temperature, while $Zn(BH_4)_2$ has a lower desorption temperature, but releases B_2H_6 upon desorption. We have used density functional theory, as well as Monte Carlo-based crystal structure prediction tools and phase diagram computational methods to explore the stability and decomposition reactions of mixed Li and Zn borohydrides to ascertain whether they possesses an intermediate decomposition temperature. Based on a combination of classical potentials, Monte Carlo optimization, and DFT calculations, we search for low-energy quarternary borohydrides as a function of the Li/Zn context. We find that this system has compounds that are lower in energy than the isolated borohydrides. In agreement with prior work, we confirm the existence of a $LiZn(BH_4)_3$ compound, which as yet has been unobserved. We find that this new mixed compound $LiZn(BH_4)_3$ decomposes via an initial decomposition of $Zn(BH_4)_2$, and a subsequent decomposition of $LiBH_4$. This sequential decomposition is favored due to the lack of stable intermediate products which involve both Li and Zn. Using this framework, we are searching for stable mixed metal borohydrides in a wide variety of other systems.

9:00AM P20.00004 First-principles studies of intermediate products in the decomposition of metal amidoboranes , YONGSHENG ZHANG, Department of Materials Science & Engineering, Northwestern University, TOM AUTREY, Pacific Northwest National Laboratory, CHRIS WOLVERTON, Department of Materials Science & Engineering, Northwestern University — Metal amidoboranes [MAB, M=metal cation] form an interesting class of recently-discovered hydrogen storage compounds. However, the decomposition products remain largely unknown. Armed with the combination of the prototype electrostatic ground state search and density-functional theory methodology (PEGS+DFT), we have searched for crystal structures of possible reaction products with $[NHBH_2]^-$, $[NBH]^-$, $[NBH_5]^-$, polymer-$[NHBH_2]$ anion groups in the decomposition of LiAB and CaAB. All these reaction pathways are significantly endothermic, which is in disagreement with the experimentally measured enthalpies in these systems, which are found to be nearly thermoneutral [$-3 \sim -5$ kJ/(mol H_2) in LiAB and 3.5 kJ/(mol H_2) in CaAB]. Using newly developed dianion group $[NHBHNHBH_3]^{2-}$, our PEGS+DFT methodology predicts structures and energies of Li/Ca-dianion compounds. Including vibrational thermodynamics and zero-point effects, we successfully obtain a nearly thermoneutral enthalpy of decomposition into these dianion compounds. This agreement lends strong support to the dianion phases as energetically preferred products in the decomposition of metal amidoboranes.

9:12AM P20.00005 Theoretical study of the vibrational properties of $\mathrm{NaAlH_4}$ with $\mathrm{AlH_3}$ vacancies , MEI-YIN CHOU, FENG ZHANG, YAN WANG, School of Physics, Georgia Institute of Technology — We investigate from first-principles calculations the vibrational properties in the presence of the $\mathrm{AlH_3}$ vacancy in both α and γ phases of $\mathrm{NaAlH_4}$. When $\mathrm{AlH_3}$ is removed from an $\mathrm{AlH_4^-}$ anion, the remaining H recombines with another neighboring $\mathrm{AlH_4^-}$ anion and forms an $\mathrm{AlH_5^{2-}}$ unit with slightly deformed D_{3h} symmetry. For both α- and γ-$\mathrm{NaAlH_4}$, the $\mathrm{AlH_3}$ vacancy induces several isolated phonon modes that are highly localized on the $\mathrm{AlH_5^{2-}}$ unit with frequencies within the band gap separating the Al-H stretching modes and Al-H bending modes in pure $\mathrm{NaAlH_4}$. Similar localized phonon modes also exist in the gap separating the Al-H bending modes and the modes involving the rotation of $\mathrm{AlH_4^-}$ anions for the γ phase. On the other hand, for both α and γ phases of $\mathrm{NaAlH_4}$ with charged $\mathrm{AlH_4^-}$ vacancies, no isolated phonon modes were found to be localized in the vacancy region with frequencies within the band gap of the pure crystal. These theoretical findings suggest further experimental studies to identify the defects that are involved in the decomposition of $\mathrm{NaAlH_4}$.

9:24AM P20.00006 Hexagonal Antiprismatic Metallacarborane Clusters for Hydrogen Storage , CÜNEYT BERKDEMIR, PING LIN, JORGE SOFO, Penn State — We investigated the adsorption properties of molecular hydrogen attached to hexagonal antiprismatic metallacarborane clusters, $RuNiC_2B_{10}H_{12}$ and $Ru_2C_2B_{10}H_{12}$, using density functional theory. These clusters have been recently synthesized using the reduction-metallation (RedMet) approach [1] and their structures have been resolved. The hydrogen molecules are sequentially attached to these clusters until the H_2 binding energies fall below 0.2 eV, which is the minimum value of ideal H_2 binding energy in the range of 0.2-0.4 eV/H_2 for the practical vehicle applications [2]. We included the van der Waals interactions between metallacarborane clusters and molecular hydrogens. We also evaluated the contribution of zero point vibrational energies to the H_2 binding energy. The kinetic stability of these clusters before and after hydrogen adsorption is discussed by analyzing the energy gap. The results show that $RuNiC_2B_{10}H_{12}$ and $Ru_2C_2B_{10}H_{12}$ clusters can bind up to 8.5 wt % and 9.8 wt % molecular hydrogen, respectively. These results suggest that these metallacarborane clusters are potential hydrogen storage materials to meet the targets of DOE for 2015.

9:36AM P20.00007 Diffusion-limited Kinetic Pathway for Hydrogen Release from $\mathrm{LiNH_2/LiH}$, BILJANA ROLIH, VIDVUDS OZOLINS, UCLA — From experimental work on decomposition of hydrogen storage materials it has been suggested that bulk diffusion of metal species is the bottleneck for hydrogen release. In this work we study the underlying mechanism for diffusion reactions in the dehydrogenation of $LiNH_2$. Using first-principle, density functional theory methods we have calculated concentration gradients and diffusivities of neutral and charged defects in $LiNH_2$ and Li_2NH phases. The overall activation energy is obtained from these calculations. The calculated activation energies are found to agree well with experimental work on the kinetics of $LiNH_2$ decomposition, suggesting that diffusion of metal species is a possible method for dehydrogenation of Lithium Amide.

9:48AM P20.00008 Reaction Pathways in the Reactive Composite $\mathrm{Mg(NH_2)_2 + LiH}$, DENIZ CAKIR, University of Twente, GILLES A. DE WIJS, Radboud University Nijmegen, GEERT BROCKS — Chen *et al* [1] reported reversible hydrogen storage in a mixture of LiH + $LiNH_2$ with a storage capacity of 6.5 wt %. However, this system requires an operating temperature in excess of 250 C to achieve a hydrogen pressure of 1 bar. Several efforts including cation substitution have been considered in order to improve the operating conditions, which is necessary for onboard applications. For instance, replacing LiH with MgH_2 markedly reduces the operating temperature through the reaction $MgH_2 + 2LiNH_2 \rightarrow Li_2Mg(NH)_2 + 2H_2 \leftrightarrow Mg(NH_2)_2 + 2LiH$. Recent experimental results however indicate that the latter is not a simple one-step reaction and full hydrogenation of $Li_2Mg(NH)_2$ occurs in a two-step sequence via an intermediate $Li_2Mg_2(NH)_3$ [2]. In this work we examine the stability and structure of possible intermediates compounds, namely $Li_{2-2x}Mg_xNH$, $Li_{1-2x}Mg_xNH_2$, and $Li_{2-x}Mg(NH)_{2-x}(NH_2)_x$, by means of first-principles DFT calculations. All intermediate compounds are thermodynamically stable with respect to the elements. The hydrogenation reaction of $Li_2Mg(NH)_2$ via the intermediate imides $Li_{2-2x}Mg_xNH$ is energetically favorable compared to other intermediates.

10:00AM P20.00009 First-Principles Study of Native Defects in $\mathrm{Li_4BN_3H_{10}}$ Under Varied Chemical Conditions , DAVID FARRELL, CHRISTOPHER WOLVERTON, Northwestern University — Hydrogen desorption from many complex hydrides, such as $Li_4BN_3H_{10}$, is known to be kinetically limited. At temperatures below melting, the motion of point defects is one possible factor affecting chemical reactions. Therefore, an understanding of their formation and migration will yield insight into the kinetic limitation of hydrogen desorption. To explore this, we have determined the 0 K formation energy for a number of neutral and charged point defects in $Li_4BN_3H_{10}$ under a variety of chemical conditions via density functional theory calculations. We determined chemical potentials based on thermodynamically predicted hydrogen desorption reactions and provide a physical interpretation of the resulting equilibrium conditions. Our results indicate that: 1) The lowest energy defect varies with chemical conditions. 2) neutral defects are always lower energy than analogous pairs of oppositely charged defects. 3) Hydrogen defects are rarely the lowest energy defect.

10:12AM P20.00010 First-principles Modeling of Diffusion Reactions in the Hydrogenation of $\mathrm{NaAlH_4}$, KYLE MICHEL, VIDVUDS OZOLINS, University of California, Los Angeles — The hydrogenation of $NaAlH_4$ has been studied extensively since it was discovered that doping with Ti greatly increases its reversible hydrogen storage capacity. Experimental studies have suggested that diffusion of metal-containing defects may be the rate-limiting step in this reaction. We present a model to study the diffusion of defects during a solid-state reaction and apply it to this hydrogen storage reaction. The flux of defects in simple, model systems is calculated and from these values the activation energy for these processes is determined. We find that the activation energy for the diffusion of metal defects matches well to the experimental activation energy for the reaction when doped with Ti. The model that is presented can easily be applied to other systems in which a reaction takes place in the solid state.

10:24AM P20.00011 Catalytic effect of carbon nanomaterials on light metal hydride systems , ZHAO QIAN, RAJEEV AHUJA, Cond. Mat. Theory Group, Dept of Physics and Astronomy, Uppsala Univ; Dept of Mat. Sci. and Eng., Royal Inst. of Tech. (KTH), Stockholm, Sweden, C. MOYSES ARAUJO, ANDREAS BLOMQVIST, BISWARUP PATHAK, RALPH H. SCHEICHER, CMT Group, Uppsala University — Carbon nanomaterials are becoming recognized for their use in catalyzing hydrogen desorption from light metal hydride systems, in particular complex borohydrides and alanates. For example, it was shown by us that graphene, carbon nanotubes, and especially fullerenes can improve the hydrogen sorption properties of sodium alanate [Nano Lett. 9, 1501 (2009)]. In parallel to ongoing experimental investigations, we have carried out further theoretical studies in order to better understand the underlying catalyzing mechanism. Our most recent work is concentrated on the interaction of lithium borohydride with fullerene where a complete dehydrogenation process was simulated using the cluster approach. Furthermore, the catalytic effect of graphene nanofibres on sodium alanate has been experimentally demonstrated by our collaborators, and we have studied this system from first principles as well, to better understand the origin of its catalytic effect.

10:36AM P20.00012 Adsorbed Natural Gas Storage in Optimized High Surface Area Microporous Carbon , JIMMY ROMANOS, TYLER RASH, ERIK NORDWALD, JOSHUA SHAWN SHOCKLEE, CARLOS WEXLER, PETER PFEIFER, University of Missouri — Adsorbed natural gas (ANG) is an attractive alternative technology to compressed natural gas (CNG) or liquefied natural gas (LNG) for the efficient storage of natural gas, in particular for vehicular applications. In adsorbants engineered to have pores of a few molecular diameters, a strong van der Walls force allows reversible physisorption of methane at low pressures and room temperature. Activated carbons were optimized for storage by varying KOH:C ratio and activation temperature. We also consider the effect of mechanical compression of powders to further enhance the volumetric storage capacity. We will present standard porous material characterization (BET surface area and pore-size distribution from subcritical N_2 adsorption) and methane isotherms up to 250 bar at 293K. At sufficiently high pressure, specific surface area, methane binding energy and film density can be extracted from supercritical methane adsorption isotherms. Research supported by the California Energy Commission (500-08-022).

10:48AM P20.00013 On the reversibility of the adsorption of methane-mercaptan for natural gas storage[1] , M. GOLEBIOWSKA, U. Missouri, L. FIRLEJ, U. Montpellier 2, B. KUCHTA, U. Provence, M. ROTH, U. N. Iowa, C. WEXLER, U. Missouri — Methane is the main constituent of natural gas (NG). As fuel for vehicular applications NG requires sorbents that allow efficient, reversible and safe storage at room temperature and moderate pressure. To enable easy human detection of gas leaks the fuel gas should be added with compounds having low odor threshold, such as thiols (mercaptans). Thus a full understanding of the behavior of methane-mercaptan mixtures is necessary for the development of safe storage systems. In this talk we present results of molecular dynamics simulations in the temperature range 150–350 K and for a large range of methane partial pressures, up to the saturation pressure of methane. We observe the presence of 2D (and to a lesser degree 3D) diffusion of the thiols indicating that though thiols adsorb preferentially relative to methane, the adsorption is still reversible. We estimate that only a small increase in mercaptan concentration is necessary for the desorbed phase to be above the threshold for human detection.

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P21 GIMS: Focus Session: Advances in Scanned Probe Microscopy III - Novel SPM of Spin, Force & Conductance D161

8:00AM P21.00001 A New Ultra-Low Temperature, High Magnetic Field STM in an Ultra-Quiet Laboratory , BRIAN B. ZHOU, SHASHANK MISRA, LUKAS URBAN, JUNGPIL SEO, ANDRAS GYENIS, Princeton University, SEJONG KAHNG, Korea University, ALI YAZDANI, Princeton University — We report progress in the construction of a new UHV STM capable of operating at the extremes of temperature (25 mK) and magnetic field (14 T), allowing atomically resolved studies in previously unexplored areas of phase space. Our novel design is based on a bottom-loading dilution refrigerator in which the entire dilution stage and mounted microscope are moved between measurement and sample transfer positions. Pumping for the dilution fridge and large magnetic fields introduce demanding challenges in vibration isolation, which we have addressed with an ultra-quiet laboratory setting and rigid microscope design. Our system is situated inside both acoustic and RF-shielded enclosures in complement with various stages of isolation for both pump and ambient vibration sources. We will discuss unique aspects of the microscope design, such as a two-in-one double sample holder, and assess preliminary system performance. Supported by the W. M. Keck Foundation. Infrastructure at Princeton Nanoscale Microscopy Laboratory is also supported by grants from DOE, NSF, and ARO.

8:12AM P21.00002 Low Temperature Scanning Tunneling Microscope for Spin Polarization Measurements[1] , SEONG HEON KIM, RYAN JAEHNE, LEUJEN CHEN, ALEX DE LOZANNE, Department of Physics, University of Texas at Austin — We describe a new design for a 4K scanning tunneling microscope (STM) with an 8 tesla superconducting magnet to be used for spin polarized measurements. The novel aspects include a compact design for the chamber and the STM, the use of a secondary STM for in-situ tip characterization, and new ideas for vibration isolation. We developed a new STM head unit with 1 inch diameter and 3.2 inch length. This microscope is small enough to be installed within the small space available in the 2 inch diameter bore of our superconducting magnet. To achieve this small size, we modified the typical Pan-type z-approach walker. We also developed new simple and inexpensive electronics to control any stick-slip walker.

8:24AM P21.00003 Compact probe design for Scanning Hall Probe Microscopy[1] , NELIZA LEON-BRITO, SEONGSOO KWEON[2], ALEX DE LOZANNE, Texas Materials Insitute, The University of Texas at Austin — In the search for new materials with desirable magnetic properties for applications such as spintronics the study of magnetic properties at the micro and nanoscale is necessary. Magnetic Force Microscopy (MFM) has been the technique of choice for these types of studies, but its invasive nature makes it unsuitable for low coercivity materials like diluted magnetic semiconductors. Scanning Hall Probe Microscopy (SHPM) is an alternative technique which provides a magnetically non-invasive, calibrated measurement of the stray fields above the sample with good resolution ($\sim$1um). We have built a compact cryogenic variable-temperature (4 - 300K) SHPM with unique features such as an inverted tapered seal that also performs as a heat sink for the microscope body and a new coarse approach mechanism. Details of this design will be presented in this talk.

8:36AM P21.00004 Realizing Spin Logic Atom by Atom[1] , ALEXANDER KHAJETOORIANS, Institute of Applied Physics, Hamburg University — Scanning tunneling microscopy (STM) has emerged as a leading technique which can address single atom magnetism with high energy and spatial resolution. With the development of sub-Kelvin high-magnetic field STM, two complementary methods, namely spin-polarized scanning tunneling spectroscopy (SP-STS) and inelastic STS (ISTS), can address the fundamental properties of individual magnetic impurities at surfaces [1,2]. We use a map of the distance-dependent RKKY interaction between Fe atoms on Cu(111) obtained by SP-STS to engineer complex magnetic nanostructures with tailored magnetic properties with atomic manipulation. By combining constructed anti-ferromagnetic structures with spin frustration, we realize an atomic-scale logic device which functions solely on the spin-degrees of freedom of its magnetic constituents. This work was done in collaboration with J. Wiebe, S. Lounis, B. Chilian, A. T. Costa, L. Zhou, D. L. Mills, and R. Wiesendanger.

9:12AM P21.00005 Visualizing spin-dependent scattering in strong spin-orbit systems , ANNA STROZECKA, Institute of Experimental Physics, Free University Berlin, Germany, ASIER EIGUREN, Dpto. Fisica de la Materia Condensada, Universidad del Pais Vasco, Bilbao, Spain, JOSE IGNACIO PASCUAL, Institute of Experimental Physics, Free University Berlin, Germany — For surfaces which exhibit spin-orbit coupling, electrons originating from spin polarized surface bands are protected against backscattering by time reversal symmetry. Electron interference patterns observed in STM confirm the chiral spin texture of the surface Fermi contours of such materials and reveal the dominant role of spin in the scattering processes. Using a combined experimental and theoretical approach, we distinguish the role of spin in the electron scattering processes on Bi(110). Utilizing spectroscopic imaging of the local density of states, we studied the energy dependence of the interference patterns formed around single adsorbates. Simulations based on Green's functions correctly reproduce the interference patterns, unveiling the role of spin in the interference process and allowing identification of the dominant scattering events.

9:24AM P21.00006 Cotunneling theory for STM spin-flip spectroscopy , F. DELGADO, J. FERNANDEZ-ROSSIER, Departamento de Fisica Aplicada, Universidad de Alicante, San Vicente del Raspeig, 03690 Spain — Scanning Tunneling Spectroscopy of both magnetic atoms and molecules adsorbed on surfaces is analyzed from the theoretical point of view. We show that cotunneling is the leading mechanism that explains the spin assisted inelastic conductance reported in recent experiments [1-4]. We describe the electronic transport between the scanning tip and the conducting surface through the magnetic system (MS) with a generalized Anderson model. The correlations in the MS are calculated exactly and transport is considered to fourth order in the tip-MS and MS-surface coupling. Our theory accounts for the observed [2,4] asymmetric conductance and provides an explanation of the large inelastic contribution.

9:36AM P21.00007 Analysis of Tunneling Spectra in Constant-Current Distance-Voltage Mode , DANIEL DOUGHERTY, ALEX PRONSCHINSKE, DANIEL MARDIT, Department of Physics North Carolina State University — A technical challenge associated with the use of traditional constant height tunneling spectroscopy in current-voltage mode is that tunneling current increases very rapidly at even modest voltages. This can result in tip-induced damage or motion for soft or delicate materials like organic molecules. One solution to this problem is to measure tunneling spectra in constant current distance-voltage mode where the STM feedback loop maintains a constant small tunneling current. Using the standard integral expression for tunneling current with a WKB transmission function, it is possible to create a first order differential equation connecting distance-voltage spectra with sample density of electronic states. This can be used to experimentally extract density of states or to theoretically predict distance-voltage tunneling spectra from a known density of states. We illustrate the use of this approach with numerical and experimental examples.

9:48AM P21.00008 Quantitative force measurements with intermodulation atomic force microscopy , DANIEL PLATZ, DANIEL FORCHHEIMER, CARSTEN HUTTER, ERIK THOLÉN, DAVID HAVILAND, Royal Institute of Technology (KTH), Stockholm, Sweden — Dynamic atomic force microscopy (dynamic AFM) is a key tool for surface characterization on the nanoscale. Operation close to a cantilever resonance increases sensitivity and allows for the measurement of the phase of the cantilever response. This phase is traditionally interpreted as a measure of the energy dissipation due to the tip-sample interaction. However, a full understanding of dissipative processes remains a challenge in dynamic AFM. To address this problem we have developed Intermodulation AFM. With this multi-frequency technique we can tremendously increase the number of information carrying signals close to resonance. Using Fourier analysis and linear algebra we combine the amplitudes and phases of these signals to separately reconstruct the conservative and non-conservative tip-sample interactions. We have tested this method both on simulated and on experimental data. The method works at one tip-surface separation, providing quantitative high resolution maps of surface properties while imaging at normal rates.

10:00AM P21.00009 Nano-scale Strain Mapping using Near-field Microscopy , ANTONIO LLOPIS, ARKADII KROKHIN, University of North Texas, SERGIO PEREIRA, CICECO, University of Aveiro, IAN WATSON, University of Strathclyde, ARUP NEOGI, University of North Texas — Advances in nanophotonics are beginning to allow for the creation of nano-scale light emitting devices. Improving the quality of these next-generation emitters requires similarly advanced methods for characterization. These techniques need to be capable of imaging operational prototypes with nanometric resolution. We demonstrate here a new method for mapping strain capable of meeting the demands of next-generation device characterization. This technique makes use of near-field spectroscopy along with theoretical modelling to achieve non-destructive strain mapping with a resolution on the order of 10-100nm. An InGaN ELOG MQW sample is mapped using a SNOM, producing near-field maps of the intensity and Huang-Rhys parameter. Theoretical calculations are then used to obtain the relation between the Huang-Rhys parameter and the biaxial strain ε_{xx}, thereby allowing the production of a near-field map of the biaxial strain in the sample. Finally, to verify the efficacy of the method, we compare the results with those obtained using high-resolution XRD.

10:12AM P21.00010 Non-linear optical nano-structured probe for photonic force microscopy , ASWINI KANNEGANTI, HARSHIT VALLABH, NINAD INGLE, UT Arlington, XIAO ZHANG, JING LI, Rutgers Univ., SAMARENDRA MOHANTY, UT Arlington — Use of second-harmonic (SH) optical probes for imaging of microscopic samples has distinct advantages over fluorescence, which suffers from photobleaching. Further, SH nanoparticles can be optically trapped for probing interaction forces and even for topographic imaging of nanostructures. Here, we report SH generation in $ZnS(pda)_{1/2}$ (pda = propanediamine), a new class of nanostructured crystals. $ZnS(pda)_{1/2}$ is an isostructure of $ZnTe(pda)_{1/2}$ as confirmed by PXRD pattern. The SHG imaging of the nanocrystals was carried out by an ultrafast (∼100fs) Ti: Sapphire laser beam (wavelength: 960 nm; repetition rate: 80 MHz) focused to a diffraction limited spot by use of a 100X microscope objective leading to very high peak power density. Dependence of SHG intensity as a function of laser power and axial position of the nanoparticle in the focused laser microbeam was quantitated for the purpose of photonic force microscopy. The suspended $ZnS(pda)_{1/2}$ nanocrystals could be trapped using the near-IR Ti: Sapphire laser microbeam. The SHG intensity was found to fall very rapidly as the nanocrystal is displaced from the focused spot, which led to highly sensitive height measurements. Non-linear optical characterization of the $ZnS(pda)_{1/2}$ nanocrystals and its use in photonic force microscopic imaging will be presented.

10:24AM P21.00011 Design of a scanning gate microscope in a cryogen-free dilution refrigerator , MATTHEW PELLICCIONE, ADAM SCIAMBI, DAVID GOLDHABER-GORDON, Stanford University — We report on our design of an ultra-low temperature scanning gate microscope housed in a system with no liquid helium bath. The recent increase in efficiency of pulse-tube cryocoolers and pending scarcity of liquid helium have made "cryogen-free" dewars popular in recent years. However, this new style of dewar presents challenges for performing scanning measurements, most notably the increased vibrations introduced by the cryocooler. We will highlight the tradeoffs made in choosing such a system to house a scanner, and describe our efforts to achieve a stability suitable for measurements on mesoscopic systems.

10:36AM P21.00012 Electronic characterization of 1-D defects using scanning gate spectroscopy , STEVEN R. HUNT, Department of Physics and Astronomy, Univ. of California at Irvine, Irvine, CA 92697-4576, BRAD L. CORSO, PHILIP G. COLLINS — Scanning gate microscopy (SGM) is a technique particularly useful for characterizing transport in electronic devices. We have extended the SGM technique into a spectroscopy by measuring the entire bias dependence of conductance at every position on a surface. Much as in current imaging tunneling spectroscopy (CITS), the resulting data set is a multidimensional, detailed map of the electronic behavior of a surface. We apply this scanning gate spectroscopy (SGS) technique to scattering in one-dimensional, carbon nanotube circuits. Transport in one-dimensional systems depends critically on inhomogeneities, including isolated point defects. The SGS technique enables straightforward investigation of low-dimensional transport physics at such sites. In our experiments, metallic single-walled carbon nanotubes are investigated before and after the electrochemical introduction of a point defect, in order to clearly establish the contribution of different defect types. SGS directly images the energy dependence of a defect's scattering, providing a way to distinguish between different defect chemistries and quantitatively model its energy levels and transmission. This research is partly supported by the NSF (DMR-0801271).

10:48AM P21.00013 Scanning gate transconductance microscopy and spectroscopy of a mesoscopic ring , BENOIT HACKENS, FREDERICO MARTINS, SEBASTIEN FANIEL, VINCENT BAYOT, Universite catholique de Louvain, Louvain-la-Neuve 1348, Belgium, MARCO PALA, MINATEC, Grenoble, France, HERMANN SELLIER, SERGE HUANT, CNRS and Institut Neel, Grenoble, France, LUDOVIC DESPLANQUE, XAVIER WALLART, IEMN, Villeneuve d'Ascq, France — In scanning gate microscopy (SGM), a dc voltage is applied to a sharp tip moving in the vicinity of a device. This alters the electrostatic potential seen by electrons inside the device, and consequently changes the device conductance [1]. Here, we superimpose a small ac voltage to the dc bias applied on the tip, and record the change of device conductance at the tip bias modulation frequency, i.e. the local transconductance. We first image the low temperature transconductance of a mesoscopic ring patterned in a two-dimensional electron system (2DES) hosted in an InGaAs/InAlAs heterostructure. The tranconductance images are decorated by concentric features that we associate with charging of electron traps located close to the 2DES. We perform spectroscopy of these traps by positioning the tip close to them, and recording the ring transconductance as a function of the tip dc voltage and the bias accross the quantum ring. We observe Coulomb diamonds in our spectroscopic data, which confirms that Coulomb blockade is at play. [1] B. Hackens et al., Nature Physics 2, 826 (2006).

Wednesday, March 23, 2011 8:00AM - 11:00AM –
Session P22 DCMP: Metal-Insulator Phase Transitions I D163

8:00AM P22.00001 Revisiting the Anderson Model with Power-Law Correlated Disorder in 1D and 2D[1] , GREG PETERSEN, NANCY SANDLER, The Ohio University — The dimensionality of a disordered system directly affects the critical energy where a localization/delocalization transition occurs. In non-interacting systems with uncorrelated disorder, it is widely known that all states in one-dimension are localized. However, for some correlations there exist transition energies similar to mobility edges or small subsets of extended states that are robust against disorder. In this talk, we will present results on the diffusion of a wavepacket in a power-law correlated random potential of the form $\langle V(r)V(0)\rangle = \frac{1}{(a+r)^\alpha}$. We also report results for the participation ratio $P_r = \frac{1}{N}\frac{\langle|a_i|^2\rangle^2}{\langle|a_i|^4\rangle}$. Preliminary results for 1D chains support the existence of a mobility edge near the band center. Square and graphene lattices will also be discussed.

8:12AM P22.00002 Higher order correction to the RG β-function for the 3-d Anderson localization transition at unitary symmetry , TOMOYUKI NAKAYAMA, KHANDKER MUTTALIB, University of Florida, PETER WÖLFLE, Karlsruhe Institute of Technology — We have recently calculated the β-function of the conductance for Anderson Metal-Insulator transition including contributions from the ballistic regime. In three dimensional unitary case, the result of two-loop order diagrams is β(g)=1-a/g, where a is a constant and g is the dimensionless conductance. However, this result is valid only if there is no diagram with extra diffusons which contributes to the order of 1/g. We show that diagrams with extra diffuson propagators only have higher order contributions in the ballistic regime, which confirms our previous result.

8:24AM P22.00003 Singular Behavior of Electronic Eigenstates in the Anderson Model of Localization[1] , SONIKA JOHRI, Department of Electrical Engineering, Princeton University, Princeton, NJ 08544, R.N. BHATT, Department of Electrical Engineering and Princeton Center for Theoretical Science, Princeton University, Princeton, NJ 08544 — We report the observation of a singularity in the electronic properties of the Anderson Model of Localization with diagonal disorder[2] which is clearly distinct from the well- established mobility edge (localization-delocalization transition)[3,4] that occurs in dimensions $d > 2$. We present results of numerical calculations for various disorder distributions in dimensions $d = 1$, 2 and 3, of different properties of the electronic wavefunctions to establish this, and to understand its evolution with disorder distribution, dimension and lattice type. Our data suggest that the model is richer than has been originally believed.

8:36AM P22.00004 Temperature dependence of the zero-bias anomaly in the two-site Anderson-Hubbard model[1] , R. WORTIS, W.A. ATKINSON, Trent University — Experiments on disordered strongly correlated electron systems show zero-bias anomalies which are not consistent with either of the two prevailing pictures, by Altshuler and Aronov and by Efros and Shklovskii. Numerical work on the two-dimensional Anderson-Hubbard model shows a zero-bias anomaly with a number of unique features. It has recently been shown that a zero-bias anomaly with many of the same features occurs in an ensemble of two-site Anderson-Hubbard systems. The simplicity of this system allows direct understanding of the mechanism of the anomaly. Here, the temperature dependence of this anomaly is explored. A novel feature is the existence of a temperature driven zero-bias anomaly which appears even in the atomic limit and augments the kinetic energy driven one in the presence of hopping.

8:48AM P22.00005 Theoretical perspective on nearly frozen coulomb liquids , HANNA TERLETSKA, YOHANES PRAMUDYA, SERGEY PANKOV, EFSTRATIOS MANOUSAKIS, VLADIMIR DOBROSAVLJEVIC, Department of Physics and NHMFL, Florida State University — Various studies on systems with charge ordered states, such as Wigner crystal, show their extreme fragility resulting from strong frustrations caused by long-range Colulomb-like interactions. Here, a so-called nearly-frozen Coulomb liquid regime is identified featuring a soft Coulomb pseudo-gap with unconventional insulating-like transport. Despite intensive studies, such pseudo-gap regime is still poorly understood. By employing extended dynamical mean field theory (EDMFT) [1] to study a semi-classical lattice gas model of spinless electrons, we successfully demonstrate the existence of such an intermediate liquid regime, and show that the pseudo-gap is, in fact, a general feature for models with long-range interactions. Our analytical results are well supported by exact Monte Carlo calculations. Moreover, we show that standard theories, like self-consistent Gaussian approximation ("spherical model") and RPA, are ill-suited to describe this interesting regime. The spherical model approach provides the same as EDMFT freezing temperature Tc, but fails to capture the pseudo-gap feature. RPA, however, not only overestimates Tc, but also completely misses the pseudo-gap regime.

9:00AM P22.00006 Bound states in the continuum in a multi-electron system[1] , RAHUL HARDIKAR, GONZALO ORDONEZ, Butler University — Bound states in a continuum (BIC) occur due to quantum interference of two identical adatoms in a one-dimensional (1D) band. In the past such states have been studied for a one- electron system using several analytical and theoretical methods. We extend the idea of BIC to a multi-electron system. To study this numerically we use the pure Hubbard hamiltoninan and add impurity sites at specific locations. Using this variant of the Hubbard model and an exact diagonalization method we prove that BIC can exist for multi-electron systems. We will also show theoretical proof of such states using the Bethe-Ansatz method

9:12AM P22.00007 Spectral functions across the Metal-Insulator transition in the disordered 2D Hubbard model[1] , KARIM BOUADIM, NGANBA MEETEI, YEN LEE LOH, NANDINI TRIVEDI, Ohio State University — We study the metal-insulator transition in the repulsive disordered 2D Hubbard model [1,2] using Determinant Quantum Monte Carlo (DQMC). We calculate the spin-spin and current-current correlations to learn about the nature of the conducting and insulating phases. We also obtain local spin-dependent spectroscopic properties, using the maximum entropy method, to understand the role of disorder on the transition in this highly correlated fermion system. We discuss implications of our results for scanning tunneling spectroscopy and dynamical conductivity experiments [3].

9:24AM P22.00008 Time-Correlated Soliton Tunneling in Density Waves , JOHN H. MILLER, ASANGA IROSHAN WIJESINGHE, ZHONGJIA TANG, ARNOLD M. GULOY, University of Houston — In the quantum sine-Gordon model of a pinned charge or spin density wave, the electrostatic energy generated by charged soliton domain walls leads to a Coulomb blockade threshold electric field for quantum soliton-antisoliton pair creation. This field can be much smaller than the classical depinning field, since the quantum instability occurs as soon as the formerly lowest energy potential well rises to become a metastable well, or "false vacuum." The analogy to time-correlated single electron tunneling and comparison to recent experimental results, as well as broader implications of the proposed tunneling process, are briefly discussed. This work was supported by the State of Texas though the Texas Center for Superconductivity at the University of Houston and the Norman Hackerman Advanced Research Program, and by NIH R21CA133153 and ARRA supplement 3R21CA133153-03S, and by the Robert A. Welch Foundation, and DoE Basic Energy Sciences.

9:36AM P22.00009 Level spacing statistics for quantum k-core percolation , L. CAO, J.M. SCHWARZ, Syracuse University — Quantum percolation is the study of hopping transport of a quantum particle on randomly diluted percolation clusters. Quantum k-core percolation is the study of quantum transport on k- core percolation clusters where each occupied bond must have at least k occupied neighboring bonds. Within the random phase approximation, we found a random first-order phase transition for the k-core conduction transition on the Bethe lattice, and p_q, the quantum percolation critical probability, is equal to p_c, the geometric percolation critical probability [Phys. Rev. B **82**,104211 (2010)]. To further test this result, we numerically compute the level spacing distribution as a function of occupation probability p and system size. The simulation results provide confirmation for the existence of a discontinuous onset of quantum conduction at $p_q = p_c$.

9:48AM P22.00010 The onset of superfluidity of hardcore bosons in disordered ladders , JUAN CARRASQUILLA, FEDERICO BECCA, MICHELE FABRIZIO, International School for Advanced Studies, Trieste — The effect of disorder on the zero-temperature phase diagram of a two-leg ladder of hardcore bosons is investigated using quantum Monte Carlo simulations. We first review some aspects of the clean system which are relevant for the understanding of the disordered case. In the disordered case, an intervening Bose-glass phase between the frozen Mott insulator with zero (or one) bosons per site and the superfluid phase is found. We also investigate the effect of disorder exactly at half filling, where for small values of disorder, there is a commensurate phase with a gap to all excitations, which is eventually destroyed for larger values of disorder. We argue that this phase is always surrounded by the so-called Bose glass and a direct transition from the superfluid is found only in the clean system. Finally, a phase diagram based on our numerical evidence is suggested.

10:00AM P22.00011 Global phase diagram of the spinless Falicov-Kimball model in $d = 3$: renormalization-group theory[1] , OZAN S. SARIYER, Koç University, MICHAEL HINCZEWSKI, University of Maryland, A. NIHAT BERKER, Sabanci University — The global phase diagram of the spinless Falicov-Kimball model in $d = 3$ spatial dimensions is obtained by renormalization-group theory [1]. This global phase diagram exhibits five distinct phases. Four of these phases are charge-ordered (CO) phases, in which the system forms two sublattices with different electron densities. The phase boundaries are second order, except for an intermediate interaction regime, where a first-order phase boundary between two CO phases occurs. The first-order phase boundary is delimited by special bicritical points. The cross-sections of the global phase diagram with respect to the chemical potentials of the localized and mobile electrons, at all representative interaction and hopping strengths, are calculated and exhibit three distinct topologies. The phase diagrams with respect to electron densities are also calculated.

10:12AM P22.00012 Improved determination of the self-energy and vertex function in Strong-Coupling Continuous-time Quantum Monte Carlo , HARTMUT HAFERMANN, Centre de Physique Théorique, École Polytechnique, 91128 Palaiseau Cedex, France, KELLY R. PATTON, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, Louisiana 70803, PHILIPP WERNER, Theoretische Physik, ETH Zurich, 8093 Zurich, Switzerland — The continuous-time quantum Monte Carlo method based on the strong coupling expansion is an efficient and flexible tool for the solution of multiorbital Anderson impurity models. However it is known that it is difficult to accurately compute the intermediate and high-frequency behavior of measured quantities. This leads to large errors, in particular for the self-energy when computed from Dyson's equation. A similar problem occurs for the vertex function when computed directly from the two-particle Green function. We propose an improved way of measuring these quantities, based on higher-order impurity correlation functions. The method yields very accurate estimates for the self-energy and vertex function over the full frequency range. In the segment representation, the improved estimators can be accumulated at essentially no additional computational cost.

10:24AM P22.00013 Surface effects in doping a Mott insulator , REZA NOURAFKAN, FRANK MARSIGLIO, Department of Physics, University of Alberta, Edmonton, Alberta, Canada T6G 2G7 — The physics of doping a Mott insulator is investigated in the presence of a solid-vacuum interface. Using the embedding approach for dynamical mean field theory we show that approaching a Mott insulating phase from the metallic side, a dead layer forms at the surface of the solid, where quasiparticle amplitudes are exponentially suppressed. In particular, we have demonstrated that the reduction of the quasiparticle weight detected by surface sensitive photoemission experiments of a doped Mott insulator are caused by both charge transfer and enhanced correlation effects at the surface. The expected modification of the intra-layer hopping at the surface and inter-layer hopping between the surface and the subsurface layer amplifies the surface effects.

10:36AM P22.00014 The Role of the Van Hove Singularity in the Quantum Criticality of the Hubbard Model , SANDEEP PATHAK, K.-S. CHEN, SHUXIANG YANG, MARK JARRELL, JUANA MORENO, Louisiana State University — A quantum critical point, separating a non-Fermi liquid region from a Fermi liquid, exists in the phase diagram of the Hubbard model [Vidhyadhiraja *et. al*, Phys. Rev. Lett. **102**, 206407 (2009)]. This quantum critical point is characterized by a vanishing spectral weight and a van Hove singularity (vHS) in the dispersion that crosses the Fermi level. The real part of the critical particle-particle susceptibility exhibits a algebraic decay with temperature, which results in the imaginary part showing scaling at large frequencies. This algebraic decay leads to higher superconducting transition temperatures as compared to the BCS theory, where the pairing susceptibility decays only logarithmically. In this talk, we examine the role of the van Hove singularity in determining this critical behavior. We calculate the bare particle-particle susceptibility of a d-wave pair field for the standard two-dimensional tight binding dispersion and for a hypothetical quartic dispersion having "flatter" or "extended" singularities. We find that the standard logarithmic vHS cannot correctly describe the critical algebraic behavior and it is essential to have an extended vHS that displays an algebraic singularity. Thus, our results emphasize the possible role of the extended vHS in the unexpectedly higher T_c of cuprates.

10:48AM P22.00015 Numerical study of real-time quantum dynamics in spin-electron coupled system , WATARU KOSHIBAE, CMRG, RIKEN, Japan, NAOTO NAGAOSA, Dept. of Appl. Phys., Univ. of Tokyo, CMRG, RIKEN, CERG, RIKEN, Japan, NOBUO FURUKAWA, ERATO-MF, Aoyama-Gakuin Univ., Japan — The photo-induced metal-insulator transition is studied by the numerical simulation of real-time quantum dynamics of a double- exchange model. The spatial and temporal evolutions of the system during the transition have been revealed including (i) the threshold behavior with respect to the intensity and energy of light, (ii) multiplication of particle-hole (p-h) pairs by a p-h pair of high energy, and (iii) the space-time pattern formation such as (a) the stripe controlled by the polarization of light, (b) coexistence of metallic and insulating domains, and (c) dynamical spontaneous symmetry-breaking associated with the spin spiral formation imposed by the conservation of total spin for small energy-dissipation rates.

Wednesday, March 23, 2011 8:00AM - 10:36AM –
Session P23 DCMP: Superconductivity: Josephson Effects I D165

8:00AM P23.00001 Tunable terahertz emission from Bi2Sr2CaCu2O8 mesa devices[1] , TIMOTHY BENSEMAN, ULRICH WELP, WAI-KWONG KWOK, ALEXEI KOSHELEV, Materials Science Division, Argonne National Laboratory, Argonne, IL 60439, CIHAN KURTER, University of Maryland, LUTFI OZYUZER, Izmir Institute of Technology, Turkey, KAZUO KADOWAKI, TAKASHI YAMAMOTO, University of Tsukuba, Japan — The so-called "terahertz gap," covering frequencies from approximately 0.3 to 1.5 THz, is of particular interest for a number of scientific and security applications, although no bright sources of coherent radiation presently exist in this range. However, stacks of high-temperature superconducting intrinsic Josephson junctions are a promising candidate. [1] Here we discuss recent progress in improving the performance of these devices. In particular, we demonstrate that via control of bias voltage and operating temperature, the emission from an 80-μm wide $Bi_2Sr_2CaCu_2O_8$ mesa can be tuned continuously over a frequency range in excess of 10% in the vicinity of 0.5 THz. We find that as the emission frequency increases from 0.420 to 0.492 THz, the linewidth increases from $<$2.25 GHz (limited by instrument resolution) to $\sim$9 GHz.

8:12AM P23.00002 The relationship between oscillation modes and single crystalline Bi2212 mesa structures[1] , T. KASHIWAGI, K. DEGUCHI, M. TSUJIMOTO, N. ORITA, T. KOIKE, R. NAKAYAMA, K. DELFANAZARI, H. MINAMI, T. YAMAMOTO, K. KADOWAKI, University of Tsukuba, CREST-JST, WPI-MANA — Continuous electromagnetic (EM) radiation in terahertz region has been observed from a rectangular mesa structure of $Bi_2Sr_2CaCu_2O_{8+\delta}$(Bi2212) single crystals.[2] It has been established that the radiation frequency is determined by both ac Josephson effect and geometrical cavity resonance condition.[3] The observed radiation frequencies in the many rectangular mesas studied were inversely proportional to the width of the mesa and the fundamental modes equal to twice the mesa width. Recently, several mesas show different radiation characteristics which suggest the existence of the higher excitation modes such as one wave length excitation mode. The observed frequencies from above mesas are almost explained by the geometrical cavity model. In order to clarify the detail of the excitation modes, we also measured the radiation pattern of EM waves.

8:24AM P23.00003 Coherent THz-wave emission from voltage- and number-controlled intrinsic Josephson junctions in $Bi_2Sr_2CaCu_2O_{8+\delta}$[1] , MANABU TSUJIMOTO, RYO NAKAYAMA, NAOKI ORITA, TAKASHI KOIKE, KOTA DEGUCHI, KAVEH DELFANAZARI, TAKASHI YAMAMOTO, TAKANARI KASHIWAGI, HIDETOSHI MINAMI, MASASHI TACHIKI, KAZUO KADOWAKI, University of Tsukuba — Intense and coherent terahertz electromagnetic wave (THz-wave) emission from the intrinsic Josephson junctions (IJJs) in single crystalline high-T_c superconductor $Bi_2Sr_2CaCu_2O_{8+\delta}$ (Bi-2212) was reported in 2007 [L. Ozyuzer *et al.*, Science **318**, (2007) 1291.]. In the present work, we demonstrate the relationship between the bias condition and the resonance state by controlling both the applied voltage, V, and the number of resistive junctions, N. We directly observed that if N junctions are in resistive state, the resonance frequency, f_J, varies in accordance with the ac-Josephson relation; $f_J = (2|e|/h)V/N$, although frequency f_J has previously been thought to be uniquely determined by the geometrical condition due to the cavity resonance effect [M. Tsujimoto *et al.*, Phys. Rev. Lett. **105**, (2010) 037005.]. We also found that the emission intensity varies as a function of both f_J and N.

[1]CREST-JST, WPI-MANA, Strategic Initiative A (University of Tsukuba)

8:36AM P23.00004 Angular distribution and Josephson plasma modes of THz radiation emitted from Bi2212 mesas with various shapes[1] , KAZUO KADOWAKI, TAKANARI KASHIWAGI, MANABU TSUJIMOTO, TAKASHI YAMAMOTO, HIDEHIRO ASAI, HIDETOSHI MINAMI, Institute of Materials Science, University of tsukuba, RICHARD A. KLEMM COLLABORATION[2] — So far, we have measured angular dependence of the intensity of the THz emission from mesas of high-T_c superconductor $Bi_2Sr_2CaCu_2O_{8+\delta}$ with various shapes such as rectangulars, squares, cylinders, triangulars, etc. and various dimensions larger or smaller than the penetration depth λ_c. The results have been analized by a model developed by Klemm and Kadowaki[3], which assumes coherent generation of the standing of wave cavity modes in a mesa due to the ac-Josephson effect. The higher harmonic modes are observed in some cases as expected in the model. However, it is often observed that the emission frequency does not obey the simple cavity mode, indicating that the cavity resonance may not be a stringent condition for the emission of the THz radiation. The implication is argued in terms of the emission dynamics from the Bi2212 mesa structure.

8:48AM P23.00005 Superconductivity induced by current injection into non-superconducting $Bi_2Sr_2CaCu_2O_8$, Y. SIMSEK, Y. KOVAL, X.Y. JIN, S. PROBST, P. MÜLLER, Department of Physics, Universität Erlangen-Nürnberg, Germany — The carrier-doping induced transition from the antiferromagnetic state to the superconducting phase is still one of the most fascinating properties of high-Tc materials. Usually hole doping is achieved by non-stoichiometry. However, we already have shown that we can change the carrier concentration of $Bi_2Sr_2CaCu_2O_{8+\delta}$ single crystals by current injection along the c-axis. This effect is persistent up to annealing temperatures of approximately 270 K. Now, the interesting question is if "chemical" doping by oxygen excess is necessary at all. For this purpose we performed current-injection experiments on fully oxygen depleted $Bi_2Sr_2CaCu_2O_8$ which was not superconducting above 4.2 K. In order to eliminate the contact resistance of the highly resistive depleted material, we realized a "true" 4-point geometry by fabricating double cross-bar crystal stacks. C-axis resistivity, critical current, and critical temperature were measured by c-axis transport. We have observed that by carrier injection the conductivity can be increased until superconductivity above 4.2 K is reached. Continuing the doping by current injection, optimum-doped and even overdoped states were obtained. Using current injection at higher bias, we were able to reduce the hole concentration again.

9:00AM P23.00006 Magnetic-field-driven phase transitions in Josephson arrays , JOSHUA PARAMANANDAM, MATTHEW BELL, ALEKSANDR VEREVKIN, LEV IOFFE, MICHAEL GERSHENSON, Rutgers University — We have studied the phase transitions induced by the magnetic field B in arrays of small Josephson junctions. The number of nearest-neighbor junctions connected to a single superconducting island varied between 4 and 11 for different arrays. When frustrated by the magnetic field, the arrays demonstrated several quantum phase transitions at different critical values of the resistance between R=3-10 k, which is in line with earlier observations. In particular, with increasing B we observed transitions between three states: a) the superconducting state with zero R, b) the "metallic" state with a weak R dependence on T in the range 40mK<T<200mK, and c) the "insulating" state with an activation dependent $R(T)$. The activation energy, extracted from the current-voltage characteristics and the Arrhenius fitting of $R(T)$ in the "insulating" regime, has been studied in detail as a function of the temperature and the magnetic field. The data indicate the possible development of a strongly inhomogeneous state when approaching the superconducting-to-insulating transition.

9:12AM P23.00007 Series-parallel two dimensional arrays of $YBa_2Cu_3O_{7-\delta}$ thin film ion damage Josephson junctions[1] , JASPER DRISKO, SHANE CYBART, STEVEN ANTON, STEPHEN WU, JAMES PARKER, ROBERT DYNES, University of California, Berkeley — We have fabricated a number of series-parallel two dimensional arrays of $YBa_2Cu_3O_{7-\delta}$ thin film ion damage Josephson junctions. The arrays contain 1,000 to 15,000 Superconducting QUantum Interference Devices (SQUIDs) in different dimensional configurations and different SQUID area distributions. We have measured the electrical transport characteristics of each array and compare it to computer simulations based on the resistively shunted junction model to investigate the effect of mutual inductance between the SQUIDS within the array. We find there is good agreement between our simulation model and our experimental device when the parallel dimension of the device is less than 15 SQUIDs.

9:24AM P23.00008 Properties of linear arrays of Josephson junctions capacitively coupled to a diffusive metal[1] , ALEJANDRO LOBOS, THIERRY GIAMARCHI, DPMC-MaNEP, University of Geneva, Switzerland — Josephson junctions arrays (JJAs) are strongly-correlated quantum systems showing a rich and complex behavior at low-temperatures.[2] Besides their potential uses in applications, JJAs allow to investigate (under controlled conditions) many aspects of low-dimensional superconductivity which remain to be understood. In this work we study the phase diagram and the low-energy properties of a one-dimensional (1D) JJA capacitively coupled to a diffusive two-dimensional electron gas (2DEG) placed at a distance d, which provides dissipation.[3] We derive an effective field-theoretical model for the 1D JJA coupled to the 2DEG, and predict a superconductor-insulator transition (SIT) at $T = 0$, in agreement with former theoretical predictions. We discuss implications for transport experiments and for the observed SIT in 1DJJAs. Both in the superconducting and insulating phases, the coupling to the 2DEG produces deviations with respect to the resistivity as a function of T predicted for an isolated array.

9:36AM P23.00009 Measurement of Aharonov-Casher effect in a Josephson junction chain[1] , IOAN MIHAI POP, CNRS, Institute NEEL, Grenoble, FLORENT LECOCQ, BERNARD PANNETIER, OLIVIER BUISSON, WIEBKE GUICHARD, CNRS, Institut NEEL, Grenoble — We have recently measured the effect of superconducting phase-slips on the ground state of a Josephson junction chain[2] and a rhombi chain.[3] Here we report clear evidence of Aharonov-Casher effect in a chain of Josephson junctions. This phenomenon is the dual of the well known Aharonov-Bohm interference. Using a capacitively coupled gate to the islands of the chain, we induce oscillations of the supercurrent by tuning the polarization charges on the islands. We observe complex interference patterns for different quantum phase slip amplitudes, that we understand quantitatively as Aharonov-Casher vortex interferences.

9:48AM P23.00010 Josephson Junction as a Magnetic Switch , LIUFEI CAI, CUNY-Lehman College and Graduate Center, EUGENE CHUDNOVSKY, CUNY Lehman College — We study electromagnetic interaction of a nanomagnet with a weak superconducting link. Equations that govern coupled dynamics of the two systems are derived and investigated numerically. We show that despite very weak magnetic field generated by the weak link, a time-dependent bias voltage applied to the link can initiate a non-linear dynamics of the nanomagnet that leads to the reversal of its magnetic moment. We also consider quantum problem in which a nanomagnet interacting with a weak link is treated as a two-state spin system due to quantum tunneling between spin-up and spin-down states. L. Cai and E. M. Chudnovsky, Phys. Rev B **82**, 104429 (2010).

10:00AM P23.00011 Switching Experiments on a Current-Biased MgB_2 Josephson Junction[1] , ROBERTO RAMOS, JEROME MLACK, JOSEPH LAMBERT, STEVEN CARABELLO, Department of Physics, Drexel University — As the current through a Josephson junction is increased, the voltage across the junction switches from zero to a finite voltage. This is analogous to the escape of a phase particle originally oscillating with a plasma frequency ω in a washboard potential well, to the running state. We report results of our switching experiments on current-biased MgB_2/I/Pb thin film junctions through a broad range of sub-Kelvin temperatures. Our results exhibit features in the escape rate Γ suggestive of substructure within the pi gap of MgB_2, which is consistent with our recent work demonstrating sub- structure within the pi and sigma superconducting energy gaps of MgB_2. Upon irradiation of microwaves with frequencies resonant with the plasma frequency, we observe enhancement of escape rates, which is a clear demonstration of microwave resonant activation in these devices. By manipulating frequency and power, we demonstrate good control over the escape of the phase particle.

[1]We wish to thank Profs. Xiaoxing Xi and Ke Chen for providing high-quality MgB_2 Josephson junctions.

10:12AM P23.00012 ABSTRACT WITHDRAWN –

10:24AM P23.00013 Cavity mode waves during terahertz radiation from rectangular $Bi_2Sr_2CaCu_2O_{8+\delta}$ mesas , RICHARD KLEMM, ERICA LABERGE, DUSTIN MORLEY, University of Central Florida, TAKANARI KASHIWAGI, MANABU TSUJIMOTO, KAZUO KADOWAKI, University of Tsukuba, Tsukuba, Japan — We re-examined the angular dependence of the radiation from the intrinsic Josephson junctions in rectangular mesas of $Bi_2Sr_2CaCu_2O_{8+\delta}$, in order to determine if the cavity mode part of the radiation arises from waves across the width w or along the length ℓ of the mesas, associated with "hot spots" [Wang *et al.*, Phys. Rev. Lett. **105**, 057002 (2010)]. Fits to the data of Kadowaki *et al.* [J. Phys. Soc. Jpn. **79**, 02373 (2010)] using both a uniform ac Josephson current source and a non-uniform cavity mode (or magnetic surface current) source suggest that both scenarios are equally probable. However, when $n\ell/2w$ is integral, where n is the index of the rectangular $TM^z(n,0)$ mode, standing cavity wave modes along the length of the mesa do not radiate in the xz plane perpendicular to the length of the mesa, suggesting experiments on such mesas could help to resolve the question.

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P24 DCOMP: Focus Session: What is Computational Physics? II followed by Computational Methods: Numerical Methods for Strongly Correlated Systems II D167

8:00AM P24.00001 US-Japan Workshops on Computational Physics - International Liaison Activities - , YUKO OKAMOTO, Nagoya University — In this talk, I will report on US-Japan workshops on computational physics. I will summarize what was done in the past workshops that were held in Hawaii and talk about future plans.

8:12AM P24.00002 Opportunities for Computational Discovery in Basic Energy Sciences , MARK PEDERSON, Department of Energy, Office of Basic Energy Sciences, Washington DC, 20585-1290 — An overview of the broad-ranging support of computational physics and computational science within the Department of Energy Office of Science will be provided. Computation as the third branch of physics is supported by all six offices (Advanced Scientific Computing, Basic Energy, Biological and Environmental, Fusion Energy, High-Energy Physics, and Nuclear Physics). Support focuses on hardware, software and applications. Most opportunities within the fields of condensed-matter physics, chemical-physics and materials sciences are supported by the Officeof Basic Energy Science (BES) or through partnerships between BES and the Office for Advanced Scientific Computing. Activities include radiation sciences, catalysis, combustion, materials in extreme environments, energy-storage materials, light-harvesting and photovoltaics, solid-state lighting and superconductivity. A summary of two recent reports by the computational materials and chemical communities on the role of computation during the next decade will be provided. In addition to materials and chemistry challenges specific to energy sciences, issues identified include a focus on the role of the domain scientist in integrating, expanding and sustaining applications-oriented capabilities on evolving high-performance computing platforms and on the role of computation in accelerating the development of innovative technologies.

8:24AM P24.00003 Discussion of Opportunities in Computational Physics[1] , BERND BERG, Florida State University, MARK PEDERSON, Department of Energy — A discussion of the points raised in the previous talk by Mark Pederson (DOE) will be encouraged, including: (1) Identifying models and strategies for effectively organizing and availing complex computational simulation capabilities to a broader scientific and technical community. (2) Identifying cross-discipline communication of capabilities to ensure sharing of algorithms. (3) Opinions on evolution of overlap between the basic energy scientific mission and the fields that are typically represented by the March-Meeting participants. (4) Interactions between the domains of computational physics, computer science, and applied mathematics. (5) The proper balance between individual and group achievement. (6) What role could DCOMP have in this?

[1]In part supported by the DOE grant DE-FG02-97ER41022.

8:36AM P24.00004 Enabling Computational Discovery and Design , DARYL HESS, Division of Materials Research, National Science Foundation, USA — Advanced cyberinfrastructure(CI), increases in computing power, and increasing use of data volumes are revolutionizing how science is done, changing the nature of the questions we ask, and opening new frontiers. From discovering new phenomena and states of matter to the challenge of designing new materials and matter, the focus on problems with many complex interacting degrees of freedom through computational investigation often leads to large amounts of data that require analysis, preservation, curation, and sharing across the community. Data from many sources plays an increasingly important role as a driver of discovery. I will discuss opportunities in computational and data enabled science and in building the CI of the 21^{st} century. Sustainable, maintained, and reliable shared software is an important component of a National CI framework that will empower computational scientists to engage the scientific frontiers and the pressing problems around us. The success of computational data enabled science requires innovation that leads to paradigms in attacking difficult problems. Education will play an important role in realizing the full potential of computation and data enabled science for discovery and design. Participation of the computational science community is an important ingredient to create a CI that will propel science forward; some self-assembly is required. NSF provides funding opportunities to help.

8:48AM P24.00005 Building Foundations for Future Advances in Computational Physics , BARRY SCHNEIDER, DARYL HESS, National Science Foundation — We continue the discussion on laying the cyberinfrastructure foundations to support future advances in computational science. We will focus on how NSF can help and encourage communication with the community in achieving this goal.

9:00AM P24.00006 Quo Vadis Computational Physics?[1] , RICHARD SCALETTAR, University of California, Davis — In this Focus Session, and in the preceding DCOMP Invited Symposium, "Great Advances of Computational Physics: Past, Present and Future," we have heard about the vision for our field, reviewed (and previewed) cutting-edge numerical work, and considered where the resources might come to support our endeavors. In this talk I will summarize some of the common themes of this discussion, as well as open up the floor for further thoughts on where our APS Division is heading.

[1]Research supported by the DOE SCIDAC program, DOE-DE-FC0206ER25793, and under ARO Award W911NF0710576 with funds from the DARPA OLE Program.

9:36AM P24.00007 Magnetic impurities in real lattices: A DMRG and ECA study , CARLOS BUSSER, University of Wyoming, WY, GEORGE MARTINS, Oakland University, MI, KHALED AL-HASSANIEH, Los Alamos National Laboratory, NM, ADRIAN FEIGUIN, University of Wyoming, WY — Magnetic interactions between strongly correlated impurities coupled to a sea of conduction electrons is a subject of great interest from both, experimental and theoretical studies. When many magnetic impurities are attached to the same conduction band a rich phase diagram can arise. By one hand the magnetic impurities can be strongly coupled to the spin of the electrons of the conduction band forming a Kondo singlet. By the other, through electron of the conduction band, a spin-spin interaction between the impurities can appears as a consequence the RKKY interaction. A competition between this two singles is expected. For these two effects is important to have a good description of the electrons with energy close to the Fermi level. Systems like the square lattice, with a van-Hove singularity at the middle of the band, or Graphene, with Dirac electrons, or Carbon nanotubes with multiple bands and multiples van Hove singularities need a proper description of the electrons in the lattice Hamiltonian. In this work we present, through a canonical transformation, a numerical method to study problems with several magnetic impurities coupled to arbitrary lattices using DMRG or ECA techniques.

9:48AM P24.00008 Quantum Monte Carlo simulations with tensor-network states[1] , JEONG PIL SONG, R.T. CLAY, Mississippi State University — Matrix-product states, generated by the density-matrix renormalization group method, are among the most powerful methods for simulation of quasi-one dimensional quantum systems. Direct application of a matrix-product state representation fails for two dimensional systems, although a number of tensor-network states have been proposed to generalize the concept for two dimensions. We introduce a useful approximate method replacing a 4-index tensor by two matrices in order to contract tensors in two dimensions. We use this formalism as a basis for variational quantum Monte Carlo, optimizing the matrix elements stochastically. We present results on a two dimensional spinless fermion model including nearest- neighbor Coulomb interactions, and determine the critical Coulomb interaction for the charge density wave state by finite size scaling.

[1]This work was supported by the Department of Energy grant DE-FG02-06ER46315.

10:00AM P24.00009 Diagonalization with matrix-product states[1] , CHEN LIU, ANDERS SANDVIK, Boston University — We consider matrix-product states (MPSs) combined with diagonalization as a method to study correlated quantum many-body systems. The Hamiltonian matrix is constructed in a non-orthogonal basis of MPSs. Diagonalizing this matrix (a generalized eigenvalue problem) gives the ground state as well as excitations. The accuracy is significantly improved compared to individual optimized MPSs. We discuss several ways to generate the MPS basis states in a suitable way and present results for one- and two-dimensional quantum spin systems.

[1]NSF DMR-0803510

10:12AM P24.00010 Multi-scale entanglement renormalization for critical systems , BELA BAUER, Theoretische Physik, ETH Zurich, LIZA HUIJSE, Department of Physics, Harvard University, KARELJAN SCHOUTENS, Institute for Theoretical Physics, University of Amsterdam, GUIFRE VIDAL, The University of Queensland, Department of Physics, Brisbane, MATTHIAS TROYER, Theoretische Physik, ETH Zurich — Determining information about the underlying conformal field theory of a critical system in one dimension, such as the central charge and scaling dimensions, is a notoriously difficult problem for numerical methods. Using a suitable tensor network state, the multi-scale entanglement renormalization ansatz [1], this information is directly accessible [2]. We apply this method to several critical systems in one dimension, including a supersymmetric model for lattice fermions and Yang-Lee chains.

[1] G. Vidal, Phys. Rev. Lett. 99, 220405 (2007)
[2] R.N.C. Pfeifer et al, Phys. Rev. A 79(4), 040301(R) (2009)

10:24AM P24.00011 Simulation of fermionic and frustrated lattice models in two dimensions with tensor network algorithms , PHILIPPE CORBOZ, Theoretische Physik, ETH Zurich, Switzerland/Institute for theoretical Physics, EPF Lausanne, Switzerland, GLEN EVENBLY, JACOB JORDAN, ROMAN ORUS, GUIFRE VIDAL, School of Mathematics and Physics, The University of Queensland, Australia, BELA BAUER, MATTHIAS TROYER, Theoretische Physik, ETH Zurich, Switzerland, FREDERIC MILA, Institute for theoretical Physics, EPF Lausanne, Switzerland, FRANK VERSTRAETE, Faculty of Physics, University of Vienna, Austria — The simulation of strongly correlated fermionic and frustrated systems in two dimensions is one of the biggest challenges in computational physics. Borrowing ideas and tools from quantum information and condensed matter physics, a new generation of simulation techniques for many-body systems, the so-called tensor network algorithms (e.g. PEPS, MERA), have been proposed in the last few years. These algorithms have been generalized to fermionic systems recently. We present a particularly simple formalism to account for the statistics of fermionic degrees of freedom in a tensor network. Benchmark results confirm the validity of this approach, and show that the computational cost of simulations does not depend a priori on the particle statistics, but on the amount of entanglement in the system.

10:36AM P24.00012 Dynamical simulation of integrable and non-integrable models in the Heisenberg picture[1] , DOMINIK MUTH, RAZMIK UNANYAN, MICHAEL FLEISCHHAUER, Fachbereich Physik und Forschungszentrum OPTIMAS, Technische Universitaet Kaiserslautern, D-67663 Kaiserslautern, Germany — The numerical simulation of quantum many-body dynamics is typically limited by the linear growth of entanglement with time. Recently numerical studies have shown, however, that for 1D Bethe-integrable models the simulation of local operators in the Heisenberg picture can be efficient as the corresponding operator-space entanglement grows only logarithmically. Using the spin-1/2 XX chain as generic example of an integrable model that can be mapped to free particles, we here provide a simple explanation for this. We show furthermore that the same reduction of complexity applies to operators that have a high-temperature auto correlation function which decays slower than exponential, i.e., with a power law. This is amongst others the case for models where the Blombergen-De Gennes conjecture of high-temperature diffusive dynamics holds. Thus efficient simulability may already be implied by a single conservation law (like that of total magnetization), as we will illustrate numerically for the spin-1 XXZ model.

10:48AM P24.00013 ABSTRACT WITHDRAWN –

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P25 DCMP: Superconductivity: Devices and Applications D166

8:00AM P25.00001 Microwave amplifier based on an inline dc SQUID , DAVID HOVER, YUNG-FU CHEN, LEON MAHER, GUILHEM RIBEILL, SHAO-JIANG ZHU, STEVE SENDELBACH, ROBERT MCDERMOTT, University of Wisconsin — The dc SQUID can be used as a sensitive, low-noise microwave amplifier if the signal to be amplified is suitably coupled to the SQUID. We have designed and fabricated microwave amplifiers based on inline dc SQUIDs, where the SQUID loop is formed from a thin ($\sim$ 100 nm) dielectric layer separating the base and counterelectrode wiring traces. The SQUID is embedded in a microstrip transmission line resonator at a current anti-node, and signal current is injected directly into the SQUID loop. With this design we have achieved gain greater than 20 dB at a frequency of 8.5 GHz. We provide a theoretical analysis of amplifier noise temperature, bandwidth, and gain, and describe measurements of amplifier noise temperature. We discuss application of these devices to the readout of superconducting quantum circuits.

8:12AM P25.00002 Spatial correlations of magnetic fluctuations in DC SQUIDS , STEVEN SENDELBACH, UMESHKUMAR PATEL, ROBERT MCDERMOTT, UW-Madison Department of Physics — Recent experiments indicate that there is a high density of unpaired spins residing on the surfaces of superconducting thin films used to implement SQUIDs and superconducting qubits. Fluctuations of these spins give rise to low frequency flux noise and dephasing of the qubit state. Realization of phase and flux qubits with improved dephasing times will require a deeper understanding of the microscopic physics that governs fluctuations of the surface spins. Here we describe experiments to probe the spatial correlation of magnetic fluctuators in a SQUID circuit. The SQUID loop incorporates multiple current taps, enabling one to locally address magnetic fluctuators. Preliminary data reveal correlated fluctuations on a length scale of order 10 μm. We discuss implications for qubit dephasing.

8:24AM P25.00003 Simulations of dependence of low frequency flux noise on SQUID geometry[1] , STEVEN ANTON, KEENAN PEPPER, JOHN CLARKE, UC Berkeley, IDA SOGNNAES, NTNU Norway, UC BERKELEY TEAM, NTNU NORWAY TEAM — It is generally accepted that the 1/f magnetic flux noise observed in dc SQUIDs and superconducting qubits originates in the random flipping of a uniform distribution of electron spins localized at the superconductor-insulator interface. Computer simulations and analytical calculations based on this model confirm the experimental result that the noise power at 1 Hz varies only slowly with SQUID dimensions. In particular, analytical calculations for a circular loop with radius R much greater than the loop linewidth W predict that the noise power scales as R/W. We present numerical computations that are valid for arbitrary geometry, including that of the square washer SQUID for which W approaches R. Making use of the reciprocity theorem, we solve the London equations numerically to find the current distribution in the superconductor, evaluate the Biot-Savart integral to find the corresponding magnetic field at any point and integrate over all spins, including those at the edges of the films, to find the total flux noise. We compare our results with our recent experimental measurements.

[1]Work supported by ARO and IARPA

8:36AM P25.00004 Dependence of low frequency flux noise on SQUID-washer dimensions[1] , J. BIRENBAUM, S.M. ANTON, A.D. FEFFERMAN, S.R. O'KELLEY, J. CLARKE, UC Berkeley, H-M CHO, G.C. HILTON, K.D. IRWIN, NIST Boulder, F.C. WELLSTOOD, Univ. of Maryland — The 1/f spectral density of low frequency magnetic flux noise at 1 Hz in dc SQUIDs and qubits varies slowly with the dimensions of the superconducting loop, in reasonably good agreement with predictions. Previous measurements on SQUIDs fabricated from a variety of superconductors under different conditions and in a variety of geometries, however, showed that the slope of the power spectrum varied considerably. We report flux noise measurements on six resistively-shunted dc SQUIDs fabricated simultaneously on a single Si chip using a Nb-trilayer process. The noise spectra of all six devices were measured using a SQUID in a single cool-down of our dilution refrigerator. The linewidths of the SQUID loops were varied systematically by a factor of more than 30. The variation in noise power at 1 Hz was small compared with the variation in line width, while the slope varied significantly, from approximately -0.5 to -1. Furthermore, for a given SQUID, the slope depended on temperature.

[1]Work supported by ARO and IARPA.

8:48AM P25.00005 A Novel System for Accurate Cryogenic S-Parameter Measurements , LEONARDO RANZANI, LAFE SPIETZ, JOSE AUMENTADO, NIST, Boulder — In order to study microwave devices operating at cryogenic temperatures (4K and below), an accurate characterization of their full scattering parameters is needed. Simple response calibration using a single through standard is usually performed at cryogenic temperatures due to its simplicity, but it is inaccurate since it only determines 4 of the 10 unknowns present in a general two port network environment. In this talk we will discuss a fully automated through-reflect-line (TRL) calibration system suitable for accurately characterizing 2-port S parameters for devices such as SQUID amplifiers and other cryogenic microwave circuits. Data for some typical devices up to 8GHz will be presented.

9:00AM P25.00006 Josephson Junction Circuits for Passive Non-Reciprocal Microwave Devices , LAFE SPIETZ, NORM BERGREN, JOSE AUMENTADO, NIST — We propose a method for using Josephson junction circuits to build non-reciprocal passive microwave components. We show that strong analogies can be made between the physics of ferrites used in traditional passive non-reciprocal microwave devices (that of the gyroscope) and certain classes of Josephson junction circuits. We describe a simple circuit which demonstrates these physical principles, and present both theoretical experimental results on this circuit.

9:12AM P25.00007 Probing the origin of 1/f critical-current noise in nanoscale Al/AlOx/Al Josephson junctions[1] , CHRISTOPHER NUGROHO, VLADIMIR ORLYANCHIK, ALLISON DOVE, GUSTAF OLSON, ZACHARY YOSCOVITS, JAMES ECKSTEIN, DALE VAN HARLINGEN, Department of Physics, University of Illinois at Urbana-Champaign — We present measurements of the low frequency noise in nanoscale Al/AlOx/Al Josephson junctions made by the shadow/angle evaporation technique. We investigate the differences in the nature of the charge trap fluctuations when the junction electrodes are in the normal state vs. in the superconducting state, as a test of some recent theoretical models. To do that, we compare the magnitude, temperature dependence, and magnetic field dependence of junction resistance fluctuations in the normal state above the Al transition temperature to that of the resistance and critical current fluctuations measured in the superconducting state. We also explore whether the observed fluctuators are thermally-activated or tunneling as a function of temperature.

[1]Supported by the IARPA Advanced Materials and Fabrication for Coherent Superconducting Qubits Program

9:24AM P25.00008 Decoherence and energy shift in phase qubits due to nonequilibrium quasiparticles , M. LENANDER, R.C. BIALCZAK, E. LUCERO, M. MARIANTONI, A. O'CONNELL, M. NEELEY, D. SANK, H. WANG, M. WEIDES, J. WENNER, T. YAMAMOTO, Y. YIN, J. ZHAO, A.N. CLELAND, J.M. MARTINIS — Nonequilibrium quasiparticle excitations are thought to be an important source of decoherence in Josephson qubits. We present a model analogous to the Mattis-Bardeen theory wherein the effects of quasiparticles introduce a complex environmental impedance to the junction. The real part causes energy relaxation in the qubit while the imaginary part causes a frequency shift. We present experimental data comparing these effects while injecting nonequilibrium quasiparticles into the system. The theory is used to qualitatively check the injection process. Then by comparing the decay rate and frequency shift, we quantitatively verify the theory without the need to directly measure the quasiparticle density. Agreement between theory and experiment is observed to within experimental uncertainty, about 10%. We examine infrared radiation as a source of nonequilibrium quasiparticles. Using these new tools, we hope to develop methods for improving qubit performance and to bound the contribution to energy decay from quasiparticles.

9:36AM P25.00009 Effect of an Ohmic environment on an optimally controlled flux-biased phase qubit , AMRIT POUDEL, MAXIM VAVILOV, University of Wisconsin-Madison — We analyze the effect of environment on the gate operation of flux-biased phase qubits. We employ the master equation for a reduced density matrix of the qubit system coupled to an Ohmic environment, described by the Caldeira-Leggett model. Numerically solving this equation, we evaluate the gate error as a function of gate time, temperature and environmental coupling strength for experimentally determined qubit parameters. Here we present the analysis for single-quadrature microwave (control) pulses as well as for two-quadrature pulses, which lower the gate error significantly for idealized systems in the absence of environment. Our results indicate that two-quadrature pulses with fixed and variable driving frequency have similar performance, which outweighs the performance of single-quadrature pulses, in the presence of environment.

9:48AM P25.00010 Quasiparticle relaxation of superconducting qubits in the presence of flux , GIANLUIGI CATELANI, Yale University, JENS KOCH, Northwestern University, LUIGI FRUNZIO, ROBERT SCHOELKOPF, MICHEL DEVORET, LEONID GLAZMAN, Yale University — Quasiparticle tunneling across a Josephson junction sets a limit for the lifetime of a superconducting qubit state. We develop a general theory of the corresponding decay rate in a qubit controlled by a magnetic flux. The flux affects quasiparticles tunneling amplitudes, thus making the decay rate flux-dependent. The theory is applicable for an arbitrary quasiparticle distribution. It provides estimates for the rates in practically important quantum circuits and also offers a new way of measuring the phase-dependent admittance of a Josephson junction.

10:00AM P25.00011 ABSTRACT WITHDRAWN –

10:12AM P25.00012 High count-rate superconducting transition edge sensors for near-IR single photon detection , FAUSTIN CARTER, DANIEL SANTAVICCA, LUIGI FRUNZIO, Yale University, ANTHONY ANNUNZIATA, IBM, Yale University, DANIEL PROBER, Yale University — Detection of individual near-IR photons with GHz count rates, good timing resolution, and high quantum efficiency is important in a number of applications. These include quantum key distribution, single-photon classical communication, and CMOS imaging for defect analysis. We propose a nano-scale superconducting niobium transition edge sensor (TES). The extremely small detector volume allows for single-photon sensitivity at 4 K, with a much faster response time (nsec) than conventional TES detectors operating below 0.4 K. Efficient photon coupling is achieved with a resonant near-IR planar antenna. The proposed device is intrinsically photon number resolving, unlike a niobium-nitride nanowire detector or an avalanche photodiode. We present preliminary results for device performance.

10:24AM P25.00013 Nano-structuring on the surface of high Tc-superconductors by STM&AFM , KAZUTO HIRATA, National Institute for Materials Science, TADASHI MACHIDA, SHUUICHI OOI, MINORU TACHIKI, National Institute for Materials Science, TAKASHI MOCHIKU — We demonstrate local insulation on a cleaved surface of Bi- 2212 single crystals using a local anodic oxidation by a atomic force microscope (AFM) and a scanning tunneling microscope (STM) for the first time. We have investigated the electrical properties of the modified region by using an STM-assisted near- field microwave microscope. From the experimental observations, we conclude that the modified region becomes an insulator with an associated dielectric loss locally. Varying the applied bias- voltage and the scanning speed can control the protrusion height and the line width of the regions. This provides a potential technique for reproducibly fabricating high temperature superconducting devices with stable electronic characteristics.

10:36AM P25.00014 An Integrated Balanced Superconductor-Insulator-Superconductor Heterodyne Mixer on a Silicon Membrane , M.P. WESTIG, K. JACOBS, M. SCHULTZ, M. JUSTEN, J. STUTZKI, C.E. HONINGH, I. Physikalisches Institut, Universitaet zu Koeln, Zuelpicher Straße 77, 50937 Koeln, Germany — We have designed and fabricated a 380-520 GHz integrated balanced Nb\Al\AlOx\Nb superconductor-insulator-superconductor (SIS) heterodyne waveguide mixer for submillimeter astrophysics. The response of the mixer measured with a Fourier transform spectrometer shows excellent agreement with the design. The novelty of our device is that we deposit the complete superconducting mixer circuit (tapered slotline antennas, hybrid coupler, MIM capacitors, SIS junctions, tuning circuits and blocking filters) on top of a 9 μm silicon membrane. The membrane is held suspended in a waveguide by 2.5 μm thick gold plated beamleads. We will show that silicon membrane technology and a thorough device design render the integration of SIS devices with larger circuits feasible. This is an important step towards large arrays of mixers. When using an appropriate superconductor technology, these devices are scalable to higher frequencies. We will present the design, fabrication results and first results of heterodyne measurements.

10:48AM P25.00015 c-Axis current flow arises in helically wound wire , YING JIA, U. WELP, G.W. CRABTREE, W.K. KWOK, Materials Science Division, Argonne National Laboratory, Argonne, IL 60439, USA, M. RUPICH, S. FLESHLER, A.P. MALOZEMOFF, American Superconductor Corp., 64 Jackson Road, Devens, MA 01434-4020, USA — c-Axis critical current density of second-generation YBCO wires in HTS cables due to the interaction of current flow with the induced magnetic field. However, the importance of c-axis critical current density (J_c^c) on the overall transport critical current is not clearly understood. We measured the temperature and field dependence of J_c^c using a mesa structure patterned into the YBCO layer of 2^{nd}-generation HTS tapes. We found, J_c^c –values of $\sim$ 4 kA/cm^2 at 77 K in self-field, corresponding to an unexpectedly high anisotropy of the critical current density $\gamma = J_c^{ab}\big/J_c^c$ = 500$\sim$600. We also investigated the effect of pinning microstructures on J_c^c and γ. Our result shows a direct correlation of J_c^c (77 K, sf) and γ to the density of stacking faults. An estimation reveals that the fraction of tape width associated with c-axis current flow grows linearly from 5% to 20% with increasing γ for a typical geometry and could affect the performance of power transmission in HTS cables.

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P26 DMP DCOMP: Focus Session: Iron Based Superconductors – Spin Dynamics D162/164

8:00AM P26.00001 High Energy Spin Excitations in Optimal doped Superconducting $BaFe_{1.9}Ni_{0.1}As_2$, MENGSHU LIU, Department of Physics and Astronomy, The University of Tennessee, Knoxville, Tennessee 37996-1200, USA, HUIQIAN LUO, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, RUSSELL EWINGS, TATIANA GUIDI, ISIS Facility, Rutherford Appleton Laboratory, STFC, Chilton, Didcot, Oxon, OX11 0QX, United Kingdom, PENGCHENG DAI, Department of Physics and Astronomy, The University of Tennessee, Knoxville, Tennessee 37996-1200, USA — The recent discovered iron pnictide superconductor which shows a transition temperature up to 50K has drawn much attention in the community. There are indications that superconductivity in the iron arsenides family may be driven by a magnetic pairing mechanism, the nature of which remains poorly understood. In our recent inelastic neutron scattering experiment on optimal doped $BaFe_{1.9}Ni_{0.1}As_2$ sample, spin excitation data are collected throughout the Brillouin zone and up to energy transfer of 400meV which was not probed before. We found that the scattering persists as high as 300 meV in the superconducting sample, and a spectra transfer similar to the parent compound with a spin nematicity was also observed

8:12AM P26.00002 Spin-phonon coupling in iron arsenide superconductors[1] , JENNIFER NIEDZIELA, DANIEL PARSHALL, KONSTANTIN LOKSHIN, U. of Tennessee - Knoxville, TN, ATHENA SEFAT, ORNL, Oak Ridge, TN, AHMET ALATAS, APS, Argonne National Laboratory, Darien, IL, TAKESHI EGAMI, U. of Tennessee - Knoxville, TN USA — In this work we present the results of an inelastic x-ray scattering experiment measuring the softening of the TA[110] phonon in $BaFe_2As_2$ as a function of temperature. Cooling through the structural transition temperature yields a softening of the phonon energy of the transverse acoustic mode nearly 1 meV from the value at room temperature at $\mathbf{q} = 0.1$. This phonon controls the structural phase transition, changing the symmetry from tetragonal to orthorhombic at the same temperature as the transition to long range antiferromanetic order. Even though the lattice distortion is minor, the anisotropy in the magnetic exchange constants is very large. We posit that this phonon mode couples to the orbital moment, and softening of this mode is required for the onset of long range antiferromagnetic ordering and the dramatic change in the exchange constants. This observation is suggestive that a mechanism of spin-phonon coupling is present in the pnictide systems, and is a possible contributor to the superconducting mechanism.

[1]The work was supported by Department of Energy Office of Basic Energy Sciences.

8:24AM P26.00003 Collapse of the spin resonance spectral weight in overdoped $Ba_{1-x}K_xFe_2As_2$[1] , RAY OSBORN, STEPHAN ROSENKRANZ, JOHN-PAUL CASTELLAN, EUGENE GOREMYCHKIN, DUCK-YOUNG CHUNG, HELMUT CLAUS, Argonne National Laboratory, MERCOURI KANATZIDIS, Northwestern University, TATIANA GUIDI, Rutherford Appleton Laboratory, UK — We report inelastic neutron scattering measurements of magnetic excitations in $Ba_{1-x}K_xFe_2As_2$ over a broad range of electron band filling within the superconducting phase. In an itinerant model, these excitations are resonantly enhanced when the superconducting energy gap changes sign on different parts of the electron Fermi surface. They are therefore sensitive both to the superconducting gap symmetry and to the Fermi surface geometry. Our results show that, in addition to becoming incommensurate because of the growing mismatch in the hole and electron Fermi surface volumes, the resonant spectral weight decreases proportionally to the resonance binding energy, vanishing at $x \sim 0.72$. A tight-binding model including $s_\pm$-symmetry pairing is able to reproduce these observations confirming that the resonance arises from the pairing of band electrons.

[1]Supported by U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under contract No. DE-AC02-06CH11357.

8:36AM P26.00004 Spin Correlations in Superconducting $Ba(Fe_{1-x}Co_x)_2As_2$[1] , STEPHEN HAYDEN, University of Bristol — Elastic and inelastic neutron scattering are used to study the spin correlations in superconducting $Ba(Fe_{1-x}Co_x)_2As_2$. Measurements on the antiferromagnetically ordered parents of this system [1] show a strongly anisotropic spin-wave velocity. Here we report [2] measurements of the magnetic excitations in a the superconducting composition, x=0.065, up to 80 meV and show that a similar anisotropy persists for superconducting compositions. The dispersive mode measured here connects directly with the spin resonance previously observed in this compound. When placed on an absolute scale, our measurements show that the local- or wavevector- integrated susceptibility is larger in magnitude than that of the ordered parents over the energy range probed. I will discuss the interpretation of our results in terms of the electronic structure and possible fluctuating nematic order.

9:12AM P26.00005 Multiband effect on the magnetic resonance spectrum of pnictide superconductors , TANMOY DAS, A.V. BALATSKY, LANL — The magnetic resonance behavior which is directly probed by the inelastic neutron scattering (INS) spectroscopy gives valuable information about the pairing mechanism of the unconventional superconductors. In high-T_c cuprate superconductors, INS exhibits a clear signature of a magnetic resonance mode in addition to its characteristic dispersive feature (known as "hour-glass" behavior) which are enhanced dramatically below T_c and the mode energy scales universally with the SC gap amplitude. In a multiband unconventional superconductors, the situation is more complex due to the presence of multi-orbital band structure, multiple-SC gaps as well as possibilities of having multiple pairing symmetries. We calculate magnetic susceptibility to show how does the magnetic resonance mode and its dispersion evolve both in energy as well as in momentum as a function of doping in both electron and holed doped pnictide superconductors. The inputs in our calculations are the Fermi surface information from ARPES or LDA and experimental values of superconducting gaps. We find that the magnetic resonance behavior is dramatically different in pnictide than in cuprates. The effects of multiple orbitals, gaps and different pairing symmetry play an important role. We argue that doping dependence of the resonance spectra can be understood from the topological change of the Fermi surface and the gap magnitudes, in good accord with experiments.

9:24AM P26.00006 Spin-orbit coupling in Fe-based superconductors[1] , M.M. KORSHUNOV, Department of Physics, University of Florida, Gainesville, Florida 32611, USA, I. EREMIN, Institut fuer Theoretische Physik III, Ruhr-Universitaet Bochum, D-44801 Bochum, Germany, P.J. HIRSCHFELD, Department of Physics, University of Florida, Gainesville, Florida 32611, USA — The recently discovered iron-based superconductors have attracted considerable attention mainly for their unconventional pairing state. In connection with the determination of pairing symmetry, the resonance peak observed in neutron scattering experiments [1] agrees well with predicted results for the extended s-wave ($s_\pm$) gap symmetry [2]. However, recent neutron measurements shows that there is anisotropy in the spin resonance [3]. In particular, S^zS^z component is different from S^+S^- component of the dynamical spin susceptibility. Such breaking of the spin-rotational invariance in the spin-liquid phase without long-range order can occur due to spin-orbit (SO) coupling. We study the role of the SO coupling in the multiorbital model for Fe-pnictides, and discuss how it influences spin resonance feature and the relation to SC pairing.

9:36AM P26.00007 A LDA+DMFT+Vertex function study of dynamical magnetic susceptibility in iron based superconductors , HYOWON PARK, KRISTJAN HAULE, GABRIEL KOTLIAR, Rutgers University — We developed a method for computing dynamical magnetic susceptibility in complex correlated materials based on LDA+DMFT+Vertex function calculation. The dressed Greens function was obtained from the charge self-consistent LDA+DMFT calculation and the local Vertex function was computed from the quantum impurity model using a CTQMC impurity solver. We applied this method to compute the normal state magnetic susceptibility in iron pnictides and iron chalcogenides. Our result shows good agreement with inelastic neutron scattering data. At a low energy, the dynamical structure factor S(Q,w) is peaked at (π,0) momentum in $BaFe_2As_2$ and at ($\pi/2$,$\pi/2$) in FeTe, as expected for the distinct ordering of these compounds. At higher energy, the peak positions shifts to the (π,π) wave vector, in agreement with recent neutron experiments. We argue that this (π,π) magnetic response at high energy and the full spin dispersion above Neel temperature is captured by our realistic band structure method, LDA+DMFT.

9:48AM P26.00008 Neutron scattering study of spin fluctuations on hole-overdoped KFe_2As_2 , C.H. LEE, K. KIHOU, A. IYO, H. EISAKI, AIST, Jpn, H. K.-FURUKAWA, Ocha. Univ., H. USUI, K. KUROKI, The Univ. of Electro-Commun., T. SAITO, H. FUKAZAWA, Y. KOHORI, Chiba Univ., K. YAMADA, WPI, Tohoku Univ. — Spin fluctuations in Fe-based superconductors have attracted great attention since they can be a key factor of the formation of superconducting states. The inelastic neutron scattering technique is a powerful method to examine spin fluctuations, whereas measurements using a single crystal were restricted to Fe(Te,Se) or electron-doped AFe_2As_2 (A=Ba, Ca, or Sr) due to difficulty of growing a large single crystal. To overcome this problem, we have improved growth procedure and succeeded to grow single crystals of heavily hole-overdoped superconducting KFe_2As_2 ($T_c = 3.4$ K). It was believed that no spin fluctuation can be observed in KFe_2As_2, since the nesting of the Fermi surface disappears. To confirm the hypothesis, we have studied spin fluctuations of KFe_2As_2 by neutron scattering using single crystals at JRR-3 reactor of JAERI in Tokai. As results, a well-defined low-energy incommensurate spin fluctuation has been observed at ($\pi(1 \pm 2\delta)$,0) with $\delta = 0.16$. The direction of the peak splitting is perpendicular to that observed in Fe(Te,Se) or in $Ba(Fe,Co)_2As_2$ at high energies. The results suggest that spin fluctuation is more robust in hole-doped than in electron-doped Fe-based superconductors, or a new type of spin fluctuation emerges by heavily hole doping.

10:00AM P26.00009 Neutron Scattering Experiment on Magnetic Field Effect in Under-doped Superconducting $BaFe_{1.915}Ni_{0.085}As_2$, MIAOYIN WANG, PENGCHENG DAI, Department of Physics and Astronomy, University of Tennessee, Knoxville, MENG WANG, HUIQIAN LUO, Institute of Physics, Chinese Academy of Sciences, JEFFREY LYNN, SUNG CHANG, SONGXUE CHI, DEEPAK SINGH, JOSE RODRIGUEZ, NIST Center for Neutron Research, National Institute of Standards and Technology — In under-doped $BaFe_{2-X}(Ni,Co)_XAs_2$, superconductivity coexist with the anti-ferromagnetic (AFM) order. By applying a ~10 Tesla magnetic field parallel to a-b plan, we performed a series of elastic and inelastic neutron scattering measurement on BT-7 instrument in NCNR, NIST. We measured how magnetic bragg-peaks and spin excitation in $BaFe_{1.915}Ni_{0.085}As_2$ will change upon the change of the field.

10:12AM P26.00010 Spin excitations as in hole-doped $Ba_{0.67}K_{0.33}Fe_2As_2$ superconductor , CHENGLIN ZHANG, MENG WANG, MIAOYING WANG, JUN ZHAO, University of Tennessee, Physics Dept, MARTY KAROL, MARK LUMSDEN, Oak Ridge National Laboratory, SONGXUE CHI, SUNG CHANG, JEFFREY LYNN, National Institute of Standards and Technology, HUIQIAN LUO, TAO XIANG, Institute of Physics, Chinese Academy of Sciences, JIANGPING HU, Department of Physics, Purdue University, PENGCHENG DAI, University of Tennessee, Physics Dept, UNIV OF TENNESSEE, PHYSICS DEPT TEAM, OAK RIDGE NATIONAL LABORATORY TEAM, NIST TEAM, INSTITUTE OF PHYSICS, CHINESE ACADEMY OF SCIENCES TEAM — We used inelastic neutron scattering to study the optimally doped $Ba_{0.67}K_{0.33}Fe_2As_2$ (Tc=38K). In contrast to electron doped counterpart, we found that resonance is almost none-L dependence as shown in Fig.1 (b), but the spin gaps are. It is gaped along (0.5,0.5,0), however essentially gapless along (0.5,0.5,1). Meanwhile, the spin correlation is strongly temperature dependence which has not been observed in electron-doped 122 materials at all. The above findings clearly suggest that hole-doped region is indeed different from electron-doped region.

10:24AM P26.00011 ABSTRACT WITHDRAWN –

10:36AM P26.00012 Finite temperature spin dynamics of a square lattice $J_1 - J_2$ antiferromagnet and its implications for iron arsenides[1] , ELIHU ABRAHAMS, University of California Los Angeles, PALLAB GOSWAMI, RONG YU, QIMIAO SI, Rice University — Motivated by recent inelastic neutron scattering measurements in the paramagnetic phase of iron arsenides, we have studied the finite temperature spin dynamics of a square lattice $J_1 - J_2$ antiferromagnet in the parameter regime that gives rise to a collinear $(\pi, 0)$ ground state at zero temperature. We have calculated the dynamical structure factor $S(\mathbf{q}, \omega)$ in the paramagnetic state at finite temperatures using a modified spin wave theory. We have shown that short range antiferromagnetic correlations below the mean-field Ising transition temperature give rise to elliptic features for $S(\mathbf{q}, \omega)$ in momentum space. Employing an effective nonlinear sigma model analysis for the low energy and wave vector limit, we also account for fermion damping and circumvent the shortcoming of modified spin wave theory. Finally, considering a matrix $J_1 - J_2$ model, we point out the connection between the Ising transition and the putative orbital ordering in iron arsenides.

10:48AM P26.00013 Neutron and ARPES constraints on the couplings of the multiorbital Hubbard model for the iron pnictides[1] , QINLONG LUO, ADRIANA MOREO, ELBIO DAGOTTO, Univ. of Tennessee/ORNL, GEORGE MARTINS, Oakland Univ., DAO-XIN YAO, Sun Yat-Sen Univ., MARIA DAGHOFER, IFW Dresden, RONG YU, Rice Univ. — The results of neutron-scattering and angle-resolved photoemission experiments for the Fe-pnictide parent compounds are shown to impose severe constraints on the range of values that can be considered "realistic" for the intraorbital Hubbard repulsion U and Hund coupling J in multiorbital Hubbard models treated in the mean-field approximation. Phase diagrams for undoped three- and five-orbital models are discussed, and the physically realistic regime of couplings is highlighted [1].

Session P27 GQI: Focus Session: Semiconductor Qubits - Spin Readout, Backaction, and Valley Physics in Silicon C155

8:00AM P27.00001 Development of a Si/SiO_2based double quantum dot charge qubit with dispersive microwave readout[1] , M.G. HOUSE, University of California, Los Angeles, E. HENRY, A. SCHMIDT, University of California, Berkeley, O. NAAMAN, University of Calfornia, Berkeley, I. SIDDIQI, University of California, Berkeley, H. PAN, M. XIAO, H.W. JIANG, University of California, Los Angeles — Coupling of a high-Q microwave resonator to superconducting qubits has been successfully used to prepare, manipulate, and read out the state of a single qubit, and to mediate interactions between qubits. Our work is geared toward implementing this architecture in a semiconductor qubit. We present the design and development of a lateral quantum dot in which a superconducting microwave resonator is capacitively coupled to a double dot charge qubit. The device is a silicon MOSFET structure with a global gate which is used to accumulate electrons at a Si/SiO_2 interface. A set of smaller gates are used to deplete these electrons to define a double quantum dot and adjacent conduction channels. Two of these depletion gates connect directly to the conductors of a 6 GHz co-planar stripline resonator. We present measurements of transport and conventional charge sensing used to characterize the double quantum dot, and demonstrate that it is possible to reach the few-electron regime in this system.

[1]This work is supported by the DARPA-QuEST program.

8:12AM P27.00002 Dispersive microwave readout of a double quantum dot charge qubit in silicon , EDWARD HENRY, ANDREW SCHMIDT, QNL, UC Berkeley, MATHEW HOUSE, UCLA, OFER NAAMAN, H. PAN, MING XIAO, HONG-WEN JIANG, UCLA, IRFAN SIDDIQI, QNL, UC Berkeley, QNL, UC BERKELEY TEAM, JIANG GROUP, UCLA TEAM — Microwave resonators coupled to quantum systems have been used for fast dispersive measurement in many different architectures in solid state and atomic physics. The electronic states of a semiconductor quantum dot represent a promising candidate for quantum information processing. Our work is geared toward developing a fast, non-demolition readout of semiconductor qubit by coupling to a superconducting resonant circuit. We report on microwave measurements of a lateral quantum dot, realized using a silicon MOSFET structure, where the charge degree of freedom is capacitively coupled to a shorted quarter wave 6 GHz resonator. We characterize the sensitivity of this charge detection scheme and its implications for qubit readout fidelity.

8:24AM P27.00003 Radio Frequency Single Electron Transistors on Si/SiGe[1] , MINGYUN YUAN, ZHEN YANG, A.J. RIMBERG, Department of Physics and Astronomy, Dartmouth College, M.A. ERIKSSON, Department of Physics, University of Wisconsin, D.E. SAVAGE, Material Science Center, University of Wisconsin — Superconducting single electron transistors (S-SETs) are ideal for charge state readout due to their high sensitivity and low back-action. Upon successful formation of quantum dots(QDs) on Si/SiGe, aluminum S-SETs are added in the vicinity of the QDs. Coupling of the S-SET to the QD is confirmed by using the S-SET to perform sensing of the QD charge state at 0.3 K. We have formed a matching network for an SET with an off-chip inductor. The reflection coefficient of the radio frequency(RF) signal is shown to be modulated by the SET resistance. Efforts to develop an on-chip matching network and perform charge sensing with the RF-SETs are in progress. Recent experimental results will be discussed.

[1]This research was supported by the NSA, LPS and ARO.

8:36AM P27.00004 Two-detector two-qubit correlated continuous measurements and their implications for quantum computing , RUSKO RUSKOV, Laboratory for Physical Sciences,College Park, MD 20740, CHARLES TAHAN, Laboratory for Physical Sciences, College Park, MD 20740 — We calculate the full counting statistics for a system of two interacting qubits which are simultaneously measured by weakly coupled linear detectors. Two approaches are considered based on rate equations for the full system-detectors density matrix and on quantum filtering equations. Implications for the assessment of quantumness in physical devices based on charge qubits are considered. In addition we consider applications of such systems to practical quantum computing in silicon and/or GaAs quantum dots.

8:48AM P27.00005 Backaction due to Resonant Phonon Absorption in Quantum Dots Measured by a Quantum Point Contact , CAROLYN YOUNG, AASHISH CLERK, McGill University — Recent experiments have observed unexplained periodic resonances in the charging diagrams of both double [1] and triple [2] quantum dots (DQDs and TQDs). These resonances correspond to the generation of inelastic transitions, driven by energy transfer from a biased quantum point contact (QPC) charge detector used for measurement. In this talk, we present theoretical results describing how quantum backaction due to hot phonons, generated by the out-of-equilibrium QPC, can lead to excited state occupation under certain "blocking" conditions that result in slow ground state filling. We propose that recent experiments can be understood in terms of resonant phonon absorption in DQDs and TQDs; a process complementary to resonant phonon emission [3]. Our results shed light on an important contribution to the backaction of the QPC readout scheme widely used for QD-based quantum computation.

9:00AM P27.00006 Measurement fidelity in the presence of coherent dynamics or dissipation , JIAN-QIANG YOU, Fudan University & RIKEN, S. ASHHAB, FRANCO NORI, RIKEN & University of Michigan — We analyze the problem of a charge qubit probed by a quantum point contact when the measurement is concurrent with Hamiltonian-induced coherent dynamics or dissipation. This additional dynamics changes the state of the qubit before the measurement is completed. As a result, the measurement fidelity is reduced. We calculate the reduction in measurement fidelity in these cases. References: S. Ashhab, J. Q. You, and F. Nori, New J. Phys. 11, 083017 (2009); Phys. Scr. T137, 014005 (2009).

9:12AM P27.00007 Probing coherent tunneling in semiconductor quantum dots using electromechanical backaction , JAMIE GARDNER, AASHISH CLERK, Department of Physics, McGill University — Self-assembled quantum dots have been studied intensely because of their possible applications to quantum information processing. While such dots are difficult to characterize using direct electrical transport measurements, it has recently been shown both theoretically [1] and experimentally [2] that a capacitively coupled AFM cantilever can serve as a sensitive probe of dot charge dynamics and electronic level structure. This sensitivity is based on the fact that the dot, which is tunnel-coupled to electrons in a reservoir, acts as a dissipative bath for the cantilever. Here, we extend previous theoretical work to describe an AFM cantilever coupled to a double quantum dot. Unlike a single-dot, the double-dot system exhibits both incoherent tunneling to the leads and coherent tunneling between the dots. We find that the cantilever's motion is affected by both kinds of tunneling and can yield significant information even in regimes where the total double-dot charge does not fluctuate. Cantilever dynamics can also be used to learn about the strength of dephasing processes in the double-dot. After presenting the theoretical approach to this problem, we will discuss the results in the context of current experimental efforts using InAs dots. These effects should also be accessible in a variety of other quantum dot setups. [1] S. D. Bennett, et al., Phys. Rev. Lett. **104**, 017203 (2010). [2] L. Cockins, et al., Proc. Nat. Acad. Sci. **107**, 9496 (2010).

9:24AM P27.00008 Few-electron states in SiGe double quantum dot structures with non-planar interfaces[1] , A.A. KISELEV, R.S. ROSS, M.F. GYURE, HRL Laboratories LLC, 3011 Malibu Canyon Road, Malibu CA 90265 — Valley-orbit effects of planar, non-planar, and imperfect heterointerfaces (both on the intra- and inter-dot scale) are directly captured in numerical simulations and analyzed theoretically for electrostatically defined accumulation mode (001) SiGe multi-dot structures. Our modeling is facilitated by explicitly allowing for an arbitrary and spatially inhomogeneous stacking of heterolayers in the active area of the device. Here we focus on results obtained for a double quantum dot (DQD) system, establishing the detailed structure of few-electron states, and, for two electrons, their spin- and valley-selective dynamics when the system is driven by pulse-modulating dot gate potentials. We identify valley-related avoided crossings and evaluate their strength affecting adiabaticity of applied bias sweeps. We consider a number of experimentally relevant scenarios stemming from (i) macroscopic interface imperfections, e.g., interface steps, and (ii) randomness of the substitutional solid solution in the SiGe barrier layers. Our findings are critically compared with results available for single valley III-V DQDs.

9:36AM P27.00009 Extended interface states enhance valley splitting in Si/SiO2[1] , ANDRE SARAIVA, BELITA KOILLER, U. F. Rio de Janeiro, MARK FRIESEN, U. of Wisconsin — Interface disorder and its effect on valley degeneracy in the conduction band present an important theoretical challenge for operating spin qubit in silicon. Here, we demonstrate and investigate a counterintuitive effect occurring at Si/SiO2 interfaces. By applying tight binding methods, we show that intrinsic interface states can hybridize with conventional valley states to produce an anomalously large ground state energy gap. Such hybridization effects have not previously been explored in detail for valley splitting. We find that the splitting can be enhanced by disorder in the chemical bonds at the interface, in agreement with recent experiments.

9:48AM P27.00010 Interface-mediated intervalley coupling in Si[1] , BELITA KOILLER, A.L. SARAIVA, Instit. de Fisica, UFRJ, Rio de Janeiro, Brazil, M.J. CALDERON, Instit. de Ciencia de Materiales de Madrid (CSIC), Spain, XUEDONG HU, Dep. of Physics, University at Buffalo-SUNY, S. DAS SARMA, Dep. of Physics, Condensed Matter Theory Center, University of Maryland, College Park, Maryland — The conduction band degeneracy in Si is detrimental to spin qubits, for which a nondegenerate ground orbital state is desirable. The Si valley degeneracy is reduced to 2 near an interface with an insulator, and it may be lifted by the spatially abrupt change in the crystal potential. Basic physical mechanisms for Si/barrier mediated valley coupling in different situations are addressed here. Theoretical studies of the interface-induced valley splitting in Si are presented. Abrupt and smooth interface profiles are considered, and the full plane wave expansions of the Bloch functions at the conduction band minima are included. Simple criteria are suggested for optimal fabrication parameters affecting the valley splitting, emphasizing the relevance of different interface-related properties. Refs: A.L.Saraiva et al, PRB 80, 081305 R (2009); arXiv:1006.3338

10:00AM P27.00011 Atomistic simulations of multi-valley silicon double quantum dots in the presence of disorder in the few electron regime[1] , RAJIB RAHMAN, ERIK NIELSEN, RICHARD MULLER, MALCOLM CARROLL, Sandia National Laboratories, Albuquerque, NM 87185 — The singlet-triplet based silicon double quantum dot (DQD) is a promising system for implementing a long-lived and controllable quantum bit. The multiple valleys present in silicon, however, may complicate the operation of such a qubit if the valley splitting is small. The valley splitting is affected by a large number of factors including interface roughness, lattice miscuts, electric and magnetic fields, barrier material, and alloy disorder. We employ an atomistic tight-binding (TB) method and a full configuration interaction (CI) to investigate few electron states of a multi-valley Si DQD. This unprecedented approach involving few million atoms allows us to investigate the role of atomic scale disorder (i.e., random alloy effects or interface roughness) on the energy levels and spin configurations of many electron DQDs.

[1]Sandia is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. DOE's NNSA under contract DE-AC04-94AL85000.

10:12AM P27.00012 Engineering anisotropic exchange interactions between quantum dot spin qubits , YUN-PIL SHIM, MARK FRIESEN, Department of Physics, Unviersity of Wisconsin-Madison, Madison WI 53706 — We present a method for engineering anisotropic exchange interactions between quantum dot spin qubits using a Heisenberg antiferromagnetic spin chain as a spin bus. An external magnetic field is applied to create XXZ interactions between spin qubits that are weakly connected to a spin bus whose ground state is non-degenerate. We analyze the dependence of the anisotropy of the effective interaction on the external field and on the length of the spin bus. We show that the tunable XXZ interaction mediated by the spin bus can be used to generate multi-qubit entanglement and to efficiently implement universal gates based on encoded qubits. We also show that the operation of the spin bus is qualitatively different when the spin bus is near one of its magnetic field-induced quantum phase transitions. In this case, the qubits interact with a bus pseudo-spin and the resulting entanglement between pairs of qubits is enhanced.

10:24AM P27.00013 Asymmetric Quantum Pd Films for Enhanced Hydrogen Separation[1] , GUANGFEN WU, Southeast U, U of Tennessee-Knoxville, Oak Ridge National Laboratory, WENGUANG ZHU, U of Tennessee-Knoxville, Oak Ridge National Laboratory, JINLAN WANG, Southeast U, ZHENYU ZHANG, Oak Ridge National Laboratory, U of Tennessee-Knoville,U of Science and Technology of China — Based on density functional theory calculations and numerical simulations, we have investigated the permeation of H2 through ultra-thin Pd quantum films. The H2 flux can be highly increased by the elevation of the chemisorption-well on the permeate side without significantly blocking the subsurface-surface penetration. We find that Cu-coated asymmetric Pd quantum films (with the Cu monolayer on the permeate side) will enhance the capability for H2 separation: the recombination barrier for H is reduced from 1.36 to 0.79 eV, while the subsurface-surface penetration barrier is only slightly increased from 0.04 to 0.10 eV. Numerical simulations show enhanced H2 flux by 5 orders of magnitude as an upper-limit for asymmetric Pd films over symmetric ones under similar conditions.

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P28 DCMP: Carbon Nanotubes: Optical Properties C156

8:00AM P28.00001 Empirical Study of the π electron Plasmon Energy Dependence on the Bundling/De-bundling Effect in Single Wall Carbon Nanotubes , KIRAN LINGAM, RAMAKRISHNA PODILA, PENGYU CHEN, Clemson University, CODRUTA LOEBICK, NAN LI, LISA PREFFERLE, Yale University, APPARAO RAO, Clemson University — Many researchers have done detailed studies on optical, thermal and electronic properties of SWNTs. But, very few studies have been done on sub-nanometer SWNTs. Here we studied collective electron excitations in this quasi 1D system. At high excitation energies, broad absorption peak is observed which is attributed to the π plasmon (5-7 eV). We used UV-Vis NIR spectroscopy to determine the energy of the π plasmons in sub nanometer diameter SWNTs (0.4 nm to 0.9 nm). SWNTs form bundles due to van der Waal forces and this bundling influences their electronic structure. It is known that SWNTs wrapped with a surfactant can be isolated with long centrifugation. The hydrodynamic sizes of the dispersed SWNTs at different centrifugation times were determined by using the Dynamic Light Scattering technique. Systematic studies have been done on the dependence of the π plasmon energy on the nanotube bundle diameter. The energy of the π plasmon was found to vary with the bundle diameter and the energy to be given by the relation E= (-0.022 eV)*ln(d/1 nm)+5.34 eV. We have done similar studies on HiPCo and Carbolex SWNTs and the empirical relation obtained is consistent with the results above.

8:12AM P28.00002 Simultaneous measurement of length, concentration and brightness of single-walled carbon nanotubes with fluorescence correlation spectroscopy , DENIS PRISTINSKI, CONSTANTINE KHRIPIN, XIAOMIN TU, MING ZHENG, NIST — We report on the application of fluorescence correlation spectroscopy (FCS) to simultaneously measure the brightness, concentration, and length of single-walled carbon nanotubes (SWCNTs). The technique relies on the intrinsic bandgap luminescence of (6,5) chirality semiconducting SWCNTs in the near infra-red (NIR) range and does not require sample labeling. The nanotubes used in this study have been dispersed in solution of single stranded DNA and length fractionated via size exclusion chromatography. The SWCNT length measured by FCS was in excellent agreement with more traditional techniques - polarized dynamic light scattering (DLS) and atomic force microscopy (AFM). The apparent nanotube brightness is shown to grow linearly with the mean nanotube length, having a zero intensity cut-off at 110 nm, implying an exciton diffusion length of 55 nm for SWCNTs dispersed in sodium deoxycholate.

8:24AM P28.00003 Absolute Rayleigh Intensity and Uniform Optical Conductivity in Carbon Nanotubes , LIHONG HERMAN, Cornell Applied Physics, DANIEL JOH, JESSE KINDER, SANG-YONG JU, MICHAEL SEGAL, JEFFREYS JOHNSON, GARNET CHAN, JIWOONG PARK — We used a novel on-chip Rayleigh imaging technique to measure the absolute intensity of Rayleigh scattering of single-walled carbon nanotubes. The spatial distribution of the radiation scattered by the nanotubes is determined by their shape, but the intensity and spectrum of the scattered radiation are determined by exciton dynamics, quantum-dot-like optical resonances and other intrinsic properties. Moreover, the nanotubes display a uniform peak optical conductivity $\sim$8 e^2/ h, which we derive using an exciton model, suggesting universal behaviour similar to that observed in nanotube conductance. We further demonstrate a radiative coupling between two distant nanotubes, with potential applications in metamaterials and optical antennae. This is in contrast to the optical properties of metal nanostructures and show that nanotubes can form ideal optical wires.

8:36AM P28.00004 Dielectric screening dependence of excitonic transition energies in single-wall carbon nanotubes , PAULO ARAUJO, MILDRED DRESSELHAUS, Massachusetts Institute of Technology, ADO JORIO, Universidade Federal de Minas Gerais, KENTARO SATO, AHMAD NUGRAHA, RICHIIRO SAITO, Tohoku University — The measured optical transition energies E_{ii} of single-wall carbon nanotubes are compared with bright exciton energy calculations. The E_{ii} differences between experiment and theory are minimized by considering first, a diameter/chiral angle-dependent dielectric constant and second, a diameter/exciton size-dependent dielectric constant (k). In our description, k is composed of the screening contributions from the tube, represented by k_{tube}, and from the environment, represented by k_{env}. We discuss the main aspects of each approach and show that in the first case, different k dependencies are obtained for (E^S_{11}, E^S_{22}, E^M_{11}) relative to (E^S_{33}, E^S_{44}) which is understood as follows: A changing environment changes the k diameter dependence for (E^S_{11}, E^S_{22}, E^M_{11}), but for (E^S_{33}, E^S_{44}) the environmental effects are minimal. We show that in order to achieve a single dependence for all E_{ii}, the exciton's size should be taken into account, as considered in the second approach. The resulting calculated exciton energies reproduce experimental E_{ii} values within |50| meV for a diameter range (0.7< dt <3.8 nm) and 1.2 < Eii <2.7 eV, thus providing a theoretical justification for E_{ii} and important insights into the dielectric screening in one-dimensional structures.

8:48AM P28.00005 Temperature-Dependent Maximum Density of 1D Excitons in Carbon Nanotubes , THOMAS SEARLES, IAN WALSH, TAKAYUKI NOSAKA, WILLIAM RICE, JUNICHIRO KONO, Dept. of Electrical and Computer Engineering, Rice University — Previous studies have shown that an upper limit exists on the density of 1D excitons in single-walled carbon nanotubes (SWNTs) due to very efficient exciton-exciton annihilation (EEA). A recent theoretical study based on a dark-bright two-band exciton model predicts that there is a temperature at which the achievable exciton density will be maximized, surpassing the room-temperature upper limit. Therefore, we performed temperature-dependent (300 K to 11 K) photoluminescence (PL) on HiPco SWNTs embedded in an i-carrageenan matrix under high resonant excitation. To achieve high densities, we used pump fluences up to $\sim 10^{14}$ photons/cm^2, utilizing intense fs pulses from a wavelength-tunable optical parametric amplifier. We found that for each temperature the PL intensity saturates as a function of pump fluence and the saturation intensity increases from 300 K to a moderate temperature around 100-150 K. Below that critical temperature, the PL intensity decreases with decreasing temperature. Within the framework of diffusion-limited EEA, we successfully estimated the upper limit of the density of 1D excitons in SWNTs as a function of temperature and chirality

9:00AM P28.00006 Experimental Kataura Plot in Single-walled Carbon Nanotubes , KAIHUI LIU, FAJUN XIAO, RODRIGO CAPAZ, JACK DESLIPPE, Phys Dept. UC Berkeley, WENLONG WANG, IOP, CAS, Beijing, China, SHAUL ALONI, The Molecular Foundry, LBNL, Berkeley, STEVEN LOUIE, Phys Dept. UC Berkeley, ENGE WANG, ICQM, Peking University, Beijing, China, FENG WANG, Phys Dept. UC Berkeley, PHYS DEPT. UC BERKELEY TEAM, THE MOLECULAR FOUNDRY, LBNL, BERKELEY COLLABORATION, IOP, CAS, BEIJING, CHINA COLLABORATION, ICQM, SCHOOL OF PHYSICS, PEKING UNIVERSITY, BEIJING, CHINA COLLABORATION — Single-walled carbon nanotubes (SWNTs) comprise a family of more than 400 structures characterized by different chiral indices n-m, each having a distinct electronic structure that can be either metallic or semiconducting. An outstanding question is how the physical properties, such as optical transitions, vary with the exact nanotube structures. By combining TEM diffraction and Rayleigh scattering spectroscopy on the same individual nanotubes, we determine independently the chiral indices and optical transitions of over 170 single-walled nanotubes. These data permit us to create an experimental Kataura plot for single-walled carbon nanotubes.

9:12AM P28.00007 Optical Properties of Empty and Water-Filled Single-Wall Carbon Nanotubes , J.R. SIMPSON, Towson University, J.A. FAGAN, J.Y. HUH, A.R. HIGHT WALKER, National Institute of Standards and Technology, J.L. BLACKBURN, B.A. LARSEN, J. HOLT, National Renewable Energy Laboratory — The necessity for separation of single-wall carbon nanotube (SWCNT) populations to achieve desired properties presents a major technical barrier for the development of SWCNT-based applications, and has been the focus of significant academic and industrial research. Recent advances include the separation of SWCNT populations by diameter through buoyancy differences. Here we report on the optical spectroscopic properties of large diameter SWCNTs synthesized by laser ablation and electric arc methods and then separated by centrifugation to produced isolated bands of empty and water-filled nanotubes. This separation is consistent across multiple nanotube populations dispersed from different source material. Optical absorption, near-infrared fluorescence, and Raman spectroscopic measurements of the resulting empty and filled fractions reveal that water filling leads to systematic changes in the optical properties. Specifically, the peak locations in absorbance and fluorescence display red-shifts with the presence of water in the nanotube cavity and a hardening of the Raman radial breathing modes. The presence of water in the SWCNT interior is found to facilitate the subsequent separation into sub-populations of metallic and semiconducting SWCNTs.

9:24AM P28.00008 Rapid widefield Raman imaging of individual carbon nanotubes , ROBIN HAVENER, SANG-YONG JU, MICHAEL SEGAL, LIHONG HERMAN, JIWOONG PARK, Cornell University — Raman spectroscopy is a powerful tool for characterizing carbon nanotubes. Confocal micro-Raman imaging can provide detailed spatial and spectral information about individual nanotubes, but this technique is often time-consuming. We present a widefield Raman microscope capable of rapid and large-area imaging of carbon nanotube samples. Thanks to a widefield excitation geometry, a high-power excitation laser (3W in our experiment) can be used without causing thermal damage to nanotubes, which dramatically shortens image acquisition time ($\sim$20sec for G- band for a 60μm field of view). With a custom-built tunable bandpass filter, our widefield Raman images let us quantitatively compare the D, G and 2D-band intensities of many nanotubes with different known resonant energies, diameters, and metallicities, while providing the Raman scattering cross-section length for individual nanotubes. This technique allows Raman-based spatially resolved investigation of dynamic processes in nanotubes for the first time, which we demonstrate by real-time imaging of the oxidation of nanotubes at high temperatures.

9:36AM P28.00009 Absence of Broad G$^-$ Feature in Resonant Raman Spectra of Armchair Carbon Nanotubes , E.H. HAROZ, W.D. RICE, J. KONO, Department of Electrical & Computer Engineering, Rice University, J.G. DUQUE, C.G. DENSMORE, S.K. DOORN, Center for Integrated Nanotechnologies, Los Alamos National Laboratory — Unlike the radial breathing mode in carbon nanotubes (CNTs), the G-band Raman feature does not display a strong frequency dependence on nanotube structure. The appearance of a broad G$^-$ peak in CNT Raman spectra has been attributed to numerous phenomena including the presence of metallic nanotubes, although a consensus has yet to be achieved amongst researchers. Here, we present resonant Raman measurements on macroscopic ensembles enriched in armchair CNTs produced by density gradient ultracentrifugation. Our G-band data clearly show that the broad, lower-frequency G$^-$ mode is absent for armchair structures, in contrast with recent theoretical and experimental results, and only occurs with resonance of non- armchair metals. This forms a generalized correlation between G-band lineshape and nanotube structure due to the sampling of a large number of nanotubes of several armchair species.

9:48AM P28.00010 Infrared active vibrations in carbon nanotubes[1] , KATALIN KAMARAS, ARON PEKKER, Research Institute for Solid State Physics and Optics, Hungarian Academy of Sciences, Budapest — The method of choice for the study of vibrational modes of carbon nanotubes has been almost exclusively Raman spectroscopy. Although calculations predict also infrared-active modes in nanotubes, so far only very few experimental results have been published. We conducted a systematic investigation of the infrared transmission of various types of single- and double-walled carbon nanotubes. Experiments were done on self-supporting transparent films in order to avoid perturbation from substrates. We find weak but reproducible vibrational peaks in the infrared spectrum. Their frequency scales with the diameter of the tubes, indicating their intrinsic character. Furthermore, on doping, some of the peaks change from Lorentzian to Fano-like character. This change can be explained by coupling of the tube vibrations to the conduction electrons introduced by doping. Finally, in double-walled nanotubes peaks typical of both outer and inner tubes can be distinguished. The vibrations of the inner tubes occur at the same frequency as those of single-walled tubes with the same diameter.

10:00AM P28.00011 Far Infrared Optical Studies of Single and Double Walled Carbon Nanotubes , SHIN GRACE CHOU, NIST, AHMED ZEESHAN, GEORGY SAMSONIDZE, JING KONG, MILDRED DRESSELHAUS, JEFFREY FAGAN, DAVID PLUSQUELLIC — Variable temperature far infrared absorption measurements were carried out for single walled and double walled carbon nanotubes samples (SWCNT and DWCNT) encased in a polymer matrix to investigate the effects of temperature and surface interaction on the low frequency phonons associated with the circumferential vibrations. At a temperature where kBT is significantly lower than the phonon energy, the broad absorption features as observed at room temperature become well resolved phonon transitions. For a DWCNT sample whose inner tubes have a similar diameter distribution as the SWCNT sample studied, a series of sharp features were observed at room temperature at similar positions as for the SWCNT samples studied. The narrow linewidth is attributed to the fact that the inner tubes are isolated from the polymer matrix and from the weak inter-tubule interactions. First principles calculations are carried out to understand the pertinent interactions and the temperature-dependent effects.

10:12AM P28.00012 Influence of Defects and Doping on Optical Phonon Dynamics in Carbon Nanotubes , DANER ABDULA, KHOI NGUYEN, KWANGU KANG, SCOTT FONG, TANER OZEL, DAVID CAHILL, MOONSUB SHIM, University of Illinois Champaign- Urbana — The relaxation of electronic excitations induced by high bias or photoexcitation occurs primarily through optical phonon emission. Optical phonon relaxation may be affected by metallic/semiconducting character of carbon nanotubes, defect concentration, as well as doping. Changes in carbon nanotube G-band optical phonon population and pure dephasing lifetimes with doping and defects are described. Time-resolved incoherent anti-Stokes Raman spectroscopy is used to directly measure phonon decay lifetime, T_1, while total dephasing rate is inferred from static Raman linewidths. Defect concentration is varied by sample annealing and covalent functionalization showing increasing disorder reduces T_1 as well as overall dephasing time, T_2, with an even greater dependence. Samples with different metallic and semiconducting contribution have similar lifetimes, $T_1 \sim 1.2 \pm 0.1$ ps in the no defect limit. Doping is shown to increase G-band linewidth, and therefore overall dephasing rate, for semiconducting nanotubes while leaving T_1 unaffected.

10:24AM P28.00013 Ultrafast Terahertz Probes of Individualized, Chirality-Enriched Single-Walled Carbon Nanotubes , LIANG LUO, IOANNIS CHATZAKIS, JIGANG WANG, Department of Physics and Astronomy and Ames Laboratory, Iowa State University — Singled-walled carbon nanotubes (SWNTs) represent a model system to systematically investigate correlated charge excitation in 1-D limits. One of the most outstanding issues both in fundamental nanotube physics and for their technological development is to detect and understand optically-forbidden, dark collective states. Thus far supporting evidence of dark states has been demonstrated in static magneto-optics and light scattering. However, the unique internal transitions from dark excitonic ground states and their dynamic evolution remain highly elusive. We report our investigation of this problem using optical-pump, terahertz probe spectroscopy of individualized, (6,5) and (7,5) SWNTs. We measure transient THz conductivity from 1-15 meV at low temperature down to 4K with resonant and off-resonant excitation at the E_{22} transitions of (6,5) and (7,5) nanotubes. The intra-excitonic spectroscopy with THz pulses represents a fundamentally different spectroscopy tools to study dark excitons and shine new lights on the nature of excitonic ground states.

10:36AM P28.00014 Nonlinear Optical Response of Individual Carbon Nanotubes , TATYANA SHEPS, BRAD L. CORSO, ERIC O. POTMA, PHILIP G. COLLINS, Department of Physics and Astronomy and Department of Chemistry, Univ. of California at Irvine, Irvine, CA 92697 — Single walled carbon nanotubes (SWCNTs) are low dimensional conductors with unique nonlinear electro-optic properties. To investigate these properties we study the third-order, coherent anti-stokes (CAS) response of electrically connected individual SWCNTs on quartz substrates, using a four-wave-mixing (FWM) technique with femtosecond laser pulses. Because the CAS response is primarily electronic in nature [1], the signal from metallic SWCNTs is much stronger than from semiconducting ones. CAS easily distinguishes between the two types, as well as between semiconducting SWCNTs doped to be conductive or insulating. Furthermore, the CAS signal is sensitive to excitation resonances, the same effect that allows SWCNT fingerprinting by photoluminescence and Raman techniques. In addition to the strong electronic signal, we can also resolve a vibrational signal component at the G-band frequency, which suggests a method for studying chemical bond vibrations with this coherent technique. The good spatial resolution and high signal-to-noise achieved with femtosecond laser pulses provides opportunities for time-resolved optical measurements of SWCNT excitation dynamics. Funded by NSF Center for Chemistry at the Space-Time Limit at UCI (CHE-0847097).

10:48AM P28.00015 Second Harmonic Generation in Highly Aligned Carbon Nanotubes on GaAs , D.T. MORRIS, G.L. WOODS, J. KONO, ECE Dept., Rice University, C.L. PINT, R.H. HAUGE, Chemistry Dept., Rice University — Optical properties of carbon nanotubes (CNTs) have been extensively investigated during the last decade, and much basic knowledge has been accumulated on how light emission, scattering, and absorption occur in CNTs. However, their nonlinear optical properties remain largely unexplored, except for theoretical studies predicting highly chirality-selective nonlinear optical processes. In particular, all chiral nanotubes are expected to possess finite second-order nonlinear susceptibilities due to the lack of inversion symmetry. Here, we have observed second harmonic generation (SHG) from samples consisting of highly aligned CNTs on GaAs with linearly-polarized intense mid-infrared femtosecond radiation. SHG is expected from both the CNTs and the substrate, thus the contribution of the CNTs to the overall enhanced SHG signal will be obtained by factoring out contributions from the GaAs substrate, which include any anisotropic effects (absorption, polarization) from the CNTs on the fundamental light incident in the GaAs substrate. We performed detailed angular dependent measurements to separate the two contributions, based on the crystal symmetries of the two. The results will be shown as a function of laser power and wavelength, and discussed in light of CNT band structure.

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P29 GQI: Focus Session: Superconducting Qubits C148

8:00AM P29.00001 LeRoy Apker Award Talk: Parallel State Transfer and Efficient Quantum Routing on Quantum Networks[1] , CHRISTOPHER CHUDZICKI, MIT — We study the routing of quantum information in parallel on multi-dimensional networks of tunable qubits and oscillators. These theoretical models are inspired by recent experiments in superconducting circuits using Josephson junctions and resonators. We show that *perfect parallel state transfer* is possible for certain networks of harmonic oscillator modes. We further extend our model to analyze the distribution of entanglement between every pair of nodes in the network, and find that the routing efficiency of hypercube networks is both optimal and robust in the presence of dissipation and finite bandwidth.

[1]This research was supervised by Frederick W. Strauch; it was supported by Williams College and Research Corporation. A paper preprint based on this work is available online: (arXiv: 1008.1806).

8:36AM P29.00002 Towards long coherence superconducting qubits , MATTHIAS STEFFEN, IBM, ANTONIO CORCOLES, JERRY CHOW, CHAD RIGETTI, MARK KETCHEN, MARY BETH ROTHWELL, GEORGE KEEFE, JIM ROZEN, MARK BORSTELMANN, JACK ROHRS, DAVID DIVINCENZO — The capacitively shunted flux qubit (CSFQ) has recently been shown to have coherence times of 1-2 microseconds repeatedly over many devices at typical qubit operating frequencies. Experiments in our group strongly suggest that losses associated with the shunting capacitor limit the current coherence times. As a result we propose novel approaches towards decreasing capacitive losses by employing geometric and/or materials developments. We show experimental data and compare these with theoretical predictions

8:48AM P29.00003 Circuit QED without selection rules: the dispersive regime of the fluxonium qubit , GUANYU ZHU, JENS KOCH, Northwestern University — Manipulation and readout of superconducting qubits with microwave photons, as realized in circuit QED, commonly employ the dispersive regime. In this regime, the qubit-photon interaction strength is small compared to the relative detuning Δ, and manifests itself only in the dispersive energy shifts χ, crucial for dispersive readout and spectroscopy of the qubit. For Cooper Pair Box and transmon, these shifts are known to scale like $1/\Delta$ and $1/\Delta^2$, respectively, making readout at very large detuning challenging. We show that the relation between χ and Δ is mainly dictated by selection rules, and derive general expressions describing the dispersive regime of a multi-level qubit with arbitrary matrix elements. This generalization turns out essential for describing the dispersive regime of the fluxonium qubit, where no simple selection rules exist. We show that this lack of selection rules explains the suprising magnitude of disperse shifts, at detunings as large as $\sim$8GHz, and also causes peculiarities observed in the fluxonium spectroscopy.

9:00AM P29.00004 Tunable coupling in circuit quantum electrodynamics with a superconducting V-system , SRIKANTH SRINIVASAN, ANTHONY HOFFMAN, DEVIN UNDERWOOD, Princeton University, JAY GAMBETTA, Institute for Quantum Computing and Department of Applied Mathematics, University of Waterloo, ANDREW HOUCK, Princeton University — We demonstrate a new superconducting charge qubit that realizes a V-shaped energy level spectrum, enabling tunable coupling between the qubit and a superconducting cavity while retaining all of the advantages, including charge noise insensitivity, common to other charge qubits such as the transmon. Tunable coupling is achieved with quantum interference between the two excited states of the qubit. We report measurements of the vacuum Rabi splitting, showing that the coupling strength can be tuned from greater than 40 MHz to less than 200 kHz using fast flux bias lines. This dynamically tunable coupling is an intrinsic property of the qubit and requires no additional coupling circuit elements. This new qubit design shows great promise for future quantum information processing and quantum optics experiments.

9:12AM P29.00005 Inductive coupling of superconducting qubits to coplanar waveguide resonators[1] , J.D. STRAND, M.P. DEFEO, P. BHUPATHI, C. SONG, M. WARE, B. XIAO, B.L.T. PLOURDE, Syracuse University — Superconducting qubits coupled to microwave resonators provide a promising basis for a scalable quantum computing architecture and enable explorations of circuit quantum electrodynamics. One approach for achieving strong coupling between a qubit and resonator involves sharing the kinetic inductance of a narrow superconducting line. We are investigating different designs for inductively coupling qubits, including capacitively shunted flux qubits, to coplanar waveguide resonators. We are working to optimize the coupling while accommodating the space requirements of different qubit types and preserving the performance of the resonator. We present microwave measurements of these structures as well as modeling of the qubit-resonator coupling.

[1]Work supported by IARPA

9:24AM P29.00006 Transmon qubits coupled to compact resonators[1] , S. SHANKAR, K. GEERLINGS, E. EDWARDS, L. FRUNZIO, R.J. SCHOELKOPF, M.H. DEVORET, Applied Physics Dept., Yale University — Compact resonators comprising of a meander inductor and an interdigitated capacitor are desirable building blocks for a multi-qubit processor due to their small size. We present an experiment on a superconducting transmon qubit coupled capacitively to such a compact resonator. We have fabricated low-loss Nb based compact resonators with an area within 1 mm^2 on a sapphire substrate to operate between 5 and 8 GHz. The resonator geometry was optimized to achieve an intrinsic quality factor above 300,000 at single-photon microwave powers and temperatures below 100 mK. Transmon qubits were made using Al/AlOx/Al Josephson junctions shunted by an Al interdigitated capacitor with an identical width and gap as the resonator. We will present our experimental progress towards measuring relaxation times of these qubits.

[1]Work supported by IARPA, ARO and the NSF.

9:36AM P29.00007 Design of a dc SQUID Phase Qubit with Controlled Coupling to the Microwave Signal[1] , R.P. BUDOYO, A.J. PRZYBYSZ, B.K. COOPER, H. KWON, Z. KIM, B. CHENG, A.J. DRAGT, J.R. ANDERSON, C.J. LOBB, F.C. WELLSTOOD, University of Maryland, College Park, M. KHALIL, S. GLADCHENKO, M. STOUTIMORE, B.S. PALMER, K.D. OSBORN, Laboratory for Physical Sciences — We have designed an Al/AlO$_x$/Al dc SQUID phase qubit on a sapphire substrate with a qubit junction area of 0.3 μm^2 to minimize loss associated with two-level systems in the junction oxide barrier. The qubit junction is shunted with a 1.5 pF interdigitated capacitor, and is isolated from the bias leads by an LC filter and an inductive isolation network using a larger Josephson junction. A previous device we built with similar parameters had its relaxation time T_1 limited by coupling to the microwave line. To reduce this coupling, we adopted a transmission line design and verified the coupling strength using microwave simulations. The new design will also allow us to measure the coupling to the SQUID by throughput measurements. We will discuss our design, the microwave simulations, our estimates for the overall coherence time due to losses and noise from various sources, and our progress towards testing the device.

[1]Acknowledgement: DOD, JQI, and CNAM

9:48AM P29.00008 Two junction effects in dc SQUID phase qubit[1] , B.K. COOPER, H. KWON, A.J. PRZYBYSZ, R. BUDOYO, J.R. ANDERSON, C.J. LOBB, F.C. WELLSTOOD, JQI and CNAM, U. of Maryland — The dc SQUID phase qubit was designed to allow one isolation junction to filter bias current noise from a second junction operating as a single junction phase qubit. As junctions shrink to minimize dielectric loss, the Josephson inductances of each junction approach the coupling loop inductance and this single junction picture appears inadequate. We consider a two-junction model of the dc SQUID phase qubit, where the qubit now corresponds to one of the normal oscillatory modes of the full SQUID. We discuss applications of this model to sweet spots in various control parameters and unusual behavior in the tunneling state measurement.

[1]Funded by DOD, CNAM and JQI

10:00AM P29.00009 Two-Dimensional quantum dynamic in a dc SQUID[1] , FLORENT LECOCQ, Institut Neel, CNRS, Grenoble, France, I.M. POP, Z. PENG, I. MATEI, C. NAUD, F.W. HEKKING, W. GUICHARD, O. BUISSON, Institut Neel and LPMMC, CNRS, Grenoble, France, R. DOLATA, A.B. ZORIN, PTB, Braunschweig, Germany — The dynamics of a dc SQUID presents a large variety of quantum effects at very low temperature such as 2D MQT signature, multilevel and phase qubit dynamics. We have shown that along the zero current bias line, the quantum dynamics is protected from current fluctuations. Along this line, the potential is quadratic-quartic and enhanced phase qubit properties have been demonstrated[2] When the dc SQUID loop inductance is of the order of the Josephson inductance the dynamic becomes two dimensional. As a consequence, in addition to the oscillation mode producing the phase qubit, a second oscillation mode exists, called transverse mode. Here we report spectroscopic evidence and coherence properties of both oscillators as well as coherent oscillations between the quantum states of these two coupled oscillators.

10:12AM P29.00010 Stark effect and generalized Bloch-Siegert shift in a strongly driven two-level system , MATTI SILVERI, JANI TUORILA, University of Oulu, MIKA SILLANPÄÄ, Aalto University, School of Science, YURIY MAKHLIN, Landau Institute for Theoretical Physics, ERKKI THUNEBERG, University of Oulu, PERTTI HAKONEN, Aalto University, School of Science — A superconducting qubit was driven in an ultrastrong fashion by an oscillatory microwave field, which was created by coupling via the nonlinear Josephson energy. The observed Stark shifts of the "atomic" levels are so pronounced that one has to go beyond the rotating wave approximation to properly explain the measurements. The difference between the prediction of the rotating wave approximation and the full calculation including all higher orders constitutes the generalized Bloch-Siegert shift which was verified in the measurement. Based on the Floquet approach for the driven two-level system, we calculate the landscape of the quasienergy splitting and the matrix elements of the probe transition, which were probed by resonant absorption via a cavity. The calculation taking into account both the resonance condition and the magnitude of the probe absorption agrees well with the measurement results.

10:24AM P29.00011 Time-Reversal Symmetry and Temporal Coherent Back-Scattering in a Driven Two-Level System , SIMON GUSTAVSSON, Massachusetts Institute of Technology, MARK RUDNER, Harvard University, JONAS BYLANDER, LEONID LEVITOV, Massachusetts Institute of Technology, WILL OLIVER, MIT Lincoln Laboratory — Coherent backscattering, resulting from quantum interference of the paths related by time-reversal symmetry, is a phenomenon fundamental for quantum-chaotic dynamics. It manifests itself in diverse transport phenomena which were predicted and studied in mesoscopic electron systems in 1980's and 1990's: universal conductance fluctuations (UCF), weak localization and anti-localization, etc. Here we present first experimental realization of the essential physics of coherent backscattering in a driven quantum system, a two-level system repeatedly driven through an avoided level crossing. Our experiment is performed with a superconducting qubit driven through level crossing by a sequence of RF pulses. Each passage through the level crossing serves a Landau-Zener-type "scattering event," with the wave function splitting between the up and down qubit states in a coherent fashion and recombining at a subsequent passage through the level crossing. Time-reversal symmetry can be enforced in our system by the driving protocol, resulting in constructive interference in the up-down transition rates. We observe an enhancement of the speckle-like fringe contrast analogous to UCF, which is suppressed in the absence of time reversal symmetry.

10:36AM P29.00012 Dark states of cavity-coupled qubits , S. FILIPP, A.F. VAN LOO, A. WALLRAFF, ETH QUANTUM DEVICE TEAM — In circuit quantum electrodynamics (QED) the cavity-mediated dispersive interaction is the dominant inter-qubit coupling mechanism when the qubits are detuned from the resonator. This mechanism can be used to realize two-qubit gates. Here, we investigate the strength of this interaction explicitly considering the Fabry-Perot like multi-mode structure of the microwave frequency transmission line resonator. We observe the formation of dark states when the qubits are driven jointly by the same resonator microwave field and tuned into resonance with each other [1]. These dark states arise from the symmetry properties of the coupled quantum system at the avoided level crossing. Furthermore, we study the suppression of spontaneous emission of the coupled-qubit system by driving it into its dark state using microwave fields local to the individual qubits.

[1] S. Filipp *et al.*, arXiv:1011.3732 (2010).

10:48AM P29.00013 Entanglement between the charge and phase degrees of freedom in a superconducting qubit , MUN DAE KIM, Yonsei University — The charge and phase are conjugate variables with each other in superconducting qubits which are characterized by either the charge or the phase degree of freedom. In this study we propose a qubit scheme where the charge and phase degrees of freedom are entangled in the qubit. In our qubit the qubit states consists of the phase states of the qubit, while the qubit states can be measured through the charge state detection. The qubit operation can be performed at the optimal point with respect to both the external magnetic flux and gate voltage. We discuss the fidelity of the Rabi oscillation and the possible way of enhancement of fidelity.

Wednesday, March 23, 2011 8:00AM - 11:00AM –
Session P30 DCMP: Nanowires & Nanotubes: Growth & Absorption Kinetics C147/154

8:00AM P30.00001 Covalent functionalization of ZnO nanowires , ANDREIA LUISA DA ROSA, NEY MOREIRA, ADRIEL GARCIA, THOMAS FRAUENHEIM, University of Bremen — Understanding the interaction of organic species with inorganic nanostructures constitutes a step forward in the development of semiconductor based biosensors. In this work we have used density functional theory to investigate ZnO-(1010) nanowire surfaces modified with substituted methane molecules (Me-X, with X= OH, NH2, SH, COOH, and CN). We have found three relevant stabilization mechanisms acting on the surface stabilization: passivation of surface oxygen lone-pairs via dissociative chemisorption processes, electrostatic adsorbate-interations involving Zn surface sites and hydrogen bonding interactions involving oxygen surface sites. Covalent adsorbate-substrate interactions were found to play only a marginal role on the surface stabilization. Contradicting the usual chemical intuition, we have found no significant evidence for the formation of classical Lewis acid-base adducts on Zn surface sites. Finally we suggest that the functionalization with Me-COOH is also expected to be stable under ordinary laboratory conditions or in aqueous media.

8:12AM P30.00002 Growth and Characterization of Serrated GaN Nanowires , ZHENG MA, DILLON MCDOWELL, MOHAMED ABD ELMOULA, EUGEN PANAITESCU, DALMAU REIG, LATIKA MENON, Northeastern University — We describe our results on the growth of single crystalline GaN nanowires on catalyst-patterned substrates by means of chemical vapor deposition. The growth is carried out in a horizontal quartz tube inside a tube furnace wherein gallium oxide powder is used as reactor source and a mixture of ammonia and hydrogen gas is used as precursor. Growth of GaN nanowires are demonstrated on both Au and Ni-catalyst patterned substrates (either sapphire or silicon). The growth temperature is maintained at around 960 °C. We show that by controlling the deposition parameters, specifically the size of the catalyst and amount of gallium oxide GaN nanowires grow in a "serrated" pattern. The serrated nanowires maintain a stable, single crystalline state with very regular periodic serrations. The wires have been characterized by means of scanning electron microscopy, transmission electron microscopy and energy dispersive x–ray scattering measurements. Preliminary electrical transport measurements on single serrated GaN nanowires released onto a Si substrate show that the wires exhibit improved electron transport capabilities in comparison with regular GaN nanowires.

8:24AM P30.00003 GaAs nanowires and GaAs/AlGaAs core/shell nanowires synthesized by MOCVD[1] , BRIAN PETERS, NICHOLAS MINUTILLO, JOHN CARLIN, FENGYUAN YANG, The Ohio State University — Nanowires made by the "bottom-up" approach can be used in a variety of electrical and optoelectronic devices as well as in the study of low dimensional transport physics. We have grown GaAs nanowires using Au catalysts in a closed couple showerhead MOCVD system. A number of growth parameters, including the substrate temperature, growth rate, and Arsine/TMGa ratio, are explored to identify optimal conditions for growth of GaAs nanowires with large aspect ratio and minimal tapering. Higher substrate temperatures result in larger tapering and lower temperature leads to "kinks." Meanwhile, large V/III source ratio gives large tapering as well. We have found that our optimal conditions are at a substrate temperature of 420 °C and V/III ratio of ∼25, which gives a tapering of less than 1 nm increase in diameter per micron in length. In addition, GaAs/AlGaAs core/shell structured nanowires were also grown to minimize the surface states. Characterizations by SEM and photoluminescence will be presented.

[1]This work is supported by Department of Energy (DE-SC0001304).

8:36AM P30.00004 Fe doped ZnO nanotubes synthesized by low temperature electrochemical process , GOPAL SAPKOTA, KAROL GRYCZYNSKI, ARUP NEOGI, USHA PHILIPOSE, University Of North Texas, Denton,TX — We report the synthesis of Fe doped ZnO nanotubes (NTs) with tube diameter of about 60-100 nm and wall thickness of about 20nm. To the best of our knowledge, this is the first report on Fe doped ZnO NTs, that could possibly be ferromagnetic. Fe doping will enable us to tune the electrical, optical and magnetic properties of the NTs which are crucial for practical applications (spintronics and optoelectronics). The morphology of the NTs was found to be very sensitive to concentration and temperature of the electrolyte and growth time. Structural and compositional analysis revealed that Fe was incorporated into the ZnO lattice. High Resolution Transmission Electron Microscopy and X-ray diffraction shows good crystalline quality of the NTs with preferential growth along the wurtzite c-axis. Room temperature photoluminescence (PL) measurement of the NTs exhibit strong UV emission around 370nm whereas low temperature PL of the NTs exhibits the optical signature of Fe doping.

8:48AM P30.00005 Growth and Characterization of ZnMgO Nanowires by Thermal Chemical Vapor Deposition , GANG SHEN, SHAWN DAVID WILBERT, NICK HARRIS, NABIL DAWAHRE, WILLIAM BAUGHMAN, LEE BUTLER, JOSEPH BREWER, SEONGSIN MARGARET KIM, PATRICK KUNG — Zinc oxide (ZnO) nanowires are promising structures for nano-optoelectronic devices and applications ranging from solid-state lighting to photovoltaics because of the wide bandgap and large exciton binding energy of ZnO, in addition to serving as template matrices for nanoscale sensors. Alloying ZnO with MgO to achieve ternary ZnMgO compounds represents a potential approach for future optoelectronic heterostructure devices. Well-aligned ZnMgO nanowires (NWs) were grown on a sapphire substrate by thermal Chemical Vapor Deposition (CVD). The alignment of the ZnMgO NWs was confirmed by x-ray diffraction and electron microscopy along with elemental composition information through EDS analysis. The optical and vibrational properties of the ZnMgO NWs were studied by micro-Raman and micro-photoluminescence (PL) measurement. Through the combination of confocal laser scanning microscopy and the micro-Raman and micro-PL, the ZnMgO NWs were imaged at sub-micron resolution.

9:00AM P30.00006 Coating of Multi-walled Carbon Nanotubes with Inorganic - Organic Silicas , PURNATOSH SAHA, BRIAN GRADY, University of Oklahoma — Silica-coated multi-walled carbon nanotubes (MWCNTs) have been prepared by sol-gel techniques. An inorganic silica layer has been formed by hydrolyzation of tetraethoxy silane (TEOS) on surfactant-treated nanotubes. Additionally, a secondary layer has been deposited using organosilane precursors. Coating thicknesses have been measured by transmission electron microscopy (TEM) and thermogravimetric analysis (TGA) has also been used to determine the amount of silicates coating the nanotubes. The thickness of the final coating can be tailored by controlling reaction conditions and the number of layers. It is expected that carefully controlling the inorganic to organic ratio in the coatings will allow for the variation of its stiffness.

9:12AM P30.00007 Characterization of Co_2FeAl nanowires[1] , KESHAB R. SAPKOTA, I.L. PEGG, J. PHILIP, Catholic University of America — Heusler alloy, Co_2FeAl (CFA) is a potentially useful material in the field of spintronics due to its high spin polarization. The CFA nanowires are grown for the first time by the electrospinning method. The diameters of the wires formed are ranging from 80 – 100 nm. The structural characterization of the nanowires is done using X-Ray diffraction and Raman spectroscopy. The nanowires exhibit cubic structure with a lattice constant, $a =$ 2.44 Å. Parallel arrays of nanowires are grown for magnetic characterization using electric field applied at the collector plate. The nanowires exhibit ferromagnetic behavior with a Curie temperature higher than 400 K. Nanoscale devices are fabricated with single CFA nanowire to understand the magnetotransport properties.

9:24AM P30.00008 A study of the effect of nitrogen doping in TiO_2 , LISA DEBEER-SCHMITT, NSSD, ORNL, XIAOFENG QIU, IBM TJ Watson Research Center, LARRY ANOVITZ, CSD, ORNL, WILLIAM HELLER, KEN LITTRELL, NSSD, ORNL, M. PARANS PARANTHAMAN, CSD, ORNL — TiO_2 nanotube arrays have great potential as photovoltaics due to its unique chemical and physical properties associated with highly ordered tubular geometry. Small-angle neutron scattering (SANS) can characterize the specific nitrogen doping impact to the nanotube array structures. N-doping holds the promise of overcoming the large intrinsic bandgap barrier, which prevent TiO_2 from utilizing larger portion of solar energy. Combining with nanotube structures, N-doping could further promote the energy conversion efficiency of TiO_2. The SANS data demonstrate that the nitrogen doping during the nanotube growth alters their structure. This stabilized structure is evident in the data via extra peaks in the nitrogen doped sample as compared to the pure. The results demonstrate that the nanotube array morphology can be manipulated by varying the growth conditions, making it possible to tailor the arrays to specific purposes.

9:36AM P30.00009 Spontaneous Formation of a Nanotube from a Square Ag Nanowire[1] , SONDAN DURUKANOGLU, Faculty of Engineering and Natural Sciences, Sabanci University, MINE KONUK, Department of Physics, Istanbul Technical University — The recently observed phenomenon of spontaneous formation of a tube from a regular, square Ag nanowire has been investigated through molecular static and dynamic simulations based on the interaction potentials obtained from the embedded atom method. With molecular static calculations, we investigate the effect of strain on this particular type of transformation by focusing specifically on square Ag nanowires. Our results demonstrate that the formation of hollow structures requires a combination of minimum basis size and high gradient stress. Using molecular dynamic simulation, we also discuss the effect of temperature on the evolution of silver nanowire during the elongation.

9:48AM P30.00010 Effect of catalyst preparation on diameter of single-walled carbon nanotubes synthesized by alcohol CVD , THEERAPOL THURAKITSEREE, ERIK EINARSSON, The University of Tokyo, Tokyo 113-8656, Japan, RONG XIANG, Sun Yat-Sen University, Guangzhou 510275, China, SHINYA AIKAWA, SHOHEI CHIASHI, JUNICHIRO SHIOMI, SHIGEO MARUYAMA, The University of Tokyo, Tokyo 113-8656, Japan — We investigated the effect of various aspects of the catalyst preparation procedure on the diameters of SWNTs synthesized by the alcohol CVD method. Prior to nanotube growth, a Co/Mo binary catalyst was deposited by dip-coating, and then reduced under flowing Ar/H_2 at temperatures ranging from 300 to 800 °C. We found that the mean SWNT diameter depends on both reduction time and temperature, with lower reduction temperature or short reduction time resulting in smaller diameter SWNTs. The morphology of SWNTs changed from vertically aligned for reduction temperatures above 500 °C to randomly aligned when reduction occurred below 500 °C. Introducing small amount of water during heating, the mean diameter of the SWNTs was also reduced despite synthesis at 800 °C. Small diameter SWNTs were synthesized with this new cobalt/rhodium (Co/Rh) catalyst. The average diameter SWNT is similar to that from Co/Fe catalysts and slightly smaller than HiPco.

10:00AM P30.00011 Water monomer interaction with H-passivated Si nanowires from density functional theory , ABRAHAM HMIEL, YONGQIANG XUE, University at Albany-SUNY — A molecular-level understanding of the interaction between water and nanomaterials is essential for such important phenomena as corrosion, catalysis, electrochemistry and biology. In this talk we present density functional (DFT) study of the structure and energetics of water monomer binding to the surfaces of hydrogen terminated silicon nanowires (SiNWs), which represents the initial phase of interfacial water. We present results on the binding site and orientation of individual water molecules on the surfaces of [112] and [110] oriented SiNWs and analyze the energetics of water adsorption through potential energy surface scan along selected degrees of freedom.

10:12AM P30.00012 In-situ dynamical study of capillary absorption of molten silver nanodroplets by multiwall carbon nanotubes , YEN-SONG CHEN, YUAN-CHIH CHANG, TUNG HSU, CHIA-SENG CHANG, DEPT. OF PHYSICS, NATIONAL TAIWAN UNIVERSITY TEAM, INSTITUTE OF PHYSICS, ACADEMIA SINICA TEAM, DEPT. OF MATERIALS SCIENCE AND ENGINEERING, NATIONAL TSING-HUA UNIVERSITY COLLABORATION — Since the discovery of carbon nanotubes (CNTs), they have been widely investigated for their properties. Due to the large aspect ratio and the uniform diameters, the inner cavities of the CNTs are used as nano test tubes, siphons, catalyst carriers, and so on. Based on recent molecular dynamic simulations, a CNT with open end might act as a "capillary pipette" which can absorb nonwetting metal nanoparticles. In our study, the in-situ dynamical process of nonwetting Ag nanodroplets drawn into the hollow cores of multiwall carbon nanotubes (MWCNTs) was observed in an ultrahigh-vacuum transmission electron microscope equipped with a scanning tunneling microscopy probe. We discover this capillary absorption of melted Ag nanodroplets can occur only when the ratio of the Ag nanodroplet size to inner diameter of MWNTs is below a critical value, which is dependent on the inner diameter of MWCNTs. With continuous operations of capillary absorption for Ag nanodroplets, the one-dimensional Ag nanowires with a specific length could be fabricated inside the MWNTs for NEMS electronics or other applications.

10:24AM P30.00013 O_2 dissociation on nitrogen doped carbon nanotubes (10, 0) from first principles simulation , SHIZHONG YANG, Southern University/LONI Institute, GUANG-LIN ZHAO, EBRAHIM KHOSRAVI, Southern University — Reducing the amount of precious platinum (Pt) loading by identifying non-precious metal catalyst is essential for large-scale applications of fuel cells, which provide a cleaning energy technology. Recent experimental, theoretical, and simulation works accelerate the advance in the research area of doped carbon nanotubes acting as an alternate non-precious metal catalyst for dioxygen reduction in the fuel cells. First principles spin polarized density functional theory(DFT) simulations have been performed to understand O_2 dissociation on nitrogen doped carbon nanotubes. We have studied nitrogen substitutional doping of carbon nanotubes (CNTs) for dioxygen adsorption, reduction, and dissociation. The calculated results show that nitrogen prefers to stay at the open-edge of short CNTs. Two O_2 chemisorption sites are found, the carbon-nitrogen complex (Pauling site) and carbon-carbon long bridge (long bridge) sites. The spin polarized DFT calculations using the nudged elastic band (NEB) method show that O_2 dissociation at the Pauling site has a reaction energy barrier of about 0.55 eV. The unique open-edge structure and charge redistribution are crucial to the novel properties of nitrogen-doped CNTs as a new non-precious metal catalyst for fuel cells.

10:36AM P30.00014 Adsorption kinetics of polyatomic molecules on a heterogeneous surface , JARED T. BURDE, Southern Illinois University Carbondale, M. MERCEDES CALBI, University of Denver — We study the kinetics of adsorption of diatomic and triatomic molecules on the external surface of a carbon nanotube bundle. The Kinetic Monte Carlo algorithm is employed to track the number of particles adsorbed on the bundle and the orientation of those particles with respect to the surface at any given time. Our model is further complicated by the inclusion of a more complex surface geometry; a two dimensional, heterogeneous lattice better models the reality of groove between adjacent nanotubes on the outside of the bundle. This allows us to see interesting kinetic effects in the adsorption process, as the adsorbates have multiple transitional states through which they can pass as they evolve towards equilibrium.

10:48AM P30.00015 Simulations of adsorption on a single carbon nanotube , HYE-YOUNG KIM, Department of Chemistry and Physics, Southeastern Louisiana University, Hammond, LA 70402, SILVINA GATICA, Department of Physics and Astronomy, Howard University, Washington, DC 20059, MILTON COLE, Department of Physics, Pennsylvania State University, State College, PA 16802 — Using the grand canonical Monte Carlo method, we have evaluated the adsorption isotherms of simple gases (Ar, Kr, Xe) on a variety of carbon nanotubes. The adsorption potential is a sum of anisotropic atom-C interactions, dependent on the angle between the outward normal and the atom-C separation vector. For varying gas species and nanotube chirality, different commensurate phases are seen than on the surface of graphite. Comparison is made with recent experiments of Wang, et al, Science 327, 552 (2010).

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P31 DMP GSCCM DCOMP: Focus Session: Materials at High Pressure IV: Geophysical Materials and Magnetic Transitions C145

8:00AM P31.00001 Pressure-induced phase transitions in NaMgF3 post-perovskite[1] , KOICHIRO UMEMOTO, Department of Geophysics and Geology, University of Minnesota, RENATA WENTZCOVITCH, MSI and CEMS, University of Minnesota — Understanding the behavior of $MgSiO_3$ postperovskite(PPV) under extreme pressures is fundamental for modeling the interiors of solar giants and extrasolar planets. In 2006, $MgSiO_3$ post-perovskite was predicted to dissociate into MgO and SiO_2 at 1.1 TPa (Umemoto et al., Science 311, 983 (2006)). However, the predicted dissociation pressure is too high to be easily verified experimentally. Instead, a low-pressure analog, $NaMgF_3$ neighborite, has been studied to test for structural predictions in $MgSiO_3$. $NaMgF_3$ was predicted to dissociate at $\sim$40 GPa (Umemoto et al., Geophys. Res. Lett. 33, L15304 (2006)), but this has not been confirmed experimentally (Martin et al., Geophys. Res. Lett. 33, L11305 (2006); Grocholski et al. Geophys. Res. Lett. 37, L14204 (2010)) and the dissociation $MgSiO_3$ PPV is now being questioned. Here, we reexamine in detail the pressure dependence of crystal structures and phonon frequencies in $NaMgF_3$ and reveal the apparent reason why dissociation was not observed in this material.

8:12AM P31.00002 First-principles calculation of thermal conductivity of silicate perovskite at high pressures and high temperatures[1] , JIANJUN DONG, Auburn University, XIAOLI TANG, California Institute of Technology, ABBY KAVNER, UCLA, MOSES NTAM, Auburn University — The lattice thermal conductivity of silicate perovskite, the most abundant mineral in the Earth's lower mantle, is calculated by combining the first-principles electronic structure theory and Peierls-Boltzmann transport theory. The phonon scattering rate due to lattice anharmonicity and Mg/Fe mass disorder is evaluated for each mode at the extreme P-T conditions of the lower mantle. The predicted thermal conductivity of single crystal MgSiO3 perovskite at ambient condition, about 5.7 W/m/K, is in excellent agreement with experiment. Adding about 6% Fe will lower the thermal conductivity by nearly 40%. Our calculation also reveals an unique pressure dependence for the thermal conductivity of perovskite, and the calculated thermal conductivity of iron bearing perovskite is almost an order of magnitude lower than the previously estimates based on long extrapolation of single crystal data. Including a re-evaluation of radiative contribution, we discuss the implications of our results for the heat flow in deep Earth.

[1]Funded by NSF (EAR-0757847)

8:24AM P31.00003 Identification of post-pyrite transition in SiO2 by a genetic algorithm[1] , SHUNQING WU, Iowa state U and Xiamen U, KOICHIRO UMEMOTO, GEO, U of Minnesota, KAI-MING HO, MIN JI, CAI-ZHUANG WANG, Ames Lab, Iowa state U, RENATA WENTZCOVITCH, MSI and CEMS, U of Minnesota — Here we propose a new phase of SiO_2 beyond the pyrite-type phase. SiO_2 is one of the most important minerals in Earth and planetary sciences. So far, the pyrite-type phase has been identified experimentally as the highest-pressure form of SiO_2. In solar giants and extrasolar planets whose interior pressures are considerably higher than that on Earth, a post-pyrite transition in SiO_2 may occur at $\sim$ 1 TPa as a result of the dissociation of $MgSiO_3$ post-perovskite into MgO and SiO_2 [Umemtoto et al., Science 311, 983 (2006)]. Several dioxides considered to be low-pressure analogs of SiO_2 have a phase with cotunnite-type ($PbCl_2$-type) structure as the post-pyrite phase. However, a first-principles structural search using a genetic algorithm shows that SiO_2 should undergo a post-pyrite transition to a hexagonal phase, not to the cotunnite phase. The hexagonal phase is energetically very competitive with the cotunnite-type one.

8:36AM P31.00004 Spin crossover systems in the deep mantle , RENATA WENTZCOVITCH, Department of Chemical Engineering and Materials Science, Minnesota Supercomputing Institute, University of Minnesota — In recent years there has been much interest on spin crossovers found experimentally in the most abundant minerals of Earth's lower mantle ((Mg,Fe)O and (Mg,Fe)(Si,Fe)O_3-perovskite) under pressure. Spin crossovers are strongly dependent on thermodynamic conditions and a full understanding of this problem requires its investigation as function of pressure and temperature. There are several controversies, especially in the perovskite systems, and surprises are revealed by electronic structure calculations. The geophysical consequences of these crossovers are yet to be fully understood but could be fascinating. I will review progress we have made in understanding spin crossovers and give an overview of this phenomenon and its potential implications for the Earth.

Research carried out in collaboration with H. Hsu, K. Umemoto, P. Blaha, J. F. Justo, and C. R. S. da Silva. Research supported by the MRSEC Program of NSF under Award Number DMR-0212302 and DMR-0819885, and by NSF/ATM-0428774, EAR-0810212, and EAR-1047629.

9:12AM P31.00005 Insulator to Metal and Magnetic Transitions in FeO under High Pressure: DFT-DMFT Computations , R.E. COHEN, Geophysical Laboratory, Carnegie Institution, KRISTJAN HAULE, GABI KOTLIAR, Rutgers University — We have applied DFT+Dynamical Mean Field Theory (DMFT) to FeO under varying pressure and strain to understand possible transitions in FeO. We use an LAPW basis set, and the lattice terms are evaluated using the WIEN2K LAPW code. The impurity model is solved using continuous time quantum Monte Carlo (CTQMC). Temperature enters explicitly, so we made special efforts to understand high temperature behavior relevant to geophysics. The computations are fully self-consistent, including the impurity levels and crystal field splitting, and the total energy is evaluated using the full potential and charge density of the lattice plus impurity models. We find with increasing pressure in paramagnetic FeO in a cubic lattice and U=8 eV a high-spin low-spin transition, with a possible intermediate spin state (characterized by intermediate occupancies of the t2g and eg states) between. We find that at 300K cubic FeO remains insulating to a factor of two compression (over 600 GPa). However, high temperatures (e.g. 2000K) and rhombohedral lattice strain promote a metal insulator transition. We are delineating the phase boundaries. This work is supported by NSF.

9:24AM P31.00006 First-principles study of spin-state crossovers and hyperfine interactions of ferric iron in magnesium silicate perovskite[1] , HAN HSU, University of Minnesota, PETER BLAHA, TU Vienna, MATTEO COCOCCIONI, RENATA WENTZCOVITCH, University of Minnesota — The spin-state crossover in iron-bearing $MgSiO_3$ perovskite, the most abundant mineral in the Earth, may significantly affect the properties of Earth's lower mantle. However, details of this phenomenon have been very unclear, owing to the complicated nature of this mineral, mainly the coexistence of ferrous and ferric iron. Using the density functional theory plus Hubbard U (DFT+U) methods, we investigated the spin states and hyperfine interactions of ferric iron in this mineral. We show that a crossover from high-spin to low-spin state occurs within the lower-mantle pressure range, and it is accompanied by a noticeable volume reduction and an increase in iron nuclear quadrupole splitting (QS). These results are consistent with recent x-ray diffraction and Mössbauer spectroscopy measurements [K. Catalli *et al.*, Earth Planet. Sci. Lett. **289**, 68 (2010)].

[1]This work is primarily supported by the MRSEC Program of NSF under DMR-0212302 and DMR-0819885, and partially supported by EAR-0810212 and EAR-1047629. P.B. was supported by the Austrian Science Fund (P20271-N17). Calculations were performed at MSI.

9:36AM P31.00007 Ab initio melting curve of Fe and Fe-S alloys at extreme pressures: implications for Earth's and exoplanets' cores , JOHANN BOUCHET, CEA, GUILLAUME MORARD, Institut de Minéralogie et de Physique des Milieux Condensés, STEPHANE MAZEVET, CEA, FRANCOIS GUYOT, Institut de Minéralogie et de Physique des Milieux Condensés — Exoplanets with masses similar to that of Earth have recently been discovered in extrasolar systems [1]. A first order question for understanding their dynamics is to know whether they possess Earth like liquid metallic cores. However, the iron melting curve is unknown at conditions corresponding to planets of several times the Earth's mass (over 15 Mbar for planets with 10 times the Earth's mass [2]). In the density-temperature region of the cores of those super-Earths, we calculate the iron melting curve using first principle molecular dynamics simulations based on density functional theory. We also propose an equation of state for iron in this pressure range. Finally we show the melting curve of Fe_3S and discuss the effects of the addition of sulfur to the melting curve of pure iron.

9:48AM P31.00008 Elasticity of iron-bearing olivine polymorphs investigated by first principles , MARIBEL NÚÑEZ VALDEZ, School of Physics and Astronomy, University of Minnesota, YONGGANG YU, Dept. of Chemical Engineering and Material Sciences, University of Minnesota, RENATA WENTZCOVITCH, Dept. of Chemical Engineering and Material Sciences and Minnesota Supercomputing Institute, University of Minnesota — We calculate by first principles the effect of iron on the high pressure-temperature elasticity of olivine polymorphs: α-phase (olivine), β-phase (wadsleyite) and γ-phase (ringwoodite), the major constituents of the Earth's upper mantle and transition zone (TZ). We combine the LDA, the quasiharmonic approximation, and a model vibrational density of states for the solid solution to calculate the full elastic tensor C_{ij}, bulk (K) and shear (G) moduli of $(Mg_{0.875}Fe_{0.125})_2SiO_4$. Comparison with experimental data at ambient conditions validates our results. In the pressure and temperature range of the upper mantle and TZ we study single crystal wave propagation anisotropy and polarization anisotropy in aggregates with preferred orientation.

Research supported by NSF EAR-1019853 and EAR-0810272. Computations were performed at the Minnesota Supercomputing Institute.

10:00AM P31.00009 Polymerization of methane in the deep Earth[1] , LEONARDO SPANU, Department of Chemistry UC Davis, DAVIDE DONADIO, MPI for Polymer Research; Department of Chemistry UC Davis, DETLEF HOHL, Shell Global Solutions Inc. Houston, TX, ERIC SCHWEGLER, Lawrence Livermore National Laboratory, Livermore CA, GIULIA GALLI, Department of Chemistry and Department of Physics, UC Davis — Determining physical and chemical properties of carbon fluids at high pressure and temperature is a key step towards understanding carbon reservoirs and fluxes in the deep Earth. The stability of carbon-hydrogen systems at depth greater than few thousands meters is poorly understood and the abiogenic hypothesis on the synthesis of higher hydrocarbon (HCs) in the Earth mantle remains controversial. We have used ab initio molecular dynamics simulations to investigate the formation of higher HCs from dissociation of pure methane, and of methane in contact with carbon surfaces and transition metals, in a range of pressure of $2-30$ GPa and temperature T=$800-4,000$ K [1]. We present results on the range of stability of pure methane and discuss how the interaction with transition metals or carbon deposits (graphite and diamond) affects the formation of higher HCs.

[1]Work supported by a grant from Stichting Shell Research (SSR).

10:12AM P31.00010 Solubility and erosion of icy cores in giant planets , HUGH WILSON, BURKHARD MILITZER, University of California Berkeley — The core-mantle boundary of a giant planet consists of an interface between dense rock/ice below and fluid hydrogen-helium above. Whether this phase boundary remains stable, however, or whether the core material is dissolved and redistributed throughout the interior, remains unknown, and has major consequences for planetary interior and formation models. In this work we use density functional theory molecular dynamics calculations to compute the free energy of solubility for the icy components of the core into fluid hydrogen, to investigate whether solubility is thermodynamically preferred at the extreme temperature and pressure conditions prevalent at the core-mantle boundaries of Jupiter and Saturn. The consequences for Jupiter and Saturn, as well as for giant exoplanets, will be discussed.

10:24AM P31.00011 Post-stishovite transition in AlOOH-incorporated SiO2[1] , KATSUYUKI KAWAMURA, Tokyo Institute of Technology, KOICHIRO UMEMOTO, RENATA WENTZCOVITCH, University of Minnesota, KEI HIROSE, Tokyo Institute of Technology — In 2007, Lakshtanov et al. [Proc. Nat. Acad. Sci. 104, 13588 (2007)] showed that the incorporation of AlOOH into SiO_2 significantly reduces the transition pressure between stishovite and $CaCl_2$-type phases. In the present paper, we investigate theoretically the effect of hydrogen and aluminum on this transition. First-principles calculations show that aluminum has no effect on the transition pressure. However, hydrogen bonds play a crucial role, suggesting that a cooperative redistribution of hydrogens aids the post-stishovite transition. Large-scale molecular dynamics simulations using model potentials confirm this effect and reveal the nature of the hydrogen motion. This effect produces a strong temperature dependence on the transition pressure and should make the latter sensitive to hydrogen content in the material.

[1]This work was supported by NSF under ATM-0428774 (VLab), EAR-0757903, and EAR-1019853. The computations were performed at the Minnesota Supercomputing Institute (MSI).

10:36AM P31.00012 Thermodynamic properties of $MgSiO_3$ majorite and phase transitions near 660-km depth in $MgSiO_3$ and Mg_2SiO_4: a first principles study[1] , YONGGANG YU, Virginia Tech, RENATA WENTZCOVITCH, U. Minnesota, VICTOR VINOGRAD, U. Frankfurt, ROSS ANGEL, Virginia Tech — Thermodynamic properties of $MgSiO_3$ tetragonal majorite have been calculated at high P-T within the quasiharmonic approximation based on DFT using both LDA and GGA. The LDA results compare exceptionally well with measured thermodynamic properties. A classical Monte Carlo simulation based on a cluster expansion method demonstrates that disorder between Mg and Si in the octahedral sites in majorite does not occur below 3600 K within 30 GPa. The calculated phase boundaries between majorite (mj), perovskite (pv), and ilmenite (il) $MgSiO_3$ agree much better with experiments by using GGA than by LDA. The Clapeyron slopes (CS) predicted by GGA and LDA are close to each other: 0.9 – 1.7 MPa/K for mj-pv, 6.9 – 7.9 MPa/K for mj-il, and -7 – -3 MPa/K for il-pv transition. The triple point predicted by GGA is at 21.8 ± 1 GPa and 1840 ± 200 K which is $\sim$400 K lower than most experiments. Our calculations also reveal that wadsleyite decomposes to an assemblage of majorite plus periclase above 2280 K with a large negative CS (-22 – -12 MPa/K) and that ringwoodite decomposes to ilmenite plus periclase below 1400 K (1.2 MPa/K). The geophysical implications to mantle convection and the composition of the Earth's transition zone will also be discussed.

10:48AM P31.00013 A first-principles investigation of hydrous defect and IR frequencies in forsterite: The case for Si vacancies[1] , MARC HIRSCHMANN, KOICHIRO UMEMOTO, RENATA WENTZCOVITCH, DAVID KOHLSTEDT, ANTHONY WITHERS, University of Minnesota — We investigate charge-balanced hydrous magnesium and silicon defects ($(2H)^X_{Mg}$, $(4H)^X_{Si}$) by first principles. Here we propose two new lowest-energy hydrogen configurations for $(4H)^X_{Si}$. With these new configurations, the distribution of OH-stretching phonon frequencies in Group I ($>$ 3450 cm-1) are better reproduced. Substitution of silicon with 4 hydrogens gives rise to significant elongation of distances between oxygen ions at the tetrahedron of the silicon vacancy. Our calculations indicate that the correlation between O-O distances and O-H-stretching phonon frequencies, which has been well established for hydrous minerals, does not apply directly to nominally anhydrous minerals and should not be used to determine the identity of the hydrous defects responsible for infrared absorption peaks.

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P32 DCMP: Optical Properties and Dynamics of Quantum Dots and Quantum Wells

C144

8:00AM P32.00001 Sub micron scale patterning of material optical response through focused ion beam induced InAs/GaAs quantum dot nucleation , TIMOTHY SAUCER, JIEUN LEE, ANDREW MARTIN, DEBORAH TIEN, JOANNA MIRECKI-MILLUNCHICK, VANESSA SIH, The University of Michigan — We report on the technique of using a focused ion beam to produce preferential sites for InAs/GaAs quantum dot nucleation. We mill an array of holes in the GaAs substrate and then deposit a thin layer of InAs below the critical thickness for dot formation in unpatterned areas. The array of holes on the substrate act as preferential nucleation sites and induce quantum dot formation only in the patterned regions. We conduct photoluminescence spectroscopy in a templated multilayer quantum dot sample at temperatures down to 10K and for various patterning conditions. We find that outside of our patterning regions we have no quantum dot luminescence, indicating that the patterning modifies the optical response of the material. We find that we can control this quantum dot formation down to array spacings of 250nm, showing excellent potential for this technique to be used for sub micron spatial control of a material's optical properties.

8:12AM P32.00002 Photoluminescence imaging of Focused-Ion-Beam induced individual quantum dots , JIEUN LEE, TIMOTHY SAUCER, Department of Physics, University of Michigan, ANDREW MARTIN, Department of Materials Science and Engineering, University of Michigan, DEBORAH TIEN, Department of Physics, University of Michigan, JOANNA MILLUNCHICK, Department of Materials Science and Engineering, University of Michigan, VANESSA SIH, Department of Physics, University of Michigan — Quantum dots are nanostructures that confine electrons in 3 spatial dimensions. Due to their discrete atom-like energy levels, a wide variety of applications related to the optical properties of dots are possible. One such application is to integrate quantum dots in optical nanocavities for the enhanced interaction between electrons and photons. However, self-assembled dots typically nucleate at random locations, hindering the accurate coupling between the dot and cavity. Therefore, spatial control on self-assembled dots at the fabrication level is highly desirable. Here, we report on optical measurements conducted on InAs quantum dots that are prepatterned in a square array by a focused-ion-beam. Using scanning confocal microscopy, we spatially map the photoluminescence of individual quantum dots. Single dot luminescence with 160 μeV linewidth is observed indicating good optical quality and statistical analysis over 16 array sites show reasonable placement accuracy and emission inhomogeneity.

8:24AM P32.00003 Strongly confined excitons in self-assembled InGaAs quantum dot clusters , MEGAN CREASEY, XIAOQIN LI, Department of Physics, University of Texas at Austin, JIHOON LEE, Department of Electrical Engineering, Kwangoon University, ZHIMING WANG, GREGORY SALAMO, Institute of Nanoscale Science and Technology, University of Arkansas — Quantum dot clusters (QDCs) consisting of regular geometric patterns of six InGaAs quantum dots (QD) are grown on a GaAs substrate using a hybrid growth method that combines droplet homoepitaxy and Stranski-Krastonov growth. These novel structures have potential applications as tunable single photon sources, entangled photon sources, or error corrected qubits - devices critical to the fields of secure optical communications and quantum computing We study the photoluminescence arising from a single cluster using both continuous wave and ultrafast spectroscopic techniques with variations in the sample temperature and excitation power. Our results suggest excitons (bound electron-hole pairs) are strongly confined within the individual QDs rather than loosely confined throughout the entire QDC. The work at Texas is supported financially by NSF, ARO, AFOSR, ONR, the Welch Foundation, and the Alfred Sloan Foundation. The work at Arkansas is supported by the NSF.

8:36AM P32.00004 Selective control of polarized luminescence from GaN/AlN self-assembled quantum dots , DANIEL RICH, OFER MOSHE, Ben-Gurion University, BENJAMIN DAMILANO, JEAN MASSIES, Centre National de la Recherche Scientifique — GaN/AlN self-assembled quantum dots (QDs) were grown by the Stranski-Krastanov method on Si(111) using molecular beam epitaxy. During the subsequent cooling from growth temperatures, the thermal expansion coefficient mismatch between the Si substrate and GaN/AlN film containing vertically stacked QDs leads to an additional biaxial tensile stress at the Si/III-Nitride interface. We have modified the thermal stress in the QD layers by etching stripes of varying widths using inductively coupled Cl/Ar plasma reactive ion etching. The results show that a suitable choice of stripe width and orientation can create regions of in-plane uniaxial stress ranging from 20-30 kbar which enables a selective and local control of polarized emission from the QDs. Localized cathodoluminescence (CL) spectroscopy of the QDs exhibits emissions from both the ground and excited states, whose relative contributions depend on the level of excitation and temperature. We have studied these emissions using time- and polarization-resolved CL for ensembles of QDs. The effects of screening of the polarization field in the QD, state-filling, changes in the polarization anisotropy and lifetime with varying excitation were studied experimentally and modeled with a self-consistent 6x6 k.p calculation method.

8:48AM P32.00005 Polarization states of charged excitons in coupled InAs/GaAs quantum dot molecules , RAMANA THOTA, SWATI RAMANATHAN, KUSHAL WIJESUNDARA, ERIC STINAFF, Department of Physics and Astronomy, and Nanoscale and Quantum Phenomena Institute, Ohio University, Athens, Ohio 45701-2979, USA, ALLAN BRACKER, DAN GAMMON, Naval Research Laboratory, Washington, DC 20375, USA — The polarization state of charged excitons in coupled InAs/GaAs dots can reveal useful information about the spin state of its charge carriers. In this study, we examine the complete polarization state through Stokes parameter measurements to relate the polarization parameters of the luminescence to the spin configurations of the various charged excitons they originate from. We demonstrate that this method is a useful tool to identify and possibly create spin states for quantum computation applications.

9:00AM P32.00006 Resonant Fluorescence from Quantum Dot Molecular Excitonic Transitions , MARK KERFOOT, University of California, Merced, ALLAN BRACKER, DANIEL GAMMON, Naval Research Laboratory, MICHAEL SCHEIBNER, University of California, Merced, UNIVERSITY OF CALIFORNIA, MERCED COLLABORATION, NAVAL RESEARCH LABORATORY COLLABORATION — Quantum dot molecules formed by two vertically stacked quantum dots are a rich testing ground for basic concepts regarding the measurement and control of quantum states. The well defined geometry is ideal for studying interaction mechanisms, such as the interaction of two dipoles each located in one of the quantum dots of the quantum dot molecule. A prerequisite for doing so is the ability to detect the interaction mediated changes in the properties of the individual, uncoupled quantum dots. Here we use resonant fluorescence to study exciton transitions in quantum dot molecules. We measure the photoluminescence of the same transition we optically excite with a narrow band laser. With this method, features on the scale of the homogeneous line width of the intradot exciton transition are well resolved. This enables us to study the fine-structure of different charge and spin configurations with high sensitivity.

9:12AM P32.00007 Exchange-controlled spin dynamics in coupled quantum dots , ERIC A. STINAFF, KUSHAL C. WIJESUNDARA, Department of Physics and Astronomy, and Nanoscale and Quantum Phenomena Institute, Ohio University, Athens, OH 45701, USA, ALLAN BRACKER, DAN GAMMON, Naval Research Laboratory, Washington, DC 20375, USA — We measure circular polarization memory of neutral exciton states with polarization dependent photoluminescence spectra. As a consequence of anisotropic exchange interaction a low degree of circular polarization memory was observed in the spatially direct and indirect excitons where they anticross. With applied electric field as we tune the excitonic emission from intra-dot to inter-dot the electron-hole wave function overlap reduces and we observe an increase in polarization memory due to reduced exchange interaction. We observe a sudden unexpected dip in circular polarization memory of the spatially indirect exciton state that is coincident with the applied field where the single hole level resonance is observed. Possible mechanisms for this loss of circular polarization memory will be presented.

9:24AM P32.00008 Two-body and three-body interactions in phonon-assisted exciton energy transfer between quantum dots , KAIJIE XU, CARLO PIERMAROCCHI, Department of Physics and Astronomy, Michigan State University — We theoretically study the dynamics of exciton energy transfer between semiconductor quantum dots. Phonons play a critical role in the exciton energy transfer process when the energy of the dots involved in the process is different. We find that the phonon-assisted energy transfer cannot be correctly described by two-body exciton-photon and exciton-phonon interactions if each dot is modeled as a single-level exciton system. Higher excited levels of the exciton state have to be included to properly describe the phonon-assisted process. However, excited states can be traced out by introducing a single-level exciton model with an effective three-body exciton-photon-phonon coupling term. The three-body term describes a change in the exciton-photon dipolar coupling due to phonon-induced deformations of the ground exciton wavefunction. The multi-level exciton model with two-body interactions and the single-level exciton model with three-body interaction reproduce the same exciton transfer rates to the leading order contributions of perturbation theory.

9:36AM P32.00009 ABSTRACT WITHDRAWN –

9:48AM P32.00010 Optical lattices for electrons in semiconductors , CARLO PIERMAROCCHI, MICHAEL G. MOORE, MARTIN J. A. SCHUETZ, Michigan State University, MONIQUE COMBESCOT, Instutute of Nanosciences, Pierre et Marie Curie University, Paris France — We theoretically investigate the trapping of electrons in a semiconductor using counter-propagating laser beams. We consider two different physical mechanisms that can lead to an efficient electron trapping: (a) Pauli blocking between the electron and a virtual exciton coupled to the laser field, and (b) the virtual excitation of a three-body Coulomb resonance corresponding to a bound charged exciton state (a trion). Both processes induce a momentum transfer between photon and electron, and lead to a sinusoidal trap for electrons with a period determined by the laser beam modulation. The depth of the potential is proportional to the laser intensity and inversely proportional to the exciton-photon detuning. Competing effects such as laser heating, phonons, and disorder are analyzed.

10:00AM P32.00011 Many-body two-quantum coherences in 2DFT spectra of semiconductors , DENIS KARAISKAJ, University of South Florida, A. BRISTOW, X. DAI, JILA, CU and NIST, L. YANG, S. MUKAMEL, University of California Irvine, R. MIRIN, NIST Boulder, S. CUNDIFF, JILA, CU and NIST — Investigating the correlations of multiple excitons in semiconductors is a challenging many-body problem that has drawn considerable experimental and theoretical attention over the last two decades. Nonlinear four-wave mixing (FWM) experiments have long been known to provide direct probes for the many-body effects in the ultrafast dynamics of excitons in quantum wells. However, it is very difficult to separate the different contributions such as excitation induced dephasing, excitation induced shift, local field effects, and multiple exciton correlations. With the advent of two-dimentional Fourier-transform (2DFT) spectroscopy, the biexcitonic contributions could be isolated and the many-body contributions could be identified. Phase-resolved 2DFT spectra for the negative delay FWM signal will be presented which show interesting diagonal and off-diagonal peaks. The energy positions, line shapes, and the complexity of the 2D peaks indicate significant many-body coherences and reinforce the ability of 2DFT to disentangle two-quantum transitions (D. Karaiskaj, *et al.*, Phys. Rev. Lett. **104**, 117401 (2010)).

10:12AM P32.00012 Electron transfer and relaxation dynamics in heterovalent ZnSe/GaAs quantum well structures , AMIT DONGOL, HANS PETER WAGNER, Department of Physics, University of Cincinnati, OH-45221, USA — We investigate the electron transfer and relaxation dynamics in heterovalent ZnMgSe/ZnSe quantum wells (QW's) grown on GaAs using the nonlinear optical method of three-beam degenerate four-wave-mixing (FWM). We use ultra-short (90 fs) laser pulses with non-collinear wave-vectors $\mathbf{k}_1$, $\mathbf{k}_2$ and $\mathbf{k}_3$ at a center wavelength of 441 nm ($\sim$2.81 eV) which is resonantly tuned to the heavy hole exciton transition energy at 25 K. In the experiment the time coincident strong pump pulses $\mathbf{k}_1$ and $\mathbf{k}_2$ creates both an exciton density grating in the QW and an electron-hole pair grating in the GaAs while the delayed weak pulse $\mathbf{k}_3$ simultaneously probes the exciton lifetime T_1 as well as the electron grating injection time T_t from the substrate into the QW. Intensity dependent experiments reveal that the diffraction efficiency due to the electron grating increases faster with increasing $\mathbf{k}_1$ and $\mathbf{k}_2$ pulse intensities than the FWM efficiency due to the generated exciton density grating. This behavior which is attributed to exciton bleaching at high intensities enables the discrimination of times T_1 and T_t, both being in the order of a few tens of picoseconds.

10:24AM P32.00013 Excitons in moving lattices , JASON LEONARD, ALEXANDER WINBOW, MIKAS REMEIKA, YULIYA KUZNETSOVA, ALEXANDER HIGH, AARON HAMMACK, LEONID BUTOV, University of California at San Diego, JOSEPH WILKES, ALRUN GUENTHER, ALEXANDER IVANOV, Cardiff University, MICAH HANSON, ARTHUR GOSSARD, University of California at Santa Barbara — We report on the study of indirect excitons in moving lattices–conveyers–created by a set of AC voltages applied to the electrodes on the sample surface. The wavelength of this moving lattice is set by the electrode periodicity, the amplitude is controlled by the applied voltage and the speed is controlled by the AC frequency. We probed the conveyer speeds from well below to well above the sound velocity. We observed the dynamical localization-delocalization transitions for excitons in the conveyers and measured its dependence on the exciton density and conveyer speed and amplitude. We also developed the theory of exciton transport via conveyers.

10:36AM P32.00014 Effect of growth kinetics on intersubband transitions in GaN/AlN multiple quantum wells[1] , J. YANG, S.D. CARNEVALE, T.F. KENT, Department of Materials Science and Engineering, The Ohio State University, Columbus, OH. 43210, M.R. BRENNER, Department of Electrical and Computer Engineering, The Ohio State University, Columbus, OH, 43210, R.C. MYERS, Department of Materials Science and Engineering, Department of Electrical and Computer Engineering, The Ohio State University, Columbus, OH. 43210 — The large conduction band offset of nearly 2 eV between GaN and AlN provides very large electron confinement that could be useful for ultrafast intersubband–based photonics operating at telecommunications wavelengths. However, it is difficult to control interface roughness and compositional profiles with monolayer precision, which is crucial for engineering sublevels for quantum cascaded intersubband photonics. Here we examine the effect of Ga-rich and N-rich growth conditions of highly-confined GaN/AlN multiple quantum wells prepared by plasma-assisted molecular beam epitaxy. Structural quality is examined through high-resolution x-ray diffraction and atomic force microscopy. The efficiency of intersubband and interband transitions in these heterostructures is measured using temperature dependent absorption and photoluminescence spectroscopy.

10:48AM P32.00015 Trions and quatrons in Semiconductor Coupled Quantum Wells , ROMAN YA. KEZERASHVILI, OLEG L. BERMAN, New York City College of Thechnology, City University of New York — The three-body restricted problem for trions, when a spatially separated exciton and electron or hole are located in the parallel quantum wells (QW), is reduced to the 2D two body problem for the exciton and the projection of the electron or hole on the plane of the excitonic QW. In the limit of a large spatial separation of the QWs the eigenfunctions and energy spectrum for the trions are obtained analytically. It is shown that the Schrödinger equation for the trion can be reduced to the 2D two-body problem with Coulomb electron-hole interaction for the 2D direct exciton and the Schrödinger equation for the 2D harmonic oscillator for the relative motion of the exciton and the image of the projection of the electron or hole on the plane of the quantum well with the exciton. The 2D Wigner crystallization of the trions in the coupled QWs is discussed. The four-body restricted problem for spatially separated exciton and electron and hole, located in the in three parallel QWs, is reduced to the 2D three body problem for the exciton and the projection of the electron and hole on the plane of the excitonic QW. In the limit of a large spatial separation of the QWs the eigenfunctions and energy spectrum for quatron formed by the exciton and electron and a hole are obtained analytically. The 2D superfluidity and Kosterlitz-Thouless phase transition in the dilute Bose gas of quatrons is discussed.

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P33 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides: BiFeO3 C143/149

8:00AM P33.00001 Manipulation of the domain structure in mixed-phase BiFeO3 epitaxial films , YI-CHUN CHEN, HSIN-HUA LEE, FENG-NAN CHU, WEN-CHUAN HSIEH, Department of Physics, National Cheng Kung University, Q. HE, Advanced Light Source, Lawrence Berkeley National Laboratory, WEN-I LIANG, YING-HAO CHU, Department of Materials Science and Engineering, National Chiao Tung University — Strain-induced phase transformation in epitaxial films is the newly advance in thin-film growth techniques. Under the compressive strain from the substrate, the stable phase of multiferroic BiFeO3 (BFO) films transformed from rhombohedrally- to tetragonally- distorted monoclinic perovskite, which simulated the material system near the morphotropic phase boundary. In this study, we used piezoresponse force microscopy (PFM) to investigate the intrinsic domain structures in the mixed-phase BFO epitaxial films. PFM taken along the principal crystallographic directions revealed the domain polarizations. The IP PFM images indicated the coexistence of at least two monoclinic phases with IP distortions along [100] and [110]. The domains were distributed in the way to minimize the local electrostatic energy, and the mixed phase pattern can be effectively controlled by external fields. The dynamic switching parameters for the domain and phase manipulation, such as switching speed, switching direction, and applying voltages, were systematically investigated. This study provides basic understanding and electrical control of this unique phase boundary.

8:12AM P33.00002 Oxygen ordering and electrochromism in Ca-doped $BiFeO_3$[1] , JAN SEIDEL, Lawrence Berkeley National Laboratory, Berkeley, CA, WEIDONG LUO, Vanderbilt University, Nashville, TN and ORNL, Oak Ridge, TN, PHI NGUYEN, Rutgers University, Piscataway, NJ, SURESHA SIRIYARA JAGANNATHA, ALAN LEE, SANG-YONG KIM, Lawrence Berkeley National Laboratory, Berkeley, CA, CHAN-HO YANG, KAIST, Daejeon, Republic of Korea, STEPHEN PENNYCOOK, SOKRATES PANTELIDES, Vanderbilt University, Nashville, TN and ORNL, Oak Ridge, TN, RAMAMOORTHY RAMESH, Lawrence Berkeley National Laboratory, Berkeley, CA — We show that calcium-doped bismuth ferrite thin films exhibit an electrochromic effect arising from an intrinsic mechanism due to redistribution of carriers, without the need for additional electrolytes that are needed in common electrochromic devices. The absorption change and coloration efficiency at the band edge are $4.8\times10^6 m^{-1}$and $190 cm^2 C^{-1}$, respectively, which are among the highest reported values for inorganic electrochromes. These experimental findings are supported by optical absorption calculations from first-principles theory, confirming the strong absorption change at the band edge.

8:24AM P33.00003 Polarity Control of Ferroelectric $BiFeO_3$/Metal Junctions for Switchable Diode and Photovoltaic Devices , TAE WON NOH, DAESU LEE, T.H. KIM, ReCFI, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Republic of Korea, S.H. BAEK, C.M. FOLKMAN, C.B. EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, Madison, Wisconsin 53706, USA, J.-G. YOON, Department of Physics, University of Suwon, Kyunggi-do 445-743, Republic of Korea — Ferroelectric materials possess spontaneous polarization which can be used to control numerous functionalities of the materials by switching the polarization or modifying domain structure with an electric field. One of emerging phenomena in ferroelectrics is the control of charge transport by switching the polarization. Although charge conduction ($i.e.$, leakage current) in ferroelectrics has been considered as a detrimental factor to practical applications, an interaction between conduction and ferroelectric polarization has recently attracted much attention as a route for novel functionalities. In this presentation, we will report on the ferroelectric control of charge conduction in $BiFeO_3$/metal junctions: the $BiFeO_3$/metal interfaces can have either blocking or non-blocking contacts according to the polarization direction of the $BiFeO_3$ films, allowing non-volatile control of diode-like conduction characteristics. The resulting rectifying and photovoltaic effects can be turned on and off, as well as be flipped in polarity, depending on the ferroelectric domain structures.

8:36AM P33.00004 ABSTRACT WITHDRAWN –

8:48AM P33.00005 Magnetic Order in single-crystal $BiFeO_3$, MEHMET RAMAZANOGLU, SANG-WOOK CHEONG, VALERY KIRYUKHIN, Rutgers Univ. Physics Dept., WILLIAM RATCLIFF, NCNR, NIST, S. LEE, KAERI — We report neutron scattering studies of the magnetic order in multiferroic Bismuth Ferrite ($BiFeO_3$). In ferroelectric monodomain single crystals, there are 3 equivalent magnetic cycloidal domains. The cycloid period slowly grows with increasing temperature, and the antiferromagnetic transition is 2nd order. The equivalent magnetic domain populations do not change with temperature, except in the close vicinity of the Neel temperature. No evidence for the spin-reorientation transitions proposed in previous Raman studies is found. The magnetic cycloid is slightly anharmonic for T=5 K. The anharmonicity is much smaller than previously reported in indirect NMR studies. At room temperature, a circular cycloid is observed. The observed anharmonicity provides important clues for understanding electromagnons in $BiFeO_3$.

9:00AM P33.00006 Chemical substitution induced ferroelectric polarization rotation in $BiFeO_3$ thin films[1] , ICHIRO TAKEUCHI, DAISUKE KAN, ANBUSATHAIAH VARATHARAJAN, University of Maryland — The direction of the polarization vector in ferroelectric materials is an important parameter critical to a number of applications. Polarization orientation in ferroelectric thin films can be controlled by various approaches such as electric- field induced rotation and strain engineering using exotic substrates. We have performed systematic chemical substitution of rare earth cationic dopants, in particular Sm in the $BiFeO_3$thin films, and found that the polarization vector rotates from the (111) to the (001) direction as a continuous function of the dopant concentration. This is accompanied by enhanced dielectric ϵ_{33} as well as piezoelectric coefficient d_{33}, and the maximum in d_{33} (110 pm/V) is achieved at 14% Sm. We will discuss the correlation between the polarization rotation, structural evolution and other properties as a function of chemical substitution.

[1]Work at Maryland was supported by UMD-NSF-MRSEC (DMR 0520471) and ARO W911NF-07-1-0410. The work was also supported by the W. M. Keck Foundation and NEDO.

9:12AM P33.00007 Strain-stabilized phases of BiFeO3 and the role of first-principles calculations , ALISON HATT, Lawrence Berkeley National Lab — After many years of focused attention from the scientific community, the ferroelectric material $BiFeO_3$ (BFO) continues to be one of the most intriguing and technologically promising of the multifunctional ferroelectrics. Here I will discuss some of the recent developments on BFO thin films, including the metastable "super-tetragonal" phase achievable in epitaxial thin films. This strain-stabilized phase has been observed to coexist with a bulk-like phase, and reversible switching between the two has been demonstrated by acting on their ferroelectric polarizations with an external electric field. [Zeches *et al.*, Science 326, 977 (2009).] Related work finds a phase transition path of rhombohedral-to-monoclinic-to-tetragonal for epitaxially strained BFO, suggesting comparison to a compositional morphotropic phase boundary. I will discuss these results with an emphasis on the contributions from first-principles calculations, and provide context for understanding the calculated behaviors.

9:48AM P33.00008 Experimental evidence of stress-induced R-M_A-M_C-T phase transition in $BiFeO_3$ films , HANS CHRISTEN, JOONG-HEE NAM, CHARLEE BENNETT, HYUN-SIK KIM, MICHAEL BIEGALSKI, Oak Ridge National Laboratory — Recent reports on epitaxial $BiFeO_3$ films show that the crystal structure changes from nearly rhombohedral ("R-like") to nearly tetragonal ("T-like") at strains exceeding ≈-4.5%, with the "T-like" structure being characterized by a highly-enhanced c/a ratio. While both the "R-like" and the "T-like" phases are monoclinic, our detailed x-ray diffraction results reveal a symmetry change from M_A and M_C type, respectively. Therefore, the ferroelectric polarization is confined to different (pseudocubic) planes in the two phases. By applying additional strain or by modifying the unit cell volume of the film by substituting Ba for Bi, the monoclinic distortion in the "T-like" M_C phase is reduced, i.e. the system approaches a true tetragonal symmetry. Therefore, in going from bulk to highly-strained films, a phase sequence of rhombohedral(R)-to-monoclinic("R-like" M_A)-to-monoclinic("T-like" M_C)-to-tetragonal(T) is observed. This sequence is otherwise seen only near morphotropic phase boundaries in lead-based solid-solution perovskites (i.e. near a compositionally induced phase instability), where it can be controlled by electric field, temperature, or composition. Our results now show that this evolution can occur in a lead-free, stoichiometric material and can be induced by stress alone.

10:00AM P33.00009 Strained $BiFeO_3$ Films: Rhombohedral-Orthorhombic and Rhombohedral-Tetragonal Phase Transitions. Part I: Phase-Field Simulations[1] , GUANG SHENG, JINGXIAN ZHANG, ZI-KUI LIU, LONG-QING CHEN, Department of Materials Science and Engineering, The Pennsylvania State University, YULAN LI, Pacific Northwest National Laboratory, THE PENNSYLVANIA STATE UNIVERSITY TEAM, PACIFIC NORTHWEST NATIONAL LABORATORY COLLABORATION — In this study, the strain-temperature phase stability diagrams of (001) $BiFeO_3$ thin film were constructed using both thermodynamic analysis and phase-field simulations. The predicted diagram reveals a tetragonal to distorted rhombohedral phase boundary around 4.3% compressive strain and rhombohedral to orthorhombic boundary at around 2% tensile strain, both at room temperature. The predicted transition temperatures for rhombohedral-orthorhombic and rhombohedral-tetragonal transitions are in reasonable agreement with experimental observations. We will also discuss domain structure evolutions of $BiFeO_3$ thin films during the above two transitions from phase-field simulations.

[1]This work was supported by the DOE Basic Science under the grant No. DOE DE-FG02-07ER46417

10:12AM P33.00010 Strained BiFeO3 Films: Rhombohedral-Orthorhombic and Rhombohedral-Tetragonal Phase Transitions. Part II: Film Growth by Molecular-Beam Epitaxy , CAROLINA ADAMO, Cornell University, R. MISRA, A. MELVILLE, C. HEIKES, Q. HE, Y. CHU, J. LEE, R. HAISLMAIER, S. DENEV, V. GOPALAN, R. RAMESH, P. SCHIFFER, D. SCHLOM — Recently, Zeches et al.[1] reported the strain-temperature phase stability diagram of (001) BiFeO3 thin films. Depending on the strain and temperature the stable polymorph of BiFeO3 is predicted to be (monoclinically distorted) rhombohedral, tetragonal, or orthorhombic. To test these predictions commensurate BiFeO3 thin films were grown by adsorption-controlled reactive molecular-beam epitaxy on (110) YAlO3, (110) NdGaO3, (100) LSAT, (001) SrTiO3, (110) DyScO3, (110) TbScO3, (110) GdScO3, (110) SmScO3, (110) NdScO3, and (110) PrScO3 single crystalline substrates. The films span a biaxial strain range from -6.7% to +1.4%. Four-circle x-ray diffraction was used to determine the in-plane and out-of-plane lattice parameters. The rocking curve full widths at half maximum in omega of the films were nominally identical to the substrates on which they are grown and ranged from 11 arc sec (0.003 degrees) on (110) PrScO3 to 49 arc sec (0.014degrees) on (110) YAlO3. Magnetic data and second harmonic generation results will be presented. [1] R. J. Zeches, M. D. Rossell, J. X. Zhang, A. J. Hatt, Q. He, C.-H. Yang, A. Kumar, C. H. Wang, A. Melville, C. Adamo, G. Sheng, Y.-H. Chu, J. F. Ihlefeld, R. Erni, C. Ederer, V. Gopalan, L. Q. Chen, D. G. Schlom, N. A. Spaldin, L. W. Martin, and R. Ramesh, Science 326, 977 (2009).

10:24AM P33.00011 Strained $BiFeO_3$ films: rhombohedral-orthorhombic and rhombohedral-tetragonal phase transitions. Part IV: ultraviolet Raman spectroscopy study[1] , DMITRI A. TENNE, A.K. FARRAR, G. MOLINO, Physics Dept., Boise State University, Boise, ID, C. HEIKES, C. ADAMO, J.H. LEE, A. MELVILLE, D.G. SCHLOM, Cornell University, Ithaca, NY, G. SHENG, L.Q. CHEN, Pennsylvania State University, University Park, PA, Y.-H. CHU, National Chiao Tung University, Hsinchu, Taiwan, Q. HE, R. RAMESH, University of California, Berkeley, CA — Epitaxial $BiFeO_3$ films grown by molecular-beam epitaxy on substrates inducing different lattice-mismatch strain ($YAlO_3$, $SrLaAlO_4$, $PrScO_3$) have been studied by variable- temperature ultraviolet Raman spectroscopy. Temperature evolution of Raman spectra from $BiFeO_3$ films indicates the phase transitions from rhombohedral to tetragonal phase in compressively strained films on $YAlO_3$ and $SrLaAlO_4$ substrates. The films grown on PrScO3 substrates are subject to ∼1.3% tensile strain, and undergo the transition from rhombohedral to orthorhombic phase at about 550-600 K. The temperature dependence of Raman intensities of certain characteristic peaks indicates the possibility of coexisting rhombohedral and orthorhombic phases in the temperature range 400-550 K. Raman results are consistent with the phase diagram calculated using the phase field model.

[1]Supported by NSF and Research Corporation for Science Advancement.

10:36AM P33.00012 Emergence of 90° Domain Walls in Multiferroic $BiFeO_3$ Thin Film , JAN-CHI YANG, YING-HAO CHU, National Chiao Tung University, CHUN-YEN PENG, HSIANG-JUNG CHEN, National Chiao Tung University, LI CHANG, QING HE, RAMAMOORTHY RAMESH, UC Berkeley, CHAO-HUI YEH, HENG-JUI LIU, SHENG-JIE LIAO, PO-WEN CHIU, CHIH-HUNG LAI, National Tsing Hua University — Multiferroics have been a fascinating area for condensed materials research since these materials offer the exciting potential applications that taking advantages of multiple orders. Multiferroic $BiFeO_3$ (BFO) has played a key role in rejuvenating the field after a report of large ferroelectric polarization. Inside this material, domain walls (DWs) of BFO are of great interests. In recent study, room-temperature conductivity at ferroelectric DWs has been observed. In this work, through epitaxial strain, BFO thin films are grown on $NdScO_3$, which provide tensile strain on BFO films, and thus results in orthorhombic-like phase and corresponding periodic 90° DWs. X-ray reciprocal mapping and piezoresponse force microscopy has confirmed the orthorhombic-like and 90° DW structure. The transport behaviors of these natural formed 90° DWs as a function of temperatures and magnetic fields have been probed to understand their fundamental properties. In addition, exchange bias studies and X-ray magnetic dichroism spectromicroscopy have further revealed the magnetic properties in these DWs. Our results show that 90° DW in orthorhombic-like BFO possesses unusual electronic and magnetic behaviors, which are different from that in bulk and might be used for modern electronic devices and nanoelectronic.

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P34 DMP: Focus Session: Interfaces in Complex Oxides - Transport and Optics C141

8:00AM P34.00001 Electrodynamics and electronic structure of LVO/SVO superlattices investigated by optical spectroscopy , DA WOON JEONG, Seoul National Univ., Korea, WOO SEOK CHOI, TAE DONG KANG, Seoul National Univ, DAVID ADRIAN, CNRS, France, YUN SANG LEE, Soongsil Univ., Korea, WILFRID PRELLIER, CNRS, TAE WON NOH, Seoul National Univ — Perovskite vanadium oxide has intriguing coupling between orbital, spin and lattice degrees of freedom that bears novel physical properties. For example, filling controlled insulator to metal transition could be observed in $(La_{1-x}Sr_x)VO_3$, and orbital ordering was predicted theoretically for the interface valence state ($V^{3.5+}$) between $LaVO_3$ and $SrVO_3$ [1]. Here, we investigated the charge dynamics and electronic structures of $(LaVO_3)_{6m}(SrVO_3)_m$ (m=1,2, and 4) superlattices using optical spectroscopy. We found a reduction of Drude spectral weight as the superlattice periodicity is decreased, consistent with the transport result [2]. Moreover, interband transition of $(LaVO_3)_6(SrVO_3)_1$ was quite different from other larger period superlattices. New peak structure at 3.5eV was developed possibly due to the correlation between the electronic structure and orbital confinement. Electrodynamics and electronic structure reconstruction will be discussed.

[1] G. Jackeli *et al.*, PRL, **101**, 216804 (2008)
[2] W. C. Sheets *et al.*, APL **91**, 192102 (2007)

8:12AM P34.00002 Geometrically confined doping in $LaVO_3/SrVO_3$ superlattices , U. LUEDERS, A. DAVID, PH. BOULLAY, R. FRÉSARD, W. PRELLIER, P.-E. JANOLIN, CRISMAT TEAM[1], SPMS TEAM[2] — A number of theoretical predictions show that in complex oxides the confinement of t_{2g} electrons to two dimensions can alter strongly the physical properties of these systems compared to their 3D counterpart. To approach experimentally the 2D limit we propose geometrically confined doped superlattices as $LaVO_3/SrVO_3$. Here, a one unit cell thick layer of $SrVO_3$ is introduced between insulating $LaVO_3$ layers to create conducting zones with a 2D character. We synthesized this kind of superlattices by PLD on $SrTiO_3$ (001) substrates. The 2D character of the doped charge carriers influences strongly the physical properties of the superlattices. While the bulk solid solution is an insulating antiferromagnet, in the superlattices, room-temperature magnetism is observed due to the reduction of the bandwidth and a transition from a high temperature weakly localized phase to a low temperature metallic phase is shown to be connected to a structural transition from a metrically tetragonal to monoclinic phase. With the help of theoretical calculations, we will show that these peculiar properties are due to a change of the orbital physics in the vicinity of the $SrVO_3$ doping layers.

[2]UMR CNRS- Ecole Centrale, Châtenay-Malabry, France

8:24AM P34.00003 Theory of $LaVO_3/SrVO_3$ superlattices[1] , HUNG DANG, ANDREW MILLIS, Department of Physics, Columbia University, New York, NY 10027 — We present dynamical mean field theory calculation and compare to experimental data [1] of the magnetic, orbital order and metal-insulator phase diagrams of $LaVO_3/SrVO_3$ superlattices. The calculation is based on a three-orbital model system; semiclassical and quantum Monte Carlo impurity solvers are used.

8:36AM P34.00004 New Optical Absorption Bands in Atomic Layer Superlattices[1] , JAMES ECKSTEIN, Depertment of Physics, University of Illinois, Urbana, IL — Using atomic layer-by-layer molecular beam epitaxy, atomic layer superlattices can be constructed that exhibit new electronic, optical and lattice effects not present in the individual components. In particular, new optical transitions giving rise to sharp absorption peaks can be created by placing a layer of a material with occupied source states next to a layer of another material with unoccupied destination states. We combine atomic layers of $SrTiO_3$ and $LaMnO_3$ into superlattice structures with component layers as thin as single monolayer and find a new absorption band due to a transition from manganese- to titanium-derived states. The energy of the new transition depends on how the bands line up at the interface. Furthermore, a substantial shift of spectral weight occurs as well, while retaining a constant sum rule. This work was supported by the Department of Energy Basic Energy Sciences at the Fredrick Seitz Materials Research Laboratory, University of Illinois, Urbana. This work was done in collaboration with Xiaofang Zhai, Mao Zheng, Amish Shah, Chandra Mohapatra, and Jian-Min Zuo.

9:12AM P34.00005 Colossal Magnetoresistance in thin films of the Mott metal $CaVO_3$[1] , JIWEI LU, University of Virginia — Bulk $CaVO_3$ (CVO) is a Pauli paramagnetic metal with a singe 3d electron. Some unusual drastic changes in the magneto-resistance, magnetic susceptibility and the Hall effect have been reported in single crystal CVO. We have simultaneously synthesized epitaxial CVO films grown on three differently oriented $SrTiO_3$ substrates. The temperature dependent conductivity of these CVO films demonstrated very strong Fermi metal behavior and the resistance ratio, defined as R(300 K)/R (2K) was more than 3000. Colossal magneto-resistance (MR) as well as large crystalline anisotropic was observed at low temperatures. The maximum MR, defined as (R(7 T)-R(0 T))/R(0 T)*100 %, was over 1500 % at 2 K and 7 Telsa on the CVO films deposited on a (110) SrTiO3 single crystal substrate, and didn't show any sign of saturation. An MR of over $\sim$ 500 % and $\sim$ 200 % were observed on (111) and (100) orientation films under the same condition, respectively. The MR ratio was much larger than that of single crystal CVO. We will discuss the peculiar MR in association with the magnetic ordering, oxygen stoichiometry and Fermi surface.

[1]The author is grateful to the financial support by the ARO.

9:24AM P34.00006 High frequency conductivity of few unit cell thick $LaNiO_3$ layers[1] , DANIEL OUELLETTE, Department of Physics, University of CA, Santa Barbara, JUNWOO SON, SUSANNE STEMMER, Materials Department, University of CA, Santa Barbara, S. JAMES ALLEN, Department of Physics, University of CA, Santa Barbara — We have measured the dc and optical conductivity of ultra-thin films of the correlated metal $LaNiO_3$ and of superlattices with alternating $LaNiO_3$ and insulating $SrTiO_3$ layers, all grown epitaxially on LSAT substrates with modest tensile strain in the $LaNiO_3$. In the superlattices, the $LaNiO_3$ layers are 4 unit cells (1.6 nm) thick and the $SrTiO_3$ is either 4 or 10 unit cells thick. Isolated films thinner than 4 nm are insulating; however, both the superlattices and thicker films consistently show a coherent peak in the optical conductivity. Furthermore, the optical conductivity at several hundred GHz is in excellent agreement with the dc electrical conductivity. We consider the possibility of a percolation threshold in ultra-thin LaNiO3 layers and discuss implications for the nature of the $LaNiO_3/SrTiO_3$ interface.

9:36AM P34.00007 Quasi 2D correlated metals: Unusual transport properties in strained heteroepitaxial ultrathin films[1] , E.J. MOON, B.A. GRAY, J. LIU, M. KAREEV, Phys. Dep., Univ. of Arkansas, Fayetteville, B. DABROWSKI, Phys. Dep., Northern Illinois Univ., J.W. FREELAND, APS, Argonne National Lab., I-C. TUNG, M.J. BEDZYK, Mat. Sci. Eng., Northwestern Univ., L.H. TJENG, Max Planck Inst. for Chem. Phys. of Solids, Germany, S.G. ALTENDORF, F. STRIGARI, Physikalisches Inst., Univ. zu Köln, Germany, V.P. KUNETS, G.J. SALAMO, J. CHAKHALIAN, Phys. Dep., Univ. of Arkansas, Fayetteville — We explore the electrical transport and magnetoconductance in quasi 2D strongly correlated heteroepitaxial films of $LaNiO_3$ to investigate the effect of quantum confinement and strain on electron-electron and electron-lattice interactions over the whole temperature range (2-300K) including the effect of metal-insulator transition. The quantum corrections to the conductivity indicate that the combination of the weak localization and the electron-electron interaction in the quasi 2D limit gives rise to unusual T-dependent resistivity. Ultrathin films spanning tensile strain up to $\sim$4% are used to obtain the enhanced driving effects between the two corrections for the observed localization at low temperatures. Intrinsic transport properties of strained $LaNiO_3$ films with the characteristic multi-band structure will be discussed.

9:48AM P34.00008 Strain-modified thermopower of ultrathin $LaNiO_3$ films[1] , NARAYAN PRASAI, JOSHUA COHN, University of Miami, EUN JU MOON, JIAN LIU, MICHAEL KAREEV, BENJAMIN GRAY, JAK CHAKHALIAN, University of Arkansas, JAMES RONDINELLI, Advanced Photon Source, Argonne National Laboratory — The influence of epitaxial strain on electronic transport in the correlated metal $LaNiO_3$ is investigated through measurements of thermopower (TEP) in the temperature range $5\text{K} \leq \text{T} \leq 330\text{K}$ on a series of fully-strained, 10-unit-cell-thick films grown by pulsed-laser deposition on (100)-oriented $YAlO_3$, $LaAlO_3$, $SrTiO_3$, and $GaScO_3$ substrates. The TEP exhibits an electron-like, linear-T contribution for $T \geq 150$ K with a slope approximately independent of strain, but a magnitude that varies systematically with strain. A peak in the TEP at $T \approx 25$ K also correlates with strain and is unaffected by a 9-T magnetic field. The implications of these results for strain-modified charge-carrier diffusion and phonon drag contributions to the TEP will be discussed.

[1]Work at the Univ. Miami was supported by an award from the Research Corporation, and at Univ. Ark. by the DOD-ARO under Contract No. 0402-17291 and NSF Contract No. DMR-0747808.

10:00AM P34.00009 Strain control of the metal-insulator transition of NdNiO3 epitaxial ultrathin films , JIAN LIU, M. KAREEV, B. GRAY, University of Arkansas, P. RYAN, J.W. KIM, J.W. FREELAND, Argonne National Lab, J. CHAKHALIAN, University of Arkansas — Metal-insulator transition (MIT) is the hallmark of strongly correlated electron systems. It often couples with the multiple degrees of freedom of d electrons in complex oxides, resulting in diverse and intriguing properties. While MIT has been studied for decades, heteroepitaxy is emerging as a promising way to manipulate correlated electrons and stabilize unusual phases in nanostructures. Understanding its effect on the MIT in ultrathin structures is fundamentally and technologically critical. To this end, we have grown perfectly strained atomic layers of NdNiO3 by laser MBE on a series of substrates with large variation in lattice mismatch. The extensive measurements including electric and thermal transport, synchrotron based XRD and XAS show dramatic modifications of electronic properties with lattice mismatch. Possible microscopic mechanisms are discussed. J.C. was supported by DOD-ARO under the Contract No. 0402-17291 and NSF Contract No. DMR-0747808.

10:12AM P34.00010 Two-dimensional electron gas in $SrTiO_3$, BHARAT JALAN, Materials Department, UCSB, S. JAMES ALLEN, Department of Physics, UCSB, SUSANNE STEMMER, Materials Department, UCSB — We report on Shubnikov-de Haas (SdH) oscillations in a two-dimensional electron gas (2DEG) in delta-doped $SrTiO_3$ thin films. The existence of a 2DEG is confirmed by the angular dependence of the SdH oscillations. The observed SdH oscillation frequency corresponds to a carrier concentration of, which is only 4% of the total Hall carrier density. We show that the only electrons in one of the sub-bands confined by the delta-doping potential have sufficient mobility to exhibit quantum oscillations. Guided by the similarity of the confined d-band electron states in $SrTiO_3$ to the confined hole systems in conventional semiconductors, quantum oscillations are interpreted in terms of spin and Landau level splitting. Despite the inherent complexity of a sub-band that is derived from four d-band states near the conduction band minimum of $SrTiO_3$, we show that the quantum oscillations can be modeled quantitatively. Alternative routes to realize high mobility 2DEGs in $SrTiO_3$ will also be discussed.

10:24AM P34.00011 High Temperature Conductance Characteristics of Differently Modified $LaAlO_3/SrTiO_3$-Heterostructures , FELIX GUNKEL, SUSANNE HOFFMANN-EIFERT, FZ Juelich, PGI-7 and JARA-FIT, Juelich, Germany, JOSÉE E. KLEIBEUKER, PETER BRINKS, MARK HUIJBEN, GUUS RIJNDERS, GERTJAN KOSTER, Mesa+ Institute for Nanotechnology, University of Twente, Enschede, The Netherlands, REGINA DITTMANN, RAINER WASER, FZ Juelich, PGI-7 and JARA-FIT, Juelich, Germany — In order to understand the physical origin of the high charge carrier density at the conducting interface between $SrTiO_3$ (STO) and $LaAlO_3$ (LAO) the role of defects has to be clarified. In this study, LAO/STO-heterostructures modified in stacking sequence and growth conditions were investigated by means of high temperature conductance (HTC) measurements under changing oxygen ambience. Under measurement conditions the samples are in equilibrium with the surrounding oxygen atmosphere, which rules out the effect of mobile oxygen vacancies on the interface conductivity [Gunkel et al., APL 97(2010)]. The HTC characteristics show a significant dependency on the preparation procedure of STO and LAO close to the interface. Nevertheless, a common conduction and charge compensation mechanism can be identified. The results are discussed with respect to the defect chemistry model of perovskite oxides.

10:36AM P34.00012 Magnetotransport behavior of $LaAlO_3/SrTiO_3$ and Ar-irradiated $SrTiO_3$: implications on Rashba Spin-Orbit coupling and magnetism in quasi-2-dimensional electron gases[1] , J.H. NGAI, Y. SEGAL, F.J. WALKER, S. ISMAIL-BEIGI, K. LEHUR, C.H. AHN, Yale University, D. SU, Y. ZHU, Brookhaven National Laboratory — Quasi 2-dimensional electron gases (Q2DEG) in complex oxide heterostructures exhibit a wide range of tunable behavior that promises potentially new functionalities. In particular much interest has focused on the Q2DEG at the $LaAlO_3/SrTiO_3$ interface, where evidence for Rashba spin-orbit coupling and magnetic behavior has recently been found through magnetotransport measurements. At present it is unclear whether the spin-orbit and magnetic effects are unique to the $LaAlO_3/SrTiO_3$ interface, or if they arise from the properties of doped $SrTiO_3$. In order to shed light on this issue, we compare the magnetotransport properties of $LaAlO_3/SrTiO_3$ and Ar^+-irradiated $SrTiO_3$. Strikingly similar magnetotransport behavior is observed between $LaAlO_3/SrTiO_3$ and Ar^+-irradiated Q2DEGs. However, our analysis indicates changes in the confinement or thickness of the Q2DEG can account for the magnetotransport observed. Implications of our results on Rashba spin-orbit coupling and magnetism at the $LaAlO_3/SrTiO_3$ interface will be discussed.

[1]NSF MRSEC DMR-0520495 and DMR-1006256

10:48AM P34.00013 Can an oxygen vacancy form a Kondo center at the $LaAlO_3/SrTiO_3$ interface?[1] , MOHAMMAD SHERAFATI, BIRABAR NANDA, SASHI SATPATHY, University of Missouri — Recently a Kondo resistance minimum has been observed at the interface between $LaAlO_3$ and $SrTiO_3$[1]. It has been suggested that the effect is due to the scattering of interface electrons from magnetic centers just like in the original Kondo effect; however, the origin of such magnetic centers is not understood. In this work, we evaluate the idea of whether an oxygen vacancy in $SrTiO_3$ might produce a magnetic center. We focus on an isolated vacancy in bulk $SrTiO_3$ from density-functional calculations and provide evidence that of the two electrons released to the system by the oxygen vacancy, one becomes localized near the vacancy site, while the other forms a delocalized state. The results suggest that the localized electron could form a Kondo center resulting in a resistance minimum as observed in the experiments.

Wednesday, March 23, 2011 8:00AM - 11:00AM –
Session P35 DCMP: Topological Insulators: Magnetotransport C140

8:00AM P35.00001 Transition from n-type to p-type topological insulator thin films of Bi_2Te_3 , JIN-FENG JIA, Key Lab for Atomic, Molecular and Nanoscience, Department of Physics, Tsinghua University, Beijing 100084, P. R. China, GUANG WANG, XIE-GANG ZHU, YAO-YI LI, TONG ZHANG, JING WEN, XI CHEN, KE HE, Institute of Physics, The Chinese Academy of Sciences, Beijing 100190, P. R. China, LI-LI WANG, XU-CUN MA, YI-YANG SUN, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, Troy, New York 12180, USA, SHENG-BAI ZHANG, QI-KUN XUE — By using angle-resolved photoemission spectroscopy, we have investigated the electronic structure of the Bi_2Te_3 films on Si(111) prepared by molecular beam epitaxy. It is found that the Bi_2Te_3 films change from n-type to p-type topological insulator when the growth mode changes layer-by-layer to step-flow, for a given beam flux ratio of $Te_{2(4)}/Bi$. In situ scanning tunneling microscopy/spectroscopy (STM/STS) measurements reveal formation of different defects, i. e., Te_{Bi} and Bi_{Te} antisite defects, which are responsible for the n- and p-type conductivity transition. A mechanism for the transition is proposed based on the STM experiment and first-principles calculations. The work suggests a simple way to regulating the chemical potential and Dirac fermion density on the surface of a topological insulator without external doping.

8:12AM P35.00002 Magneto-Transport in Epitaxial Thin Film Sb_2Te_3 , E.C. GINGRICH, N.O. BIRGE, Michigan State University, G. WANG, C. UHER, University of Michigan — We report magneto-transport measurements in epitaxially grown thin films of Sb_2Te_3. Sb_2Te_3 is a topological insulator candidate expected to possess a single Dirac cone on its surface.[1] Both semiconducting and metallic samples were measured, identified by the temperature response of their resistivities. Shubnikov-deHaas (SdH) oscillations were found in measurements with fields up to 9T in metallic samples at liquid helium temperature, but have yet to be observed in semiconducting samples. Measurements will be presented along with plans for further research.

8:24AM P35.00003 Anomalous galvanomagnetism, cyclotron resonance and microwave spectroscopy of topological insulators[1] , EWELINA HANKIEWICZ, GRIGORY TKACHOV, Wuerzburg University — The surface quantum Hall state, magneto-electric phenomena and their connection to axion electrodynamics have been studied intensively for topological insulators. One of the obstacles for observing such effects comes from nonzero conductivity of the bulk. To overcome this obstacle we propose to use an external magnetic field to suppress the conductivity of the bulk carriers. The magnetic field dependence of galvanomagnetic and electromagnetic responses of the whole system shows anomalies due to broken time-reversal symmetry of the surface quantum Hall state, which can be used for its detection. In particular, we find [1] linear bulk dc magnetoresistivity and a quadratic field dependence of the Hall angle, shifted rf cyclotron resonance, nonanalytic microwave transmission coefficient and saturation of the Faraday rotation angle with increasing magnetic field or wave frequency.

8:36AM P35.00004 Experimental evidence on a diffusive metallic surface state by the magneto-resistance oscillation in the topological insulating Bi_2Te_3 , FENGQI SONG, YUYUAN QIN, ZHAOGUO LI, QIANGHUA WANG, JIANGUO WAN, GUANGHOU WANG, National Lab of Solid State Microstructures, Nanjing University, Nanjing, China, ZHE QU, High Magnetic Field Laboratory, Chinese Academy of Sciences, Hefei, China — The spin helicity seems bound to the generation of the surface state (SS) in a three-dimensional strong topological insulating system. Here we demonstrate a diffusive metallic SS by measuring the magneto-resistance oscillations in the Bi_2Te_3 nanoflakes. The products of the oscillating periods and the cross sections of the flakes result in the values of the flux quantum (h/e) and the half quantum (h/2e). The first observation of the h/2e oscillation shows the violence of the spin helicity of the SS The h/e oscillation persists during increasing the magnetic field, while the h/2e oscillation fails, indicating the diffusive origin of the SS and its weak antilocalization. The diffusive SS is found robust against the increases of the circumference till 10 micrometers and the temperatures till 64K, when the h/e oscillation disappears. The diffusive SS can be further activated by the spin-polarized scattering formed by the deposited Co islands. All the evidence agrees to recent simulations on a weak-localized SS upon the presence of strong disorder centers. This research was supported by the National Key Projects for Basic Research of China (Grant numbers: 2009CB930501, 2010CB923401).

8:48AM P35.00005 Two-dimensional surface state revealed in the quantum limit of a topological insulator[1] , R. MCDONAD, NHMFL/LANL, J. ANALYTIS, SLAC, J.-H. CHU, Standford, S. RIGGS, I. FISHER, Stanford, G. BOEBINGER, FSU/NHMFL — Topological insulators possess a metallic surface state of massless particles, known as Dirac fermions whose spin is coupled to their momentum. The realization of this in Bi2Se3 has sparked considerable interest owing both to the potential for spintronic devices and in the investigation of the fundamental nature of topologically non-trivial quantum matter. However, the conductivity of these compounds tends to be dominated by the bulk of the material owing to chemical imperfection, making the transport properties of the surface nearly impossible to measure. We have systematically reduced the number of bulk carriers in the material Bi2Se3 to the point where a magnetic field can collapse them to their lowest Landau level. Beyond this field, known as the three-dimensional (3D)'quantum limi', the signature of the 2D surface state can be seen. At still higher fields, we reach the 2D quantum limit of the surface Dirac fermions. In this limit we observe an altered phase of the oscillations, which is related to the peculiar nature of the Landau quantization of topological insulators at high field. Furthermore, we observe quantum oscillations corresponding to fractions of the Landau integers, suggesting that correlation effects can be observed in this new state of matter.

9:00AM P35.00006 The surface-state of the topological insulator Bi2Se3 revealed by cyclotron resonance , OSCAR AYALA-VALENZUELA, NHMFL, Los Alamos National Laboratory, JAMES G. ANALYTIS, JIUN-HAW CHU, SLAC, Stanford University, MOAZ-M. ALTARAWNEH, NHMFL, Los Alamos National Laboratory, IAN R. FISHER, SLAC, Stanford University, ROSS D. MCDONALD, NHMFL, Los Alamos National Laboratory — Recently, a large number of surface-sensitive probes have reported the existence of Dirac quasiparticles, similar to those reported in graphene, on the surface of single crystals of Bi2Se3 and related compounds. To date transport measurements of TIs have been dominated by the conductivity of the bulk, leading to substantial difficulties in resolving the properties of the surface. To this end, we use high magnetic field, rf- and microwave-spectroscopy to selectively couple to the surface conductivity of Bi2Se3 at high frequency. In the frequency range of a few GHz we observe a crossover from quantum oscillations indicative of a small 3D Fermi surface, to cyclotron resonance indicative of a 2D surface state. The frequency-magnetic field scaling of this resonance is inconsistent with the bulk effective mass, but more consistent with the dispersion and band filling of a Dirac-like surface state as observed by ARPES, with substantial many-body renormalization. Measurements as a function sample thickness aid in separating bulk and surface contributions and indicate that the band filling of the Dirac cone varies from cleave to cleave.

9:12AM P35.00007 Surface Hall response of 3D topological insulators , DIMITRIE CULCER, Hefei National Laboratory for Physical Sciences at the Microscale, University of Science and Technology of China, Hefei 230026, Anhui, China, SANKAR DAS SARMA, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, Maryland 20742-4111, USA — We determine the Hall conductivity due to the surface states of 3D topological insulators in the presence of a weak perpendicular magnetic field and/or magnetization. We consider electron doping and calculate all known contributions to the Hall current, including the intrinsic, skew scattering and side jump terms. Skew scattering contributes to in the Born approximation, as well as giving the usual contribution of third order in the scattering potential. We identify a side-jump scattering term together with an intrinsic side-jump term, which give contributions of a similar magnitude. The dominant term by several orders of magnitude is of the order of the conductivity quantum, and includes a topological contribution and a renormalization due to scattering. The result is independent of the Rashba spin-orbit constant, as well as of the impurity concentration. It has different signs depending on whether the principal source of scattering is charged impurities or short-range interface roughness. We expect our results to help disentangle surface transport from bulk transport in these materials [1].

9:24AM P35.00008 In Search of the Quantum Anomalous Hall Effect in Ferromagnetic Cr-Bi_2Se_3 Topological Insulator Thin Films[1] , PASCAL P.J. HAAZEN, J.-B. LALOE, Francis Bitter Magnet Lab, MIT, D. HEIMAN, Dept. of Physics, Northeastern University, P. JARILLO-HERRERO, Dept. of Physics, MIT, J.S. MOODERA, Francis Bitter Magnet Lab, MIT — A recent prediction that the topological insulator Bi_2Se_3 can become magnetically ordered upon doping with Cr or Fe opens up the possibility of observing the quantum anomalous Hall effect, in the absence of an external magnetic field [1]. We report on molecular beam epitaxy-grown Cr-Bi_2Se_3 thin-films with a Cr content of $0 \sim 10$ at.%, and their properties. Our films show highly oriented crystallinity up to a Cr content of 8%, as required for ferromagnetic ordering. Films with Cr were ferromagnetic; the measured saturation magnetic moment per Cr atom is $1\mu_B$ for the crystalline films, with a T_C of up to $\sim 25K$. Currently we are investigating the transport characteristics. Varying the electro-chemical potential level in our quantum anomalous Hall insulators by gating should give rise to plateaus of Hall conductance as the Fermi level passes through the energy gap, due to the breaking of time-reversal symmetry caused by the magnetic ions.

9:36AM P35.00009 Quantum Oscillations in a topological insulator Bi_2SeTe_2 with large bulk resistivity[1] , JUN XIONG[2], DONGXIA QU, ROBERT CAVA, N. PHUAN ONG, Princeton University — To date, transport experiments on Topological Insulators are seriously hampered by bulk conductance G_b arising from impurity bands or band bending. Because of the large G_b, the surface currents carried by the massless Dirac surface states have been very difficult to resolve. We report measurements on the new topological insulator Bi_2SeTe_2 which has an unusually highly bulk resistivity ρ (6 Ωcm at 4 K, or 1,000 times higher than in Bi2Te3). Despite the large ρ, Shubnikov-de Haas (SdH) oscillations are clearly resolved in the Hall conductance up to 38 K, which implies a very high surface mobility. In a field B of 14 T, Landau Levels (LLs) n = 4-9 are well resolved. We will describe the value of the Onsager phase γ fixed by the index plot of the LLs.

9:48AM P35.00010 Thermoelectric Properties of Non-Metallic Topological Insulator Bi_2Te_3 at High Magnetic Fields[1]

, DONG-XIA QU, YEW SAN HOR, ROBERT J. CAVA, N. PHUAN ONG, PRINCETON UNIVERSITY TEAM

— Three-dimensional topological insulators are a new class of electronic systems characterized by a bulk insulating state and conducting surface states with Dirac-like energy-momentum dispersion [1, 2]. One of the interesting aspects of this material is how the surface states affect thermoelectric properties of the whole electronic system, given that the bismuth based topological insulators are also excellent thermoelectric materials. We studied the low-temperature thermoelectric transport properties of high-mobility bulk topological insulator Bi_2Te_3 at high magnetic fields up to 35 T. We found remarkably large quantum oscillations in the thermopower of the surface states over a field range of 14 to 35 T. The existence of a non-zero Berry's phase in surface electrons is confirmed from the magneto-oscillations of both thermopower and magnetoresistance.

10:00AM P35.00011 Large thermoelectric figure of merit for three-dimensional topological Anderson insulators via line dislocation engineering[1]

, OLEG TRETIAKOV, ARTEM ABANOV, Texas A&M University, SHUICHI MURAKAMI, Tokyo Institute of Technology, JAIRO SINOVA, Texas A&M University — We study the thermoelectric properties of three-dimensional topological Anderson insulators with line dislocations. We show that at high densities of dislocations the thermoelectric figure of merit ZT can be dominated by one-dimensional topologically protected conducting states channeled through the lattice screw dislocations in the topological insulator materials with a nonzero time-reversal-invariant momentum such as $Bi_{0.9}Sb_{0.1}$. When the chemical potential does not exceed much the mobility edge the ZT at room temperatures can reach large values, much higher than unity for reasonable parameters, hence making this system a strong candidate for applications in heat management of nanodevices.

10:12AM P35.00012 Quantum Oscillations and Quantum Hall Effect in Topological Insulator Material Bi_2Se_3

, HELIN CAO, IRENEUSZ MIOTKOWSKI, TIAN SHEN, YONG CHEN, Department of Physics, Purdue University, West Lafayette, IN 47907 USA — Bi_2Se_3 has attracted strong attention recently as a prototype topological insulator material. We have measured magneto-transport in metallic Bi_2Se_3 crystals. At high magnetic field (B), the longitudinal resistance (R_{xx}) displays characteristic Shubnikov–de Haas (SdH) oscillations (periodic in 1/B). The measurements in tilted magnetic field show the SdH oscillations are only controlled by the perpendicular component of B, indicating 2D nature of charge carriers. We also observed quantized plateaus in Hall resistance (R_{xy}) concomitant with the minima in R_{xx}. From the temperature dependence of the SdH oscillations, we extract a Fermi velocity $\sim$5.9*10^5m/s, and an effective mass $\sim$0.14m_e (m_e is the electron mass). We discuss possible relations of our observations to topological surface states, as well as contributions from individual 2D quintuple layers of Bi_2Se_3.

10:24AM P35.00013 High field magnetotransport in high purity crystals of topological insulator Bi_2Se_3[1]

, NICHOLAS BUTCH, PAUL SYERS, JOHNPIERRE PAGLIONE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park — We have synthesized crystals of high purity undoped Bi_2Se_3 with carrier density less than 10^{17} cm^{-3} and high bulk mobility. Thorough characterizations of transport and optical properties in fields up to 14 T suggest a high surface scattering rate [1-3]. In a search for quantum oscillations from the surface carriers, we performed measurements of longitudinal and Hall resistance in pulsed magnetic fields of up to 60 T. Due to the as-yet poorly characterized environmental sensitivity of the Bi_2Se_3 surfaces, we performed on-site cleaving and application of leads under dry flowing nitrogen. The Hall measurements and temperature- and angle-dependence of the longitudinal magnetoresistance will be discussed.

10:36AM P35.00014 Anomalous Aharonov-Bohm Conductance Oscillations from Topological Insulator Surface States[1]

, YI ZHANG, ASHVIN VISHWANATH, University of California, Berkeley — We study Aharonov-Bohm (AB) conductance oscillations arising from the surface states of a topological insulator nanowire, when a magnetic field is applied along its length. With strong surface disorder, these oscillations are predicted to have a component with anomalous period $\Phi_0 = hc/e$, twice the conventional period. The conductance maxima are achieved at odd multiples of $\Phi_0/2$, implying that a π AB phase for electrons strengthens the metallic nature of surface states. This effect is special to topological insulators, and serves as a defining transport property. A key ingredient, the surface curvature induced Berry phase, is emphasized here. We discuss similarities and differences from recent experiments on Bi_2Se_3 nanoribbons, and optimal conditions for observing this effect.

[1]We acknowledge insightful discussions with H. Mathur, D. Carpentier, J. Moore, and G. Paulin, and DOE Grant No. DE-AC02-05CH11231 for support.

10:48AM P35.00015 First-principles calculation of the full orbital magnetoelectric response

, ANDREI MALASHEVICH, UC Berkeley, IVO SOUZA, Centro de Fisica de Materiales, San Sebastian, SINISA COH, DAVID VANDERBILT, Rutgers University — The possibility of a quantized magnetoelectric (ME) effect in Z_2 topological insulators suggests that the orbital part of the ME response can, at least in principle, be comparable in magnitude to the total response of known ME materials.[1] A band theory of the orbital ME response of generic insulators was recently developed,[2] paving the way for first-principles calculations. Two types of terms contribute to the response. The Chern-Simons term, which only depends on the unperturbed valence Bloch states, was the subject of a recent Wannier-based calculation.[1] The Kubo terms require a knowledge of the Bloch states at first order in the electric field and can be calculated by finite differences from the change in orbital magnetization induced by small electric fields.[2] We present preliminary results of such a calculation for Cr_2O_3, using the Berry-phase approach to calculate the electronic structure under a finite electrical bias. By monitoring the field-induced changes in orbital and spin magnetization and comparing the results obtained with and without structural relaxation, all contributions to the ME coupling can be computed.

Session P36 DMP: Focus Session: Graphene: Growth, Characterization, and Devices: Electronic Structure C142

8:00AM P36.00001 Electronic properties of the Graphene/SiC $(000\bar{1})$ interface: a First Principles study , THUSHARI JAYASEKERA, SHU XU, K.W. KIM, MARCO BUONGIORNO-NARDELLI, North Carolina State University — In this talk, we will discuss the electronic properties of epitaxial graphene on the SiC $(000\bar{1})$ surface (C-terminated face) using Density Functional Theory. In our calculations we focus on mono- and bi-layer graphene with AA, AB and turbostratic stacking sequences. Of the three, the turbostratic is the most observed during growth on SiC $(000\bar{1})$. However, no theoretical investigations are available to understand the effect of the substrate on this growth sequence. We will investigate the energetics of different stackings and explain their electronic properties. We will also discuss the role of the interfaces in the stabilization of the individual stacking sequences and indicate possible routes for chemical functionallizations at the heterojunction to facilitate the tuning of the electronic and transport properties of these systems.

8:12AM P36.00002 Local surface potential variations and charge puddling in graphene on SiC(0001)[1] , A.E. CURTIN, W.G. CULLEN, M.S. FUHRER, Materials Research Science and Engineering Center and Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, R.L. MYERS-WARD, L.O. NYAKITI, V.D. WHEELER, D.K. GASKILL, U.S. Naval Research Laboratory, Code 6800, Washington, DC 20375 — We performed Kelvin probe microscopy in ultra-high vacuum on epitaxial graphene grown on SiC(0001). In agreement with previous work, we see discrete surface potentials corresponding to interface layer and monolayer regions separated by steps of ∼100 mV. We used the step width to determine the spatial resolution of the probe to be approximately 20 nm. Within a monolayer area we see smaller fluctuations in surface potential of only a few mV. The data set limits on the scale of possible electron/hole puddles in monolayer graphene on SiC(0001).

[1]This work was supported by the University of Maryland MRSEC.

8:24AM P36.00003 Electric Field Effects on Electronic Structures of Epitaxial Graphene on SiC , HYUNGJUN LEE, Department of Physics and IPAP, Yonsei University, SEUNGCHUL KIM, JISOON IHM, Department of Physics and Astronomy, Seoul National University, YOUNG-WOO SON, Korea Institute for Advanced Study, HYOUNG JOON CHOI, Department of Physics and IPAP, Yonsei University — We report first-principles calculations of atomic and electronic structures of epitaxial single-layer graphene on Si-faced SiC(0001) surface under homogeneous transverse electric fields. We find that atomic positions are insensitive to applied electric fields, but the electronic band structures of the graphene layer are shifted in energy, depending strongly on the applied electric fields, while those of the buffer layer are almost unchanged. This effect finally results in field-induced closing of the energy gap at the Dirac energy point and recovery of the conic feature of the low-energy band structures of free-standing graphene, which are verified and analyzed further with a tight-binding model. The recovery of conical dispersion of the single-layer graphene and ambipolar field-effect behavior makes epitaxial single-layer graphene one of the promising alternatives to current state-of-the-art transistors for radiofrequency applications. This work was supported by the NRF of Korea (Grant No. 2009-0081204). Computational resources have been provided by KISTI Supercomputing Center (KSC-2008-S02-0004).

8:36AM P36.00004 Plasmarons in Quasi-freestanding Epitaxial Graphene , AARON BOSTWICK, Lawrence Berkeley National Laboratory — Graphene is a remarkable new electronic material with many unique properties. To realize its promise, it is essential to understand how its charge carriers interact. By measuring the spectral function of charge carriers in quasi-free-standing graphene, we show that at finite doping, the well-known linear Dirac spectrum does not provide a full description of the charge-carrying excitations. We find that there also exist composite "plasmaron" particles, consisting of holes coupled to density oscillatons of the graphene electron gas. The Dirac crossing point is resolved into three crossings: the first between pure charge bands, the second between pure plasmaron bands, and the third a ring-shaped crossing between charge and plasmaron bands.

9:12AM P36.00005 Effective screening and the plasmaron bands in Graphene , A. WALTER, FHI, Max-Planck-Gesellschaft and ALS, E. O. Lawrence Berkeley Laboratory, K.J. JEON, EETD, E. O. Lawrence Berkeley Laboratory, A. BOSTWICK, ALS, E. O. Lawrence Berkeley Laboratory, L. MORESCHINI, Y.S. KIM, ALS, E. O. Lawrence Berkeley Laboratory, Y.J. CHANG, FHI, Max-Planck-Gesellschaft and ALS, E. O. Lawrence Berkeley Laboratory, F. SPECK, M. OSTLER, T. SEYLLAR, U Erlangen-Nürnberg, K. HORN, FHI, Max-Planck-Gesellschaft, E. ROTENBERG, ALS, E. O. Lawrence Berkeley Laboratory — In the following we investigate the plasmaron bands in the presence of differing effective screening, by changing the interface layer between graphene and a SiC substrate. ARPES data is presented and the deviation of the band structure from the Dirac cone picture is attributed to electron, hole, plasmon interactions. Comparison to G_0W -RPA theory is used to determine the effective dielectric constant of the underlying layer and a range of values (ε_S ∼219 to ∼11.6) is found. This investigation indicates that, in addition to the long list of unique and interesting properties, graphene is an ideal candidate for investigating the effective screening in the context of electron-hole-plasmon interactions. It is also shown that plasmaronic and electronic properties of graphene can be manipulated semi-independently, a necessity if it is to be employed in future "plasmaronic" devices.

9:24AM P36.00006 Phonon-Induced Gaps in Graphite and Graphene Observed by Angle-Resolved Photoemission , YANG LIU, University of Illinois, Urbana-Champaign, LONGXIANG ZHANG, MATTHEW BRINKLEY, GUANG BIAN, TOM MILLER, TAI-CHANG CHIANG, UNIVERSITY OF ILLINOIS, URBANA-CHAMPAIGN TEAM — Graphene systems, made of sheets of carbon atomic layers, have unusual electronic structures known as Dirac cones. While strong interest in the electronic structure of these graphitic materials has driven extensive ARPES studies, prior work has mostly focused on the quasiparticle band dispersion relations associated with the Dirac cones. Largely unexplored are spectral regions far away from the quasiparticle bands, where direct emission from the quasiparticles is forbidden, but indirect emission through coupling to phonons is allowed. Our ARPES measurements of graphite and graphene layers at low temperatures reveal heretofore unreported gaps at normal emission, one at around 67 meV and another much weaker one at around 150 meV. The major gap features persist to room temperature and beyond, and diminish for increasing emission angles. We show that these gaps arise from electronic coupling to out-of-plane and in-plane vibrational modes at the K point in the surface Brillouin zone, respectively, in accordance with conservation laws and selection rules governed by quantum mechanics. Our study suggests a new approach for characterizing phonons and electron-phonon coupling in solids.

9:36AM P36.00007 Many-Body Interactions in Quasi-Freestanding Graphene , DAVID SIEGEL, University of California, Berkeley / Lawrence Berkeley National Lab, CHEOL-HWAN PARK, University of California, Berkeley, CHOONGYU HWANG, Lawrence Berkeley National Laboratory, JACK DESLIPPE, University of California, Berkeley / Lawrence Berkeley National Lab, ALEXEI FEDOROV, Advanced Light Source, Lawrence Berkeley National Laboratory, STEVEN LOUIE, ALESSANDRA LANZARA, University of California, Berkeley / Lawrence Berkeley National Lab — The Landau-Fermi liquid picture for quasiparticles assumes that charge carriers are dressed by many-body interactions, forming the basis of any theory of solids. Whether this picture still holds for a semimetal like graphene at the neutrality point, i.e. when the chemical potential coincides with the Dirac point energy, is one of the long-standing puzzles in this field. Here we present the first direct measurements of the self-energy in graphene near the neutrality point, by using high-resolution angle-resolved photoemission spectroscopy. These exciting findings set a new benchmark in our understanding of many-body physics in graphene and a variety of novel materials with Dirac fermions.

9:48AM P36.00008 Abnormal temperature-dependent self-energy in graphene , CHOONGYU HWANG, LBNL, DANIEL GARCIA, DAVID SIEGEL, PU YU, SWANEE SHIN, UC Berkeley, LBNL, XIAOZHU YU, LBNL, ALEXEI FEDOROV, ALS, LBNL, EUGENE HALLER, RAMAMOORTHY RAMESH, DUNG-HAI LEE, ALESSANDRA LANZARA, UC Berkeley, LBNL — Dynamics of charge carriers are determined by their self-energy associated with many-body interactions. By using angle-resolved photoemission spectroscopy, we study the origin of abnormal temperature-dependent self-energy in graphene, and discuss the results in terms of a quantum phase transition as a function of temperature. Our findings provide another example of novel electronic properties of graphene and deeper understanding of the ground state of charge carriers in graphene.

10:00AM P36.00009 Graphene/substrate charge transfer characterized by inverse photoelectron spectroscopy , LINGMEI KONG, Department of Physics, University of Nebraska-Lincoln, Lincoln, NE USA, CAMERON BJELKEVIG, SNEHA GADDAM, MI ZHOU, Department of Chemistry, University of North Texas, Denton, TX USA, YOUNGHEE LEE, GANGHEE HAN, Department of Physics, Department of Energy Science, Sungkyunkwan University, Suwon, Korea, HAEKYUNG JEONG, Department of Physics, Daegu University, Gyeongsan, Korea, NING WU, ZHENGZHENG ZHANG, JIE XIAO, PETER DOWBEN, Department of Physics, University of Nebraska-Lincoln, Lincoln, NE USA, JEFFRY KELBER, Department of Chemistry, University of North Texas, Denton, TX USA — Wave vector-resolved inverse photoelectron spectroscopy (IPES) measurements demonstrate that there is a large variation of interfacial charge transfer between graphene and various substrates. IPES measurements of CVD single layer graphene on BN(0001)/Ru(0001), Ru, Ni(poly), and Cu(poly) indicate a substrate-to-graphene charge transfer of approximately 0.07, 0.06, 0.03 e- per carbon atom respectively and a charge transfer of 0.02 e- from graphene to the MgO substrate per carbon atom. IPES and photoemission data also indicate that graphene/MgO(111) has a band gap. These data demonstrate that IPES is an effective method for precise measurement of substrate/graphene charge transfer due to the extreme surface sensitivity of IPES.

10:12AM P36.00010 Characterization of Image States in Graphene on Ir(111)[1] , JERRY I DADAP, Columbia University, New York, MARKO KRALJ, MARIN PETROVIC, Institut za fiziku, Zagreb, Croatia, KEVIN KNOX, NADER ZAKI, ROHAN BHANDARI, PO-CHUN YEH, RICHARD M. OSGOOD JR., Columbia University, New York — Two dimensional electron systems involving graphene and graphene/metallic interfaces are increasingly of interest in condensed matter physics. Here, we demonstrate two-photon photoemission to map the image states of highly perfect and weakly bonded graphene on an Ir(111) substrate to reveal the effects of interaction with the underlying metal substrate. We observe a monotonic decrease in the work function with increasing graphene coverage from 5.6±0.1 eV for clean Ir to 4.5±0.1 eV for full graphene ML. We observe n=1, 2, 3 image states with nearly free electron dispersion. Despite the minimal coupling between the graphene and Ir, the energy spacing of the image states is consistent with a single Rydberg series description, in contrast to the expected bifurcation of the image states into odd and even states for a pure graphene layer. At large $k_{||}$, we observe a weak state deviating from the n=1 dipersion. We explain this effect in terms of scattering from the Ir substrate.

10:24AM P36.00011 Electronic and chemical properties of epitaxial graphene intercalated with $FeCl_3$, KRISTIN SHEPPERD, FENG WANG, JEREMY HICKS, HOLLY TINKEY, EDWARD CONRAD, Georgia Institute of Technology — Epitaxial graphene has emerged as the platform for large-scale graphene-based electronics. To fully exploit the unique properties of graphene for electronic materials, a number of materials issues need to be resolved. One important challenge is being able to control the doping of graphene without altering its band structure and disrupting the sp2 graphene bonding. One approach to accomplish this is intercalation of atomic or molecular species between individual graphene layers. We report the intercalation of multilayers of epitaxial graphene (EG) with the electron-acceptor $FeCl_3$. We will present results on experiments focused on the intercalation of $FeCl_3$ into multilayers EG grown on the C-face of SiC(000-1). Intercalation with different staging was achieved by a standard two-zone vapor transport method. The chemical and electronic properties of the EG-$FeCl_3$ intercalation compounds were analyzed using Raman spectroscopy, X-ray photoelectron spectroscopy (XPS) and low energy electron diffraction (LEED).

10:36AM P36.00012 Accessing high energy sub-bands in bilayer graphene - a transport study , DMITRI K. EFETOV, PATRICK MAHER, SIMAS GLINSKIS, PHILIP KIM, Columbia University — In contrast to single layer graphene sheets with its two distinct valence and conduction bands merging at the Dirac Point, multilayer graphene sheets are known to have additional sub-bands at higher energies. Whereas the low energy sub-bands in these systems are well studied, the higher energy sub-bands could so far not be accessed in a transport measurement of graphene samples sitting on typical SiO_2/Si back gates. Employing a poly(ethylene)oxide-$CsClO_4$ solid polymer electrolyte gate we demonstrate the filling up of the high energy sub-bands in bilayer graphene samples at carrier densities above $\sim$ 2.7x10^{13} cm^{-2} . The onset of these sub-bands is defined by a slight increase of the resistivity and the onset of Shubnikov de Haas (SdH) oscillations. Measurements of the magneto-resistance, the SdH oscillations and the Hall Effect enable us to deduce the carrier densities and mobilities for both, the high and low energy bands simultaneously. In addition, we find that the onset energy of these sub-bands can be tuned by varying the bilayer interlayer asymmetry.

10:48AM P36.00013 Magnetic-field induced Electron-K-Phonon Interaction in the optical response of multi-layer epitaxial graphene , GERARD MARTINEZ, MILAN ORLITA, MAREK POTEMSKI, Laboratoire National des Champs Magetiques Intenses, CNRS, MIKE SPRINKLE, CLAIRE BERGER, WALTER DE HEER, School of Physics,Georgia Institute of Technology, Atlanta, LIANG TAN, STEVEN LOUIE, Department of Physics, University of California at Berkeley — Absolute magneto-optical transmission measurements have been performed in the far-infra-red range under magnetic fields up to 32 T and at a temperature of 1.8 K on a series of multi-layer epitaxial graphene samples. In all samples, transmission data show for the main optical transition involving the n=0 landau level a clear splitting of the transition in the field range 17-18 T corresponding to an energy of about 150 meV which coincides with that of the K zone boundary phonon of graphene. A global analysis of the data using a multi-dielectric model, to fit them with a single transition, reveals in that range of energies an additional increase of the line-width accompanied by a softening of the transition energy. The energy variation of these quantities is characteristic of the emission of phonons. Possible origins of this effect will be discussed but seems to be the consequence of electron-electron interactions between the two valleys K and K' assisted by K-phonons between these two valleys.

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P37 DMP: Focus Session: Graphene Structure, Dopants, and Defects: Strain Engineering II C146

8:00AM P37.00001 Beller Lectureship Talk: Gauge fields in graphene , FRANCISCO GUINEA, CSIC - Madrid — Graphene is a unique material with many special features not found in other systems. Elastic strains, and also topological defects, act on the charge carriers in the same way as effective gauge fields. The emergence of these fields, their dependence on sample parameters, and their relevance to experiments will be reviewed.

8:36AM P37.00002 Limits on electron quality in suspended graphene due to flexural phonons , EDUARDO V. CASTRO, H. OCHOA, Instituto de Ciencia de Materiales de Madrid (CSIC), Spain, M.I. KATSNELSON, Radboud University Nijmegen, Institute for Molecules and Materials, The Netherlands, R.V. GORBACHEV, D.C. ELIAS, K.S. NOVOSELOV, A.K. GEIM, School of Physics & Astronomy and Manchester Centre for Mesoscience & Nanotechnology, University of Manchester, UK, F. GUINEA, Instituto de Ciencia de Materiales de Madrid (CSIC), Spain — The temperature dependence of the mobility in suspended graphene samples has been investigated. In clean samples, flexural phonons become the leading scattering mechanism at temperature $T > 10$ K, and the resistivity increases quadratically with T. Flexural phonons limit the intrinsic mobility down to a few m^2/Vs at room T, a value that is routinely achievable for graphene on a substrate. Their effect can be eliminated by applying strain. Similar qualitative behavior, even though with important quantitative differences, has been found for suspended bilayer graphene.

8:48AM P37.00003 Topological defect clustering and plastic deformation mechanisms in functionalized graphene[1] , RICARDO NUNES, JOICE ARAUJO, HELIO CHACHAM, UFMG-Brazil — We present ab initio results suggesting that strain plays a central role in the clustering of topological defects in strained and functionalized graphene models. We apply strain onto the topological-defect graphene networks from our previous work [1], and obtain topological-defect clustering patterns which are in excellent agreement with recent observations in samples of reduced graphene oxide [2]. In our models, the graphene layer, containing an initial concentration of isolated topological defects, is covered by hydrogen or hydroxyl groups. Our results also suggest a rich variety of plastic deformation mechanism in functionalized graphene systems.

9:00AM P37.00004 Electronic states of graphene grain boundaries , ANDREJ MESAROS, Instituut-Lorentz, Universiteit Leiden, P.O. Box 9506, 2300 RA Leiden, The Netherlands, STEFANOS PAPANIKOLAOU, LASSP, Physics Department, Clark Hall, Cornell University, Ithaca, NY 14853-2501, C.F.J. FLIPSE, Department of Applied Physics, Eindhoven University of Technology, 5600 MB Eindhoven, The Netherlands, DARIUS SADRI, JAN ZAANEN, Instituut-Lorentz, Universiteit Leiden, P.O. Box 9506, 2300 RA Leiden, The Netherlands — Recent scanning tunneling spectroscopy measurements on graphite grain boundaries have identified zero energy peaks in the local density of states. These features are tied to intriguing magnetic properties observed in such samples, but are not found in existing theoretical models. We therefore study amorphous grain boundaries in graphene, and find stable structures along the boundary, responsible for local density of states enhancements both at zero and finite energies. We also consider the low energy continuum theory of arrays of dislocations forming a grain boundary in graphene. It predicts the appearance of localized zero energy states, pending the atomic scale dislocation core structure. We discuss possible stable dislocation core structures that actually carry such states.

9:12AM P37.00005 Spectromicroscopy measurements of surface morphology and band structure of exfoliated graphene , KEVIN KNOX, ANDREA LOCATELLI, Elettra Synchrotron, Trieste, Italy, DEAN CVETKO, University of Ljubljana, TEVFIK MENTES, MIGUEL NINO, Elettra Synchrotron, Trieste, Italy, SHANCAI WANG, Renmin University of China, MEHMET YILMAZ, Fatih University, Istanbul, Turkey, PHILIP KIM, RICHARD OSGOOD, Columbia University, ALBERTO MORGANTE, TASC National Laboratory, Trieste, Italy — Monolayer-thick crystals, such as graphene, are an area of intense interest in condensed matter research. However, crystal deformations in these 2D systems are known to adversely affect conductivity and increase local chemical reactivity. Additionally, surface roughness in graphene complicates band-mapping and limits resolution in techniques such as angle resolved photoemission spectroscopy (ARPES), the theory of which was developed for atomically flat surfaces. Thus, an understanding of the surface morphology of graphene is essential to making high quality devices and important for interpreting ARPES results. In this talk, we will describe a non-invasive approach to examining the corrugation in exfoliated graphene using a combination of low energy electron microscopy (LEEM) and micro-spot low energy electron diffraction (LEED). We will also describe how such knowledge of surface roughness can be used in the analysis of ARPES data to improve resolution and extract useful information about the band-structure.

9:24AM P37.00006 Snap-through instability of graphene on corrugated substrates , CESAR CHIALVO, SCOTT SCHARFENBERG, NIKHITA MANSUKHANI, RICHARD WEAVER, NADYA MASON, University of Illinois at Urbana Champaign — We discuss atomic force microscopy measurements of the interplay between interfacial bonding energy and strain energy in few-layer-graphene (FLG) placed on micro-scale corrugated metallic substrates. For fixed corrugation amplitude and wavelength, the theoretical strain energy of conformed FLG scales with the third power of its thickness. We present evidence of a so-called "snap-through instability," where the behavior of the FLG abruptly changes, as a function of thickness, from fully conformed, to completely detached. The large FLG thickness, and by implication strain energy, at the snap-through point implies that the FLG-substrate bonding is larger than expected for van der Waals forces.

9:36AM P37.00007 A Quantitative Characterization of Thermally Excited Ripples in Graphene , DONALD PRIOUR, JR, University of Missouri, Kansas City — In the framework of an atomistic model, we calculate the amplitude and typical wavelength of undulations in graphene sheets with length scales similar to those encountered in experiment. As part of a quantitative treatment, bond bending and stiffness constants are fixed by appealing to phonon frequency dispersion curves measured experimentally and from *ab initio* electronic structure calculations. Equilibrium thermodynamic quantities, such as mean square atomic deviations and the average length scale (i.e. the typical "wavelength") of graphene ripples, are calculated in the context of statistical mechanical Monte Carlo simulations. Thermally induced rippling is examined for suspended graphene, as well as graphene in the presence of a substrate, where the attractive coupling of atomic species to the substrate layer is modeled with a Lennard-Jones potential. The contribution of quenched substrate disorder to undulations in the graphene sheet relative to the component of graphene ripples due purely to thermal fluctuations is studied by examining graphene sheets bound to substrates with various levels of intrinsic positional disorder.

9:48AM P37.00008 Wrinkling of graphene membranes supported by silica nanoparticles on substrates[1] , MAHITO YAMAMOTO, WILLIAM CULLEN, MICHAEL FUHRER, THEODORE EINSTEIN, Materials Research Science and Engineering Center and Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, DEPARTMENT OF PHYSICS, UNIVERSITY OF MARYLAND TEAM — The challenging endeavor of modulating the morphology of graphene via a patterned substrate to produce a controlled deformation has great potential importance for strain engineering the electronic properties of graphene. An essential step in this direction is to understand the response of graphene to substrate features of known geometry. Here we employ silica nanoparticles with a diameter of 10-100 nm to uniformly decorate SiO_2 and mica substrates before depositing graphene, to promote nanoscale modulation of graphene geometry. The morphology of graphene on this modified substrate is then characterized by atomic force spectroscopy. We find that graphene on the substrate is locally raised by the supporting nanoparticles, and wrinkling propagates radially from the protrusions to form a ridge network which links the protrusions. We discuss the dependence of the wrinkled morphology on nanoparticle diameter and graphene thickness in terms of graphene elasticity and adhesion energy.

[1]Supported by NSF-MRSEC, Grant DMR 05-20471

10:00AM P37.00009 Magnetoresistance of Metal-Shunted Graphene Devices , PAUL CAMPBELL, ADAM FRIEDMAN, F. KEITH PERKINS, JEREMY ROBINSON, US Naval Research Laboratory — Graphene, a single atomic layer of hexagonally arranged carbon atoms, presents the optimal platform to study magnetoresistance (MR) effects because of its temperature-independent mobility and linear band structure with zero band gap. Extraordinary magnetoresistance (EMR) can be realized in metal-shunted graphene devices. Here, due to the different magnetic-field-dependent resistances of the metallic shunt, graphene, and shunt-graphene interface, current flows easily through the shunt in zero and low magnetic field, while in high magnetic field, more current flows around the shunt and is redistributed in the graphene. Devices made from chemical vapor deposition (CVD) graphene grown on copper and transferred to a SiO_2/Si substrate with Ti/Au shunts display gate-tunable longitudinal MR of $\sim$600% at 12 T and also show promise for use as Hall sensors. Graphene magnetoresistance devices have many possible applications including magnetic field sensors and magnetic read-heads. In contrast with the many proposed electronic uses for graphene, which necessitate the creation of a band-gap, graphene magnetoresistance devices that exploit LMR or EMR provide a use for as-grown or deposited graphene.

10:12AM P37.00010 A Graphene-Based Biosensor , AMAL KASRY, Visiting Scientist at IBM T. J. Watson Research Center, ALI AFZALI, GEORGE TULEVSKI, Research Staff Member, BERNHARD MENGES, Project Leader, SATOSHI OIDA, Postdoc, MATTHEW COPEL, LIBOR VYKLICKY, Research Staff Member, EGYPT NANOTECHNOLOGY CENTER COLLABORATION, IBM RESEARCH COLLABORATION, MAX PLANCK INSTITUTE FOR POLYMER RESEARCH COLLABORATION — Graphene, a single layer of carbon atoms, has attracted significant interest in several applications including biosensors. In this work graphene was grown by the CVD method. Optical parameters of graphene such as refractive index and extinction coefficient were measure by a mix of techniques including ellipsometer, XPS, Raman Spectroscopy, SPR and MEIS. Determining the optical properties of graphene allowed for study of its ability to sense biomolecular interactions. We also examined graphene modification by electrostatic interaction utilizing a molecule synthesized by IBM Research. Successful modification was proven by XPS, Raman Spectroscopy, and SPR. Studies of the chemical modification, along measurement of electrical and optical properties of graphene are components of our work to develop highly sensitive graphene-based sensors.

10:24AM P37.00011 ABSTRACT WITHDRAWN –

10:36AM P37.00012 Graphene-Silicon Schottky Diodes , CHUN CHUNG CHEN, MEHMET AYKOL, CHIA-CHI CHANG, A.F.J. LEVI, STEPHEN B. CRONIN, University of Southern California — By depositing mechanically exfoliated graphene on top of silicon substrates, the graphene-silicon Schottky barriers are observed. The resulting current-voltage characteristics exhibit rectifying diode behavior with a barrier energy of 0.41 eV on n-type silicon and 0.45 eV on p-type silicon at room temperature. The ideality factor is also evaluated for bilayer, three layer, and multiple layer graphene-silicon Schottky diodes at various temperatures. These results indicate that the number of graphene layers and the ambient temperature are major influences for the ideality factor of graphene-silicon Schottky diodes. In this work, photocurrents are observed under 532 nm laser illumination. The transparency of the thin graphene layer allows the underlying silicon substrate to absorb the laser light and generate a photocurrent. The full current-voltage characteristics under illumination are also reported. Spatially resolved photocurrent measurements also reveal the importance of inhomogeneity and series resistance in these devices.

10:48AM P37.00013 Conductance-Based Temperature Programmed Desorption with Single Defect Resolution , DENG PAN, PATRICK C. SIMS, BRAD L. CORSO, PHILIP G. COLLINS, Department of Physics and Astronomy, Univ. of California at Irvine, Irvine, CA 92697-4576 — The controlled functionalization of nanotubes and graphene requires methods of chemically attacking these inert surfaces and of removing unwanted oxidation damage. The appeal of reversible chemistries is rarely achieved: the degraded electrical properties of reduced graphene oxide compared to pristine graphene indicates residual damage that remains poorly understood. Using a high temperature, UHV apparatus to perform electrical measurements in situ, we investigate the thermal desorption of adducts that can restore conductivity in oxidized nanographites. The majority of our measurements are accomplished using SWCNTs, due to their enhanced sensitivity to even single point defects. Discrete conductance jumps accompanying the removal of different types of adducts provide a characterization method that directly distinguishes the relative electronic effects of phenolic, epoxide, and carboxylic defects. The electronic measurements complement more traditional, temperature programmed desorption from bulk material, which is insensitive to electronic disorder.

Wednesday, March 23, 2011 8:00AM - 10:48AM –

Session P38 DCP DBP: Focus Session: Quantum Coherence in Biology III A130/131

8:00AM P38.00001 Barrier compression and tunneling in enzyme catalysed reactions , NIGEL SCRUTTON, University of Manchester — Nuclear quantum mechanical tunneling is important in enzyme-catalysed H-transfer reactions. This viewpoint has arisen after a number of experimental studies have described enzymatic reactions with kinetic isotope effects that are significantly larger than the semi-classical limit. Other experimental evidence for tunneling, and the potential role of promoting vibrations that transiently compress the reaction barrier, is more indirect, being derived from the interpretation of e.g. mutational analyses of enzyme systems and temperature perturbation studies of reaction rates/kinetic isotope effects. Computational simulations have, in some cases, determined exalted kinetic isotope effects and tunneling contributions, and identified putative promoting vibrations. In this presentation, we present the available evidence – both experimental and computational – for environmentally-coupled H-tunneling in several enzyme systems, from our recent work on redox enzyme systems. We then consider the relative importance of tunneling contributions to these reactions. We find that the tunneling contribution to these reactions confers a rate enhancement of approx. 1000-fold. Without tunneling, a 1000-fold reduction in activity would seriously impair cellular metabolism. We infer that tunneling is crucial to host organism viability thereby emphasising the general importance of tunneling in biology.

8:36AM P38.00002 The control of electron transfer pathways in biomolecular systems: the role of fluctuations , SPIROS SKOURTIS, Department of Physics, University of Cyprus — Electron transfer reactions are ubiquitous in biology. They are observed in both protein and DNA systems. Biological electron transfer mechanisms range from tunnelling to thermally activated hopping. Due to the floppiness of biomolecules, molecular motion is an important determinant of the electron transfer rate. The electronic couplings that enable electron transfer in biomolecular systems can be understood in terms of competing and interfering electron transfer pathways that are controlled by structure, dynamics, and initial state preparation. We review recent theoretical progress on the effects of conformational distributions, excited-state polarization, and electron-nuclear dynamics on tunneling electron transfer reactions in different biomolecular systems. We discuss how electron-transfer-rate control can be achieved in the presence of a highly fluctuating environment.

9:12AM P38.00003 A molecular breakwater enhances electron transfer between proteins , NATHAN S. BABCOCK, University of Calgary, AURÉLIEN DE LA LANDE, Universite Paris-Sud, JAN ŘEZÁČ, Academy of Sciences of the Czech Republic, BARRY C. SANDERS, DENNIS R. SALAHUB, University of Calgary — Does natural selection optimize molecular biomachinery at the quantum level? We present statistical characterizations of molecular dynamics at an interprotein electron transfer (ET) interface. In simulations of the wild-type protein complex, we find that the most frequently occurring molecular configurations afford superior electronic coupling due to the consistent presence of a single water molecule hydrogen-bonded between the donor and acceptor sites. We attribute the persistence of this water bridge to a "molecular breakwater" composed of several hydrophobic residues surrounding the acceptor site. The breakwater supports the function of solvent-organizing residues by limiting the exchange of water molecules between the sterically constrained ET region and the surrounding bulk. When the breakwater is affected by a mutation, bulk solvent molecules disrupt the water bridge, resulting in reduced electronic coupling. These results suggest that protein surface residues may stabilize interprotein solvent dynamics to enable coherent ET along a single molecular pathway.

9:24AM P38.00004 Mixed quantum classical simulations of vibrational energy transport in alpha-helices[1] , ANNE GOJ, ERIC BITTNER, University of Houston — We use mixed classical/quantum simulations to study the time dependence of an excitation of a C=O vibration on a 3-10 helix of α-Aminoisobutyric acid (AIB), a system which represents a test case for the formation of self-trapped vibrational excitation states on protein helices. Due to the inherent disorder in the system caused by the finite temperature and fluctuations in hydrogen bonding, the excitation tunnels randomly among C=O sites along the helix. Quantum forces are insufficient to establish a coherent relationship between the location of the excitation and the contraction of hydrogen bonds around this site. Our simulations indicate that the excitation frequently becomes localized on the end of the helix due to the defect in helical structure caused by unwinding. Our results generally do not support the existance of Davydov type solitons in biological helix systems under physiological conditions.

9:36AM P38.00005 Quantum processes as a mechanism in olfaction for smell recognition?[1] , JENNIFER BROOKES, Massachussetts Institute of Technology — The physics of smell is not well understood. The biological processes that occur following a signalling event are well understood (Buck 1991). However, the reasons how and why a signalling event occurs when a particular smell molecule and receptor combination is made, remains un-established. Luca Turin proposes a signalling mechanism which determines smell molecules by quantum mechanics (Turin 1996). Investigation of this mechanism shows it to be physically robust (Brookes,et al, 2007), and consequences of the theory provides quantitative measurements of smell and interesting potential experiments that may determine whether the recognition of smell is a quantum event. Brookes, J.C, Hartoutsiou, F, Horsfield, A.P and Stoneham, A.M. (2007). Physical Review Letters 98, no. 3 038101 Buck, L. (1991) Cell, 65, no.1 (4): 175-187. Turin, L. (1996) Chemical Sences 21, no 6. 773-791

10:12AM P38.00006 Recent developments in the physics of your sense of smell[1] , ANDREW HORSFIELD, Imperial College London, LUCA TURIN, MIT, YEONG-AH SOH, Imperial College London, MARION SOURRIBES, MARSHALL STONEHAM, LIANHENG TONG, PAUL WARBURTON, UCL — A radical proposal in 1996 [L. Turin, Chem. Senses 21, 773 (1996)] was that human olfactory receptors use phonon assisted electron tunnelling to probe the vibrational spectrum of odorants in order to determine their chemical identity. A development of this model [J. C. Brookes et al., Phys. Rev. Lett., 98, 038101 (2007)] showed that this Turin mechanism is indeed physically possible, even robust, but left a number of questions open. One such question is: between which sites does the tunnelling electron pass? Our recent calculations support a particular pair of likely sites. Because of the complexity of biological environments, probing the receptor is difficult. Thus we have begun to investigate the properties of a semiconductor nanowire device that mimics the key processes [A. P. Horsfield et al., J. Appl. Phys., 108, 014511 (2010)]. We will present the latest findings of this study.

10:24AM P38.00007 A Quantum of Solace: molecular electronics of benzodiazepines[1] , LUCA TURIN, MIT, ANDREW HORSFIELD, Imperial College London, MARSHALL STONEHAM, University College London — Benzodiazepines and related drugs modulate the activity of GABA-A receptors, the main inhibitory receptor of the central nervous system. The prevailing view is that these drugs bind at the interface between two receptor subunits and allosterically modulate the response to GABA. In this talk I shall present evidence that benzodiazepines work instead by facilitating electron transport from the cytoplasm to a crucial redox-sensitive group in the gamma subunit. If this idea is correct, benzodiazepines should not only be regarded as keys fitting into a lock, but also as one-electron chemical field-effect transistors fitting into an electronic circuit.

10:36AM P38.00008 Theoretical investigation of coherent exciton flow dynamics in light harvesting complex 2 (LH2)[1] , SEOGJOO JANG, Queens College, City University of New York — The light harvesting complex 2 (LH2) is a peripheral antenna complex found in photosynthetic unit of purple bacteria. Numerous spectroscopic and computational studies demonstrated that quantum coherence plays an important role in the energetics and the dynamics of excitons created in LH2, but detailed and quantitative understanding is still missing regarding how the quantum coherence influences spectroscopic observables and how it boosts efficient energy transfer despite disorder and soft nature of the system. The present talk reports recent progress in the analysis of the single molecule spectroscopy (SMS) and application of resonance energy transfer theories, which account for multichromophoric and quantum coherence effects. These suggest that spectroscopic modeling allows development of reliable coarse-grained model for LH2 that can capture the major features of the excitons and that LH2 is a highly optimized natural system where the interplay between quantum coherence and disorder/fluctuation is maximally utilized.

Session P39 DBP: Physics of Proteins IV: Folding, Dynamics and Function A124/127

8:00AM P39.00001 Competition between chemical denaturation and macromolecular crowding effects on the folding dynamics of proteins[1] , ANTONIOS SAMIOTAKIS, MARGARET CHEUNG, University of Houston — It is well known that proteins fold and function in the crowded environment of the cell's interior. In the recent years it has been established that the so-called "macromolecular crowding" effect can enhance the folding stability of proteins by destabilizing their unfolded states. On the other hand, chemical and thermal denaturation are often used in experiments as tools to destabilize protein structures when probing a protein's folding landscape. However, little is known about the combined effects of these competing phenomena on proteins. In this work, we use coarse-grained molecular simulations to study the thermodynamic and kinetic properties of the small peptide Trp-cage, in the combined presence of macromolecular crowders and chemical denaturant. With the use of an energy function derived by all-atomistic simulations in the presence of urea, we investigate the thermodynamics and kinetics of Trp-cage's folding mechanism at several concentrations of urea. The effects of the competition between stabilization by macromolecular crowding and destabilization by chemical denaturation will also be discussed.

8:12AM P39.00002 Can understanding the packing of side chains improve the design of protein-protein interactions?[1] , ALICE ZHOU, COREY O'HERN, LYNNE REGAN, Yale University — With the long-term goal to improve the design of protein-protein interactions, we have begun extensive computational studies to understand how side-chains of key residues of binding partners geometrically fit together at protein-peptide interfaces, e.g. the tetratrico-peptide repeat protein and its cognate peptide). We describe simple atomic-scale models of hydrophobic dipeptides, which include hard-core repulsion, bond length and angle constraints, and Van der Waals attraction. By completely enumerating all minimal energy structures in these systems, we are able to reproduce important features of the probability distributions of side chain dihedral angles of hydrophic residues in the protein data bank. These results are the crucial first step in developing computational models that can predict the side chain conformations of residues at protein-peptide interfaces.

8:24AM P39.00003 Insight into the mechanics of the selectivity filter of *Escherichia coli* aquaporin Z[1] , GUODONG HU, L.Y. CHEN, University of Texas at San Antonio — Aquaporin Z (AQPZ) is a tetrameric protein that forms water channels in Escherichia coli's cell membrane. The histinine residue in the selectivity filter (SF) region plays an important role in the transport of water across the membrane. In this work, we perform equilibrium molecular dynamics (MD) simulation to illustrate influences of two different protonation states and the gate mechanics of the SF. We calculate the pore radii in the SF region versus the simulation time. We perform steered MD to compute the free energy profile, i.e., the potential of the mean force (PMF) a water molecule through the SF region. We calculate the binding energy of one water molecule with the SF region residues, using Gaussian. The hydrogen bonds formed between the side chains of Hsd 174 and side chains of Arg189 play important roles in the selectivity filter mechanics of AQPZ. The radii of the pores, hydrogen bond analysis, and free energies show that Hsd is favored than Hse.

8:36AM P39.00004 The Effect of Phosphate Buffered Saline (1x PBS) on Induced Thermal Unfolding and Low Frequency Dielectric Spectra of Lysozyme[1] , KLAIDA KASHURI, HEKTOR KASHURI, GERMANO IANNACCHIONE — It is well known that the folding / unfolding of proteins is related directly to their structure and functionality. Calorimetry (both AC and MDSC) studies as well as low-frequency (1Hz to 100 kHz) dielectric measurements have been performed on hen egg white lysozyme dissolved in PBS (pH 7.4) from 20 to 100 °C. From the heat capacity profile, the temperatures and related an enthalpy change of the protein denaturing is probed. The heat capacity peak broadens and new features are reveled as the temperature scan rate is lowered to +0.017 K/min for the AC calorimetric method. Significant differences are observed using the (M)DSC technique at scan rates of from 1 to 5 K/min. The temperature dependence of the permittivity, ϵ', and the loss factor, ϵ'', at 100 kHz of the diluted protein show features associated with those seen in the heat capacity (AC and MDSC). All results are interpreted in terms of protein denaturing then subsequent gelation that depend on protein sample concentration, which is supported by the frequency dependence of the permittivity at room temperature after thermally cycling

8:48AM P39.00005 The effect of macromolecular crowding, ionic strength and calcium binding on calmodulin dynamics[1] , QIAN WANG, KAO-CHEN LIANG, University of Houston, NEAL WAXHAM, University of Texas Health Science Center-Houston, MARGARET CHEUNG, University of Houston — The flexibility in the structure of calmodulin (CaM) allows its binding to over 300 target proteins in the cell. To investigate the structure-function relationship of CaM in response to the changing intracellular environment, we use a combined method of computer simulation and experiments based on circular dichroism (CD). The conformation, helicity and EF hand orientation of CaM are analyzed computationally to address the effect of macromolecular crowding, ionic strength and calcium binding in the experiments. We applied a unique solution of charges computed from QM/MM to accurately represent the charge distribution in the transition from apo-CaM to holo-CaM. Computationally, we found that a high level of macromolecular crowding, in addition to calcium binding and ionic strength, can impact the conformation, helicity and the EF hand orientation of CaM. Our result may provide unique insight into understanding the promiscuous behavior of calmodulin in target selection inside cells.

9:00AM P39.00006 α-Helical to β-Helical Conformation Change in the C-Terminal of the Mammalian Prion Protein , JESSE SINGH, UC Davis, PAUL WHITFORD, Los Alamos National Laboratory, NATHA HAYRE, DANIEL COX, UC Davis Physics, JOSÉ ONUCHIC, Center for Theoretical Biological Physics, UCSD — We employ all-atom structure-based models with mixed basis contact maps to explore whether there are any significant geometric or energetic constraints limiting conjectured conformational transitions between the alpha-helical (αH) and the left handed beta helical (LHBH) conformations for the C-terminal (residues 166-226) of the mammalian prion protein. The LHBH structure has been proposed to describe infectious oligomers and one class of in vitro grown fibrils, as well as possibly self- templating the conversion of normal cellular prion protein to the infectious form. Our results confirm that the kinetics of the conformation change are not strongely limited by large scale geometry modification and there exists an overall preference for the LHBH conformation.

9:12AM P39.00007 Dynamics of Protein Carbonmonoxyhemoglobin on Multiple Length Scales , JYOTSANA LAL, ROBERT FISCHETTI, LEE MAKOWSKI, Argonne National Laboratory, Argonne IL-60439, USA., PETER FOUQUET, MARCO MACCARINI, Institut Laue-Langevin, 38042 Grenoble- Cedex 9, France, NANCY HO, CHIEN HO, Carnegie Mellon Univ., Pittsburgh, PA-15213, USA. — A combination of wide-angle x-ray solution scattering (WAXS) and neutron spin echo spectroscopy (NSE) was used to probe the structure and dynamics of carbonmonoxy hemoglobin (HbCO) in the presence and absence of the allosteric effector inositol hexaphosphate (IHP). IHP shifts the structure of HbCO slightly towards an unliganded, (deoxy)-state conformation. Two potential binding sites for IHP are consistent with the WAXS data, one near each end of the central channel. IHP binding slows the self-correlation times of some protons, most likely those immediately adjacent to the bound IHP, and simultaneously induces an increase in the relaxation rate of correlated motions with length scales comparable to the $\alpha\beta$-dimer. IHP binding increases the spatial extent of these fluctuations by about 20%. This suggests that when hemoglobin binds CO, its conformation is confined to a relatively narrow structural ensemble residing within a functionally well defined energy well. On the other hand, when it binds both CO and IHP, in response to the contradictory stresses applied by these two ligands, it adopts an incommensurate structure with a conformation exploring a broad structural ensemble.

9:24AM P39.00008 Infrared Spectroscopy Measurements of Protein Dynamics and Mechanism , CURTIS W. MEUSE, JOSEPH B. HUBBARD, National Institute of Standards and Technology — Infrared spectroscopy has long been used to deduce the concentration and secondary structures of proteins in a variety of static and time resolved applications. Our focus is on developing new infrared methods to compare the structure, dynamics and function of nearly identical protein samples, in different environments, to apply to the problem of identifying bio-similar protein therapeutics. We have developed an order parameter describing protein conformation variations around the average molecular values. By comparing our order parameter and amide hydrogen/deuterium exchange methods, we explore the relationship between protein stability and the dynamics of the protein conformational distribution. Examples include lysozyme and albumin in solution, cytochrome c interacting with lipid membranes of varying net-negative surface charge density, fibrinogen on different polymer surfaces and bacteriorhodopsin during its photocycle.

9:36AM P39.00009 Comparing potential copper chelation mechanisms in Parkinson's disease protein , FRISCO ROSE, MIROSLAV HODAK, JERRY BERNHOLC, CHiPS/NCSU — We have implemented the nudged elastic band (NEB) as a guided dynamics framework for our real-space multigrid method of DFT-based quantum simulations. This highly parallel approach resolves a minimum energy pathway (MEP) on the energy hypersurface by relaxing intermediates in a chain-of-states. As an initial application we present an investigation of chelating agents acting on copper ion bound to α-synuclein, whose misfolding is implicated in Parkinson's disease (PD). Copper ions are known to act as highly effective misfolding agents in a-synuclein and are thus an important target in understanding PD. Furthermore, chelation therapy has shown promise in the treatment of Alzheimer's and other neuro-degenerative diseases with similar metal-correlated pathologies. At present, our candidate chelating agents include nicotine, curcumin and clioquinol. We examine their MEP activation barriers in the context of a PD onset mechanism to assess the viability of various chelators for PD remediation.

9:48AM P39.00010 Investigating hexameric helicases: Single-molecule studies of DnaB and T4 gp41 , OMAR SALEH, NOAH RIBECK, JOHN BEREZNEY, University of California Santa Barbara — Hexameric, ring-shaped motor proteins serve as replicative helicases in many systems. They function by encircling and translocating along ssDNA, denaturing dsDNA in advance of its motion by sterically occluding the complementary strand to the outside of the ring. We investigate the helicase activity of two such motors using single-molecule measurements with magnetic tweezers. First, we measure the activity of the *E. coli* helicase DnaB complexed with the tau subunit of the Pol III holoenzyme. Tau is known from bulk measurements to stimulate DnaB activity (Kim et al., *Cell*, 1996); we investigate the means of this stimulation. Second, we measure helicase activity of the T4 phage helicase gp41 in multiple tethered DNA geometries. Previous work on DnaB showed a dependence of helicase activity on DNA geometry (Ribeck et al., *Biophys. J.*, 2010); here, we test gp41 for similar behavior to see whether it is a common characteristic of hexameric helicases.

10:00AM P39.00011 Copper attachment to prion protein at a non-octarepeat site , MIROSLAV HODAK, North Carolina State University, JERRY BERNHOLC — Prion protein (PrP) plays a causative role in a group of neurodegenerative diseases, which include "mad cow disease" or its human form variant Creutzfeld-Jacob disease. Normal function of PrP remains unknown, but it is now well established that PrP can efficiently bind copper ions and this ability has been linked to its function. The primary binding sites are located in the so-called octarepeat region located between residues 60-91. While these are by now well characterized, the sites located outside these region remain mostly undetermined. In this work, we investigate the properties of Cu binding site located at His 111 using recently developed hybrid Kohn-Sham/orbital-free density functional simulations. Experimental data indicate that copper is coordinated by either four nitrogens or three nitrogens and one oxygen. We investigate both possibilities, comparing their energetics and attachment geometries. Similarities and differences with other binding sites and implications for PrP function will also be discussed.

10:12AM P39.00012 Pressure and Temperature Effects on Polypeptides and Biomolecules Probed by Micro-Raman Spectroscopy , SANGHOON PARK, ALFONS SCHULTE, Department of Physics and College of Optics, University of Central Florida — We investigate pressure and temperature effects on the secondary structure of Poly-L-glutamic acid (PGA) in D_2O buffer (pH 5.4) solution. Our setup employs a Raman microscope equipped with a micro-capillary high-pressure cell and a variable temperature stage. Raman spectra are acquired over the pressure range from 0.1 to 300 MPa while the temperature can be varied from 270 K to 330 K. The amide I band of PGA is sensitive to pressure and temperature, and by spectral deconvolution we determine the relative contributions due to α-helix and random coil conformations. The amount of α-helix increases with increasing pressure. Extensions of these experiments to model proteins and lipids are presented.

Wednesday, March 23, 2011 8:00AM - 11:00AM –
Session P40 DPOLY: Polymer Melts & Solutions A122/123

8:00AM P40.00001 Radical-cured block copolymer modified thermosets[1] , ERICA REDLINE, LORRAINE FRANCIS, FRANK BATES, Department of Chemical Engineering and Materials Science, University of Minnesota — Poly(ethylene-*alt*-propylene)-*b*-poly(ethylene oxide) (PEP-PEO) diblock copolymers were synthesized and added at 4 wt. % to bisphenol A glycidyl methacrylate (BisGMA). The mixture was thermally cured using free radical chemistry. In separate experiments, 4 wt. % PEP-PEO was added to a combination of poly(ethylene glycol) dimethacrylate (PEGDMA) and BisGMA and cured. Based on small angle X-ray studies of the modified monomers before curing, diblock copolymers self-assembled into well-dispersed spherical micelles with PEP cores and PEO coronas. TEM results showed that these micellar structures were retained during curing. Fracture resistance measurements indicate that the addition of block copolymers does not significantly toughen these thermoset materials. This finding is contrary to the large increase in fracture resistance observed in block copolymer-modified epoxies. We propose that differences in network structure, originating during polymerization, are responsible.

[1]This work was supported primarily by the MRSEC Program of the National Science Foundation under Award Number DMR-0212302 and DMR-0819885.

8:12AM P40.00002 Cavitation in Filled Styrene-butadiene Rubber: A Real Time SAXS Observation , HUAN ZHANG, ESPCI ParisTech, Paris, France, ARTHUR K. SCHOLZ, MRL-UC Santa Barbara, CA, FABIEN VION-LOISEL, Michelin, Clermont-Ferrand, France, EDWARD J. KRAMER, MRL-UC Santa Barbara, CA, COSTANTINO CRETON, ESPCI ParisTech, Paris, France — Cavitation of filled and unfilled elastomers under confinement at the macroscopic scale has been experimentally reported and theoretically modeled. However, cavitation occurring at the nanometer length scale has not yet been demonstrated conclusively in rubbers. Real time SAXS with synchrotron radiation was employed to probe the structure changes in carbon black filled styrene-butadiene rubber (SBR) under uniaxial loading. The scattering invariant was calculated and increased sharply at a critical extension depending on both filler content and crosslinking density around q = 0.1 nm-1, which we attributed to the formation of voids. At very large strains, a sharp and wide streak developed perpendicular to the tensile axis in reciprocal space, suggesting the deformation of the voids in elliptical voids along the tensile direction. In step cycle test, we observed that voids only appeared when the current strain exceeded the maximum historical strain (Mullins effect) and attributed the increase of the scattering invariant outside the Mullins region to the creation of new voids rather than to the reopening of old ones.

8:24AM P40.00003 Why is the tube model inapplicable for entangled polymer dynamics at large deformation , SHI-QING WANG, YANGYANG WANG, University of Akron — Accumulating experimental revelation of the phenomenology governing dynamics of entangled linear polymers at large deformations has caused us to question the legitimacy of the tube model as an acceptable theoretical description of nonlinear polymer rheology. Upon an explicit investigation of its premise, we have come to realize that the tube model did not overcome the difficulty confronted by other theories and did not contain the basic physics required to explain why and how the entanglement network must break down during large deformations. It considered an unrealistic situation where a load-bearing chain relaxed fast in an affinely deformed tube so that only the chain segment orientation produced the shear stress for applied rates lower than the Rouse rate. A non-monotonic relation between the resulting shear stress and imposed strain for startup shear and step deformations arose from excessive chain orientation not collapse of the entanglement network. In the tube model, the nature of the overshoot is not yielding (transition from elastic deformation to flow), but an elastic instability. Accumulating experimental observations contradict this picture. This presentation will elucidate how the emerging physical picture differs from that of the unrealistic tube model.

8:36AM P40.00004 Non-Gaussian Stretching Behavior of Entangled Polymers , YANGYANG WANG, SHI-QING WANG, The University of Akron — The behavior of entangled SBR melts and solutions in rapid uniaxial extension has been studied by rheometric and rheo-optical measurements. A yield-to-rupture transition occurs around the same Rouse Weissenberg number of nine for all samples when the failure mechanism changes from chain disentanglement (yielding) to chain scission. Our results show that elastic rupture takes place only when chains between entanglements are near full extension, the strain at rupture grows with increasing entanglement spacing, and the critical stress for rupture is proportional to the polymer concentration. These characteristics validate the well-known idea to represent entangled polymers in terms of a transient network.

8:48AM P40.00005 Parameters of slip-springs model of polymer entanglement from the maximum likelihood principle , TIMOTHY PALMER, ALEXEI LIKHTMAN, University of Reading, JORGE RAMIREZ, Technical University of Madrid, MARK MATSEN, University of Reading — The slip-spring model for polymer entanglements proposed by A.E.Likhtman [Macromolecules; 2005; 38(14); 6128] replaces entangling chains with slip-links, which are anchored via springs. The use of such models allows reduction of complex multi-chain problem to a simpler single chain problem. In this work we test the slip-spring model on the simplest possible situation: replacing two entangled chains by one chain with one slip-link. We demonstrate how Maximum Likelihood Estimation (MLE) can be used to generate parameters for the slip-spring model by observing a multi-chain system. The test system being considered consists of two Rouse polymer chains that are anchored by the ends in an entangled state. The effect of the entanglement is enforced by rejecting all steps that lead to topology violation. We show how the results of this MLE indicate that slip-link models with slip-links fixed in space are not satisfactory, and demonstrate analytically the dependence of the plateau modulus upon the strength of the slip-spring. Our results contradict recent calculations of Schieber and Horio [JCP; 2010; 132(7); 074905] who claimed that the plateau modulus must be independent of the slip-spring strength.

9:00AM P40.00006 Segmental orientation dynamics in bidisperse entangled linear polymer melts , ZUOWEI WANG, JING CAO, ALEXEI LIKHTMAN, Department of Mathematics and Statistics, University of Reading, Whiteknights, RG6 6AX, UK, RONALD LARSON, Department of Chemical Engineering, University of Michigan, Ann Arbor, MI 48109-2136 — Extensive molecular dynamics simulations were performed to investigate the segmental orientation dynamics in mono- and bidisperse entangled linear polymer melts. The binary blends consist of short probe chains diluted in long chain matrices of chain length up to 30 entanglements. With increase of the chain length in monodisperse melts, the bond vector autocorrelation function was found to approach a distinctive time-dependent power law, which is compared with recent NMR experiments. When introduced into long chain matrices, the segmental orientation relaxation and monomer diffusion of short probe chains slowed down strongly due to the suppression of constraint release (CR) effects. The same trend was observed for the end-to-end vector correlation function, reflecting the CR effects on contour length fluctuations. On the other hand, the time-dependent orientation coupling parameter in the entangled systems demonstrates the similar universal behaviour as that discovered in unentangled melts. Considering the stress-optical law was recovered in all simulated systems, our simulations should clarify the connection between rheology and other experimental techniques, which are essential for progress in modeling entangled polymers.

9:12AM P40.00007 Simulations of polymer melts modeled as chains of interacting soft-colloids , ANTHONY CLARK, MARINA GUENZA, University of Oregon — The range of time and length scales accessible to dynamical simulations of melts of long polymer chains is strongly limited by the computational demands of calculating large numbers of forces between monomers. Simulations modeling each polymer as a point particle interacting by an analytical soft pair potential have previously been successfully developed to extend this range. For many effects in polymer systems, however, submolecular degrees of freedom remain relevent to molecular-level behavior even at long times and large length scales. To allow for the inclusion of relevant submolecular degrees of freedom, we use analytical effective potentials based on our model of the structure of polymer melts on the level of large chain sub-blocks to simulate homopolymer melts. We demonstrate that structure on the block and center of mass level consistent with the structural model and monomer-level simulation data can be reproduced for large systems and long times at much lower computational cost than monomer-level simulations. Using this model, we also test the effects of additional short-range repulsive interactions between chain subunits on structure and dynamics.

9:24AM P40.00008 Renormalized dynamics of overdamped driven elastic media , JONATHAN LANDY, UCLA Dept. of Physics and Astronomy, ALEX J. LEVINE, UCLA Dept. of Chemistry & Biochemistry and California Nanosystems Institute — We present the results of a dynamical renormalization group calculation used to explore the fluctuations of an elastic body steadily driven through a viscous background fluid. Direct applications of this work involve the study of the fluctuation spectrum of semiflexible filament networks driven through a background fluid by e.g. polymerization, but also include the motion of one-dimensional driven elastic objects (e.g. polymers, flux vortices etc.) In that case, a previous linear stability analysis suggests that, when such elastic lines are driven in a direction perpendicular to their axis, they become unstable at any non-zero driving force [1]. We discuss the affect of nonlinearities on these conclusions, showing that such terms can stabilize the system at finite drive velocities. We similarly explore the dynamics of lines driven parallel their axis showing that these systems exhibit "weak dynamic scaling" [2]. Turning to the case of driven elastic solids, we report on the effect of molecular motor-induced forces on the long length scale and long time scale dynamics of the driven system. [1] R. Lahiri and S. Ramaswamy, Are steadily moving crystals unstable?, Phys. Rev. Lett. 79, 1150 (1997) [2] D. Das et al., Weak and strong dynamic scaling in a one-dimensional driven coupled-field model: Effects of kinematic waves, PRE 64, 021402 (2001).

9:36AM P40.00009 Thermodyanmic Scaling of Polymer Dynamics versus Shifting by T-Tg , JIAXI GUO, SINDEE SIMON, Texas Tech University — A universal scaling law for the relaxation time (τ) of amorphous liquids as a function of temperature and volume has been proposed by Roland and coworkers: τ(T,V) = F(TV$^{\gamma}$), where γ is a material-dependent constant. We test this law for four materials, linear polystyrene, star polystyrene, and two polycyanurate networks using PVT data obtained in our laboratory coupled with the temperature dependent shift factors used to reduce the viscoelastic bulk modulus at different pressures and the dynamic shear properties at ambient pressure. In all cases, τ can be reduced both by the scaling law and by shifting to account for the changes in T_g with pressure, i.e., by plotting versus T - T_g(P). In the polycyanurate case, time-crosslink density superposition holds and τ for the two materials can be reduced simply by shifting the temperature with respect to T_g to account for the changes in $T_g$with crosslink density; however, the thermodynamic scaling for the two materials does not superpose unless the thermodynamic function is normalized by $T_g V_g^{\gamma}$. The validity of the scaling function and its relationship to T - T_g will be further examined. In addition, the impact of errors in T, T_g, and V on the ability to satisfactorily reduce data and obtain universal scaling will be discussed.

9:48AM P40.00010 The linear rheological responses of dense branched brush polymers with different side chain lengths and structures , MIAO HU, GREGORY MCKENNA, Department of Chemical Engineering, Texas Tech University, YAN XIA, CHRIS DAEFFLER, ANDREW BOYDSTON, ROBERT GRUBBS, JULIA KORNFIELD, Division of Chemistry and Chemical Engineering, California Institute of Technology — We examined the linear rheological responses of three kinds of dense and regular branched brush polymers. Brush polymers with different degree of polymerization were synthesized from the ω-Norbornenyl macromolecule (as main chain) with linear, three combined short arms, and dendronized brush structures. The master curves for these brush polymers were obtained by time temperature superposition (TTS) of the dynamic moduli from the glassy plateau region to the terminal flow region. The glassy modulus and rubbery modulus for these brush polymers were greatly influenced by the side chain properties. Two different relaxation processes can be observed for those samples with the higher molecular weight, slightly entangled, side chains. The dilution effect of the side chain which is related to the side chain volume fraction doesn't follows theoretical expectations.

10:00AM P40.00011 Analytical rheology of metallocene-catalyzed polyethylenes[1] , SACHIN SHANBHAG, ARSIA TAKEH, Florida State University — A computational algorithm that seeks to invert the linear viscoelastic spectrum of single-site metallocene-catalyzed polyethylenes is presented. The algorithm uses a general linear rheological model of branched polymers as its underlying engine, and is based on a Bayesian formulation that transforms the inverse problem into a sampling problem. Given experimental rheological data on unknown single-site metallocene- catalyzed polyethylenes, it is able to quantitatively describe the range of values of weight-averaged molecular molecular weight, M_W, and average branching density, b_m, consistent with the data. The algorithm uses a Markov-chain Monte Carlo method to simulate the sampling problem. If, and when information about the molecular weight is available through supplementary experiments, such as chromatography or light scattering, it can easily be incorporated into the algorithm, as demonstrated.

[1]Financial support from NSF DMR 0953002

10:12AM P40.00012 Pressure-Volume-Temperature Behavior of Hyperbranched Polyols: Experiment and Modelling , MUKUL KAUSHIK, SERGEI NAZARENKO, BRIAN OLSON, School of Polymers and High Performance Materials The University of Southern Mississippi, Hattiesburg, MS 39406 — The pressure volume temperature behavior of two generations of hyperbranched polyesters Boltorn^{TM} H40 and H20 was studied by PVT measurements using high pressure dilatometer. Volumetric expansivity, and free volume parameters were determined for both generations in the melt state. The PVT data were fitted to Simha-Somcynsky (SS) equation of state (EOS) and Sanchez–Lacombe (SL) equation of state (EOS) to calculate occupied volume and fractional free volume. The values of occupied volume and fractional free volumes obtained through both the equations of states were similar. Simulated atmospheric pressure V-T data were generated by using Discover module of Accelrys®. Quality of equilibrium was confirmed by energy stabilization and closeness of experimental and simulation densities. WAXD and temperature-volume curves obtained by molecular dynamics simulations were comparable to the experimental data. Well relaxed amorphous cell was further utilized to study hydrogen bond network and determination of O-O pair correlation function of terminal hydroxyl groups.

10:24AM P40.00013 Influence of the Hofmeister Series on Lower Critical Solution Temperature (LCST) Polymers , RYAN TOOMEY, LEENA PATRA, University of South Florida — Lower critical solution temperature (LCST) polymers can serve as model systems for probing the effect of ions on the stability of biological macromolecules. In this talk, we show how permutations in the chemical structure of poly(N-isopropylacrylamide), including n-propylacrylamide, cyclopropylacrylamide, and N-vinylisobutyramide influence the action of ions in the Hofmeister series. By using a combination of ellipsometry and FTIR, we show that ions salt out neutral polymers by enhancing the surface tension of the hydrophobic portions of the polymer. Weakly hydrated ions (known as chaotropes) can also lead to salting-in effects through interactions with amide dipoles. This salting-in effect is strongly modulated by the surrounding hydrophobic groups. The larger the hydrophobic group the weaker the salting-in effect, indicating that the specificity of the Hofmeister series results from a combination of ion-dipole interactions and hydrophobicity.

10:36AM P40.00014 Ionic Liquids for the Imaging of Wet Polymer Morphology[1] , DAVID HOAGLAND, JOHN HARNER, MALVIKA BIHARI, Univ. of Massachusetts Amherst — Unlike convention aqueous and organic solvents, ionic liquids are essentially nonvolatile and thus compatible with the high vacuum environments of electron microscopy. Here is described the room temperature imaging of wet polymer systems such as patterned gels, gel networks, polymeric vesicles, and proteins. Both TEM and SEM images will be offered, along with a discussion of difficulties in applying the two techniques. Via SEM, imprinted surface structures as small as 100-300 nm can be captured for chemically crosslinked gels (polyHEMA), and via TEM, the structure of a physical gel (PEG) is viewed at the 50-to-10-nm scale, revealing network connectivity established by PEG crystallinity. Self-assembled vesicle and micelle structures will be presented for dispersed block copolymers, and the same approach will be applied toward discerning the quality of dispersion for proteins (ferritin) and other nanoparticles.

10:48AM P40.00015 Biaxial Strain Testing of Extremely Soft Gels , KENJI URAYAMA, YOHSUKE BITOH, TOSHIKAZU TAKIGAWA, Dept. Mater. Chem., Kyoto Univ. — We present a biaxial tensile tester to characterize the nonlinear stress–strain behavior of extremely soft polymer gels with very low shear moduli, of the order of 100 Pa, under general (equal and unequal) biaxial strain. Stretching of gel sheet specimens in a solvent bath can avoid finite self-weight bending deformations that have precluded biaxial tensile experiments with such extremely soft gels. General biaxial strain covers a wide range of physically accessible deformations in contrast to conventional uniaxial strain that is only a special one among them. The biaxial data for fully swollen chemical gels reveal that the exceptional agreement of uniaxial data with predictions of the simplest rubber elasticity model (ideal gas model), which has been known for over 60 years, is superficial because the model evidently fails to describe the biaxial data. This new biaxial tester will be a powerful tool for the full characterization of the large deformation behavior of extremely soft materials, including biological soft tissues.

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P41 DCP: Focus Session: Fundamental Issues in Interfacial Charge Transport for Energy Applications I A115/117

8:00AM P41.00001 Excitons at Interfaces , XIAOYANG ZHU, University of Texas at Austin — Solar photovoltaics based on molecular and nano materials commonly involve excitons. This results from strong Coulomb attraction between an electron and a hole due to the low dielectric constants of molecules or quantum confinement of nano materials. In this lecture, I will address the question of how excitons dissociate at donor/acceptor interfaces. The first example deals with charge separation in organic photovoltaics. Due to the low dielectric constant of organic materials, an electron-hole pair across an organic donor/acceptor interface is bound by the Coulomb potential. This gives rise to a set of H-atom like states called charge-transfer excitons, as observed experimentally. The lowest energy charge transfer exciton state has a binding energy much higher than kT at room temperature. This leads to the conclusion that hot charge transfer exciton states must be involved in charge separation in organic photovoltaics. The second example deals with hot exciton dissociation due to electron transfer from photo-excited semiconductor nanocrystals (PbSe) to an electron acceptor (TiO2), an issue of particular interest to hot carrier solar cells with theoretical solar conversion efficiency surpassing the Shockley-Queisser limit. We show that, with appropriate chemical treatment of the nanocrystal surface, ultrafast transfer of a hot electron can be competitive with hot exciton relaxation due to phonon scattering. The last example will show recent development on hot carrier scattering and multiple exciton generation (MEG) in semiconductor nanorystals.

8:36AM P41.00002 The Effect of Photoexcitation and Population Relaxation on Carrier Multiplication Efficiency in Semiconductor Nanocrystals and Bulk , ANDREI PIRYATINSKI, KIRILL VELIZHANIN, Los Alamos National Laboratory — The carrier multiplication (CM) is the process of production of two or more electron-hole pairs (excitons) per single absorbed photon. Detailed understanding of the mechanisms of this process is of importance for developing novel cheap and efficient photovoltaic devices. To model the CM dynamics, we have developed an exciton scattering model which accurately treats the contributions of different multi-exciton generation pathways on the same footing. Furthermore, the model allows one to study CM in nanocrystalline and bulk semiconductor materials. Using this model, we performed a numerical study of photogeneration and population relaxation processes contributing to CM in PbSe nanocrystals and bulk. It is found that the photogeneration provides small contribution to the total quantum efficiency compared to the population relaxation process. The resonant incoherent biexciton production is found to be main mechanism of CM in both cases of direct biexciton photogeneration and during the population relaxation. Comparison to the published experimental data shows that the calculations reproduce experimentally observed trends providing insight into the mechanisms of CM.

8:48AM P41.00003 Non-radiative Energy Transfer in Colloidal Nanocrystals/Silicon Hybrid Structures , HUE MINH NGUYEN, The University of Texas at Dallas, Department of Physics, OLIVER SEITZ, DAMIEN AUREAU, AMANDEEP SRA, YVES CHABAL, The University of Texas at Dallas, Department of Materials Science, ANTON MALKO, The University of Texas at Dallas, Department of Physics — The integration of organic and inorganic materials at the nanoscale offers the possibility of developing new photonic devices that could potentially combine the advantages of both classes of materials. Such optoelectronic structures could work both in photovoltaic as well as in light emitting modes depending on the direction of non-radiative *exciton* energy transfer (NRET). In present work, we studied hybrid structures consisting of a monolayer of the colloidal nanocrystal quantum dots (NQDs) grafted on hydrogenated Si surface via amine modified carboxy-alkyl chains linkers. Such approach allowed us to passivate Si surface to suppress non-radiative surface state defects ($N_s << 10^{11}$ cm^2) and provided with the controllable spacer lengths between NQDs and Si. We performed systematic measurements of NRET via time-resolved and steady-state photoluminescence (PL) in the range of 10K to 300K and as a function of spacer lengths and quantified NRET rates. Local field effects due to the acceptor surface (Si) are discussed.

9:00AM P41.00004 Quantum Dot Solar Cells. Understanding Charge Transfer at Nanostructure Interface[1] , PRASHANT KAMAT, University of Notre Dame — Quantum dot solar cells are designed using a chemical approach. Different size CdSe quantum dots are assembled on mesoscopic TiO_2 films either by direct adsorption or with the aid of molecular linkers. Upon bandgap excitation, CdSe quantum dots inject electrons into TiO_2 nanoparticles and nanotubes, thus enabling the generation of photocurrent in a photoelectrochemical solar cell. The interfacial processes that dictate the photoelectrochemical performance of these solar cells have now been evaluated by comparing photoelectrochemical behavior with charge transfer dynamics between different size CdSe quantum dots and various oxide substrates. The primary photochemical event in these solar cells is the charge injection from excited CdSe quantum dots into nanostructured metal oxide films. This process can be modulated by varying the particle size of CdSe quantum dots or the conduction band of the acceptor oxide. The difference in the conduction band energy of two semiconductors serves as a driving force for the interparticle electron transfer. According to Marcus theory, for a non-adiabatic reaction in the activation limit, the rate of electron transfer depends on the electronic coupling between the donor and acceptor states, the density of states (DOS) per unit volume and the driving force. Because of the quasi continuum of states in the metal oxide conduction band, the total electron transfer rate depends on the sum of all possible electronic transitions. The dependence of electron transfer rate constant on the energy gap and its implication in photoconversion efficiency of quantum dot solar cells will be presented.

9:36AM P41.00005 Ab initio theory of impact ionization applied to silicon nanocrystals[1] , MARTON VOROS, Budapest University of Technology and Economics, ADAM GALI, Hungarian Academy of Sciences, Research Institute for Solid State Physics and Optics, DARIO ROCCA, GERGELY ZIMANYI, GIULIA GALLI, UC Davis — Achieving multi exciton generation (MEG) in semiconducting nanocrystals may lead to overcome the well-known Shockley-Queisser limit when building semiconductor-based solar cells. A thourough, theoretical understanding of the experiments that reported MEG in e.g. Si and PbSe nanocrystals, is still missing and could significantly contribute to clarify the several controversial results in the field. Several theoretical and numerical studies have addressed the origin of the MEG formation, mostly supporting an impact ionization mechanism. However, impact ionization rates have only been evaluated for model nanocrystals by using empirical pseudopotentials fitted to bulk properties, and model dielectric functions to describe the screened Coulomb interaction. We present an ab-initio scheme based on Density Functional Theory in a plane-wave pseudopotential implementation that includes static screening within the random-phase approximation. We will discuss how impact ionization rates are affected by the shape and surface structure of few nm Si nanocrystals.

[1]Support from Grant NSF DMR-1035468 is acknowledged.

9:48AM P41.00006 Optical properties of crystalline and amorphous silicon slabs with adsorbed metal clusters and with dopants: A combined ab-initio electronic structure and density matrix treatment[1] , DIMITRI KILIN, University of South Dakota, DAVID MICHA, JESSICA RAMIREZ, University of Florida — The optical absorbance and surface photovoltage of slabs of Si with varying number of layers have been calculated starting from their atomic structure. Results have been obtained for nanostructured surfaces with adsorbed metal clusters and for group III and V dopants, from ab initio DFT with periodic boundary conditions for extended systems, and from time-dependent DFT for supercells. Density matrix equations of motion (EOM) have been parametrized in a basis set of Kohn-Sham orbitals, for both crystalline and amorphous Si slabs [1]. Results for properties and from electronic charge distributions provide insight on slab confinement effects for electronically excited states and for particle-hole creation. In addition, the integrodifferential EOMs have been solved for an initial femtosecond pulse excitation [2] to analyze the nature of electron transfer at the surfaces, relevant to photovoltaics.

10:00AM P41.00007 Ultrafast Single and Multiple Exciton Dissociation in CdSe and PbS Quantum Dots[1] , TIANQUAN LIAN, Emory University — Charge transfer to and from quantum dots (QDs) is of intense interest because of its important roles in QD-based devices, such as solar cells and light emitting diodes. Recent reports of multiple exciton generation (MEG) by one absorbed photon in some QDs offer an exciting new approach to improve the efficiency of QD-based solar cells and to design novel multi-electron/hole photocatalysts. However, two main challenges remain. First, the efficiency of MEG process remains controversial and may need to be significantly improved for practical applications. Second, the utilization of the MEG process requires ultrafast exciton dissociation prior to the exciton-exciton annihilation process, which occurs on the 10s to 100s ps time scale. In this presentation we report a series of studies of exciton dissociation dynamics in quantum dots by electron transfer to adsorbed electron acceptors. We show that excitons in CdSe can be dissociated on the a few picosecond timescale to various adsorbates. As a proof of principle, we demonstrated that multiple excitons (generated by multiple photons) per QD can be dissociated by electron transfer to adsorbed acceptors (J. Am. Chem. Soc. 2010, 132, 4858-4864). We will discuss the dependence of these rates on the size and the nature of the quantum dots and possible approaches to optimize the multiple exciton dissociation efficiency.

10:36AM P41.00008 Short time evolution of electronic charge transfer and separation, and quantum coherences, at photoexcited crystalline and amorphous Si surfaces: Adsorbate and dopant effects[1] , DAVID MICHA, ANDREW LEATHERS, University of Florida, DMITRI KILIN, University of South Dakota — The short time evolution of populations of electronic states and their quantum coherence at nanostructured surfaces of semiconductors provide insight on mechanisms of electronic charge transfer and separation. Starting from atomic structure, density matrix (DM)equations of motion (EOM) have been generated from a general formulation of dissipative quantum dynamics and have been parametrized in a basis set of Kohn-Sham orbitals, for both crystalline and amorphous Si slabs [1] with metal cluster adsorbates and with group III and V dopants. Integrodifferential EOMs have been solved for an initial ground state excited by femtosecond light pulses [2] to provide the time evolution of direct and indirect electron transfer at the surfaces. Results show that one of the transfer mechanisms can lead to long term separation of electronic charge, and what material properties contribute to large charge transfer and separation.

10:48AM P41.00009 Investigation of electron-hole recombination in multi-layered quantum dots using explicitly correlated wavefunction based methods , ARINDAM CHAKRABORTY, Syracuse University — Electron-hole pairs are generated by photoexcitation of electrons to excited electronic states. Accurate calculations of electron-hole binding energies and recombination probabilities can give important insights into the photovoltaic properties of semiconductor nanocrystals and quantum dots. In the present work, the challenge of accurate treatment of electron-hole correlation is addressed by developing explicitly correlated electron-hole wavefunction that depends on electron-hole interparticle distance. The explicitly correlated ansatz for the electron-hole wavefunction is used to calculate eigenvalues and eigenfunction of the electron-hole Hamiltonian in multi-layered quantum dots using self-consistent field (SCF) and configuration interaction (CI) techniques. These methods are applied to investigate influence of the core/shell structure and chemical composition on electron-hole binding energies and recombination probabilities. The calculations indicate that for a given chemical composition there exists a optimum core/shell structure than minimizes electron-hole recombination. Comparison with experimental studies on similar system show good agreement between the experimental and computed results.

Session P42 DMP DPOLY: Focus Session: Organic Electronics and Photonics – Organic Photovoltaic Devices A302/303

8:00AM P42.00001 Increasing Transport Efficiencies of Polymer Based Solar Cells by Electrophoresis , TERRENCE WONG, CSUEB — Organic polymer photovoltaic (PV) cells are an active area of Applied Physics research because of four unique characteristics: (1) relatively inexpensive costs, (2) transparent properties, (3) flexibility, and (4) ease of mass production. We are studying the effects of incorporating single-walled carbon nanotubes (SWCNs) into a mixture of poly-(3-hexylthiophene) (P3HT), to test the affects on transport characteristics. The experiment will be segregated into parallel trials, with fixed volume ratios of P3HT:SWCNs to test the effects of (1) random orientation of SWCNs or the control, and (2) an aligned orientation of SWCNs. An electrophoresis-based technique, similar to gel electrophoresis, used to separate DNA fragments of variable masses, is used for partial alignment of the SWCN. Fixed geometry metalized substrates in a four striped copper patternare used for the transport studies and the P3HT:SWCN film's resistivity is monitored in-situ. The oriented films show enhanced conductivity, indicating this plays a major role in the increased efficiencies found in P3HT:SWCN based polymer solar cells.

8:12AM P42.00002 Transparent Carbon Nanotube layers as cathodes in OLEDs , ALEXIOS PAPADIMITRATOS, ALBERT NASIBULIN, ESKO KAUPPINEN, ANVAR ZAKHIDOV, SOLARNO INC COLLABORATION, AALTO UNIVERSITY COLLABORATION, UT DALLAS COLLABORATION — Organic Light Emitting diodes (OLEDs) have attracted high interest in recent years due to their potential use in future lighting and display applications. Reported work on OLEDs traditionally utilizes low work function materials as cathodes that are expensive to fabricate because of the high vacuum processing. Transparent carbon nanotube (CNT) sheets have excellent mechanical and electrical properties. We have already shown earlier that multi-wall (MWCNT) as well as single CNT (SWCNT) sheets can be used as effective anodes in bright OLEDs [1,2]. The true advantage of using the CNT sheets lies in flexible devices and new architectures with CNT sheet as layers in tandem devices [3] with parallel connection. In this work, we are investigating the possibility of using SWCNT as cathodes in OLEDs. SWCNT sheets have been reported to show lower work function compared to MWCNT. Our work attempts to demonstrate transparent OLED devices with CNT anodes and cathodes. In the process, OLEDs with CNT cathodes have been fabricated in normal and inverted configurations using inorganic oxides (MoO3,ZnO) as invertion layers.[1] C.D. Williams et al., Appl.Phys.Lett. 93, 1, 2008.[2] A. Kaskela et al. Nano Lett., 10,11, 4349 ,2010.[3] A. Papadimitratos et al. 8th ICEL,2010.

8:24AM P42.00003 Nanoscale electro-optical measurements of photovoltaic materials using scanning probe microscopy , NIKOLAI ZHITENEV, BEHRANG HAMADANI, PAUL HANEY, CNST, NIST, SUYONG JUNG, HUA XU, Nanocenter, UMD/ CNST, NIST — The efficiency of photovoltaic devices based on inorganic thin-films or organic polymer blends is often determined by the nanoscale structure and properties of internal and contact interfaces. Measurements of local photo-conductivity, along with other scanning probe based measurements, can link the structural properties to the performance providing the desired feedback for the device optimization. However, the nature of the tip-to-sample contact can be quite different from contact interfaces in devices strongly affecting the injection and collection of charge carriers and complicating the data analysis. Here, we present the characterization of photoconductive channels in a model bulk heterojunction organic solar cell based on a p-type polymer and n-type small molecule. We directly compare the properties of the tip-to-sample interface to the nanocontact interface. We explore the nanoscale photocurrent response on two complementary device architectures using conductive tips suitable for the appropriate charge (i.e., electrons vs. holes) collection. In addition to the measurements at the top surface, we examine the response from the bulk of the film using novel sectioning technique. Our results provide significant insight into the origin of nanoscale variations in photoresponse and nanoscale morphology of such materials.

8:36AM P42.00004 Organic and hybrid organic-inorganic photovoltaic cells , MICHAEL MCGEHEE, Stanford University — The performance and limitations of the world's best organic and dye sensitized solar cells will be presented along with plans to increase the energy conversion efficiency to 15%. Topics of more detailed discussion could include the formation of polymer-fullerene co-crystals and their implications for recombination, the use of energy transfer to improve light harvesting in dye sensitized solar cells, solution deposited transparent electrodes or the use of plasmonics to improve light absorption.

9:12AM P42.00005 Studying recombination in the bulk heterojunction solar cells using lateral solar cell geometries , CHRISTOPHER LOMBARDO, ERIC DANIELSON, ANANTH DODABALAPUR, The University of Texas at Austin — Lateral structures are shown to be a very powerful tool to understand transport and recombination phenomena in bulk heterojunction materials and solar cells. Active layers of phase separated P3HT:PCBM were chosen due to their wide use in research devices and potential for commercialization. Studies of current-voltage curves for varying carrier transit lengths have resulted in information about the movement of charge carriers as well as carrier recombination. By examining typical solar cell parameters (open circuit voltage, short circuit current, fill factor, and power conversion efficiency) combined with photocurrent measurements as a function of electrode spacing, carrier density, applied electric field, and temperature under illumination conditions (0.1 – 100 suns), we have determined how these parameters depend on the carrier concentration, electric field, and temperature. This work provides a clear picture of when bimolecular recombination dominates and also if the recombination is Langevin or non-Langevin.

9:24AM P42.00006 Scaling behavior and transport in bulk heterojunction materials , ERIC DANIELSON, CHRISTOPHER LOMBARDO, ANANTH DODABALAPUR, The University of Texas at Austin — A lateral device geometry has been used to study charge transport in P3HT:C_{71}-PCBM bulk heterojunction devices. Analysis of current-voltage curves have previously been used to study charge transport in these materials. We perform ambipolar field effect transistor measurements on these structures to extract carrier mobilities. We are also able to describe the charge transport and recombination properties of these materials. Assymetric electrodes (Al, Au) separated by 100 nm-20μm enable us to gain considerable insight into transport physics. Photocurrent measruements as a function of channel length, electric field, and illumination intensity (0.1-100 suns) are used to measure the ambipolar mobility-lifetime product and study how this correlates with measured field-effect mobilities at various electric fields. Lateral structures are shown to be a powerful tool to understand transport and the role of carrier mobility on photovoltaic performance.

9:36AM P42.00007 Charge Carrier Lifetime in Poly(3-hexylthiophe)/ZnO Nanowire Array Based Photovoltaic Devices , LEE BUTLER, WILLIAM BAUGHMAN, SHAWN DAVID WILBERT, NICK HARRIS, GANG SHEN, NABIL DAWAHRE, JOSEPH BREWER, PATRICK KUNG, SEONGSIN MARGARET KIM, The University of Alabama — Nanostructured electron donor and acceptor materials have shown potential for greatly improving the efficiency of organic photovoltaic (OPV) devices. Inorganic hybrid OPVs utilizing nanowires, nanorods and nanoparticles have been shown to greatly increase the current through P3HT based devices but have yet to achieve the efficiencies of their corresponding bulk-heterojunction OPVs. Determining the carrier properties and interface structure of these hybrid devices could greatly aid in determining limitation of the device structure on the overall efficiency. Here we report the use of terahertz, micro-Raman and micro-photoluminescence spectroscopy in determining carrier lifetime and optical properties of P3HT/ZnO based OPV devices. We will also discuss the effects of surface functionalization on the available phonon modes, carrier lifetimes and absorption properties.

9:48AM P42.00008 ABSTRACT WITHDRAWN –

10:00AM P42.00009 Spectral aspects of cavity tuned absorption in organic photovoltaics , BRENT VALLE, Case Western Reserve University, STEPHEN LOSER, JONATHAN HENNEK, Northwestern University, KENNETH D. SINGER, Case Western Reserve University, JAMES ANDREWS, Youngstown State University, TOBIN MARKS, Northwestern University — In order to increase the power conversion efficiency of organic photovoltaic devices it is necessary to extend absorption to longer wavelengths and to concentrate and capture light in a thin bulk heterojunction (BHJ) layer. In this work, optical transfer matrix formalism is used to model absorption in organic photovoltaic devices as a function of BHJ thickness and incident wavelength in the optical cavity formed by the BHJ layer sandwiched between the aluminum cathode and indium tin oxide (ITO) anode. We have found that absorption can be finely tuned by adjusting the thicknesses of the BHJ and ITO layers within a relatively narrow range. We have also observed distinct spectral effects due to frequency pulling resulting in enhanced long- wavelength absorption. Because the absorption shifts arise purely from optical interference effects, tuning of the absorption spectrum can be achieved by careful cavity design without affecting the open circuit voltage. We have experimentally verified aspects of our modeling and suggest methods to improve device design. Additionally, we consider the effects of BHJ material gradients versus depth on absorption in these devices.

10:12AM P42.00010 Probing the Thickness Limits of Organic Solar Cells using Monte Carlo Simulation[1] , MIKE HEIBER, ALI DHINOJWALA, The University of Akron — Organic solar cell performance has increased dramatically in recent years, but in order to achieve higher efficiency devices, it is imperative to understand the remaining fundamental challenges. One major shortcoming is that thin film devices cannot absorb all of the targeted incoming light due to the limited optical density of the materials used. To overcome this, thicker devices that can maintain the high quantum efficiency and high fill factor, present in thin state-of-the-art devices, must be developed. We have taken advantage of recent advancements in dynamic Monte Carlo (DMC) simulation methods to study the current-voltage (J-V) behavior of organic solar cells with different thicknesses. This method allows all detailed physical mechanisms of the device to be simulated and as a result, the effects of device morphology and a range of material properties can be captured. Studying device behavior as a function of thickness highlights the importance of the competition between light absorption and charge recombination. The effects of carrier mobility and active layer morphology are also considered. Understanding this tradeoff between absorption and recombination will help direct future experimental efforts to design optimal materials and devices.

[1]Lord Corporation and The University of Akron

10:24AM P42.00011 Dehydration assisted nanoimprint of PEDOT:PSS nanogratings to improve organic photovoltaics , YI YANG, KOYAU LEE, KAMIL MIELCZAREK, WALTER HU, ANVAR ZAKHIDOV, DEPARTMENT OF ELECTRICAL ENGINEERING, THE UNIVERSITY OF TEXAS AT DALLAS TEAM, DEPARTMENT OF PHYSICS,THE UNIVERSITY OF TEXAS AT DALLAS TEAM — We demonstrate the fabrication of oly(3,4-ethylenedioxythiophene) poly(styrenesulfonate) (PEDOT:PSS)nanograting by a dehydration assisted nanoimprint lithographic technique. Dehydration of PEDOT:PSS increases its mechanical strength for high fidelity and fine precision nanoimprinting process, resuling in formation of high quality nanogratings of 60 nmin height, 70 nm in width, and70 nm in spacing. PEDOT:PSS nanograting ar used as hole injection and electron barrier layer in blended poly(3-hexylthiophene-2,5-diyl) (P3HT)[6,6]-penyl-C61-butyric-acid-methyl-ester PCBM) rganic bulk heterojuncton photovoltaic devices (OPV), showing enhancement of photocurrent and increased efficiency in comparison to non-patterned plane PEDOT:PSS film. Improved performance is discussed in terms of increased interface for charge collection and better distribution of internal electric field.

10:36AM P42.00012 High-performance inverted polymer solar cells with ITO coated with a thin layer of oxide for electron collection , JIANYONG OUYANG, HONGMEI ZHANG, National University of Singapore — Solar cells using organic or polymeric materials as the active material have been attracting strong attention due to the low fabrication cost and high mechanical flexibility. The photovoltaic efficiency has been improved to more than 8% under AM1.5 G illumination. However, polymer solar cells are usually not very stable, which severely impedes the practical application. The stability is strongly affected by the electrodes. Both PEDOT:PSS used as the buffer layer on ITO for the hole electron and active metals like Ca for the electron collection are blamed to lower the stability of polymer solar cells. Polymer solar cells with an inverted structure can have much better stability than normal devices because they do not use PEDOT:PSS and active metals. One big challenge in building the inverted polymer solar cells is to lower the work function of ITO for effective electron collection. Here, we report a new method to effectively lower the work function of ITO by depositing a thin layer of oxide and demonstrate high-performance polymer solar cells. The photovoltaic efficiency of the inverted polymer photovoltaic cells is even higher than the normal devices. The mechanism for the oxide effect on the work function of ITO will be presented as well.

Wednesday, March 23, 2011 8:00AM - 11:00AM –
Session P43 DPOLY: Focus Session: Thin Film Block Copolymers III A306/307

8:00AM P43.00001 Effect of Well-defined Roughness on the Microdomain Orientation of Block Copolymer Thin Films , KOOKHEON CHAR, YOUNGWOO CHOO, HYO SEON SUH, TAEHEE KIM, Seoul National University — It is well known that the perpendicular orientation of block copolymer (BCP) films is preferred over the parallel orientation when the BCP films are placed on rough surfaces due to the unfavorable elastic deformation of BCP chains in the parallel oriented microdomains. More recently, the approach to utilize the rough substrate for BCP domains in long range order has been reported. However, the quantitative analysis to explore the effect of each individual roughness factors, such as lateral or vertical displacement, on the microdomain orientation of BCP films has not been thoroughly studied yet. In order to examine the roughness effect systematically, we prepared substrates with well-defined roughness utilizing either nanoparticle monolayers or line patterns generated by e-beam lithographic technique. Based on the detailed observation of the orientational change of BCP films on the well-defined surface roughness, we analyzed the dependence of BCP domain orientation on each roughness parameter. Furthermore, we found that the BCP film thickness, coated on the substrate, is another important parameter determining the orientation of microphase-separated domains of BCP thin films in addition to the surface roughness.

8:12AM P43.00002 Multiple Replicas of Block Copolymer Thin Films from a Brushless Organosilicate Substrate , HYO SEON SUH, HYUNSIK YOON, KOOKHEON CHAR, Seoul National University — The chain end-grafted polymer brushes or cross-linked polymer mats have typically been utilized as the surface modification layers to induce the perpendicular orientation of block copolymer (BCP) thin films. Instead of such polymer-based approaches, we have recently introduced a new concept to control the BCP orientation using the brushless organosilicate (OS) substrates, whose surface energy can be finely tuned with thermal treatment. In this brushless case, the BCP chains do not penetrate into the underlying hard OS substrates during thermal annealing of BCP films, therefore, the BCP chains at the interface have no entangled structure with fairly weak adhesion of BCP films against the substrate. Owing to such weak adhesion of BCP films against the OS substrate, the perpendicularly oriented BCP film on a neutral OS substrate could be easily peeled off and transferred to a UV-curable resin applied onto the BCP film. The OS substrate after the peel-off process of a BCP film could regenerate the perpendicularly oriented BCP films since the surface energy of the OS substrate remains intact during the peel-off process. Furthermore, the direct-assembled BCP films on chemically patterned OS substrates could also be peeled off and transferred on to a UV-curable resin, allowing us to produce multiple replicas of direct-assembled BCP thin films from a single chemically patterned OS substrate.

8:24AM P43.00003 Rational design of block copolymer morphologies via control of the film thickness and substrate patterning: A self consistent field study , XIANGGUI YE, BRIAN J. EDWARDS, BAMIN KHOMAMI, Materials Research and Innovative Laboratory (MRAIL), Department of Chemical and Biomolecular Engineering, University of Tennessee, Knoxville — Chemically patterned substrates can direct the assembly of adsorbed layers or thin films of block copolymers. In this study we have examined the self-assembly of a lamella-forming diblock copolymer on periodically stripe-patterned substrates, and a cylinder-forming diblock copolymer on periodically doted-patterned substrates for various film thicknesses. In general, we have shown that for thin films the morphology of the block copolymer follows the chemical pattern at the substrate; however, with an increase degree of mismatch between the spacing of the pattern and the natural spacing of bulk block copolymer, a host of novel morphologies can been created, which have not to date been experimentally realized. Our studies clearly demonstrate that the film thickness and the pattern of substrate can be judiciously manipulated to rationally design morphologies for various applications such as filtration, conduction, and high-surface area membranes. Overall, these results demonstrate a promising strategy for fabrication of complex interfacial nanostructures from chemically patterned templates.

8:36AM P43.00004 Utilizing low surface energy moieties to control surface composition of a polystyrene-b-poly(2-vinylpyridine) block copolymer , MICHAEL DIMITRIOU, Materials UC Santa Barbara, DANIEL FISCHER, NIST, CRAIG HAWKER, EDWARD KRAMER, Materials UC Santa Barbara — During processing the interaction of a block copolymer film with a free surface affects its final orientation and surface composition. A strategy to control this interaction and hence tailor the final structure of a polymer film is to introduce low surface energy moieties to the system. A lamellar forming polystyrene-b-poly(2-vinylpyridine) (PS-b-P2VP) block copolymer was synthesized with varying amounts of 1-[(3-butenyloxy)methyl]-4-vinylbenzene copolymerized with the 2VP block. Utilizing thiol-ene chemistry the pendant alkene of 1-[(3-butenyloxy)methyl]-4-vinylbenzene was functionalized with 1H,1H,2H,2H-perfluorooctanethiol to efficiently and selectively incorporate fluorinated hydrocarbons into the 2VP block. Near edge X-ray absorption fine structure spectroscopy (NEXAFS) and X-ray photoelectron spectroscopy were used to characterize the polymer surface as a function of 1H,1H,2H,2H-perfluorooctanethiol incorporation. At molar incorporations of the fluorinated monomer in P2VP greater than 4% dynamic secondary ion mass spectrometry and NEXAFS indicate a P2VP rich surface.

8:48AM P43.00005 Flexible Confinement of Block Copolymer Films Between Tunable Surface Energy Elastomeric Films and Xerogel Substrates , MANISH KULKARNI, GURPREET SINGH, Department of Polymer Engineering, University of Akron, Ohio 44325, SUSHIL SATIJA, NIST Center for Neutron Research, Gaithersburg, MD 20899, ALAMGIR KARIM[1], Department of Polymer Engineering, University of Akron, Ohio 44325 — Orientation control of block copolymer (BCP) films is important for advanced technological applications such as nanoscale lithography. Here we present a different strategy whereby both interfaces of the poly(styrene)-block-poly(methylmethacrylate) BCP films are tunably controlled. The BCP films were coated on a roughness and surface energy tunable xerogel substrates and the top surface of the polymer film was conformally covered by crosslinked PDMS elastomer. The surface energies of xerogel substrate and crosslinked PDMS is tunable from 28 and 18 mJ/m^2 to 45 and 55 mJ/m^{2}resp. via UV-Ozone treatment. The confined BCP film was then thermally annealed to induce ordering. Such a unique approach allowed the BCP films to respond in its orientation of cylinders and lamellae from parallel to perpendicular. The morphology of these micro-phase separated BCP films was studied by tapping mode atomic force microscopy and neutron reflectivity.

9:00AM P43.00006 Directed Assembly of Block Copolymer on Tunable Surface Energy Flexible Substrate , ARZU HAYIRLIOGLU, ALAMGIR KARIM, Department of Polymer Engineering, The University of Akron, Akron, OH, USA — We examine the ordering properties of micro-phase separated block copolymer (BCP) films on flexible substrates. In particular, we investigated the wettability characteristics and morphology of the BCP films before and after annealing on tunable surface energy PDMS substrates. The surface energy of PDMS substrates was modified to vary from 20 to 68 mJ/m^2 by exposing them to UV-ozone (UVO). Two types of block copolymer systems were examined on these UVO exposed PDMS substrates. Our experiments were carried out with surface energy above 42 mJ/m^2 because the BCP dewets on the PDMS substrate below that surface energy. Atomic Force Microscope (AFM) and Optical Microscope (OM) were used to study of the surface morphology of the BCP films. It was observed that the BCP morphology exhibits perpendicular orientation on PDMS substrate with surface energy in the range of 42 to 66 mJ/m^2 and parallel orientation above 67 mJ/m^2. BCP film morphology on other types of soft substrates and different BCP systems as a function of annealing temperatures and film thickness will be presented.

9:12AM P43.00007 The effect of Surface Neutrality on ODT of PS-b-PMMA films , EUNHYE KIM, SEUNGHOON CHOI, RUI GUO, DU YEOL RYU, Yonsei University, CRAIG J. HAWKER, University of California, Santa Barbara, THOMAS P. RUSSELL, University of Massachusetts, Amherst, YONSEI UNIVERSITY TEAM, UNIVERSITY OF CALIFORNIA COLLABORATION, UNIVERSITY OF MASSACHUSETTS COLLABORATION — The film transitions, the order-to-disorder transition (ODT), has been investigated in a symmetric polystyrene- b-poly(methyl methacrylate) (PS-b-PMMA) on a random copolymer (P(S-r-MMA)) grafted substrate where the interfacial interactions are balanced. With decreasing film thickness less than 25L0, the ODT significantly decreases, because the interfacial interactions by a random copolymer grafted to the substrate provide a surface-induced compatibilization toward two block components. However, a plateau of the ODT for films thicker than 25L0 was observed above the bulk value. The elevation of this ODT indicates a suppression of compositional fluctuations normal to the film surface, more than likely because the dominant orientation of the lamellar microdomains was found to be parallel to the film surface.

9:24AM P43.00008 Surface Affinity Effects On Confined Thin Film Block Copolymers Using Self Consistent Field Theory Modeling , ADAM HANNON, ALFREDO ALEXANDER-KATZ, CAROLINE ROSS, Massachusetts Institute of Technology — Self consistent field theory (SCFT) applied to inhomogeneous thin film block copolymer systems allows for the exploration of a wide array of potential equilibrium ordered morphologies at the nanoscale through varying parameters such as χ, the segmental Flory-Huggins parameter, N, the polymer degree of polymerization, and f, the volume fraction of the minority polymer component. In addition, boundary conditions of the chemical potential fields in the field theory can be specified to model surface features such as polymer brush layers and topological templating features from lithography that enrich the possible morphologies observed [Macromolecules 2010, 43, 8290–8295]. In this presentation, we show how the orientation and surface morphology of diblock copolymers with large χN varies with surface affinity, surface shape, and $f$for confined thin film systems. Surfaces neutral to both polymer species are examined, as well as surfaces preferential to both the minority and majority polymer components with fine variances in the magnitude of the surface affinity. Commensurability of the ordered structures is examined as well by varying simulation cell size. The results of the study will be applied to the generation of complex features for nanolithography applications.

9:36AM P43.00009 Stress induced topographic patterning in thin diblock copolymer films , ANDREW CROLL, North Dakota State University, ALFRED CROSBY, University of Massachusetts, Amherst — When a thin rigid polymer film is attached to a soft elastic substrate and placed in a state of compressive stress, the system wrinkles as a critical stress is surpassed. This simple deformation pattern contains information about the mechanical state of both the polymer film and substrate. Although classical mechanics can be used to relate the global deformation of the film/substrate to the local wrinkle geometry as a function of materials properties, relatively little is known about how the thin capping film material accommodates the localized bending (and therefore localized stress). Here we conduct wrinkling experiments using a model diblock copolymer/elastomer composite. Wrinkling a homogeneous, disordered block copolymer film places the film in a well-defined initial stress state. When heated above its glass transition, the wrinkled film flows, microphase separates, and relaxes from the stress imposed by local wrinkle deformations. The periodic stress relaxation leads to the emergence of a new pattern in the microphase separated surface structure, thus providing new insight into how block copolymers react to stress.

9:48AM P43.00010 Shear-induced sphere-to-cylinder transition in thin films of diblock copolymers and the role of wetting layers , ALEXANDROS CHREMOS, RICHARD REGISTER, Princeton University, PAUL CHAIKIN, New York University, ATHANASSIOS PANAGIOTOPOULOS, Princeton Unversity — The shear-induced sphere-to-cylinder transition in diblock copolymer thin films has been studied using large-scale coarse- grained Langevin dynamics simulations. At zero-shear conditions and below the order-disorder transition temperature the thin film forms a monolayer or bilayer of spheres given the thickness of the film. Mimicking the experimental setup the minority block has an affinity to be adsorbed on the confining surfaces forming brushes which interpenetrate the rest of the film. Once a shear field is applied and above a critical shear rate, the spheres elongate and merge with their neighbors to form cylinders. We find that the mechanism with which the spheres merge is closely related with the stretching of individual diblock chains. In particular, we find that in monolayer thin films it is more difficult to achieve the sphere-to-cylinder transition, which is also an experimental observation, because the brushes restrict the stretching of diblock chains. The simulations were performed with the use of Graphical Processing Units allowing large-scale simulations with long polymer chains to studied.

10:00AM P43.00011 Shear alignment of standing block copolymer lamellae in thin films , SASWATI PUJARI, MICHAEL KEATON, Princeton University, PAUL CHAIKIN, New York University, RICHARD REGISTER, Princeton University — While thin films of cylinder-forming block copolymers (BCPs) can be effective templates for striped patterns (leading to parallel nanowires), a drawback is the modest aspect ratio of the final structures, because of limited etch contrast between the two polymer blocks. Using thin films of lamellar BCPs, with the lamellae standing perpendicular to the substrate, could yield structures with larger aspect ratio. To generate parallel stripes of controlled direction, the in-plane orientation needs to be guided while preserving the out-of-plane perpendicular orientation. In this study, we have produced thin films of standing lamellae of a polystyrene/polymethylmethacrylate BCP of thicknesses up to 1.5 times the domain spacing, by neutralizing the Si substrate with a random terpolymer brush layer. To date, films less than one domain spacing thick have been aligned by shear, while shearing thicker films causes the perpendicular lamellae to switch to parallel orientation. We are currently investigating the alignment as a function of stress, film thickness, terpolymer composition and domain spacing.

10:12AM P43.00012 Defect generation in thin films of block copolymer cylinders: the effect of cylinder spacing and film thickness , VINDHYA MISHRA, EDWARD KRAMER, Univ of California Santa Barbara — Understanding the fundamental physics of disordering and defect generation in block copolymer (BCP) films is important for directed assembly based block copolymer lithography. We investigate the defect generation in, and smectic-nematic-isotropic transition temperature T_m of, monolayers and bilayers of poly (styrene-b-2vinyl pyridine) diblock copolymer cylinders aligned parallel to the substrate in 2 micron wide channels. Quantitative AFM studies were supplemented with grazing incidence small angle X-ray diffraction line-shape analysis to quantify the decay of translational and orientational correlation functions with increasing temperature. We find that T_m decreases, and the dislocation density n below T_m increases, if either the number of layers or the cylinder spacing a decreases. These results are expected since $n \sim \exp(-E_d/kT)$ and E_d, the dislocation formation energy, scales as a^2h, where h is film thickness. Since only a 10% decrease in a produces a dramatic increase in n, these results suggest that using 2D smectic structures such as BCP cylinders aligned parallel to, or BCP lamellae normal to, a substrate to produce more closely spaced features will result in patterns with more and more defects.

10:24AM P43.00013 Micelle Formation of Diblock Copolymer in a Thin Film Homopolymer: a Comparison with Polymer Brush-Coated Nanoparticles , HENGXI YANG, CHELSEA CHEN, PETER GREEN, University of Michigan — We investigated micelle formation of a diblock copolymer polystyrene-*b*-poly(2-vinylpyridine) (PS-*b*-P2VP) of degree of polymerization N, in thin films of homopolymer polystyrenes (PS) of different degrees of polymerization P, supported on substrates, and compared the results with the phase behavior of PS brush-coated Au nanoparticles in homopolymer PS matrix. PS-*b*-P2VP copolymer chains aggregated to form micelles, composed of an inner P2VP core and an outer PS corona. The size of the micelle cores, D_{core}, increased with increasing P, and reached a plateau at very large P. The transition occurred at a larger P/N than expected from brush-melt interaction theories. The organization of micelles at large P regimes suggested attractions between micelles. P2VP block also adsorbed onto the substrate to form a brush layer and the surface adsorption process was affected by micellization of copolymers. We compared the micelle formation of PS-*b*-P2VP in PS with the phase behavior of PS coated Au nanoparticle/PS mixtures: the host chains penetrate into the corona of the micelles more easily than into the PS brush grafted on the particle due to low "grafting density;" what's more, micelles can self-adjust their aggregation number as the interaction between host chains and the corona changes.

10:36AM P43.00014 Bicontinuous nanoporous block copolymer films prepared from a spherical-phase architecture , EASAN SIVANIAH, PAUL ZAVALA, KEVIN CHANNON, SANNA NATARAJ, Cambridge University, SHAHEEN AL-MUHTASEB, Qatar University — In a recent discovery, we have found a way to make a bicontinuous nanoporous polymer network and subsequently transform this into interconnected mesoporous inorganic oxide sheets. Notably, these structures arise from a spherical block copolymer template. Nanoporous materials of such architecture, both polymeric and inorganic, are rare and also extremely useful. Importantly, the process is not restricted to a single block copolymer system or a narrow range of molecular weights or compositions. All of the process steps are scaleable, fast enough to be appropriate to continuous production methods, do not require vacuum technology, and can be achieved by solution processing. We discuss the process and its use to make PLEDs, photovoltaics and filtration membranes.

10:48AM P43.00015 Arrangement of the Microdomains of Block Copolymers Confined at Hemi-sphere Walls , DU SIK BAE, JIN KON KIM, Pohang University of Science and Technology — The arrangement of the microdomains of polystyrene-*block*-poly(methyl methacrylate) copolymer (PS-*b*-PMMA) confined at hemi-sphere walls was investigated by scanning and transmission electron microscopy. The hemi-spherical constraint was introduced by using anodic aluminum oxide template.. The wall surface was modified by thin layers grafted by PS, PMMA, and PS-*ran*-PMMA copolymer. We observed interesting morphologies which have not been observed. The observed microdomain arrangement was compared with theoretical predictions.

Wednesday, March 23, 2011 8:00AM - 11:00AM –

Session P44 DPOLY: Focus Session: Assembly, Structure, & Instabilities in Polymer Films, Network Films, & Interfaces I A309

8:00AM P44.00001 An interplay between self-organization and interfacial modification of diblock copolymers in bi-layered thin film laminates , JAN GENZER, North Carolina State University — We study the interfacial partitioning of poly(styrene-b-methyl methacrylate) (SM) diblock copolymers at interfaces between thin planar films of polystyrene (PS) and poly(methyl methacrylate) (PMMA) homopolymers. SM copolymers with constant PS and varying PMMA block lengths are incorporated into the top PS layer and the resulting dewetting kinetics of the top PS film decrease by reducing the length of the PMMA block and increasing the molecular weight of the host PS homopolymer. Similar behavior is observed when the SM copolymers are added to the bottom PMMA homopolymer. Systems incorporating SM copolymers possessing short PS blocks and long PMMA blocks exhibit dewetting rates that are higher than those of the copolymer-free PS/PMMA bilayer. This behavior is attributed to the segregation of SM aggregates at the PS/PMMA interface, which migrate to and roughen the interface and destabilize the film. The dewetting kinetics of systems with mixtures of asymmetric copolymers (stabilizing and destabilizing) added in the PS homopolymer lie between those of the individual copolymers pure copolymers. Using block copolymer mixtures rather than single copolymers to tune stabilizing/compatibilizing efficacy provides an unexplored route to achieving property control in thin polymer films.

8:36AM P44.00002 Formation of Nanoparticle Stripe Patterns via Flexible-Blade Flow Coating , DONG YUN LEE, HYUN SUK KIM, CASSANDRA PARKOS, CHEOL HEE LEE, TODD EMRICK, ALFRED CROSBY — We present the controlled formation of nanostripe patterns of nanoparticles on underlying substrates by flexible-blade flow coating. This technique exploits the combination of convective flow of confined nanoparticle solutions and programmed translation of a substrate to fabricate nanoparticle-polymer line assemblies with width below 300 nm, thickness of a single nanoparticle, and lengths exceeding 10 cm. We demonstrate how the incorporation of a flexible blade into this technique allows capillary forces to self-regulate the uniformity of convective flow processes across large lateral lengths. Furthermore, we exploit solvent mixture dynamics to enhance intra-assembly particle packing and dimensional range. This facile technique opens up a new paradigm for integration of nanoscale patterns over large areas for various applications.

8:48AM P44.00003 Hierarchically Organized Structures Engineered from Controlled Evaporative Self-Assembly , ZHIQUN LIN, MYUNGHWAN BYUN, WEI HAN, Iowa State University, NED BOWDEN, University of Iowa — By constraining an asymmetric comb block copolymer (CBCP) toluene solution to evaporate in a wedge-on-Si geometry composed of a wedge lens situated on a Si substrate, gradient concentric stripe-like surface patterns of CBCP at the microscopic scale were yielded as a direct consequence of *controlled* evaporative self-assembly of CBCP. The formation of either straight stripes or jagged stripes was dictated by the height of the wedge. Upon subsequent solvent vapor annealing, hierarchically organized structures of CBCP were produced, resulting from the interplay of solvent vapor-assisted, unfavorable interfacial interaction-driven destabilization of CBCP from the Si substrate at the microscopic scale and the solvent vapor-promoted reconstruction of CBCP nanodomains within the stripes at the nanometer scale. This facile approach of combining *controlled* evaporative self-assembly with subsequent solvent vapor annealing offers a new platform to rationally design and engineer self-assembling building blocks into functional materials and devices in a simple, cost-effective manner.

9:00AM P44.00004 Wrinkling instabilities in compressed networks of polymer supported single-wall carbon nanotubes[1] , JOHN HARRIS, SWATHI IYER, NDSU, JI YEON HUH, JEFFREY A. FAGAN, JUN YOUNG CHUN, STEVEN D. HUDSON, JAN OBRZUT, CHRISTOPHER M. STAFFORD, NIST, ERIK K. HOBBIE, NDSU — Strain-induced structural and electronic changes in polymer supported membranes of purified single-wall carbon nanotubes (SWCNTs) are evaluated through the wrinkling instabilities that develop under both uniaxial and isotropic compression. Nanotubes that have been purified by length or electronic type using density-gradient ultracentrifugation are assembled as surfactant-free thin membranes on prestrained polydimethylsiloxane (PDMS) substrates, and the strain response is measured using a broad range of techniques. The small-strain behavior is inferred from kinetic changes in the wrinkling topography of the SWCNT membranes during the slow drying of pre-swelled polymer supports. The measurements suggest a remarkable degree of strain softening that strongly couples to the anisotropic sheet resistance of the films, which we in turn relate to the microscale anisotropy that develops through excluded volume interactions.

[1]Supported by the NSF through CMMI-0969155 and the DOE through DE-FG36-08GO88160

9:12AM P44.00005 Confinement-Induced Molecular Stresses and Wetting Instability in Ultrathin Polymer Films , Y. CHEIN, P.W. LEE, A.C.-M. YANG, Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan — Chain packing and molecular behavior of polymers confined below unperturbed coil sizes are still poorly understood. To explore the physical state and condensation process, molecular recoiling stresses in polystyrene films (4-100 nm) were measured through wetting instability at above T_g(100 C). The films demonstrated strikingly different instability mechanisms in regimes divided by entanglement molecular weight (M_e). Moreover, the recoiling stress decreased with chain length above M_e, consistent with the condensation process dominated by solvent evaporation, but plunged below M_e, apparently due to diminishing deformations. A small fraction of MEH-PPV added in films manifested photoluminescence (PL) following the same trend as recoiling stress confirming stress-enhanced PL characteristic of conjugated polymers. As aging temperature lowered but still above T_g, film stability increased but recoiling stress underwent significant changes, in contrast to that below T_g where no changes was observed.

9:24AM P44.00006 Nucleation and growth of creases on swelled polymer gel surfaces , JINHWAN YOON, JUNGWOOK KIM, RYAN HAYWARD, Polymer Sci & Eng, UMass Amherst, UMASS AMHERST TEAM — We have studied the processes by which surface creases form, evolve, and disappear using thin temperature-responsive poly(N-isopropylacrylamide) copolymer hydrogels. For shallow quenches beyond the critical level of compression, creases nucleate and growth, and thus the observed onset and morphology are typically dominated by heterogeneous defects. Measurements of crease growth velocities at different quench depths are used to precisely determine the compression at which the surface first becomes unstable, and this critical strain is found to be slightly elevated as film thickness is reduced. This behavior is captured by a simple model for the energy change upon forming a fold, with a nucleation barrier to fold formation provided by the gel/water surface-energy. While hysteresis between onset and disappearance is often observed in experiments, this reflects predominantly the degree of "undercooling" necessary to yield nucleation and growth of creases.

9:36AM P44.00007 Effect of polymer architecture on the interfacial properties of thin films , EMMANOUIL GLYNOS, BRADLEY FRIEBERG, PETER GREEN, University of Michigan, Ann Arbor — Many physical properties of polymers, such as phase transitions, mechanical properties, dynamics, crystallization and the glass transition, Tg, are influenced by film thickness constraints, and associated with the interactions between the constituent macromolecules and external interfaces. We show that star-shaped molecules, possessing sufficiently high functionality, exhibit significant differences in their average Tg-vs-thickness (H) behavior, both in the magnitude and the thickness dependent trends, from their linear analogs. In this talk, we will discuss the effect of polymer architecture on the interfacial properties of supported thin films, and more specifically how chain segments near the free and the solid interfaces influence the average Tg of the film. These effects are discussed in terms of the role of macromolecular architecture and entropic effects on the structure and dynamics of the polymer chains close to the interfaces, and their influence on the average properties of thin supported films.

9:48AM P44.00008 Interfacial Effects on Pentablock Ionomer Thin Films , THUSITHA ETAMPAWALA, DILRU RATNAWEERA, NARESH OSTI, UMESH SHRESTHA, DVORA PERAHIA, Department of Chemistry, Clemson University, Clemson, SC, JAROSLAW MAJEWSKI, Lujan Neutron Scattering Center, Los Alamos National Laboratory, Los Alamos, NM — The interfacial behavior of multi block copolymer thin films results from a delicate balance between inherent phase segregation due to incompatibility of the blocks and the interactions of the individual blocks with the interfaces. Here in we report a study of thin films of ABCBA penta block copolymers, anionically synthesized, comprising of centered randomly sulfonated polystyrene block to which rubbery poly-ethylenebutalene is connected, terminated by blocks of poly-t-butylstyrene, kindly provided by Kraton. AFM and neutron reflectometry studies have shown that the surface structure of pristine films depends on film thickness and ranges from trapped micelles to thin layered films. Annealing above Tg for the styrene block results in rearrangements into relatively featureless air interface. Neutron reflectivity studies have shown that annealed films forms layers whose plane are parallel to the solid substrate with the bulky block at the air interface and the ionic block at the solid interface.

10:00AM P44.00009 Directed Morphology of Nanofilled Polymer Films on Flexible Substrates , DIYA BANDYOPADHYAY, ARZU HAYIRLIOGLU, MANISH KULKARNI, ALAMGIR KARIM, Department of Polymer Engineering, The University of Akron, Akron, OH, USA — We demonstrate viable meso-patterning techniques that have relevance to electronics and organic photovoltaic applications via tunable control of polymer thin film instabilities. To this end, we examine the influence of fullerene (C_{60}) nanoparticles on multicomponent polymer thin films on patterned and flexible polydimethylsiloxane substrates and compare these results to morphologies on hard silica xerogel substrates of variable roughness and surface energy. Controlled incorporation of nanoparticles (NPs) can be used to tune polymer thin film instabilities and morphology. At NP concentrations below a threshold value, we observe directed dewetting of blend thin films consisting of uniformly aligned dewet domains that mimic the periodicity of the confining media, consistent with our previous experiments where it was observed that C_{60} NPs preferentially segregate to a PS/PB blend interface up to a certain saturation concentration.

10:12AM P44.00010 Fiber Formation From the Melting of Free-standing Polystyrene, Ultra-thin Films: A Technique for the Investigation of Thin Film Dynamics, Rheological Properties and Confinement Effects , JEREMY M. RATHFON, University of Massachusetts Amherst, ROBERT W. COHN, University of Louisville, ALFRED J. CROSBY, JONATHAN P. ROTHSTEIN, GREGORY N. TEW, University of Massachusetts Amherst — The processes of fiber formation from the melting of ultra-thin films are explored in high detail and produce a new technique for the investigation of rheological properties, confinement effects, and the dynamics of thin films and polymer chains. Ultra-thin films of polystyrene are suspended atop micro-arrays of pillars. Films are then annealed above the T_g and studied via optical microscopy. Hole nucleation is quantified with a free energy barrier based on a simple capillary model. Holes then grow exponentially in a shear thinning, high shear strain regime. These holes impinge upon each other to form suspended fibers which thin according to a model for elasto-capillary thinning of fluid filaments. Monitoring fiber thinning allows for the acquisition of rheological properties as well as the apparent extensional viscosity. The breakup of the fiber network indicates the effects of confinement on chain entanglements in ultra-thin films. A transition below a critical film thickness, comparable to the dimensions of a polymer chain, shows reduced interchain entanglements and a remarkably faster breakup of fibers.

10:24AM P44.00011 Self-Repair of Polymer Films Through Monomer Filled Ni-Zn Microcapsules , MARCIA PATCHAN, LANCE BAIRD, YO-RHIN RHIM, ERIN LABARRE, ADAM MAISANO, RYAN DEACON, JASON BENKOSKI, JHU Applied Physics Lab — A novel polymer additive composed of isocyanate resin-filled metal microcapsules has been successfully synthesized through a combination of emulsification, interfacial polymerization, and electroless Ni-Zn deposition. The resulting metallic microcapsules impart self-healing and galvanic protection capabilities to off-the-shelf primers. Once scratched, the microcapsules release their contents into the scratch, where they harden and restore the moisture barrier. If healing is incomplete, the Ni-Zn shell acts as a sacrificial anode to galvanically protect the underlying steel. ASTM adhesion, wear resistance, and moisture resistance tests evaluated the ability of microcapsule-filled primers to heal scratches, provide galvanic protection, and prevent corrosion. We found that self- healing was most effective for broad, shallow scratches (3 mm) and narrow scratches (75 μm).

10:36AM P44.00012 Structural Rearrangement of Semifluorinated Diblock copolymer Thin Films Exposed to Selective Solvents , UMESH SHRESTHA, DVORA PERAHIA, Clemson University, STEPHEN CLARSON, University of Cincinnati — A neutron reflectometry study reveals the response of a semifluorinated diblock co-polymer poly trifluoro propyl methyl siloxane -*b*- polystyrene co-polymer thin films of ca. 50-70nm, to selective solvents. This diblock forms surface induced layered structure at volume fractions of the F segment ranging from 0.03 to 0.50. When exposed to toluene, a selective solvent for PS, the film swelled instantaneously, while retaining its layered structure. The solvent however penetrates into both the PS and the semifluorinated layers. In contact with decane vapor, the solvent penetrates predominantly the top fluorinated layers. The rate of penetration increases with increasing volume fraction of the fluorinated segment. In contrast with toluene, the solvent remains at the top layer only for extended periods again retaining the layered structure. The incompatibility and specific affinity of different blocks drive structural rearrangements at the interface as a response to external stimuli, retaining the layers structure.

10:48AM P44.00013 Wetting induced instabilities in miscible polymer blends , NIGEL CLARKE, Durham University, KATHERINE THOMAS, ULLRICH STEINER, ROSA POETES, University of Cambridge, MIHAI MORARIU, DSM — The behaviour of miscible blends of polystyrene (PS)/poly(vinyl methyl ether)(PVME) of varying compositions has been investigated [1] at temperatures where PS and PVME are miscible. The PVME is seen to enrich the polymer-air surface, forming a layer with a width that is comparable to the correlation length. Further heating close to the demixing temperature results in the formation of a capillary instabilities at the polymer surface exhibiting a spinodal-like pattern with a characteristic wavelength that depends on the blend composition. Formation of these instabilities is seen for all blend compositions. We propose that these wetting induced instabilities result from coupled height and composition fluctuations in the PVME enriched surface layer, driving the build-up of long wavelength fluctuations.

Session P45 DAMOP: Unitary Fermi Gases and the BCS-BEC Crossover A310

8:00AM P45.00001 Universal physics in the dilute Fermi gases[1] , SOON YONG CHANG, MOHIT RANDERIA, NANDINI TRIVEDI, The Ohio State University — Using Quantum Monte Carlo techniques, we investigate universal properties of the repulsive upper branch as well as the superfluid ground state across the Feshbach resonance. We test the Tan relations by computing (a) the equation of state, (b) the short distance behavior of the two-particle density matrix, and (c) the large-k tail of the momentum distribution $n(k)$. We have used twisted boundary conditions to improve the approach to the thermodynamic limit, which allows us to probe $n(k)$ at a dense set of k values. We find consistent estimates of the $1/k_F a$ dependence of the contact C at $T = 0$ from all three methods. We show that, just like the superfluid ground state across the BCS-BEC crossover, the repulsive upper branch also obeys these relations, albeit with different values of C. This reflects the universal behavior of dilute Fermi gases with a short range potential, in contrast to, for instance, the hard sphere gas in the $k_F a \sim 1$ regime.

[1]We acknowledge support from ARO W911NF-08-1-0338 and NSF-DMR 0706203 and the use of computational facilities at the Ohio Supercomputer Center.

8:12AM P45.00002 Thermal distribution and the contact of Fermi gases at large scattering lengths , JOAQUIN DRUT, TIMO LAHDE, Aalto University, TIMOUR TEN, UIC — A few years ago, Tan and others derived a set of exact relations valid for strongly interacting non-relativistic Fermi gases in the regime of short interaction range and large scattering length. Recent developments have shown that a central quantity in these identities, the so-called "contact" C, actually plays a crucial role in the characterization of these systems, as it determines multiple thermodynamic properties as well as linear-response sum rules. However, computing the "contact" presents a challenge as it requires non-perturbative methods such as Quantum Monte Carlo. In this contribution, we present our first results for C as a function of temperature in the limit of infinite scattering length.

8:24AM P45.00003 Investigating the Effect of Density Inhomogenity on Photoemission Spectroscopy , TARA DRAKE, JOHN GAEBLER, RABIN PAUDEL, JILA, University of Colorado, JAYSON STEWART, JILA, University of Colorado, Los Alamos NL, DEBORAH JIN, JILA, University of Colorado — Ultracold atomic gases realize clean and controllable model systems for investigating many-body quantum physics. However, trapped gases are intrinsically spatially inhomogeneous in their density, and in many cases, one would like to compare measurements of these systems with theoretical understanding for a homogeneous gas. In particular, density inhomogeneity can complicate the interpretation of data taken in momentum space, as the original spatial information is lost during time of flight expansion. The effect of density inhomogeneity due to a harmonic trapping potential is studied in a degenerate gas of 40K atoms. Using a method to select only the atoms in the center of the trap, we study how a more homogenous sample changes what can be seen in time of flight experiments, including photoemission spectroscopy.

8:36AM P45.00004 Spectral functions in ultracold Fermi gases[1] , WILLIAM SCHNEIDER, MOHIT RANDERIA, The Ohio State University — We study the fermion spectral function in the superfluid state across the BEC-BCS crossover and in the normal Fermi liquid phase in highly imbalanced Fermi gases. We focus on features that can be measured in momentum-resolved radio frequency spectroscopy experiments. We go beyond mean field theory and include the effects of Gaussian order parameter fluctuations in a manner that gives excellent agreement with asymptotically exact results for the $T = 0$ equation of state in the BEC and BCS limits, as well as quantum Monte Carlo (QMC) results near unitarity. We show that sharp Bogoliubov quasiparticles, with a substantial coherent spectral weight, exist near unitarity. We argue that this is true generally even beyond the Gaussian approximation. In addition, quasiparticle scattering and interaction with collective modes produces incoherent spectral weight. We show that the dispersion is strongly renormalized at unitarity with its minimum shifted up from its mean field value $\sqrt{2m\mu}$ and compare our results with existing QMC data. We discuss how the spectral function changes qualitatively compared with its mean field form as $1/(k_F a)$ increases and the chemical potential changes sign.

[1]Supported by NSF-DMR 0706203 and ARO W911NF-08-1-0338.

8:48AM P45.00005 Short-range correlations and entropy in ultracold atomic Fermi gases , ZHENHUA YU, Physics Department, the Ohio State University, GEORG BRUUN, GORDON BAYM — We relate short-range correlations in ultracold atomic Fermi gases to the entropy of the system over the entire temperature, T, vs. coupling strength, .1/kF a, plane. In the low temperature limit the entropy is dominated by phonon excitations and the correlations increase as T4. In the BEC limit, we calculate a boson model within the Bogoliubov approximation to show explicitly how phonons enhance the fermion correlations. In the high temperature limit, we show from the virial expansion that the correlations decrease as 1/T. By interpolating between the two limits, we predict that the correlations reach a maximum at a finite temperature. We infer the general structure of the isentropes of the Fermi gas in the T,.1/kF a plane, and the temperature dependence of the correlations in the unitary, BEC, and BCS limits. Our results compare well with measurements of the correlations via photoassociation experiments at higher temperatures.

9:00AM P45.00006 Momentum Resolved Radio Frequency Spectroscopy in Trapped Polarized Gases , KATHRYN LEVIN, James Franck Institute and Department of Physics, University of Chicago, CHIH-CHUN CHIEN[1], HAO GUO, James Franck Institute and Department of Physics, University of Chicago — With recent advances in momentum resolved radio frequency (RF) spectroscopy, both experiment and theory, one can consider doing analogous experiments on polarized Fermi gases. In this talk we present predictions for the behavior of the fermionic spectral functions in the majority and minority bands. By truncating the integrated trap contributions at varying radii, the spectral functions will reflect the increase in the local polarization from nearly zero at the center to large values at the edges. We present predictions for these spectral functions and discuss their implications for future experiments.

9:12AM P45.00007 Observation of shock waves in a unitary Fermi gas , JAMES JOSEPH, Duke University, MANAS KULKARNI, ALEXANDER ABANOV, Stony Brook University, JOHN THOMAS, Duke University — We study the nonlinear hydrodynamics of a strongly interacting (unitary) Fermi gas comprising a 50-50 mixture of the lowest two hyperfine states of ^{6}Li near a broad Feshbach resonance at 834 G. The gas is is cooled via forced evaporation in a cigar-shaped CO_2 laser trap with a repulsive optical sheet potential at the center creating two separate clouds. When the repulsive potential is turned off and the two clouds collide we observe exotic nonlinear hydrodynamics distinguished by the formation of a very sharp and stable density peak at the center of the trap and subsequent evolution into a box-like shape with sharp edges. We attribute these characteristics to shock-wave formation in the unitary gas. By solving the hydrodynamic equations numerically we can reproduce the time dependence of the observed density profiles.

9:24AM P45.00008 Theory of shock waves in a unitary Fermi gas , ALEXANDER ABANOV, Stony Brook University, MANAS KULKARNI, Stony Brook University and Brookhaven National Laboratory, JAMES JOSEPH, JOHN THOMAS, Duke University — We present here evidence of shock wave formation during the collision of two clouds of a unitary Fermi gas. A unitary Fermi gas is an ideal test ground for extreme quantum hydrodynamics. By its very nature the system exhibits universality, i.e., the properties of the gas, constrained by an underlying scale invariance, depend entirely on the density and temperature. The nonlinear hydrodynamics exhibited in this experiment is understood by using a dimensionally reduced quasi- 1D form of the quantum hydrodynamic equations of motion. We found a near perfect agreement with the experiment. The evidence of shock wave formation is a hallmark of nonlinear physics in a universal quantum hydrodynamic system. The hydrodynamic approach works well deep in the nonlinear regime even at low density and for a system far from equilibrium.

9:36AM P45.00009 Finite Size Effects in the BCS-BEC Crossover from Functional Renormalization , MICHAEL SCHERER, Institute for Theoretical Solid State Physics, RWTH Aachen — We apply the functional renormalization group approach to the BCS-BEC crossover for an ultracold gas of fermionic atoms. Formulated in terms of a scale-dependent effective action, the functional RG interpolates continuously between the atomic or molecular microphysics and the macroscopic physics on large length scales. A systematic derivative expansion provides for both a description of the many-body physics and its expected universal features as well as an accurate account of the few-body physics and the associated BEC and BCS limits. Furthermore we put the system into a finite volume and employ periodic boundary conditions to study the effect of a finite size on the few-body scattering physics as well as the critical temperature for the phase transition to superfluidity.

9:48AM P45.00010 Effects of particle-hole channel on the behavior of BCS-BEC crossover[1] , QIJIN CHEN, Zhejiang University — BCS-BEC crossover is effected by increasing pairing strength between fermions from weak to strong. Such pairing is associated primarily with the particle-particle channel. Effects of the particle-hole channel is often dropped. On the other hand, Gor'kov et al argued that the particle-hole channel can cause a substantial reduction in both Tc and the pairing gap. However, this result has largely been neglected until recent years when BCS-BEC crossover has been realized experimentally in ultracold Fermi gases. In this talk, we study the effects of the particle-hole channel on BCS-BEC crossover in a G_0G scheme. While in the BCS limit, such effects may be approximated by a shift in the pairing strength, the situation becomes more complex as the interaction becomes stronger where the gap is no longer very small. References: Q.J. Chen, I. Kosztin, B. Janko, and K. Levin, Phys. Rev. Lett. 81, 4708 (1998); Q.J. Chen, J. Stajic, S.N. Tan, and K. Levin, Physics Reports 412, 1-88 (2005).

10:00AM P45.00011 Microscopic Approach to Viscosities in Superfluid Fermi Gases: From BCS to BEC , PETER SCHERPELZ, HAO GUO, DAN WULIN, James Franck Institute and Department of Physics, University of Chicago, CHIH-CHUN CHIEN, Los Alamos National Laboratory, KATHRYN LEVIN, James Franck Institute and Department of Physics, University of Chicago — We compute the shear viscosity, η, in a BCS-BEC crossover scheme which is demonstrably consistent, via sum rules, with conservation laws. The onset of a normal state pairing gap and the contribution from bosonic (non-condensed pair) degrees of freedom lead to a considerable reduction in the magnitude of these viscosities at general temperatures T. When quantitatively compared with shear viscosity experiments (we independently infer an estimated lifetime from radio frequency data) the agreement is reasonable, as is a comparison of η/s, where s is the trap entropy density. Our fermionic picture is to be contrasted with that of others in the literature which presume that Goldstone bosons are crucial. As in conventional BCS superconductors, we show these Goldstone bosons do not couple to transverse probes such as the shear viscosity. As a result our calculated viscosity at low T becomes arbitrarily small, rather than exhibiting the upturn predicted by others.

10:12AM P45.00012 Triply degenerate quantum mixture of ^{41}K, ^{40}K and ^{6}Li , PEYMAN AHMADI, CHENG-HSUN WU, IBON SANTIAGO, JEE WOO PARK, MARTIN ZWIERLEIN, Massachusetts Institute of Technology — We report the observation of a triply quantum degenerate mixture of ^{41}K, ^{40}K and ^{6}Li atoms. It is demonstrated that bosonic ^{41}K atom is an efficient coolant for sympathetic cooling of fermionic ^{40}K and ^{6}Li atoms. The ^{40}K and ^{6}Li mixture provides access to a strongly correlated Fermi-Fermi mixture allowing us to study superfluidity and Cooper pairing with imbalanced masses. We also present our investigation of ^{41}K and ^{40}K, a Bose-Fermi mixture where a 12 G p-wave resonance and a 40 G s-wave resonance are observed. Negligible differential gravitational sag between ^{41}K and ^{40}K makes these resonances excellent candidates for studying unexplored properties of Bose-Fermi mixtures such as Boson mediated Cooper pairing.

10:24AM P45.00013 The superfluid-insulator transition in disordered Fermi gases near unitarity , SARANG GOPALAKRISHNAN, University of Illinois at Urbana-Champaign — Superfluids, whether composed of weakly interacting fermions (i.e., in the BCS limit) or bosons (i.e., in the BEC limit), undergo quantum phase transitions into an insulating phase in the presence of strong disorder. In the BCS limit, such a transition occurs when the disorder is strong enough to overcome the fermions' kinetic energy; in the BEC limit, it occurs when the disorder is strong enough to overcome the bosons' interaction energy. We address the fate of the disorder-driven superfluid-insulator transition in the intermediate "unitary" regime, discuss the conditions under which the superfluid-insulator phase boundary is non-monotonic in this regime, and investigate the properties of the insulating phase. Our analysis is quantitatively valid at high densities or for narrow Feshbach resonances, but its qualitative implications are expected to hold beyond these regimes; it can also be adapted to show that the superfluid-insulator transition occurs at infinitesimally weak disorder for a unitary Fermi gas in four dimensions.

10:36AM P45.00014 ABSTRACT WITHDRAWN –

10:48AM P45.00015 Population imbalance and pairing in the BCS-BEC crossover of three-component ultracold fermions , TOMOKI OZAWA, GORDON BAYM, University of Illinois at Urbana-Champaign — We investigate the phase diagram and the BCS-BEC crossover of a homogeneous three-component ultracold Fermi gas with a U(3) invariant attractive interaction. We show that the system at sufficiently low temperatures exhibits population imbalance, as well as fermionic pairing. We describe the crossover in this system, connecting the weakly interacting BCS regime of the partially population-imbalanced fermion pairing state and the BEC limit with three weakly interacting species of molecules, including pairing fluctuations within a t-matrix calculation of the particle self-energies.

Wednesday, March 23, 2011 11:15AM - 1:39PM –

Session Q1 DCMP: Gapless Spin Liquids Ballroom A1

11:15AM Q1.00001 Thermal-transport Studies of Quantum Spin Liquids , MINORU YAMASHITA, Department of Physics, Kyoto University — Quantum spins, coupling antiferromagnetically on a 2D triangular lattice, cannot simultaneously satisfy all interactions. This frustrated situation is expected to give rise to mysterious fluid-like states of spins without long- range order, so called quantum spin liquid (QSL). The ground state of QSL and its exotic phenomena, such as fractionalized excitation with an artificial gauge field, have been extensively discussed for decades, yet to be identified by lack of any real materials. This is why the recent discoveries of materials possessing an ideal 2D triangular lattice have spurred a great deal of interest. To understand the nature of QSL, knowledge of the low-lying excitation, particularly the presence/absence of an excitation gap, is of primary importance. We employ thermal transport measurements on newly discovered QSL candidates, κ-(BEDT-TTF)$_2$Cu$_2$(CN)$_3$ and EtMe$_3$Sb[Pd(dmit)$_2$]$_2$, and report that the two organic insulators possess different QSLs characterized by different elementary excitations. In κ-(BEDT-TTF)$_2$Cu$_2$(CN)$_3$ [1], heat transport is thermally activated in low temperatures, suggesting presence of a spin gap in this QSL. In stark contrast, in EtMe$_3$Sb[Pd(dmit)$_2$]$_2$ [2], a sizable temperature-linear term of thermal conductivity is clearly resolved in the zero-temperature limit, showing gapless excitation with long mean free path ($\sim$1,000 lattice distances), analogous to excitations near the Fermi surface in normal metals. These results are consistent with theoretical suggestions including 2D gapless spinons with a Fermi surface. This work was done in collaboration with N. Nakata, Y. Senshu, M. Nagata, Y. Kasahara, S. Fujimoto, T. Shibauchi, Y. Matsuda, T. Sasaki, N. Yoneyama, N. Kobayashi, H. M. Yamamoto and R. Kato.

11:51AM Q1.00002 Spin liquids, spin-orbit coupling, and band topology , LEON BALENTS, Kavli Institute of Theoretical Physics — Much of the search for quantum spin liquids has focused on spin-rotationally invariant model Hamiltonians, appropriate for weakly spin-orbit coupled materials. With strong spin-orbit interactions, distinct theoretical approaches are required, and novel spin liquid states may occur. Some such candidate states will be discussed, along with the mechanisms leading to them.

12:27PM Q1.00003 Time-reversal symmetry breaking and spontaneous Hall effect without magnetic dipole order in $Pr_2Ir_2O_7$, SATORU NAKATSUJI, Institute for Solid State Physics, University of Tokyo — An electric current flowing through a conductor in a magnetic field produces a transverse voltage drop known as the Hall effect. In the absence of the field, this effect also appears in ferromagnets in a plane normal to its spontaneous magnetization vector owing to the spin-orbit coupling. Generally, it may also detect a nontrivial order parameter breaking the time-reversal symmetry on a macroscopic scale, for example, scalar spin chirality. In this talk, we present our recent results in the study of the frustrated magnetism and Hall transport of the metallic pyrochlore magnet $Pr_2Ir_2O_7$.[1,2] Strikingly, a spontaneous Hall effect is observed in the absence of both an external magnetic field and conventional magnetic long-range order.[3] This strongly suggests the existence of a chiral spin liquid, a spin-liquid phase breaking the time-reversal symmetry. Both our measurements indicate that spin-ice correlations in the liquid phase lead to a non-coplanar spin texture forming a uniform but hidden order parameter: the spin chirality. Interesting phenomena seen under high field will also be discussed. This is the work performed in collaboration with Y. Machida, Y. Ohta, T. Sakakibara, T. Tayama, Y. Uwatoko (ISSP, Univ. of Tokyo), S. Onoda (Riken, Tokyo), L. Balicas (NHMFL), D. E. MacLaughlin (UC, Riverside) and C. Broholm (JHU).

1:03PM Q1.00004 Fractional spin textures in the frustrated magnet SCGO , ARNAB SEN, Boston University — Spin liquids are remarkable states of matter that do not order magnetically even at very low temperatures and show collective phenomena like emergent gauge fields and topological order. Impurities can potentially reveal the underlying correlations in such states that appear deceptively featureless in their ground state properties. We consider the archetypal frustrated antiferromagnet $SrCr_{9p}Ga_{12-9p}O_{19}$ (SCGO) in which Ga ions act as non-magnetic impurities in the magnetic lattice composed of Cr^{3+} S=3/2 spins for disordered $p < 1$ samples. We demonstrate that a spin in direct proximity to a pair of vacancies is cloaked by a spatially extended spin texture that encodes the correlations of the parent spin liquid. In this spin liquid regime, our analytic theory predicts that the combined object has a magnetic response identical to a classical spin of length S/2=3/4, which dominates over the small intrinsic susceptibility of the pure system. We calculate the full texture on the lattice in the spin liquid regime and check that it agrees well with Monte-Carlo simulations. This fractional-spin texture leaves an unmistakable imprint on the measured ^{71}Ga nuclear magnetic resonance (NMR) lineshapes, which we compute using Monte-Carlo simulations and compare with experimental data. We also study the long-ranged interactions between these spin textures at low temperatures to gain a better understanding of the case of finite dilution in the parent spin liquid.

Wednesday, March 23, 2011 11:15AM - 2:15PM –

Session Q3 DCMP DMP: The Kavli Foundation Special Symposium: Superconductivity Centennial: Future Research Opportunities Ballroom A3

11:15AM Q3.00001 Superconductivity: A Continuous Surprise or "How I Learned to Love the Surprises" , ROBERT DYNES, University of California, San Diego — When I was invited to give this talk, I thought I would talk about new materials, or new opportunities, or the electron-phonon interaction, or non electron phonon interactions. Then when I looked at the speakers in this symposium and the subjects that they were scheduled to talk about, I realized that they were better equipped to talk individually about each of these subjects than I was, and it was my role to introduce the subject and give a perspective on the future of research and applications in superconductivity. My experience over the past decades has been that it is very dangerous to make predictions in this field. There are many examples of our distinguished colleagues who have engaged in this practice only to be proven wrong by surprise after surprise Fortunately, this has not harmed their reputations or their courage to continue to make predictions. In this talk I will reflect on my personal experience over several decades of research in superconductivity and how my own thinking has changed. Hopefully, I will

1. Transmit a flavor of this field and stimulate other younger investigators to be adventuresome
2. Prepare the audience for the talks that follow
3. Motivate the following speakers to reveal their own predictions and surprises.

11:51AM Q3.00002 Research opportunities in new superconducting materials[1] , L.H. GREENE, University of Illinois at Urbana Champaign — Since the discovery of superconductivity 100 years ago, new superconducting materials have rarely successfully been designed, with almost every new superconductor being discovered serendipitously. Through the years we have developed a variety of guidelines based on observations, but some of these guidelines remain disparate - such as, reduced dimensionality seems to give rise to higher Tc but isotropic materials would be better for applications. It is encouraging to note that this is an area where physicists, chemists, and material scientists seamlessly work together without boundaries, and ideas between groups are exchanged freely. Just as the theory of superconductivity and its development has had a major impact on how we do theoretical physics, our approach, with consilience, in searching for "better" superconductors may change the way we do experimental physics. I will present some of our guidelines and how our approach will help to provide exciting new research opportunities in superconducting materials.

[1]This work was supported by the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number DE-AC0298CH1088.

12:27PM Q3.00003 Iron-based superconductors and relevant materials:progress and opportunity[1] , HIDEO HOSONO, Tokyo Institute of Technology — Iron, a representative magnetic element, was believed to the last constituent for emergence of superconductivity because long range magnetic ordering competes with the formation of Cooper pair requisite for superconductivity. However, once LaFeAs(O,F) with Tc=26K was discovered, many iron-pnictide (chalcogenide) superconducting materials have been found and the maximum Tc reached 56K, which is next to the high Tc cuprates exceeding MgB_2. I think there are two significances in discovery of iron-based superconductors. First, we realized that magnetic element is not a hateful enemy but a powerful friend to realize high Tc superconductors. Second it provides a large opportunity to find new high Tc materials because there exist several hundreds of layered compounds containing square lattice of transition metal cations taking tetrahedral coordination with non-oxide anions. We expect materials with higher Tc and/or novel class of superconductors would be hidden among these. To our interest, the crystal structure of 122 is the same as that of a representative heavy fermion superconductor $CeCu_2T_2$(T=Si,Ge). One may expect some clue to bridge these two superconducting systems would be found. What we have not to forget is a historical fact that most of ground-breaking materials including high Tc superconductors have been discovered by serendipity in the course of concentrated exploration effort. I am anticipating new material functions would be discovered as a result of concentrated material exploration with a help of theoretical modeling and advanced characterization. Iron is the most important element led to leap of civilization. I hope iron would serve as the same role in the history of superconductivity. *Strike while the iron is hot*. I think this saying is still true for superconductivity research.

[1]This work was supported by the FIRST program, JSPS.

1:03PM Q3.00004 Exploring electron-phonon interactions in superconductors[1] , MARVIN COHEN, University of California, Berkeley — Superconductors can be roughly assigned to two classes. The first class contains materials in which the electronic pairing induced by electron-phonon interactions is the fundamental mechanism giving rise to the superconductivity. The BCS theory, together with its extensions, explains the properties of these superconductors extremely well . The second class is all other superconductors including the cuprate, Fe based, and heavy Fermion superconductors. Again, electronic pairing appears to be evident, but there is no consensus on the correct underlying theory of the superconducting mechanism at this time. I will discuss calculations for materials in the former class and describe the progress made in explaining and predicting their superconducting properties. I will emphasize calculations of the transition temperature and discuss some suggestions for raising the maximum transition temperature for materials in this class.

[1]This work was supported by National Science Foundation Grant No. DMR10-1006184 and the U.S. Department of Energy under Contract No. DE-AC02-05CH11231.

1:39PM Q3.00005 Electronic Pairing Interactions[1] , D.J. SCALAPINO, University of California, Santa Barbara — The heavy fermion, actinide, cuprate, iron-pnictide/chalcogenide and Bechgaard organic salts form a class of superconducting materials which are believed to share an electronic pairing mechanism. While the early electronic pairing interactions which were suggested involved charge fluctuations, it appears that for these materials it is the spin (and orbital) fluctuations that play a central role. Here I will discuss some of what is known about the electronic pairing interaction in this class of materials and conclude with some questions for future research.

Wednesday, March 23, 2011 11:15AM - 2:15PM –

Session Q4 DPOLY DBP: Macromolecular Crowding Effects in the Cytoplasm Ballroom A4

11:15AM Q4.00001 Formation of protein-complexes in crowded environments: from in vitro to in vivo[1] , GIDEON SCHREIBER, Dept Biological Chemistry, the Weizmann Institute of Science — Rates of protein interactions are one to five orders of magnitude slower than the theoretically calculated collision rate of spheres of the same size. The rates can be increased by favorable electrostatic forces between the two proteins. Recent studies have established that the association reaction proceeds through transient complexes, which may be specific or diffusive in nature. To bring binding studies closer to the in vivo environment, we investigated the role of crowding on binding. For crowding we added various polymers to the solution, including Dextran and PEGs of different molecular weights. While crowding enhances oligomerization and polymerization of macromolecules, it has only a small effect on the binding rates and affinities of transient protein-protein interactions. We suggest that the limited effect of crowders, which is much bellow the expected from the increased viscosity of the solutions, is a result of the occluded volume effect in high crowder concentrations. Direct measurements of the stability of the encounter complex shows that crowders slow both k1 and k-1, resulting in an increased half-life of the encounter complex. High crowder concentrations also slow k2, suggesting an increased size of the encounter region. These results fit double-mutant cycle measurements on the activated complex, which suggest an increased size of the fruitful encounter region. These results are in line with the suggested occluded volume effect of crowders. We contrasted these with the effect of crowding on the weak binding pair CyPET-YPET. On this pair, aggregation, and not enhanced dimerization, was detected in PEG solutions. The results suggest that typical crowding agents have only a small effect on specific protein-protein dimerization reactions while promoting aggregation. To further validate these results, we performed real time binding assays in living cells, showing that even in the crowded cellular environment binding can be fast and specific.

[1]This research is supported by the Israel Science Foundation.

11:51AM Q4.00002 Crowding effects on protein association , ARUN YETHIRAJ, University of Wisconsin–Madison — The cell cytoplasm is a dense environment where the presence of inert cosolutes can significantly alter the rates of protein folding and protein association reactions. These crowding effects can either increase or decrease the rates of association reactions (or protein folding) depending on the nature of the crowding agents and the type of reaction. Our work aims to obtain a quantitative understanding of crowding effects. We present the first kinetic study of the effect of hard sphere crowding agents on protein association reactions where reactants and crowding agents are both hard spheres. If every collision results in a reaction, crowding always decreases the reaction rate but if the probability of a reaction is low then crowding increases the reaction rate. We find that the thermodynamics of crowding are relatively insensitive to interactions between the crowding agents suggesting that the hard sphere model of crowding agents has a surprisingly large regime of validity, and should be sufficient for a qualitative understanding of the thermodynamics of crowding effects.

12:27PM Q4.00003 Protein structure, stability and folding in the cell – *in silico* biophysical approaches[1] , MARGARET CHEUNG, University of Houston — How the crowded environment inside a cell affects the structural conformation of a protein with aspherical shape is a vital question because the geometry of proteins and protein-protein complexes are far from globules in vivo. Here we address this question by combining computational and experimental studies of several aspherical proteins (calmodulin, VlsE, and phosphoglycerate kinase) under crowded, cell-like conditions. The results show that macromolecular crowding affects protein folding dynamics, structures and functions. Our work demonstrates the malleability of "native" proteins and implies that crowding-induced shape changes may be important for protein function and malfunction in vivo.

[1]Source of Support: National Science Foundation, Molecular & Cellular Biosciences (MCB0919974).

1:03PM Q4.00004 Phosphoglycerate kinase in crowded and cellular environments , SIMON EBBINGHAUS, Ruhr-University Bochum — We developed the temperature-jump fluorescence microscope to spatio-temporally resolve fast biomolecular kinetics and stability inside a single mammalian cell. We measured the reversible fast folding kinetics as well as folding thermodynamics of a fluorescent phosphoglycerate kinase construct in a bone marrow cell with subcellular resolution. The same instrument was also used to perform the comparative in vitro measurement in dilute buffer and crowded environments. Investigating an ensemble of cells, each cell has its own unique kinetic signature that can differ substantially from the in vitro result. Variations in the cytoplasmic environment are significant modulators of the protein energy landscape. We quantitate these variations with a statistical analysis of multiple cells and compare folding dynamics on the nm length scale with μm length scale diffusion processes. Cytoplasmic energy landscape modulation may be a candidate for non-genetic regulation of proteins but also challenges protein homeostasis.

1:39PM Q4.00005 Crowding and hydrodynamic interactions likely dominate in vivo macromolecular motion , JEFFREY SKOLNICK, Georgia Institute of Technology — To begin to elucidate the principles of intermolecular dynamics in the crowded environment of cells, employing brownian dynamics (BD) simulations, we examined possible mechanism(s) responsible for the great reduction in diffusion constants of macromolecules in vivo from that at infinite dilution. In an Escherichia coli cytoplasm model comprised of 15 different macromolecule types at physiological concentrations, BD simulations of molecular-shaped and equivalent sphere representations were performed with a soft repulsive potential. At cellular concentrations, the calculated diffusion constant of GFP is much larger than experiment, with no significant shape dependence. Next, using the equivalent sphere system, hydrodynamic interactions (HI) were considered. Without adjustable parameters, the in vivo experimental GFP diffusion constant was reproduced. Finally, the effects of nonspecific attractive interactions were examined. The reduction in diffusivity is very sensitive to macromolecular radius with the motion of the largest macromolecules dramatically slowed down; this is not seen if HI dominate. In addition, long-lived clusters involving the largest macromolecules form if attractions dominate, whereas HI give rise to significant, size independent intermolecular dynamic correlations. These qualitative differences provide a testable means of differentiating the importance of HI vs. nonspecific attractive interactions on macromolecular motion in cells.

Wednesday, March 23, 2011 11:15AM - 2:15PM –

Session Q5 FIAP: The Physics of Confronting Weapons of Mass Destruction: Chemical, Biological and Nuclear Ballroom C1

11:15AM Q5.00001 Physics in the Confrontation of Nuclear Weapons , JAMES TOEVS, James W. Toevs Consulting — Had the detonations on 9/11 involved nuclear explosives rather than jet fuel the number of deaths and the costs would have been multiplied by 100 or 1,000. This talk will briefly describe the nuclear threat and then focus on the technologies, both extant and evolving, for the detection and interdiction of clandestine trafficking of nuclear weapons and nuclear and radiological material. The methods vary from passive detection of heat, gamma radiation, neutrons, or other signatures from nuclear material, through radiological approaches to examine contents of vehicles and cargo containers, to active interrogation concepts that are under development. All of these methods have major physics components ranging from simple gamma ray detection as learned in a senior undergraduate lab to the latest ideas in muon production and acceleration.

11:51AM Q5.00002 Discrimination and classification of bio-aerosol particles using optical spectroscopy and scattering , JAY D. EVERSOLE, Naval Research Laboratory — For more than a decade now, there has been significant emphasis for development of sensors of agent aerosols, especially for biological warfare (BW) agents. During this period, the Naval Research Laboratory (NRL) and other labs have explored the application of optical and spectroscopic methods relevant to biological composition discrimination to aerosol particle characterization. I will first briefly attempt to establish the connection between sensor performance metrics which are statistically determined, and aerosol particle measurements through the use of computational models, and also describe the challenge of ambient background characterization that would be needed to establish more reliable and deterministic sensor performance predictions. Greater attention will then be devoted to a discussion of basic particle properties and their measurement. The NRL effort has adopted an approach based on direct measurements on individual particles, principally of elastic scatter and laser-induced fluorescence (LIF), rather than populations of particles. The development of a LIF instrument using two sequential excitation wavelengths to detect fluorescence in discrete spectral bands will be described. Using this instrument, spectral characteristics of particles from a variety of biological materials including BW agent surrogates, as well as other "calibration" particles and some known ambient air constituents will be discussed in terms of the dependence of optical signatures on aerosol particle composition, size and incident laser fluence. Comparison of scattering and emission measurements from particles composed of widely different taxa, as well as from similar species under different growth conditions highlight the difficulties of establishing ground truth for complex biological material compositions. One aspect that is anticipated to provide greater insight to this type of particle classification capability is the development of a fundamental computational model of fluorescent emission for a particle of known composition but arbitrary size and shape. Finally if time permits, I will review the recent development and use of a 40 MHz mode-locked 524 nm laser source to evaluate the utility of sub-picosecond excitation of fluorescence with 2-photon absorption in biological aerosols.

12:27PM Q5.00003 Minimizing the bioterrorist threat: Fear, fancy, folly, and physics , PHILIP WYATT, Wyatt Technology Corporation — There can be little doubt that a bioterrorist attack represents one of the most significant dangers facing the Nation today. It is cheap, relatively easy to use, and can produce huge casualties and significant financial losses. Because of its apparent simplicity, there has been a great amount of attention directed towards developing means for early detection of an attack in progress. Most developmental funding for protective strategies comes from the Federal government: DoD is focused on protecting the military (personnel and facilities) whereas DoHS is most concerned with civilian response (police, triage, epidemiology, cure). Associated with such activities are some pretty amazing ideas both concerning the threat and means to detect its presence. These include the belief that certain bioterrorist attacks could equal the consequences of a nuclear weapon, that crop dusters with the proper agents could wipe out a city, that if it "glows" (i. e. is fluorescent) it must be an agent, or even that gravitational forces are actually far greater than believed. From the early warning side of things, the huge costs associated with a false positive call have resulted in the generally recognized need to identify before any alarm is triggered. Some consequences of this strategy have been the development of so-called smart chips and even handheld mass spectrometers! A brief review of some of these devices and the physics required for their success is discussed. An approach based upon some simple features of inverse scattering theory is proposed whereby identification may be unnecessary.

1:03PM Q5.00004 Physics and National Security: The Spectrum of Opportunities , JAY DAVIS, The Hertz Foundation — Physicists reflexively tend to approach their role in addressing national security problems by reaching for technologies and inventing devices or systems. While this is appropriate, the space for contribution is much larger. The application of technology is frequently constrained by doctrinal, operational, financial, and logistic constraints, not to mention those of security. The speaker, who has played a role in technology development, field operations, advisory processes, and policy considerations will discuss the role physicists can have in definition of the threat space, creation and assessment of technologies needed, and helping with response and recovery. In particular, he will address the opportunities and risks for both academic and industrial physicists in trying to assist in these matters, i.e., when in career to address such problems, what are the obstacles or consequences, and when do you know you have contributed?

1:39PM Q5.00005 Detecting Chemical Weapons: Threats, Requirements, Solutions, and Future Challenges , BRIAN BOSO, Smiths Detection — Although chemicals have been reportedly used as weapons for thousands of years, it was not until 1915 at Ypres, France that an industrial chemical, chlorine, was used in World War I as an offensive weapon in significant quantity, causing mass casualties. From that point until today the development, detection, production and protection from chemical weapons has be an organized endeavor of many of the world's armed forces and in more recent times, non-governmental terrorist organizations. The number of Chemical Warfare Agents (CWAs) has steadily increased as research into more toxic substances continued for most of the 20^{th} century. Today there are over 70 substances including harassing agents like tear gas, incapacitating agents, and lethal agents like blister, blood, chocking, and nerve agents. The requirements for detecting chemical weapons vary depending on the context in which they are encountered and the concept of operation of the organization deploying the detection equipment. The US DoD, for example, has as a requirement, that US forces be able to continue their mission, even in the event of a chemical attack. This places stringent requirements on detection equipment. It must be lightweight (<2 lbs), detect a large array of chemical warfare agents and toxic industrial chemicals, detect and warn at concentration levels and time duration to prevent acute health effects, meet military ruggedness specifications and work over a wide range of temperature and humidity, and have a very high probability of detection with a similarly low probability of false positives. The current technology of choice to meet these stringent requirements is Ion Mobility Spectrometry. Many technologies are capable of detecting chemicals at the trace levels required and have been extensively developed for this application, including, but not limited to: mass spectroscopy, IR spectroscopy, RAMAN spectroscopy, MEMs micro-cantilever sensors, surface acoustic wave sensors, differential mobility spectrometry, and amplifying fluorescence polymers. In the future the requirements for detection equipment will continue to become even more stringent. The continuing increase in the sheer number of threats that will need to be detected, the development of binary agents requiring that even the precursor chemicals be detected, the development of new types of agents unlike any of the current chemistries, and the expansion of the list of toxic industrial chemical will require new techniques with higher specificity and more sensitivity.

Wednesday, March 23, 2011 11:15AM - 2:15PM –
Session Q6 DCOMP: Hydrogen Storage Materials Ballroom C2

11:15AM Q6.00001 First-Principles Prediction of Crystal Structures, Reaction Pathways, and Intermediate Products in Hydrogen Storage Reactions[1] , CHRIS WOLVERTON, Northwestern University — Practical hydrogen storage for mobile applications requires materials that exhibit high hydrogen densities, low decomposition temperatures, and fast kinetics for absorption and desorption. Unfortunately, no reversible materials are currently known that possess all of these attributes. Here we present an overview of our recent efforts aimed at developing a first-principles computational approach to the discovery of novel hydrogen storage materials. We have developed computational tools which enable accurate prediction of decomposition thermodynamics, crystal structures for unknown hydrides, and thermodynamically preferred decomposition pathways. We present examples that illustrate each of these three capabilities. Specifically, we focus on recent work on crystal structure and dehydriding reactions of (i) borohydride materials, such as $Ca(BH_4)_2$ and $Mg(BH_4)_2$, (ii) amidoboranes and their decomposition products, and (iii) mixtures of complex hydrides.

11:51AM Q6.00002 Towards predictor based design of thermodynamic and kinetic properties of complex materials for hydrogen storage , JENS HUMMELSHOEJ, Technical University of Denmark — A calculational approach for the design of new complex materials for hydrogen storage with favorable thermodynamic stability and enhanced diffusion kinetics is presented. By combining density functional theory (DFT) calculations on stable crystal structures and local coordination models with database methods, we perform large-scale screening studies to determine a number of potential alloys/mixtures with favorable thermodynamic stabilities and identify simple descriptors for subsequent materials prediction. Predictors for the kinetic properties of the materials are derived from combining materials screening with path techniques and harmonic transition state theory (TST) to indentify materials parameters, e.g. the hydrogen binding energy, which correlate with the macroscopic diffusion rates. These predictors are then used to design new alloy/mixture compositions and ratios to favor structures with optimal diffusion kinetics. We present results from binary and ternary alkali-transition metal borohydrides and Perovskite based hydrogen permeable membranes, as well as results from studies of binary and mixed metal ammines. Results from the modeling of pathways and rates of dynamical processes involved in the ab-/desorption mechanisms will also be presented and compared to quasi elastic neutron scattering data.

12:27PM Q6.00003 Theory of molecular hydrogen sorption for hydrogen storage[1] , SHENGBAI ZHANG, Department of Physics, Applied Physics and Astronomy, Rensselaer Polytechnic Institute — Molecular hydrogen (H_2) sorption has the advantage of fast kinetics and high reversibility. However, the binding strength is often too weak to be operative at near room temperatures. Research into such hydrogen sorption materials has branched into the study of pure van der Waals (vdW) physisorption and that of weak chemisorption (known to exist in the so-called Kubas complexes). In either case, however, theoretical tools to describe such weak interactions are underdeveloped with error bars that often exceed the strength of the interaction itself. We have used quantum-chemistry (QC) based approaches to benchmark the various available DFT methods for four classes of weak chemisorption systems [Sun et al., Phys. Rev. B **82**, 073401 (2010)]. These involve complexes containing Li, Ca, Sc, and Ti with increased strength of H_2 binding from predominantly vdW to mostly Kubas-like. The study reveals that most of the DFT functionals within the generalized gradient approximation underestimate the binding energy, oppose to overestimating it. The functionals that are easy to use yet yielding results reasonably close to those of accurate QC are the PBE and PW91. I will also discuss the effort of implementing vdW interaction into the currently available density functional methods [Sun, J. Chem. Phys. **129**, 154102 (2008)]. The rationale is that while the true vdW is an electron-electron correlation, a DFT plus classical dispersion approach may be too simple and unnecessary within the DFT. A local pseudopotential approach has been developed to account for the core part of the polarizability of the elements. Applications to a number of benchmark systems yield good agreement with QC calculations. The application of this method and the QC methods to vdW hydrogen binding will also be discussed.

1:03PM Q6.00004 Point-defect-mediated dehydrogenation of alane[1] , LARS ISMER, University of California, Santa Barbara — For the engineering of better hydrogen storage materials a systematic understanding of their hydrogen sorption kinetics is crucial. Theoretical studies on metal hydrides have indicated that in many cases point defects control mass transport and hence hydrogen uptake and release. Manipulating point-defect concentrations thus allows control over hydrogen sorption kinetics, opening up new engineering strategies. However, in some cases the relevance of kinetic limitations due to point defects is still under debate; kinetic inhibition of hydrogen sorption has also been attributed to surface effects, e.g. oxide layers or low recombination rates. We present a systematic analysis of the dehydrogenation kinetics of alane (AlH3), one of the prime candidate materials for hydrogen storage. Using hybrid-density functional calculations we determine the concentrations and mobilities of point defects and their complexes. Kinetic Monte Carlo simulations are used to describe the full dehydrogenation reaction. We show that under dehydrogenation conditions charged hydrogen vacancy defects form in the crystal, which have a strong tendency towards clustering. The vacancy clusters denote local nuclei of Al phase, and the growth of these nuclei eventually drives the AlH3/Al transformation. However, the low concentration of vacancy defects limits the transport of hydrogen across the bulk, and hence acts as the rate-limiting part of the process. The dehydrogenation is therefore essentially inactive at room temperature, explaining why AlH3 is metastable for years, even though it is thermodynamically unstable. Our derived activation energy and dehydrogenation curves are in excellent agreement with the experimental data, providing evidence for the relevance of bulk point-defect kinetics.

[1]Work performed in collaboration with A. Janotti and C. G. Van de Walle, and supported by DOE.

1:39PM Q6.00005 Kinetics of hydrogen transport in metal hydrides, crystalline alloys, and amorphous metals , DAVID SHOLL, Georgia Tech — The diffusion of hydrogen is critical in the kinetics of hydrogen uptake and release in metal hydrides and in membrane-based approaches to hydrogen purification. First principles calculations have become a valuable counterpart to experimental methods to study hydrogen diffusion. Examples will be presented of using first principles calculations to understand hydrogen diffusion in a diverse range of solid materials, including metal hydrides in their bulk state and near interfaces, crystalline alloys for membrane applications, and amorphous metals for membrane applications.

Wednesday, March 23, 2011 11:15AM - 2:15PM –

Session Q7 DBP DCP: System Biology III: The Physics of Evolution Ballroom C3

11:15AM Q7.00001 Does Tumor Development Follow a Programmed Path?[1] , ROBERT AUSTIN, Princeton University — The initiation and progression of a tumor is a complex process, resembling the growth of a embryo in terms of the stages of development and increasing differentiation and somatic evolution of constituent cells in the community of cells that constitute the tumor. Typically we view cancer cells as rogue individuals violating the rules of the games played within an organism, but I would suggest that what we see is a programmed and algorithmic process. I will then question If tumor progression is dominated by the random acquisition of successive survival traits, or by a systematic and sequential unpacking of "weapons" from a pre-adapted "toolkit" of genetic and epigenetic potentialities? Can we then address this hypothesis by data mining solid tumors layer by layer?

[1]Support of the NSF and the NCI is gratefully acknowledged.

11:51AM Q7.00002 Adaptation Driven by Spatial Heterogeneities[1] , RUTGER HERMSEN, Center for Theoretical Biological Physics, University of California, San Diego, CA, USA — Biological evolution and ecology are intimately linked, because the reproductive success or "fitness" of an organism depends crucially on its ecosystem. Yet, most models of evolution (or population genetics) consider homogeneous, fixed-size populations subjected to a constant selection pressure. To move one step beyond such "mean field" descriptions, we discuss stochastic models of evolution driven by spatial heterogeneity. We imagine a population whose range is limited by a spatially varying environmental parameter, such as a temperature or the concentration of an antibiotic drug. Individuals in the population replicate, die and migrate stochastically. Also, by mutation, they can adapt to the environmental stress and expand their range. This way, adaptation and niche expansion go hand in hand. This mode of evolution is qualitatively different from the usual notion of a population climbing a fitness gradient. We analytically calculate the rate of adaptation by solving a first passage time problem. Interestingly, the joint effects of reproduction, death, mutation and migration result in two distinct parameter regimes depending on the relative time scales of mutation and migration. We argue that the proposed scenario may be relevant for the rapid evolution of antibiotic resistance.

[1]This work was supported by the Center for Theoretical Biological Physics sponsored by the National Science Foundation (NSF) (Grant PHY-0822283).

12:27PM Q7.00003 Experimental Ignition of Evolution on Fitness Landscapes , KRISTELLE ROBIN, Institute for Advanced Studies, HKUST — Microbiologist are starting to revise the single cell centered view of evolution to a multicellular view, considering it at entire population scale, and even whole ecosystem. Indeed, as Darwin recognized on the Galapagos Island, evolution of a community of bacteria is strongly influenced by the global spatial stress and depends of the neighboring communities. This collective dynamical process can be studied using micro-nanofabricated landscape to create stressed conditions. Our microfluidic device consists of interconnected chambers in 2D hexagonal geometries. The design of our ecology enables to combine gradients of antibiotic and nutrient, thus generating population gradient and motion of bacteria across them. We study here evolution of resistance to the antibiotic ciprofloxacin in highly-stressed conditions. Non-random mutations are induced in the collectivity to develop resistance to the antibiotic. Channels between microhabitats allow motion of bacteria between different islands, and once evolution is ignited in a local metapopulation, a very fast spread through the collectivity happens. In such environments, evolution is observed in typical time scales of few hours. Knowing the complexity of natural world, we believe that our approach provide a model to understand the rapid emergence of resistance to antibiotic and its spread in the entire population.

1:03PM Q7.00004 Towards a Quantitative Endogenous Network Theory of Cancer Genesis and Progression: beyond "cancer as diseases of genome"[1] , PING AO, Shanghai Jiaotong University — There has been a tremendous progress in cancer research. However, it appears the current dominant cancer research framework of regarding cancer as diseases of genome leads impasse. Naturally questions have been asked that whether it is possible to develop alternative frameworks such that they can connect both to mutations and other genetic/genomic effects and to environmental factors. Furthermore, such framework can be made quantitative and with predictions experimentally testable. In this talk, I will present a positive answer to this calling. I will explain on our construction of endogenous network theory based on molecular-cellular agencies as dynamical variable. Such cancer theory explicitly demonstrates a profound connection to many fundamental concepts in physics, as such stochastic non-equilibrium processes, "energy" landscape, metastability, etc. It suggests that neneath cancer's daunting complexity may lie a simplicity that gives grounds for hope. The rationales behind such theory, its predictions, and its initial experimental verifications will be presented.

1:39PM Q7.00005 Understanding the distribution of fitness effects of mutations by a biophysical-organismal approach , SHIMON BERSHTEIN, Harvard University — The distribution of fitness effects of mutations is central to many questions in evolutionary biology. However, it remains poorly understood, primarily due to the fact that a fundamental connection that exists between the fitness of organisms and molecular properties of proteins encoded by their genomes is largely overlooked by traditional research approaches. Past efforts to breach this gap followed the "evolution first" paradigm, whereby populations were subjected to selection under certain conditions, and mutations which emerged in adapted populations were analyzed using genomic approaches. The results obtained in the framework of this approach, while often useful, are not easily interpretable because mutations get fixed due to a convolution of multiple causes. We have undertaken a conceptually opposite strategy: Mutations with known biophysical and biochemical effects on E. coli's essential proteins (based on computational analysis and in vitro measurements) were introduced into the organism's chromosome and the resulted fitness effects were monitored. Studying the distribution of fitness effects of such fully controlled replacements revealed a very complex fitness landscape, where impact of the microscopic properties of the mutated proteins (folding, stability, and function) is modulated on a macroscopic, whole genome level. Furthermore, the magnitude of the cellular response to the introduced mutations seems to depend on the thermodynamic status of the mutant.

Wednesday, March 23, 2011 11:15AM - 2:15PM –
Session Q8 GMAG: New Developments in Organic Spintronics Ballroom C4

11:15AM Q8.00001 Spin Injection/detection using organic-based magnetic semiconductor , ART EPSTEIN, Ohio State University — This abstract not available.

11:51AM Q8.00002 Magnetic Field Effect in Organic Devices: the Role of Hyperfine, Exchange and Spin Orbit Interactions , EITAN EHRENFREUND, Physics Dept., Technion-Israel Institute of Technology — Recently we have observed a novel phenomenon in both magneto-electroluminescence (MEL) and magneto-conductance (MC) in a variety of organic light emitting diodes that consists of a sign reversal at very small magnetic fields ($B \leq$1 mT), dubbed hereafter ultra-small magnetic field effect (USMFE) [1]. Similar response has been obtained in MC(B) of unipolar organic diodes [2]. As B is reduced below the zero crossing field, the magnitude of the obtained MEL and MC increases to a maximum value at $B = B_m$, before diminishing at B=0. We found that B_m is isotope dependent: it is lower when the protons in the organic material are replaced by deuterons having a smaller nuclear magnetic moment and reduced hyperfine interaction (HFI), and is higher when the ^{12}C atoms (nuclear spin I=0, no HFI) are replaced by ^{13}C atoms (I=$1/2$, with finite HFI). We also found that B_m scales with the half width at half maximum, ΔB, of the high field response. From the MEL(B) and MC(B) responses, the marked isotope effect, and voltage and temperature dependencies we explain the USMFE as well as the width ΔB, as due to loosely coupled pairs of polarons (either with same or opposite charges) of which spins are intermixed via the HFI [1,2]. The model captures the sign reversal and its dependence on the HFI strength. The role of the HFI anisotropy, exchange interaction between the polaron pair spins, and spin orbit interaction effect on the USMFE will be discussed. *Supported by the Israel Science Foundation grant 745/08, and NSF grant DMR 08-03325. **In collaboration with T. D. Nguyen, B. R. Gautam, and Z. V. Vardeny, University of Utah.

12:27PM Q8.00003 Molcular spntronics: tailoring spin polarization with molecules , PIERRE SENEOR, Unite Mixte de Physique CNRS/thales — Organic/molecular spintronics is a rising research field at the frontier between spintronics and organic chemistry. Organic molecules and semiconductors were first seen as promising for spintronics devices due to the expected long spin lifetime. An exciting challenge is now to find opportunities arising from chemistry to develop new spintronics functionalities that were unavailable with inorganic materials. Here one can hope to control the spin dependent transport by using the chemical versatility brought by molecules and molecular engineering. Starting from the use of Alq3 and Phthalocyanine molecules we will show how the ferromagnetic metal/molecule hybridization can strongly influence the interfacial spin properties: from spin polarization enhancement to its sign control. CNRS/Thales team: C. Barraud, P. Seneor, R. Mattana, S. Tatay, K. Bouzehouane, S. Fusil, C. Deranlot, F. Petroff, A. Fert in collaboration with ISMN, Bologna, Italy & IPCMS, Strasbourg, France

1:03PM Q8.00004 Spin relaxation in organic semiconductors , PETER BOBBERT, Technische Universiteit Eindhoven — Intriguing magnetic field effects in organic semiconductor devices have been reported: anomalous magnetoresistance in organic spin valves and large effects of small magnetic fields on the current and luminescence of organic light-emitting diodes. Influences of isotopic substitution on these effects points at the role of hyperfine coupling. We performed studies of spin relaxation in organic semiconductors based on (i) coherent spin precession of the electron spin in an effective magnetic field consisting of a random hyperfine field and an applied magnetic field and (ii) incoherent hopping of charges. These ingredients are incorporated in a stochastic Liouville equation for the dynamics of the spin density matrix of single charges as well as pairs of charges. For single charges we find a spin diffusion length that depends on the magnetic field, explaining anomalous magnetoresistance in organic spin valves. For pairs of charges we show that the magnetic field influences formation of singlet bipolarons, in the case of like charges, and singlet and triplet excitons, in the case of opposite charges. We can reproduce different line shapes of reported magnetic field effects, including recently found effects at ultra-small fields.

1:39PM Q8.00005 Coherent spin spectroscopy in organic thin film semiconductor devices[1] , CHRISTOPH BOEHME, University of Utah, Department of Physics and Astronomy — With the emergence of organic spintronics and renewed interest in magnetoresistive effects, there is much need to illuminate the properties of spins in molecular electronic materials. Examples include spin-relaxation times, spectral diffusion times, spin dephasing times and spin interactions. In this presentation, an overview is given about the concepts of pulsed, electrically and optically detected magnetic resonance spectroscopy as techniques to manipulate and observe and thus characterize these fundamental properties of electron and nuclear spins in organic semiconductors [1]. By coherent (pulsed) magnetic resonant perturbation of spin states one may cause the spins to coherently propagate in a defined manner [2]. Spin-dependent charge carrier-transport or -recombination allow the observation of this coherent spin motion through electrical or optical measurements in working devices, such as organic light-emitting diodes. The ubiquitous presence of hydrogen nuclei gives rise to strong hyperfine interactions, which appear to provide the basis for many of the magnetoresistive effects observed in these materials. Since hyperfine coupling influences resonantly driven quantum spin beating in electrically or optically detectable electron-hole pairs, an extraordinarily sensitive probe for hyperfine fields in such pairs is given [3]. This allows scrutinizing the various existing models for these electronic processes. Qualitative as much as quantitative insights are gained into some of the physical intricacies of organic semiconductor device fabrication such as the influence of contact materials on spin-orbit coupling.

Wednesday, March 23, 2011 11:15AM - 2:03PM –
Session Q9 DFD: Fluid Dynamics at Interfaces D220

11:15AM Q9.00001 Slosh dynamics and rebound suppression of a partially filled sphere , TAYLOR KILLIAN, Brigham Young University Dept. Mathematics, ROBERT KLAUS, TADD TRUSCOTT, Brigham Young University Dept. Mechanical Engineering — We introduce a study on the slosh dynamics of a partially filled elastic sphere. Currently the physical design of fluid-filled containers utilizes clever construction and machinery to mitigate sloshing motions. There are numerous cases that have been observed but we focus on the impact of a sphere under free fall with an initially undisturbed free surface. The study focuses on measurement and simulation of the force distribution between the fluid and the sphere through the use of high-speed imaging and finite element analysis. Using the cavity shape data, a potential flow numerical model is developed that predicts the unsteady forces. Our hypothesis is that the sphere's movements can be counteracted or cancelled by the exchange of energy between the sphere and the fluid. Forces are modulated by the formation of a parabolic cavity in the fluid, formed after the first impact. The second impact results in a collapse of this cavity forming a powerful jet which effectively dampens the motion of the sphere.

11:27AM Q9.00002 Shrinking Instabilities of Toroidal Liquid Droplets in The Stokes Flow Regime , ZHENWEI YAO, MARK BOWICK, Syracuse University — We analyze the stability and dynamics of toroidal liquid droplets. In addition to the Rayleigh instabilities akin to those of a cylindrical droplet there is a shrinking instability that is unique to the topology of the torus and dominates in the limit that the aspect ratio is near one (fat tori). We first find an analytic expression for the pressure distribution inside the droplet. We then determine the velocity field in the bulk fluid, in the Stokes flow regime, by solving the biharmonic equation for the stream function. The flow pattern in the external fluid is analyzed qualitatively by exploiting symmetries. This elucidates the detailed nature of the shrinking mode and the swelling of the cross-section following from incompressibility. Finally the shrinking rate of fat toroidal droplets is derived by energy conservation.

11:39AM Q9.00003 Normal elasticity of liquid bridge by atomic force microscope[1] , BONGSU KIM, WONHO JHE, Seoul National University, CENTER FOR NANO-LIQUID TEAM — The quartz tuning-fork based atomic force microscope (QTF-AFM) has previousely been established as a suitable measurement technique for investigating liquid bridges. By operating a QTF-AFM in the non-contact tapping mode, we are able to measure the normal elasticity of liquid bridges that are formed via capillary condensation or that result from an adsorbed liquid layer. Elasticity, a property typically associated with solids, is studied here for the case of the nano-scale water bridge. We present results that add to our understanding of the origin of the elasticity in nano liquid bridges.

[1]Work supported by Korean Ministry of Science and Technology.

11:51AM Q9.00004 Droplet impact and the dynamics of rapidly moving contact lines , SHMUEL M. RUBINSTEIN, JOHN M. KOLINSKI, Harvard University , SHREYAS MANDRE, Brown University , LAKSHMINARAYANAN MAHADEVAN, DAVID A. WEITZ, Harvard University — When a liquid drop approaches a flat solid surface, the air beneath it is compressed, flattening the bottom of the drop and forcing initial contact to occur in a ring-shape, trapping a pocket of air in its center as two wetting fronts rapidly expand both outward and inwards to completely wet the surface. We combine total internal reflection (TIR) microscopy with a novel virtual frame technique (VFT) to directly observe the sub-micron length scales above a solid surface as the drop approaches, impacts and then spreads over it.

12:03PM Q9.00005 Interfacial Effects on Droplet Dynamics in Poiseuille Flow , JONATHAN SCHWALBE, KENDRA ERK, National Institute of Standards and Technology, JEFFREY MARTIN, Unilever, PETIA VLAHOVSKA, Brown University, STEVEN HUDSON, National Institute of Standards and Technology — Interfacial rheology governs many properties of emulsions, and here we report theory and experiments that account for and measure surface viscous and elastic forces. For the theoretical portion, Stokes flow is assumed in bulk phases and a jump in hydrodynamic stress at the interface is balanced by Marangoni and surface viscous forces according to the Boussinesq-Scriven constitutive law. Our model employs linear equation of state for the surfactant. Our analysis predicts slip, cross-stream migration and droplet-circulation velocities for a spherical drop in plane Poiseuille flow. These results and the corresponding interfacial parameters are separable: e.g., cross- stream migration occurs only if surfactant is present; slip velocity depends on viscosity contrast and dilatational Boussinesq number, but not shear Boussinesq number. Drop dynamics in plan Poiseuille flow are measured experimentally using microfluidics, particle velocimetry, and shape analysis. Several types of surfactant-stabilized aqueous drops in oil are examined and the interfacial properties depend on interfacial composition.

12:15PM Q9.00006 ABSTRACT WITHDRAWN –

12:27PM Q9.00007 Nonequilibrium molecular dynamics of vapor–liquid interface , TAKERU YANO, Osaka University, Japan — Evaporation and condensation at a vapor–liquid interface are studied by moderately large-scale nonequilibrium molecular dynamics simulations for a vapor–liquid two phase system composed of about 0.3 million Lennard-Jones molecules. Constant evaporation and condensation are realized by driving two vapor regions on the either side of a planar liquid film, and thereby the simulation is free from artificial controls of molecular motions in the liquid film and in the neighborhood of the interfaces. This enables us to evaluate the mass, momentum, and energy fluxes across the system, which are relevant to the velocity distribution of molecules leaving the interface at the vapor–liquid nonequilibrium states.

12:39PM Q9.00008 Evaporation out of a 2D model soil , BERTRAND SELVA, REMI DREYFUS, Complex Assemblies of Soft Matter, CNRS-Rhodia-UPenn UMI 3254, Bristol, Pennsylvania 19007, USA — Our goal is to improve our understanding of water transport in the soil-plant-atmosphere continuum. For this purpose, we focus on water losses due to evaporation at the soil surface. Such losses are known to be important at places where plants do not entirely cover the surface. Our model soil is a 2D porous medium with controlled wettability and humidity. It has been reported that evaporation is characterized by three stages: a first stage with a strong and constant evaporation flux, a second stage where mass transfer is dominated by diffusion mechanisms, and a third stage that occurs when the medium is almost empty. Here we focus on the first two stages and the transition between them which occurs when an intermediate unsaturated zone has reached its maximum width. This width strongly depends on the wettability distribution of the porous medium. In our experiments, we have explored a regime where gravity effects and capillary forces have similar contributions. In this particular regime we found that the first stage is characterized by a continuously decreasing evaporation flux and the second stage by usual diffusion transfer mechanisms. In order to understand this behavior, we have developed a model which allows us to predict the transition between the two stages and which is in agreement with the decreasing values of the first stage evaporation flux.

12:51PM Q9.00009 Effects of Sub-Phase Thickness on Interfacial Microrheology , PAUL CHRISTOPHEL MARTIN, KENNETH W. DESMOND, ERIC R. WEEKS, Emory University — The interface between two fluids is known to have a rheological response. In our work, we study human serum albumin protein molecules (HSA) at an air-water interface. Prior experimental work showed that the ratio of the surface viscosity to the sub-phase "bulk" viscosity influences the rheology of the HSA interface. Recent theoretical work has shown that the thickness of the sub-phase h can also influence the rheology of the interface. The finite thickness of the sub-phase only becomes important once h is on the order of the ratio of the surface viscosity to the sub-phase "bulk" viscosity, which is on the order of 100 microns for an HSA-air-water interface. To characterize the interfacial rheology, we suspend tracer particles at the interface, measure their correlated motions, and investigate how the results depend on h for water layers O(100 microns) thick.

1:03PM Q9.00010 Probing single- and multi-phase flow at the pore level , SUJIT DATTA, Department of Physics, Harvard University, AMBER KRUMMEL, Department of Chemistry, Colorado State University, DAVID WEITZ, Department of Physics, Harvard University — We use a new experimental technique to study 3D flow behavior in a porous medium in situ with high spatiotemporal resolution. At the multi-pore level, we probe the fluid configurations resulting from two-phase flow conditions imposed upon the system and correlate these to bulk flow measurements.

1:15PM Q9.00011 Viscous flow and heat transfer in channels with structured walls , VLADIMIR AJAEV, Southern Methodist University, STEFFEN HARDT, PETER STEPHAN, Center of Smart Interfaces, TU Darmstadt — We develop a mathematical model of pressure-driven flow in channels with walls structured by arrays of parallel grooves filled with air or gas. Motivated by cooling applications, we study heat transfer from a heater embedded in the wall to the liquid. The flow in the liquid is described using a Stokes flow model, and thermocapillary effects due to presence of the liquid-gas interface segments in the grooves are also taken into account. The rate of heat transfer is determined by a competition of two physical effects: the insulating effect of the gas in the grooves, due to small thermal conductivity of the gas phase, and the reduction of the effective slip length at the channel wall due to the presence of the liquid-gas interface segments in the grooves. Criteria for heat transfer enhancement are formulated for different parameters of the structuring.

1:27PM Q9.00012 Utilizing an Automated Home-Built Surface Plasmon Resonance Apparatus to Investigate How Water Interacts with a Hydrophobic Surface , ADELE POYNOR, Allegheny College — By definition hydrophobic substances hate water. Water placed on a hydrophobic surface will form a drop in order to minimize its contact area. What happens when water is forced into contact with a hydrophobic surface? One theory is that an ultra-thin low- density region forms near the surface. We have employed an automated home-built Surface Plasmon Resonance (SPR) apparatus to investigate this boundary.

1:39PM Q9.00013 Quantification of slip at a liquid-solid interface – a novel approach[1] , ALEKS PONJAVIC, MOURAD CHENNAOUI, JANET WONG, Imperial College — Much effort has been spent recently on experimentally proving the existence of interfacial slip of a Newtonian fluid. A constant limitation is the proximity to the surface at which the velocity of a fluid can be measured. A new technique is developed to maximise this proximity. The objective is to acquire velocity measurements of a fluid as close as possible to the liquid-solid interface while still using a direct method of observation. To ensure proximity to the surface the technique of photobleaching is adopted. Dye-doped water is pumped through a microfluidic channel. A short, intense pulse from a laser causes dye within the focal volume to bleach, creating a spot. The geometry of this spot evolves depending on the velocity profile of the fluid. By fitting the evolution of the spot with a Poiseuille velocity profile with slip the slip length is extracted. The hydrophobicity of the channel is varied by flowing silane through the channel prior to measurement, forming a self-assembled monolayer. Effects of shear rate and wettability on interfacial slip length are investigated.

1:51PM Q9.00014 Effects of Interfacial Translation-rotation Coupling for Confined Ferrofluids[1] , ANGBO FANG, Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay Road, Kowloon, Hong Kong — Ferrofluids have wide applications ranging from semiconductor fabrications to biomedical processes. The hydrodynamic spin diffusion theory for ferrofluids has been successful in explaining many experimental data, but it suffers from some fatal flaws. For example, it fails to predict the incorrect flow direction for a ferrofluid confined in a concentric cylinder channel in the presence of a rotating magnetic field. In this work we develop a method to establish the general hydrodynamic boundary conditions (BCs) for micro-polar fluids such as ferrofluids. Through a dynamic generalization of the mesoscopic diffuse interface model, we are able to obtain the surface dissipation functional, in which the interfacial translation-rotation coupling plays a significant role. The generalized hydrodynamic BCs can be obtained straightforwardly by using Onsager's variational approach. The resulted velocity profile and other quantities compares well with the experimental data, strikingly different from traditional theories. The methodology can be applied to study the hydrodynamic behavior of other structured fluids in confined channels or multi-phase flows.

Session Q10 DCMP: Chemisorption and Surface Reactions D221

11:15AM Q10.00001 Catalytic Reactions of DNT and TNT Molecules on Porphyrin Complexes

, KEITH WARNICK, BIN WANG, Vanderbilt University, SOKRATES PANTELIDES, Vanderbilt University, Oak Ridge National Laboratory — Reactions of molecules with substrates can be used to identify them, as in sensor applications. Here we examine reactions of DNT and TNT molecules on porphyrin and metal-porphyrin via first-principles DFT calculations. We find that the oxidation of DNT by O_2 using Fe-porphyrin as a catalyst is exothermic. The affinity of O_2 to Fe-porphyrin weakens the O_2 intramolecular bond, which lowers the oxidation reaction barrier is lowered by $\sim$1 eV. Substrate effects on this process are accounted for. One way to use this selective oxidation reaction for DNT/TNT sensor applications is to exploit the metal-semiconductor transition in thin-film VO_2 to detect the energy deposited by the exothermic reaction between the adsorbed molecules. This work was supported in part by DTRA grant HDTRA1-10-0047.

11:27AM Q10.00002 Reactivity of TiO_2 Rutile and Anatase Surfaces toward Nitroaromatics

, SHAO-CHUN LI, ULRIKE DIEBOLD[1], Department of Physics and Engineering physics, Tulane University, New Orleans, LA 70118, USA — The Au-TiO_2 system is a promising catalyst for the synthesis of nitro-aromatic compounds. The adsorption of azobenzene (C_6H_5N-NH_5C_6) and aniline ($C_6H_5NH_2$) on two single-crystalline TiO_2 surfaces, anatase (101) and rutile (110), has been investigated with scanning tunneling microscopy (STM), low energy electron diffraction (LEED), and X-ray photoemission spectroscopy (XPS), and synchrotron Ultraviolet photoemission (UPS). While azobenzene adsorbs as an intact molecule at low coverages, ordered overlayers of phenyl imide (C_6H_5N) form at saturation coverage, indicating that TiO_2 surfaces cleave the N-N bond even without the presence of Au. The same superstructures, p(1 $\times$ 2) on anatase and c(2 $\times$ 2) on rutile and the same electronic structures, form upon adsorption of aniline, suggesting the formation of the same, or a very similar, reaction intermediate. These results suggest that the main role of the supported Au in catalytic aniline $\leftrightarrow$ azobenzene conversion is the activation of O_2/H_2 for de/hydrogenation reactions.

11:39AM Q10.00003 The role of subsurface oxygen in the selectivity enhancement of ethylene epoxidation on Ag-Cu Catalysts

, NGOC LINH NGUYEN, STEFANO DE GIRONCOLI, International School for Advanced Studies (SISSA), via Bonomea 265 Trieste Italy, SIMONE PICCININ, CNR-IOM, DEMOCRITOS National Simulation Center, Theory@Elettra Group, Trieste, Italy — The role of subsurface oxygen on the Ag-Cu alloy catalysts for the ethylene epoxidation reaction has been studied by means of first principles Density Functional Theory (DFT) calculations. We find that in presence of oxygen and ethylene reactants, the subsurface oxygen adsorption is energetically favorable on fcc sites under the thin oxide-like CuO layer formed at the catalyst surface. On this substrate the reaction proceeds via the formation of a common oxametallacycle precursor. The calculated activation energies show favorable energetics for the pathway leading to the formation of the desired product, ethylene oxide, with respect to the one leading to the formation of the undesired product, acetaldehyde, while the opposite order is obtained on pure Ag catalyst. These findings provide an understanding, at the atomistic level, of the selectivity enhancement of Ag-Cu alloy with respect to pure Ag catalysts. Furthermore, we find that under temperature and partial pressure conditions close to the experimental ones, the ethylenedioxy intermediate is present on the phase diagram of Ag-Cu (111) surface. Our calculations indicate, however, that the formation of this structure could poison the catalyst surface.

11:51AM Q10.00004 Surface defects activate new reaction paths: formation of formate during methanol oxidation on defective Ru(0001)

, I. PALACIO, O. RODRÍGUEZ DE LA FUENTE, Complutense University Madrid-SPAIN — An optimum understanding of the existing molecular mechanisms taking place while reactions occur on surfaces, should preferably be based on a correct identification of the intermediate species and the reaction paths, so to avoid trial-and-error approaches. Otherwise, a good control of the chemical activity is not easily attainable. We have adsorbed methanol on Ru(0001), with surfaces having a variable density of defects. In this way, with Auger Electron Spectroscopy (AES), Low Energy Electron Diffraction (LEED) and Infrared Reflection-Absorption Spectroscopy (IRAS) we have identified reaction paths in the methanol/Ru(0001) system. While the sole methanol adsorption leads to its complete dehydrogenation towards CO, we show that oxygen coadsorption stabilizes intermediate products, namely methoxy (CH_3O), formaldehyde (CH_2O) and formyl (CHO). We show as well that a new reaction path appears just on the defective surface: the formation of formate (HCOO). The presence of the defects (mainly steps) catalyzes the oxidation of formaldehyde to formate. This particular case shows how surface defects profoundly affect the catalytic activity, opening new reaction channels which are not available when the density of defects is low.

12:03PM Q10.00005 Dynamics of Low-Energy Electron Induced Reactions in Condensed

, MICHAEL BOYER, CHANMYAEMYAE SOE, KRISTAL CHAMBERLAIN, YOMAY SHYUR, CHRISTOPHER ARUMAINAYAGAM, Wellesley College — We present insights into the dynamics of low-energy electron-induced reactions in thin films of methanol (CH_3OH). Low-energy electrons in matter can initiate chemical reactions though electron impact ionization of a molecule, electron impact excitation of a molecule, or through dissociation of a transient negative ion formed by electron attachment to a molecule. Our studies focus on the dynamics by which low-energy electron interaction with condensed methanol initiates chemical reactions which lead to the formation of methoxymethanol (CH_3OCH_2OH) and ethylene glycol ($HOCH_2CH_2OH$). The results of our post-irradiation temperature programmed desorption experiments indicate that both products can form from irradiating methanol with electrons at subionization energies. In addition, we find evidence that dissociative electron attachment plays a role in the formation of methoxymethanol but not in ethylene glycol.

12:15PM Q10.00006 X-ray Induced Reorganization/Polymerization of Resorcinol on the TiO_2 Rutile (110) Surface

, VINOD KUMAR PALIWAL[1], SHAO-CHUN LI, ULRIKE DIEBOLD[2], Department of Physics and Engineering Physics, Tulane University, New Orleans, LA 70118, USA. — The room-temperature adsorption of resorcinol (1, 3 benzenediol, $C_6H_4(OH)_2$) on the (110) surface of rutile TiO_2 was investigated with STM and x-ray photoemission (XPS). The saturation coverage of resorcinol is smaller as compared to catechol (1,2 benzenediol) with a C1s/Ti2$p_{3/2}$ ratio of $\sim$ 7.3% and 12%, respectively. This indicates that resorcinol occupies on average more than two Ti sites on the surface. STM suggests that resorcinol molecules are mobile at lower coverage, whereas a weakly-ordered overlayer with a periodicity of 3 unit-cells along [001] is observed at higher coverages. Interestingly, exposure of resorcinol-saturated TiO_2 surface to an XPS Mg-Kα beam (1253.6 eV) induces a reorganization of adsorbed resorcinol molecules. STM shows well-resolved double chains that run across [001]-oriented rows of TiO_2(110) surface. These results suggest that irradiation induces a polymerization reaction of adsorbed resorcinol molecules, where neighboring aromatic rings are arranged in a zig-zag configuration.

12:27PM Q10.00007 Propane-1,3-diol Adsorption and Dissociation on Rutile TiO_2(110): A Scanning Tunneling Microscopy Study , ZHENRONG ZHANG, Department of Physics, Baylor University, XIAO LIN, BRUCE KAY, ZDENEK DOHNÁLEK, Chemical and Materials Sciences Division, Fundamental and Computational Sciences Directorate, Pacific Northwest National Laboratory — Titanium Dioxide (TiO_2) has attracted great attention in the past decades due to its importance in heterogeneous catalysis. Here the adsorption and dissociation of Propane-1,3-diol molecules on partially reduced rutile TiO_2(110) surfaces are studied via variable temperature scanning tunneling microscopy (VT-STM). STM images of TiO_2(110) surfaces obtained before and after *in-situ* doses of melecules at room temperature show that the molecules preferentially bind in bridge-bonded oxygen vancanies (BBO_V's) *via* one O-H bond scission. The dynamics of Propane-1,3-diol molecules motion has been investigated at room and elevated temperatures. Propane-1,3-diol molecules swing on TiO_2 surface with one end (-CH_2-O^-) anchored on vacancies. Strong interaction of the other end (-O-H) with Ti_{5c} reduces the swing rate when compared with octanol.

12:39PM Q10.00008 First-Principles Studies of Electric Field Effects in Heterogeneous Catalysis: NH_3on Ru(0001) , AARON SISTO, Department of Mechanical Engineering, Purdue University, West Lafayette, IN 47906, ALEXEY ZAYAK, JEFFREY NEATON, Molecular Foundry, LBNL, Berkeley, CA 94720 — The catalytic dissociation of NH_3 has been the focus of recent studies due to the prospect of efficient hydrogen storage and generation. The effects of a static electric field on the surface electronic structure and energy barriers of reactions are examined using density functional theory calculations with gradient corrections. It is found that the interaction strength between the adsorbate and surface can be tuned based on the magnitude and polarity of the field, as evidenced by a field-induced shift of the d-electron band. Correspondingly, energy barriers along minimum energy pathways for desorption and dissociation reactions are significantly affected by the change in substrate-adsorbate interaction. It is concluded that the application of an electric field enhances the catalytic performance of Ru through increased activity and selectivity of NH_3 dissociation. We acknowledge support from DOE, DOE CSGF Fellowship. Computational resources provided by NERSC.

12:51PM Q10.00009 Adsorption and dissociation of molecular oxygen on α-Pu (020) surface: A density functional study[1] , JIANGUANG WANG, ASOK RAY, University of Texas at Arlington — Molecular and dissociative oxygen adsorption on the (020) surface of α-Pu have been studied using the full-potential linearized augmented-plane-wave plus local orbitals (FP-LAPW+lo) basis method. Four adsorption sites and three approaches of O_2 molecule have been considered. Adsorption energies have been optimized according to the distance of the adsorbates from the Pu surface as well as the oxygen dimer bond length. Dissociative adsorption is found for two horizontal approaches (O_2 is parallel to the surface and parallel/perpendicular to a lattice vector) and to be more energetically favorable at the scalar and "fully" relativistic (NSOC vs. SOC) levels of theory. Hor2 approach on the top site was the preferred adsorption site among all cases studied here. Molecular adsorption occurs at the Vert (O_2 is vertical to the surface) approach. The work functions, net spin magnetic moments, and charge transfer are also calculated.

1:03PM Q10.00010 ABSTRACT WITHDRAWN –

1:15PM Q10.00011 Structure and Adsorption on Hydrated Alumina Surfaces , VINCENZO LORDI, PATRICK HUANG, ERIC SCHWEGLER, Lawrence Livermore National Lab — Understanding the mechanisms of adsorption of chemical agents on environmental materials under different atmospheric conditions is important for applications in environmental remediation, industrial catalysis, and protection against chemical warfare. In this work, we study molecular adsorption of the chemical agent simulant dimethyl-methylphoshonate (DMMP) on various alumina surfaces, using density functional theory-based molecular dynamics simulations. Both alpha and gamma alumina surfaces of different orientations (and thus surface terminations/reconstructions) are studied, under both wet and dry conditions. Adsorption from the gas phase onto dry and hydroxylated surfaces is compared to adsorption from an aqueous layer in the limit of a fully bulk-like liquid water layer. Interfacial structure and dynamics are directly compared to previous synchrotron X-ray scattering and sum-frequency vibrational spectroscopy experiments, from which specific contributions of different surface functional groups are identified and resolved. Differences in site reactivity on the various surfaces are also compared. Prepared by LLNL under Contract DE-AC52-07NA27344.

1:27PM Q10.00012 Ag/Al_2O_3/FeAl(110): Electronic structure and NO_2 adsorption , MATTHEW PATTERSON, Department of Physics and Astronomy, Louisiana State University, ORHAN KIZILKAYA, Center for Advanced Microstructures and Devices, Louisiana State University, RICHARD KURTZ, PHILLIP SPRUNGER, Department of Physics and Astronomy and Center for Advanced Microstructures and Devices, Louisiana State University — Ag/Al_2O_3 systems are widely studied as catalysts in the selective catalytic reduction of NO_x with hydrocarbons. The exact nature of the active sites and the role of the Ag clusters in such reactions is still not fully understood. In this study, we characterize thermally evaporated Ag clusters on the ultrathin alumina film produced by oxidizing FeAl(110). ARPES demonstrates the evolution of Ag cluster electronic structure and morphology with increasing Ag coverage. Changes in electronic binding energy distinguish charged from metallic clusters. Vibrational EELS of NO_2 adsorbed on the Ag/Al_2O_3/FeAl(110) system elucidates the nature of the NO_x binding site and the changes in the surface chemistry both as a function of Ag cluster size and NO_x adsorption temperature.

1:39PM Q10.00013 Neutron and Thermodynamic Studies of Hydrogen on Pd Decorated Metal Oxides , PAIGE LANDRY, University of Tennessee, A. RAMIREZ-CUESTA, ISIS, E. CRUZ SILVIA, B. SUMPTER, Oak Ridge National Lab, J.Z. LARESE, University of Tennessee — We report our investigations of thermodynamic, inelastic and quasielastic neutron scattering (INS and QENS) studies of H2 adsorbed on bare and Pd decorated metal oxide (MO) surfaces, specifically ZnO, SBA-15 silica, and alumina. Guided by our volumetric adsorption measurements, we used INS and QENS to probe the dynamics of the adsorbed hydrogen molecules. These measurements provide insight into how the microscopic behavior of hydrogen is changed when it is confined at interfaces or interacts with a Pd catalyst. Using INS, the motion of the adsorbed hydrogen are examined as a function of surface adsorbate composition. For rotational motion we use the ortho-to-para transition as a guide and find that the rotational barrier for H2 adsorbed on some of these MO surfaces shift to lower energy (relative to bulk H2). For comparison, the hydrogen adsorption and microscopic behavior when the MO are decorated with 1% Pd metal will be discussed. Evidence for the presence of adsorbed H2, Zn hydroxide and the potential role of spillover will be discussed. This work was partially supported by the U.S. DOE, BES under contract No. DE-AC05-00OR22725 with ORNL managed and operated by UT-Battelle, LLC, the NSF under grant DMR-0412231 and a grant from the University of Tennessee, JINS.

1:51PM Q10.00014 Atomistic Mechanism of Surface Oxide Formation on Pt(111) , ZHENGZHENG CHEN, CHAO WU, Department of Chemical and Biomolecular Egineering, University of Notre Dame, WILLIAM SCHNEIDER, Department of Chemical and Biomolecular Egineering, Department of Chemistry and Biochemistry, University of Notre Dame — A detailed understanding of the interaction of oxygen with Pt surfaces is essential for understanding its catalytic activity and deactivation in oxidizing environments. Here we analyze the transition between metallic and oxidized Pt surfaces. Using first-principles calculations, we characterize the chain-like oxide reconstruction on the Pt(111) surface associated with O coverage $>$50%. We describe the sensitivity of the reconstruction energy to the occupancy of adjacent fcc and hcp sites and present a phenomenological model that relates the reconstruction to the balance between elastic strain energy and screening of O-O repulsions. Core level shift calculations indicate the reconstruction generates two O states with different binding energies and reactivity. Finally, we analyze the thermodynamic stability and equilibrium states of the reconstruction a cluster expansion model. The results are important in developing models of oxidation catalysis on Pt (111) surface.

2:03PM Q10.00015 Tuning Semiconductor Band Edge Energies via Surface Ligand Passivation[1] , SHENYUAN YANG, DAVID PRENDERGAST, JEFFREY NEATON, Molecular Foundry, Lawrence Berkeley National Laboratory — Semiconductor band gaps and band edge energies are key parameters that can dictate the efficiency of photocatalysis in solar energy conversion applications. CdSe is a representative semiconducting system with an ideal band gap for solar photon absorption, but with band edge energies that are not positioned for efficient water splitting. Using first-principles calculations within density functional theory, we present a study of the electronic structure of passivated CdSe surfaces and nanostructures, exploring the ability to tune band edge energies in this system via chemisorbed ligands. We predict substantial shifts in band edge energies that are electrostatic in origin, and due to the induced dipole at the CdSe-ligand interface and the intrinsic dipole of the ligand. We further show that, by changing the size and orientation of the ligand's intrinsic dipole moment via novel functionalization strategies, we can control the magnitude and direction of the shifts of CdSe energy levels. The effect of ligands on energy levels of two-dimensional CdSe surfaces and nanocrystal surfaces are thoroughly discussed.

Session Q11 FIAP: Fractional Quantum Hall Effect II D222

11:15AM Q11.00001 Unexpected Roles for Spin Degrees of Freedom in Competing Phases of the Second Landau Level[1] , TREVOR D. RHONE, J. YAN, U. WURSTBAUER, Columbia University, Y. GALLAIS, Université de Paris 7, A. PINCZUK, Columbia University, L. PFEIFFER, K. WEST, Princeton University, PINCZUK GROUP TEAM — Competing liquid and solid ground states as well as intriguing quantum Hall fluids such as that at ν=5/2 create great current interest in the N=1 Landau level. The spin degrees of freedom in quantum phases of the 2nd Landau level is probed by resonant light scattering. The long wavelength spin wave mode, which monitors the degree of spin polarization, is at the Zeeman energy in the spin polarized state at ν=3. At lower filling factors the intensity of the Zeeman mode collapses indicating loss of spin polarization. At filling factors slightly lower the intensity of the spin wave attenuates and a broad continuum of low-lying excitations emerges - sharp and broad modes coexist. While the coexistence of spectral features has not been explained, the observation could manifest the presence of mixed quantum phases and some loss of spin polarization. A continuum of low-lying excitations emerges that dominates near ν=8/3 and ν=5/2. Resonant Rayleigh scattering reveals that the quantum fluids away from ν=3 break up into robust domains. It is conceivable that these domains could comprise both spin polarized and depolarized quantum fluids. While the state at ν=5/2 is considered to be polarized, these results reveal unprecedented roles for spin.

[1]Work supported by NSF and DOE.

11:27AM Q11.00002 Electron teleportation via Majorana Bound States in a Mesoscopic Superconductor , LIANG FU, Harvard University — Majorana fermions are non-Abelian anyons in 5/2 fractional quantum Hall states and superconductors, which can store quantum information in an inherently nonlocal way. We describe a phase-coherent electron transport phenomena through two spatially separated Majorana bound states in a mesoscopic superconductor. This striking nonlocal effect arises from the interplay between topological order, superconducting order parameter and mesoscopic effects. We discuss its implications for experimental detection of Majorana fermions and topological quantum computation. Ref: Liang Fu, Phys. Rev. Lett. 104, 056402

11:39AM Q11.00003 Entanglement Entropy as a Function of the Aspect Ratio in the First and Second Landau Level , BARRY FRIEDMAN, CURTIS BALUSEK, DARWIN LUNA, Physics Department, Sam Houston State University — Entanglement entropy as a function of aspect ratio has been studied by direct diagonalization in the first and second Landau levels. The torus geometry is used and spin polarized electrons interact via long range Coulomb interaction . As previously noted by Haque et al. (N J Phys 12, 2010 075004), in the first Landau level there is very smooth behavior as a function of aspect ratio making it possible to obtain the topological entanglement entropy. In the second Landau level, the entanglement entropy is much less regular, with possible signatures of quantum phase transitions.

11:51AM Q11.00004 The phase diagram and particle-hole asymmetry of the reentrant integer quantum Hall states of the second Landau level , A. KUMAR, M.J. MANFRA, Department of Physics, Purdue University, L.N. PFEIFFER, K. W. WEST, Princeton University, G.A. CSATHY, Department of Physics, Purdue University — The second Landau level of a two-dimensional electron gas reveals a rich set of competing ground states. Besides an increasing number of fractional quantum Hall states, there are also eight reentrant integer quantum Hall states observed. These reentrant integer states are currently not understood, although they are believed to be collective insulators akin to the field induced Wigner solid with one or more electrons per site. These states are strongly affected by tilt in magnetic field and carrier density but surprisingly there is very limited data on their temperature dependence. We present a detailed study of the melting of the reentrant integer quantum Hall states of the second Landau level from which we extract the phase diagram in the temperature versus filling factor plane. We find that the melting temperatures of the various reentrant integer states violate the particle-hole symmetry. We also report that as the temperature is lowered the magnetoresistance deviates from an activated dependence.

12:03PM Q11.00005 The even denominator fractional quantum Hall states at large Landau level mixing , NODAR SAMKHARADZE, MICHAEL MANFRA, GABOR CSATHY, Purdue University, LOREN PFEIFFER, KEN WEST, Princeton University — We present a study of the energy gaps of the even denominator fractional quantum Hall states of the second Landau level in a two-dimensional electron gas with a record low density of n = 8.2x10^{10} cm^{-2}. These measurements are motivated by the expectation that Landau level mixing present in samples of low densities breaks the degeneracy of the Pfaffian and its particle-hole conjugate anti-Pfaffian. Cooling the electron gas in our Helium-3 immersion cell to 5mK reveals at filling factor 5/2 a fully quantized Hall plateau and a vanishingly small magnetoresistance. Because of the low density of our sample, the 5/2 fractional state is observed at the highest degree of Landau level mixing reported to date. We have measured the energy gaps of the 5/2 and 7/2 fractional quantum Hall states. The intrinsic gap deduced in the limit of no disorder will be compared to previously reported values for samples with higher densities.

12:15PM Q11.00006 Nonconventional odd denominator fractional quantum Hall states in the second Landau level , GABOR CSATHY, ASHWANI KUMAR, MICHAEL MANFRA, Purdue University, LOREN PFEIFFER, KEN WEST, Princeton University — The odd denominator fractional quantum Hall states in the second Landau level of a two-dimensional electron gas are believed to be different from those of the lowest Landau level. While at first sight these states could be part of the composite fermion hierarchy, several recent theoretical works suggest that some might be supporting generalized Pfaffian-like correlations. Recent progress in cooling electrons allowed us to observe a new fractional quantum Hall state at the filling factor 2+6/13. By assuming that the effective mass of the composite fermions does not explicitly depend on the Landau level index we find that energy gaps of the prominent 2+1/3 and 2+2/3 states are consistent with the values predicted by the free composite fermion model. However, the weaker 2+2/5 and 2+6/13 states deviate significantly from the prediction of this model. This deviation constitutes a first demonstration of the nonconventional nature of the latter two odd denominator fractional quantum Hall states.

12:27PM Q11.00007 Tunneling experiments in the lowest Landau level[1] , C. DILLARD, XI LIN, M.A. KASTNER, MIT, L.N. PFEIFFER, K.W. WEST, Princeton University — Recently, a quasiparticle-tunneling experiment on the 5/2 state [1] led to the unintentional discovery of a process we term annealing. In this experiment top gates are used to bring counter-propagating edge states close enough together for tunneling to occur. By keeping the quantum point contact (QPC) top gates energized for a few days at 4 Kelvin, one can create equal electron densities in the QPC region and the bulk of a GaAs heterostructure. This is a great advantage for studying quasiparticle tunneling in QPCs. Conditions under which annealing has proved effective are presented. In addition, in order to better understand and control quasiparticle tunneling in QPCs, further tunneling experiments have been performed in the lowest Landau level.

12:39PM Q11.00008 Haldane Statistics in the Finite Size Entanglement Spectra of Laughlin States , MARIA HERMANNS, ANUSHYA CHANDRAN, Princeton University, NICOLAS REGNAULT, ENS Paris, BOGDAN ANDREI BERNEVIG, Princeton University — We conjecture that the counting of the levels in the orbital entanglement spectra (OES) of finite-sized Laughlin Fractional Quantum Hall (FQH) droplets at filling $1/m$ is described by the Haldane statistics of particles in a box of finite size. This principle explains the observed deviations of the OES counting from the edge-mode conformal field theory counting and directly provides us with a topological number of the FQH states inaccessible in the thermodynamic limit- the boson compactification radius. It also suggests that the entanglement gap in the Coulomb spectrum in the conformal limit protects a universal quantity- the statistics of the state.

12:51PM Q11.00009 Polarized Fractional Quantum Hall States at 1/3 and 5/2 Filling: a Density-Matrix Renormalization Group Calculation , JIZE ZHAO, DONNA SHENG, Department of Physics and Astronomy, California State University, Northridge, California 91330, USA, F. DUNCAN M. HALDANE, Department of Physics, Princeton University, Princeton, NJ 08544 — In this talk, the density-matrix renormalization group method is employed to investigate the fractional quantum Hall effect (FQHE) at filling numbers $\nu = 1/3$ and $5/2$. We present benchmark results for both filling numbers for larger system sizes to show the accuracy as well as the capacity of our numerical algorithm. Furthermore, we demonstrate that by keeping a large number of states, one can also obtain reliable entanglement spectrum at $\nu = 5/2$, which characterizes the topological properties of FQHE states. Based on a finite-size scaling analysis, we also confirm that the entanglement gap defined by Li and Haldane for $\nu = 5/2$ state with Coulomb interaction remains finite in the thermodynamic limit.

1:03PM Q11.00010 Paired composite fermion wavefunctions for excitations at 5/2 , SREEJITH GANESH JAYA, The Pennsylvania State University, CSABA TOKE, Institute of Physics, University of Pecs, Hungary, ARKADIUSZ WOJS, Institute of Physics, Wroclaw University of Technology, JAINENDRA JAIN, The Pennsylvania State University — The Pfaffian wave function, which is thought to be relevant for the ground state at filling fraction $\frac{5}{2}$, represents a paired state of composite fermions. It can be expressed as an antisymmetrized bilayer (331) wave function. This formulation can be extended to construct wave functions for neutral as well as charged excitations of the Pfaffian. The space spanned by the quasihole excitations exactly matches that of the previously known quasihole wave functions. By comparison to exact results with up to 14 particles, we find that our neutral excitations and also the quasiparticle excitations describe well the actual excitations of the model three body interaction for which the Pfaffian ground state wave function is exact. The relevance to the solutions of the second Landau level Coulomb interaction is less conclusive. Also, the counting of states on the quasihole and quasiparticle sides is significantly different. Relation of our wave functions to other ansatz wave functions in the literature will be discussed.

1:15PM Q11.00011 Suppression of Interlayer Phase Coherence by Gauge Fluctuations in Bilayer Composite Fermi Liquids , ROBERT CIPRI, YAFIS BARLAS, N.E. BONESTEEL, Dept. of Physics and NHMFL, Florida State University — The ν =1/2+1/2 bilayer quantum Hall system exhibits at least two phases as a function of layer spacing, d. For $d/l \gg 1$, (l is magnetic length), the system decouples into two $\nu = 1/2$ composite fermion (CF) liquids. For d/l sufficiently small, the system enters an incompressible bilayer quantum Hall state. Recently, Alicea et al. [1] have proposed a state which might exist for intermediate layer spacing ($d \sim l$). In this "interlayer phase coherent" state, CFs tunnel coherently between layers forming well-defined bonding and antibonding Fermi seas, though there is no actual tunneling of physical electrons. Here we show that scattering from gauge fields in the CF liquids leads to strong layer-dependent fluctuations in the Aharonov-Bohm phases seen by CFs which suppress interlayer phase coherence. This suppression appears as a singular contribution to the correlation energy which inhibits any T=0 phase transition into an interlayer phase coherent state, and drives any such transition first order. Work supported by US DOE.

1:27PM Q11.00012 Pinning mode of 2D electron system with short-range alloy disorder , B.H. MOON, B.A. MAGILL, L.W. ENGEL, NHMFL/FSU, D.C. TSUI, L.N. PFEIFFER, K.W. WEST, Princeton University — At the low Landau filling (ν) termination of the fractional quantum Hall effect (FQHE) series, a two-dimensional electron system (2DES) becomes an insulator, which is identified in sufficiently low-disorder samples as a form of pinned Wigner solid. The microwave conductivity spectrum of such a solid shows a striking resonance, which is understood as a pinning mode, in which pieces of solid oscillate within the disorder potential. We report on the observation of the pinning mode of a 2DES that resides within $Al_xGa_{1-x}As$ with x=0.85%. For a carrier density of n= 8.7 x10^{10} /cm^2, a resonance with a peak frequency (f_{pk}) of about 5 GHz appears as ν goes below the 2/3 FQHE. A local minimum in resonance amplitude vs. ν occurs around ν =1/2. We will discuss the contribution of the alloy disorder to f_{pk}.

1:39PM Q11.00013 Properties of the Composite Fermion Wigner Crystal , ALEX ARCHER, JAINENDRA JAIN, The Pennsylvania State University — In two dimensional electron systems at small filling factor the ground state is a Wigner crystal. Wigner crystals can also be observed for systems near integer fillings, where electrons or holes in the partially filled Landau Level form a Wigner crystal. Recent experimental evidence (PRL 105, 126803 (2010)) suggests that a Wigner crystal of composite fermions forms near the filling factor of $v = \frac{1}{3}$. Motivated by these results, we calculate the shear modulus of the composite fermion Wigner crystal in the vicinity of several fillings of the form $v = \frac{1}{3}, \frac{2}{5}, \frac{3}{7}$, following the procedure of Maki-Zotos, using the effective two-body real space interactions between composite fermions calculated by Lee, Scarola, and Jain. We discuss the differences from the electron Wigner crystal, and also the experimental implications of our results.

1:51PM Q11.00014 Fabry-Perot Interferometry in the Integer and Fractional Quantum Hall Regimes[1] , DOUGLAS MCCLURE, WILLY CHANG, ANGELA KOU, CHARLES MARCUS, Harvard University, LOREN PFEIFFER, KEN WEST, Princeton University — We present measurements of electronic Fabry-Perot interferometers in the integer and fractional quantum Hall regimes. Two classes of resistance oscillations may be seen as a function of magnetic field and gate voltage, as we have previously reported. In small interferometers in the integer regime, oscillations of the type associated with Coulomb interaction are ubiquitous, while those consistent with single-particle Aharonov-Bohm interference are seen to co-exist in some configurations. The amplitude scaling of both types with temperature and device size is consistent with a theoretical model. Oscillations are further observed in the fractional quantum Hall regime. Here the dependence of the period on the filling factors in the constrictions and bulk of the interferometer can shed light on the effective charge of the interfering quasiparticles, but care is needed to distinguish these oscillations from those associated with integer quantum Hall states.

[1]We acknowledge funding from Microsoft Project Q and IBM.

2:03PM Q11.00015 Topological screening and interference of fractionally charged quasi-particles , IVAN LEVKIVSKYI, University of Geneva, JUERG FROEHLICH, ETH Zurich, EUGENE SUKHORUKOV, University of Geneva — Interference of fractionally charged quasi-particles is expected to lead to Aharonov-Bohm oscillations with periods larger than the flux quantum Φ_0. However, according to the Byers-Yang theorem, observables of an electronic system are invariant under insertion of a quantum of singular flux. We resolve this paradox by considering a *microscopic* model of an electronic interferometer made from quantum Hall edges at filling factor $\nu = 1/m$. An approximate ground state of such an interferometer is described by a Laughlin type wave function, and low-energy excitations are incompressible deformations of this state. We construct a low-energy effective theory by projecting the state space onto the space of such deformations. Amplitudes of quasi-particle tunneling in this theory are found to be insensitive to the singular flux. This behavior is a consequence of *topological screening* of the flux by the quantum Hall liquid. We describe strong coupling of the edges to Ohmic contacts and the resulting quasi-particle current through the interferometer with the help of a master equation. As a function of the singular magnetic flux, the current oscillates with the period Φ_0. These oscillations are suppressed with increasing system size. When the magnetic flux is varied with a modulation gate, current oscillations have the quasi-particle period $m\Phi_0$ and survive in the thermodynamic limit.

Session Q12 DMP: Focus Session: Dopants and Defects in Semiconductors: Conducting Oxides

D223/224

11:15AM Q12.00001 Transparent Conductors: Understanding and Optimization[1] , JULIA MEDVEDEVA, Missouri University of Science and Technology — The unique combination of two mutually exclusive properties – optical transparency and electrical conductivity – is known to be a prerogative of only a few oxides of post-transition metals, namely, In_2O_3, ZnO, CdO and SnO_2. Advances in theoretical understanding of the underlying physical phenomena in conventional transparent conducting oxides (TCOs) and rapid development of the technologies for which TCO is a vital component, stimulate further research aimed at (i) broadening the range of the electronic and optical properties of application-specific transparent conductive materials in a controllable way; (ii) improving the functional capabilities and efficiency of TCOs in a device; and (iii) designing novel materials as a viable, inexpensive alternative to conventional TCOs. Here, we employ first-principles density-functional approach to investigate the structural, electronic and optical properties of several classes of transparent conductors including conventional single-cation main-group oxides, multi-component binary and ternary oxides, as well as several non-oxide materials. Systematic comparative investigations allow us to determine the role of the crystal structure, chemical composition and carrier generation mechanisms on the resulting optical and electronic properties and predict ways to optimize the properties.

11:51AM Q12.00002 Origins of superior symmetrical doping ability of monoclinic BiVO4 , YANFA YAN, WAN-JIAN YIN, SU-HUAI WEI, MOWAFAK AL-JASSIM, JOHN TURNER, National Renewable Energy Laboratory — Application of semiconductors for functional devices depends critically on their dopability. However, there are strong doping bottlenecks for wide-band-gap semiconductors – symmetrical doping is usually difficult, which severely restrict their potential applications. Here, we report superior symmetrical doping properties, i.e., n-type and p-type, of monoclinic $BiVO_4$ by first-principles density-functional theory calculation. Our results reveal that without external doping, $BiVO_4$ with moderate n-type and p-type conductivities can be obtained. However, doping of Sr, Ca, Na, and K atoms under oxygen-rich growth conditions can lead to outstanding p-type conductivity, whereas doping of Mo and W under oxygen-poor growth conditions can result in excellent n-type conductivity. We find that Bi 6s state is responsible for the good p-type doping and the presence of V 3d state is responsible for the good n-type doping. Furthermore, the Bi $6s$ and V $3d$ states are also responsible for producing very dispersive valence and conduction band edges, leading to small electron and hole effective masses. The superior symmetrical doping properties and high carrier mobility make $BiVO_4$ a promising candidate for electronic and optoelectronic device applications.

12:03PM Q12.00003 Donors and H impurities in SnO_2 studied by IR spectroscopy[1] , FIGEN BEKISLI, MICHAEL STAVOLA, W. BEALL FOWLER, Lehigh Univ, LYNN BOATNER, Oak Ridge National Lab, ERIK SPAHR, GUNTER LUEPKE, College of William and Mary — Theory predicts that SnO_2 is an attractive wide band gap candidate for achieving p-type conductivity. Interstitial H and H_O are suggested to be shallow donors in SnO_2 [1-3]. We have studied the properties of H in SnO_2 single crystals. An O-H line is observed at 3261 cm^{-1} that is polarized perpendicular to the c direction along with weaker features at 3258 and 3272 cm^{-1}. When D is introduced into SnO_2 by annealing in a D_2 ambient at 700 °C, a variety of new O-H and O-D lines is produced along with the low-frequency absorption that is characteristic of free carriers. To probe the relationship between H and the free carriers it introduces, we have examined the thermal stabilities of the O-H and O-D lines and their relationship to the thermal stability of the free-carrier absorption.

12:15PM Q12.00004 ABSTRACT WITHDRAWN –

12:27PM Q12.00005 Asymmetric Cation stoichiometry in Spinels : Site occupancy in Co_2ZnO_4 and Rh_2ZnO_4[1] , TULA PAUDEL, S. LANY, A. ZUNGER, A. SIGDEL, A. ZAKUTAYEV, J. PERKINS, D. GINLEY, National Renewable Energy Laboratory, J. BETTINGER, Y. SHI, M. TONEY, SLAC National Accelerator Laboratory, A. NAGARAJA, N. PERRY, T. MASON, North Western University — Cations A and B in A_2BX_4 spinels normally appear in precise 2:1 Daltonian ratio only at low temperature. At finite temperature, they become either A-rich or B-rich, which control dopability of the compound. We survey the experimentally observed stoichiometry asymmetries and describe the first principles framework for calculating these. The results of the calculations compare well with the phase boundary determined from XRD and the site occupancy measured by anomalous-XRD on Co_2ZnO_4 and Rh_2ZnO_4 samples grown in thermodynamic equilibrium. Good comparison between theory and experiment allows us predict the co-existence line in composition range form first principle for other spinels, which in turn can be extended to predict the nature of electrical conductivity of a compound, while designing the material with the desired properties via principle of inverse design.

12:39PM Q12.00006 Dopants and defects in conductive oxide spinels[1] , ANDRIY ZAKUTAYEV, JOHN PERKINS, PHILLIP PARILLA, TULA PAUDEL, STAPHAN LANY, DAVID GINELY, ALEX ZUNGER, National Renewable Energy Laboratory — We will discuss the effects of extrinsic and intrinsic imperfections (dopants and defects) in a group of conductive oxide materials related to Co3O4. Co3O4 is a spinel with Co2+ and Co3+ on tetrahedral and octahedral sites, respectively. Doping of Co3O4 with Zn and Ni represent two limiting cases: Zn2+ ions have a preference to occupy tetrahedral (Co2+) sites and are predicted to be unable to dope effectively; Ni2+ ions have a preference to occupy octahedral (Co3+) sites, so these atoms are expected to be efficient dopants. We found that substitution of Co3O4 spinel with up to 33 percent of Zn and Ni results in formation of ZnCo2O4 normal spinel and NiCo2O4 inverse spinel, and causes 100-fold and 1000-fold increases in conductivity, respectively, matching the predicted trend. Increase in Zn and Ni concentraion up to 40 percent cause phase separation of ZnO and NiO and leveling out of the conductivity. The conductivity decreases sharply above 50-60 percent Zn and Ni substitution level. Small differences with the theoretical predictions may be explained by non-equilibrium character of the thin film deposition process.

12:51PM Q12.00007 Possible *n*-type carrier producers in $In_2O_3(ZnO)_k$ homologous compounds[1] , HAOWEI PENG, Northwestern University, JUNG-HWAN SONG, ARTHUR J. FREEMAN — $In_2O_3(ZnO)_k$ (k = integers) homologous compounds are promising intrinsic *n*-type transparent conducting semiconductors.[2] To find out the carrier producers, we investigated the energetics and thermodynamic properties of *n*-type defects and their complexes in $In_2O_3(ZnO)_k$, with the k=3 phase as prototype, using the first-princiles density functional method. We calculated the defect formation energies and defect transition energy levels of oxygen vacancies (V_O), substitutional indium on zinc sites (In_{Zn}), zinc and indium interstitials (Zn_i and In_i) on different atomic sites, and also some V_O–In_{Zn} and V_O–Zn_i defect complexes. We find, under the experimental growth condition of O-poor and $T = 1300°$C, that V_O, In_{Zn}, and V_O-In_{Zn} complexes have much lower formation energies than the others, among which V_O will stay in the neutral charged state and the latter two are the most possible *n*-type carrier producers. The V_O-In_{Zn} complex tends to form between V_O and In_{Zn} in the same atomic layer; thus its distribution should be affected by the site-preference of V_O.

1:03PM Q12.00008 Protonic motion in $Pr_{0.7}Ca_{0.3}MnO_3$ thin films and its implications on resistance change properties[1] , MIHIR TENDULKAR, NICHOLAS BREZNAY, YOSHIO NISHI, Stanford University — Thin films of $Pr_{0.7}Ca_{0.3}MnO_3$ (PCMO) exhibit resistance-change properties that are of acute interest for next-generation memory solutions. Recent work has demonstrated that oxidation / reduction of a reactive electrode is critical to the switching process, suggesting that interface engineering will solve the reliability issue. We show that an overlooked contributor to the process is hydrogen, which dopes the bulk film. Activated conduction and loss tangent measurements are correlated with FTIR spectra to demonstrate protonic motion through the repeated breaking and reforming of –OH bonds. SIMS and Hall measurements are presented in conjunction with UV-Vis spectroscopy to show that hydrogen also alters the electronic structure of the PCMO film. The implications of these effects on forming and switching are discussed.

1:15PM Q12.00009 Dynamics of Interstitial H in TiO_2[1] , W.B. FOWLER, A. MURPHY[2], M. STAVOLA, Lehigh Univ. — H transport in rutile TiO_2 is important because of the low energy barriers within the open lattice in the c-direction [1]. As part of a study of the dynamics of interstitial H, potential energy functions for the vibration of hydrogen between two cross-channel O were generated. Double-well functions were modeled using experimental data [2] for the fundamental stretching vibrational frequencies of the three isotopes of H along with theoretical information obtained from quantum-mechanical calculations using [3] CRYSTAL06. These functions were then used to predict where the first overtone may lie, and its relative transition probability. The unexpectedly large anharmonicity observed for the OH vibration is correlated with the hydrogen-bond nature of the O-H —-O potential.

1:27PM Q12.00010 Interstitial and substitutional Zr in SrTiO3[1] , JOHN JAFFE, RENEE VAN GINHOVEN, WEILIN JIANG, Pacific Northwest National Lab — We investigate Zr in $SrTiO_3$ (STO) as an electronic dopant and as a model for nuclear waste forms in which radioactive Sr decays to Y and then to stable Zr through beta emission. Density functional theory (DFT) within the supercell model is used to predict the thermodynamic stability and electronic states of interstitial and Sr- or Ti-substituted Zr atoms in the STO lattice. Native point defects such as vacancies and antisites are also considered. When Zr replaces Sr, its most stable configuration is to simply occupy the Sr site (instead of, for example, replacing a Ti and displacing the Ti to the Sr site.) For Zr added to the lattice, its most stable configuration is to replace a Ti, making a Zr_{Ti} impurity plus a Ti interstitial (as opposed to the Zr just remaining as an interstitial atom.) Zr_{Sr} is predicted to be a double electron donor, Zr_{Ti} is electrically inactive and interstitial Zr and Ti are predicted to be quadruple donors, with all donor levels in the conduction band. Zr_{Sr} and the tetravalent interstitials are all predicted to increase the crystal volume, and the interstitials also are predicted to lead to a tetragonal distortion of the lattice. Experiments with injection of Zr atoms into STO qualitatively confirm these predictions of crystal structural changes.

Session Q13 GSNP DFD: Glassy Systems and Jamming I D225/226

11:15AM Q13.00001 The Influence of Boundary Roughness on the Dynamics of Confined Colloidal Suspensions near the Glass Transition[1] , DANIEL J. REAL, KAZEM V. EDMOND, ERIC R. WEEKS, Emory University — We study the relationship between boundary conditions and particle motion in confined, concentrated colloidal suspensions. Studies of polymer fluids in confinement have shown that changes in mobility are strongly dependent upon the polymer/surface interaction. We model this interaction by observing the effects of textured surfaces on colloidal particle mobility in confined dense suspensions (near the glass transition). We use high-speed confocal microscopy to directly image and track the colloidal particles in thin, wedge-shaped sample chambers made from textured glass. We texture the glass in a controlled, reproducible manner by spincoating and sintering colloidal suspensions onto glass slides. We expect the texturing to frustrate the formation of layers seen in smooth-walled confinement, resulting in decreased translational diffusion as compared to the smooth wall case. By studying these dynamics we gain a better understanding of the glass transition and its dependence on interfacial dynamics versus finite size effects.

11:27AM Q13.00002 Structural Rearrangements in Confined Colloidal Liquids under Oscillatory Shear , PRASAD SARANGAPANI, University of Notre Dame, ANDREW SCHOFIELD, University of Edinburgh, Y. ELAINE ZHU, University of Notre Dame — We have investigated the dynamics of confined suspensions under oscillatory shear using a micron-gap rheometer interfaced with confocal microscopy. Our system consists of sterically stabilized poly-(methyl methacrylate) (PMMA) particles suspended in density and refractive index matched solvents at particle volume fractions, ϕ = 0.40-0.43, confined between two solid surfaces with gaps ranging from ∼10-30 particle layers. Above a threshold strain of ∼6% where an applied deformation is sufficient to induce plastic behavior, we find that structural rearrangements are highly anisotropic. Non-affine motion, determined by subtracting the globally uniform strain from the bare particle coordinates, reveals that particles move as cooperatively rearranging groups with a preferred orientation transverse to the flow direction. Measures which probe cooperative dynamics all reveal a strong amplitude, thickness, and directional dependence on the characteristic sizes of cooperatively rearranging regions. Interestingly, we find that medium range orientational order has a significant influence on shear-induced dynamics, particularly the shapes of rearranging regions.

11:39AM Q13.00003 Application of Edwards' statistical mechanics to polydisperse and high-dimensional jammed sphere packings , MAXIMILIEN DANISCH, Ecole Normale Superieure de Cachan, YULIANG JIN, HERNAN MAKSE, The City College of New York, PATRICK CHARBONNEAU, Duke University, SAM MEYER, Université de Lyon, CHAOMING SONG, Northeastern University, FRANCESCO ZAMPONI, Ecole Normale Supérieure — The Edward's statistical mechanics of jammed sphere packings [Song et al., Nature (London) 453, 629 (2008)] is generalized to different systems: polydisperse sphere packings in three dimensions, and high-dimensional monodisperse sphere packings. The theory predicts the density of random close packing and random loose packing of polydisperse systems for a given distribution of particle size and describes packings for any interparticle friction coefficient. In the high-dimensional limit, an asymptotic solution of the self-consistent relation is obtained by saddle-point evaluation and checked numerically. The resulting random close packing density scaling is consistent with that of other approaches, such as replica theory and density-functional theory. The theory could serve as a starting point to solve more difficult problems: such as predicting the optimal density of non-spherical packings, and understanding the higher-order correlations present in amorphous jammed packings.

11:51AM Q13.00004 Cyclic simple shear in a two-dimensional granular system[1] , JIE REN, JOSHUA DIJKSMAN, ROBERT BEHRINGER, Department of Physics, Duke University — We study the evolution of a 2D granular system consisting of frictional photo-elastic disks under large numbers of small-amplitude cyclic shear cycles. We are particularly interested in the reversibility of the system under cyclic shear. The experiments are carried out on a specially designed apparatus which can create quasi-static, nearly uniform simple shear. By using photo-elastic particles and a fluorescent labelling technique, we obtain information about displacement, rotation and contact forces for each particle following each small strain. We also obtain the system-level behaviour over many shear cycles. To better understand the nature of jamming, we have carried out shearing runs that explore various initial states which are initially unjammed, isotropically jammed or anisotropically jammed, and we compare the results for different initial states.

12:03PM Q13.00005 Microscopic Dynamics of Quasi-2D Dense Colloidal Gels[1] , MATTHEW LOHR, ARJUN YODH, University of Pennsylvania — In this work, we investigate the microscopic dynamics of quasi-2D dense attractive colloidal systems. We confine bidisperse polystyrene spheres between glass coverslips in a suspension of water and 2,6-lutidine; as we increase the temperature of the sample into a critical regime, lutidine wets the colloids, creating a strong attractive interaction ($>$ 4kT). We specifically study suspensions in the "dense gel" regime, i.e., at a volume fraction high enough that the attractive particles form a spanning cluster, yet just low enough that there exists some structural heterogeneity larger than the individual particle size. We track the particle locations via bright-field video microscopy and analyze the dynamics of the system in order to compare them to lower-volume-fraction gel states and higher-volume-fraction glassy states. In doing so, we pinpoint the similarities and differences in the mechanisms for dynamic arrest in low-density colloidal gels and high-density colloidal glasses.

12:15PM Q13.00006 Structural Correlations in Glass-Forming Hard Spheres Fluids , PATRICK CHARBONNEAU, Duke University, BENOIT CHARBONNEAU, St. Jerome's University and University of Waterloo — Recent studies have detected the presence of a growing static length scale associated with the glassy dynamical slowdown. Yet no fully satisfying microscopic description of such a length scale has yet been formulated. We critically evaluate the hypothesis that correlated structural defects could underlie the growing relaxation time in deeply supersaturated fluid. Though a clear structural signature of a developing order in these systems is found, the resulting defect geometry does not lead quite match the Frank- Kasper defect scenario. The dimensionally generalizable nature of the defects, however, make them promising options for defining static observables.

12:27PM Q13.00007 Study of experimental protocols for producing random close packed colloids , KELSEY HATTAM, ERIC R. WEEKS — A collection of spheres can be packed tightly into an amorphous state known as "random close packing." In our experiment, colloidal particles are allowed to slowly sediment forming a random close packed state. By adjusting the solvent's density we finely control the rate at which the sedimentation occurs. We then use confocal microscopy to image the sample. By imaging overlapping regions we determine the positions of hundreds of thousands of particles. From this data, we measure the distribution of Voronoi volumes and the contact number distribution, and examine how these distributions depend on the sedimentation rate.

12:39PM Q13.00008 Rotational and Translational Phonon Modes in Glasses Composed of Ellipsoidal Particles[1] , PETER J. YUNKER, KE CHEN, University of Pennsylvania, ZEXIN ZHANG, Soochow University, WOUTER G. ELLENBROEK, Eindhoven University of Technology, ANDREA J. LIU, ARJUN G. YODH, University of Pennsylvania — The effects of particle shape on the vibrational properties of colloidal glasses are studied experimentally. 'Ellipsoidal glasses' are created by stretching polystyrene spheres to different aspect ratios and suspending the resulting ellipsoidal particles at high packing fraction. By measuring displacement correlations between particles, we extract vibrational properties of the ellipsoidal glass. Low frequency modes in glasses composed of ellipsoidal particles with major/minor axis aspect ratios $\sim$1.1 are observed to have predominantly rotational character. By contrast, low frequency modes in glasses of ellipsoidal particles with larger aspect ratios ($\sim$3.0) exhibit a mix of rotational and translational character. All glass samples were characterized by a distribution of particles with different aspect ratios. Interestingly, even within the same sample it was found that small- aspect-ratio particles participate relatively more in rotational modes, while large-aspect-ratio particles tend to participate relatively more in translational modes.

12:51PM Q13.00009 Dynamical heterogeneities and fluctuations of the time variables in structural glasses , KARINA E. AVILA, HORACIO E. CASTILLO, Ohio University, AZITA PARSAEIAN, Northwestern University — The existence of dynamical heterogeneities in disordered materials is considered now as a crucial element in explaining many observed features of their dynamical behavior. In this work, we investigate a possible hypothesis for their origin, which assumes that they emerge from soft (Goldstone) modes associated with a broken continuous symmetry under time reparametrizations. To test this hypothesis, we construct coarse grained observables from data obtained in simulations of four models of structural glasses. The fluctuations of these observables are decomposed into transverse components associated with the postulated time-fluctuation soft modes and a longitudinal component unrelated to them. We find that as temperature is lowered and timescales are increased, the time reparametrization fluctuations become increasingly dominant and their correlation volumes grow together with the correlation volumes of the dynamical heterogeneities, while the correlation volumes for longitudinal fluctuations remain small.

1:03PM Q13.00010 Experimental observation of deformation and structural defects in hard-sphere colloid glasses , KATHARINE JENSEN, Harvard University Department of Physics, NOBUTOMO NAKAMURA, Harvard University School of Engineering and Applied Sciences, DAVID WEITZ, Harvard University Department of Physics, Harvard University School of Engineering and Applied Sciences, FRANS SPAEPEN, Harvard University School of Engineering and Applied Sciences — We performed experiments on a 1.55-μm-diameter monodisperse, hard-sphere colloid glass under simple shear at various strain rates, while simultaneously tracking real-time individual positions of roughly 100,000 particles by confocal microscopy. We probe the elastic, anelastic, and plastic responses of the system to applied strain, with particular focus on identifying the local mechanisms of deformation. In plastic deformation, we observe thermally activated rearrangements of groups of particles, the nature and concentration of which are correlated with local parameters such as strain, Voronoi volume, and free volume.

1:15PM Q13.00011 Aging dynamics of a colloidal glass - time resolved viscoelastic properties and the role of flow history[1] , CHINEDUM OSUJI, AJAY NEGI, Yale University — Many colloidal suspensions are inherently out of equilibrium and display a slow evolution of their dynamics over time. However, many features of the glass transition as encountered in polymer and molecular glasses are not conserved. This phenomenon is still not completely understood and little is known of the connection between flow history, as a determinant of the initial system state, and subsequent aging dynamics. Further, the changes in the energy landscape during aging can be understood from the frequency and strain dependence of the shear modulus but the non-stationary nature of these systems frustrates investigation of their instantaneous underlying properties. Here we discuss the use of stress jump experiments that investigate the role of flow history on aging, and the systematic reconstruction of the frequency and strain dependence as a function of age for a repulsive colloidal glass undergoing structural arrest and aging. We uncover a connection between the aging behavior and the rate of flow cessation that is additionally reflected in the dynamics of residual stress relaxation. Strikingly, the frequency dependence at fixed times can be rescaled onto a master curve, implying a simple connection between the aging of the system and the change in the frequency dependent modulus.

1:27PM Q13.00012 Jamming, Clogging, and Fragility in Frictionless Disk Systems with Quenched Disorder , CHARLES REICHHARDT, Los Alamos National Laboratory, EVAN GROOPMAN, ZOHAR NUSSINOV, Washington University, CYNTHIA OLSON REICHHARDT, Los Alamos National Laboratory — We consider a two-dimensional simulation model of binary frictionless disks which have a well defined jamming density of $\phi_j \approx 0.84$ in the absence of quenched disorder. When quenched disorder is added in the form of impenetrable immobile disks, the jamming density is reduced. As the density of the quenched disorder sites increases, we observe a crossover from a jamming transition to a clogging transition. The clogged state is defined as a highly heterogeneous granular packing that resists shear along one direction and that is composed of a combination of high density patches at the clean jamming density and very low density patches or voids. These clogged states are fragile in the sense that they are only clogged in the direction of an externally applied drive. After a clogged state has formed, if a new drive is applied in a different direction the disks can flow freely for a period of time before reorganizing into a new clogged state. In contrast, jammed systems are jammed in all directions simultaneously.

1:39PM Q13.00013 Coupling Between Translational and Orientational Order in Fiber Suspensions[1] , ALEXANDRE FRANCESCHINI, EMMANOUELA FILIPPIDI, Center for Soft Matter Research, New York University, ELISABETH GUAZZELLI, IUSTI-CNRS UMR 6595 - Polytech Marseille - Aix-Marseille University, DAVID PINE, Center for Soft Matter Research, New York University — Suspensions of non-Brownian fibers under a small oscillatory shear flow find a random but completely reversible state, called "random organization": at each period, the non-hydrodynamic interactions modify both the orientation and positions of fibers, until a reversible configuration is found. As observed in sphere suspensions, there is a nonequilibrium absorbing phase transition when the strain is increased above a concentration-dependant threshold. The transient time, during which the activity decays algebraically, has a diverging duration; critical exponents are consistent with Manna universality class. Above the threshold, fibers get progressively aligned towards the vorticity and a reversible steady state is eventually found for a range of strain. This behavior is specific to fiber suspensions. We study whether or not these oriented reversible states are critical states. We experimentally evaluate the angles distribution of fibers in both vertical and horizontal planes and discuss the relation between these distributions and the existence of a reversible state.

1:51PM Q13.00014 Force correlations near point J in a lattice model of jamming , SCOTT MILNER, JILLIAN NEWHALL, Penn State University — We have constructed a lattice model of a jammed system in $d = 2$ dimensions near the isostatic point (Point J). Adapting the Tighe model, we represent a jammed pack of particles as a regular hexagonal array, with repulsive forces between nearest neighbors. We generate near-isostatic jammed configurations by carrying out a Monte Carlo simulation with Tighe "wheel moves", which rearrange forces locally while preserving force balance on every particle. (Wheel moves correspond to a small dilation of a given particle.) The MC simulation is progressively biased towards the creation of "missing contacts", bonds which bear zero force. We reveal long-range correlations in the force network near Point J by determining for each particle the smallest "collective move" — a set of wheel moves that taken together dilates the given particle, while preserving the existing missing contacts. The size of these collective moves diverges as Point J is approached.

2:03PM Q13.00015 Time and volume fraction dependence of dynamic heterogeneity in a glass-forming binary hard-sphere mixture , ELIJAH FLENNER, GRZEGORZ SZAMEL, Colorado State University - Chemistry Department — We examined dynamic heterogeneity in a glass-forming binary hard-sphere mixture for volume fractions up to and including the so-called mode-coupling transition. We calculated the dynamic susceptibility $\chi_4(t)$, the four-point structure factor $S_4(q;t)$ and the dynamic correlation length $\xi(t)$. We find that the correlation length increases with time as $\xi(t) \sim \ln(t)$ and is independent of ϕ for times approximately between the β and α relaxation time. The dynamic length plateaus at a ϕ dependent value $\xi_{\max}(\phi)$. We find that $\xi_{\max}(\phi)$ is proportional to the dynamic length at the α relaxation time, $\xi(\tau_\alpha)$. Finally, while for a limited range of volume fractions $\xi(\tau_\alpha) \sim \tau_\alpha^{1/z}$ with $1/z \approx 0.2$, we find that $\xi(\tau_\alpha) \sim \ln(\tau_\alpha)$ describes our data well for all ϕ.

Session Q14 GSNP: Focus Session: Extreme Mechanics: Elasticity and Deformation I D227

11:15AM Q14.00001 Geometric Nonlinear Computation of Thin Rods and Shells[1] , EITAN GRINSPUN, Columbia University — We develop simple, fast numerical codes for the dynamics of thin elastic rods and shells, by exploiting the connection between physics, geometry, and computation. By building a discrete mechanical picture from the ground up, mimicking the axioms, structures, and symmetries of the smooth setting, we produce numerical codes that not only are consistent in a classical sense, but also reproduce qualitative, characteristic behavior of a physical system—-such as exact preservation of conservation laws—-even for very coarse discretizations. As two recent examples, we present discrete computational models of elastic rods and shells, with straightforward extensions to the viscous setting. Even at coarse discretizations, the resulting simulations capture characteristic geometric instabilities. The numerical codes we describe are used in experimental mechanics, cinema, and consumer software products.

11:51AM Q14.00002 Wrinkling of an Annulus , KAMIL TOGA, University of Massachusett, Amherst, BENOIT ROMAN, JOSE BICO, Laboratoire de Physique et Mecanique des Milieux Heterogenes, ESPCI Paris, France, THOMAS RUSSELL, NARAYANAN MENON, University of Massachusett, Amherst, UNIVERSITY OF MASSACHUSETT, AMHERST TEAM, LABORATOIRE DE PHYSIQUE ET MECANIQUE DES MILIEUX HETEROGENES, ESPCI PARIS, FRANCE TEAM — We report on an experiment in which we study the wrinkling of an annular elastic film subject to different radial tensions at the inner and outer diameter. The annuli were made from polystyrene films of thickness ranging from 62 to 180 nm, and floated on water. They were then transferred onto a Langmuir-Blodgett trough filled with acidic aqueous subphase. The surface tension on the inside of the annulus is held fixed, while the surface tension outside the annulus is continuously varied by compressing an insoluble surfactant. When the differential tension is increased beyond a threshold value, radial wrinkles form in the interior of the annulus and extend outwards. We studied the length of wrinkles formed as a function of the differential tension produced by the surfactant, and for a range of film thickness.

12:03PM Q14.00003 Dancing Discs: Bending and Twisting of Soft Materials by Anisotropic Swelling , DOUGLAS HOLMES, MATTHIEU ROCHÉ, TARUN SINHA, HOWARD STONE, Princeton University — Soft materials, e.g. biological tissues and gels, undergo morphological changes, motion, and instabilities when subjected to external stimuli. Tissues can exhibit residual internal stresses induced by growth, and generate elastic deformations to move in response to light or touch, curl articular cartilage, aid in seed dispersal, and actuate hygromorphs, such as pine cones. Understanding the dynamics of such osmotically driven movements, in the influence of geometry and boundary conditions, is crucial to the controlled deformation of soft materials. We examine how thin elastic plates undergo rapid bending and buckling instabilities after anisotropic exposure to a favorable solvent that swells the network. An unconstrained beam bends along its length, while a circular disc bends and buckles with multiple curvatures. In the case of a disc, a large-amplitude transverse travelling wave rotates azimuthally around the disc. Theoretical interpretations inspired by the complementary thermal expansion problem of transient shape changes triggered by time-dependent heating are presented and allow collapse of time-dependent data on universal curves. Understanding the dynamics of strain-driven shape changes provides new insight into natural systems and control of advanced functional materials.

12:15PM Q14.00004 Sinusoidal to helical buckling of a thin rod under a cylindrical constraint , JAMES MILLER, Massachusetts Institute of Technology, ARNAUD LAZARUS, MIT, NATHAN WICKS, JAHIR PABON, Schlumberger-Doll Research, PEDRO REIS, MIT — We investigate the buckling and post-buckling behavior of a thin, elastic rod loaded under cylindrical constraint. Our desktop experiments consist of compressing a hyper-elastic rod inside a transparent acrylic pipe with a motorized linear actuator. Under imposed displacement, the initially straight rod first buckles into a sinusoidal mode and eventually undergoes a secondary instability into helical buckling. This buckling and post-buckling behavior is found to be highly dependent on the systems' geometry, namely the rod length and the aspect ratio of the rod to pipe diameter. We quantify the wavelength and pitch of the period patterns through direct digital imaging and record the reaction forces at both end of the pipe. The observed behavior is rationalized through scaling arguments.

12:27PM Q14.00005 Shape evolution of a thin loop sedimenting in a viscous fluid , JAMES HANNA, CHRISTIAN SANTANGELO, Department of Physics, UMass-Amherst — We consider the non-local elastic problem of a closed thin filament settling under gravity in a fluid at zero Reynolds number. The filament is modeled as an inextensible chain, with no bending or twist rigidity. Although the equations admit rigid motions of the chain, there are no stable trajectories. We explore whether a stable envelope may exist around a recirculating blob and tail arrangement.

12:39PM Q14.00006 3D micro-modeling of wrinkling phenomena , DAMIEN EGGENSPIELER, GOZDE INCE, KAREN GLEASON, MARY BOYCE, MIT — Wrinkles, formed by the buckling of stiff layers adhering to soft substrates, are commonplace in nature. From wrinkles on smiling or aging faces to the wrinkled shape of pumpkins or the wrinkled electrospun nano-fibers due to the radial evaporation of the solvent used in the processing of these fibers, wrinkles have been found ranging from the nano- to the macroscopic scales. More recently, studies have shown that this buckling phenomenon can be directed via a selective stiffening of either ones of the layers composing this composite system. We are introducing a 3D numerical model for the buckling of a shell on a soft layer. The selective stiffening of the shell can reproduce the "stiffness patterning" obtained experimentally by UV-Ozone treatment of a soft PDMS substrate through a photomask. This model can predict the final shape of the surface of this composite system for periodic photomasks and might be used in the design of specific micro-topographies.

12:51PM Q14.00007 Coiling Spaghetti: Deposition of a Thin Rod onto a Moving Substrate , PEDRO REIS, Massachusetts Institute of Technology, JUNGSEOCK JOO, UCLA, JOSEPHINE MANNENT, MIT, JOEL MARTHELOT, ESPCI, Paris, DANNY KAUFMAN, EITAN GRINSPUN, Columbia University — We investigate the oscillatory coiling patterns obtained when a thin elastic rod is deposited onto a moving solid boundary (conveyor belt). Through a combination of well controlled desktop experiments and numerics, we explore the phase diagram of this coiling process and identify the underlying physical ingredients. Our novel numerical method implements a discrete notion of bending and twist based on ideas ported from differential geometry, and exhibits excellent performance and robustness. This enables us to carry out predictive direct simulations of the large deformations of the thin elastic rod interacting with the moving substrate, that are in excellent agreement with our experiments. Applications of this coiling process range from the coiling of nanotubes to the laying down of transoceanic cable and pipelines in the ocean bed.

1:03PM Q14.00008 Geometry-ruled deformation of thin elastic shells , ARNAUD LAZARUS, Massachusetts Institute of Technology, PEDRO MIGUEL REIS, MIT — We study the mechanical response of thin elastic shells subject to point or plate load and in different mechanical environments (with or without an in-out pressure difference). The geometry and material properties of the ellipsoidal shells used in our experiments can be accurately controlled using digital fabrication techniques. The linear and nonlinear mechanical response of the shells is quantified through load-displacement compression tests and the post-buckling patterns are analyzed using digital imaging. In the linear regime, we explore the geometry-induced rigidity of shells with different shapes. In the nonlinear regime, we focus on the formation of structures with localized curvature, which we denote by s-cones (shell-cones) and examine their mechanical and morphological properties.

1:15PM Q14.00009 The Buckliball: Pressure Induced Pattern Transformation of a Structured Elastic Shell , JONGMIN SHIM, Harvard University, CLAUDE PERDIGOU, Massachusetts Institute of Technology, KATIA BERTOLDI, Harvard University, PEDRO REIS, Massachusetts Institute of Technology — We report an experimental and computational study of a patterned elastic shell which, under pressure loading, undergoes a transformation in its structural configuration. The geometry of the ball comprises of an elastomeric spherical shell patterned with a regular array of circular holes. These voids are covered with a thin membrane, thereby making the ball air tight. Upon reduction of the internal pressure, the thin membranes first invert their curvatures inward. Consequently, beyond the critical pressure, the thin ligaments between the holes buckle leading to a cooperative buckling cascade of the skeleton of the ball. During this process, the initially circular holes evolve into an elliptical shape, and eventually become fully closed. This pattern transformation is induced by mechanical instability that opens the possibility for reversible encapsulation, over a wide range of length scales.

1:27PM Q14.00010 Polymer Thin Film Buckling: Wrinkling and Strain Localizations[1] , YURI EBATA, University of Massachusetts, Amherst, ANDREW B. CROLL, North Dakota State University, ALFRED J. CROSBY, University of Massachusetts, Amherst — Out of plane deformations of thin films are observed in everyday life, e.g. wrinkled aging human skin or folded fabrics. Recently, these deformations are being pursued for fabricating unique patterned surfaces. In this study, the transition from wrinkling, a low-strain buckling behavior, to localized deformations such as fold and delamination, is investigated for polystyrene films with thickness ranging from 5nm to 180nm. The thin films are attached to a uniaxially strained polydimethysiloxane substrate and the strain is released incrementally to apply increasing compressive strain to the attached film. The wavelength and the amplitude of local out-of-plane deformation are measured as global compression is increased to distinguish between wrinkling, folding, and delamination. The transition from wrinkling to strain localizing events is observed by tracking the statistics of amplitude distribution sampled across a large lateral area. A critical strain map is constructed to denote the strain regimes at which wrinkle, fold, and delamination occur.

[1]NSF-DMR 0907219

1:39PM Q14.00011 Statistical Mechanics of Pressurized Shells , JAYSON PAULOSE, Harvard School of Engineering and Applied Sciences, Cambridge, MA 02138, GERRIT VLIEGENTHART, GERHARD GOMPPER, Institut fur Festkorperforschung, Forschungszentrum Juelich, Germany, DAVID NELSON, Physics Department, Harvard University, Cambridge, MA 02138 — It is well known that thermal fluctuations strongly modify the large length scale elastic behavior of flat solid membranes. A thin spherical shell may be considered a solid membrane with a uniform nonzero curvature. This curvature couples the in-plane stretching modes with the out-of-plane undulation modes, giving rise to qualitative differences in the fluctuations of spherical shells compared to flat membranes. In addition, a shell can support a pressure difference between its interior and exterior. We study the statistical mechanics of deformations of a spherical shell using perturbation theory and Monte Carlo simulations, explicitly including the effects of curvature and pressure. Thermal corrections to the predictions of classical shell theory for point indentation and pressure-induced buckling experiments on microscale shells diverge as the ratio of shell radius to thickness tends to infinity.

1:51PM Q14.00012 Complex Morphogenesis from Elastic Instability of Thin Sheets , PASCAL DAMMAN, Universite de Mons — Thin sheets are mechanically unstable to boundary or substrate-induced compressive loads. Moderate compression results in regular wrinkling while further confinement can lead to crumpling. In this communication, we will first show the emergence of a new morphological instability triggered by a period-doubling bifurcation observed for large compression ratio. A periodic self-organized focalization of the deformation energy is observed provided a symmetry breaking, induced by the elastic foundation, occurs. This effect will be explained by considering geometrical nonlinearities leading to a Euler-Lagrange equation similar to the equation of a parametric resonance in nonlinear oscillator. In the second part, we will show that thin sheets, from suspended graphene to ordinary hanging curtains, under boundary confinement spontaneously generate a universal self-similar cascade of wrinkled patterns. We develop a formalism based on *wrinklons*, a localized transition zone in the merging of two wrinkles, as building-blocks to describe the cascade morphology. These physical models based on elasticity and geometry constitutes a new theoretical toolkit to understand the morphology of various confined systems, such as coated materials or living tissues. Moreover, it also opens the way to new kind of microfabrication design of multiperiodic or chaotic (aperiodic) surface topography via self-organization.

2:03PM Q14.00013 Stability of a drop-strip system , MARCO RIVETTI, SÉBASTIEN NEUKIRCH, ARNAUD ANTKOWIAK, Institut d'Alembert, Paris, UPMC & CNRS — When a flexible material is placed in contact with a liquid-air interface, capillary forces may cause deformations and large displacements in the structure. Such kind of elastocapillary interactions play a crucial role in many technological applications, like deflection of nanotubes carpets or microscale self-assembly. We study the problem of a drop deposited on a thin and narrow strip. Using a simplified 2D model including surface tension interactions, elastic and gravitational energies, we are able to predict the shape of the equilibrium solutions, as well as the appearance of instability in the system. Theoretical predictions are confronted to experiments and a good agreement is obtained.

Wednesday, March 23, 2011 11:15AM - 2:15PM –

Session Q15 DMP GMAG FIAP: Focus Session: Spins in Semiconductors - Quantum Dots and Nuclear Spins D171

11:15AM Q15.00001 Protecting the electron spin coherence in a quantum dot with inhomogeneously polarized nuclear spins via dynamic nuclear polarization[1] , WENXIAN ZHANG, JUN ZHUANG, Department of Optical Science and Engineering, Fudan University, Shanghai 200433, China, J.Q. YOU, Department of Physics, Fudan University, Shanghai 200433, China — An electron spin in a quantum dot is decohered by its surrounding nuclear spins via hyperfine coupling. During the dynamic nuclear polarization process, when the nuclear spins are polarized inhomogeneously by repeatedly injected polarized electron spins, a fully polarized nuclear spin core is formed. As a consequence, the polarized nuclear spin core can be harnessed to protect the electron spin coherence. In this way, we find that the electron spin coherence time can be extended tens times with the total nuclear polarization as low as 20%, in contrast to the usual requirement of 90% polarization, in a quantum dot with 256 nuclear spins. The total nuclear polarization goes even lower for larger quantum dots. The effect of the dipolar interaction between nuclear spins is also discussed.

[1]Supported by the 973 Program under Grant No. 2009CB929300, NCET, Specialized Research Fund for the Doctoral Program of Higher Education of China under Grant No. 20090071120013, Shanghai Pujiang Program under Grant No. 10PJ1401300.

11:27AM Q15.00002 Electrically detected nuclear magnetic resonance in GaAs/AlGaAs-based quantum point contacts , ZACHARY KEANE, MATTHEW GODFREY, ADAM BURKE, JASON CHEN, SEBASTIAN FRICKE, OLEH KLOCHAN, ADAM MICOLICH, University of New South Wales, HARVEY BEERE, DAVE RITCHIE, University of Cambridge, KIRILL TRUNOV, DIRK REUTER, ANDREAS WIECK, Ruhr Universitaet Bochum, ALEX HAMILTON, University of New South Wales — Nuclear magnetic resonance (NMR) is a well-known technique with widespread applications in physics, chemistry and medicine. Conventional NMR studies use inductive coils to detect the magnetic field produced by precessing nuclear spins; this approach requires on the order of 10^{12} spins for detection. Recently, resistive detection of NMR through the hyperfine interaction has been demonstrated with electrons in mesoscopic 2- and 1-dimensional devices based on high-quality GaAs/AlGaAs heterostructures. These studies are typically sensitive to 10^8 spins, enabling NMR on much smaller sample volumes. Holes are predicted to have much weaker nuclear spin coupling than electrons, which could be relevant to the emerging fields of spintronics and quantum information processing. We present a preliminary comparison between the magnitude of the NMR signal in electron and hole quantum point contacts.

11:39AM Q15.00003 Enhancing 29Si Dynamic Nuclear Polarization Through Microwave Frequency Modulation[1] , MAJA CASSIDY, MEN YOUNG LEE, CHARLES MARCUS, Harvard University — We demonstrate up to a four-fold enhancement in the dynamic nuclear polarization (DNP) of silicon particles by applying an a.c. modulation to the microwave frequency used for irradiation of the electron spin system. The DNP enhancement is studied at temperatures ranging from 2-20 K and across a range of microwave powers. The total nuclear polarization is found to increase with decreasing temperature and increasing microwave power however, surprisingly, the polarization enhancement increases as the temperature is increased. The DNP enhancement is seen to increase with polarization time and is highest in spin-diffusion regime of polarization. By varying the frequency and amplitude of the applied modulation, dynamics of the electron spin system are probed. We find that the highest polarization enhancements are achieved with the frequency is modulated at a rate much greater than the electron spin lattice relaxation rate, where higher order electron spin processes can contribute to the polarization process.

[1]Supported by the NSF-BISF and the Harvard NSEC

11:51AM Q15.00004 Dynamic Nuclear Polarization in Double Quantum Dots , MICHAEL GULLANS, Department of Physics, Harvard University — We theoretically investigate the controlled dynamic polarization of lattice nuclear spins in GaAs double quantum dots containing two electrons.[1] Three regimes of long-term dynamics are identified, including the build up of a large difference in the Overhauser fields across the dots, the saturation of the nuclear polarization process associated with formation of so-called "dark states," and the elimination of the difference field. We show that in the case of unequal dots, build up of difference fields generally accompanies the nuclear polarization process, whereas for nearly identical dots, build up of difference fields competes with polarization saturation in dark states. The elimination of the difference field does not, in general, correspond to a stable steady state of the polarization process.

[1]M. Gullans, et. al., Phys. Rev. Lett. 104, 226807 (2010).

12:27PM Q15.00005 Spin-dependent tunneling into an empty lateral quantum dot , PETER STANO, PHILIPPE JACQUOD, Physics Department, University of Arizona, 1118 E 4th Street, Tucson, Arizona 85721, USA — In a recent experiment [Phys. Rev. B **78**, 041306(R) (2008)] Amasha *et al.* reported a strong spin dependence of the rate for electrons to tunnel into an empty quantum dot in a Zeeman field. Such dependence is intriguing, as one expects tunneling rates to depend on the orbital structure of the wavefunction, over which a Zeeman field has no effect. In search for an explanation, we find two mechanisms leading to a spin-dependent tunneling rate. The first originates from different electronic g-factors in the lead and in the dot, and favors the tunneling into the spin ground (excited) state when the g-factor magnitude is larger (smaller) in the lead. The second is triggered by spin-orbit interactions via the opening of off-diagonal spin-tunneling channels. It systematically favors the spin excited state. Numerically modeling the experimental setup, we find that in GaAs the spin-orbit interaction is unable to explain the experimental results, as it leads to no more than a $\sim$10% discrepancy in the spin up vs spin down tunneling rates. We conjecture that the significantly larger discrepancy observed experimentally originates from the enhancement of the g-factor in the laterally confined lead. Reference: P. Stano and Ph. Jacquod, Phys. Rev. **B** 82, 125309 (2010)

12:39PM Q15.00006 Theory of spin blockade in a triple quantum dots[1] , CHANG-YU HSIEH, Department of Physics, University of Ottawa, Ottawa, Ontario, Canada K1N 6N5, YUN-PIL SHIM, Department of Physics, University of Wisconsin-Madison, Madison WI 53706, PAWEL HAWRYLAK, Quantum Theory Group, Institute for Microstructural Sciences, National Research Council, Ottawa, Canada, K1A 0R6 — We present a theory of electronic properties and spin blockade in a linear triple quantum dots. We use micoroscopic LCHO-CI and double-band Hubbard model to analyze the electronic and spin properties of a triple quantum dots near a symmetrical quadruple point involving the (1,1,1) configuration which is essential for implementing quantum information processing with electron spin. We calculate spectral functions and relate them via the rate equation, including coupling with a phonon bath, to current as a function of applied bias. We show that the spin blockade in a triple quantum dots can serve as a spectroscopic tool to distinguish spin polarized states from spin depolarized states. We also show that a spin blockade is developed only at high bias when an onsite triplet state on the edge quantum dot connected to the source lead becomes accessible in the transport window. In contradiction to the case of double quantum dot molecule, the onsite triplet is not only essential for lifting spin blockade but also important for building up spin polarisation and spin blockade in the system.

[1]The authors would like to acknowledge financial support from NSERC, OGS, and QuantumWorks.

12:51PM Q15.00007 Spin-polarized current generation in multiterminal quantum dot in Kondo regime , MIKIO ETO, TOMOHIRO YOKOYAMA, Keio University — We theoretically study the generation of spin-polarized current in a quantum dot with strong spin-orbit interaction, such as InAs quantum dot. As a minimal model, we consider two energy levels in a quantum dot, which is connected to N leads through tunnel barriers. When an unpolarized current is injected from a lead, spin-polarized currents are ejected to other leads in the case of $N \geq 3$. First, we show that the spin polarization of the output currents is markedly enhanced by resonant tunneling, around current peaks of Coulomb oscillation, when the level spacing in the dot is smaller than the level broadening. Next, we examine the many-body resonance induced by the Kondo effect in the Coulomb blockade regime. A large spin current is created in the presence of the SU(4) Kondo effect when the level spacing is less than the Kondo temperature.[1]

1:03PM Q15.00008 Spin blockade in the optical response of a charged quantum dot , ELEFTHERIA KAVOUSANAKI, GUIDO BURKARD, University of Konstanz, Germany — We theoretically model the population dynamics in a semiconductor quantum dot charged with a single electron in an optical pump-probe setup when the two lowest quantum dot levels are photoexcited. We calculate the differential transmission spectrum as a function of the time delay between the two circularly polarized optical pulses by using a density matrix formalism and treating intraband relaxation with the Lindblad equation. Taking into account both spin conserving and spin-flip relaxation processes we investigate the possibility for spin-dependent blocking of intraband relaxation due to the presence of the ground state electron for zero and finite magnetic fields. We show that the differential transmission spectrum is initially dominated by the fast spin-conserving mechanism before the slower spin-flip processes start to contribute at longer time scales. As a consequence of spin conservation for short time scales, we find a spin blockade effect in the optical recombination process.

1:15PM Q15.00009 Simulating electron spin entanglement in a double quantum dot[1] , M.A. RODRIGUEZ-MORENO, A.D. HERNANDEZ DE LA LUZ, Centro de Investigaciones en Dispositivos Semiconductores, Instituto de Ciencias BUAP, LILIA MEZA-MONTES, Instituto de Fisica BUAP — One of the biggest advantages of having a working quantum-computing device when compared with a classical one, is the exponential speedup of calculations. This exponential increase is based on the ability of a quantum system to create and operate on entangled states. In order to study theoretically the entanglement between two electron spins, we simulate the dynamics of two electron spins in an electrostatically-defined double quantum dot with a finite barrier height between the dots. Electrons are initially confined to separated quantum dots. Barrier height is varied and the spin entanglement as a function of this variation is investigated. The evolution of the system is simulated by using a numerical approach for solving the time-dependent Schrödinger equation for two particles.

1:27PM Q15.00010 Exchange coupling between hole qubits and between electron qubits in quantum dot molecules[1] , ALEX GREILICH[2], STEFAN C. BADESCU[3], DANNY KIM[4], ALLAN S. BRACKER, DANIEL GAMMON, NRL, Washington, DC — The exchange interaction between electron spins has been a paradigm for solid-state implementation of quantum gates. Holes are receiving an increasing attention for their reduced hyperfine coupling as compared to electrons in III-V semiconductors. Besides the isotropic exchange, both electrons and holes couple through spin-nonconserving interactions. Here we present detailed experimental evidence of these interactions for electrons and for holes in stacked InAs/GaAs quantum dots, achieved through electrical and magnetic fields that induce energy level resonances. Particularly large spin-mixing effects are found for holes, which involve their multi-band structure. We provide a theoretical understanding of the essential mixing mechanisms involved, tracing them down to system asymmetries and inhomogeneities.

1:39PM Q15.00011 Chiral spin currents and spectroscopically addressable single merons in quantum dots , CATHERINE STEVENSON, JORDAN KYRIAKIDIS, Dalhousie University — We provide unambiguous theoretical evidence for the formation of correlation-induced isolated merons in rotationally-symmetric quantum dots beyond the lowest-Landau-level approximation. For experimentally accessible system parameters, unbound merons condense in the ground state at magnetic fields as low as B* = 0.3 T and for as few as N = 3 confined fermions. The four-fold degenerate ground-state at B* corresponds to four orthogonal merons characterised by their winding number ± 1 and topological charge ± 1. This degeneracy is completely lifted by the Rashba and Dresselhaus spin-orbit interactions, yielding spectroscopic accessability to individual merons. We further derive a closed-form expression for the topological chirality in the form of a chiral spin current and use it to both characterise our states and predict the existence of other topological textures in other regions of phase space.

1:51PM Q15.00012 Magnetoconductance of a Single-Electron Transistor in the Kondo Regime[1] , TAI-MIN LIU, BRYAN HEMINGWAY, ANDREI KOGAN, University of Cincinnati, STEVEN HERBERT, Xavier University, MICHAEL MELLOCH, Purdue University, THEO A. COSTI, Institut fur Festkorperforschung, Forschungszentrum Julich, 52425 Julich, Germany — We have measured the zero-bias conductance of a Single-Electron Transistor (SET) in the Kondo regime as a function of temperature, T, and magnetic field, B, oriented parallel to the plane of the device. Our SETs are fabricated on a GaAs/AlGaAs heterostructure with electron sheet density 4.8×10^{11} cm^{-2} and mobility 5×10^5 cm^{2}V^{-1}s^{-1}. Scaled plots of both the T and B-dependent data show universal behavior. At moderate and high B, the magnetoconductance data show good agreement with renormalization group calculations in the spin-1/2 Kondo regime. At very low B, we observe a non-monotonic behavior: as B increases, the conductance initially increases and only starts to decrease at a finite B. A possible explanation of this effect due to the presence of multiple orbital dot levels with similar energies will be discussed.

2:03PM Q15.00013 Measuring mesoscopic spin currents by spin-to-charge conversion , PHILIPPE JACQUOD, PETER STANO, Physics Department, University of Arizona, 1118 E 4th Street, Tucson, Arizona 85721, USA — A number of theoretical investigations show that spin currents can be magneto-electrically generated by passing electric currents through spin-orbit coupled quantum dots. Measuring these currents has however not been achieved to date. In this talk, we present a theoretical proposal for measuring such mesoscopic spin currents with a voltage probe connected to the quantum dot via a single channel quantum point contact. We demonstrate that a spin current flowing through the quantum point contact results in an odd dependence of the charge current $I_{\rm qpc}$ on an externally applied Zeeman field, while this response is even in the absence of the spin current. The magnitude of the spin current is proportional to the zero field derivative of $I_{\rm qpc}$, with a constant of proportionality depending weakly on the geometry of the point contact. Numerical estimates suggest that in this way, mesoscopic spin currents can successfully be measured in GaAs quantum dots.

Session Q16 DCOMP: Electronic Structure III D173

11:15AM Q16.00001 Oxides – a challenge for (theoretical) spectroscopy , P. RINKE, H. JIANG, M. SCHEFFLER, Fritz-Haber-Institut der MPG, 14195 Berlin, A. GREULING, M. ROHLFING, Universitaet Osnabrueck, 49069 Osnabrueck, A. JANOTTI, E. KIOUPAKIS, C. G. VAN DE WALLE, University of California at Santa Barbara, CA 93106 — Oxides are of tremendous technological importance, yet challenging materials to characterize. In many cases the agreement between experimental and theoretical spectroscopy observed for other material classes has not been attained. We use rutile TiO_2 as an example to illustrate some of the problems. Many-body perturbation theory in the G_0W_0 approach based on density-functional theory in the local-density approximation gives a fundamental band gap of 3.3 eV in seemingly good agreement with the 3.3±0.5 eV measured in direct and inverse photoemission [1]. However, the lowest exciton computed in Bethe-Salpeter calculations for the optical spectrum is found at an energy of 3.21 eV, while optical experiments only give 3.03 eV [2]. Polaronic effects, i.e. the renormalization of the band edges due to electron-phonon coupling, reduce the band gap, but it remains a challenge to include the ionic contribution to the dielectric function, which can be substantial in oxides, in the G_0W_0 calculations and to incorporate both effects consistently into Bethe-Salpeter calculations. Another aspect to consider is the role of electron correlations. [1] Y. Tezuka *et al.*, J. Phys. Soc. Jpn.**63**, 347 (1994). [2] J. Pascual *et al.*, Phys. Rev. B **18**, 5606 (1978).

11:27AM Q16.00002 Calculated Electronic Properties of Rutile TiO_2 and Cubic $SrTiO_3$, CHINEDU EKUMA, Louisiana State University, Baton Rouge, LA, DIOLA BAGAYOKO, Southern University and A&M College, Baton Rouge, LA — We present preliminary, calculated, electronic properties of rutile titanium dioxide (TiO_2) and of cubic strontium titanate ($SrTiO_3$). Our computations employed local density approximation (LDA) and generalized gradient Approximation (GGA) potentials for TiO_2 and $SrTiO_3$, respectively. We implemented the linear combination of atomic orbitals (LCAO) within the framework of the Bagayoko, Zhao, and Williams (BZW) method. In doing so, we solved, self-consistently, both the Kohn-Sham equation and the equation giving the ground state charge density in terms of the wave functions of the occupied states. Our preliminary findings indicate that TiO_2 has an indirect band gap of 2.95 eV, from Γ to R. The direct gap at Γ is 0.10 eV larger. The indirect band gap of $SrTiO_3$, from L to Γ or X, is 3.05 eV.

11:39AM Q16.00003 The confinement error corrections for the exchange energy in transition metal oxides , FENG HAO, Sandia National Laboratories, RICKARD ARMIENTO, MIT, ANN E. MATTSSON, Sandia National Laboratories — We present some recent advances towards a straightforward scheme to correct for the confinement errors of the exchange energy of the transition metal oxides (TMO). This approach includes two steps: (i) identifying the spatial regions where the confinement errors exist, using local density and kinetic energy density information, and (ii) mapping these spatial regions to harmonic-oscillator (HO) models [1], and quantifying and correcting the relative confinement errors based on the model system. The scheme has been applied to calculations with several local and semi-local functionals, and a trend of improvement for the equilibrium structure is obtained after applying these confinement error corrections. Sandia is a multiprogram laboratory operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Company, for the U.S. Department of Energy's National Nuclear Security Administration under Contract No. DE-AC04-94AL85000.

11:51AM Q16.00004 First principles study of electronic and structural properties of CuO , BURAK HIMMETOGLU, MATTEO COCOCCIONI, University of Minnesota — The ground state of CuO is particularly challenging to study with DFT-based computational techniques even below its Neel temperature. This situation is due to the inability of most approximate DFT energy functionals to describe electronic regimes hat are dominated by many-body effects. In this study, we show how a description of the ground state of this material in better agreement with observations can be obtained using extended Hubbard-based corrective energy functionals (DFT+U and DFT+U+V). In particular we uncover an orbitally ordered insulating ground state for the cubic phase of CuO (that was expected, but never reported before) whose appearance is determined by a fine interplay between correlation effects and magnetic interactions. Starting from this ground state we also study the tetrahedral distortion of the unit cell (recently reported in experiments), characterizing the reorganization of the electronic states and identifying all the equilibrium structures.

12:03PM Q16.00005 Transition metal dioxides: a case for the intersite term in Hubbard-model functionals , HEATHER KULIK, Stanford University, NICOLA MARZARI, Oxford University — Triatomic transition-metal oxides in the "inserted dioxide" (O-M-O) structure represent one of the simplest examples of systems that undergo qualitative geometrical changes via subtle electronic-structure modulation. We discuss three transition-metal dioxide molecules (MO_2 where M = Mn, Fe, or Co), for which equilibrium structural (eg bent or linear geometry) and electronic (eg spin or symmetry) properties have been challenging to assign both theoretically and experimentally. Augmenting a standard density-functional theory (DFT) approach with a Hubbard term (DFT+U) occasionally over-localizes the $3d$ manifold, leading to incorrect bond elongation and, in turn, poor equilibrium geometries for MO_2 molecules, while preserving good spin-state splittings. We recover a proper description of both geometry and energetics for these molecules through either calculating DFT+U relaxations at fixed M-O bond lengths or by inclusion of an inter-site interaction term V that favors M($3d$)-O($2p$) interactions. In the latter case, both U and V are calculated fully from first-principles and are not fitting parameters. Finally, we present an approach that more accurately determines the Hubbard U over a coordinate in which the character of bonding varies.

12:15PM Q16.00006 On the origins of the deficiencies of density functional theory exchange-correlation functionals for transition metal oxides , ANN E. MATTSSON, Sandia National Laboratories, RICKARD ARMIENTO, MIT, FENG HAO, Sandia National Laboratories — The transition metal oxides (TMO) are a class of compounds that are difficult to treat in density functional theory (DFT) with simple local and semi-local functionals. Especially for CuO, they failed to give the correct equilibrium monoclinic structure. The major source of the deficiency is attributed to the imperfect cancellation of the electronic self-interaction (SI) in the approximated exchange energy. Previous studies [1] show that a large part of the SI error is connected to the confinement error that can be modeled by harmonic-oscillator (HO) systems. We discuss recent advances towards a simple methodology to quantify the confinement errors in real TMO systems. Our results show that these confinement errors may account for the deficiencies of DFT functionals in obtaining the correct equilibrium structure of the TMO. Sandia is a multiprogram laboratory operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Company, for the U.S. Department of Energy's National Nuclear Security Administration under Contract No. DE-AC04-94AL85000.

12:27PM Q16.00007 Ab initio calculation of the orbital magnetization by Wannier interpolation , GRAHAM LOPEZ, Wake Forest University, DAVID VANDERBILT, Rutgers University, IVO SOUZA, University of California Berkeley, TIMO THONHAUSER, Wake Forest University — We present an analytic, first-principles scheme to efficiently calculate exactly the spontaneous orbital magnetization of ferromagnetic crystals [1,2]. This is in contrast to the standard method of integrating inside muffin-tin spheres which, while a good approximation in practice, is still an approximation. The method uses Wannier interpolation to perform the necessary Brillouin-zone integrals in a similar way as was done previously for the anomalous Hall conductivity [3]. The method has been implemented to work with a plane-wave density-functional code, and calculations were done on iron, cobalt and nickel. We compare our calculations of the orbital magnetization in these systems to recent ab initio and experimental results and find good agreement with both [4].

12:39PM Q16.00008 Origin for the disorder-induced quantum criticality in $NbFe_2$[1] , AFTAB ALAM, DUANE JOHNSON, Division of Materials Science and Engineering, Ames Laboratory, Ames, Iowa — Using KKR-CPA ab-initio electronic-structure method founded on an optimal site-centered basis-set, we investigate the key features giving rise to the quantum critical transitions observed in $NbFe_2$ upon doping with 1.75% Nb [1]. These phase transitions involve lowest-energy excitations at/near the Fermi surface. In particular, it is suggested to arise due to an accidental unconventional band critical point (uBCP) with vanishing quasi-particle velocity [2]. Moving off-stoichiometry by increasing Nb, or reducing electrons (e/a), we find the Fermi level E_f increases (rather than decreases based only on band-filling) and meet the uBCP to produce excitations driving the anomalies. We detail the concentration-dependence electronic dispersion, density of state, E_f shift, and energies for $NbFe_2$, and why disorder increase the E_f with electron loss. At stoichiometry all our results agree with those from full potential calculations, including itinerant magnetism.

12:51PM Q16.00009 Electronic structures of superionic conductor Li_3N , MASARU AOKI, Shizuoka Sangyo University, YOSHIYUKI ODE, KAZUO TSUMURAYA, Meiji University — Lithium nitride is a superionic conductor with high Li conductivity. The compound has been studied extensively because of its potential utility as electrolyte in solid-state batteries. Though the mobility of the cations within the crystalline solid is high comparable to that of molten salts, the mechanism of the high mobility of the cations remains unsolved. To clarify the origin of the mobility we investigate the electronic states of the Li cations in the Li_3N crystal with the first principles electronic structure analysis, focusing a correlation between the cations and the ionicities of the constituent atoms. We have found the existence of the covalent bonding between the Li atoms in the Li_3N crystal in spite of the ionized states of the constituent atoms.

1:03PM Q16.00010 Why are the copper cations superionic in the α-CuI crystal? , KAZUO TSUMURAYA, TAKAMITSU OHTSUKA, HIDEKAZU TOMONO, Meiji University — The mechanism of the superionic conduction is an unresolved issue in the solid-state physics. The cations are mobile species in α-CuI and α-AgI crystals. In these conductors, the constituent atoms are ionized. The clarification of the mechanism of the high mobility of the cations needs to investigate the electronic structures in the α-CuI crystal. We obtain the dynamically-averaged local (DAL) positions of the mobile copper cations in the crystal from the pair distribution function and the angle distribution functions, which we calculate from the first principles molecular dynamics simulations at 700 K. The positions predict the existence of a correlation among the cations in the α-CuI. The static electronic structure analysis, of the DAL structure, allows us to clarify the correlation. The correlation enables us to clarify the mechanism of the migration and the difference in the electronic structures between the conductors and the ionic crystals.

1:15PM Q16.00011 First-principles investigation of band offsets and dielectric properties of Silicon-Silicon Nitride interfaces[1] , TUAN ANH PHAM, Department of Chemistry, UC Davis, TIANSHU LI, Department of Chemistry, UC Davis and Department of Civil and Enviromental Engineering, The George Washington University, FRANCOIS GYGI, Department of Applied Science and Department of Computer Science, UC Davis, GIULIA GALLI, Department of Chemistry and Department of Physics, UC Davis — Silicon Nitride (Si3N4) is a possible candidate material to replace or be alloyed with SiO2 to form high-K dielectric films on Si substrates, so as to help prevent leakage currents in modern CMOS transistors. Building on our previous work on dielectric properties of crystalline and amorphous Si3N4 slabs [1], we present an analysis of the band offsets and dielectric properties of crystalline-Si/amorphous Si3N4 interfaces based on first principles calculations. We discuss shortcomings of the conventional bulk-plus line up approach in band offset calculations for systems with an amorphous component, and we present the results of band offsets obtained from calculations of local density of states. Finally, we describe the role of bonding configurations in determining band edges and dielectric constants at the interface.

1:27PM Q16.00012 STEM-EELS calculations including both fine structure and diffraction[1] , M.P. PRANGE, M.P. OXLEY, Vanderbilt University, S.J. PENNYCOOK, Oak Ridge National Lab, S.T. PANTELIDES, Vanderbilt University — Electron energy loss spectroscopy in scanning transmission electron microscopy (STEM-EELS) probes electronic excitations with high spatial and energy resolution. Interpretation of the spectra requires accurate treatment of both the diffraction of the electron probe and the electronic excitation of the sample. We present a theory of core loss STEM-EELS based on a detailed calculation of the mixed dynamic form factor (MDFF) using DFT which informs a Bloch wave treatment of the probe/sample interaction. No dipole approximation is made. The probe diffraction is computed using the Bloch wave method which includes the microscope geometry, multiple elastic, and thermal diffuse scattering. We illustrate the method with calculations of complex oxide materials.

1:39PM Q16.00013 Extended Pi-Sigma tilde orbital model for CO adsorption on Pt and Ru[1] , THOMAS MION, NICHOLAS DIMAKIS, University of Texas Pan American, FAISAL ALAMGIR, National Institute of Standards and Technology, CHERNO JAYE, Hunter College of CUNY, DANIEL FISCHER, National Institute of Standards and Technology, PAUL MCGINN, JAMES COOPER, University of Notre Dame, STEVE GREENBAUM, Hunter College of CUNY, EUGENE SMOTKIN, Northeastern University — Several discrepencies between the predicted Blyholder-type adsobtion models and experimental, as well as DFT calculated infared spectra have been addressed for atop CO on Pt in contrast to Ru. This model correlates increased Near Edge X-Ray Absorbtion Fine Structure intensity as the result of a sub-eV downshift from CO on Ru compared to CO on Pt thereby forming a weaker C-O bond. The model accounts for the hybrid orbitals electron transfer between the CO - metal bonds while taking in to consideration the orbital polarization within the CO itself. The charge redistribution of the s-tilde orbitals and reduced charge donation from CO to the surface results in a weaker internal CO bond upon Ru relative to Pt. The extended Pi-Sigma model explains why atop C-O stretching frequencies do not correlate with carbon p-type vacancies.

1:51PM Q16.00014 Chirality and Electronic Structure of the Thiolate-Protected Au_{38} Nanocluster , OLGA LOPEZ-ACEVEDO, Department of Physics and Chemistry, Nanoscience Center, University of Jyväskylä, Finland, HIRONORI TSUNOYAMA, TATSUYA TSUKUDA, Catalysis Research Center, Hokkaido University, Japan, HANNU HÄKKINEN, Department of Physics and Chemistry, Nanoscience Center, University of Jyväskylä, Finland, CHRISTINE M. AIKENS, Department of Chemistry, Kansas State University, US — Our joint computational and experimental investigation of the structural properties of the $Au_{38}(SR)_{24}$ gold protected nanocluster will be presented [1]. We have identified a new low-energy, chiral, D_3 symmetric structure that yields an excellent match between computed and measured powder XRD function. We have characterized the electronic shell structure of this nanocluster in terms of a particle-in-a-cylinder model. The CD response in the low-energy region (below 2.2 eV) of the new structure is very similar to the one reported several years ago from experiments for $Au_{38}(SG)_{24}$. The mechanism of the chiral response for low excitation energies is related to the chiral arrangement of the gold-thiolate ligand shell around the bi-icosahedral Au_{23} core. The determination of the total structure of $Au_{38}(SC_2H_4Ph)_{24}$ nanoparticles by single crystal X-ray crystallography confirmed our results [2].

2:03PM Q16.00015 Pseudospectral Calculation of Helium Wave Functions, Expectation Values, and Oscillator Strength[1] , PAUL GRABOWSKI, Los Alamos National Laboratory, DAVID CHERNOFF, Cornell University — We extend the pseudospectral method from the solution of Schrödinger's equation for two-electron atom S states to arbitrary angular momentum states. We evaluate the oscillator strength for the helium $1^1S \rightarrow 2^1P$ transition. The result, 0.27616499(27), compares favorably to the best determination in the literature. The length, velocity, and acceleration expressions all have roughly the same accuracy in a pseudospectral treatment. We evaluate leading order finite-nuclear-mass and relativistic corrections for the helium ground state. The pseudospectral method achieves near state-of-the-art accuracy without requiring the implementation of any special-purpose numerical treatments. All the relevant quantities tested converge exponentially with increasing resolution and at roughly the same rate. Quantum mechanical matrix elements are directly and reliably calculable with pseudospectral methods. A general prescription is given for choosing coordinates and subdomains to achieve exponential convergence when two-particle Coulomb singularities are present.

Session Q17 DMP GMAG: Focus Session: Bulk Properties of Complex Oxides - Ruthenates

11:15AM Q17.00001 High-pressure Synthesis and Magnetic Properties of 4d and 5d Transition-metal Oxides[1]

, J.-G. CHENG, University of Texas at Austin — The pressure effect on synthesis of oxides with perovskite ABO_3 and perovskite-related structures has become more clear in recent years. The geometric tolerance factor t $\equiv$ (A-O)/$\sqrt{2}$(B-O) measures the structural stability. High-pressure synthesis enlarges the range of the t factor where the perovskite structure can be stabilized. For the ABO_3 compounds with t $>$ 1, high pressure reduces the t factor since the A-O bond is more compressible than the B-O bond. Therefore, perovskite would be the high-pressure phase for ambient-pressure polytype structures. However, the bonding compressibility argument is no longer valid for the ABO_3 with t $<$ 1. A dt/dP $>$ 0 is normally obtained for t less than but very close to 1, *i.e.* the orthorhombic distortion becomes smaller under pressure. For those highly distorted perovskites with t factor far less than one, pressure enlarges further the orthorhombic distortion and eventually leads to a phase transition to the post-perovskite phase. As for $PbRuO_3$, high pressure prefers the small-volume perovskite phase relative to a competitive pyrochlore phase $Pb_2Ru_2O_7$. Understanding the pressure effect and the new capacity provided by a Walker-type multianvil press enabled us to expand the perovskite family and to obtain new phases of 4d and 5d oxides. Studies of these new 4d and 5d oxides allow us not only to address long-standing problems, but also to explore exotic physical properties. (1) In the perovskite $ARuO_3$ (A= alkaline earth), we have completed the phase diagram from A= Ca to Sr and to Ba and also accounted for the A-cation size-variance effect. A systematic study of the Curie temperature T_c and the critical behavior as a function of the average A-site size and the size variance as well as external high pressures reveals explicitly the crucial role of the lattice strain on the ferromagnetism. The mean-field critical behaviour near T_c found previously in $SrRuO_3$ is not typical of these perovskite ruthenates. T_c is completely suppressed by Pb doping in $Sr_{1-x}Pb_xRuO_3$ not due to the steric effect, but to the orbital hybridization between Pb^{2+} 6s and Ru^{4+} 4d. As the end member, metallic $PbRuO_3$ undergoes a first-order phase transition to a metallic *Imma* phase at $T_t \approx 90$ K. (2) A new polytype phase 5H has been synthesized under a narrow pressure range, which fits the structural sequence along with other polytypes 9R, 6H and 3C of $BaIrO_3$. The ground states of these $BaIrO_3$ polytypes evolve from a ferromagnetic insulator with $T_c \approx 180$ K in the 9R phase to a ferromagnetic metal with $T_c \approx 50$ K in the 5H phase, and finally to an exchange-enhanced paramagnetic metal in the 6H phase, which may be close to a quantum critical point. (3) In the $Ca_{1-x}Sr_xIrO_3$ system, high pressure stabilizes the post-perovskite structure on the Ca side (x $<$ 0.3), but favors the perovskite structure on the Sr side (x $>$ 0.6). Refs. J.-G. Cheng, *et al.* PRB **80**, 104430(2009); **80**, 174426 (2009); **81**, 134412(2010); JACS **131**, 7461(2009).

11:51AM Q17.00002 Spectroscopic Imaging - Scanning Tunneling Microscopy studies of the Nematic Metamagnet $Sr_3Ru_2O_7$

, M.P. ALLAN, Cornell University, University of St. Andrews, T.-M. CHUANG, Cornell University, National High Magnetic Field Lab, Y. XIE, Cornell University, A.W. ROST, University of St. Andrews, R.S. PERRY, University of Edinburgh, J.-F. MERCURE, University of Bristol, A. GIBBS, A.P. MACKENZIE, University of St. Andrews, J.C. DAVIS, LASSP, Dep. of Physics, Cornell University, Ithaca NY; CMPMS, Brookhaven National Laboratory, Upton, NY; University of St. Andrews, Fife, Scotland — The metamagnetic perovskite $Sr_3Ru_2O_7$ can be tuned towards a putative quantum critical point in an external magnetic field, and in ultrapure samples, an electronic nematic forms in a small region of the phase diagram around this putative quantum critical point. Much insight about these phenomena in $Sr_3Ru_2O_7$ come from a wealth of high-quality thermodynamic experiments but little is known about the microscopic electronic origin of criticality and nematicity. We recently re-engineered our SI-STM to achieve sub-Kelvin temperatures and magnetic fields up to 9T, and are now imaging the local density of states in different regions of the $Sr_3Ru_2O_7$ phase diagram, including within the nematic phase.

12:03PM Q17.00003 Entropy Accumulation near Itinerant Magnetic Quantum Critical Points

, JIANDA WU, Rice University, LIJUN ZHU, LANL, QIMIAO SI, Rice University, ANDREAS ROST, ANDY MACKENZIE, University of St. Andrews — Quantum critical point (QCP) occurs at a continuous phase transition at zero temperature. It follows from general hyperscaling argument that, near a QCP, the Grüneisen ratio (ratio of thermal expansion coefficient to specific heat) diverges and entropy accumulates [1]. The enhanced entropy has been observed near the field-induced metamagnetic QCP in Sr3Ru2O7[2]. Here we present a detailed theoretical study of entropy across itinerant-magnetic QCPs, with a focus on the ferromagnetic cases. We propose a regularization scheme for the effect of a dangerously irrelevant quartic coupling on the free energy [3], and calculate the entropy using this scheme. While the entropy accumulation near the QCP basically follows the hyperscaling arguments, the correction to scaling is sizeable especially for the two-dimensional case. We compare the theoretical results with the experimental data for Sr3Ru2O7 [2], providing an entropic characterization of the degree to which the metamagnetic QCP in this system is described by the itinerant-magnetic quantum criticality.

12:15PM Q17.00004 Thermodynamics of the critical fluctuations and nematic phase formation of $Sr_3Ru_2O_7$

, ANDREAS W. ROST, SUPA/Univ. of St Andrews, ROBIN S. PERRY, SUPA/Univ. of Edinburgh, JEAN-FRANCOIS MERCURE, Univ. of Bristol, SANTIAGO A. GRIGERA, SUPA/University of St Andrews; IFLYSIB, ANDREW P. MACKENZIE, SUPA/Univ. of St Andrews — The itinerant metamagnet $Sr_3Ru_2O_7$ has motivated a wide range of experimental and theoretical work in recent years because of the discovery of an unusual low temperature phase which is forming in the vicinity of a proposed quantum critical point. The transport properties of this phase which exhibit strong electron-nematic-like behaviour [1] have led to a range of theoretical proposals for the underlying physics [2]. A major challenge both experimentally and theoretically is the investigation of the thermodynamic properties of both this unusual phase and the fluctuations associated with the quantum critical point. Here I will report on recent thermodynamic measurements. I will concentrate on new specific heat measurements investigating the nature of the critical fluctuations of the system as well as the low energy excitations of the novel phase.

12:27PM Q17.00005 ABSTRACT WITHDRAWN –

12:39PM Q17.00006 Magnetic and structural transitions tuned by non-magnetic Ti doping in Ca3Ru2O7

, JIN PENG, GAOCHAO WANG, Department of Physics and Engineering Physics, Tulane University, New Orleans, LEONARD SPINU, Advanced Material Research Institute and Physics Department, University of New Orleans, LA, XIANGLIN KE, TAO HONG, Scattering Science Division, Oak Ridge National Laboratory, Oak Ridge, TN, ZHIQIANG MAO, Department of Physics and Engineering Physics, Tulane University, New Orleans — We report the effect of Ti doping on the structural and magnetic transitions in the bilayer Ruthenate Ca3Ru2O7. Ca3Ru2O7 orders antiferromagnetically at 56 K followed by a simultaneous structural and metal-insulator transition at 48 K [1]. Ti doping in Ca3Ru2O7 causes dramatic changes in both antiferromagnetic and structural transitions. With the Ti doping concentration above 5%, both transitions move to much higher temperature and merge, e.g. TN 85 K for 5% Ti, 113 K for 10% Ti. For the latter sample, the structural parameters change much more remarkably through the transition compared to Ca3Ru2O7 [2]. Such structural and magnetic transitions tuned by Ti-doping highlight the strong spin-lattice coupling in Ca3Ru2O7. Neutron scattering measurement on these samples will also be discussed.

12:51PM Q17.00007 Element-resolved electronic and magnetic properties of $Sr_3(Ru_{1-x}Mn_x)_2O_7$, V.B. NASCIMENTO, Louisiana State University, Baton Rouge LA, J.W. FREELAND, APS - Argonne National Laboratory, Argonne IL, BIAO HU, R. JIN, E.W. PLUMMER, Louisiana State University, Baton Rouge LA — Bulk $Sr_3Ru_2O_7$ is a metal with short-range antiferromagnetic correlation developed at low temperatures. In the $Sr_3(Ru_{1-x}Mn_x)_2O_7$ series, the partial substitution of Ru by Mn changes both electronic and magnetic correlations driven by the modification of lattice degree of freedom. We have employed polarized x-rays to perform an element-resolved study of electronic and magnetic properties of this system with $0 < x \leq 0.5$. Our results indicate that at low doping Mn goes in as an electron acceptor (i.e. Mn 3+) which effectively dopes holes into the Ru system in a systematic way with increasing x. Using x-ray magnetic circular dichroism we have extracted the Mn and Ru contributions to the total magnetic moment, which will be connected to measurements of the total moment.

1:03PM Q17.00008 Metastable Magnetic states in $Ca_3Ru_2O_7$, D. FOBES, J. PENG, Z.Q. MAO, Department of Physics and Engineering Physics, Tulane University, New Orleans, LA 70118 — We have performed systematic in-plane angle dependent c-axis transverse magnetotransport measurements on the double layered ruthenate $Ca_3Ru_2O_7$ throughout a broad field and temperature range. Our results reveal the magnetic states for $H \| b$ to be significantly more complex than for $H \| a$. When magnetic field is applied along the b-axis we probe several metastable magnetic states in close proximity to phase boundaries of long-range ordered antiferromagnetic (AFM) states previously revealed by neutron scattering, i.e. AFM states with magnetic moments oriented along the b-axis (AFM-b) and a-axis (AFM-a); canted AFM state (CAFM) (Wei Bao *et al.*, Phys. Rev. Lett. **100**, 247203 (2006)). These metastable states are characterized by magnetoresistivity anisotropy distinct from that seen in the AFM-a, AFM-b, or CAFM phases, and switch either to a weakly ferromagnetic or AFM-b state when the magnetic field is rotated toward the *a*-axis. Additionally, our results highlight the complex nature of the spin-charge coupling in $Ca_3Ru_2O_7$.

1:15PM Q17.00009 Interplay of oxygen octahedral rotations and electronic instabilities in strontium ruthenate Ruddlesden-Poppers from first principles , JOHANNES VOSS, CRAIG J. FENNIE, School of Applied and Engineering Physics, Cornell University, Ithaca, NY — The Ruddlesden-Popper ruthenates $Sr_{n+1}Ru_nO_{3n+1}$ display a broad range of electronic phases including p-wave superconductivity, electronic nematicity, and ferromagnetism. Elucidating the role of the number of perovskite blocks, n, in the realization of these differently ordered electronic states remains a challenge. Additionally dramatic experimental advances now enable the atomic scale growth of these complex oxide thin films on a variety of substrates coherently, allowing for the application of tunable epitaxial strain and subsequently the ability to control structural distortions such as oxygen octahedral rotations. Here we investigate from first principles the effect of oxygen octahedral rotations on the electronic structure of Sr_2RuO_4 and $Sr_3Ru_2O_7$. We discuss possible implications for the physics of the bulk systems and point towards new effects in thin films.

1:27PM Q17.00010 $Ca_2Ru_{1-x}Cr_xO_4(0 < x < 0.13)$: Negative volume thermal expansion via orbital and magnetic orders[1] , T.F. QI, O.B. KORNETA, M. GE[2], L.E. DE LONG, G. CAO, Department of Physics and Astronomy, University of Kentucky, S. PARKIN, Department of Chemistry, University of Kentucky, P. SCHLOTTMANN, Florida State University — Ca_2RuO_4 undergoes a metal-insulator transition at T_{MI}= 357 K, followed by a well-separated transition to antiferromagnetic order at T_N= 110 K. Dilute Cr doping for Ru reduces the temperature of the orthorhombic distortion at T_{MI} and induces ferromagnetic behavior at T_C. The lattice volume V of $Ca_2Ru_{1-x}Cr_xO_4$ ($0 < x < 0.13$) abruptly expands with cooling at both T_{MI} and T_C, giving rise to a total volume expansion $\Delta V/V \approx 1$ %, which sharply contrasts the smooth temperature dependence of the few known examples of negative volume thermal expansion driven by anharmonic phonon modes. In addition, the near absence of volume thermal expansion between T_C and T_{MI} represents an Invar effect. The two phase transitions, which surprisingly mimic the classic freezing transition of water, suggest an exotic ground state driven by an extraordinary coupling between spin, orbit and lattice degrees of freedom.

1:39PM Q17.00011 Correlation between Structural and Magnetic Properties in $Sr_3(Ru_{1-x}Mn_x)_2O_7$ Single Crystals , BIAO HU, Department of Physics and Astronomy, Louisiana State University, GREGORY T. MCCANDLESS, Department of Chemistry, Louisiana State University, O.V. GARLEA, Neutron Scattering Science Division, Oak Ridge National Laboratory, S. STADLER, E.W. PLUMMER, R. JIN, Department of Physics and Astronomy, Louisiana State University — We have studied the Mn-doping (x) dependence of structural and magnetic properties in $Sr_3(Ru_{1-x}Mn_x)_2O_7$. The system remains tetragonal as determined by single-crystal X-ray diffraction with the lattice parameters a and c varying with x. Correspondingly, the value of Jahn-Teller distortion (Δ_{JT}) of (Ru,Mn)O_6 octahedron decreases with increasing x with Δ_{JT}= 1.0 for x$\sim$0.5. At the same doping level, we note the sign change of Curie-Weiss temperature Θ_{CW} derived from high-temperature magnetic susceptibility. The correlation between structural and magnetic properties will be discussed.

1:51PM Q17.00012 Managing magnetization and antiferromagnetic coupling in epitaxially grown magnetic oxide heterostructures of (Ga,Fe)2O3 and SrRuO3[1] , JIHYE LEE, WILLIAM JO, Department of Physics, Ewha Womans University, CHRISTIAN MENY , FRANCOIS ROULLAND, NATHALIE VIART, Institute of Physics and Chemistry of Materials of Strasbourg — We have grown b-axis oriented epitaxial (Ga,Fe)2O3 (GFO) thin films on (111) oriented SrRuO3 (SRO) by pulsed laser deposition to know spin interaction in multilayer system. The easy axis of magnetization of the GFO is located on the plane of the thin films. On the other hand, SRO has unique anisotropic properties on various crystallographic directions in their structure. Magnetic properties of the films were measured as a function of temperature and external magnetic field by a superconducting quantum interference magnetometer. Curie temperature of SRO and GFO was measured at 150K and 370K, respectively. According to the direction of external magnetic field, the magnetic moment value of the GFO/SRO heterostructures show different behavior due to antiferromagnetic coupling.

[1]This research was supported by Leading Foreign Research Institute Recruitment Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education, Science and Technology(MEST) (2010-00453)

2:03PM Q17.00013 ARPES Studies of the Evolution of the Ruthenate Family with Dimensionality , JOHN HARTER, DAWEI SHEN, CAROLINA ADAMO, Cornell University, CHARLES BROOKS, Penn State University, DANIEL SHAI, ERIC MONKMAN, DARRELL SCHLOM, KYLE SHEN, Cornell University — The Ruddlesden-Popper homologous series of ruthenates exhibits a wide range of remarkable electronic phenomena coupled to dimensionality, from spin-triplet superconductivity in quasi-two-dimensional single-layer Sr_2RuO_4, to metamagnetism and nematicity in bilayer $Sr_3Ru_2O_7$, to ferromagnetism in the fully three-dimensional pseudocubic end-member $SrRuO_3$. We report high resolution angle-resolved photoemission spectroscopy measurements of the electronic structure of ruthenate films grown by molecular beam epitaxy, with particular interest in the evolution of the quasiparticle interactions with increasing dimensionality. We start by investigating the anisotropic renormalization of quasiparticles in $SrRuO_3$ by strong electron-boson coupling, and examine changes in the Fermi surface and associated quasiparticles as a function of temperature through the Fermi-liquid to non-Fermi-liquid crossover and above the ferromagnetic Curie temperature. We also investigate the strain dependence of the low-energy electronic structure and quasiparticle interactions of $Sr_3Ru_2O_7$.

Wednesday, March 23, 2011 11:15AM - 2:15PM –

Session Q18 DMP GMAG: Focus Session: Magnetic Oxide Thin Films - Multiferroic Thin Films

D172

11:15AM Q18.00001 Enhanced magnetoelectric effects via strain engineering and structural softness[1]

, JORGE INIGUEZ, ICMAB-CSIC — After describing a general theory of the magnetoelectric response, I will argue that inducing *structural softness* – i.e., tuning a material so that it takes a small amount of energy to distort its structure – constitutes a general and robust strategy to obtain very large effects. Further, I will argue that this design strategy will be effective at room temperature, and will not affect other desirable properties of the materials (i.e., their insulating character). I will illustrate this possibility with first-principles results for thin films of room-temperature multiferroic $BiFeO_3$, where the structural softness is induced by epitaxial strain. I will also present results for $BiFeO_3$-based solid solutions, discussing several alternative mechanisms by which their electromechanical and magnetoelectric responses can be enhanced. Finally, I will discuss the prospect of inducing in $BiFeO_3$ a so-called *morphotropic phase boundary*, where the material is expected to display very large functional responses in analogy to what occurs in strong piezoelectric $PbZr_{1-x}Ti_xO_3$.

11:51AM Q18.00002 Electrically Controllable Magnetism in Strained $BiFeO_3$ Thin Films

, QING HE, University of California, Berkeley, W. LUO, R. RAMESH, UC Berkeley, J.-C. YANG, Y.-H. CHU, National Chiao Tung University, A. SCHOLL, LBNL — multiferroic $BiFeO_3$ (BFO) thin films epitaxial strain can lead to the formation of a mixed phase system – highly distorted rhombohedral (R') and distorted tetragonal (super-tetragonal) (T) phases. Interestingly, this R' phase has been observed to be with enhanced magnetization compare to bulk BFO. Then, in order to investigate the origin of the magnetism in R' phase, synchrotron x-ray absorption, and x-ray (magnetic) circular/linear dichroism have been employed with assistance of spectra simulation and the ferroelectric, antiferromagnetic and ferromagnetic properties of this magnetic R' films have been clearly identified. Surprisingly, enhanced magnetization emerges in (001) plane as soon as a critical DC field is applied to the film in $< 001 >$ direction. The key is that the movement of Fe^{3+} can be controlled by external electric field, which magnifies the effect of Dzyaloshinsky-Moriya interaction to the system, and enlarges the canting magnetic moment of Fe spins. Finally, the direction of the local magnetic moment can be deterministically by external electric field will be demonstrated.

12:03PM Q18.00003 Origin of Reversible Electric Exchange Bias Modulation in a Multiferroic Field Effect Device[1]

, STEPHEN WU, SHANE CYBART, PU YU, R. RAMESH, R.C. DYNES, Materials Sciences Division, Lawrence Berkeley National Lab — We report the fabrication and characterization of two different oxide heterostructure based electric field effect devices: the multiferroic/ferromagnet, $BiFeO_3$(BFO) / $La_{0.7}Sr_{0.3}MnO_3$(LSMO) and the ferroelectric/ferromagnet, $Pb(Zr_{0.2}Ti_{0.8})O_3$(PZT)/LSMO. By switching FE polarization of BFO in the multiferroic device we observe a change in conductivity in the channel of 50%, and a 55% change in magnetic coercivity at 5.5 K. Furthermore, we can reversibly switch between two distinct exchange bias states corresponding to the different FE polarizations without additional field cooling. The difference in exchange bias between the two states is approximately 20mT. We further characterize the device by performing Hall Effect and temperature dependent exchange bias modulation measurements. Finally, we compare this device to a similarly fabricated PZT/LSMO field effect device. We observe no exchange bias and significantly smaller coercivity. No change in magnetic coercivity is observed when ferroelectric polarization is switched in PZT. Models based on these results will be presented.

12:15PM Q18.00004 Electrical Transport Measurements of a Manganite Multiferroic Field Effect Device[1]

, JAMES PARKER, SHANE CYBART, STEPHEN WU, PU YU, R. RAMESH, R.C. DYNES, Materials Sciences Division, Lawrence Berkeley National Laboratory — We report electrical transport measurements of multiferroic/ferromagnet, BiFeO3 (BFO) / La0.7Sr0.3MnO3 (LSMO), electric field effect devices. The antiferromagnetic (AFM) ordering of the BFO dielectric layer is coupled to the ferromagnetic (FM) ordering of the LSMO channel layer and is observed as exchange bias –a shift of the LSMO magnetic hysteresis curve along the applied field axis. We will present the temperature dependence of this exchange bias between 2K and 100K. Furthermore, we also investigate the exchange bias with respect to multiple gating variables, including channel current and gate pulsing patterns. We have observed that the current in the channel during gating plays an important role in setting the exchange bias.

12:27PM Q18.00005 Magnetic Structure of Engineered Multiferroic Thin Films[1]

, XIANGLIN KE, Neutron Scattering Science Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA — The intriguing properties of multiferroics, i.e., materials exhibiting the coexistence of magnetism and ferroelectricity, have stimulated intense research interest in recent years. From the viewpoint of practical applications, one needs to exploit the thin film architectures of multiferroic materials. However, fewer studies have addressed the magnetic structures of multiferroic thin films. I will present recent experimental works on two multiferroic films, $BiFeO_3$ and $EuTiO_3$, physical properties of which can be engineered via the epitaxial growth on appropriate substrates. Neutron diffraction studies on $BiFeO_3$ films deposited on vicinal $SrTiO_3$ substrates show that the magnetic structure of these films is closely correlated with the ferroelectric states that depend on the chosen substrate miscut [1]. Epitaxial $EuTiO_3$ grown on $DyScO_3$ susbtrate, which is a paraelectric antiferromagnet in its bulk form, is strain-tuned into multiferroics, displaying both ferroelectric and ferromagnetic characters [2]. The relationship between the strong magnetic anisotropy and the film microstructure will be discussed.

[1]In collaboration with P.P. Zhang, S.Y Baek, C. B. Eom, J.H Lee, P. Ryan, J.W. Freeland, D.A. Muller, C.J. Fennie, V. Gopalan, P. Schiffer, E. Johnston-Halperin, and D.G. Schlom. This work was supported by the Clifford G. Shull Fellowship at ORNL.

1:03PM Q18.00006 Electric-field control of spin waves at room temperature in multiferroic $BiFeO_3$, MAXIMILIEN CAZAYOUS, PAULINE ROVILLAIN, YANN GALLAIS, ALAIN SACUTO, MARIE-AUDE MEASSON, Laboratoire Materiaux et Phenomenes Quantiques, Paris, France, ROGERIO DE SOUSA, Department of Physics and Astronomy, Victoria, Canada, DOROTHEE COLSON, ANNE FORGET, Service de Physique de l Etat Condense, CEA Saclay, France, MANUEL BIBES, AGNES BARTHELEMY, Unite Mixte de Physique CNRS/Thales, France — A particularly exciting prospect in the field of spintronics is to use the wave like excitations of a magnetic material as a means to transmit and process information. This technology named magnonics relies on the control of spin waves. The key goal of magnonics is to read/write non-volatile spin information with minimal energy consumption. Multiferroic materials have at least two coupled magnetic and ferroelectric orders leading to electrical control of magnetic effects and vice-versa. Multiferroic materials are thus potentially interesting as a medium for spin-wave-based information processing. Here we show that the spin wave excitations in $BiFeO_3$, a room temperature multiferroic can be controlled by an electric field at low power and in a non-volatile way. The present experiment clearly demonstrates spin waves can be tuned over 30% of their frequencies, several orders of magnitude larger than with previous methods. The switch and the control of the polarization is used to manage this tuning.

1:15PM Q18.00007 Electric-field control of spin waves in multiferroic BiFeO3: Theory[1] , ROGÉRIO DE SOUSA, Dept. of Physics and Astronomy, University of Victoria, BC Canada, P. ROVILLAIN, Y. GALLAIS, A. SACUTO, M.A. MÉASSON, Universite Paris Diderot-Paris 7, D. COLSON, A. FORGET, Service de Physique de l'Etat Condense, CEA Saclay, M. BIBES, A. BARTHÉLÉMY, Unite Mixte de Physique CNRS/Thales, France, M. CAZAYOUS, Universite Paris Diderot-Paris 7 — Our recent experiment [1] demonstrated gigantic (30%) electric-field tuning of magnon frequencies in multiferroic BiFeO3. We demonstrate that the origin of this effect is related to two linear magnetoelectric interactions that couple the component of electric field perpendicular to the ferroelectric vector to a quadratic form of the Néel vector. We calculate the magnon spectra due to each of these interactions and show that only one of them is consistent with experimental data. At high electric fields, this interaction induces a phase transition to a homogeneous state, and the multi-magnon spectra will fuse into two magnon frequencies. We discuss the possible microscopic mechanisms responsible for this novel interaction and the prospect for applications in magnonics.

1:27PM Q18.00008 Ultrafast dynamics in multiferroic $BiFeO_3$, YU-MIIN SHEU, ROHIT PRASANKUMAR, ANTOINETTE TAYLOR, Los Alamos National Laboratory — We report the ultrafast time-resolved optical measurements of multiferroic $BiFeO_3$, which exhibits both magnetic and ferroelectric ordering at room temperature. The coupling between these two orders makes it an attractive material for potential data-storage devices. However, a detailed understanding of this coupling is still under debate. Ultrafast optical spectroscopy can potentially shed light on magnetoelectric coupling in $BiFeO_3$ by unraveling the different contributions in the time domain. Here, we use degenerate 400 nm pump-probe spectroscopy to excite and probe a $BiFeO_3$ thin film above its bandgap. The measured relaxation consists of a fast decay ($\sim$1 ps) followed by a slow recovery ($\sim$150 ps). We attribute the fast component to the recovery of photoexcited carriers. The slow recovery may be due to spin-lattice relaxation.

1:39PM Q18.00009 Substrate induced strain effects on the multiferroism of $BiMnO_3$ thin films[1] , HYOUNG JEEN JEEN, PATRICK MICKEL, A.F. HEBARD, AMLAN BISWAS, Department of Physics, University of Florida, Gainesville, FL 32611, VALENTIN CRACIUN, Major Analytical Instrumentation Center University of Florida Gainesville, FL 32611 — $BiMnO_3$ is a single phase multiferroic material, which shows ferroelectricity and ferromagnetism at low temperature. However, it is difficult to grow $BiMnO_3$ either in bulk or thin film form, since it is metastable with substantial desorption of Bi ions at high growth temperature. Here we have used $SrTiO_3$ and $SrLaGaO_4$ substrates, which provide different degrees of compressive strain, to stabilize the $BiMnO_3$ phase and have introduced fast quenching after deposition in oxygen atmosphere to suppress re-evaporation of Bi-ions but retain film crystallinity. Surface morphology indicates island growth mode. X-ray diffraction (XRD) shows that the $BiMnO_3$ [111] is parallel with [001] $SrTiO_3$ and [001] $SrLaGaO_4$. XRD results confirm that the $BiMnO_3$ films on $SrTiO_3$substrates are epitaxial, with in-plane alignment. The films have a magnetization of 1 μ_B/Mn at 5 T and 10 K. We also observed ferroelectricity in our $BiMnO_3$ films. Based on these results, we will discuss the substrate induced strain effects on the multiferroic properties of $BiMnO_3$ thin films.

[1]NSF DMR-0804452 (AB) and NSF DMR-1005301 (AFH)

1:51PM Q18.00010 Room-Temperature Multiferroic Properties of Bismuth Manganite Thin Film , W.C. KUO, C.Y. KUO, H.J. LIU, H.J. LIN, Y.H. CHU, Y.C. CHEN, T.M. UEN, J.Y. JUANG — In multiferroic materials, low temperature multiferroic properties in perovskite type $BiMnO_3$ has been demonstrated. In this work, through epitaxial strains exerted by $LaAlO_3$ single crystal substrate, we successfully demonstrate the growth the c-axis oriented new phase in BMO thin film. After the deposition, HRXRD has been used to characterize the lattice structure, which show new fascinating phase that are different from the papers early reported. We further revealed manganese valence through the X-ray Magnetic Linear Dichroism measurement and exhibit the mixed +3 and +4 valence of manganese. With $LaNiO_3$ bottom electrode, room-temperature ferroelectricity is demonstrated by piezoelectric force microscopy, which revealed the reversible ferroelastic switching through the external electrical bias. M-H curves are measured by SQUID magnetometer as a function of temperatures. Ferromagnetic behaviors have been probed from room temperature (300K) to low temperature (10K), furthermore, ferromagnetic phenomenon has been observed at 300K. In our preliminary results, room temperature ferroelectric and ferromagnetic properties could be coexistent in single phase material through epitaxial strain, thus provide a modeling system to study the multiferroic material and a powerful candidate for the next- generation electronic devices.

2:03PM Q18.00011 Magnetic field dependence of the spin wave excitations in $Sr_2FeSi_2O_7$, KAZUKI IIDA, JOOSEOP LEE, NAOYUKI KATAYAMA, SUNGDAE JI, SEUNGHUN LEE, University of Virginia, DUC LE, Helmholtz Zentrum Berlin, SUNG CHANG, NIST Center for Neutron Research, TAEHWAN JANG, YOONHEE JEONG, SANGWOOK CHEONG, Pohang University of Science and Technology, UNIVERSITY OF VIRGINIA TEAM, HELMHOLTZ ZENTRUM BERLIN COLLABORATION, NIST CENTER FOR NEUTRON RESEARCH COLLABORATION, POHANG UNIVERSITY OF SCIENCE AND TECHNOLOGY COLLABORATION — Without field, the multiferroic $Sr_2FeSi_2O_2$ orders below 4.7 K into a simple square-lattice antiferromagnetic collinear structure. Application of a magnetic field at low temperatures induces four different magnetic phases with spontaneous electric polarization. We report inelastic neutron scattering measurements on a single crystal of $Sr_2FeSi_2O_7$ under magnetic fields to investigate how the magnetic fluctuations change with field. In zero field, no dispersion was observed in L-direction, indicating that $Sr_2FeSi_2O_7$ is a two dimensional magnet. The dispersion relation along (H 0 0.5) shows a Goldstone mode arising from the magnetic Bragg position at (1 0 0.5) with a periodicity of $2 \times 2\pi/a$, suggesting that the strongest magnetic interaction is between the nearest neighbor Fe^{2+} ions. Under the field, the magnetic fluctuations become more complex than the simple splitting of the doubly degenerate Goldstone mode into two gapped modes.

Wednesday, March 23, 2011 11:15AM - 2:15PM –

Session Q19 GMAG: Ising, Spin Glass, Frustrated Magnets D170

11:15AM Q19.00001 Thermodynamics of the two-dimensional random-bond Ising model , CREIGHTON K. THOMAS, Texas A&M University, HELMUT G. KATZGRABER, Texas A&M University and ETH Zurich — The two-dimensional Ising spin glass possesses the disorder and frustration necessary to describe the rich behavior found in glassy materials with complex free-energy landscapes. Recently-developed exact algorithms for this model with arbitrary quenched bond disorder have allowed for equilibrium simulations of systems far larger than those accessible by other methods. We use a Pfaffian technique to measure thermodynamic quantities such as the specific heat and the domain-wall free energy to characterize the phase transitions in this model as either temperature or disorder strength is varied. We also present precision measurements on the disorder-temperature phase diagram of this model, including a detailed study of the reentrance that has been seen for bimodal disorder.

11:27AM Q19.00002 Competing Low-Temperature Phases in a Dilute Ising Magnet , M.A. SCHMIDT, D.M. SILEVITCH, T.F. ROSENBAUM, University of Chicago, G. AEPPLI, University College, London — LiHo(x)Y(1-x)F4 serves as a physical manifestation of the Ising model in transverse field with controllable disorder. At dilute Ho3+ dipole concentration, the combination of ferromagnetic and antiferromagnetic couplings via the spatial anisotropy of the dipolar coupling, disorder, and random internal fields combine to produce a variety of possible ground states. We show for x = 0.045 the ability to choose between spin liquid and spin glass behavior with proper thermal preparation. We present both linear and nonlinear magnetic susceptibility data as well as magnetic pump/probe techniques to quantify the stability of the liquid, and to probe the coupling between the spin states and the nuclear spin bath.

11:39AM Q19.00003 The p, q-binomial distribution applied to the Ising model , PER HÅKAN LUNDOW, ANDERS ROSENGREN, KTH — Monte Carlo simulations have shown that the p, q-binomial distribution closely fits the magnetisation distribution for the d-dimensional Ising model at all temperatures when $d > 4$. It also fits well for some temperatures near T_c for $d = 2, 3$ and especially so for $d = 4$. At high and low temperatures, away from T_c, the p, q-distribution always fits extremely well. However, it appears very difficult to determine how the parameters p and q depend of the temperature. From high and low temperature series expansions we can get partial results on their temperature dependence. Near T_c for $d = 5$ we have approximately that $p = 1 - 0.0736/L^5$ and $q = 1 - 9.87/L^5$ whereas for $d < 5$ the linear coefficient of q grows logarithmically. We show numerically how the parameters behave near T_c with increasing d.

11:51AM Q19.00004 ABSTRACT WITHDRAWN –

12:03PM Q19.00005 An ab initio study of radiation damage effects on the magnetic structure of bulk Iron[1] , YANG WANG, Carnegie Mellon University, G. MALCOLM STOCKS, ROGER STOLLER, DON NICHOLSON, AURELIAN RUSANU, MARKUS EISENBACH, Oak Ridge National Laboratory — A fundamental understanding of radiation damage effects in solids is of great importance in assisting the development of structural materials with improved mechanical properties for nuclear energy applications. In this presentation, we discuss our recent theoretical investigation on the magnetic structure evolution in bulk Fe after an energetic particle has disturbed the lattice by a displacement cascade. We applied a linear scaling ab initio method to the study of magnetic moment distributions in a low energy cascade for a series of time steps. The primary damage state and the evolution of the defects were simulated using molecular dynamics with a Finnis-Sinclair interatomic potential. We will show the statistics of the magnetic moments in the sample and discuss its relationship with the atomic volume distribution.

[1]1This research is based upon work supported as part of the Center for Defect Physics in Structural Materials (CDP), an Energy Frontier Research Center funded by DOE, Office of Science, Office of Basic Energy Sciences.

12:15PM Q19.00006 Chaos, broken hyperscaling, and nonuniversality in a spin glass[1] , A. ALAN MIDDLETON, Syracuse University, CREIGHTON THOMAS, Texas A&M University, DAVID HUSE, Princeton University — Recently extended precise numerical methods and newly modified scaling arguments allow for a coherent picture of the glassy state in a two-dimensional spin glass to be assembled. This glassy state, where the correlation length is larger than the system size, is characterized by "chaos," the extreme sensitivity of the state to temperature. This chaos is shown to lead to a breakdown of hyperscaling in spin glasses. The length scale at which entropy becomes important is found to depend on the type of randomness, so that though there is a type of universality, the critical exponents depend on the distribution of disorder. The numerical simulations use multiprecision arithmetic to exactly compute the partition function in samples of sizes up to $L^2 = 512^2$ down to temperatures of less than $J/20$, where the typical strength of the disorder is J. These results can be used in support of studies of the non-equilibrium behavior of glassy models.

12:27PM Q19.00007 Disordered Pinned Anyons in Two Dimensions , CHRIS LAUMANN, Harvard University, DAVID HUSE, Princeton University, ANDREAS LUDWIG, UCSB, GIL REFAEL, Caltech, SIMON TREBST, UCSB, MATTHIAS TROYER, ETH Zurich — We consider the effect of disorder on the behavior of pinned anyons in two spatial dimensions. Within an approximate numerical strong disorder renormalization group (SDRG) treatment, we find that both Fibonacci and Majorana anyons exhibit flows back to weaker disorder rather than toward infinite randomness phases such as those they exhibit in d=1. Restricting to the technically simpler Majorana anyons, we map out the effects of sign and coupling strength disorder on the proposed translation invariant topological liquid found in the absence of disorder. In disordered Hall bars, the nature of this descendant phase, and in particular its localization properties, may be relevant to the interpretation of transport and non-Abelian interferometry.

12:39PM Q19.00008 Effective potential study of the Diluted Antiferromagnet in a Field , DAVID YLLANES, L.A. FERNANDEZ, V. MARTIN-MAYOR — We present a numerical study of the three-dimensional Diluted Antiferromagnet in a Field (DAFF), one of the experimental realizations of the Random Field Ising Model. We work in a constrained ensemble (tethered ensemble) where the Helmholtz effective potential is featured, rather than the free energy. Our method cures the problem of a strong violation of self-averaging, thus allowing us to compute the correlation length for systems sizes up to $L = 32$. This quantity, when measured in units of the lattice size, is independent of the system size at the critical point, a strong indication of a second-order phase transition. This scale invariance allows us to apply finite-size scaling in the form of Nightingale's phenomenological renormalization. We obtain accurate estimates of the critical exponents. Since our method reconstructs the effective potential, we can also compute accurately the hyperscaling violation exponent. We perform as well an investigation of the geometrical properties of the instanton-like configurations, namely, the minimal cost configurations joining the two ordered phases. This study sheds light on previous claims of a first-order phase transition in this system.

12:51PM Q19.00009 Quantum Fidelity Susceptibilities of the Anisotropic Triangular Antiferromagnet: Conjugate Field Fidelity Susceptibilities , MISCHA THESBERG, ERIK S. SORENSEN, McMaster University — The Heisenberg model of the Anisotropic Triangular Antiferromagnet(HATM) has seen a surge of interest owing to its relation to Cesium Copper Chloride, an inorganic salt with a potential spin-liquid phase. In this talk a new approach to quantum fidelity susceptibilities will be introduced and used to explore the phase diagram of the HATM. These fidelity susceptibilities are computable via exact diagonalization techniques and can be coupled to specific order parameters. We present results from such calculations shedding new light on the phase diagram of the Anisotropic Triangular Antiferromagnet.

1:03PM Q19.00010 Stabilization of surface spin glass behavior in core/shell-Fe67Co33/CoFe2O4 nanoparticles , GHULAM JAFFARI, Department of Physics and Astronomy, University of Delaware, Newark DE 19716, SYED ALI, Physikalisches Institut (IIA), RWTH Aachen University, 52056 Aachen, Germany, SYED HASANAIN, Department of Physics, Quaid-i-Azam University, Islamabad 45320, Pakistan, GERNOT GÜNTHERODT, Physikalisches Institut (IIA), RWTH Aachen University, 52056 Aachen, Germany, SYED SHAH, Department of Physics and Astronomy, University of Delaware, Newark DE 19716, Department of Materials Science and Engineering, University of Delaware — Magnetic properties of Co33Fe67–CoFe2O4 (core-shell) nanoparticles are presented. Both dc magnetization and ac susceptibility measurements indicate a spin glass (SG) like transition occurring at TF ∼175 K. The SG nature of the transition is also confirmed by the field dependence of the freezing temperature TF(H) following the well known Almeida–Thouless line, δTF∼H$^{2/3}$. Additionally, the particles exhibit a large exchange bias (HEB ∼ 1357 Oe) arising from the core-shell (ferromagnetic-SG) coupling. The unusually high SG transition temperature and large exchange bias effects are attributed to a combination of several factors including the thickness of the amorphous oxide shell and large values of the exchange and anisotropy constants associated with the CoFe2O4 shell.

1:15PM Q19.00011 Critical Behavior of Lévy Spin Glasses , JUAN CARLOS ANDRESEN, Department of Physics, ETH Zurich, HELMUT G. KATZGRABER, Department of Physics, Texas A&M University & ETH Zurich — Universality, one of the foundations of the theory of critical phenomena, is well established for many problems in statistical physics. However, there is still debate if changing the disorder between the spins-spin interactions in spin glasses can influence the universality class of the system. This apparent violation of universal behavior can be attributed to the numerical complexity of these systems which limits simulations to small systems sizes, typically paired with strong corrections to scaling. Although it is well established that universality is not violated for nearest-neighbor spin glasses with compact disorder distributions (e.g., Gaussian and bimodal), some studies suggest that this might not be the case when the disorder distributions are broad, as in the case of the Lévy distribution. Using large-scale Monte Carlo simulations that combine parallel tempering with specialized cluster moves, as well as innovative scaling techniques, we show that Lévy spin glasses do obey universality for the system sizes studied. Furthermore, we probe recent analytical predictions made for the critical temperature of Lévy spin glasses as a function of the disorder distribution width.

1:27PM Q19.00012 Spin glasses on scale-free networks: Simple models to describe opinion formation? , HELMUT G. KATZGRABER, Texas A&M University and ETH Zurich, CREIGHTON K. THOMAS, Texas A&M University — We study the critical behavior of Ising spin glasses on scale-free networks using large-scale Monte Carlo simulations. Our results show that when the exponent that describes the decay of the interaction degree in the scale-free graph is strictly larger than 3 the system undergoes a finite-temperature spin-glass transition. However, when the exponent is equal to or less than 3, the spin-glass phase is stable for all temperatures. This robustness to local (temperature) perturbations and global biases (field) is compared to experimental data from social networks.

1:39PM Q19.00013 Using Azimuthal Hysteresis for Determining the Anti-ferromagnet Moment Density at the Spin Glass Interface: The case of BFO , KHALID ASHRAF, SAYEEF SALAHUDDIN, UC Berkeley — We report a systematic procedure for extracting the anisotropies, exchange energies and the surface anti-ferromagnet (AFM) moment of AFM-ferromagnet (FM) systems that show spin glass (SG) behavior. In any SG system, the hysteresis characteristics at a critical angle combined with the azimuthal hysteresis properties give important information about the surface AFM moment density and the coupling energy. Using this scheme we report the interface magnetic energy parameters of the epitaxial BFO-FM system. We find a single value for the interface coupling energy that reproduces both the exchange bias and the enhancement. Our extracted surface AFM moment density is of the order of the FM moment density that is independent of the FM material used. The high moment density on the BFO surface indicates a significant magnetic property modification at the BFO-FM interface. The implication of the presence of this high AFM moment is discussed in the context of achieving deterministic electric field driven magnetic moment switching.

1:51PM Q19.00014 Study of the Grüneisen Parameters at a Field-induced Quantum Critical Point in NiCl2-SC(NH2)2[1] , FRANZISKA WEICKERT, Los Alamos National Laboratory, MPA-CMMS, Los Alamos, NM, 87545, USA, ROBERT KUECHLER, ALEXANDER STEPPKE, LUIS PEDRERO OJEDA, MICHAEL NICKLAS, MANUEL BRANDO, FRANK STEGLICH, Max Planck Institute for Chemical Physics of Solids, Dresden 01087, Germany, VIVIEN ZAPF, MARCELO JAIME, Los Alamos National Laboratory, MPA-CMMS, Los Alamos, NM, 87545, USA, A. PADUAN-FILHO, Univ. of Sao Paulo, Sao Paulo, Brazil — $NiCl_2$-SC(NH_2)$_2$, also known as DTN, is a quantum paramagnet, where the Ni^{2+} single ion anisotropy D = 8.9K opens an energy gap between the $S_z = 0$ ground state and the $S_z = \pm 1$ exited state. In this material an XY-antiferromagnetic ordered state is induced at low temperatures by applying magnetic fields between H_{c1} ≈ 2T and H_{c2} = 10.5T. At the phase boundaries critical exponents consistent with Bose-Einstein condensation of magnons are found. Here we present investigations of quantum criticality close to H_{c1} by thermal expansion, magnetization and specific heat measurements. Our data reveal a divergency for T→ 0 of the thermal and magnetic Grüneisen parameters as expected for a quantum critical point of a diluted Bose gas.

[1]Part of this work was carried out at the MPI for Chemical Physics of Solids in Dresden, Germany.

2:03PM Q19.00015 Characteristic time scales and overlap distributions in replica exchange Monte Carlo simulations of spin glasses[1] , BURCU YUCESOY, JON MACHTA, University of Massachusetts Amherst , HELMUT G. KATZGRABER, Department of Physics, Texas A & M University & ETH Zurich — We present a large-scale numerical study using replica exchange Monte Carlo (parallel tempering) of time scales of the three- dimensional Ising spin glass. We measure the integrated and exponential autocorrelation times for several observables, as well as the round-trip times for different disorder realizations in order to investigate the relationship between the characteristic time scales of a disorder realization and its overlap distribution.

[1]Supported in part by NSF DMR-0907235.

Wednesday, March 23, 2011 11:15AM - 2:15PM –

Session Q21 GIMS: THz and Impedance Spectroscopy D161

11:15AM Q21.00001 Bulk focused ion beam fabrication of nanoelectromechanical systems , WAYNE HIEBERT, DOUG VICK, National Institute for Nanotechnology, National Research Council of Canada, VINCE SAUER, Department of Electrical and Computer Engineering, University of Alberta, ALASTAIR FRASER, OLEKSIY SVITELSKIY, MARK FREEMAN, Department of Physics, University of Alberta — Focused ion beam (FIB) nanomilling of NEMS devices out of bulk material will be presented. Ion impingement from multiple directions allows sculpting with considerable 3-dimensional control of device shape, including tapering and notching. Finite element modeling of device frequencies agrees with interferometric measurements, including for the effect of a localized notch. The measurements are sensitive enough to determine the thermomechanical noise floor of a bulk FIBed NEMS device with displacement sensitivity of 166 fm per root Hz, limited only by a combination of optical shot noise and detector dark current. We envision that bulk FIB fabrication will be useful for NEMS prototyping, milling of tough-to- machine materials, and generalized nanostructure fabrication with 3-dimensional shape control.

11:27AM Q21.00002 Terahertz spectroscopy of ionized air and explosive vapor , BENJAMIN GRABER, US. Naval Research Laboratory / Temple University, RONGJIA TAO, Temple University, DONG HO WU, US. Naval Research Laboratory — In the past it has been demonstrated that terahertz spectroscopy could identify various chemical agents and explosives in solid and liquid phases. However peaks and dips in the terahertz spectra obtained from solid and liquid phases are not sharp and often ambiguous or ill-defined, as the interferences among the molecules in the solid or liquid obscure the molecule's characteristic resonances. Hence there has been considerable interest in obtaining terahertz spectrum of gas phase. Recently we have increased terahertz output power of our terahertz spectrometer, and measured terahertz spectra of gases, including water vapor, and ionized air produced by various ionization sources as well as explosive vapors. Our experiments revealed: (1) our terahertz spectrum of water vapor was highly consistent with other published data, (2) the spectra of ionized air produced by corona discharge and nuclear isotopes including Am-241, Bi-207, Ba-133, Co-60, Na-22 and Cs-137 were all different, and the characteristic spectrum changes largely depending on the type of ionization source, and (3) terahertz spectra of explosive vapor taken from TNT, PETN and RDX which were dissolved in acetonitrile or water exhibit very sharp resonance peaks and dips. We will present details of our experimental results.

11:39AM Q21.00003 Characterization of high power near THz radiation from CMOS circuits using a Michelson Interferometer[1] , DANIEL J. ARENAS, Department of Physics, University of North Florida, DONGHA SHIM, Department of Computer and Electrical Engineering, University of Florida, DIMITRIOS KOUKIS, Department of Physics, University of Florida, EUNYOUNG SEOK, Texas Instruments, Inc., DAVID B. TANNER, Department of Physics, University of Florida, KENNETH K. O, Texas Analog Center of Excellence, Department of Electrical and Computer Engineering, University of Texas, Dallas — Recently, a high frequency SiGe BiCMOS Colpitts oscillator circuit was reported capable of emitting a second, third and fourth harmonic signal at 295, 442 and 589 GHz, respectively. The operating frequencies of the circuit and the emission powers were characterized using a Fourier transform interferometric spectrometer. The results show that this optical technique is an efficient way to characterize high-frequency circuits. The power emitted from the circuit at each frequency was also compared to that emitted from conventional blackbody sources. The results show that the high power emission of these circuits makes them ideal candidates for future spectroscopic applications.

11:51AM Q21.00004 CNT Quantum dots as Terahertz detectors[1] , MOHAMED RINZAN, Physics Department, Georgetown University, GREG JENKINS, DENNIS DREW, Department of Physics, University of Maryland, SERHII SHAFRANJUK, Department of Physics and Astronomy, Northwestern University, PAOLA BARBARA, Physics Department, Georgetown University — We study Carbon Nanotube (CNT) quantum dots as detectors of THz radiation via photon assisted single electron tunneling. Although successful detection was recently demonstrated [1], the coupling between the CNT and THz radiations was very weak. Here, we implement a novel device design where the radiation is effectively coupled to the CNT quantum dot through broad band on-chip antennas. We show that the enhanced coupling yields a highly sensitive broad band Terahertz sensor.

12:03PM Q21.00005 Highly absorbing metal nanolaminates for THz bi-material detectors[1] , DRAGOSLAV GRBOVIC, FABIO ALVES, APOSTOLOS KARAMITROS, GAMANI KARUNASIRI, Naval Postgraduate School — Interest in THz-ray sensing has significantly increased in recent years. It has been demonstrated that bi-material MEMS detectors show a great potential to be used for THz imaging. Our work aims to identify metal nanolaminates to improve the detector absorption in the range of interest. Using a finite element simulation tools we demonstrate that Chromium and Nickel films can absorb up to 50 and 35%, respectively, between 1 and 5 THz, depending on the thickness of the layer. Different thickness of Cr and Ni layers were deposited on Si substrate using e-beam evaporation and the wafers were characterized using a FTIR expanded to THz range. The experimental results show excellent match with the simulations. Further analysis shows that by decreasing the surface filling fill-factor of Ni, it is possible to increase absorption closeup to the values obtained for the Cr films indicating that much lower stress Ni films can be used in bi-material MEMS detectors with absorption comparable with Cr films.

12:15PM Q21.00006 Nanocoax arrays via NIL for high resolution sensing applications[1] , BINOD RIZAL, PATRICK JAMIESON, SVET SIMIDJIYSKI, HUAIZHOU ZHAO, DONG CAI, STEPHEN SHEPARD, THOMAS C. CHILES, MICHAEL J. NAUGHTON, Boston College — We have used nanoimprint lithography to fabricate nanocoax array-based chemical sensors, starting from SU-8 polymer replicas of silicon nanopillars. Nanocoaxes are formed by metalizing the polymer pillars, followed by oxide dielectric coating and outer metal deposition, and a polymer filling for stabilization. Chemical mechanical polishing and reactive ion etching were then used to open the ends of the coaxes and form coaxial cavity (with a nanoporous component) structures, respectively. Adsorption of water and organic solvent molecules into the coax annuli caused significant changes to the complex impedance of the coaxial capacitor array ($\Delta C/C > 100\%$ for 50% relative humidity air). Impedance measurements with such coaxial nanocavity arrays thus provide highly sensitive and selective information for molecular detection, with ultimate sensitivity below 1 ppb, or $\sim$1 $\mu g/m^3$.

12:27PM Q21.00007 A high performance humidity sensor based on dielectric detection with a novel coaxial nanostructure[1] , DONG CAI, HUAIZHOU ZHAO, BINOD RIZAL, TIMOTHY KIRKPATRICK, ZHIFENG REN, MICHAEL J. NAUGHTON, THOMAS C. CHILES, Boston College — High throughput coaxial nanocavity arrays are developed by overlaying porous Al_2O_3 and Al layers on vertically aligned carbon nanotube arrays. The porosity of Al_2O_3 was electrochemically characterized. The dielectric properties of the nanocoax structure were measured by impedance spectroscopy, from 10 mHz to 1 MHz. The capacitance of the sensor responded to humidity applied to the chip, *i.e.* soaking the array with water increased the capacitance by 130%. The detection mechanism was established for sensing changes to the dielectric constant due to adsorbed moisture in the porous Al_2O_3 coax annulus, with theoretical calculations based on the Clausius-Mossotti equation in agreement with the measurements. Highly sensitive humidity detection was demonstrated by applying relative humidity between 0.1% and 100%, with a power-law response, $RH \sim x^{\alpha}$. This nanocoaxial structure thus offers the possibility of unprecedented performance of porous Al_2O_3-mediated capacitancer sensing for humidity detection.

12:39PM Q21.00008 Capacitance response of porous and cavitized nanocoax arrays to various gases[1] , PATRICK JAMIESON[2], BINOD RIZAL, SVET SIMIDJIYSKI, HUAIZHOU ZHAO, DONG CAI, MARK HASENAUER, MICHELLE ARCHIBALD, STEPHEN SHEPARD, GREGORY MCMAHON, MICHAEL J. BURNS, THOMAS C. CHILES, MICHAEL J. NAUGHTON, Boston College — Arrays of nanoscale coaxial electrodes with hollow or porous annuli offer the potential of highly sensitive detection and identification of gases and molecules. We report on the response of a porous and a partially hollow (cavitized) array to the introduction of various vaporized laboratory solvents. The response is measured as the capacitance and loss changes due to the introduction of molecules into the annuli, associated with the dielectric constant of the solvents, as well as the quantity and pressure. A monotonic dependence on concentration in dry nitrogen was observed.

12:51PM Q21.00009 Damping effects of capacitive comb fingers on biomimetic MEMS directional microphone[1] , JOHN ROTH, MICHAEL TOUSE, JOSE SINIBALDI, GAMANI KARUNASIRI, Naval Postgraduate School — MEMS directional sound sensors that use two coupled wings moving in air are subjected to viscous damping. The amplitude of oscillation of the sensors is read out by measuring the capacitance of interdigitated comb fingers along the edges of the wings. In this presentation, effects of damping on MEMS sensors with and without comb fingers will be described. It was found that the sensors with comb fingers have a significantly larger damping indicating that the longer perimeter due to combs is responsible for the observed increase [1]. However, the increase in damping reduces the quality factor which improves the response time of the device.

1:03PM Q21.00010 Attofarad capacitance measurement on organic thin films using Scanning Microwave Microscopy , SHIJIE WU, Agilent Technologies, Inc, JING-JIANG YU, Agilent Technologies, Inc. — Scanning microwave microscopy (SMM) is a recent development in SPM technique that combines the lateral resolution of AFM and the measurement precision of microwave analysis. It consists of an AFM interfaced with a vector network analyzer (VAN). In the reflection mode (S11 measurement), the measured complex reflection coefficient of the microwave from the contact point directly correlates to the impedance of the sample under test. The maximum sensitivity of the measurement is obtained at the resonance where the impedance of the sample under test matches the characteristic impedance. Since the measured load impedance is largely determined by the impedance of the sample under test, SMM can be used to measure the capacitances over dielectric thin films. In this presentation, we report the calibration of SMM using a capacitance standard developed by NIST. Then SMM is used to measure the minute capacitance difference between decanethiol and octadecanthiol SAM layers. The coexistence of two different SAMs on the same substrate with a well-known height difference of 0.88 nm is achieved via an AFM-based nanolithography method known as Nanografting. The measured capacitance difference is about 24 attofarads under the condition that the effective tip/sample contact area was estimated to be about 60nm in diameter.

1:15PM Q21.00011 Intermodulation Spectral Analysis and The Intermodulation Lockin , DAVID HAVILAND, Royal Institute of Technology (KTH), ERIK THÖLEN, DANIEL PLATZ, DANIEL FORCHHEIMER, CARSTEN HUTTER — High quality factor oscillators are very useful for sensitive measurement. A weak perturbation to the oscillator gives a large change of response near resonance, which is typically analyzed to first order as change in the linear response (e.g. shift of resonance frequency). In many cases the measurement can be greatly enhanced by detecting higher order nonlinear response. With a single drive frequency, high order non-linearity gives response at high frequency harmonics, which are filtered out by the high Q oscillator. With two drive frequencies, high-order nonlinear response can be crowded near resonance by intermodulation, or frequency mixing. The intermodulation spectrum near resonance is highly correlated and from its analysis one can reconstruct high-order non-linearity[1] without high frequency spectral data. We developed a general-purpose lockin measurement instrument and software analysis algorithms for preforming this type of measurement. The instrument drives a system with two pure tones while simultaneously measuring both quadratures of response at 32 intermodulation product frequencies.[2]

1:27PM Q21.00012 A Study of Ionic Transport Through Randomly-Aligned Silica Nanospring Using Electrochemical Impedance Spectroscopy , YUKTA P. TIMALSINA, JOSHUA BRANEN, ERIC ASTON, KEN NOREN, DAVID N. MCILROY, University of Idaho, Moscow, ID 83844 — A study of ionic transport through randomly aligned (silica) nanospring (RANS) using electrochemical impedance spectroscopy is presented. The device used for this study is a parallel plate capacitor consisting of two conducting surfaces with RANS as the dielectric spacer layer. The device response is evaluated with test solutions consisting of sodium chloride in a phosphate buffer. The experimental impedance data is analyzed using a model equivalent resistor-inductor-capacitor (RLC) circuit. The solution resistance through RANS and electric double layer formed at solution- electrode interface are elements of equivalent circuit that are more responsive and are more likely to be affected by changes of ionic concentrations. From our analysis we have determined that an electric double layer forms at the solution- RANS interface, which acts as a barrier to diffusion of ions from the solution into the RANS, and vice versa. We have also determined that ion diffusion is impeded by the RANS, as illustrated by changes in the resistance of the element of the equivalent circuit that corresponds to diffusion of ions through the RANS. The linear response of the RANS-based device below 10 kHz is potentially useful for many sensing applications.

1:39PM Q21.00013 Gas Sensing Properties of Hybrid SnO_2/Carbon Nanotubes , AZLIN BIAGGI-LABIOSA, LAURA J. EVANS, JENNIFER C. XU, GARY W. HUNTER, NASA Glenn Research Center, GORDON BERGER, National Center for Space Exploration Research, FRANCISCO SOLA, NASA Glenn Research Center — Chemical sensors involving nanostructured materials can be developed into sensor systems with unique properties and improved performance. One approach is to combine different nanomaterials in order to form hybrid structures with properties different than that of the constituent materials. Hybrid nanostructures consisting of tin oxide (SnO_2) nanocrystals distributed on the surface of multiwalled carbon nanotubes (MWCNTs) and singlewalled carbon nanotubes (SWCNTs) were fabricated and incorporated on a sensor platform in a controlled and efficient manner with a novel approach that combines dielectrophoresis with standard microprocessing techniques. Current vs. voltage and current vs. temperature curves were taken at different concentrations of hydrogen (H_2), hydrocarbons and nitrogen oxides (NO_x) at various operating temperatures for the hybrid nanostructures and were compared with their counterparts without SnO_2 nanocrystals. The tests showed that the hybrid nanostructures exhibit room temperature sensing capability when exposed to low concentration gases in contrast to the high operating temperature typically required for SnO_2 nanocrystals alone. High resolution electron microscopy and electron energy-loss spectroscopy will also be presented.

1:51PM Q21.00014 Development of a Tunnel Diode Resonator technique for magnetic measurements in Electrostatic Levitation chamber[1] , N.S. SPYRISON, P. PROMMAPAN, H. KIM, J. MALONEY, G.E. RUSTAN, A. KREYSSIG, A.I. GOLDMAN, R. PROZOROV, Department of Physics and Astronomy, ISU, Ames, IA 50011, USA — The incorporation of the Tunnel Diode Resonator (TDR) technique into an ElectroStatic Levitation (ESL) apparatus was explored. The TDR technique is known to operate and behave well at low temperatures with careful attention to coil-sample positioning in a dark, shielded environment. With these specifications a frequency resolution of 10^{-9} in a few seconds counting time can be achieved.[2] Complications arise when this technique is applied in the ESL chamber where a sample of molten metal is levitating less then 10 mm from the coil in a large electrostatic field. We have tested a variety of coils unconventional to TDR; including Helmholtz pairs and Archimedean spiral coils.

2:03PM Q21.00015 Microwave impedance imaging on semiconductor memory devices , WORASOM KUNDHIKANJANA, KEJI LAI, YONGLIANG YANG, MICHAEL KELLY, ZHI-XUN SHEN, Geballe Laboratory for Advanced Materials, Departments of Physics and Applied Physics, Stanford University, CA 94305 — Microwave impedance microscopy (MIM) maps out the real and imaginary components of the tip-sample impedance, from which the local conductivity and dielectric constant distribution can be derived. The stray field contribution is minimized in our shielded cantilever design, enabling quantitative analysis of nano-materials and device structures. We demonstrate here that the MIM can spatially resolve the conductivity variation in a dynamic random access memory (DRAM) sample. With DC or low-frequency AC bias applied to the tip, contrast between n-doped and p-doped regions in the dC/dV images is observed, and p-n junctions are highlighted in the dR/dV images. The results can be directly compared with data taken by scanning capacitance microscope (SCM), which uses unshielded cantilevers and resonant electronics, and the MIM reveals more information of the local dopant concentration than SCM.

Wednesday, March 23, 2011 11:15AM - 2:15PM –

Session Q22 DCMP: Metal-Insulator Phase Transitions II D163

11:15AM Q22.00001 Fast pulsed measurements of the electric-field-driven metal-insulator transition in magnetite[1] , J. SPENCER MORRIS, Rice University, Houston, TX, R.G. SUMESH SOFIN, IGOR V. SHVETS, Trinity College, Dublin, IE, DOUGLAS NATELSON, Rice University, Houston, TX — Magnetite, Fe3O4, is an example of a strongly correlated material in which strong electron-electron interactions lead to unusual magneto-electronic properties. In particular, it undergoes a first-order phase transition on cooling through TV∼122K in bulk, in which a structural transition is accompanied by a significant drop in electrical conductivity. Recent electronic transport measurements have shown an electric-field driven breakdown of the insulating state in large aspect-ratio nanogaps fabricated on magnetite thin-films. The mechanism of this breakdown is of great interest in understanding the Verwey transition, and probing the intrinsic speed of the breakdown may further constrain possible mechanisms. We investigate the kinetics of this nonequilibrium transition by employing a high-speed pulse generator to apply voltages approaching the nanosecond time scale that exceed the critical switching value, and measuring the transmitted pulse via a high-speed oscilloscope. A significant change in transmission is observed for pulses that exceed the critical amplitude necessary to initiate the transition. Our initial results include an evaluation of the material response as a function of temperature and amplitude of the applied voltage.

[1]This work is supported by DOE award DE-FG02-06ER46337.

11:27AM Q22.00002 Magnetic field dependence of the nonequilibrium metal-insulator transition in magnetite nanostructures[1] , DOUGLAS NATELSON, Department of Physics and Astronomy, Rice University, ALEXANDRA A. FURSINA, Department of Chemistry, Rice University, R. G. S. SOFIN, IGOR V. SHVETS, School of Physics, Trinity College, Dublin, IE — At low temperatures magnetite undergoes a Verwey transition from a comparatively conducting state to a strongly correlated, ordered, more insulating state, the detailed nature of which remains under active debate. Recent experiments using nanostructures based on epitaxial magnetite films have shown that an applied dc electric field can lead to a nonequilibrium transition out of the insulating state. The kinetics of this nonequilibrium transition are nontrivial, with switching taking place over a distribution of applied voltages in a particular device at a given temperature below the Verwey transition. An externally applied magnetic field is observed to alter the kinetics of the nonequilibrium transition as the magnetization of the magnetite film is coerced out of plane. We present this data and discuss what it implies about the nature of the ordered, insulating ground state.

[1]This work is supported by DOE award DE-FG02-06ER46337.

11:39AM Q22.00003 Mesoscopic transport in ultrathin films of $La_{0.67}Ca_{0.33}MnO_3$, C. BEEKMAN, J. ZAANEN, J. AARTS, University of Leiden — We investigate the electrical transport in mesoscopic structures of $La_{0.67}Ca_{0.33}MnO_3$ in the regime of the metal-insulator transition by fabricating microbridges from strained and unstrained thin films. We measure current-voltage characteristics as function of temperature and in high magnetic fields and with varying film thickness. For strained films, in warming from the metallic to the insulating state, we find non-linear effects in the steep part of the transition characterized by a differential resistance with a strong peak around zero applied current, and saturating at higher currents after resistance drops up to 60 %. We propose that this nonlinear behavior is associated with melting of the insulating state by injecting charge carriers, signalling the occurrence of an intervening phase which involves the formation of short range polaron correlations.

11:51AM Q22.00004 In-situ TEM Analysis and Transport in Manganites $La_{5/8-y}Pr_yCa_{3/8}MnO_3$ Exhibiting Phase Separation below Metal-Insulator Transition , V. VOLKOV, J. HE, T. OSAKA, Y. ZHU, Brookhaven National Laboratory, S. CHAUDHURI, R. BUDHANI, Indian Institute of Technology — Epitaxial films of doped $La_{5/8-y}Pr_yCa_{3/8}MnO_3$ (LPCMO: y = 0.275-0.375) manganites were examined by *in-situ* Lorentz microscopy and other TEM methods below the metal-insulator transition point T_{MI} ~164 K. Such films are known for colossal magneto-resistance effect (CMR). Clear evidences were obtained for mesoscale two-phase separation process involving antiferromagnetic charge-ordered (AFM/CO) and ferromagnetic (FM) phases, coexisting below T_{MI} in LPCMO films. The first-order CO-FM phase transition is accompanied by partial magnetic melting of the CO phase at CO/FM interfaces thereby creating charge-disordered spin-glass metastates. In contrast, FM phase shows specific "zig-zag" magnetic domains coupled with dense (101) crystal twins. This allows refining relations for charge-orbital and spin-ordering vectors in films. Transport resistance data show that T_{MI} point is decreased with Pr_y growth in LPCMO. On cooling films below T_{MI} their resistance drops by several orders in magnitude. The observed M-I transition shows striking linear relation for log-conductance curve versus FM fraction measured by TEM, which does not follow typical percolation equations, suggesting that percolation transport model in manganites needs further revisions.

12:03PM Q22.00005 First Order CMR Transitions and Spin-Charge Dynamics Above the Curie Temperature in the Two-Orbital Model for Manganites[1] , CENGIZ SEN, University of Tennessee, GONZALO ALVAREZ, Oak Ridge National Lab, ELBIO DAGOTTO, University of Tennessee — We study the two e_g-orbital model including Jahn-Teller lattice distortions and the superexchange interaction using exact diagonalization Monte Carlo techniques at various dopings, x. We report the presence of first order CMR transitions at the Curie temperature (T_C) for doping $x = 0.25$ for the clean system and with weak disorder [1], in qualitative agreement with several experiments. We also discuss spin and charge dynamics as a function of Monte Carlo time above T_C, addressing the properties that characterize the exotic CMR state. It is observed that in CMR regimes there are various quasidegenerate spin states that may play an important role in this phenomenon [2].

12:15PM Q22.00006 Spin frustration effect near the Mott transition in the pyrochlore-type molybdates , SATOSHI IGUCHI, YUTA KUMANO, KOJI OISHI, Univ. of Tokyo, YOSHINORI TOKURA, Univ. of Tokyo, Multiferroics Project ERATO, and CMRG-RIKEN — Spin frustration and nontrivial spin structures by antiferromagnetic spins on a frustrated lattice have been widely studied such as a spin ice system with the pyrochlore structure $Ho_2Ti_2O_7$. However, spin frustration effects on conduction electrons have been less studied so far. Here, we have investigated spin frustration effects near the insulator-metal (Mott) transition in pyrochlore molybdates, where a paramagnetic diffuse metal state with antiferromagnetic spins is characteristic. Hole carriers were introduced by doping of Cd ions into the spin glass (Mott) insulator $Y_2Mo_2O_7$. The insulator to metal transition occurs at around $x = 0.1$ in $(Y_{1-x}Cd_x)_2Mo_2O_7$ with magnetically spin glass ground state. With increasing in the hole concentration, the spin glass transition disappears at around $x = 0.30$ and the resistivity shows almost no temperature dependence. Such a paramagnetic diffusive metallic character has been widely observed in $R_2Mo_2O_7$ (R = rare-earth ion) under high pressures. We have also measured the heat capacity in the system and found the anomalous enhancement of effective electron mass at around the transition from the spin glass metal to the paramagnetic metal phase.

12:27PM Q22.00007 Mott transition in multi-orbital Hubbard models for iron pnictides , RONG YU, QIMIAO SI, Department of Physics and Astronomy, Rice University — The bad-metal behavior of the iron pnictides has motivated a theoretical description in terms of a proximity to Mott localization. Since the parent compounds of the iron pnictides contain an even number of 3d-electrons per Fe, it is important to determine whether a Mott transition robustly exists and the nature of the possible Mott insulating phases. We address these issues in multi-orbital Hubbard models for the parent iron pnictides using a slave-spin approach. We show a metal-to-Mott-insulator transition in xz and yz orbitals generally exists in these models [1]. The nature of the metal-to-insulator transition may be strongly affected by the Hund's couplings. For certain values of Hund's couplings, we show there is a orbitally selective metal-to-insulator transition: the transition to a Mott insulator in the xz and yz orbitals takes place at the same critical coupling as the transition to either an orbitally polarized insulator or a band insulator in the other orbitals. Implications for the electronic and magnetic properties of the iron pnictides are discussed.

12:39PM Q22.00008 Transport and spectra in the half–filled Hubbard model , HIMADRI BARMAN, VIDHYADHIRAJA SUDHINDRA, Jawaharlal Nehru Centre for Advanced Scientific Research (JNCASR), Bangalore, India — We study the issues of scaling and universality in spectral and transport properties of the infinite dimensional particle–hole symmetric Hubbard model within dynamical mean field theory. We have used and reformulated the iterated perturbation theory approach to avoid problems such as analytic continuation of Matsubara frequency quantities or calculating multi-dimensional integrals, while taking full account of the very sharp structures in the Green's functions that arise close to the Mott transitions. We find a "coherence peak" in the dc resistivity of the metallic regime, which appears to be a universal feature occurring at a temperature roughly equal to the low energy scale of the system and agrees qualitatively well with the pressure dependent dc resistivity experiments on Selenium doped NiS_2. Resistivity hysteresis across the Mott transition is found and a direct comparison of the thermal hysteresis observed in V_2O_3 with our theoretical results yields a value of the hopping integral, which we find to be in the range estimated through first-principle methods. Finally, a systematic study of optical conductivity is carried out and the changes in absorption as a result of varying interaction strength and temperature are identified.

12:51PM Q22.00009 Spectral function near the Mott transition in the one-dimensional Hubbard model , MASANORI KOHNO, National Institute for Materials Science, Japan — Spectral properties near the Mott transition are investigated in the one-dimensional Hubbard model. The single-particle spectral function is calculated using the dynamical density-matrix renormalization group method, and the dominant modes are identified using the Bethe ansatz. Characteristic features near the Mott transition, such as the pseudogap, hole-pocket behavior, spectral-weight transfer, and upper Hubbard band, are explained in a unified manner in terms of spinons, holons, antiholons, and doublons. From the insulating side, the Mott transition is characterized by the emergence of a gapless mode whose dispersion relation extends up to the order of hopping (spin exchange) in the weak (strong) interaction regime caused by infinitesimal doping. From the metallic side, the transition is characterized as a loss of charge character from the mode having both spin and charge characters, while the spin excitation remains gapless and dispersing. These features cannot be explained in either the rigid-band picture or the Fermi liquid theory. I expect that generic features near Mott transitions can be deduced from the present results.

1:03PM Q22.00010 ABSTRACT WITHDRAWN –

1:15PM Q22.00011 Localized states in Mott insulator κ-(BEDT-TTF)$_2$Cu[N(CN)$_2$]Cl probed by photoluminescence[1] , NATALIA DRICHKO, Johns Hopkins University, RUDI HACKL, Walter Meissner Institute Garching Germany, JOHN SCHLUETER, Argonne National Laboratory — We present the luminescence spectra of a low-temperature Mott insulator (T_c=35 K) κ-(BEDT-TTF)$_2$Cu[N(CN)$_2$]Cl and a metal with a superconductor transition κ-(BEDT-TTF)$_2$Cu[N(CN)$_2$]Br in the temperature range between 300 and 10 K. In the Mott insulating state we observe an appearance of a luminescence at 1.95 eV, which corresponds to a LUMO-HOMO transition in a BEDT-TTF molecule. This luminescence is quenched both in the higher-temperature semiconducting state of κ-(BEDT-TTF)$_2$Cu[N(CN)$_2$]Cl and metallic κ-(BEDT-TTF)$_2$Cu[N(CN)$_2$]Br. To our knowledge, it is the first observation of luminescence driven by electronic correlations. This observation gives an evidence of the local character of BEDT-TTF energy levels in the Mott insulating state, in contrast to the band-character in the metallic and semiconducting states.

1:27PM Q22.00012 Quantum electric dipoles in spin liquid dimer Mott insulator , CHISA HOTTA, Kyoto Sangyo University — We present an effective dipolar-spin model based on the strong coupling analysis, which may explain the possible origin of the "spin liquid Mott insulator" of the organic triangular lattice system, kappa-ET_2Cu_2 $(CN)_3$, whose gapless spin liquid state had been discussed in the context of geometrical frustration of exchange coupling, J, between spins on dimer orbitals. We find out that another degrees of freedom within the insulator, quantum electric-dipoles on dimers, interacts with each other by the Coulomb interaction and brings about a significant suppression of$J$ through the dipolar-spin coupling.

1:39PM Q22.00013 Numerical study on the ionic Hubbard model in one and two dimensions , JI-WOO LEE, YONG CHUL LEE, SOO HYUN CHO, Myongji University — We investigate the quantum phase transition of an ionic Hubbard model in one and two dimensions. There are three parameters in the ionic Hubbard model, one is the hopping term t, the other is the Coulomb term U between local spin-up and spin-down electrons, and another is the band energy Δ which corresponds to the difference in local chemical potentials of bipartite lattice. Via exact diagonalization and quantum Monte Carlo simulations, we obtained the phase boundary of Mott insulator, metal, and band insulator. We measure the ground state energy and the energy gap between the ground-state and the first excited-state energy, and also measure the order parameters such as Drude weight and double occupancy in the three phases to understand the nature of three phases.

1:51PM Q22.00014 Spectral properties of the one-dimensional Hubbard model: cluster dynamical mean-field approaches[1] , ARA GO, GUN SANG JEON, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea — We investigate static and dynamic properties of the one-dimensional Hubbard model using cluster extensions of the dynamical mean-field theory. It is shown that the two different extensions, the cellular dynamical mean-field theory and the dynamic cluster approximation, yield the ground-state properties which are qualitatively in good agreement with each other. We compare the results with the Bethe ansatz results to check the accuracy of the calculation with finite sizes of clusters. We also analyze the spectral properties of the model with the focus on the spin-charge separation and discuss the dependency on the cluster size in the two approaches.

2:03PM Q22.00015 Temperature Effects on Metal-Insulator Transitions in the Ionic Hubbard Model[1] , AARAM KIM, GUN SANG JEON, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea — The ionic Hubbard model is known to exhibit interesting transitions between metallic and insulating phases at zero temperature. We investigate finite-temperature phase transitions in the model. For an extensive finite-temperature study, we apply a dynamical mean- field theory with continuous-time quantum Monte Carlo method employed as an impurity solver. We examine how the transitions at zero temperature evolve as the temperature increases. We also discuss the effects of temperature on the nature of transitions and other properties of the system.

Session Q23 DMP DCOMP: Focus Session: Iron Based Superconductors – Fermi Topology

D165

11:15AM Q23.00001 Ab initio study of de Haas van Alphen effect in $BaRh_2P_2$ and $BaIr_2P_2$, SIMON BLACKBURN, MICHEL COTE, BOBBY PREVOST, ANDREA BIANCHI, Departement de physique, Universite de Montreal, QC, Canada, MAREK BARTKOWIAK, Paul Scherrer Institut-LDM, PSI, Switzerland, BEATE BERGK, OLEG IGNATCHIK, JOCHEN WOSNITZA, Dresden High Magnetic Field Laboratory, Forschungszentrum Dresden, Rossendorf, Germany, GABRIEL SEYFARTH, Univ Geneva, DPMC, CH-1211 Geneva, Switzerland, CIGDEM CAPAN, ZACHARY FISK, Department of Physics & Astronomy, University of California Irvine, Irvine, CA, USA — The de Haas-van Alphen (dHvA) effect is a powerful probe of the Fermi surface (FS) of a metal. Since it measures the area of a cross-section of the Fermi surface, a theoretical description of this surface complements well these experiments. However, a very accurate description of the FS is required from the ab initio calculations in order to calculate the dHvA frequencies. This is achieved using maximally localized Wannier functions (MLWF) (Marzari & Vanderbilt, *Phys. Rev. B*, 56, 12847)to interpolate the Hamiltonian on a dense k-point grid. In this work, we present a dHvA study of $BaRh_2P_2$ and of its isovalent material $BaIr_2P_2$, both structurally analog to the iron pnictide $BaFe_2As_2$. We also present results concerning $LaFe_2P_2$ and $CeFe_2P_2$ which are also related to $BaFe_2As_2$ by a rigid electronic band shift to account for the difference in the number of electrons.

11:27AM Q23.00002 ABSTRACT WITHDRAWN –

11:39AM Q23.00003 Transport properties of 3D extended s-wave states appropriate for iron-based superconductors[1]

, VIVEK MISHRA, University of Florida, SIEGFRIED GRASER, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, PETER HIRSCHFELD, University of Florida — The Fermi surfaces of Fe-pnictide superconductors are fairly two-dimensional (2D), and it has thus come as a surprise that recent penetration depth and thermal conductivity measurements on some systems have reported c-axis transport at low temperatures in the superconducting state comparable to or even larger than that in the ab plane. These results should provide important information on both the Fermi surface and the superconducting state. Here we consider the theory of the superfluid density and thermal conductivity in models of extended-s wave superconducting states expected to be appropriate for Fe-pnictide systems. We include both intra- and interband disorder and consider a range of different Fermi surfaces where gap nodes might exist. We show that qualitative fits can be obtained to match recent experiments on $Ba(Fe_{1-x}Co_x)_2As_2$, and discuss their implications.

11:51AM Q23.00004 Fermi Surface of the Pnictide Superconductor $LaRu_2P_2$ studied by quantum oscillations

, PHILIP MOLL, Solid State Physics, ETH Zurich, FEDOR BALAKIREV, ROSS MCDONALD, NHMFL, LANL, Los Alamos, NM, JANUSZ KARPINSKI, ZBIGNIEW BUKOWSKI, Solid State Physics, ETH Zurich, PETER BLAHA, KARLHEINZ SCHWARZ, Computational Quantum Chemistry Group, TU Vienna, BERTRAM BATLOGG, Solid State Physics, ETH Zurich — $LaRu_2P_2$ is a stochiometric pnictide superconductor ($T_c \sim 4.1$K) and crystallizes in the $ThCr_2Si_2$ structure (the "122" pnictide family). We have mapped out its Fermi surface via the deHaas-vanAlphen effect in pulsed magnetic fields up to 60T (LANL/NHMFL). Pronounced oscillations were observed in the magnetic torque measured with a microcantilever setup. Two features are particularly noteworthy: The oscillations can be followed to surprisingly high temperatures beyond 20K, and the main frequency component at $\theta = 20^\circ$ ($\theta = 0^\circ$ at HIIc) is at 349T (α-peak), significantly lower than in the related compounds $LaFe_2P_2$. A second frequency originating from a larger Fermi surface cross-section at 1921 T (β-peak) is identified. The temperature dependence of the amplitudes is well described by the Lifshitz- Kosevich formalism and gives low effective masses $m^*/m = 0.80$ (α sheet) and 1.09 (β sheet). Therefore, most "122" metals appear to have similarly low effective masses.

12:03PM Q23.00005 Campbell penetration depth in stoichiometric LiFeAs - evidence for static fishtail effect

, PLENGCHART PROMMAPAN, HYUNSOO KIM, MAKARIY A. TANATAR, RUSLAN PROZOROV, Ames Laboratory, Ames, IA 50011, USA, BUMSUNG LEE, SEUNGHYUN KHIM, KEE HOON KIM, CeNSCMR & Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Republic of Korea — The "fishtail" or second magnetization peak is one of the most intriguing properties of high$-T_c$ cuprate superconductors. Now it has also been observed in iron-based materials and has been associated with weak collective pinning. To understand whether the fishtail effect has dynamic (due to field-dependent magnetic relaxation) or static behavior (due to actual non-monotonic field dependence of the true critical current) one needs to measure the clean system, which are rare in pnictide superconductors. A stoichiometric LiFeAs is one of the cleanest of the pnictides with RRR=65. We measured the Campbell penetration depth using a 10 MHz tunnel-diode resonator in DC magnetic fields of up to 9 T. As opposed to the "apparent" current density, estimated from the magnetization relaxed over tens of seconds, the Campbell penetration depth depends on the curvature of the pinning potential sampled at time intervals of 0.1 μsec, thus allowing one to estimate the unrelaxed, "true" $j_c(T, B)$. The obtained $j_c(T, B)$ shows a non-monotonic trend with a second peak shifting toward lower fields at higher temperatures implying a static origin of the fishtail effect in LiFeAs.

12:15PM Q23.00006 Measuring the Absolute Penetration Depth in Superconducting Materials.

, NICHOLAI SALOVICH, University of Illinois at Urbana-Champaign, RUSSELL GIANNETTA, University of Illinois at Urbana Champaign, RUSLAN PROZOROV, PAUL CANFIELD, Iowa State University, Ames Laboratory, SERGEY BUD'KO — The absolute penetration depths of a variety of superconductors were measured using a method involving a high precision tunnel diode oscillator and an Aluminum film coating method [1]. Variations of the Al film geometry (thickness, coverage area, etc) and microstructure (grain size, RRR, etc) were used to test the reliability and versatility of the coating technique. A variety of supplemental techniques (dual beam SEM, EBS, AFM, XRD, etc) were used to independently characterize the films and control their quality. Special emphasis was placed on measurements of cobalt doped iron pnictide samples given the well established quality of such samples now available. Work at UIUC supported by NSF DMR 10-05708, and Center for Emergent Superconductivity USDOE Award No. DE-AC02-98CH10886. Work at the Ames Laboratory was supported by the division of Materials Science and Engineering, Basic Energy Sciences, Department of Energy (US DOE), under Contract No. DEAC02-07Ch11358.

12:27PM Q23.00007 dHvA studies of the Fermi topology of Iron-based Superconductors and Metals[1]

, AMALIA COLDEA[2], University of Oxford — Quantum oscillations studies on various non-magnetic iron pnictides reveal a Fermi surface in broad agreement with the details of the band structure calculations and moderate enhancement of the electronic correlations [1,2,3,4]. Whether or not the nesting of the electron and hole bands are essential for explaining the superconducting behaviour in these materials is still under debate but it is becoming clear that structural alteration have a significant effect in determining their electronic properties. In this talk I will present quantum oscillations studies in materials in which the Fermi surface suffers major topological changes. I will discuss the effect of isoelectronic substitution and doping on the Fermi surface and the quasiparticle masses and their relevance for understanding the complex physics of these materials. This work is in collaboration with groups at Bristol University, Stanford University and Kyoto University [1,2,3,4] and experiments were performed at high magnetic field facilities in Tallahassee, Nijmegen and Toulouse.

1:03PM Q23.00008 London penetration depth measurements in $Ba(Fe_{1-x}Ru_x)_2As_2$ single crystals

, RYAN GORDON, MAKARIY TANATAR, ALEXANDER THALER, RUSLAN PROZOROV, Department of Physics and Astronomy, Iowa State University and Ames Laboratory, Ames, IA — The variation of the in-plane London penetration depth with temperature, $\Delta\lambda_{ab}(T)$, has been measured in $Ba(Fe_{1-x}Ru_x)_2As_2$ single crystals by using a tunnel diode resonator (TDR). The crystals were grown out of self- flux, with superconductivity stabilized for $x > 0.2$ and the maximum $T_c \approx 16$ K corresponding to $x \approx 0.29$. The substitution of Ru for Fe in this compound is particularly interesting because it is isovalent, so that no additional charge carriers are added by the Ru. The low-temperature penetration depth has been found to exhibit a power law dependence, $\Delta\lambda_{ab}(T) \propto T^n$, with an x- dependent exponent, n. Using the penetration depth data, the superfluid density has been constructed and compared to known theoretical models for different superconducting pairing symmetries and impurity scattering limits. These results will be compared to previous measurements on different iron-based superconductors.

1:15PM Q23.00009 Superfluid Density Measurements of $Ba(Co_xFe_{1-x})_2As_2$ Films near Optimal Doping , JIE YONG, Dept. of physics, The Ohio State University, SANGHAN LEE, Dept. of M.S.E, University of Wisconsin, Madison, J. JIANG, Applied Superconductivity Center, National High Magnetic Field Laboratory, Florida State University, C.W. PARK, J.D. WEISS, E.E. HELLSTORM, D.C. LARBALESTIER, C.B. EOM, T.R. LEMBERGER — We report the first direct, low-frequency measurements of superfluid density, $n_s(T) \propto \lambda^{-2}(T)$, in $Ba(Co_xFe_{1-x})_2As_2$ thin films, near optimal doping. 100 nm thick films are fabricated by Pulsed Laser Deposition (PLD) in high vacuum and $SrTiO_3$ is used as template to match Ba layer in ba-122. Temperature dependence of superfluid density is measured by our two-coil mutual inductance apparatus down to 1.3K. The magnetic penetration depth, λ, at $T \approx 0$ is 350 to 430 nm. The T-dependence of λ^{-2} is well characterized by a small s-wave gap, $2\Delta(0)/k_BT_c = 2.2 \pm 0.1$. In detail, λ has power-law behavior at low T: $\lambda(T)/\lambda(0) - 1 = 0.60*(T/T_c)^{2.5\pm0.1}$. A tail of superfluid density near T_c is the only possible indication of a bigger gap. The small gap, together with power-law behavior at low-T, suggests strong intraband scattering on the larger-gap Fermi surface plus significant interband scattering between large-gap and small-gap Fermi surfaces.

1:27PM Q23.00010 Linear magnetoresistance in the underdoped iron pnictide $Ba(Fe_{1-x}Co_x)_2As_2$[1] , JIUN-HAW CHU, HSUEH-HUI KUO, SCOTT RIGGS, JAMES ANALYTIS, IAN FISHER, Stanford University — $BaFe_2As_2$ suffers an antiferromagnetic transition which has been described in terms of a nodal spin density wave. The material exhibits a striking linear magnetoresistance in the low temperature antiferromagnetic state, possibly related to the unique character of the reconstructed Fermi surface. Here we present data showing the evolution of the magnetoresistance as a function of both composition and temperature for the specific case of $Ba(Fe_{1-x}Co_x)_2As_2$, revealing a correlation with other transport properties, including the in-plane resistivity anisotropy.

[1]This work is supported by the DOE, Office of Basic Energy Sciences, under Contract No. DE-AC02-76SF00515.

1:39PM Q23.00011 Hall effect study of iron chalcogenide $Fe_{1+y}(Te_{1-x}Se_x)$, T.J. LIU, J. HU, B. QIAN, Z.Q. MAO, Department of Physics and Engineering Physics, Tulane University, New Orleans, LA 70118 — Our previous work reveals three composition regions with distinct physical properties in the phase diagram of $Fe_{1+y}(Te_{1-x}Se_x)$ (Liu *et al.*, Nature Materials **9**, 719 (2010)). Region I ($0 \leq x \leq 0.09$) exhibits long range $(\pi, 0)$ antiferromagnetic (AFM) order, while Region II ($0.09 < x < 0.29$) displays short range $(\pi, 0)$ magnetic correlations and is characterized by a weakly localized electronic state. Only in Region III ($x \geq 0.29$) do we find evidence of bulk superconductivity. In this talk, we will report Hall effect studies of this system. In the AFM state of Region I, we find that the inverse Hall angle (IHA) exhibits a quadratic temperature dependence, consistent with the Fermi liquid behavior probed by resistivity and specific heat measurements. In the weakly localized state of Region II, however, the IHA shows a linear temperature dependence, implying that the quasiparticle scattering rate in this region changes significantly compared with the AFM phase. We will discuss how quasiparticle scattering is associated with $(\pi, 0)$ magnetic fluctuations.

1:51PM Q23.00012 Upper Critical Field and the Fulde-Ferrel-Larkin-Ovchinnikov Transition in Multiband Superconductors , ALEX GUREVICH, National High Magnetic Field Laboratory, FSU, Tallahassee, FL 32303 — The effect of orbital and Zeeman pairbreaking on the upper critical field H_{c2} and the Fulde-Ferrel-Larkin-Ovchinnikov (FFLO) transition in clean Fe-based superconductors is addressed using a multiband BCS theory. It is shown that the crystalline anisotropy and the $s^{\pm}$ pairing symmetry with the sign change of the order parameter on different sheets of the Fermi surface can significantly increase the orbitally-limited $H_{c2}(T)$ and facilitate the FFLO transition. Small pockets of the Fermi surface emerging upon doping can trigger the FFLO transition even for moderate values of the Maki parameter in the main bands.

2:03PM Q23.00013 Upper critical field study of a LiFeAs single crystal grown by Sn flux , SEUNGHYUN KHIM, BUMSUNG LEE, JAE WOOK KIM, Seoul National University, EUN SANG CHOI, Florida State University, G. R. STEWART, University of Florida, KEE HOON KIM, Seoul National University, SEOUL NATIONAL UNIVERSITY TEAM, FLORIDA STATE UNIVERSITY COLLABORATION, UNIVERSITY OF FLORIDA COLLABORATION — Temperaturedependence of the upper critical fields $H_{c2}(T)$ was investigated in a LiFeAs single crystal by measuring resistivity at a fixed magnetic field up to 36 T. $H_{c2}^{ab}(0)$ and H_{c2}^{ab} (0) values are obtained as 30 and 17.2 T respectively. $H_{c2}^{ab}(0)$ is lower than expected one from the orbital limiting field $H_{c2}^{orb}(0)$ because of the presence of a moderate Pauli limiting effect; upon fitting $H_{c2}^{ab}(T)$ with the WHH formula, the Maki parameter $\alpha = 0.65$. For $H_{c2}^{c}(T)$, rather a linearly increasing behavior of $H_{c2}(T)$ could be explained by a two-band model in a dirty limit. The anisotropy $H_{c2}^{ab}/H_{c2}^{c}(T)$ is ∼2.3 near $T_c$and decreases with temperature being lowered to reaches ∼1.3 at $T = 0$. We also compare H_{c2} (T) of this 111 system with those of other Fe-based superconductors and conclude that the moderateness of the spin-paramagnetic effect is related with rather a weak slope of $H_{c2}(T)$ near T_c, which is inversely proportional to the Fermi velocity and mean free path. Thus, the comparison of the slope of H_{c2} supports that LiFeAs is located in a rather clean limit among the Fe-based superconductors.

Wednesday, March 23, 2011 11:15AM - 2:15PM –

Session Q24 DCOMP DMP: Focus Session: Multiscale Modeling: Heterogeneous Systems and Interfaces D167

11:15AM Q24.00001 Kinetic Monte Carlo with fields: diffusion in heterogeneous systems , JOSE ALFREDO CARO, Los Alamos National Laboratory — It is commonly perceived that to achieve breakthrough scientific discoveries in the 21^{st} century an integration of world leading experimental capabilities with theory, computational modeling and high performance computer simulations is necessary. Lying between the atomic and the macro scales, the meso scale is crucial for advancing materials research. Deterministic methods result computationally too heavy to cover length and time scales relevant for this scale. Therefore, stochastic approaches are one of the options of choice. In this talk I will describe recent progress in efficient parallelization schemes for Metropolis and kinetic Monte Carlo [1-2], and the combination of these ideas into a new hybrid Molecular Dynamics-kinetic Monte Carlo algorithm developed to study the basic mechanisms taking place in diffusion in concentrated alloys under the action of chemical and stress fields, incorporating in this way the actual driving force emerging from chemical potential gradients. Applications are shown on precipitation and segregation in nanostructured materials. Work in collaboration with E. Martinez, LANL, and with B. Sadigh, P. Erhart and A. Stukowsky, LLNL. Supported by the Center for Materials at Irradiation and Mechanical Extremes, an Energy Frontier Research Center funded by the U.S. Department of Energy (Award # 2008LANL1026) at Los Alamos National Laboratory

[1] B. Sadigh et al. to be published
[2] E. Martinez et al. J. Comp. Phys. 227 (2008) 3804-3823

11:51AM Q24.00002 On the atomic-scale design of metal-metal heterointerfaces[1] , MICHAEL DEMKOWICZ, MIT Department of Materials Science and Engineering — I will describe a multiscale modeling effort to understand and control the properties of heterointerfaces in metal-metal nanocomposites, using their effect on radiation response as an example. For selected model interfaces, atomistic simulations are used to characterize interface structure and to determine the mechanisms of interface-point defects interactions, including trapping, diffusion, and defect reactions. This information is then incorporated into mesoscale dislocation-based and continuum approaches to investigate the steady-state interface response to radiation-induced defect fluxes. With insights gained from studying this "forward" problem of predicting radiation response of selected model interfaces, one may attempt to solve the "inverse" problem of determining what interfaces will yield desired radiation response.

12:27PM Q24.00003 Atomistic Mechanism of Kinking in the Vapor-Liquid-Solid Growth of Silicon Nanowires , SEUNGHWA RYU, WEI CAI, Stanford University — Understanding the atomistic growth mechanism of semiconductor nanowires from the catalytic droplet is important for better control of the shape and orientation of nanowires deposited through the Vapor-Liquid-Solid (VLS) process. Kinking is a frequently observed event, in which the nanowire suddenly changes the growth orientation. This behavior is usually undesirable, but can also be explored to grow nanowires of complex shapes if it can be controlled. Unfortunately, the atomistic origin of kinking is not well understood. We employ advanced sampling methods to compute the probability of the orientation change during VLS growth. Several growth directions and nanowire diameters are simulated at 1000 K. The simulation uses a recently developed Au-Si inter-atomic potential fitted to the experimental binary phase diagram.

12:39PM Q24.00004 Prediction of the anisotropic properties of energetic materials at elevated pressures and temperatures[1] , OSCAR OJEDA, TAHIR CAGIN, Texas A&M University — Localization of strain and changes under extreme conditions in energetic materials (EM) can cause runaway reactions and unexpected initiation. A clear understanding of the mechanical properties is a perquisite in understanding the interplay between mechanical, chemical and thermodynamic properties that relate sensitivity and EM's before they undergo initiation. We have conducted first principles ground state studies, complemented by atomistic calculations at elevated temperatures and pressures, for energetic commonly used secondary EM's with varying sensitivities. Chemical information found from ab intio methods, and from compression at elevated temperatures show that external conditions relevant to impact and shock behavior can have different effects on the studied systems. These range from changes in local conformation, changes in the hydrogen-bonding network, and more drastically to a full crystallographic transition in which the symmetry of the system undergoes a transformation. Due to the chemical, mechanical and thermodynamic level information that provides, multiscale modeling methods, can then be applied to the understanding of other type of systems and give a clearer understanding of the molecular processes that undergo energetic materials, prior to initiation.

12:51PM Q24.00005 Migration energies of native defects and fission products in uranium dioxide[1] , ALEXANDER THOMPSON, CHRIS WOLVERTON, Northwestern University — Despite the importance of fission products like Xe in nuclear fuels, the mechanism of how these atoms diffuse in the lattice is not known. In an effort to identify this mechanism, we have used density functional theory as well as a variety of different classical potentials for to study the migration energies of a variety of atomic steps in UO2, with and without Xe impurities and native defects. We find that the classical potential of Basak gives results which compare favorably with density functional theory for the diffusion of a Schottky defect cluster. We observe a new path for xenon-tetravacancy (a UO2 Schottky defect plus an additional U vacancy) motion using molecular dynamics. This path has a lower energy barrier than previously reported xenon-tetravacancy paths. We examine the possibility of a uranium vacancy dissociating from the xenon-tetravacancy cluster and find that large barriers for this dissociation. We also calculate xenon-double Schottky defect migration and find it has a slightly larger barrier than xenon-tetravacancy motion with the oxygen vacancies being weakly bound to the defect.

[1]NERI-C 08-051

1:03PM Q24.00006 Interface Mediated Nucleation and Growth of Dislocations in fcc-bcc nanocomposite , RUIFENG ZHANG, JIAN WANG, IRENE J. BEYERLEIN, TIMOTHY C. GERMANN, Los Alamos National Laboratory — Heterophase interfaces play a crucial role in determining material strength for nanostructured materials because they can block, store, nucleate, and remove dislocations, the essential defects that enable plastic deformation. Much recent theoretical and experimental effort has been conducted on nanostructured Cu-Nb multilayer composites that exhibited extraordinarily high strength, ductility, and resistance to radiation and mechanical loading. In decreasing layer thicknesses to the order of a few tens of nanometers or less, the deformation behavior of such composites is mainly controlled by the Cu/Nb interface. In this work, we focus on the cooperative mechanisms of dislocation nucleation and growth from Cu/Nb interfaces, and their interaction with interface. Two types of experimentally observed Cu/Nb incoherent interfaces are comparatively studied. We found that the preferred dislocation nucleation sites are closely related to atomic interface structure, which in turn, depend on the orientation relationship. The activation stress and energies for an isolated Shockley dislocation loop of different sizes from specific interface sites depend strongly on dislocation size, atomic interface pattern, and loading conditions. Such findings provide important insight into the mechanical response of a wide range of fcc/bcc metallic nanocomposites via atomic interface design.

1:15PM Q24.00007 Atomic and Surface Interactions of Electrode Metals with a p-Type Organometallic Conductor[1] , BHASKAR CHILUKURI, THOMAS CUNDARI, Department of Chemistry, Center for Advanced Scientific Computing and Modeling (CASCaM), University of North Texas, Box 305070, Denton, TX 76203-5070 — A computational study of the interaction of high and low work function electrode metal atoms (M' = Al, Au, Cu, La, Ni, Pd, Pt, Ru, Ni) used in electronic devices with cyclo-[Au(μ-Pz)]$_3$ trimer (T) (Pz = pyrazolate ligand), a p-type organometallic semiconductor is presented. Metal (M'$_M$) and ligand (M'$_L$) sites of the gold trimer are investigated as the possible sites of deposition for the metal atoms. Examination of metal binding, geometric and electronic properties suggest that these metal-based, p-type conductors will form stable interfaces with good electron transfer with typical source/drain electrode metals. Encouraged by the molecular simulation results, we performed periodic interface calculations of metal (001) and (111) surfaces with a monolayer of cyclo-[Au(μ-Pz)]$_3$ trimer using a plane-wave DFT approach. Structural and electronic properties of metal-trimer interfaces and implications for interface stability and electron transfer will be discussed.

1:27PM Q24.00008 Structure of charge trapping in cerium-doped aluminophosphate and phosphosilicate glasses: combining molecular dynamics simulations and *ab initio* DFT calculations , LEOPOLD KOKOU, YUN LI, JINCHENG DU, University of North Texas, MSE TEAM — Cerium doping glasses find wide applications in optical and photonic devices. Both Ce^{3+} and Ce^{4+} can be present in oxide glasses, and their ratio depends on the glass composition, heat history and melting environment. In either oxidation state, the environments of cerium ions are important to the optical absorption and emission properties. In this paper, we present classical molecular dynamic simulations of cerium-containing aluminosilicate and phosphosilicate glasses using newly developed potential models containing cerium ions. The local environments around Ce^{3+} and Ce^{4+} are studied, and the bond length and coordination of cerium ions are determined. Small samples of the glasses are simulated using MD and then further relaxed with Density Functional Theory (DFT) calculations. Comparison of the structure of glasses from MD and after DFT relaxation is made, and the two are found to be in reasonable agreement. It is found that Ce^{3+} has a longer bond distance and higher coordination number of oxygen. Most interestingly, cerium ions are found to be preferentially coordinated by phosphorus ions in the second coordination shell in the glasses.

1:39PM Q24.00009 Surface Structure and Work Function of ZnO Based on First Principle DFT Calculations , YUN LI, JINCHENG DU, UNT — Zinc Oxide is a well known n-type wide band gap semiconductor material and remains actively as a strategic material for various photonic applications. The fabricate ZnO, is effectively used as a sensor in various applications, Because of its high infrared reflectance and high visible transmittance. Due to that fact, its electron property plays vital role and attract our attention. Via simulation method, their electron properties were studied through density function theory. Based on first principle theory, their structures with distinct cleaved planes were obtained and completed relaxed in DFT based methods. Depending on cleaved planes, there were Oxygen or Zinc atoms terminated along (001) direction and both of them locating on the cleaved surface (110). Work function and other electron properties will be discussed in detail for all of them and compared with the experimental values, the difference and prediction will be made.

1:51PM Q24.00010 Coupling Fluctuating Hydrodynamics with Molecular Dynamics at the Nanoscale , NIKOLAOS VOULGARAKIS, JHIH-WEI CHU, Department of Chemical and Biomolecular Engineering, University of California, Berkeley — Hydrodynamic fluctuations and solvation interactions are essential driving forces of transport phenomena in the micrometer to nanometer regime, including inter- and intra-cellular flows and flows in nanofabricated devices. Although all-atom molecular dynamics (MD) simulations can be used to model molecular fluids, the accessible time- and length-scales are severely limited. Since most of computational cost for MD simulations comes from the represetion of solvent molecules, a possible solution to this limitation is to model fluids with fluctuating hydrodynamics (FHD). While this approach reduces the computational time of MD simulations by three orders of magnitude, an accurate protocol to couple FHD with MD is still necessary. In this work we present a new methodology that couples FHD with MD by allowing the fluctuating fields to directly interact with particles through repulsive, attractive, and dissipating/fluctuating forces without introducing new degrees of freedom or boundary conditions. Numerical results show that solvation energy and diffusion dynamics are correctly described within our framework. Simulations on the collapse of two hydrophobic particles are also presented.

2:03PM Q24.00011 Multiscale Modeling of Solutions , OLAYINKA OLATUNJI-OJO, SANDRA BOETCHER, THOMAS CUNDARI, Center for Advanced Scientific and Computer Modeling, University of North Texas, Denton Tx 76203 — The sequestration of carbon dioxide is one proposed solution to alleviate the growing problem of increased atmospheric CO_2 concentration, and its resulting effect on global climate. However, the efficacy of such methods has yet to be demonstrated. Improved CO_2 sequestration methods are needed and this can be achieved through a better understanding of the chemical and physical consequences of CO_2 encapsulation through multiscale modeling. Multiscale modeling is an effective tool for combining different methods thereby creating an efficient way of modeling diverse chemical and physical phenomena. The goal of this research is to model carbon dioxide interactions in solutions from the quantum to continuum level. This is achieved through a combination of DFT calculations, molecular modeling (mesoscale) and computational fluid dynamics (continuum) simulations on CO_2 + H_2O. Interaction energies and interatomic distances are obtained from DFT calculations, which are used to derive a Lennard-Jones potential, from which one may obtain continuum properties such as viscosity via reverse non-equilibrium molecular dynamics (RNEMD) simulations.

11:15AM Q25.00001 Networks of ultra-small MoGe nanowires: fabrication and properties[1] , ZHILI XIAO, Argonne National Laboratory, MICHAEL LATIMER, QIONG LUO, WAI-KWONG KWOK, Argonne National Laboratory — By developing a template-based method we were able to fabricate networks of MoGe nanowires with widths and thicknesses of few nanometers. Resistive measurements reveal magnetoresistance oscillations with a field period up to 2 Tesla. Detailed information on sample fabrication will be presented. Possible mechanisms on the observed magnetoresistance oscillations will be discussed.

[1]This work was supported by the Department of Energy Grant DE-FG02-06ER46334

11:27AM Q25.00002 Magnetization-dependent resistance of double ferromagnet-superconductor junctions , KUEI SUN, U. of Cincinnati & U. of Illinois at Urbana-Champaign, M. COLCI, U. of Illinois at Urbana-Champaign & Naval Research Laboratory, Washington DC, D.J. VAN HARLINGEN, U. of Illinois at Urbana-Champaign, NAYANA SHAH, U. of Cincinnati, SMITHA VISHVESHWARA, U. of Illinois at Urbana-Champaign — Studies of the crossed Andreev reflection (CAR) process in double ferromagnet-superconductor junctions have attracted a lot of attention as way of realizing solid-state entanglement. Here, we perform a theoretical analyses of such a system motivated by our surprising experimental findings that the resistance in the antiparallel alignment of the magnetization of ferromagnets is larger than that in the parallel state. We model the system using an extended Blonder-Tinkham-Klapwijk (BTK) treatment with spin-dependent interfacial barriers associated with the magnetization. We compute scattering amplitudes of CAR and other possible processes as well as the resistance as a function of interfacial parameters. Our results reveal significantly altered physics due to the magnetization-dependent scattering, such as a sign change in the relative resistance between the parallel and antiparallel cases. We can model the positive relative resistance corresponding to our experimental findings as well as the negative results observed in other experiments, both within sufficiently large parameter regions.

11:39AM Q25.00003 Measurements of the critical current of small Sr_2RuO_4 crystals , YIQUN YING, NEAL STALEY, YING LIU, Department of Physics, The Pennsylvania State University, YAN XIN, National High Magnetic Field Laboratory, Florida State University, DAVID FOBES, TIJIANG LIU, ZHIQIANG MAO, Department of Physics, Tulane University — We report critical current measurements of chiral p-wave superconductor Sr_2RuO_4. Because of the strong anisotropy possessed by Sr_2RuO_4, vortex lines along the in-plane direction are expected to be pinned more strongly than those along the c axis, resulting in anisotropic critical currents. We prepared small single crystals of Sr_2RuO_4 with a typical size of 50μm$\times$ 10μm$\times$1μm by mechanical exfoliation and characterized them by Raman spectroscopy and high-resolution transmission electron microscopy, showing that they were either pure Sr_2RuO_4 or eutectic phase containing one or more Ru microdomains. Four-point or Hall probes were prepared on the small crystals by photo lithography. While samples of pure Sr_2RuO_4 exhibited a typical transition temperature (T_c) of 1.2K, slightly lower than the optimal bulk T_c, 1.5K, those with Ru microdomains showed multiple resistive transitions with the highest T_c around 2K. The critical current and critical field phase diagrams were determined for these small crystals. Surprisingly, the in-plane critical current density, measured for the first time, was found to be significantly larger than that along c-axis of the bulk. The physical implications of these observations will be discussed. Supported by DOE.

11:51AM Q25.00004 Angle-dependent transport behavior near the magnetic-field tuned superconductor-insulator transition , MIN-SOO KIM, TAI-LUNG WU, Department of Physics, University at Buffalo-SUNY, L.W. ENGEL, National High Magnetic Field Laboratory, G. SAMBANDAMURTHY, Department of Physics, University at Buffalo-SUNY — Thin films of superconducting, amorphous indium oxide were driven insulating by the application of magnetic field and their transport behavior at different magnetic field values are studied. Well below the critical field of the transition, the current-voltage characteristics follow a power law V$\propto$ I^p, where p depends on the magnetic field. The dependence of the power p on magnetic field and the angle between the sample plane and the magnetic field direction will be presented. In particular, we find two distinct magnetic field values, well above the critical field, where the sample resistance is independent of the angle. Implications of these results in improving our current understanding of the transition will be presented.

12:03PM Q25.00005 T_c Enhancement in Electron-Doped Cuprate Heterostructures , P.L. BACH, K. JIN, X.H. ZHANG, Center for Nanophysics and Advanced Materials, University of Maryland, R.L. GREENE[1], University of Maryland, U. GRUPEL, E. ZOHAR, E. DIAMANT, Y. DAGAN, Raymond and Beverly Sackler School of Physics and Astronomy, Tel-Aviv University, S. SMADICI, P. ABBAMONTE, Frederick Seitz Materials Research Laboratory, University of Illinois — Multilayer thin films of $La_{2-x}Ce_xCuO_4$ (LCCO) and $Pr_{2-x}Ce_xCuO_4$ (PCCO) were fabricated as superlattices of different dopings. Pairing over-doped and under-doped (or un-doped) layers is found to increase T_c significantly above that of the single-phase films corresponding to the under- or over-doped layers. We report transport measurements on these mulitlayer films and discuss possible mechanisms for the T_c enhancement. This work was supported by the US-Israel Binational Science Foundation Grant #2006385 and the Center for Nanophysics and Advanced Materials (CNAM).

12:15PM Q25.00006 Electronic Transport and Superconductivity in Bi Confined in a 200nm Opal Host[1] , MICHAEL NIESKOSKI, Fairfield University, RYAN JOHNSON, STEVEN DISSELER, MICHAEL GRAF, Boston College, TITO HUBER, Howard University, AUSTIN HOWARD, ANVAR ZAKHIDOV, University of Texas at Dallas — While bulk bismuth at ambient pressure is not a superconductor, changes in morphology are known to induce superconductivity in Bi at low temperatures. We present a study of bismuth nanoparticle arrays fabricated by confining bismuth into a porous opal host consisting of close-packed 200 nm silica spheres. Electrical transport was studied down to temperatures of 0.3K and magnetic fields up to 2T. We find the onset of superconductivity at 4.4K (confirmed by AC magnetic susceptibility) and global superconductivity at a temperature of 1.3K. This two step transition is typical for granular superconductors. Measurements of the critical temperature in magnetic field show that the higher temperature transition consists of at least two transitions. The low temperature upper critical field was calculated to be approximately 0.82T. These results are discussed in terms of the morphologies, namely amorphous and granular structure, that are known to make Bi a superconductor, and the three characteristic sizes for the nanoparticles in that has been used to describe superconductivity in lead imbedded in these host materials

12:27PM Q25.00007 Electrostatic Modification of Properties of Ultrathin YBCO Films using an Electronic Double Layer Transistor , XIANG LENG, ALLEN GOLDMAN, University of Minnesota — We have modified the transport properties of ultrathin films of YBCO using an electronic double layer transistor configuration employing the ionic liquid DEME-TFSI [1]. The films were prepared on STO substrates using high pressure oxygen sputtering. The electronic double layer configuration permits extraordinarily large transfers either involving the accumulation or depletion of carriers, employing relatively low gate voltages. Thus far the transition temperature of a 10 unit cell thick film has been shifted by as much as 30K, and the insulating state has been induced in a 7 unit cell thick film. The latest results will be reported on the use of this technique as an alternative to chemical doping. This work was supported by the National Science Foundation under grant NSF/DMR-0709584.

12:39PM Q25.00008 Phase-fluctuating superconductivity in overdoped $La_{2-x}Sr_xCuO_4$, P.M.C. ROURKE, I. MOUZOPOULOU, University of Bristol, X. XU, C. PANAGOPOULOS, Nanyang Technological University, Y. WANG, Peking University, B. VIGNOLLE, C. PROUST, LNCMI Toulouse, E.V. KURGANOVA, U. ZEITLER, HFML Nijmegen, Y. TANABE, T. ADACHI, Y. KOIKE, Tohoku University, N.E. HUSSEY, University of Bristol — In underdoped cuprates, an energy gap (pseudogap), appears in the electronic density of states well before superconductivity develops. Similarities between the pseudogap and superconducting gap have led to the idea that the pseudogap is a precursor superconducting state in which the superconducting order parameter is finite but the phase fluctuates. However, this picture of precursor pairing has been challenged by measurements indicating that the pseudogap itself closes at a critical doping concentration just beyond optimal doping. By tracking the restoration of the normal state magnetoresistance in overdoped $La_{2-x}Sr_xCuO_4$, we show that the phase fluctuation regime remains broad across the entire superconducting composition range, in contrast to the evolution of the pseudogap. The universal low phase stiffness is shown to be correlated with a low superfluid density, a characteristic of both underdoped and overdoped cuprates. The formation of the pseudogap, by inference, is therefore both independent of and distinct from superconductivity.

12:51PM Q25.00009 Voltage Oscillations in Silver Doped $YBa_2Cu_3O_{7-x}$, ATILGAN ALTINKOK, MURAT OLUTAS, KIVILCIM KILIC, ATILLA KILIC, Abant Izzet Baysal University — Nonlinear transport phenomena and time effects were investigated by the time evolution of sample voltage ($V - t$ curves) on long time scales in Ag-doped $YBa_2Cu_3O_{7-x}$ sample (YBCO/Ag). We also investigated influence of bidirectional square wave current with various periods (P) and dc currents (I) on the evolution of $V - t$ curves in YBCO/Ag sample material at different temperatures (T) and external magnetic (H) fields. It was observed that a non-linear response seen in $V - t$ curves to bidirectional square wave (BSW) current with sufficiently short periods or sufficiently low amplitude reflects itself as regular sinusoidal- type voltage oscillations. The observed oscillating mode was correlated to the dynamic competition between pinning and depinning. Further, the similarity between the flux dynamics and the charge density waves is considered as a possible explanation of voltage oscillations in YBCO/Ag. Detailed analysis of $V - t$ curves and voltage oscillations reveals that adding of Ag causes degradation in both intergranular and surface pinning of YBCO material.

1:03PM Q25.00010 Andreev and Single-Particle Tunneling Spectra of Underdoped Cuprate Superconductors , KUN HUANG, Department of Physics, The University of Hong Kong, Hong Kong, KAI-YU YANG, Institut fuer Theoretische Physik, ETH Zrich, WEI-QIANG CHEN, Department of Physics, The University of Hong Kong, Hong Kong, T.M. RICE, Institut fr Theoretische Physik, ETH Zrich, FU-CHUN ZHANG, Department of Physics, The University of Hong Kong, Hong Kong — We study tunneling spectroscopy between a normal metal and an underdoped cuprate superconductor modeled by a phenomenological theory in which the pseudogap is a precursor to the undoped Mott insulator. In the low barrier tunneling limit, the spectra are enhanced by Andreev reflection only within a voltage region of the small superconducting energy gap. In the high barrier tunneling limit, the spectra show a large energy pseudogap associated with single particle tunneling. Our theory semi- quantitatively describes the two gap behavior observed in tunneling experiments.

1:15PM Q25.00011 Doping evolution of nodal quasiparticles in the cuprate superconductor YBCO via low-temperature thermal conductivity , SAMUEL RENE DE COTRET, J.-PH. REID, N. DOIRON-LEYRAUD, L. TAILLEFER, University of Sherbrooke, Sherbrooke, Canada, B.J. RAMSHAW, R. LIANG, D.A. BONN, W.N. HARDY, University of British Columbia, Vancouver, Canada — The thermal conductivity of the cuprate superconductor $YBa_2Cu_3O_y$ was measured at temperatures down to $T \sim 50$ mK in magnetic fields up to $H = 15$ T on high-quality single crystals with a hole doping ranging from $p = 0.08$ to $p = 0.18$. The residual linear term at $T \to 0$, a direct measure of the nodal quasiparticle velocities [1], is tracked as a function of doping, and compared to recent, high-resolution ARPES measurements of the Fermi velocity and gap magnitude as a function of doping, in the related cuprate superconductor $Bi_2Sr_2CaCu_2O_{8+\delta}$ [2].

1:27PM Q25.00012 Correlation Strength, Optical Conductivity and d-d excitons in high T_c cuprates[1] , ANDREW MILLIS, Columbia University, XIN WANG, University of Maryland, LUCA DEMEDICI, CNRS-Universite de Paris Sud — A single site dynamical mean field analysis is presented of models of high T_c copper-oxide superconductors, including oxygen orbitals and both $x^2 - y^2$ and $3z^2 - r^2$ Cu d-orbitals. The optical conductivity, doping dependent effective mass and the e_g portion of the d-d exciton spectrum are determined. The details of the oxygen-oxygen hopping are shown to be unimportant. A general connection between d valence and the metal/charge transfer insulator phase boundary is outlined.

1:39PM Q25.00013 Determining Transport Parameters for Superconductor/Normal Metal Point Contacts in an Applied Magnetic Field from Conductance versus Field Data at Fixed Temperature , PAUL J. DOLAN, JR., Northeastern Illinois University, CHARLES W. SMITH, University of Maine — Superconductor/normal metal point contact transport data often consists of normalized conductance as a function of reduced temperature, from which the elastic scattering parameter and the inelastic scattering parameter for the contact can be determined, in addition to other features of interest. We show a strategy for determining these parameters from normalized conductance as a function of reduced applied magnetic field, at fixed temperature, even when conductance versus variable temperature data is absent. This analysis strategy will be demonstrated for several point contacts, over a wide range of parameter values.

Wednesday, March 23, 2011 11:15AM - 2:15PM –

Session Q26 DMP DCOMP: Focus Session: Iron Based Superconductors – Optics, Heat Capacity, Thermopower D162/164

11:15AM Q26.00001 Optical Investigation of the Charge Dynamics in $Ba(Co_xFe_{1-x})_2As_2$[1] , L. DEGIORGI, ETH-Zurich — We report on a thorough optical investigation over a broad spectral range and as a function of temperature of the charge dynamics in $Ba(Co_xFe_{1-x})_2As_2$ compounds for Co-doping ranging between 0 and 18%. For the parent compound as well as for x=0.025 we observe the opening of a pseudogap, due to the spin-density-wave phase transition and inducing a reshuffling of spectral weight from low to high frequencies. For compounds with $0.051 \leq x \leq 0.11$ we detect the superconducting gap, while at x=0.18 the material stays metallic at all temperatures. We describe the effective metallic contribution to the optical conductivity with two Drude terms, representing the coherent components, and extract the respective scattering rates. Finally through spectral weight arguments, we give clear-cut evidence for moderate electronic correlations for $0 \leq x \leq 0.061$, which then crossover to values appropriate for a regime of weak interacting and nearly-free electron metals for $x \geq 0.11$. We also investigate the optical conductivity with light polarized along the in-plane orthorhombic a- and b-axes of $Ba(Co_xFe_{1-x})_2As_2$ for x=0 and 2.5% under uniaxial pressure across their structural and magnetic transitions. The charge dynamics at low frequencies and temperatures on these detwinned, single domain samples reveals an enhancement of both the scattering rate and Drude weight of the charge carriers along the antiferromagnetic a-axis with respect to the ferromagnetic b-axis. Our findings also allow us to estimate the dichroism, which extends to high frequencies. These results demonstrate the electronic nature of the structural transition found in underdoped Fe-pnictides. Co-authors: A. Dusza, A. Lucarelli, F. Pfuner, J.-H. Chu, I.R. Fischer.

11:51AM Q26.00002 In-plane and c-axis optical spectroscopy study on 122 Fe-pnictides , NAN LIN WANG, Institute of Physics, Chinese Academy of Sciences — I present the in-plane and the c-axis optical spectroscopy investigations on 122 Fe-pnictides. For the parent compound $BaFe_2As_2$, the in-plane measurement revealed two different energy gaps in the SDW state, whereas for the c-axis polarized measurement only the energy gap at smaller energy scale could be clearly observed. We suggest different driving mechanisms for the formation of the two energy gaps. The large energy gap is caused by the nesting between disconnected 2D cylinder-like electron and hole Fermi surfaces. It is the main driving force for the SDW instability. The small energy gap is the one formed on the 3D Fermi surface due to the presence of reduced magnetic Brillouin zone which crosses the 3D Fermi surface. It is the consequence of the establishment of the magnetic order. For the doped superconducting 122 samples, the in-plane optical measurement revealed a formation of full superconducting energy gap, whereas the c-axis optical measurement indicated a large residual quasiparticle population down to very low temperature. Those quasiparticles contribute specifically to the c-axis transport. We suggest that there exist horizontal nodes in the superconducting gap in regions of the 3D Fermi surface that contribute dominantly to the c-axis optical conductivity. Work done with Z. G. Chen, W. Z. Hu, B. Cheng, G. Li, J. Dong, T. Dong, R. H. Yuan, P. Zheng, G. F. Chen, J. L. Luo, Z. Fang, X. Dai, C. L. Zhang and P. Dai.

12:03PM Q26.00003 Optical signature of sub-gap absorption in the superconducting state of $Ba(Fe_{1-x}Co_x)_2As_2$[1] , URMAS NAGEL, T. RÕÕM, Nat.-l Inst. of Chem. Phys. & Biophys., Tallinn, Estonia, R.P.S.M. LOBO, Y.M. DAI, LPEM, CNRS, UPMC, ESPCI-ParisTech, Paris, France, J. CARBOTTE, T. TIMUSK, McMaster Univ., Hamilton, Canada, D. COLSON, CEA, IRAMIS, SPEC, Gif sur Yvette, France — The optical conductivity of $Ba(Fe_{0.92}Co_{0.08})_2As_2$ shows a clear signature of the superconducting gap, but a simple s-wave description fails in accounting for the low frequency response. This task is achieved by introducing an extra Drude peak in the superconducting state representing sub-gap absorption, other than thermally broken pairs. This extra peak and the coexisting s-wave response respect the total sum rule indicating a common origin for the carriers. We discuss the possible origins for this absorption as (i) quasiparticles due to pair-breaking from interband impurity scattering in a two band $s_\pm$ gap symmetry model, which includes (ii) the possible existence of impurity levels within an isotropic gap model; or (iii) an indication that one of the bands in is highly anisotropic. The results are published in Phys. Rev B vol 82, 100506(R) (2010).

12:15PM Q26.00004 Femtosecond low-energy dynamics of superconducting and spin-density wave gaps in pnictides , K.W. KIM, A. PASHKIN, M. BEYER, H. SCHÄFER, M. PORER, T. WOLF, C. BERNHARD, J. DEMSAR, R. HUBER, A. LEITENSTORFER — Magnetism and superconductivity (SC) in pnictides as well as a possible link between them are subjects of intense studies. The infrared spectral regime plays a pivotal role en route to a microscopic understanding since it provides direct access to the fundamental low-energy excitations, such as spin-density waves (SDW) and SC-induced energy gaps. We investigate Ba(Fe,Co)2As2 by combining ellipsometry and ultrabroadband terahertz (THz) pump-probe experiments. Following a femtosecond near-infrared excitation, the spectral hallmark of SDW located in the 10 - 30 THz window disappears with a characteristic saturation fluence of $\Phi_s \approx 50$ J/cm^2 and recovers fast ($\tau < 1$ ps), while the SC gaps below 3 THz are fully closed at a much smaller fluence $\Phi_s \approx 3$ J/cm^2 and exhibit a slower relaxation behavior ($\tau > 10$ ps). The distinct spectral, temporal and saturation behavior provide a unique environment to monitor the interplay of the two order parameters. Furthermore we observe coherent oscillation at 5.5 THz which corresponds to an Arsenic vibration. Our results may add new aspects toward an understanding of interactions between fundamental excitations in pnictides.

12:27PM Q26.00005 Optical properties of $BaFe_{1.85}Co_{0.15}As_2$[1] , J.J. TU, Dept. of Physics, CCNY/CUNY, New York, L.J. LI, G.H. CAO, Z.A. XU, Dept. of Physics, Zhejiang University, Hangzhou 310027, China, C.C. HOMES, Condensed Matter Physics and Materials Science Dept., Brookhaven National Laboratory, Upton, New York — The detailed in-plane optical properties of the electron-doped iron-arsenic superconductor $BaFe_{1.85}Co_{0.15}As_2$ have been determined over a wide frequency range above and below $T_c = 25$ K. Despite being a multiband system, the normal state reveals that a single (electron) band dominates the low-frequency conductivity, which can be modeled by a single Drude component with plasma frequency $\omega_{p,D} \simeq 7840$ cm^{-1} and scattering rate $1/\tau_D \simeq 126$ cm^{-1}, determined just above T_c. For $T \ll T_c$ the superconducting plasma frequency is $\omega_{p,S} \simeq 5200$ cm^{-1} ($\lambda_{eff} \simeq 3000$ Å), indicating that less than half the free carriers in the normal state have collapsed into the condensate, suggesting that this material is not in the clean limit. There are two energy scales for the superconductivity, $\Delta_1(0) = 3.1 \pm 0.2$ meV and $\Delta_2(0) = 7.4 \pm 0.3$ meV. This corresponds to either the gapping of the electron and hole pockets, respectively, or an anisitropic *s*-wave gap on the electron pocket; both views are consistent with the $s^\pm$ model.[2]

12:39PM Q26.00006 Raman investigation of the magneto-structural transition in electron doped $Ba(FeAs)_2$[1] , YANN GALLAIS, LUDIVINE CHAUVIERE, MAXIMILIEN CAZAYOUS, MARIE-AUDE MEASSON, ALAIN SACUTO, Universite Paris Diderot, DOROTHEE COLSON, ANNE FORGET, SPEC CEA Saclay — We report a doping dependent Raman scattering study of the magneto-structural transition in Co doped Ba(FeAs)2. Several zone centered phonons display significant anomalies at the tetragonal to orthorhombic transition. In particular, the doubly degenerate in-plane Eg phonon shows an enhanced splitting in the ortho phase. The splitting weakens considerably with doping and gives evidence for strong spin-phonon coupling in iron-pnictides. The electronic Raman continuum displays a systematic upturn at low energy around the magneto-structural transition. This quasi-elastic scattering is similar to magnetic energy fluctuations usually observed in magnetic insulators. Interestingly significant fluctuations are observed at low temperature even for x=0.065 doping, where the Neel temperature goes to zero and optimal Tc is reached. At high energy and low doping, the electronic Raman continuum displays clear signatures Fermi surface reconstruction due to the opening of the spin density wave gap at the magnetic transition.

[1]Work funded by Agence Nationale de la Recherche (ANR).

12:51PM Q26.00007 Effect of annealing on the gap structure of $Ba(Fe_{1-x}Co_x)_2As_2$: low temperature specific heat studies , K. GOFRYK, F. RONNING, E.D. BAUER, J.D. THOMPSON, Los Alamos National Laboratory, A.B. VORONTSOV, Montana State University, I. VEKHTER, Louisiana State University, A.S. SEFAT, Oak Ridge National Laboratory, T. IMAI, McMaster University — We report on the effect of annealing on the temperature and field dependencies of the low temperature specific heat of the electron-doped $Ba(Fe_{1-x}Co_x)_2As_2$ for under- (x = 0.045), optimal- (x = 0.08) and over-doped (x = 0.105 and 0.14) regimes. We observed that annealing significantly improves some superconducting characteristics in $Ba(Fe_{1-x}Co_x)_2As_2$. It considerably increases T_c, decreases γ_0 in the superconducting state and suppresses the Schottky-like contribution at very low temperatures. The improved sample quality allows for a better identification of the superconducting gap structure of these materials. We examine the effects of doping and annealing within a self-consistent framework for an extended s-wave pairing scenario. At optimal doping our data indicates the sample is fully gapped, while for both under- and over-doped samples significant low-energy excitations remain, possibly consistent with a nodal structure. The difference of sample quality offers a natural explanation for the variation in low temperature power laws observed by many techniques.

1:03PM Q26.00008 The low-temperature specific heat of Co-doped $BaFe_2As_2$, JIUNN-YUAN LIN, Institute of Physics, National Chiao Tung University, Hsinchu 30010, Taiwan — We have measured the low-temperature specific heat of $Ba(Fe_{1-x}Co_x)_2As_2$ (x=0,0.08,0.2) single crystals. The electronic specific heat of $Ba(Fe_{0.92}Co_{0.08})_2As_2$ in the superconductiong state with T_c=21 K is revealed. A T^2 term was observed at low temperatures, providing the evidence of nodes in the gap. Furthermore, the data suggest a multi-gap feature for $Ba(Fe_{0.92}Co_{0.08})_2As_2$. The mixed state data will also be reported.

1:15PM Q26.00009 The Electronic Specific Heat of $Ba_{1-x}K_xFe_2As_2$ from 2K to 380K[1] , JAMES STOREY, JOHN LORAM, JOHN COOPER, University of Cambridge, ZBIGNIEW BUKOWSKI, JANUSZ KARPINSKI, ETH Zurich — Using a unique differential technique, we have measured the specific heat capacity of polycrystalline $Ba_{1-x}K_xFe_2As_2$ with x = 0, 0.1, 0.2, 0.3, 0.5 0.9 and 1.0, between 2K and 380K and in magnetic fields (H) from 0 – 13T. We determine the electronic specific heat coefficient γ ($\equiv C_{el}/T$) over the entire range of T, H and x and compare it with the magnetic susceptibility of the seven samples. We show that our results are consistent with single crystal studies but give further interesting information. For $x < 0.3$, γ is progressively reduced at low T by a SDW gap, but is only weakly doping and T-dependent above the structural/magnetic transition. For $x = 0.3$ the normal state γ_n is constant up to 380K, but as x increases from 0.3 to 1.0, γ_n becomes increasingly T-dependent, increasing by a factor two at low-T and decreasing by a factor 1.5 at 380K for $x = 1$. We consider possible explanations for this striking T-dependence in terms of a sharp peak in the electronic density of states, a strongly x- and T-dependent effective mass enhancement, or low energy magnetic excitations. The H-dependent measurements allow us to extract the critical fields, superfluid density and coherence length as functions of doping and temperature.

1:27PM Q26.00010 Specific Heat to 35 T in P-doped and Co-doped $BaFe_2As_2$: Evidence for Nodes or Not?[1] , G.R. STEWART, J.S. KIM, P.J. HIRSCHFELD, Physics, University of Florida, F. RONNING, K. GOFRYK, MPA-10, Los Alamos National Laboratory, A.S. SEFAT, MST Division, Oak Ridge National Laboratory, S. KASAHARA, T. SHIBAUCHI, T. TERASHIMA, Y. MATSUDA, Physics, Kyoto University — We have measured the low temperature specific heat of annealed single crystal $Ba(Fe_{0.955}Co_{0.045})_2As_2$, unannealed single crystal $BaFe_2(As_{0.7}P_{0.3})_2$, and other $BaFe_2As_2$ derivatives in fields to 35 T. We report contrasting behavior, with the underdoped Co sample exhibiting behavior (specific heat $\gamma \sim H^{0.7}$) essentially up to H_{c2} similar to the Volovik effect prediction ($\gamma \sim H^{**}0.5$) for nodal behavior for fields $H < 0.1H_{c2}$. In contrast, γ up to 35 T (2/3 of H_{c2}) in $BaFe_2(As_{0.7}P_{0.3})_2$ exhibits linear with field dependence, consistent with fully gapped behavior but inconsistent with indications of nodal behavior from other measurements. Possible explanations, and up-to-date measurements will be presented.

1:39PM Q26.00011 Thermoelectric power of $Ba(Fe_{1-x}Ru_x)_2As_2$ and $Ba(Fe_{1-x}Co_x)_2As_2$: possible changes in Fermi surface with and without changes in electorn count[1] , HALYNA HODOVANETS, EUNDEOK MUN, ALEX N. THALER, SERGEY L. BUD'KO, PAUL C. CANFIELD, Ames Laboratoty/ Iowa State University, Ames, IA 50011, USA — Temperature-dependent, in-plane, thermoelectric power (TEP) data are presented for $Ba(Fe_{1-x}Ru_x)_2As_2$ ($0 \leq x \leq 0.36$) single crystals. The previously outlined by resistivity and susceptibility $x - T$ phase diagram for this system is confirmed. The analysis of TEP evolution with Ru-doping suggests two concentrations, $x \sim 7\%$ and $x \sim 30\%$ of Ru-doping levels, near which significant changes in the electronic structure, correlations and/or scattering occur. These results are compared with an extended set of TEP data for the electron doped $Ba(Fe_{1-x}Co_x)_2As_2$ ($0.13 \leq x \leq 0.42$) single crystals. An analysis of TEP data for Co-doping in the overdoped region suggests two more concentrations, $x \sim 11\%$ and $x \sim 22\%$, in addition to x$\sim$ 2% previously reported, where Lifshitz transition might occur. These data for Co-doping were recently confirmed by ARPES measurements.

[1]Work at the Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

1:51PM Q26.00012 Nernst and Seebeck coefficients of the iron-pncitide superconductor $Ba_{1-x}K_xFe_2As_2$, XIGANG LUO, H. SHAKERIPOUR, J. CHANG, F. LALIBERTE, J. -PH. REID, N. DOIRON-LEYRAUD, L. TAILLEFER, Universite de Sherbrooke, M.A. TANATAR, R. PROZOROV, Ames Laboratory, H.Q. LUO, Z.S. WANG, H.-H. WEN, Institute of Physics, Beijing — The Nernst and Seebeck coefficients of the iron-pnictide superconductor $Ba_{1-x}K_xFe_2As_2$ were measured in single crystals for K concentrations ranging from the parent compound at x=0 to the optimally-doped superconductor at x=0.40, where Tc=38 K. Both coefficients show sharp anomalies at T_N, the onset temperature for antiferromagnetic order. This allows us to track the doping dependence of T_N and hence to map out the T-x phase diagram of $Ba_{1-x}K_xFe_2As_2$. The reconstruction of the Fermi surface by the antiferromagnetic order causes a huge enhancement of the quasiparticle Nernst signal, suggesting that carrier density and Fermi temperature are dramatically reduced in the magnetic phase. The Nernst signal due to superconducting fluctuations is small by comparison, and it remains detectable up to a temperature approximately 15% above T_c, in the optimally-doped sample.

2:03PM Q26.00013 Coherence peak and pair-breaking effects in the ac conductivity of $BaFe_{2-2x}Co_{2x}As_2$ epitaxial thin films , N.P. ARMITAGE, ROLANDO VALDÉS AGUILAR, L.S. BILBRO, The Johns Hopkins University, S. LEE, C.W. BARK, C.B. EOM, University of Wisconsin, THE JOHNS HOPKINS UNIVERSITY TEAM, UNIVERSITY OF WISCONSIN TEAM — We report a study of high quality pnictide superconductor $BaFe_{1.84}Co_{0.16}As_2$ epitaxial thin films using time-domain THz spectroscopy. Near T_c we find evidence for a coherence peak and qualitative agreement with the weak-coupling Mattis-Bardeen form of the conductivity. At low temperature, we find that the real part of the THz conductivity is not fully suppressed and σ_2 is significantly smaller than the Matthis-Bardeen expectation. The temperature dependence of the penetration depth λ follows a power law with an unusually high exponent of 3.1. We interpret these results as consistent with impurity scattering induced pair-breaking. Taken together our results are strong support for an extended s$\pm$ symmetry order parameter.

Session Q27 GQI: Focus Session: Semiconductor Qubits- Quantum Control C155

11:15AM Q27.00001 Control and Manipulation of Two-Electron Spin Qubits in GaAs Quantum Dots[1] , AMIR YACOBY, Harvard University — We have developed means to both couple and decouple a two electron spin qubit from its environment. Using dynamic nuclear polarization we are able to suppress fluctuations in the nuclear environment and prolong T2* by nearly an order of magnitude reaching 150 nano seconds. Our polarization scheme employs a quantum feedback mechanism that directly conditions the rate at which the qubit polarizes its nuclear environment on a quantum limited measurement of the hyperfine field seen by the same qubit. In addition, the stabilized state of the nuclear environment allows us to perform controlled X rotations and thereby demonstrate full control over the entire Bloch sphere as well as full quantum state tomography. Using dynamic decoupling of the two electron spin qubit from its environment we are able to prolong T2 by nearly three orders of magnitude reaching nearly 300 micro seconds. Our results indicate that gate fidelities of up to 99.99% are within reach despite the fluctuating nuclear environment. Moreover, the demonstrated ultra long coherence time allows for more than 10^5 coherent gate operations which exceed the estimated threshold for quantum error corrections by a substantial margin.

11:51AM Q27.00002 Quantum gates for the singlet-triplet T_+ qubit , HUGO RIBEIRO, University of Konstanz, J.R. PETTA, Princeton University, GUIDO BURKARD, University of Konstanz — We theoretically show that hyperfine interactions can be harnessed for quantum gate operations in GaAs semiconductor quantum dots [1]. In the presence of an external magnetic field B, which splits the triplet states, the hyperfine interaction results in an avoided crossing between the spin singlet S and spin triplet T_+, which form the basis of a new type of spin qubit. Coherent quantum control for this qubit is achieved through Landau-Zener-Stückelberg transitions at the S-T_+ avoided crossing [2]. A set of suitable transitions allows to build any single qubit gates on timescales shorter than the decoherence time $T_2^* \sim 16\mathrm{ns}$ [1]. We also show how to build a conditional two-qubit gate by capacitively coupling two S-T_+ qubits.

12:03PM Q27.00003 Coherent spin manipulation with a triple quantum dot , GHISLAIN GRANGER, Institute for Microstructural Sciences, National Research Council Canada, LOUIS GAUDREAU, National Research Council Canada and University of Sherbrooke, ALICIA KAM, SERGEI STUDENIKIN, PIOTR ZAWADZKI, GEOF AERS, Institute for Microstructural Sciences, National Research Council Canada, MICHEL PIORO-LADRIÈRE, University of Sherbrooke, ZBIGNIEW WASILEWSKI, ANDREW SACHRAJDA, Institute for Microstructural Sciences, National Research Council Canada — Recently, Landau-Zener-Stuckelberg (LZS) oscillations have been demonstrated in a double quantum dot device [1]. In this talk we demonstrate LZS oscillations in a triple quantum dot environment. Our triple quantum dot design allows us to tune to either the charge or spin qubit regimes. Using a pulsing technique in the spin qubit regime, we create a superposition of triple quantum dot states, allow for phase accumulation, and interfere. We demonstrate coherent LZS oscillations with three spins across the triple quantum dot structure. We investigate their dependence on pulse rise time, separation time, energy detuning, and magnetic field.

[1] J. R. Petta et al., Science 327, 669 (2010).

12:15PM Q27.00004 Novel Coherent Spin Oscillations in a Triple Quantum Dot Circuit , ANDREW SACHRAJDA, GHISLAIN GRANGER, LOUIS GAUDREAU, ALICIA KAM, SERGEI STUDENIKIN, PIOTR ZAWADZKI, GEOF AERS, National Research Council of Canada, MICHEL PIORO-LADRIERE, Sherbrooke University, ZBIG WASILEWSKI, National Research Council of Canada — We have demonstrated Landau-Zener-Stuckelberg oscillations in a triple quantum dot circuit related to pairs of triple quantum dot states. Different initialization schemes and pulse shapes involving all three dots will be discussed. However, the complexity of a triple quantum dot system suggests that in general coherent behaviour can be expected from interplays between various combinations of states. Here we demonstrate both experimentally and theoretically in a triple quantum circuit containing three spins, a coherent interplay between two coexisting qubits as a function of pulse amplitude and rise time. To further clarify the behaviour within the system we also observe and study coherent oscillations after a fourth spin has been added to the system in one of the relevant dots.

12:27PM Q27.00005 A Single Electron Charge Qubit in the Strong Driving Limit[1] , J. STEHLIK, Y. DOVZHENKO, J. R. PETTA, Department of Physics, Princeton University, H. LU, A. C. GOSSARD, Materials Department, University of California at Santa Barbara — The dynamics of strongly driven two-level systems in the presence of dissipation have been thoroughly studied using theoretical models.[1] We use a model system, a GaAs double quantum dot (DQD) containing a single electron, to experimentally explore the strong-driving regime. We measured the transport through the DQD as a function of detuning and applied microwave power and compare with the Tien-Gordon model. In contrast with previous experiments, we directly access the occupation of the DQD using a quantum point contact charge sensor. In the high frequency regime ($\hbar\omega_{driving} \gg \Delta$, where Δ is the tunnel coupling) we observe up to 9-photon transitions and clear Bessel function behavior of the DQD occupation with applied microwave power. We also studied the intermediate frequency regime, observing 18-photon transitions. The data are modeled using the time-dependent Schrodinger equation.[2] By comparing the data with the simulations, we estimate $T_1 \sim 15$ ns and $T_2 \sim 3$ ns.

12:39PM Q27.00006 Non-adiabatic Quantum Control of a Semiconductor Charge Qubit[1] , YULIYA DOVZHENKO, JIRI STEHLIK, KARL PETERSSON, JASON PETTA, Princeton University, HONG LU, ARTHUR GOSSARD, University of California, Santa Barbara — A GaAs double quantum dot is configured in the single-electron regime and operated as a charge qubit. The two basis states correspond to the electron being in either the left or the right dot. Non-adiabatic voltage pulses are applied to the depletion gates to drive coherent rotations, and the double dot occupation is read out using a nearby quantum point contact charge sensor. In contrast with previous work, where a single non-adiabatic pulse was applied for quantum control, we apply multiple pulses working towards a charge echo.[1,2] Data for $\frac{\pi}{2}$ - τ - $\frac{\pi}{2}$ and the $\frac{\pi}{2}$ - τ_1 - π - τ_2 - $\frac{\pi}{2}$ "charge echo" pulse sequences are obtained and compared with numerical simulations of the charge qubit evolution. 12:51PM Q27.00007 Extended coherence of exchange operations in double quantum dot spin qubits using Hahn echo , MICHAEL SHULMAN, HENDRIK BLUHM, OLIVER DIAL, Harvard University, VLADIMIR UMANSKY, Weizmann Institute of Science, AMIR YACOBY, Harvard University — Semiconductor spin qubits are promising candidates for quantum computation because of their long coherence times and potential for scalability. The exchange interaction is a powerful resource in these qubits, as it can drive single qubit rotations and inter-qubit entanglement. However, spin qubits driven by exchange become sensitive to charge noise, which in free induction decay experiments has lead to dephasing after a few coherent exchange oscillations. We perform a Hahn echo measurement in two-electron spin qubits in GaAs quantum dots. The π-pulse is applied by means of a stabilized nuclear gradient in the quantum dots. We find an exponential dephasing with a time constant of up to 10μs, which is more than an order of magnitude larger than T_2^*, and corresponds to 500 coherent exchange operations within T_2. This increase in T_2 is expected to allow for several cPHASE operations between two charge coupled two-electron qubits within T_2.

1:03PM Q27.00008 Two-qubit operations of two-electron spin qubits in GaAs quantum dots , HENDRIK BLUHM, MICHAEL SHULMAN, OLIVER E. DIAL, Harvard University, VLADIMIR UMANSKY, Weizmann Institute, AMIR YACOBY, Harvard University — The realization of two-qubit entangling gates is one of the most important milestones for the development of quantum-dot based electron spin qubits. Our measurements and simulations of the coupling strength and the relevant coherence time indicate very favorable prospects for the realization of such gates using the Coulomb interaction between adjacent spin qubits. This operation can be protected against dephasing due to low frequency electric noise by simultaneously applying a π-pulse to both qubits, which is essential to achieve the required coherence time. We report the experimental realization of this echo operation in a two-qubit device, conditional evolution of one qubit depending on the charge state of the neighboring double dot, and further progress toward two-qubit entanglement.

1:15PM Q27.00009 Spin Manipulation in InAs Nanowire Double Quantum Dots[1] , M.D. SCHROER, M. JUNG, K.D. PETERSSON, C.M. QUINTANA, J.R. PETTA, Princeton University — Recently, much effort has been devoted to the development of physical qubits for integration into quantum computers. Qubits allowing control with electric fields are attractive, as ac magnetic fields are more difficult to generate and localize on the nanoscale. The material properties of InAs allow efficient driving of electron spin resonance via the spin–orbit interaction. Our work has focused on developing quantum dots in InAs nanowires as fully characterized and controllable qubits. We have optimized our nanowire growth to eliminate the presence of planar defects, which impede the predictable formation of quantum dots. Using a bottom–gated architecture [1], we demonstrate tunable InAs nanowire double quantum dots, with the occupation controllable to the last electron. Pauli blockade is observed in the two-electron regime, demonstrating spin-dependent transport. We are able to drive single spin rotations by applying microwaves to one of the local metallic gates; from the electron spin resonance condition we extract a g–factor of ∼9. Finally, we demonstrate full electrical control of the two-electron system and characterize gate fidelities.

1:27PM Q27.00010 On-demand single-electron transfer between distant quantum dots with nanosecond pulses of surface acoustic waves , R.P.G. MCNEIL, M. KATAOKA[1], C.J.B. FORD, C.H.W. BARNES, J.P. GRIFFITHS, G.A.C. JONES, I. FARRER, D.A. RITCHIE, University of Cambridge — Quantum dots (QDs) provide a useful system for manipulating and storing quantum information. Methods for moving quantum information (spin) between processor and storage, or to a region of holes for conversion to photon qubits, will be required. Tunnelling of electrons over long distances between QDs is not viable. We show controlled long-range transfer of single electrons between QDs through a depleted 1D channel using pulses of surface acoustic waves (SAWs). In our device, two QDs are connected by a 4μm channel with QD occupancy monitored by 1D charge detectors. Electrons may be trapped and raised above the Fermi energy by stepping gate voltages. Having set the first QD to be 'full' and the other QD 'empty', a short SAW pulse is sent to transfer the electron to the opposite QD. This bi-directional process may be repeated over 100 times with the same electron. SAW power and pulse-width dependences suggest that transfer is achieved during the first few SAW cycles allowing sub-20ns pulses to be used.

[1]now at NPL Teddington

1:39PM Q27.00011 A proposed all-electrical spin qubit CNOT gate robust against charge noise[1] , SANKAR DAS SARMA, JASON KESTNER, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, MD — We shall propose an alternative to the Loss-DiVincenzo implementation of the CNOT gate in a quantum dot spin qubit system. Our all-electrical proposal has the advantage of being robust against uncertainties and fluctuations in the tunnel coupling, barrier gate voltage pulse area, and interwell detuning which typically arise due to charge noise. The core idea is to introduce an auxiliary dot and use an analog to the stimulated Raman adiabatic passage (STIRAP) pulse sequence in three-level atomic systems, often referred to in the context of electron transport in quantum dot systems as CTAP (Coherent Tunneling by Adiabatic Passage). Spin-dependent tunneling opens the possibility of performing entangling two-qubit gates by this method.

1:51PM Q27.00012 Sensitivity to electronics error in coupled double quantum dot qubits , ERIK NIELSEN, RICHARD MULLER, MALCOLM CARROLL, Sandia National Laboratories — Reducing the effects of electronics control error in double quantum dot (DQD) quantum bits (qubit) is a central challenge to the creation of a solid-state quantum computing architecture. We investigate a system of capacitively coupled DQDs which implement a variant of the controlled phase gate when using each DQD as a singlet-triplet qubit. We identify regimes in which the gate action is more robust to sources of noise such as error around the applied bias point due to electronics or charge noise. Energy spectra are found using a configuration interaction (CI) method that accurately captures the (2,0) configuration of the DQD system, which is important for operating in these potentially low-noise regimes. This work was supported by the Laboratory Directed Research and Development program at Sandia National Laboratories. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin company, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

2:03PM Q27.00013 Gate Capacitance Reproducibility and Modeling in Silicon Double Quantum Dots , TED THORBECK, JQI: NIST & U. of Maryland, AKIRA FUJIWARA, NEIL ZIMMERMAN, NTT — For many applications the ability to design quantum dots with a specific set of gate capacitances and then rely on the reproducibility of those capacitances is crucial. For quantum computing, the ability to design our gate capacitances would help in reaching the few electron regime and in coupling multiple devices. For other applications the ability to design our gate capacitances would enable higher temperature operation. Our double quantum dots are formed by electrostatic gates on a silicon nanowire. We have measured 20 similar devices with 8 different sets of lithographic parameters. We will report on the reproducibility of the gate capacitances. For example, the range of capacitances is typically within 10% of the average. We will also compare our measured capacitances to simulations based on lithographic parameter. This simulation could then be used to design new devices.

Wednesday, March 23, 2011 11:15AM - 2:15PM –
Session Q28 DMP: Focus Session: Carbon Nanotubes and Related Materials: Devices II C156

11:15AM Q28.00001 Carbon nanotube based NEMS actuators and sensors , MICHAEL FORNEY, UNC Charlotte, JORDAN POLER — Single-walled carbon nanotubes (SWNTs) have been widely studied due to superior mechanical and electrical properties. We have grown vertically aligned SWNTs (VA-SWNTs) onto microcantilever (MC) arrays, which provides an architecture for novel actuators and sensors. Raman spectroscopy confirms that the CVD-grown nanotubes are SWNTs and SEM confirms aligned growth. As an actuator, this hybrid MC/VA-SWNT system can be electrostatically modulated. SWNTs are excellent electron acceptors, so we can charge up the VA-SWNT array by applying a voltage. The electrostatic repulsion among the charged SWNTs provides a surface stress that induces MC deflection. Simulation results show that a few electrons per SWNT are needed for measureable deflections, and experimental actuators are being characterized by SEM, Raman, and an AFM optical lever system. The applied voltage is sinusoidally modulated, and deflection is measured with a lock-in amplifier. These actuators could be used for nano-manipulation, release of drugs from a capsule, or nano-valves. As a sensor, this MC/VA-SWNT system offers an improved sensitivity for chemical and bio-sensing compared to surface functionalized MC-based sensors. Those sensors only have a 2D sensing surface, but a MC/VA-SWNT system has significantly more sensing surface because the VA-SWNTs extend microns off the MC surface.

11:27AM Q28.00002 High yield assembly and electron transport investigation of semiconducting-rich local-gated single-walled carbon nanotube field effect transistors , KRISTY KORMONDY, PAUL STOKES, SAIFUL KHONDAKER, Nanoscience Technology Center and Department of Physics, University of Central Florida, Orlando, Florida, 32826 — Single-walled carbon nanotubes (SWNTs) are ideal for use in nanoelectronic devices because of their high current density, mobility and subthreshold slope. Using individual local gates and scaling the gate oxide has shown faster switching behavior and lower power consumption. However, assembly methods must be developed to reproducibly align all-semiconducting SWNTs at specific locations with individually addressable gates for future integrated circuits. We show high yield assembly of local-gated semiconducting SWNTs assembled via AC-dielectrophoresis (DEP). Detailed electron transport investigations on the devices show that 98% display good FET behavior, with an average threshold voltage of 1V and subthreshold swing as low as 120 mV/dec.

11:39AM Q28.00003 Measurement of quantum capacitance in individual semiconducting single-walled[1] , YANFEI YANG, Physics Department, Georgetown University, GEORGY FEDOROV, RRC Kurchatov Institute, Russia, SERHII SHAFRANJUK, Physics and Astronomy Department, Northwestern University, PAOLA BARBARA, Physics Department, Georgetown University, PHYSICS DEPARTMENT, GEORGETOWN UNIVERSITY TEAM, SERHII SHAFRANJUK COLLABORATION, GEORGY FEDOROV COLLABORATION — The capacitance of a carbon nanotube consists of its geometrical capacitance and its quantum capacitance. The latter is determined by the electronic density of states of the nanotube and the electron interactions, therefore it is a tool for probing fundamental electronic properties in carbon nanotubes, as well as an important parameter to design carbon nanotube electronic devices. The quantum capacitance of a carbon nanotube was first measured by using a capacitance bridge at 77K [1]. Here we extract the quantum capacitance of a semiconducting single-walled carbon nanotube in two one-dimensional subbands from electronic transport measurements at 4.2 K. We compare our results to other experiments and predictions from theoretical models.

11:51AM Q28.00004 Electronic transport in intermediate sized carbon nanotubes[1] , MARKUS AHLSKOG, University of Jyvaskyla, Department of Physics, DAVIE MTSUKO, ANTTI JUUTILAINEN, University of Jyvaskyla — We have measured low temperature transport properties of multiwalled carbon nanotubes (MWNT) of different diameters in the range 2-10 nm [1]. In nearly all samples the gate dependent conductance exhibits a gap whose size increases with decreasing tube diameter and increasing electrode separation. This so called transport gap is attributed, based on the experimental findings, on a combination of localization effects and narrow diameter induced gaps in the electronic band structure.

12:03PM Q28.00005 Resistance of individual long suspended carbon nanotubes with known atomic structures , MITSUHIDE TAKEKOSHI, VIKRAM DESHPANDE, YUHEI MIYAUCHI, ZHENGYI ZHANG, CHENGUANG LU, TONY HEINZ, JAMES HONE, PHILIP KIM, Columbia University — We present electrical transport measurement on long individually suspended carbon nanotubes. Single walled carbon nanotubes (SWNTs) are grown by a chemical vapor deposition method across a slit made on silicon oxide/silicon substrate with pre-patterned platinum electrodes. Rayleigh spectroscopy allows us to determine atomic structure indices of individual SWNTs that connect the electrodes across the slit. We investigate the temperature dependent resistance of metallic SWNTs. The relation between electron-phonon interaction in SWNTs in the connection of the atomic structure will be discussed.

12:15PM Q28.00006 Electrical Resistance of Double-Wall Carbon Nanotubes with Determined Chiral Indices , LETIAN LIN, University of North Carolina at Chapel Hill, Curriculum in Applied Sciences and Engineering, TAORAN CUI, LU-CHANG QIN, SEAN WASHBURN, University of North Carolina at Chapel Hill, Department of Physics and Astronomy — The properties of carbon nanotubes (CNT), especially single-wall nanotubes (SWNT) and double-wall nanotubes (DWNT), are profoundly sensitive to the atomic structure described by its chirality. CNTs connected to sub-micron electrodes were suspended for transmission electron microscope (TEM) study. We determined the chiral indices of each individual CNT via its nano beam electron diffraction patterns and measured its electrical resistance by the four-probe method at room temperature. We studied the factor of different combinations of semiconducting/metallic shells on the electrical characterizations of DWNTs. The electrical properties were compared between DWNTs and SWNTs and the result show that the electrical transport of a DWNT is dominated by the chiral indices of outer shell.

12:27PM Q28.00007 Carbon nanotubes for interconnects in integrated circuits , JEAN DIJON, CEA/Liten — Carbon nanotubes are one of the materials that may be used for advanced interconnects beyond the 16nm node thanks to there extreme resistance to electro migration and to bottom up approach which allow to grow them in tiny holes with very high aspect ratio. The resistance of a via with area A and height h filled with CNT is expressed by $R_{via} = \frac{rq+rsh+rc}{Ad_t}$ where rq, rs, rc are respectively the 6.5kΩ quantum resistance, the scattering resistance and the contact resistances of one tube. To be competitive with copper via resistance, a large density d_t of carbon walls have to be paralleled. Following ITRS needs a density of 2 or 3 10^{13}cm^{-2} conducting CNT walls have to be obtained. This optimum wall density requests the growth of highly packed few nanometre diameter CNTs. Such density has been the main bottleneck for the development of CNT interconnects. Recently ultra high density integration scheme have been demonstrated and for the first time wall density close to the requested one have been integrated in devices. Such density comes from the development on conductive substrates of a CNT growth mode normally used to obtain forests of small tube diameter on insulating substrate like alumina. With this mode, CNTs are grown with base growth mode which is the mode requested for SWCNT or DWCNT thus by continuity it will be possible to increase the density still further by increasing the density of catalyst particles. Our bottom metal of choice is AlCu with iron as catalyst. With this system tube contact resistance between 10^4 to 10^6 Ohm have been measured on blanket AlCu substrates. This resistance must be decreased by one or two order of magnitude while increasing further CNT density. In this paper we will present our last integration developments and the role of plasma pre-treatment of the iron aluminium interface in order to decrease the contact resistance. We will show that the bottom profile of via has a major impact on the quality of CNT growing in the holes and discuss future evolutions of this technology.

1:03PM Q28.00008 Wide Contact Structures for Low-noise Nano-channel Devices based on Carbon Nanotube Network , HYUNGWOO LEE, MINBAEK LEE, SEON NAMGUNG, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea, SEUNGHUN HONG, Department of Physics and Astronomy; Department of Biophysics and Chemical Biology, Seoul National University, Seoul 151-747, Korea — We developed a wide-contact structure for low-noise devices based on carbon nanotube (CNT) networks. This wide-contact CNT network-based device has a dumbbell-shaped channel which is comprised of a narrow channel region and wide CNT/electrode contact regions. We showed that the wide-contact structure reduced 1/f noise which originated from CNT/electrode contact regions. We also systematically analyzed the noise characteristics of the structured CNT networks and established an empirical formula that can describe the noise behavior of CNT network-based devices including the effect of contact regions and CNT alignment. Interestingly, our noise analysis revealed that the noise amplitude of aligned CNT networks behaves quite differently compared with that of randomly-oriented CNT networks. These results would be an important guideline in designing low-noise nanoscale devices based on CNT networks for various applications such as a highly sensitive low-noise sensor.

1:15PM Q28.00009 Physics of aligned arrays of single-walled NTs: From transistor to diode applications , SLAVA V. ROTKIN, Department of Physics and Center for Advanced Materials and Nanotechnologies, Lehigh University, JOHN A. ROGERS, Beckman Institute and Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign — NTs have been originally proposed as a 1D high mobility semiconductor material for field-effect transistors (FET). This format is though appeared to be less practical due to low values of the currents through a single NT channel. On contrary, NT massive parallel arrays have already found implementation in flexible and RF electronics. Can we think of NT arrays being another semiconductor thin film materials? Where does the conventional knowledge apply for NT parallel array devices? This talk discusses specialized aspects of physics of electronic and optoelectronic device prototypes and presents recent results for NT FETs and LEDs (light-emitting diode) in parallel array geometries. Cross-talk between individual NTs in the array allows to beat the statistical "noise" in the device properties which appears due to randomized NT distribution in the array. Although, taking this into account, device-level characteristics should be used with a care to extract a single NT physical parameters.

1:27PM Q28.00010 ABSTRACT WITHDRAWN –

1:39PM Q28.00011 Macroelectronic Integrated Circuits Using High-Performance Separated Carbon Nanotube Thin-Film Transistors , CHUAN WANG, JIALU ZHANG, CHONGWU ZHOU, University of Southern California — Macroelectronic integrated circuits are widely used in applications such as flat panel display, transparent electronics, as well as flexible and stretchable electronics. However, the challenge is to find the channel material that can simultaneously offer low temperature processing, high mobility, transparency and flexibility. Here in this paper, we report the application of high-performance separated nanotube thin-film transistors (TFTs) for macroelectronic integrated circuits. We have systematically investigated the performance of TFTs using separated nanotubes with 95% and 98% semiconducting nanotubes, and high mobility transistors have been achieved. In addition, we observed that while 95% semiconducting nanotubes are ideal for applications requiring high mobility (up to 67 $cm^2V^{-1}s^{-1}$) such as analog and radio-frequency applications, 98% semiconducting nanotubes are ideal for applications requiring high on/off ratios ($>10^4$ with channel length down to 4 μm). Furthermore, integrated logic gates such as inverter, NAND and NOR have been designed and demonstrated using 98% semiconducting nanotube devices, and symmetric input/output behaviour is achieved, which is crucial for the cascading of multiple stages of logic blocks and larger scale integration. Our approach can serve as the critical foundation for future nanotube-based thin-film macroelectronics.

1:51PM Q28.00012 Anisotropic electronic transport in highly aligned carbon nanotube films , SEBASTIEN NANOT, XUAN WANG, JUNICHIRO KONO, ECE Dpt, Physics and Astronomy Dpt, Rice University, YANHUA DAI, RUI-RUI DU, Physics and Astronomy Dpt, Rice University, CARY PINT, ROBERT H. HAUGE, Smalley Institute for Nanoscale Science and Technology, Rice University — Electronic transport in carbon nanotube (CNT) networks has recently attracted much renewed interest due to the numerous advancements in controlling, sorting, and aligning CNTs. Understanding the roles of intra-tube and inter-tube transport in these systems is fundamentally important both from basic and applied points of view. We have studied samples of ultra-long and highly-aligned CNTs grown by CVD and laid down on Si/SiO2 substrates. We designed and fabricated a novel device structure in which we can separately study intra-tube and inter-tube transport. In the intra-tube configuration, ends of ultra-long CNTs were contacted and the current parallel to the alignment direction was measured, whereas, in the inter-tube configuration, transport perpendicular to the alignment direction was probed. We studied the magnetic field and temperature dependence of the resistance between 0.3 K and 300 K, revealing an interesting evolution of transport regimes as for the localization of charge carriers. Preliminary results of photoconductivity measurements will also be presented.

2:03PM Q28.00013 Air-Stable Conversion of Separated Carbon Nanotube Thin-Film Transistors from P-type to N-type Using Atomic Layer Deposition of High-κ Oxide and Its Application in CMOS Logic Circuits , JIALU ZHANG, CHUAN WANG, YUE FU, YUCHI CHE, CHONGWU ZHOU, University of Southern California — Pre-separated, high purity semiconducting carbon nanotubes hold great potential for thin-film transistors (TFTs) and integrated circuit applications. One of the main challenges it still faces is the fabrication of air-stable N-type nanotube TFTs with industry compatible techniques. Here in this paper, we report a novel and highly reliable method of converting the P-type TFTs using pre-separated semiconducting nanotubes into air-stable N-type transistors by adding a high-κ oxide passivation layer using atomic layer deposition (ALD). The N-type devices exhibit symmetric electrical performance compared with the P-type devices in terms of on-current, on/off ratio and mobility. Various factors affecting the conversion process including ALD temperature, metal contact material, channel length, have also been systematically studied. A complementary metal-oxide-semiconductor (CMOS) inverter with rail-to-rail output, symmetric input/output behavior and large noise margin has been further demonstrated. The excellent performance gives us the feasibility of cascading multiple stages of logic blocks and larger scale integration. Our approach can serve as the critical foundation for future nanotube-based thin-film macroelectronics.

Session Q29 GQI: Focus Session: Quantum Information for Quantum Foundations - Experiments and Tests C148

11:15AM Q29.00001 Foundational aspects of energy-time entanglement , JAN-ÅKE LARSSON, Linkoping University — This presentation will discuss whether energy-time entanglement is a properly Quantum Information representation, by considering its relation to Einstein-Podolsky-Rosen (EPR) elements of reality. The interferometric experiment proposed by J. D. Franson in 1989 provides the background, and the main issue here is whether a Local Realist model can give the Quantum-Mechanical predictions for this setup. The Franson interferometer gives the same interference pattern as the usual Bell experiment (modulo postselection). Even so, depending on the precise requirements made on the Local Realist model, this can imply a) no violation, b) smaller violation than usual, or c) full violation of the appropriate statistical bound. The discussion will include the nature of the requirements, the motivation for making them, and their effect. The alternatives include using a) only the measurement outcomes as EPR elements of reality, b) the emission time as EPR element of reality, and c) path realism. These subtle requirements need to be taken into account when designing and setting up future experiments of this kind, intended to test Local Realism, or indeed to do Quantum Information Processing.

11:27AM Q29.00002 Large violation of Bell's inequalities using both counting and homodyne measurements , VALERIO SCARANI, DANIEL CAVALCANTI, CQT, National University of Singapore, NICOLAS BRUNNER, PAUL SKRZYPCZYK, University of Bristol, ALEJO SALLES, Bohr Institute, Copenhagen — So far, all the optical demonstrations of violations of Bell's inequalities have involved discrete degrees of freedom (e.g. polarization, time-bins) and are plagued by the detection-efficiency loophole. Continuous degrees of freedom would be a very interesting alternative because of the efficiency of the homodyne measurement; but the feasible schemes proposed so far reach very weak violations. We show that large violations for easily-prepared states can be achieved if both photon counting and homodyne detections are used. Our simple scheme may lead to the first violation of Bell's inequalities with continuous variables and pave the way for a loophole-free Bell test.

11:39AM Q29.00003 A non-local quantum eraser[1] , X. MA, J. KOFLER, A. QARRY, N. TETIK, T. SCHEIDL, R. URSIN, S. RAMELOW, L. RATSCHBACHER, T. HERBST, A. FEDRIZZI, T. JENNEWEIN, A. ZEILINGER, Univ. of Vienna and OEAW — The complementarity behavior of quantum systems is strikingly illustrated by the quantum eraser, where one can actively choose whether or not to erase which-path information of one particle by performing suitable measurements on another particle entangled with it [1-2]. Quantum mechanics predicts that this choice can be arbitrarily delayed and spatially separated from interference [1-3]. We report the first quantum eraser experiment performed under Einstein locality, i.e. under relativistic space-like separation. We employ the hybrid entanglement between path and polarization of photon pairs and distribute the photons over an optical fibre link of 55 m and, in another experiment, over a free-space link of 144 km. A complementarity inequality is measured and well fits the predictions of quantum mechanics. Our experiment represents a conclusive demonstration of the quantum eraser concept.

11:51AM Q29.00004 On the Experimental Violation of Mermin's High-Spin Bell Inequalities in the Schwinger Representation , RUFFIN EVANS, OLIVIER PFISTER, University of Virginia — Since Bell's original paper in 1964, a wide variety of experimental tests have overwhelmingly supported the completeness of quantum mechanics over local hidden-variable theories. However, relatively little effort has focused on systems of spins larger than $\frac{1}{2}$; generalizing Bell's result to higher dimensions is difficult, and the experiments needed to test these high-spin Bell inequalities are exacting. New advances in high efficiency photon-number-resolving detectors suggest that experimental tests of these inequalities should be possible in the Schwinger representation, using the continuous-variable entangled (two-mode squeezed) fields produced by an optical parametric oscillator below threshold. In this paper, we explore the realistic experimental implementation of this proposal to violate Mermin's high-spin inequalities. We demonstrate that violation for spin values greater than 1 should be attainable under a range of feasible experimental conditions that include finite squeezing and nonideal detection efficiency.

12:03PM Q29.00005 Surface based detection schemes for molecular interferometry experiments - implications and possible applications , THOMAS JUFFMANN, ADRIANA MILIC, MICHAEL MUELLNERITSCH, MARKUS ARNDT, Univ. of Vienna - Faculty of Physics — Surface based detection schemes for molecular interferometry experiments [1] might be crucial in the search for the quantum properties of larger and larger objects [2] since they provide single particle sensitivity. Here we report on molecular interferograms of different biomolecules imaged using fluorescence microscopy. Being able to watch the build-up of an interferogram live and in situ reveals the matter-wave behavior of these complex molecules in an unprecedented way. We examine several problems encountered due to van-der-Waals forces between the molecules and the diffraction grating and discuss possible ways to circumvent these. Especially the advent of ultra-thin (1-100 atomic layers) diffraction masks might path the way towards molecular holography. We also discuss other possible applications such as coherent molecular microscopy.

12:15PM Q29.00006 Matter wave interferometry with large and complex molecules , STEFAN GERLICH, SANDRA EIBENBERGER, MATHIAS TOMANDL, University of Vienna, Faculty of Physics, JENS TÜXEN, MARCEL MAYOR, University of Basel, Department of Chemistry, MARKUS ARNDT, University of Vienna, Faculty of Physics — Matter wave interferometry with molecules of increasing size, mass and complexity explores the frontiers of quantum mechanics and it is a promising tool for determining molecular properties with high precision. The quantum wave nature of organic molecules is used in a Kapitza-Dirac-Talbot-Lau interferometer to generate a set of high-contrast interference fringes that are highly sensitive to external forces. This is exploited to access thermally averaged internal molecular properties, such as optical and static polarizabilities, static and thermally activated electric dipole moments, information about conformational differences and state changes, optical absorption spectra and more. The information about the internal states can be extracted through conservative interactions, i.e. allowing the persistence of full quantum delocalization in position space.

12:27PM Q29.00007 Violation of local realism with freedom of choice , JOHANNES KOFLER, THOMAS SCHEIDL, RUPERT URSIN, SVEN RAMELOW, XIAO-SONG MA, Institute for Quantum Optics and Quantum Information (IQOQI), Austrian Academy of Sciences, THOMAS HERBST, Faculty of Physics, University of Vienna, LOTHAR RATSCHBACHER, ALESSANDRO FEDRIZZI, NATHAN LANGFORD, THOMAS JENNEWEIN, ANTON ZEILINGER, Institute for Quantum Optics and Quantum Information (IQOQI), Austrian Academy of Sciences — Bell's theorem shows that local realistic theories place strong restrictions on observable correlations between different systems, giving rise to Bell's inequality which can be violated in experiments using entangled quantum states. Bell's theorem is based on the assumptions of realism, locality, and the freedom to choose between measurement settings. In experimental tests, "loopholes" arise which allow observed violations to still be explained by local realistic theories. Violating Bell's inequality while simultaneously closing all such loopholes is one of the most significant still open challenges in fundamental physics today. We present an experiment that violates Bell's inequality while simultaneously closing the locality loophole and addressing the freedom-of-choice loophole, also closing the latter within a reasonable set of assumptions. Reference: T. Scheidl et al., Proc. Natl. Acad. Sci. USA 107, 19708 (2010)

12:39PM Q29.00008 Experimental non-classicality of an indivisible system[1] , RADEK LAPKIEWICZ, PEIZHE LI, CHRISTOPH SCHAEFF, NATHAN LANGFORD, SVEN RAMELOW, MARCIN WIESNIAK, ANTON ZEILINGER, University of Vienna, Faculty of Physics, Vienna; Institute for Quantum Optics and Quantum Information, Austrian Academy of Sciences, Vienna — In Quantum Mechanics (QM) not all properties can be simultaneously well defined. An important question is whether a joint probability distribution can describe the outcomes of all possible measurements, allowing a quantum system to be mimicked by classical means. Klyachko et al. [PRL 101, 020403 (2008)] derived an inequality which allowed us to answer this question experimentally. The inequality involves only five measurements and QM predicts its violation for single spin-1 particles. This is the simplest system where such a contradiction is possible. It is also indivisible and as such cannot contain entanglement. In our experiment with single photons distributed among three modes (isomorphic to stationary spin-1 particles) we obtained a value of -3.893(9), which lies more than 90 standard deviations below the "classical" bound of -3.

12:51PM Q29.00009 Testing spontaneous localization with ultra-massive cluster interferometry , STEFAN NIMMRICHTER, University of Vienna, KLAUS HORNBERGER, MPIPKS Dresden, MARKUS ARNDT, University of Vienna — Understanding the transition from the microscopic domain of quantum mechanics to our everyday classical world is still an open problem in modern physics. Collapse models are a possible way to resolve this issue by introducing mechanisms which break the quantum superposition principle above a certain mass and time scale. One of the best studied models is the theory of continuous spontaneous localization (CSL) by Ghirardi, Pearle and Rimini [1]. We show that it should be possible to test the predictions of the CSL model in the new matter-wave interferometer for heavy metal clusters that is currently built in Vienna. Extending the original Talbot-Lau setup for biomolecules, the new scheme will operate in the time-domain using three pulsed standing-wave gratings of UV laser light. We argue that this should enable us to see single-particle interference in an unprecedented mass range from 10^5 up to even 10^8 atomic mass units. Recent estimates of the strength of the CSL effect by Adler and Bassi [2,3] suggest that a breakdown of the quantum superposition principle would occur in precisely this mass regime.

1:03PM Q29.00010 Hardy's paradox and a violation of a state-independent Bell inequality in time , ALESSANDRO FEDRIZZI, MARCELO P. ALMEIDA, MATTHEW A. BROOME, ANDREW G. WHITE, Department of Physics and Centre for Quantum Computer Technology, University of Queensland, Brisbane QLD 4072, Australia, MARCO BARBIERI, Groupe d'Optique Quantique, Laboratoire Charles Fabry, Institut d'Optique, CNRS, Universite Paris-Sud, France — Tests such as Bell's inequality and Hardy's paradox highlight the differences between local realistic theories and quantum predictions for measurement probabilities and correlations between distant particles. Transposing these tests to the temporal domain, i.e. making two measurements on the one quantum particle at different times, yield Hardy and Bell tests mathematically identical to their spatial counterparts, but give very different physical results. Here, we use a photonic entangling gate to implement non-destructive temporal measurements on a quantum system. We measure a much stronger form of Hardy's paradox and demonstrate violation of a Bell inequality in time independent of the quantum state, including for fully-mixed states. Our work yields interesting fundamental insights and opens up a path to more efficient quantum information processing protocols based on temporal quantum correlations.

1:15PM Q29.00011 Experimental Violation of Two-Party Leggett-Garg Inequalities with Semi-weak Measurements , JUSTIN DRESSEL, CURTIS BROADBENT, JOHN HOWELL, ANDREW JORDAN, University of Rochester — We generalize the derivation of Leggett-Garg inequalities to systematically treat a larger class of experimental situations by allowing multi-particle correlations, invasive detection, and ambiguous detector results. Furthermore, we show how many such inequalities may be tested simultaneously with a single setup. As a proof of principle, we violate several such two-particle inequalities with data obtained from a polarization-entangled biphoton state and a semi-weak polarization measurement based on Fresnel reflection. We also point out a non-trivial connection between specific two-party Leggett-Garg inequality violations and convex sums of strange weak values.

1:27PM Q29.00012 Causality, Bell's theorem, and Ontic Definiteness , JOE HENSON, Perimeter Institute — Bell's theorem shows that the reasonable relativistic causal principle known as "local causality" is not compatible with the predictions of quantum mechanics. It is not possible maintain a satisfying causal principle of this type while dropping any of the better-known assumptions of Bell's theorem. However, another assumption of Bell's theorem is the use of classical logic. One part of this assumption is the principle of *ontic definiteness*, that is, that it must in principle be possible to assign definite truth values to all propositions treated in the theory. Once the logical setting is clarified somewhat, it can be seen that rejecting this principle does not in any way undermine the type of causal principle used by Bell. Without ontic definiteness, the deterministic causal condition known as Einstein Locality succeeds in banning superluminal influence (including signalling) whilst allowing correlations that violate Bell's inequalities. Objections to altering logic, and the consequences for operational and realistic viewpoints, are also addressed.

1:39PM Q29.00013 On dipole anisotropy in spatial distribution of Plank's constant values , SIMON BERKOVICH, The George Washington University — The work relates to the remarkable fact discovered by John Webb et al. of angular variations of the fine structure constant $\alpha = e^2/hc$. We elaborate on this fact using our model of quantum mechanics (see [1] and references within). The peculiarity of quantum behavior stems from interactive holography appearing on top of the cellular automaton mechanism of the Universe. Nonlocality comes naturally from sliced holographic processing. As to the anisotropy of α, its is due to variations of h caused by different undulation control patterns in different positions with respect to the source of the holographic reference beam. The angular divergences in α are determined by the eccentric placement of the Solar system with respect to this reference holographic beam. This eccentricity factor imposes dipole structuring on several types of astrophysical observations. So, following [1], small opposite changes in h with respect to the eccentricity displacement of the Solar system could be anticipated. Before we have shown that the same eccentricity factor leads to the appearance of the "axis-of-evil" in CMB. Further, the recently discovered anisotropy in high-energy cosmic rays should be also determined by the eccentricity factor, i.e. it should adhere to the same dipole. [1] S. Berkovich, "A Comprehensive Explanation of Quantum Mechanics", http://www.bestthinking.com/topics/science/physics/ quantum_physics/a-comprehensive-explanation-of-quantum-mechanics

1:51PM Q29.00014 Scaling of quantum Zeno dynamics in thermodynamic systems , WING CHI YU, LI-GANG WANG, SHI-JIAN GU, Department of Physics, The Chinese University of Hong Kong, Hong Kong — Quantum Zeno effect (QZE) refers to the inhabitation of the unitary time evolution of a quantum system by repeated frequent measurements. It has been studied intensively within the content of quantum optics in recent decades. Among those analyses, the systems under consideration are only of a few levels. Little attention of QZE in thermodynamic systems has been paid so far. In this presentation, we will investigate the QZE in thermodynamic systems from the viewpoint of condensed matter physics. We take the one-dimensional transverse-field Ising model and the Lipkin-Meshkov-Glick (LMG) model as examples to illustrate analytically the criteria, in terms of the size dependence of the leading term of the survival probability in the short-time limit, for observing the QZE. Our analysis shows that in order to observe the QZE in the Ising model, the frequency of the projective measurement should be of comparable order to that of the system sizes. The same criterion also holds in the symmetry broken phase of the LMG model. However, in the polarized phase of the LMG model, the leading term of the survival probability is independent of the system size and the QZE can be easily observed.

2:03PM Q29.00015 Decoherence Free Neutron Interferometry , DMITRY A. PUSHIN, DAVID G. CORY, IQC, University of Waterloo, MICHAEL G. HUBER, NIST, MOHAMED ABUTALEB, MIT, MUHAMMAD ARIF, NIST, CHARLES W. CLARK, Joint Quantum Institute, NIST and the University of Maryland — A neutron interferometer (NI) is a unique example of the macroscopic quantum coherence and has been used to test fundamental principles of quantum mechanics. In practice, neutron interferometers are not widely used because of their extreme sensitivity to environmental noise which is in part due to the slow velocity (relative to light) of the neutron. We show that a neutron interferometer design can benefit from concepts of quantum information processing. We have machined a Decoherence Free (DF) neutron interferometer designed using a quantum error correction code,[1] and have shown it to be much less sensitive to mechanical vibrations than is the standard Mach-Zehnder (MZ) interferometer. Both the MZ and DF geometries are incorporated in one crystal, which allows direct comparisons to be made. We believe that our results and related quantum information approaches, such as "the power of one qubit,"[2] will enable a new series of compact neutron interferometers that can be tailored to specific applications in soft condensed matter and spintronics.

Session Q30 DCMP: Graphene: Electron-Electron Interactions C147/154

11:15AM Q30.00001 The effective fine-structure constant of freestanding graphene measured in graphite[1] , YU GAN, JAMES REED, BRUNO UCHOA, YOUNG-IL JOE, University of Illinois at Urbana-Champaign, DIEGO CASA, Argonne National Laboratory, EDUARDO FRADKIN, PETER ABBAMONTE, University of Illinois at Urbana-Champaign — Electrons in graphene behave like Dirac fermions, permitting phenomena from high- energy physics to be studied in a solid-state setting. A key question is whether or not these fermions are critically influenced by Coulomb correlations. We performed inelastic x-ray scattering experiments on crystals of graphite and applied reconstruction algorithms to image the dynamical screening of charge in a freestanding graphene sheet. We found that the polarizability of the Dirac fermions is amplified by excitonic effects, improving screening of interactions between quasiparticles. The strength of interactions is characterized by a scale-dependent, effective fine-structure constant, $\alpha_g^*(\mathbf{k},\omega)$, the value of which approaches $1/7$ at low energy and large distances. This value is substantially smaller than the nominal $\alpha_g = 2.2$, suggesting that, on the whole, graphene is more weakly interacting than previously believed.

11:27AM Q30.00002 Excitonic Gap from Long-Range Coulomb Interaction in Graphene , JOSE GONZALEZ, Instituto de Estructura de la Materia (CSIC), Madrid, Spain — We apply renormalization group methods to analyze the development of an excitonic gap in the theory of Dirac fermions in graphene with long-range Coulomb interaction. In the large-N approximation, we show that the chiral symmetry is only broken below a critical number of two-component Dirac fermions $N_c = 32/\pi^2$, that is precisely half the value found in quantum electrodynamics. Adopting otherwise a ladder approximation, we give evidence of the existence of a critical coupling at which the order parameter of the transition to the gapped phase diverges. This result supports that the opening of an excitonic gap may be driven by a sufficiently strong Coulomb interaction, despite the divergence of the Fermi velocity at low energies in the Dirac theory of graphene.

11:39AM Q30.00003 Manifestation of explicit and spontaneous chiral symmetry breaking in graphene , SUNG-HOON LEE, HYUN-JONG CHUNG, JINSEONG HEO, HEEJUN YANG, SUNAE SEO, Samsung Advanced Institute of Technology, Korea — Using first-principles calculations of graphene having high- symmetry distortion or defects, we investigate the chiral symmetry breaking in graphene as the source of gap opening. We identify that the gap opening by the chiral symmetry breaking in the honeycomb lattice is an ideal two-dimensional (2D) extension of the Peierls metal-insulator transition in a linear lattice, the elemental 1D Dirac lattice, and find that the chiral symmetry breaking manifests itself in graphene by the formation of an internal structure of the lattice, which represents the intrinsic internal structure of massive Dirac fermions. We then show that the gap opening of many of previously reported structures of gapped graphene occurs by explicit breaking of the chiral symmetry, rather than by quantum confinement effects or others, and also show that spontaneous chiral symmetry breaking takes place via electron- phonon coupling at certain quasi-1D graphene structures and at 2D graphene under strain.

11:51AM Q30.00004 Theory of Kekule superconductor on graphene's honeycomb lattice[1] , BITAN ROY, IGOR HERBUT, Department of Physics, Simon Fraser University — A spatially non-uniform superconducting state is proposed as a variational ground state on honeycomb lattice, with the chemical potential close to and right at the Dirac point, when the nearest-neighbor attraction is the dominant component of the interaction. This state spontaneously breaks the translational invariance of the underlying lattice into the Kekule pattern of superconducting bond order parameters. Otherwise it is fully gapped, spin triplet, and odd under the exchange of two sublattices. Symmetries of the ground state for a range of nearest-neighbor interaction, the topological excitations of the Kekule superconductor, and its competition with other superconducting orders proposed in literature will also be discussed.

12:03PM Q30.00005 Pairing in graphene: A Monte Carlo study , TIANXING MA, Department of Physics, Beijing Normal University, ZHONGBING HUANG, FEIMING HU, HAI-QING LIN — To address the issue of possibility of inducing superconductivity in graphene, we study the behavior of pairing correlation in the extended repulsive Hubbard model on a honeycomb lattice within both determinant quantum Monte Carlo and constrained path Monte Carlo method. We find that the system shows an antiferromagnetic correlation below Van Hove fillings. In the filling range of $<n>$=1.00 $\sim$ 1.20, pairing with $d+id$ symmetry is dominant over pairing with extent s symmetry, especially at low temperatures. The $d+id$-wave pairing susceptibility is enhanced as the electron filling increases, while the effective pairing interaction is suppressed. The summation of pairing correlation for long-range part is enhanced as the repulsion increases, however, for various lattice sizes and interactions, we find that the long-range part of $d+id$-wave pairing correlations both vanishes. Our results suggest that there maybe no superconductivity in pure and low doped graphene.

12:15PM Q30.00006 Interacting fermions on the honeycomb bilayer: From weak to strong coupling[1] , OSKAR VAFEK, National High Magnetic Field Lab/FSU — Many-body instabilities of the half-filled honeycomb bilayer are studied using weak-coupling renormalization group (RG) as well as strong-coupling expansion [1,2]. For spinless fermions, there are 4 independent four-fermion contact couplings. Generally, we find runaway RG flows which we associate with ordering tendencies. The broken symmetry state is typically a gapped insulator with either broken inversion or broken time-reversal symmetry, with a quantized anomalous Hall effect. Additionally, a tight-binding model with nearest-neighbor hopping and nearest-neighbor repulsion is studied in weak and strong couplings and in each regime a gapped phase with inversion symmetry breaking is found. In the strong-coupling limit, the ground-state wave function is constructed for vanishing in-plane hopping but finite interplane hopping, which explicitly displays the broken inversion symmetry and a finite difference between the number of particles on the two layers. In the spin-1/2 case we use Fierz identities to show that there are 9 independent four-fermion contact couplings[2]. The 9 RG equations in this case reduce to the 3 found in Ref.[1] under the assumptions stated in Ref.[1]. They are further used to show that, just as in strong coupling, the most dominant weak-coupling instability of the repulsive Hubbard model (at half filling) is an antiferromagnet. [1] O. Vafek and K. Yang, PRB **81**, 041401 (2010). [2] O. Vafek, PRB **82**, 205106 (2010)

12:27PM Q30.00007 Compressibility Instability of Interacting Electrons in Bilayer Graphene , XIN-ZHONG YAN, Institute of Physics, CAS, C.S. TING, Texas Center for Superconductivity/UH — Using the self-consistent Hartree-Fock approximation, we study the compressibility instability of the interacting electrons in bilayer grapheme at finite temperature. The chemical potential and the compressibility of the electrons can be significantly altered by an energy gap (tunable by external gate voltages) between the valence and conduction bands. For zero gap case, we show that the homogeneous system is stable. When the gap is finite, the compressibility of the electron system becomes negative at low carrier doping concentrations and low temperature. We also present the phase diagram distinguishing the stable and unstable regions of a typically gapped system in terms of temperature and doping.

12:39PM Q30.00008 Limits to universal conductance fluctuations of massless Dirac fermions[1] , MARIO BORUNDA, Harvard University, JESSE BEREZOVSKY, Case Western Reserve University and Harvard University, ROBERT WESTERVELT, ERIC HELLER, Harvard University — We study conductance fluctuations (CFs) and the sensitivity of the conductance to the motion of a single scatterer in two-dimensional massless Dirac systems. Our extensive numerical study finds limits to the predicted universal value of CFs. We find that CFs are suppressed for ballistic systems near the Dirac point and approach the universal value at sufficiently strong disorder. The conductance of massless Dirac fermions is sensitive to the motion of a single scatterer. CFs of order e^2/h result from the motion of a single impurity by a distance comparable to the Fermi wavelength. This result applies to graphene systems with a broad range of impurity strength and concentration while the dependence on the Fermi wavelength can be explored via gate voltages. Our prediction can be tested by comparing graphene samples with varying amounts of disorder and can be used to understand interference effects in graphene mesoscopic devices.

12:51PM Q30.00009 Interplay between curvature and in-plane magnetic field in bilayer graphene , AVADH SAXENA, LANL, YOGESH JOGLEKAR, IUPUI — For a two-dimensional electron gas (2DEG) in a uniform magnetic field, the effect of the in-plane component on the orbital motion of carriers is ignored because "it can be gauged away." However, the effect of such a field on a massive quantum particle confined to a curved surface has been only recently explored [1]. We obtain the single-particle spectra for such a particle on a sphere, a cylinder, and a torus in the presence of a constant magnetic field. In addition to the geometric potential V_G that arises due to the confinement on a curved surface, we find that in-plane field leads to energy shifts $\Delta E \propto V_G(R/l_B)^4$ where R is the radius of curvature of the surface, and l_B is the magnetic length for the in-plane field. With bilayer graphene as a model for massive quantum particle on a curved surface, we estimate the energy shift for a cylindrical geometry, and show that it is significant for typical experimental parameters.

1:03PM Q30.00010 Plasma Instability in Graphene Bilayers , ANTONIOS BALASSIS, Fordham University, GODFREY GUMBS, Hunter College of the City University of New York — The problem of plasma instability in a pair of coupled semiconductor layers when a dc current is passed through one of the layers has been vigorously investigated over the years. This may be carried out by solving for the real and imaginary parts of the frequency in the polarization function making the dielectric function vanish. We analyze the conditions for plasma instability in a graphene bilayer for various chemical potentials (doping) as well as layer separation.

1:15PM Q30.00011 Tight-binding theory of the spin-orbit coupling in graphene structures[1] , SERGEJ KONSCHUH, MARTIN GMITRA, JAROSLAV FABIAN, University of Regensburg, Germany — Spin-orbit coupling changes qualitatively the electronic band structure of graphene. Most important, the coupling induces spectral gaps at the K(K') points. Earlier theories estimated the *intrinsic* gap of 1 μeV for the single layer and several meVs for bi- and tri-layer graphene, based on σ-π coupling. Our first-principles calculations give the value of 24 μeV for all these systems, due to the presence of the orbitals of the d symmetry in the Bloch states of the π bands. A realistic multiband tight-binding model is presented to explain the effects the d orbitals play in the spin-orbit coupling of graphene and derive an effective single-orbital next-nearest-neighbor hopping model that accounts for the spin-orbit effects. We also study the *extrinsic* spin-orbit coupling, due to an applied transverse electric field. In a single layer the *extrinsic* effect is dominated by the π-σ hybridization. In contrast, in the multi-layer structures the *extrinsic* spin-orbit band splittings come from an interplay of the d-orbitals, the inter-layer hopping, and the electrostatic potential from the applied field.

1:27PM Q30.00012 Spin-orbit coupling in bi-layer and tri-layer graphene in transverse electric field: first-principles calculations[1] , MARTIN GMITRA, SERGEJ KONSCHUH, JAROSLAV FABIAN, University of Regensburg, Germany — Few-layer graphene structures may be potentially useful for optical and transport applications, due to the possibility of electrical control of the band gaps. Here we investigate the spin-orbit coupling of bilayer and tri-layer graphene around the Fermi level. We show, by performing first-principles full potential linearized augmented plane waves calculations that the spin-orbit physics in these structures derives essentially from monolayer graphene. In particular, the spin splitting of the bands is due to the spin-orbit coupling of the d-orbitals. These give a splitting of the order of 24 μeV at the K point, as in graphene. Breaking the spatial inversion symmetry by a transverse electric field does not change this (intrinsic) picture, unlike what we know from graphene.

1:39PM Q30.00013 Dynamical Jahn-Teller Effect at a Vacancy Center in Graphene[1] , SASHI SATPATHY, MOHAMMAD SHERAFATI, BIRABAR NANDA, University of Missouri, ZORAN POPOVIC, Institute for Nuclear Sciences, Belgrade — We study the substitutional vacancy center in graphene from density-functional LAPW calculations and show that it is magnetic and at the same time forms a dynamical Jahn-Teller center. A net magnetic moment of $2\mu_B$ is found, which is explained in terms of the occupation of the $sp^2\sigma$ dangling bond state and the zero-mode state derived from the π bands. The adiabatic potential surface resulting from the $E \otimes e$ vibronic coupling was computed and subsequently the Schrödinger equation was solved for the nuclear motion of the carbon atoms. Our calculations show the tunneling splitting 3Γ to be about 80 cm^{-1}, which is substantially larger than the typical strain fields, leading to a dynamical Jahn-Teller effect (JTE). This explains the puzzling behavior of why in the STM measurements a symmetric carbon triangle is observed around the vacancy, while at the same time we predict the splitting of the vacancy-induced electron states by the static JTE *in spite of* the triangular symmetry.

1:51PM Q30.00014 Plasma Excitations in Graphene: Their Spectral Intensity and Temperature Dependence in Magnetic Field , JHAO-YING WU, SZU-CHAO CHEN, GODFREY GUMBS, MING-FA LIN — We calculated the dielectric function, the loss function, the magnetoplasmon dispersion relation and the temperature-induced transitions for graphene in a uniform perpendicular magnetic field. The calculations were performed using the Peierls tight-binding model to obtain the energy band structure and the random-phase approximation to determine the collective plasma excitation spectrum. The single-particle and collective excitations have been precisely identified based on the resonant peaks in the loss function. The critical wave vector at which plasmon damping takes place is clearly established. This critical wave vector depends on the magnetic field strength as well as the levels between which the transition takes place. The temperature effects were also investigated. At finite temperature, there are plasma resonances induced by the Fermi distribution function. Whether such plasmons exist is mainly determined by the field strength, temperature, and momentum.

2:03PM Q30.00015 Field Modulation on the Electronic Structure for the Bilayer and Trilayer Graphene[1] , BI-RU WU, Department of Nature Science, Center for General Education, Chang Gung University, Tao-Yuan, Taiwan — The electronic band gap plays a central role in modern device physics and a tunable band gap provides great flexibility in device design. I present the investigation of electric filed effect on the electronic structure of the bilayer and trilayer graphene. The hexagonal and Bernal type structures are studied for the bilayer and trilayer graphene, additionally, the rhombohedral type is also take into account for the trilayer one. It is found the band gaps of the Bernal type bilayer graphene and the Rhombohedral type trilayer graphene are tunable by a perpendicular electric field. The symmetry of the graphene plays a crucial role in the field modulation. The perpendicular electric field opens the band gap of the Bernal type bilayer graphene and the Rhombohedral type trilayer graphene by breaking the symmetry in z-direction.

Session Q31 DMP GSCCM DCOMP: Focus Session: Materials at High Pressure V: Structure Prediction and Complex Materials C145

11:15AM Q31.00001 Crystal structure prediction using evolutionary algorithms: how to predict large and complex systems , ANDRIY LYAKHOV, Stony Brook University — Evolutionary crystal structure prediction proved to be a powerful approach in discovering new materials. Algorithm USPEX allows one to predict the most stable crystal structure for a given compound without requiring any experimental input. However, certain limitations are encountered for systems with a large number of degrees of freedom and complex energy landscapes. We explore the nature of these limitations and address them with a number of newly developed tools. For large systems a major problem is the lack of diversity. It is countered with modified variation operators that favor atoms with higher local order and a special initialization procedure for the first generation. For complex energy landscapes, the key problem is the possible existence of several energy funnels. To address this problem, we develop an algorithm incorporating the ideas of abstract "distance" between structures using the so called "fingerprint function." We will compare the efficiency of the old and new algorithm USPEX for different systems and show that the range of application for algorithm is increased. Some systems, where old algorithm couldn't find a solution are now solvable with the new algorithm. And the speed of finding the solutions for systems with the complicated energy landscape is substantially increased.

11:51AM Q31.00002 Prediction of complex high-pressure M-B crystal structures with an evolutionary algorithm , ALEKSEY KOLMOGOROV, SHEENA SHAH, ROXANA MARGINE, University of Oxford — We have carried out an ab initio ground state search in two binary metal-boron systems using an evolutionary algorithm [1] and identified remarkably complex configurations stabilized at high pressures [2,3]. An alkali-earth metal boride is shown to undergo a structural transformation from a semiconducting to a metallic state while a new semiconducting transition metal boride is stabilized at a composition known to have only metallic ground states. For the proposed candidate materials we calculate the electron-phonon coupling and demonstrate their potential to be phonon-mediated superconductors.

12:03PM Q31.00003 Structure prediction for molecular crystals using evolutionary algorithms: methodology and applications[1] , QIANG ZHU, Geosciences Department, Stony Brook University — Evolutionary crystal structure prediction proved to be a powerful approach in determining the atomic crystal structure of materials. Here, we present a specifically designed algorithm for the prediction of the structure of molecular crystals. The main feature of this new approach is that each molecule is treated as a whole body, which drastically reduces the search space and improves the efficiency, but necessitates the introduction of new variation operators described here. We illustrate the efficiency of this approach by a search for ice (H2O) structures at zero pressure and temperature, which easily finds the structures of ice Ih and Ic, as well as the thermodynamically stable at these conditions ice XI. We successfully apply this method to finding the hitherto unknown structures of plastic phases of methane at high pressure. These structures are distinguished by an icosahedral packing of the molecules, and are likely candidate solutions for methane A and B.

12:15PM Q31.00004 Burnett-Cattaneo Continuum Theory for Shock Waves[1] , B.L. HOLIAN, Los Alamos National Laboratory, M. MARESCHAL, Universite Libre de Bruxelles, R. RAVELO, University of Texas-El Paso — We model strong shockwave propagation, both in the ideal gas and in the dense Lennard-Jones fluid, using a refinement of earlier work [2], which accounts for the cold compression by a nonlinear, Burnett-like, strain-rate dependence of the thermal conductivity, and relaxation of temperature components on the hot, compressed side of the shock front. The relaxation of the disequilibrium among the three components of the kinetic temperature, namely, the difference between the temperature in the direction of a planar shock wave and those in the transverse directions, particularly in the region near the shock front, is accomplished by a rigorous application of the Cattaneo-Maxwell relaxation equation to a reference state, namely, the steady shockwave solution of linear Navier-Stokes-Fourier theory, along with the nonlinear Burnett heat-flux term. Our new continuum theory is in nearly quantitative agreement with non-equilibrium molecular-dynamics simulations under strong shockwave conditions.

12:27PM Q31.00005 High-pressure behavior of a novel, nitrogen-rich energetic material[1] , R. STEWART MCWILLIAMS, Howard University, JENNIFER CIEZAK-JENKINS, Army Research Laboratory, YASMIN KADRY, University of Maryland College Park, VITALY PRAKAPENKA, Advanced Photon Source, MOHAMMAD MAHMOOD, Howard University, ALEXANDER GONCHAROV, Carnegie Institution of Washington — Energetic materials are of great interest in energy and defense applications. In the search for new energetic materials with improved properties, such as reduced environmental impact, a crystalline solid Triaminoguanidinium 1-methyl-5-nitriminotetrazolate (TAG), $C_3H_{12}N_{12}O_2$, has recently been synthesized (Klapötke et. al. 2008). We have studied the properties of TAG under static compression, and under reaction initiation at high pressure, using Raman and IR spectroscopy and x-ray diffraction. TAG appears to remain a stable, crystalline solid up to at least 35 GPa at room temperature. Laser initiation at 10-15 GPa reveals a rapid self-propagating reaction (deflagration) that consumes the sample, similar to other energetic materials such as nitromethane. Post-initiation products include crystalline molecular nitrogen (delta-phase), and nitrogen crystallites with regular defects. The formation of bulk molecular nitrogen during deflagration - in both phase segregated and impurity-hosting forms - distinguishes TAG from other known energetic materials, and suggests a pathway for the generation of novel phases from element-enriched energetic substances.

12:39PM Q31.00006 High pressure–high temperature studies of ammonia , JULIUS OJWANG, RYAN MCWILLIAMS, ALEXANDER GONCHAROV, Carnegie Institution of Washington — Raman scattering measurements and x-ray diffraction of ammonia have been made under simultaneous conditions of high temperature and high static pressure in the laser heated diamond anvil cell. The experimental results on phase transitions with pressure increase at room temperature are found to be in accord with previous studies [1]. Pressure was increased up to 52 GPa and temperature ramped up to 2000 K. On increasing temperature at high pressure, strong changes in the ammonia Raman spectra are observed, which could be associated with melting. On melting, ammonia undergoes partial decomposition into nitrogen and hydrogen. We also observed the appearance of new N-H stretch bands at high temperatures which may be related to the formation of new bonds. When quenched back to room temperature the starting phase of solid ammonia is recovered. The shift in frequencies of the vibron bands of nitrogen with pressure shows that it is phase segregated from ammonia.

12:51PM Q31.00007 Atomic structure and elastic properties at high pressure of aluminum oxynitride in cubic phase , I.G. BATYREV, J.W. MCCAULEY, B.M. RICE, G.A. GAZONAS, U.S. Army Research Laboratory, Aberdeen Proving Ground, MD 21005, A.R. OGANOV, Department of Geosciences and Department of Physics and Astronomy, State University of New York, Stony Brook, NY 11794-2100 — The atomic structure and elastic properties of aluminum oxynitride spinel (AlON) at high pressure (up to 40 GPa) have been calculated from first principles. We have assumed an "ideal" stoichiometry of cubic AlON with 35.7 mole % AlN using the constant anion model. The elastic constants were calculated from independent strains that were applied to a unit cell, parameterizing the total energy as a function of the strain and from a stress-strain relationship. At ambient conditions a clustered distribution of N atoms has $\sim$ 1 eV per 55 atoms higher total energy than for a random distribution and slightly, but systematically lower elastic constants. The pressure dependence of C_{11}, C_{12} and C_{44} for random and cluster distributions of N atoms was calculated in the range of 0-40 GPa by performing six finite distortions of the lattice and deriving the elastic constants from the strain-stress relationship. The calculated values of dC_{11}/dP are in the range of 4.0-6.2 and for dC_{44}/dP $\sim$0.8-1.5. The estimates are in reasonable agreement with experimental measurements of polycrystalline AlON. The minimum energy structure of AlON was found using the evolutionary algorithm USPEX (Oganov & Glass, 2006)

1:03PM Q31.00008 In Situ Neutron and Synchrotron X-ray Diffraction Studies of Jarosite at High-Temperature High-Pressure Conditions , H. XU, Y. ZHAO, D. HICKMOTT, J. ZHANG, S. VOGEL, L. DAEMEN, M. HARTL, Los Alamos National Laboratory — Jarosite ($KFe_3(SO_4)_2(OH)_6$) occurs in acid mine drainage and epithermal environments and hot springs associated with volcanic activity. Jarosite is also of industrial interest as an iron-impurity extractor from zinc sulfide ores. In 2004, jarosite was detected by the Mars Exploration Rover Mössbauer spectrometer, which has been interpreted as a strong evidence for the existence of water (and possibly life) on ancient Mars. This discovery has spurred considerable interests in stability and structural behavior of jarosite and related phases at various temperature, pressure, and aqueous conditions. In this work, we have investigated the crystal structure and phase stability of jarosite at temperatures up to 900 K and/or pressures up to 9 GPa using *in situ* neutron and synchrotron X-ray diffraction. To avoid the large incoherent scattering of neutrons by hydrogen, a deuterated sample was synthesized and characterized. Rietveld analysis of the obtained diffraction data allowed determination of unit-cell parameters, atomic positions and atomic displacement parameters as a function of temperature and pressure. In addition, the coefficients of thermal expansion, bulk moduli and pressure-temperature stability regions of jarosite were determined.

1:15PM Q31.00009 Testing the minimum thermal conductivity model for amorphous polymers using high pressure , WEN-PIN HSIEH, Department of Physics, University of Illinois, Urbana, MARK LOSEGO, PAUL BRAUN, Department of Materials Science and Engineering, University of Illinois, Urbana, SERGEI SHENOGIN, PAWEL KEBLINSKI, Department of Materials Science and Engineering, Rensselaer Polytechnic Institute, Troy, NY, DAVID CAHILL, Department of Materials Science and Engineering, University of Illinois, Urbana — Pressure dependence of thermal conductivity provides a critical test of the validity of the model of the minimum thermal conductivity for describing heat transport by molecular vibrations of an amorphous polymer. We measure the pressure dependence of the thermal conductivity of poly(methyl methacrylate) (PMMA) brushes grafted from SiC substrates using a combination of time-domain thermoreflectance and SiC anvil cell techniques. We also determine the pressure dependence of the thermal conductivity from a computational model of amorphous polystyrene. In both cases, thermal conductivity as a function of pressure is accurately predicted by the minimum thermal conductivity model via the pressure dependence of the elastic constants and density.

1:27PM Q31.00010 The Influence of Crystal Structure on the Thermal Expansion Behavior of $GeZn_2O_4$, MICHAEL CRAWFORD, R.L. HARLOW, W.E. GUISE, DuPont Company, R.A. FISHER, Los Alamos National Laboratory, W. WOERNER, J.B. PARISE, Stony Brook University, Q. HUANG, J.W. LYNN, NIST Center for Neutron Research, R. STEVENS, California Institute of Technology, B. WOODFIELD, J. BOERIO-GOATES, Brigham Young University, J. LASHLEY, Los Alamos National Laboratory, O. GOURDON, A. HUQ, Spallation Neutron Source, Oak Ridge National Laboratory, J. HORMADALY, Ben Gurion University, P.L. LEE, Y. ZHANG, Argonne National Laboratory — $GeZn_2O_4$ synthesized at ambient pressure adopts the rhombohedral phenacite crystal structure, whereas cubic or tetragonal inverse spinel phases are formed at high pressures. We have measured the thermal expansion for all three forms of $GeZn_2O_4$ at temperatures from 10 K to 400 K (or higher) using synchrotron x-ray powder diffraction. The phenacite form exhibits negative thermal expansion below 300 K, changing to positive thermal expansion above that temperature. In contrast to this behavior, the cubic and tetragonal inverse spinel phases exhibit positive thermal expansion below room temperature. Characterization of these materials using x-ray and neutron diffraction, as well as heat capacity and Raman spectroscopy, will be described. Possible structural reasons for the different thermal expansion behaviors of the phenacite and spinel forms of $GeZn_2O_4$ will be discussed.

1:39PM Q31.00011 First-principles calculation of Ca2RuO4 at high pressure , NOBUMI MIYAWAKI, TATSUYA SHISHIDOU, Hiroshima University, TAMIO OGUCHI, Osaka University — It has been observed that the layered perovskite antiferromagnetic insulator Ca_2RuO_4 reveals a phase transition into a ferromagnetic metal at 0.5GPa [1]. This insulator-metal transition is accompanied by a structural change with tilt and rotation of RuO_6 octahedron within the space group $Pbca$. Above about 9GPa, another transition from the ferromagnetic to superconducting phase has been recently reported [2]. The transition includes a structure change from $Pbca$ to $Bbcm$. In this study, a first-principles calculation is performed to study the electronic structure of Ca_2RuO_4, especially focusing on the changes of Ru $4d$ states, with pressure. As the pressure is increased, calculated ferromagnetic spin moment of Ru is gradually decreased in $Pbca$ owing to the widening of Ru $4d$ band. It is interesting that a ferromagnetic solution still exists in $Bbcm$. Similar structural changes (the tilt and rotation of RuO_6 octahedron) take place in $Ca_{2-x}Sr_xRuO_4$, where orbital hybridization with spin-orbit coupling (SOC) is crucial [3]. We also investigated effects of SOC, with the result that those appear even in the electronic structure of Ca_2RuO_4. Calculation results optimizing the structure will be also discussed. [1] F. Nakamura, et al., Phys. Rev. B **65**, 220402(R) (2002). [2] P. L. Alireza, *et al.*: J. Phys.: Condens. Matter **22**, 052202 (2010). [3] T. Oguchi, J. Phys. Soc. Jpn. **78**, 044702 (2009).

1:51PM Q31.00012 Effect of high pressure on transport and structural properties of topological insulator Bi_2Se_3[1] , J.J. HAMLIN, Department of Physics, University of California San Diego, J.R. JEFFRIES, Lawrence Livermore National Laboratory, N.P. BUTCH, P. SYERS, Department of Physics, University of Maryland, D. A. ZOCCO, Department of Physics, University of California San Diego, S.T. WEIR, Lawrence Livermore National Laboratory, Y.K. VOHRA, Department of Physics, University of Alabama at Birmingham, J. PAGLIONE, Department of Physics, University of Maryland, M.B. MAPLE, Department of Physics, University of California San Diego — We report a series of electrical resistivity, magnetotransport, and xray diffraction measurements on the topological insulator Bi_2Se_3 under pressures as high as 34 GPa. The results demonstrate that applied pressure can be used to controllably tune the transport properties without chemical substitution.

[1]Support from the DOE/NNSA and NSF-MRSEC is acknowledged.

Wednesday, March 23, 2011 11:15AM - 2:15PM –

Session Q32 DMP: Focus Session: Optical Properties of Semiconductor and Metal Nanostructures C144

11:15AM Q32.00001 Application of modified phonon confinement model in Raman characterization of Ge nanowires , K. ROODENKO, University of Texas at Dallas, I.A. GOLDTHORPE, P.C. MCINTYRE, Stanford University, Y.J. CHABAL, University of Texas at Dallas — Raman spectroscopy is an attractive tool for characterization of low-dimensional materials, such as carbon nanotubes, graphene sheets or semiconductor nanowires. Phonon confinement model [1,2] was proposed to interpret Raman signal obtained from low-dimensional materials. Due to the finite-size of the nanostructures, the fundamental q∼0 Raman selection rule is relaxed, allowing the contribution from phonons away from the Brillouin-zone center. In this contribution we address several unresolved issues, such as the factors within the confinement function, incorporation of crystallographic orientation, and the interplay between the temperature and the nanostructure size [3]. Application of the modified model to the interpretation of Raman signal from Ge nanowires will be discussed.

11:27AM Q32.00002 Laser-Induced, Local Oxidation of Copper Nanoparticle Films During Raman Measurements , ANGELA R. HIGHT WALKER, GUANGJUN CHENG, IRENE CALIZO, National Institute of Standards and Technology (NIST), Gaithersburg, MD 20899 — The optical properties of gold and silver nanoparticles and their films have been thoroughly investigated as surface enhanced Raman scattering (SERS) substrates and chemical reaction promoters. Similar to gold and silver nanoparticles, copper nanoparticles exhibit distinct plasmon absorptions in the visible region. The work on copper nanoparticles and their films is limited due to their oxidization in air. However, their high reactivity actually provides an opportunity to exploit the laser-induced thermal effect and chemical reactions of these nanoparticles. Here, we present our investigation of the local oxidation of a copper nanoparticle film induced by a visible laser source during Raman spectroscopic measurements. The copper nanoparticle film is prepared by drop-casting chemically synthesized copper colloid onto silicon oxide/silicon substrate. The local oxidation induced by visible lasers in Raman spectroscopy is monitored with the distinct scattering peaks for copper oxides. Optical microscopy and scanning electron microscopy have been used to characterize the laser-induced morphological changes in the film. The results of this oxidation process with different excitation wavelengths and different laser powers will be presented.

11:39AM Q32.00003 Observation of UV Surface-Enhanced Raman Spectra using Ga Nanoparticles , YANG YANG, Department of Physics, Duke University, JOHN CALLAHAN, Army Aviation and Missile RD&E Center, KEVIN LANTZ, Dept of ECE, Duke Univ, JOHN FOREMAN, Army Aviation and Missile RD&E Center, PAE WU, TONG-HO KING, APRIL BROWN, Dept of ECE. Duke Univ, HENRY EVERITT, Dept of Physics/ECE, Duke Univ; Army Aviation and Missile RD&E Center — Ultraviolet (UV) surface enhanced Raman spectra (SERS) are observed for the first time using gallium nanoparticles (Ga NPs). Ga NP ensembles were synthesized on sapphire substrates at room temperature by molecular beam epitaxy. In situ spectroscopic ellipsometry was used to tune the UV local surface plasmon resonance (LSPR) wavelengths of the Ga NP ensembles during deposition. Three samples were prepared with LSPR wavelengths of 325, 295, and 260nm. UV Raman spectra using a 325nm HeCd laser were collected from fixed thicknesses of cresyl violet, poly(3-hexylthiopene), or MEH-CN-PPV that were spin cast onto these three samples, each of which had a NP-free region. A sample¡¯s enhancement was measured by comparing selected Raman signal intensities from the NP-covered and bare surfaces. Enhancements were found to decrease with increasing detuning between the laser and LSPR wavelengths. Similar behavior was observed from Ga NPs after 3 months of exposure to air, demonstrating the resilience of Ga NPs to oxidation.

11:51AM Q32.00004 Electronic origin of photoluminescence from Si nanocrystal embedded in amorphous SiO2 matrix[1] , TIANSHU LI, Department of Civil and Environmental Engineering, George Washington University, FRANCOIS GYGI, Department of Applied Science & Department of Computer Science, University of California, Davis, GIULIA GALLI, Department of Chemistry & Department of Physics, Unversity of California, Davis — Through combining classical molecular dynamics and *ab initio* calculation, we have created composite models of Si nano crystal embedded in SiO_2 amorphous matrices, with the sizes of Si nanocrystals ranging from 1.3 nm $\sim$ 1.9 nm. Electronic structure calculations showed that the band gap of composite structure increases as the size of Si nanocrystal reduces, however the increase of gap is mainly attributed to the *lowering of valence band edge*, with conduction band edge virtually unchanged. It was also found that while the wavefucntions from conduction band edges are extended over the entire Si nanocrystal, those from the valence band edges are mainly distributed near the nanocrystal/matrix interface. Further analysis identified that the valence band edges are dominated by the local distortion of nanocrystal from diamond cubic structure, which increases as both approaching the surface of Si nanocrystal, and decreasing the size of Si nanocrystal. This finding suggests that the local strain induced by surrounding amorphous SiO_2 matrix may play a key role in the photoluminescence of Si nanocrystal/SiO_2 amorphous matrix composite structures.

12:03PM Q32.00005 Enhanced luminescence in terbium-cerium co-doped tin oxide quantum dots , CHRISTIE LAROCHELLE, KELLY MCCUTCHEON, Franklin & Marshall College, REBECCA SOBEL, MIT — SnO_2 quantum dots doped with Tb^{3+} exhibit strong luminescence from the Tb^{3+} dopants due to efficient energy transfer from the SnO_2 donors to the Tb^{3+} acceptor ions. We report results from a study of the effect of co-doping the SnO_2 dots with both Tb^{3+} and Ce^{3+} on the photoluminescence properties of the samples. The dots were synthesized using a sol-gel technique and the Ce^{3+}/Tb^{3+} ratio was varied while keeping the total doping level at 1wt%. X-ray diffraction and TEM results confirm the presence of nanocrystals of less than 10 nm in diameter. Photoluminescence results indicate that the Tb^{3+} ions are incorporated in a crystalline environment and that co-doping with Ce^{3+} enhances the energy transfer efficiency and therefore the intensity of the Tb^{3+} luminescence.

12:15PM Q32.00006 Stabilization of fluorescent silver clusters by RNA homopolymers and their DNA analogs: C,G vs A,T(U) Dichotomy , DANIELLE SCHULTZ, ELISABETH GWINN, UCSB — We show that single-stranded RNA stabilizes fluorescent silver nanoclusters (Ag:RNAs) in aqueous solution, analogous to previously studied Ag:DNAs. To determine whether the different canonical nucleosides play similar roles in stabilizing fluorescent silver species in RNA and DNA hosts, we compare RNA homopolymers of rA,rC,rG and rU to their DNA counterparts, and observe the same base-dependent dichotomy: visible- to IR-emitting silver complexes are stabilized by C and G homopolymers, but not by A or T(U) homopolymers at neutral pH. Shifts in emission wavelengths between Ag:RNA and Ag:DNA analogs show that both base and sugar influence populations of fluorescent species. The data indicate a minimum binding-pocket size of roughly five C or G bases for fluorescent species. These findings open the scope of silver cluster fluorophores to the diversely structured and functional arena of RNA and have implications for rational designs of nucleic acid hosts. Supported by NSF CHE-0848375.

12:27PM Q32.00007 Electronic and Optical Excitations in Perylene Diimide Derived Dye Molecules from First Principles , KOPINJOL BAISHYA, SERDAR OGUT[1], University of Illinois at Chicago, ERSEN METE, Balikesir University, OGUZ GULSEREN, Bilkent University, SINASI ELLIALTIOGLU, Middle East Technical University, Turkey — Halogenated perylene diimide dyes, such as Br-PDI ($Br_2C_{24}H_8N_2O_4$) and their glycine (BrGly) and aspartine (BrAsp) derivatives are known to absorb and emit light in the visible range with high quantum yields, and have good heat and chemical stability. As such, they are promising alternatives to the expensive (Ru-based) metal-driven dye sensitizers for solar cell applications. In this talk, we present results for the electronic structures, quasiparicle gaps, and the absorption spectra of PDI-derived dye molecules BrPDI, BrGly, and BrAsp, computed within the time-dependent density functional theory as well as many body perturbation techniques such as the GW method and the solution of the Bethe-Salpeter equation. In addition to discussing our results for bare molecules, we also present our preliminary studies for the change in their electronic and optical properties when they are attached to stoichiometric and reduced rutile TiO_2 (110) surfaces.

12:39PM Q32.00008 Enhanced light emission via plasmonic and non-plasmonic effects in metal ion-implanted Silicon , AKHILESH SINGH, KAROL GRYCZYNSKI, ARKADII KROKHIN, FLOYD MCDANIEL, ARUP NEOGI, University of North Texas, Department of Physics, Denton, TX, USA — We have observed enhanced photoluminescence from metal implanted nanoscale Silicon light emitters. Low energy (30 keV) Au and Ag metal ions were implanted in crystalline silicon to achieve non-plasmonic and plasmonic enhancement of light emission over a broad spectral range. The emission in the UV region can be significantly enhanced by the surface plasmon (SP) induced radiative recombination process. The recombination of carriers in Si bound exciton is also influenced by transverse optical phonon due to the polarization of the surface of bound exciton complex. The recombination life time of the electron-hole pair as estimated from the time resolved PL measurement changes from $\sim$ 2 ns to 400 ps in the presence of Ag ion induced SP polaritons. The non-resonant emission can be enhanced by electrostatic-image charge effects. The emission in the visible (570 nm) and UV (370 nm) wavelength range can also be significantly enhanced by electrostatic image charge effects induced by Au nanoparticles

12:51PM Q32.00009 Exciton-plasmon and spin-plasmon interactions in hybrid semiconductor-metal nanostructures , ALEXANDER GOVOROV, Department of Physics and Astronomy, Ohio University, Athens, OH, 45701 — Coulomb and electromagnetic interactions between excitons and plasmons in nanocrystals cause several effects: energy transfer between nanoparticles, plasmon enhancement, Lamb shifts of exciton lines, Fano interference. In a complex composed of semiconductor quantum dot and metal nanoparticle, plasmons interact with spin-polarized excitons. This interaction leads to the formation of coupled spin-plasmon excitations and to spin-dependent Fano resonances. If an exciton-plasmon system includes chiral elements (chiral molecules or nanocrystals), the exciton-plasmon interaction is able to create new plasmonic lines in circular dichroism spectra.

1:03PM Q32.00010 Generalized Ellipsometry on Ferromagnetic Sculptured Thin Films. , DANIEL SCHMIDT, TINO HOFMANN, University of Nebraska-Lincoln, KAH MOK, HEIDEMARIE SCHMIDT, Forschungszentrum Dresden-Rossendorf, RALF SKOMSKI, EVA SCHUBERT, MATHIAS SCHUBERT, University of Nebraska-Lincoln — We present and discuss generalized ellipsometry and generalized vector-magneto-optic ellipsometry investigations on cobalt nanostructured thin films with slanted, highly-spatially coherent, columnar arrangement. The samples were prepared by glancing angle deposition. The thin films are highly transparent and reveal strong form-induced birefringence. We observe giant Kerr rotation in the visible spectral region, tunable by choice of the nanostructure geometry. Spatial magnetization orientation hysteresis and magnetization magnitude hysteresis properties are studied using a 3-dimensional Helmholtz coil arrangement allowing for arbitrary magnetic field direction at the sample position for field strengths up to 0.4 Tesla. Analysis of data obtained within this novel vector-magneto-optic setup reveals magnetization anisotropy of the Co slanted nanocolumns supported by mean-field theory modeling.

1:15PM Q32.00011 Coupled Quantum Dot-Metal Nanoparticle Systems: Hybrid Behavior and Excitation Transport , RYAN ARTUSO, University of Maryland-College Park, GARNETT BRYANT, National Institute of Standards and Technology — Transmission of information between qubits for quantum communication and quantum computing will require directed nanoscale transmission where the quality of the information can be maintained. One paradigm proposes to achieve directed nanoscale transmission by coupling qubits, for example in quantum dots, to plasmonic nanoantennas or nanoguides made from metallic nanowires and nanoparticles. We study theoretically the response of hybrid nanostructure molecules consisting of multiple semiconductor quantum dots (SQD), and metal nanoparticles (MNP) subject to an applied optical field. We consider the situation where the SQDs interact directly without an MNP and the case in which the interaction is mediated by a MNP. We find modifications to the previously predicted SQD-MNP hybrid response. We also find a new regime of behavior in which breaking the SQD-SQD identical particle symmetry causes the system to no longer reach a steady state and instead oscillate at a beating frequency. Lastly, we identify the effects that MNP size and shape, and the placement of the SQDs have on the SQD-SQD interaction.

1:27PM Q32.00012 Plasmon Behavior in Gold Nano-dot Media , N. LIMBEROPOULOS, J. DEROV, A. DREHMAN, E. CRISMAN, Air Force Research Laboratory, Hanscom AFB, MA — We present correlations between the plasmon resonance of a gold nano-dots medium suspended in Al_2O_3 and the plasmon resonance of a single layer film of solid gold. We also present the effective medium properties of multi-layered, dot-film media. The gold dots were fabricated on Al_2O_3 substrates by sputter-depositing the gold and then annealing the resultant films. The median dot size ranged from 70 to 250 nm depending on the processing. Successive Au-dot layers were made by depositing Al_2O_3 over the previous dot pattern followed by depositing another gold film, followed by re-annealing. We used attenuated-total-reflection to couple transverse-magnetic optical waves to the plasmon resonance and controlled the degree of coupling by varying the spacing between the dot medium and the coupling prism. The plasmon resonances for the dot media had asymmetric line shapes compared to that for the continuous gold film. We were able to show correlations between that asymmetry and the spatial parameters of the dot/Al_2O_3 media construction. Effective media parameters and the dispersion characteristics for nano-dot/Al_2O_3 bi-layer were determined.

1:39PM Q32.00013 Surface Plasmon Generation by Excitons in Carbon Nanotubes[1] , IGOR BONDAREV, TODOR ANTONIJEVIC, North Carolina Central University — Optical properties of semiconducting carbon nanotubes (CNs) originate from excitons and may be tuned by either electrostatic doping [1], or via the quantum confined Stark effect (QCSE) by means of an electrostatic field applied perpendicular to the CN axis[2]. In both cases exciton properties are mediated by surface plasmon excitations [2,3]. We have shown recently that the QCSE allows one to control the exciton-interband-plasmon coupling in individual CNs and their optical absorption, accordingly [2]. Here, we extend our studies to demonstrate the possibility of low-energy localized surface plasmon generation by optically excited excitons in small-diameter ($\sim$1nm) CNs. The stimulated character of such an energy transfer causes the buildup of the macroscopic population numbers of coherent localized surface plasmons and, as a consequence, high-intensity coherent optical-frequency fields localized at nanoscale, which can be used for various applications, such as near-field nonlinear-optical probing, sensing, or materials nanoscale modification. 1:51PM Q32.00014 Nanocrystal optoelectronic devices by plasmon-based optical trapping , KENNETH EVANS, Rice University, Applied Physics Graduate Program, DANIEL WARD, Rice University, Department of Physics and Astronomy, GAUTAM KINI, MICHAEL WONG, Rice University, Department of Chemical and Biomolecular Engineering, DOUGLAS NATELSON, Rice University, Department of Physics and Astronomy — Optical trapping is an important tool for studying and manipulating nanoscale objects. In conventional laser trapping, the trapping volume is diffraction limited. Recent experiments have shown that subwavelength control of nanoparticles can be achieved by using plasmonic nanostructures, rather than using the laser directly, to generate the electric fields necessary for trapping. We present a numerical model describing the trapping forces on an individual semiconducting nanocrystal in a nanoscale metallic junction, and discuss initial experimental results. Calculations of the fields are performed in COMSOL, a commercial finite element solver package, and the trapping forces are computed using the full Maxwell stress tensor formalism. We propose the use of plasmonic optical trapping in this geometry as a method to fabricate electrically driven, single nanocrystal light-emitting devices.

2:03PM Q32.00015 The Morphology and Evolution of Bipyramidal Gold Nanoparticles for Plasmon-assisted Nanosheet Biosensor[1] , NICHOLAS GEITNER, Miami University, AMOS DEOPKE, MELODIE FICKENSCHER, University of Cincinnati, JAN YARRISON-RICE, Miami University, WILLIAM HEINEMAN, HOWARD JACKSON, LEIGH SMITH, University of Cincinnati — We examine the growth and evolution bipyramidal gold nanoparticles. These particles are then characterized based on their longitudinal LSPR peak and their physical dimensions. Bipyramidal particles are grown using a seed-mediated growth process, and variations in the particles are produced by varying silver nitrate concentration and growth time. While each growth's physical dimensions were well defined and consistent with previous results, two different distinct modes of temporal evolution are observed after the primary growth period. We also observe a distinct linear relationship between tip radius of curvature and wavelength of longitudinal LSPR peak, in agreement with numerical calculations. These particles are to be functionalized and dispersed onto CdS nanosheets for biosensor applications.

Session Q33 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides: Interfaces and Optical Properties C143/149

11:15AM Q33.00001 Engineering exotic phenomena at oxide interfaces[1] , PHILIPPE GHOSEZ, Universite de Liege — Complex transition metal oxides form an important class of compounds, exhibiting a wide variety of functional properties exploited in many applications. Thanks to advances in deposition techniques, these oxides can also nowadays be combined in heterostructures, with a structural quality comparable to what is achieved for conventional semiconductors, and the appearance of new phenomena at the interfaces where oxides with different properties meet brought recently the field to an entirely new level. Such phenomena include, for instance, the appearance of a two- dimensional electron gas at the interface between insulator oxides, the possibility of unexpected coupling between structural instabilities at some interfaces yielding unusual functional properties or the tunneling through ferroelectric and multiferroic barriers. Concentrating on few selected examples, I will illustrate how first-principles calculations can efficiently help the experimentalists to characterize the interfaces between complex transition metal oxides and sometimes guide them toward the design of new interesting heterostructures with exotic properties.

[1]Work funded by the EC-FP7 OxIDes and IAP-Belgian QCN projects.

11:51AM Q33.00002 Harnessing competition in artificially layered ferroelectric superlattices to engineer enhanced piezoelectrics , MATTHEW DAWBER, BENEDIKT ZIEGLER, SARA CALLORI, JOHN SINSHEIMER, Dept of Physics and Astronomy, Stony Brook University, VALENTINO COOPER, Materials Science and Technology Division, Oak Ridge National Laboratory, TAHIR YUSUFALY, KARIN M. RABE, PREMALA CHANDRA, Department of Physics and Astronomy, Rutgers University — First principles calculations by Cooper and Rabe (V. R. Cooper and K.M. Rabe, Phys. Rev. B 79, 180101 (R) (2009)), predicted that in $PbTiO_3/BaTiO_3$ superlattices an enhancement of the d_{33} piezoelectric coefficient could be achieved at a particular ratio of the thickness of the constituent layers. We have fabricated high quality artificially layered $PbTiO_3/BaTiO_3$ superlattices on $SrTiO_3$ substrates (with $SrRuO_3$ bottom electrodes) using an off-axis RF magnetron sputtering technique, allowing us to perform x-ray diffraction, electrical measurements and atomic force microscopy on this system. The experimental results confirm the prediction from first principles calculations, and we apply a Landau theory model as a useful bridge between the first principles predictions and experimental results at elevated temperature. In this work we have demonstrated that by finely balancing competing material properties in artificial heterostructures, desirable properties that exceed those of the parent compounds can be achieved.

12:03PM Q33.00003 Ferroelectrical and Dielectric Properties of $BaTiO_3/Ba_{(1-x)}Sr_xTiO_3$ Superlattices , NORA ORTEGA, ASHOK KUMAR, RAM S. KATIYAR, University of Puerto Rico — Artificially designed superlattices (SL) composed of alternate layers of $BaTiO_3$ (BT) and $SrTiO_3$ (ST) have attracted interests due to the possibility of producing superior and new functional properties, which are attractive for device applications. We have fabricated SL of BT/$Ba_{(1-x)}Sr_xTiO_3$ (BST) with x = 0, 0.3, 0.4, 0.5, 0.6, 0.7, 1, utilizing multi-target by pulsed laser deposition technique. The modulation period (Λ) in all SL was Λ= 80 Å and the total thickness of each SL films were 600 nm. The x-ray diffraction revealed well oriented (00l) perovskite structure and the so-called satellite peaks. The polarized Raman spectra showed the substantial transformation of the ferroelectric E(1TO) soft mode, depending of the ratio of Ba/Sr in BST layer. The dielectric constant of SL showed linear frequency dispersion above of 20 kHz, and their values are in the range of 400 to 900 at 1 kHz, while the tangent loss values were below to 0.1 at 1 kHz. Well defined ferroelectric loop was observed in all the SL at different frequencies (1 kHz-10 kHz), with remanent polarization ($2P_r$) 10 $\mu C/cm^2$. Improvement in saturation in the ferroelectric loop was observed with increase of Ba composition in BST layer. All these superlattices show very low leakage current far above its coercive field.

12:15PM Q33.00004 Artificially layered $PbTiO_3/CaTiO_3$ superlattices , JOHN SINSHEIMER, YOUCEF BENKARA, JONATHAN DALEY, SARA CALLORI, MATTHEW DAWBER, Dept of Physics and Astronomy, Stony Brook University — It has been shown that in artificially layered $PbTiO_3/SrTiO_3$ superlattices, a form of improper ferroelectricity occurs where the rotations of the oxygen octahedra at the interfaces couple with the polar mode and increase the ferroelectric polarization of the material when the layers are very thin. $PbTiO_3/CaTiO_3$ superlattices grown on $SrTiO_3$ substrates are also highly likely to display this kind of behavior, as the $CaTiO_3$ ground state is dominated by rotational distortions. This system should also play host to a competition between in-plane ferroelectricity (as $CaTiO_3$ is subjected to a large tensile strain when grown on $SrTiO_3$) and out-of-plane ferroelectricity (the usual result when in $PbTiO_3$ is grown on $SrTiO_3$). Using off-axis RF magnetron sputtering, we have produced high quality superlattices of $PbTiO_3/CaTiO_3$ with various layer thicknesses on $SrTiO_3$ substrates with $SrRuO_3$ bottom electrodes. The samples were analyzed using x-ray diffraction, electrical measurements, and atomic force microscopy. Our experimental results reveal a fascinating transition region at certain ratios of the relative layer thicknesses.

12:27PM Q33.00005 Polarization switching and dielectric properties of ferroelectric bilayers , MANDANA MEISAMI AZAD, The University of Tulsa, DANIEL TINBERG, The Pennsylvania State University, DONALD WALKO, Argonne National Laboratory, SUSAN TROLIER-MCKINSTRY, The Pennsylvania State University, ALEXEI GRIGORIEV, The University of Tulsa — In this work, we analyze polarization switching and dielectric properties of ferroelectric multilayer thin films of lead zirconate titanate. The interlayer coupling and polarization dynamics of ferroelectric multilayers are largely unknown. The studies of multilayers present a significant interest due to both fundamental understanding of interlayer interactions and practical applications of ferroelectrics in nanoelectronics and nanoelectromechanical systems. It is predicted that unusual switching characteristics and domain configurations such as the antiparallel alignment of the spontaneous polarization in adjacent layers can be observed in these materials. Using electrical measurements and time-resolved x-ray microdiffraction we analyzed physical properties of $PbZr_{0.8}Ti_{0.2}O_3/PbZr_{0.6}Ti_{0.4}O_3$. Strong nonlinearities in piezoelectric and dielectric responses of the bilayer to applied electric fields, which were observed in our experiments, can be explained by unusual polarization domain dynamics and interface charging effects.

12:39PM Q33.00006 Metallic oxides as dielectrics in artificially layered ferroelectric superlattices , SARA CALLORI, Dept. of Physics and Astronomy, Stony Brook University, DONG SU, Center for Functional Nanomaterials, Brookhaven National Laboratory, JOHN SINSHEIMER, MATTHEW DAWBER, Dept. of Physics and Astronomy, Stony Brook University — Artificially structured oxides provide many opportunities to develop systems with novel and tunable properties. $SrRuO_3$ has a metal-insulator transition as a function of thickness, which suggested to us the idea that we could use extremely thin layers (less than 3 unit cells) of $SrRuO_3$ as a novel dielectric component within an artificially layered superlattice system. We have created high quality $PbTiO_3/SrRuO_3$ superlattices by using an off-axis RF magnetron sputtering technique. The samples were characterized by x-ray diffraction, atomic force microscopy, transmission electron microscopy, and electrical measurements. When the $PbTiO_3$ layers are above a certain critical thickness, significant out-of-plane ferroelectricity develops in the system and the overall material has a semiconducting character. In this talk we will present a detailed experimental investigation of the behavior of ferroelectric polarization and domain size as the relative thicknesses of the superlattice layers are varied. Our work serves as a demonstration that a new set of materials, metallic oxides, can be considered for inclusion as novel dielectric layers in ferroelectric superlattices.

12:51PM Q33.00007 Stabilizing ferroelectric polarization of ultrathin BaTiO3 films through interface engineering , XIAOHUI LIU, YONG WANG, PAVEL LUKASHEV, J.D. BURTON, EVGENY TSYMBAL, Department of Physics and Astronomy & Nebraska Center for Materials and Nanotechnology, University of Nebraska, Lincoln, NE 68588, UNIVERSITY OF NEBRASKA–LINCOLN TEAM — Ferroelectric tunnel junctions have recently attracted considerable interest due to their potential for device applications [1]. The main challenge for the implementation of these devices is to stabilize ferroelectricity in nanometer- thick films where depolarizing fields and interface effects play an important role. Here, we report results of first- principles calculations of ferroelectric polarization in epitaxial SrRuO3/BaTiO3/SrRuO3 junctions. We show that the ferroelectric polarization is very sensitive to the surface termination of the electrodes and film thickness. In particular, we find that the presence of RuO2/BaO interface is detrimental to ferroelectricity due to the pinning of polar displacements in BaTiO3 in the direction away from the interface making the polarization of ultra-thin films non- switchable. We find that ferroelectricity can be stabilized by adding a thin layer of SrTiO3 at this interface. A phenomenological model is developed to explain the correlation between ferroelectric properties and junction geometry.

1:03PM Q33.00008 Inverse layer capacitance in perovskite oxide superlattices , XIFAN WU, Temple University, MASSIMILIANO STENGEL, ICMAB(CSIC), Barcelona, DAVID VANDERBILT, Rutgers University — Ferroelectricity is one of the most important functionalities that can be tuned in perovskite oxide superlattices. At fixed displacement field D, the overall polar instability can be accessed by the inverse of the capacitance per basal area as $C^{-1} = \partial V/\partial D$, where V is the potential drop across the supercell.[1] Here we propose that C^{-1} can be further rigorously decomposed into contributions from individual AO or BO_2 layers, giving an *layer inverse capacitance* defined as $c_j^{-1} = \epsilon_0^{-1}(h_j + D\partial h_j/\partial D - \partial p_j/\partial D)$, where h_j and p_j are the layer height and Wannier-based layer polarization[2] of layer j, respectively. We compute the c_j^{-1} in several typical multicomponent perovskite superlattices such as $CaTiO_3/BaTiO_3$ and $PbTiO_3/SrTiO_3$, and demonstrate that they satisfy a *locality* principle: their behavior depends mainly on the local chemical environment (i.e., the identities of neighboring layers). Thus, we show that the c_j^{-1} can provide an insightful *local* analysis of the ferroelectric tendency at interfaces in functional oxide superlattices.

1:15PM Q33.00009 Light-Driven Ferroelectric Polarization Dynamics Probed with Time-Resolved X-ray Scattering , D. DARANCIANG, Stanford University, M. HIGHLAND, H. WEN, Argonne National Lab, N. BRANDT, H. HWANG, M.I.T., J. LARSSON, Lund University, K. SOKOLOWSKI-TINTEN, University of Duisberg-Essen, D. REIS, SLAC, K. NELSON, M.I.T., P. FUOSS, G.B. STEPHENSON, Argonne National Lab, A.M. LINDENBERG, SLAC — We report femtosecond resolution time-resolved x-ray scattering measurements of dynamical changes in the polarization of PbTiO3 (PTO) nanolayers on SrTiO3 (STO) and DyScO3 (DSO) substrates under 400 nm, 40 fs optical excitation. For PTO on STO, an optically-induced polarization enhancement occurs on picosecond timescales that can be associated with a carrier-induced screening of the depolarization field. For PTO on DSO, qualitatively different effects are observed, indicating that the light initially couples to c-domains. We also observe optically-driven ferroelectric to paraelectric phase transitions (and vice versa) near the Curie temperature. The optical response of PTO on STO in the monodomain phase is consistent with a bulk photovoltaic effect. Optical excitation in the stripe phase at 515 C drives strains of order 1 percent, with an associated non-thermal disordering of the stripe domains. For PTO on DSO, temperature-dependent in-plane and out-of-plane structural dynamics are simultaneously captured, allowing the complex coupling between a- and c-domain motions to be mapped out.

1:27PM Q33.00010 Optical Properties of Epitaxial Sr-Ti-O Compounds from First Principles[1] , ROBERT BERGER, JEFFREY NEATON, Molecular Foundry, Lawrence Berkeley National Laboratory — $SrTiO_3$ is a representative of the property-rich perovskite family, and a material whose ability to convert solar photons to H_2 fuel would be more efficient if its wide optical bandgap (3.25 eV) better matched the solar spectrum. The Sr- and Ti-based Ruddlesden-Popper (RP) phases, $Sr_{n+1}Ti_nO_{3n+1}$, are structural modifications of $SrTiO_3$ with potentially useful electronic properties. While bulk growth is limited to $n < 4$ and $n = \infty$ ($SrTiO_3$), thin films of larger finite n structures have been grown epitaxially. In optical experiments, bandgaps of these films decrease monotonically with increasing n.[2] In density functional theory (DFT), however, the $n = \infty$ gap is larger than those for finite $n > 3$. This disagreement could stem from limitations in both experiment and theory. We explore this issue in depth using DFT, many-body perturbation theory, and tight-binding techniques.

[1]This work was done at the Molecular Foundry (LBNL), and supported by the DOE through the Energy Materials Center (Cornell University).

1:39PM Q33.00011 Spectroscopic investigation on the electronic structure of a $5d$ band insulator $SrHfO_3$, YUNSANG LEE, Y.K. SEO, D.J. LEE, Soongsil University, H.J. NOH, Chonnam National University — We investigated the high-energy electronic structure of a 5d perovskite $SrHfO_3$. By using optical spectroscopy and O $1s$ x-ray absorption spectroscopy, the values of electronic structure parameters are estimated properly. In particular, the crystal field splitting energy, which is closely associated with the $p-d$ hybridization strength, is as high as 5 eV, and the Sr $4d$ bands appear to be strongly mixed with the Hf $5d$ bands. Moreover, the emission spectra with a 325 nm light excitation exhibit a sizable strength near 500 nm at low temperatures due to oxygen defects. These findings in $SrHfO_3$ are compared with electronic properties of similar compounds, $3d$ $SrTiO_3$ and $4d$ $SrZrO_3$.

1:51PM Q33.00012 Precise measurements of index of refraction at Brewster angle , WEI-TAI HSU, Department of Physics, Lamar University, CHRISTIAN BAHRIM, Research Center for Adaptive Data Analysis, National Central University, Chungli, Taiwan — A simple and accurate method is proposed for finding the index of refraction of solid and liquid dielectrics using the polarization of light reflected by a dielectric surface near the Brewster angle. The method allows measuring the Brewster angle with a precision better than 0.01 degrees and the index of refraction with a precision of 0.0001 by running a parabolic fit of the parallel component of the reflectance normalized to the total reflectance in a narrow region of about 15 degrees around the Brewster angle [1]. Our measurement is about 100 times better than other existing methods. The best precision in our measurements is achieved when a computer-based filtering procedure of the experimental reflectance is used during the data acquisition [2]. Our apparatus allows measuring small variation of the index of refraction, such as due to the change in temperature or the interference with another E-field.

Wednesday, March 23, 2011 11:15AM - 2:15PM –
Session Q34 DMP: Focus Session: Interfaces in Complex Oxides - Polar Interfaces C141

11:15AM Q34.00001 Effect of polar interfaces on thin-film ferroelectricity , YONG WANG, MANISH NIRANJAN, KAROLINA JANICKA, Department of Physics and Astronomy, University of Nebraska, Lincoln, NE, USA, JULIAN VELEV, Department of Physics, University of Puerto Rico, USA, MIKHAIL ZHURAVLEV, Kurnakov Institute for General and Inorganic Chemistry, Moscow, Russia, SITARAM JASWAL, EVGENY TSYMBAL, Department of Physics and Astronomy, University of Nebraska, Lincoln, NE, USA — Based on first-principles and model calculations we investigate the effect of polar interfaces on the ferroelectric stability of thin-film ferroelectrics [1]. We consider Vacuum/LaO/BaTiO3/LaO, LaO/BaTiO3, and SrRuO3/LaO/BaTiO3/LaO heterostructures as representative systems, where a LaO monolayer at the interface with a TiO2-terminated BaTiO3 produces a polar interface. The polar interfaces create an intrinsic electric field which produces electric polarization in BaTiO3 directed into the interior of the BaTiO3 layer. This creates a ferroelectric dead layer near the interfaces that is non-switchable and thus detrimental to ferroelectricity. The effect is stronger for a larger effective ionic charge at the interface and longer screening length due to a stronger intrinsic electric field that penetrates deeper into the ferroelectric. The predicted mechanism for a ferroelectric dead layer at the interface controls the critical thickness for ferroelectricity in systems with polar interfaces. [1] Y. Wang et al., Phys. Rev. B. 82, 094114 (2010).

11:27AM Q34.00002 Lattice screening of the polar catastrophe in $KNbO_3/BaTiO_3$ interfaces , PABLO GARCIA-FERNANDEZ, PABLO AGUADO-PUENTE, JAVIER JUNQUERA, CITIMAC, Universidad de Cantabria, Avda. de los Castros s/n, E-39005 Santander, Spain — The discovery of a bidimensional electron gas (2DEG) in the interface between two insulating lattices like $LaAlO_3$ and $SrTiO_3$ has triggered much interest around bidimensional conductivity in these heterostructures. In this work we study polar interfaces between $KNbO_3$ (KNO) and $BaTiO_3$ (BTO), equivalent from the layer by layer charge point of view to the LAO/STO. In particular we focus on: (a) the possibility of formation of a 2DEG, (b) its interaction with the ferroelectric distortions of these materials, and (c) the effect of external electric fields. For this, we have performed Density Functional Theory calculations for a KNO(m)/BTO($2m$)/KNO(m) slab (m= width in unit cells) with different kinds of interfaces (n or p). We find that a 2DEG is formed only in the unrelaxed configuration, where there is no rumpling between the atoms of a given layer. However, when geometry is relaxed, $KNbO_3$ polarizes and the 2DEG is effectively screened. This effect is robust even under application of electric fields of moderate size. Finally, we find that an easily-rotated [110] in-plane polarization, driven by electrostatic effects, appears in the vicinity of the KO/TiO_2-type interface even thought the system is under in-plane compressive strain.

11:39AM Q34.00003 Evolution of the Band Alignment at Polar Oxide Interfaces , J.D. BURTON, EVGENY TSYMBAL, University of Nebraska - Lincoln — The next generation of electronic devices and systems are envisioned to exploit the multifunctional properties of complex oxide interfaces. Fundamental to this endeavor is an understanding of the electronic band alignment across such interfaces. Engineering this band alignment in all-oxide systems by properly preparing the interfaces is highly desirable. Here we explore an all-oxide metal-insulator interface between, $SrTiO_3$ (STO), and $La_{1-x}A_xMnO_3$ (LAMO), where A is a divalent cation [1]. The doping level of the manganite, x, offers a parameter which can be varied to engineer the band alignment. We use first-principles density-functional calculations to determine the evolution of the band alignment at $La_{0.7}A_{0.3}MnO_3|La_{1-x}A_xO|TiO_2|SrTiO_3$(001) heterointerfaces as the interfacial composition, $La_{1-x}A_x$, is varied. The position of the valence band maximum (VBM) with respect to the Fermi level increases linearly with interfacial composition x due to the linear dependence of the screened electrostatic interface dipole on the interfacial ionic charge. The importance of the polar nature of LAMO and its background dielectric properties will be discussed. Our results are agreement with recent experimental data reported by Hikita *et al* [2].

11:51AM Q34.00004 Polarization discontinuities and compensation mechanisms at oxide-oxide interfaces , MASSIMILIANO STENGEL, ICMAB (CSIC), DAVID VANDERBILT, Rutgers University — Polar interfaces between insulating perovskite materials have been the subject of special attention in the past few years, following the discovery of two-dimensional conductivity in $LaAlO_3/SrTiO_3$. In this talk I will introduce the problem by using general concepts of macroscopic electrostatics, in the framework of the modern theory of polarization [1]. Based on these ideas, I will show how we can understand the origin and the spatial distribution of the metallic electron gas in terms of few basic ingredients, which can be readily extracted from bulk calculations of $SrTiO_3$. These results provide an unified view over the factors determining the confinement and decay of the compensating free charge within arbitrary electrical boundary conditions.

12:03PM Q34.00005 First-principles study of the band offset at the anatase $TiO_2/SrTiO_3$ (001) interface , ALEXANDER DEMKOV, HOSUNG SEO, CHANDRIMA MITRA, The University of Texas at Austin — Band offsets at the interface of two oxides have recently attracted considerable attention in the context of the high-k dielectric gate stack in field effect transistors. The problem is also important in oxide heteroepitaxy. Recently, Chambers et al. reported that using the x-ray photoelectron spectroscopy no valence band offset is found between anatase TiO_2 (001) and $SrTiO_3$ (001). In this talk we describe the electronic structure at the $TiO_2/SrTiO_3$ (001) interface. We calculate the valence band offset to be 0.94 eV in the Schottky limit and 0.76 eV when the oxides are brought in contact, in apparent contradiction with experiment. A careful analysis of the electronic structure evolution from the bulk region of $SrTiO_3$ to the interface and through anatase all the way to the surface allows us to clarify the experimental results. We compare local density approximation results to those obtained with the GW method.

12:15PM Q34.00006 Many-body effects on the capacitance of multilayers made from strongly correlated materials[1] , SIMON HALE, JIM FREERICKS, Georgetown University — Recent work by Kopp and Mannhart on novel electronic systems formed at oxide interfaces has shown interesting effects on the capacitances of these devices. In our work, we identify effects on the capacitance that stem from many-body physics and from other factors. In order to do so, we employ inhomogeneous dynamical mean- field theory to calculate the capacitance for multilayered nanostructures. These multilayered nanostructures are composed of semi-infinite metallic leads coupled via a strongly correlated dielectric barrier region. The barrier region can be adjusted from a metallic regime to a Mott insulator through adjusting the interaction strength. We are able to vary the barrier thickness allowing comparison to the expected geometric capacitance. We also examine the effects of varying the temperature, potential difference, screening length, chemical potential, and electron filling. We set up a system that depletes the charge from the barrier so that the capacitance approaches the geometric capacitance, allowing us to study nonlinear effects.

12:27PM Q34.00007 Electronic Reconstruction at oxide interfaces: from an electron-hole bilayer to a spin-polarized 2DEG , ROSSITZA PENTCHEVA, University of Munich — The origin of conductivity at the interface between the band insulators $LaAlO_3$ and $SrTiO_3$ has been subject of continued interest and debate. Density functional theory calculations can provide not only insight into the underlying mechanisms but also allow one to identify further parameters to tune the electronic reconstruction in this system in view of device applications. In particular, the potential build up induced by the polarity of the $LaAlO_3$ film is found to be counteracted by a strong lattice polarization in the $LaAlO_3$ film. The latter allows the system to remain insulating for the first several $LaAlO_3$ layers before a crossover to an electronic reconstruction takes place at around 4-5 monolayers (ML). We demonstrate that, owing to a dispersive surface state, an additional $SrTiO_3$ capping layer can trigger the insulator-to-metal transition already at two ML of $LaAlO_3$. As a result, two spatially separated sheets of carriers emerge: electrons at the interface and holes at the surface that are only 1 nm apart and can be used to study excitonic phenomena. Furthermore, we explore the effect of a metallic contact layer on top of the $LaAlO_3$ film which not only eliminates the potential build up but turns out to be a promising way to enhance the carrier concentration and possibly to realize a spin-polarized electron gas at the interface. Work in collaboration with W.E. Pickett, K. Otte, V. Ruiz López.

1:03PM Q34.00008 Electronic properties of the conducting interface in $LaAlO_3/SrTiO_3$ heterostructures - the view from x-ray spectroscopies , M. SING, G. BERNER, A. MULLER, J. WALDE, F. PFAFF, R. CLAESSEN, Wurzburg University, Germany, H. HOLLMARK, L.-C. DUDA, Uppsala University, Sweden, S. PAETEL, C. RICHTER, J. MANNHART, Augsburg University, Germany, S. THIESS, W. DRUBE, HASYLAB, Hamburg, Germany, S.A. PAULI, C.W. SCHNEIDER, P.R. WILLMOTT, Paul Scherrer Institut, Villigen, Switzerland — Novel phases with often unexpected electronic and magnetic properties may form at the interfaces of epitaxial heterostructures composed out of complex oxides. A case in point is $LaAlO_3$ (LAO) on TiO_2-terminated $SrTiO_3$ (STO), for which a conducting interface has been found if the LAO thickness exceeds 3 unit cells. Although there is growing evidence that the origin is intrinsic and involves a transfer of charge to the interface to compensate the electric potential due to the polar nature of LAO there are a number of open issues. These refer, e.g., to the LAO thickness dependence of the charge carrier concentration, the potential gradient and the role of defects in LAO, the band alignment and bending at the interface, the lateral mobility or confinement of the interface charge carriers etc. We address these questions from the viewpoint of high-energy spectroscopies, i.e. hard x-ray photoelectron spectroscopy and resonant inelastic soft x-ray scattering, both of which we applied for the first time to these materials.

1:15PM Q34.00009 Internal electric field in $SrTiO_3/LaAlO_3$ heterostructures probed with hard x-ray photoemission spectroscopy , ERIK SLOOTEN, University of Amsterdam, Z. ZHONG, H. MOLEGRAAF, University of Twente, S. DE JONG, F. MASSEE, E. VAN HEUMEN, University of Amsterdam, M. GORGOI, Helmholtz Zentrum Berlin, G. RIJNDERS, D. BLANK, M. HUIJBEN, P. KELLY, University of Twente, M. S. GOLDEN, University of Amsterdam — The origin of the conducting layer at the interface between insulating $SrTiO_3$ (STO) and $LaAlO_3$ (LAO) is still widely debated. The alternatingly charged layers within the LAO blocks give rise to an internal electric field, which at some point has to be screened. This built-in potential is predicted to close the LAO bandgap at a critical thickness of 4 layers of LAO. Using hard x-ray photoemission spectroscopy we study the core levels of these systems as a function of the LAO layer thickness. By measuring the La 4d and Al 2s core levels with respect to the Sr 3d core level we carefully determine the core level shifts for samples with 2 to 6 layers of LAO. Although the observed shifts are an order of magnitude smaller than predicted, we do find an interesting increase of the core level shifts for samples with more than 4 layers. We perform DFT slab calculations to show that oxygen vacancies can significantly reduce the potential build-up. Our results suggest that in real materials the electronic reconstruction is pre-empted by other effects of which oxygen vacancies are one possibility.

1:27PM Q34.00010 Interfacial Electronic Properties of $LaAlO_3/SrTiO_3$ superlattice Probed with Hard X-ray Photoemission , DI-JING HUANG, NSRRC, Taiwan, YING-YI CHU, Dept. NHTU, Taiwan, JAN-CHI YANG, Dept. of Materials Science and Engineering, Taiwan, KU-DING TSUEI, NSRRC, Taiwan, WEN-CHUNG LIU, Dept of Phys, NHTU, Taiwan, YEN-FA LIAO, NSRRC, Taiwan, YING-HAO CHU, Dept of Materials Science and Engineering, NCTU, Taiwan, JONAS WEINEN, STEFANO AGRESTINI, VALERIO OLIANA, HAO TJENG, MPI-CPfS, Dresden, Germany, C.T. HUANG, NSRRC, Taiwan — Unexpected electronic and magnetic properties at interfaces between distinct transition-metal oxides have received much attention recently. The electronic phase at the interface of a heterostructure often differs from those of the sandwiching bulks. For instance, the interface between two band insulators $LaAlO_3$ and $SrTiO_3$ exhibits rich interfacial phases, drastically different from their original bulks. Here we will present measurements of hard X-ray photoemission and x-ray absorption on a $LaAlO_3/SrTiO_3$ superlattice to address the issue of interfacial electron at interfaces.

1:39PM Q34.00011 ARPES studies in LaTiO3/SrTiO3 heterostructures[1] , YOUNG JUN CHANG, Advanced Light Source and Fritz-Haber-Institut, LUCA MORESCHINI, ALS, YONG SU KIM, ALS and Hanyang University, ANDREW L. WALTER, ALS and Fritz-Haber-Institut, DAVIDE INNOCENTI, ALS and University of Rome "Tor Vergata", AARON BOSTWICK, GEOFFREY A. GAINES, ALS, KARSTEN HORN, Fritz-Haber-Institut, ELI ROTENBERG, ALS — Electronic band structure of LaTiO3/SrTiO3 heterostructures was studied using angle resolved photoemission spectroscopy (ARPES). LaTiO3 films, grown by in situ pulsed laser deposition (PLD) on beamline 7.0.1 at Advanced Light Source, exhibit a thickness-dependent phase transition from the correlated metallic interface to Mott insulator. We observed the quasi-particle peak at the Fermi level explaining the metallic interface for ultrathin LaTiO3, and the band gap opened for thick LaTiO3 similar to the bulk. We compare the thickness dependent electronic structure with theoretically calculated phase diagram (S. Okamoto and A. J. Millis, Nature 428, 630 (2004)).

[1]Work supported by U.S. DOE (DE-AC02-05CH11231 for ALS), the Max Planck Society, and Swiss National Science Foundation (PBELP2-125484).

1:51PM Q34.00012 Direct Spectroscopic Evidence of Charge Reversal at PZT/LSMO Heterointerface , CHUNG-LIN WU, PEI-WEI LEE, YI-CHUN CHEN, Department of Physics, National Cheng Kung University, Taiwan, LO YUEH CHANG, CHIA-HAO CHEN, National Synchrotron Radiation Research Center, Taiwan, CHEN-WEI LIANG, Department of Materials Science and Engineering, National Chiao Tung University, Taiwan, PU YU, QING HE, RAMAMOORTHY RAMESH, Department of Physics, University of California, Berkeley, USA, YING-HAO CHU, Department of Materials Science and Engineering, National Chiao Tung University, Taiwan — At the heterointerface of a top ferroelectric $Pb(Zr_{0.2}Ti_{0.8})O_3$ (PZT) ultrathin film and a bottom $La_{0.7}Sr_{0.3}MnO_3$ (LSMO) electrode, we used continuous synchrotron radiation photoelectron spectroscopy (SR-PES) to probe *in situ* and demonstrated that the interfacial charges are reversible and their affected valence-band barrier height becomes modulated on switching the polarization in the top layer. By monitoring the core-level shifting of the buried LSMO layer under continuous illumination of synchrotron radiation, we directly observed a temporal screening of polarization induced by the photon-generated carriers in the top PZT layer. This dynamic characterization of the core-level shifting of the buried layer demonstrates an effective method to probe the electric conduction and ferroelectric polarization of an ultra-thin ferroelectric oxide thin film.

2:03PM Q34.00013 Scanning tunneling microscopy investigation of the electronic structure across $LaAlO_3/SrTiO_3$ heterointerfaces , YA-PING CHIU, BO-CHAO HUANG, Department of Physics, National Sun Yat-sen University, JAN-CHI YANG, YING-HAO CHU, Department of Materials Science and Engineering, National Chiao Tung University — Atomically controlled polarity discontinuities induced unusual charge states have been found in the model interface between two insulating perovskite oxides, $LaAlO_3$ and $SrTiO_3$. In this work, by using cross-sectional scanning tunneling microscopy, local and direct evidence of nontrival local structural and electronic information across the heterointerfaces are investigated. A combination of scanning tunneling spectroscopy analysis with atomic resolution across the $LaAlO_3/SrTiO_3$ heterointerface reveals how the oppositely charged atomic planes undergo electronic reconstructions and introduce a built-in electric field across the polar $LaAlO_3$ thin films grown on $SrTiO_3$ substrates. Further analysis of the related electronic and geometrical properties not only realizes the properties both in bands of electron and hole characters across the $LaAlO_3/SrTiO_3$ heterointerfaces but also helps to elucidate the mechanism of the interface conductivity.

Wednesday, March 23, 2011 11:15AM - 2:15PM –

Session Q35 DCMP: Topological Insulators: Interactions C140

11:15AM Q35.00001 Fragile Mott Insulators[1] , STEVEN KIVELSON, Department of Physics, Stanford University, HONG YAO, Department of Physics, University of California Berkeley — We prove that there exists a class of crystalline insulators, which we call "fragile Mott insulators" which are not adiabatically connected to any sort of band insulator provided time-reversal and certain point-group symmetries are respected, but which are otherwise unspectacular in that they exhibit no topological order nor any form of fractionalized quasiparticles. Different fragile Mott insulators are characterized by different nontrivial one-dimensional representations of the crystal point group. We illustrate this new type of insulators with two examples: the d-Mott insulator discovered in the checkerboard Hubbard model at half-filling and the Affleck-Kennedy-Lieb-Tasaki insulator on the square lattice.

[1]This work was supported, in part, by DOE grants DE-FG02-06ER46287 and DE- AC02- 05CH11231

11:27AM Q35.00002 Correlation effects in quantum spin Hall states: a Quantum Monte Carlo study , THOMAS C. LANG, MARTIN HOHENADLER, FAKHER F. ASSAAD, Department of Theoretical Physics & Astrophysics, University of Wuerzburg — We consider a quantum spin hall insulator as realized by the Kane-Mele model with spin orbit coupling λ supplemented by a Hubbard U term. On the basis of projective auxiliary field quantum Monte Carlo simulations on lattice sizes up to 12×12, we map out the magnetic phase diagram. Beyond a critical value of $U > U_c$ the quantum spin Hall insulating state is unstable towards magnetic ordering. At $U < U_c$ we study the spin, charge and single particle dyanmics of the helical edge state by retaining the Hubbard interactions only on the edge of a ribbon. As U_c is approached we observe a substantial depletion of low-lying spectral weight in the dynamical charge structure factor, and a robust signature of the helical edge state in the single particle spectral function.

11:39AM Q35.00003 Quantum Monte Carlo simulations on interaction effects in the 2D Kane-Mele-Hubbard model , DONG ZHENG, The Department of Physics, Tsinghua University, CONGJUN WU, GUANG-MING ZHANG, The Department of Physics, University of California, San Diego — Interaction effects in topological insulators remain an open question. We have proved that the determinant quantum Monte-Carlo simulation on the two dimensional Kane-Mele model augmented by the Hubbard interaction is free of the sign-problem. Consequentially, the interplay between band topology and strong interaction can be studied at a high numeric precision. The process how the topological band insulator evolves into the antiferromagnetic Mott insulator as increasing interaction strength is studied by calculating both the bulk and edge electronic properties. The possibility of an exotic topological Mott-insulator is examined.

11:51AM Q35.00004 Interactions and doping effects in a topological insulator , STEPHAN RACHEL, KARYN LE HUR, Yale University, Department of Physics, New Haven, CT 06520 — We investigate the effect of repulsive and attractive onsite interactions on a Quantum Spin Hall Insulator (QSHI). For repulsive interactions, we show that the topological phase is stable up to quite large interactions $U \sim t$ before the system reaches a magnetically ordered phase [1]. For attractive interactions, we discuss superconductivity in a doped QSHI and compare it with a doped trivial band insulator. We also consider the effect of spin orbit coupling to zero–mode bound states at vortex cores.

[1] S.Rachel and K.Le Hur, Phys. Rev. B 82, 075106 (2010).

12:03PM Q35.00005 Mott Physics at the Boundaries of Topological Insulators[1] , AMAL MEDHI, PRAMOD KUMAR VERMA, VIJAY SHENOY, H. R. KRISHNAMURTHY, Indian Institute of Science, Bangalore — We address how the nature of linearly dispersing edge states of a topological insulating solid evolves with increasing electron-electron correlation engendered by a Hubbard like on-site repulsion. We report studies on strips (2D) and slabs (3D) of varying widths and thicknesses of topological insulators described by model Hamiltonians using an inhomogeneous slave rotor mean-field theory. Motivated by these studies, we construct variational wavefunctions with approriate Gutzwiller-Jastrow correlations and study them using the Monte-Carlo method. These studies reveal the width/thickness dependence of the critical on-site repulsion that obtains an edge Mott insulating state, and uncover the mechanism of the Mott transition in such systems.

[1]Work supported by DAE, SRC and DST, India

12:15PM Q35.00006 Interaction and distortion driven topological phases in multi-band lattices[1] , JUN WEN, MEHDI KARGARIAN, GREGORY FIETE, University of Texas at Austin — In this work we investigate the phase diagram of $5d$ transition metal oxides on the pyrochlore lattice. In particular, the competition between Coulomb interaction, spin-orbit coupling and distortion are discussed. Spin-orbit coupling entangles the spin and t_{2g} orbitals giving rise to doublet $j = 1/2$ and quadruplet $j = 3/2$ states. While most pervious works discussed the doublet manifold, we focus on the quadruplet manifold which is relevant for several perovskites. Coulomb interaction is taken into account using the slave-rotor mean field theory and we obtain a phase diagram for this model, which includes exotic phases. We extend the model by including lattice distortion which further splits the quadruplet $j = 3/2$ manifold. Under a variety of distortions a topological phase is stabilized, and we discuss how the overall phase diagram is altered with lattice distortions.

[1]We gratefully acknowledge funding from ARO grant W911NF-09-1-0527.

12:27PM Q35.00007 Magnetic responce in the quantized spin Hall system with electron correlation , JUN GORYO, Institute of Industrial Science, the University of Tokyo, NOBUKI MAEDA — We investigate the magnetic response in the quantized spin Hall (SH) phase of layered-honeycomb lattice system with intrinsic spin-orbit coupling $\lambda_{\rm SO}$ and on-site Hubbard U. The response is characterized by a parameter $g = 4Ua^2d/3$, where a and d are the lattice constant and interlayer distance, respectively. When $g < (\sigma_{xy}^{s2}\mu)^{-1}$, where σ_{xy}^{s} is the quantized spin Hall conductivity and μ is the magnetic permeability, the magnetic field inside the sample oscillates spatially. The oscillation vanishes in the non-interacting limit $U \to 0$. When $g > (\sigma_{xy}^{s2}\mu)^{-1}$, the system shows perfect diamagnetism, i.e., the Meissner effect occurs. We find that superlattice structure with large a is favorable to see these phenomena. We also point out that, as a result of Zeeman coupling, the topologically-protected helical edge states shows weak diamagnetism which is independent of g.

12:39PM Q35.00008 Electrostatic Effects in Topological Insulators , DIMITRIS GALANAKIS, Nanyang Technological University, Singapore, TUDOR STANESCU, West Virginia University — We study electrostatic effects in topological insulators generated by non-uniform charge distributions and by external electric fields. The system is modeled using a tight-binding model and the Coulomb interaction is included at a mean-field level within a self-consistent calculation. The self-consistent charge profiles are calculated numerically for both insulating and low density metallic systems. Using this approach, we investigate the bending of the bulk bands due to the presence of surface states and of charged surface impurities and the effect of applying gate voltages to topological insulator films of variable thickness. Our results shed new light on the potential differences between surface- and bulk-sensitive measurements of topological insulators.

12:51PM Q35.00009 Coulomb drag between helical edge states , VLADIMIR ZYUZIN, GREGORY FIETE, University of Texas at Austin — We theoretically investigate the Coulomb drag between the edge states of two quantum spin Hall systems. Using an interacting theory of the one-dimensional helical edge modes, we show that the drag vanishes at second order in the inter-edge interaction, where it is typically finite in other systems, due to the absence of backscattering within the edges. However, in the presence of a small external magnetic field, the drag is finite and scales as the fourth power of the magnetic field, a behavior that sharply distinguishes it from other systems. We obtain the temperature dependence of the drag for regimes of both linear and quadratic edge dispersion in the presence of a finite field. This work was financially supported by ARO under Grant No. W911NF-09-1-0527. V. A. Zyuzin and G. A. Fiete, Phys. Rev. B 82, 113305 (2010).

1:03PM Q35.00010 Effect of electron-electron interaction on surface transport in three-dimensional topological insulators , HRIDIS PAL, DMITRII MASLOV, University of Florida — We study the effect of electron-electron interaction on the temperature dependence of surface charge transport in three dimensional topological insulators. In conventional two dimensional materials at small temperatures, the presence or absence of T^2 dependence in the resistivity is found to depend on the Fermi surface geometry- whether it is concave or convex and whether it is simply connected or multiply connected. In the recently discovered three-dimensional topological insulators such as Bi_2Te_3, Bi_2Se_3, and Sb_2Te_3 the Fermi surface of the two dimensional surface states, owing to the underlying lattice symmetry, changes curvature from convex to concave as a function of energy. The contribution from electron-electron interaction is therefore expected to affect the resistivity in these materials which we investigate in this study.

1:15PM Q35.00011 Cooper Pair Injection into Topological Insulators , KOJI SATO, University of California, Los Angeles — We theoretically study tunneling of Cooper pairs (CP's) from a superconductor spanning a two-dimensional topological insulator strip into its helical edge states. The coherent low-energy electron-pair tunneling sets off positive nonlocal current cross-correlations along the edges, which reflect an interplay of two quantum-entanglement mechanisms. First of all, superconducting spin pairing dictates a CP partitioning into the helical edge liquids, which transport electrons in the opposite directions for opposite spin orientations. Luttinger-liquid (LL) correlations for the electron-density fluctuations are, furthermore, forcing paired electrons to enter into opposite insulator-strip edges, revealing CP spin entanglement in the inter-edge current correlations. At the same time, the LL behavior, in the absence of Fermi-liquid leads, fractionalizes electrons injected at a given edge into counter-propagating charge pulses carrying definite fractions of the elementary electron charge. The superconductivity as well as LL correlations thus introduce positive current cross-correlations, which reveal a wealth of information about both subsystems. Sato, Loss, Tserkovnyak, arXiv:1003.4316v1. To be published in Physical Review Letters

1:27PM Q35.00012 Instabilities of quadratic band crossing points , STEFAN UEBELACKER, CARSTEN HONERKAMP, RWTH Aachen University — The variation of the orbital composition of bands around band crossing points near the Fermi level can generate interesting effects. In particular, rather simple interactions can give rise to the spontaneous formation of topological insulating phases (S. Raghu et al., Phys. Rev. Lett. 100, 156401 (2008)). In contrast with Dirac points, quadratic band crossing points offer the advantage of a nonzero density of states at the crossing point, and instabilities occur already at small interaction strengths. Here, we present results of functional renormalization group calculations for models with a quadratic band crossing point and discuss the possibilities for nontrivial insulating phases induced by local interactions.

1:39PM Q35.00013 Fractionalization and topological point defects in the charge-ordered kagome lattice[1] , ANDREAS RUEGG, GREGORY A. FIETE, The University of Texas at Austin — The charge-ordered state on the kagome lattice shows some features which are closely related to two-dimensional topological insulators. This motivated us to study a two-dimensional system of spin-polarized fermions on the kagome lattice at filling fraction $f = 1/3$ interacting through a nearest-neighbor interaction V using the unrestricted mean-field approach. Above a critical interaction strength V_c, a charge-density wave is stabilized. We find that topological point defects in the charge order bind a fractional charge. The value of the bound charge is $1/2$ as long as an effective sublattice symmetry is preserved but changes continuously with the strength of the symmetry-breaking field. Moreover, we compute the confinement potential between two fractionally charged defects and argue that the polaron state, formed upon doping the charge-density wave, can be viewed as a bound state of two defects.

1:51PM Q35.00014 Stability of spontaneous quantum Hall state in the Triangular Kondo-lattice model , YASUYUKI KATO, IVAR MARTIN, CRISTIAN BATISTA, Theoretical Division, Los Alamos National Laboratory — We study the behavior of the quarter-filled Kondo lattice model on a triangular lattice by combining a zero-temperature variational approach and finite-temperature Monte-Carlo simulations. For intermediate coupling between itinerant electrons and classical moments $\mathbf{S}_j$, we find a thermodynamic phase transition into an exotic spin ordering with uniform scalar spin chirality and $\langle \mathbf{S}_j \rangle = 0$. The state exhibits spontaneous quantum Hall effect. We also study how its properties are affected by the application of an external magnetic field.

2:03PM Q35.00015 Quantum corrections to conductivity in topological insulator thin films: Weak localization and electron-electron interaction , ASHLEY DASILVA, JIAN WANG, Penn State University, CUI-ZU CHANG, Chinese Academy of Sciences and Tsinghua University, KE HE, XU-CUN MA, Chinese Academy of Sciences, QI-KUN XUE, Tsinghua University, JAINENDRA JAIN, NITIN SAMARTH, MOSES CHAN, Penn State University — We study quantum corrections to transport in topological insulator candidate Bi_2Se_3, with and without doping with Pb. We study thin films with the expectation that the topological surface states will have substantial contribution to transport. Our observations are not consistent with the theory of diffusive transport of noninteracting electrons, because while the temperature dependence is consistent with weak localization, the magnetoresistance is positive, suggestive of weak anti-localization. We show that the theory including quantum corrections from both electron-electron interaction and disorder is qualitatively correct in all magnetic field directions that we have studied. We mention the implications of our results to the possibility of conducting surface states.

Session Q36 DMP: Focus Session: Graphene Structure, Dopants, and Defects: Nanoparticles

11:15AM Q36.00001 Manipulating graphene mobility and charge neutral point with ligand-bound nanoparticles as charge reservoir[1] , DEQI WANG, Department of Physics & Astronomy, University of California, Riverside, XINFEI LIU, LE HE, YADONG YIN, DI WU, JING SHI — In this work, we first demonstrate a significant enhancement in carrier mobility in SiO2-supported graphene decorated with a layer of ligand-bound nano-particles (NPs) such as iron oxide, titanium dioxide, or cadmium selenide acting as a charge reservoir. By transferring charges between graphene and the NP reservoir through the molecules, we show a remarkable reversible tunability in mobility (4,000 – 19,000 cm2/Vs) in the same device, which unambiguously proves that the charged impurity scattering is the prevailing mechanism for graphene mobility. In addition, the charge neutral point can also be independently tuned over a wide gate voltage range. Finally, we study the thermopower of graphene sample with different mobility. By properly taking account of the high temperature effects, we obtain good agreement between the Boltzmann transport theory and our experimental data.

[1]This work was supported in part by a DOE grant.

11:27AM Q36.00002 Imaging grain boundaries in monolayer graphene by transmission electron microscopy , KWANPYO KIM, Department of Physics, UC Berkeley, ZONGHOON LEE, National Center for Electron Microscopy, Lawrence Berkeley National Laboratory, WILLIAM REGAN, Department of Physics, UC Berkeley, C. KISIELOWSKI, National Center for Electron Microscopy, Lawrence Berkeley National Laboratory, M. CROMMIE, A. ZETTL, Department of Physics, UC Berkeley — Using transmission electron microscopy (TEM), we investigate the structure of grain boundaries in large-area monolayer polycrystalline graphene sheets at micron and atomic length scales. At micron scale, grain boundary mapping is performed by electron diffraction and dark field imaging techniques. The atomic scale imaging by an aberration-corrected ultra-high resolution TEM reveals an alternating pentagon-heptagon structure along the high-angle tilt grain boundary.

11:39AM Q36.00003 Electromagnetic interaction of graphene with nanoparticles: applications to nanoscale imaging spectroscopy and plasmonics , L.M. ZHANG, A.H. CASTRO NETO, Boston U, MICHAEL FOGLER, UCSD — Interaction of graphene-covered substrate with a nearby nanoscale particle is studied theoretically. Graphene is shown to induce broadening and frequiency shifts of electromagnetic resonaces (cavity modes) localized near the particle. The effect is strongly enhanced for substrates that possess narrow surface polariton excitations. In turn, the coupling to polaritons modifies the spectrum of graphene plasmons. The theory is applied to model scanning near-field optical microscopy (SNOM) experiments where the role of nanoparticle is played by the sharp tip of the scanned probe. The origin of the extraordinary fine spatial resolution of SNOM is explained and proposals for detecting the novel modes by SNOM in the infrared and THz domains are outlined. Also discussed are other applications, including infrared and Raman scattering from graphene covered by a layer of colloidal nanoparticles.

11:51AM Q36.00004 Interlayer Physics in Few Layer Graphenes[1] , E.J. MELE, University of Pennsylvania — Few layer graphenes (FLG's) represent a family of materials with physical properties distinct from those of single layer graphene and bulk graphite. Their electronic behavior is determined by the nature of electronic motion between layers and by the interactions of electrons in different layers. This talk reviews our experimental and theoretical work studying aspects of nanoparticle growth on FLG's that are determined by this interlayer physics. We observe and analyze: (1) a systematic film thickness dependence of the surface potential for FLG's deposited on SiO_2 substrates, (2) a related thickness dependence of the sizes of gold nanoparticles that nucleate on the exposed surface of FLG's and (3) a shape instability for growing nanoparticles formed from low workfunction metals adsorbed on FLG's. Finally we discuss some novel aspects of the interlayer electronic motion that are controlled by the rotational registry of neighboring layers.

[1]Work done in collaboration with: Y. Dan, S.S. Datta, A.T. Johnson, N.J. Kybert, Z. Luo, T. Ly, L.A. Somers, D.R. Strachan and N. Zimbovskaya.

12:27PM Q36.00005 Energetics and Electronic Structure of Transition Metal Adatoms and Clusters on Graphene[1] , CHRISTOPHER PORTER, DAVID STROUD, Ohio State University — Using density functional theory (DFT), we calculate both the atomic arrangement and electronic structure of transition metal (TM) adatoms, and clusters of adatoms, on graphene. We use a periodic arrangement of unit cells which typically include about 64 C atoms. For Fe on graphene, we have found that the stable position of the adatom is above the center of a hexagon of C and that most of the relaxation in the graphene occurs in the six C atoms closest to the adatom. We use DFT to map out a potential energy surface for Fe adatoms on graphene at any point in the unit cell, allowing an estimate of the energy barrier for an adatom to hop from one energy minimum to another. We also calculate the lowest energy configurations of pairs and larger clusters of TM adatoms on graphene. Finally, we have calculated the electronic structure and density of states associated with the adatoms and clusters on graphene, and have extended these calculations to spin- dependent properties, using a spin density functional approach. These results should be relevant to electronic and spin transport properties of graphene, both of which are expected to be strongly influenced by TM adatom impurities.

12:39PM Q36.00006 Doping efficiencies and physisorption of small molecules on graphene , ALEXANDER SAMUELS, DAVID CAREY, University of Surrey — Ab initio calculations have been employed to study the doping efficiencies of NO_2, NO and NH_3 on graphene. We have used both the local density approximation (LDA) and the generalised gradient approximation (GGA) to obtain the molecular binding energies and have employed the Hirshfield charge transfer method to calculate the charge transfer. Spin polarised calculations were employed for the open shell molecules (NO and NO_2) and we explored the effects of different adsorption sites and orientations. It was found that for all orientations of the molecule and using both LDA and GGA functionals that the adsorption of NO_2 results in p type doping of graphene with 0.06 e transferred to the molecule. For NO, LDA calculations show a p type behaviour with 0.03 e transferred per molecule but both n and p type doping of 0.003 – 0.004 e/molecules is calculated using a GGA functional. Finally for NH_3 both donor and acceptor behaviour (0.03 – 0.05 e/molecule) is calculated. In all cases the origin of the doping is related to the relative position of the HOMO and LUMO molecular orbitals with respect to the graphene Dirac point and low energy density of states. The effect of molecular adsorption on electron scattering is also discussed.

12:51PM Q36.00007 Surface Functionalization of Graphene Field Effect Transistors with Polyhistidine-Tagged Proteins[1] , YE LU, JOSEPH MITALA, JONG-HSIEN LIM, MITCHELL LERNER, ZHENGTANG LUO, NICHOLAS KYBERT, BRETT GOLDSMITH, BOHDANA DISCHER, A.T. CHARLIE JOHNSON, University of Pennsylvania, PHYSICS AND ASTRONOMY TEAM, BIOCHEMISTRY AND BIOPHYSICS TEAM — We have developed a facile and reliable method to covalently functionalize the surface of graphene field effect transistors (FETs) with polyhistidine-tagged proteins We demonstrated success of chemical functionalization by both atomic force microscopy (AFM) and Raman spectroscopy. Additionally, we characterized the electronic properties of graphene FETs at successive functionalization stages. The specificity enabled by such functionalization, along with the two dimensional nature and intrinsic high sensitivity of graphene, facilitates the emergence of graphene as a promising candidate in surface biochemistry research as well as graphene-based biosensor applications.

[1]Funding: NSF-NSEC/NBIC DMR-0425780

1:03PM Q36.00008 First principles simulations of molecules and nanostructures subjected to ion irradiation[1] , KALMAN VARGA, SERGIY BUBIN, BIN WANG, SOKRATES PANTELIDES, Vanderbilt University — In the framework of real-time real-space time-dependent density functional theory complemented with classical molecular dynamics for ions, we have studied the behavior of small molecules and nanostructure fragments, such as graphene sheets, irradiated by charged energetic particles. In particular, we have investigated the importance of electronic excitations and examined the regime when bond breaking (or defect formation) occurs. Based on the microscopic description of these processes, several quantities that are of interest for ion beam physics have been determined, such as the amount of energy transferred to the target system and the distribution of this energy between electronic excitations and vibrational motion.

[1]This work has been supported by NSF grants ECCS-0925422 and CMMI-0927345 and DTRA grant HDTRA1-10-1-0016

1:15PM Q36.00009 Point and Line Defect-mediated Binding of Metal Nanoparticles to Graphene , IOANNA FAMPIOU, ASHWIN RAMASUBRAMANIAM, University of Massachusetts Amherst — The synthesis of well dispersed, size-controlled metal nanoclusters on carbon supports is highly desirable since such clusters have been shown to possess enhanced catalytic activity and selectivity in a variety of chemical reactions. However, metal clusters interact rather weakly with defect-free carbon supports and can coarsen over time leading to loss of surface area and thence catalytic activity. Defects in carbon supports play an important role in enhancing metal-carbon bonding, thereby reducing the propensity for cluster coalescence. Using a combination of density functional theory and empirical potential simulations, we examine the interaction of metal Pt clusters with point (vacancies, holes) and line defects (dislocations, grain boundaries) in graphene. We compare and contrast the binding energies and diffusivities of clusters bound at defects and on pristine graphene. Our results suggest possible avenues for controlling the dispersion of Pt catalyst clusters on carbon supports via defect engineering.

1:27PM Q36.00010 Molecular Mechanics on Graphene Surface and its Detection[1] , KABEER JASUJA, NIHAR MOHANTY, VIKAS BERRY, Kansas State University — In this talk, we demonstrate that the light-induced reversible mechanical motion of an azo-molecule-tethered on graphene can be sensitively detected electronically by motion-induced molecular-gating of graphene (without external gate). The *in-situ* mechanical actuation of the azo-molecule is shown to redistribute the fermionic density *via* due to the change in the proximity of electron-rich benzene moiety of the azo molecule. The results demonstrate that the ultra-sensitive platform offered by graphene makes it possible to electrically detect molecular-scale mechanics. We envision that this research will enable development of next-generation graphene based actuating systems with applications including FETs, optoelectronic-switches and nano-pistons.

Wednesday, March 23, 2011 11:15AM - 2:15PM –

Session Q37 DMP: Focus Session: Graphene Structure, Dopants, and Defects: Transport II

C146

11:15AM Q37.00001 Quantum motion of electrons and holes in the random puddle landscape of graphene[1] , ENRICO ROSSI, Department of Physics, College of William and Mary — The transport properties of graphene, especially close to the Dirac point, have puzzled physicists since its discovery in 2004. Only recently a fairly complete understanding of transport in graphene has emerged [1]. The interplay of disorder, gapless nature of the dispersion, and chirality of the quasiparticles induces the anomalous transport properties of graphene close to the Dirac point. In particular, in presence of long-range disorder the carrier density landscape close to the Dirac point breaks up in electron-hole puddles. In this highly inhomogeneous density landscape the standard theoretical approaches to transport are not valid. I will present a transport theory for graphene, and bilayer graphene, that is able to properly take into account the strong disorder-induced density inhomogeneities. The theory has three main features: *1)* it treats disorder microscopically and can therefore take into account its long-range nature, *2)* it provides a fully quantum mechanical analysis of transport, *3)* it is able to model experimentally relevant sizes. In particular the theory presented can be used to calculate the transport properties in the crossover regime, particularly relevant for graphene, between the ballistic and the diffusive regime. I will present results for single layer graphene and bilayer graphene. In addition I will discuss the transport properties of disordered graphene p-n-p junctions for which the semiclassical approaches are inadequate and the full quantum transport analysis is necessary.

11:51AM Q37.00002 Interplay between density inhomogeneity and temperature in graphene transport[1] , QIUZI LI, EUYHEON HWANG, SANKAR DAS SARMA, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, MD 20742 — Motivated by recent experimental measurements of the temperature-dependent resistivity in graphene, we study the transport properties in monolayer graphene in the presence of electron-hole puddles induced by charged impurities in the environment. We explain the apparent insulating behavior of temperature-dependent conductivity observed in low mobility samples using an analytic statistical theory, which takes into account the non-mean-field nature of transport in the highly inhomogeneous density and potential landscape. In particular, the existence of puddles allows local activation of carriers in low density samples, mimicking an insulating temperature dependence in graphene conductivity.

[1]Work supported by ONR-MURI, NRI-NSF-SWAN and CNAM.

12:03PM Q37.00003 Electron scattering in graphene by a correlated charged impurities[1] , MICHAEL FUHRER, JUN YAN, JIANHAO CHEN, SHUDONG XIAO, Center for Nanophysics and Advanced Materials, Univesity of Maryland — We study charge transport in graphene with correlated charged impurities. Potassium is deposited on graphene in ultra-high vacuum at temperatures below 20 K, and the conductivity of graphene is measured as a function of carrier density in situ. Upon heating, the potassium ions order due to repulsive interactions, resulting in significant improvement of device mobility due to decrease of long range scattering. The charge density dependence of the conductivity becomes increasingly non-linear with increase of annealing temperature of the potassium/graphene. We find the experimental carrier-density-dependent conductivity in good agreement with a model of correlated charged impurities including a Gaussian-broadened structure factor at a finite wavevector corresponding to the potassium lattice.

12:15PM Q37.00004 Tunneling between two independently contacted graphene layers , CHRISTOPHER CORBET, SEYOUNG KIM, DAVID C. DILLEN, BABAK FALLAH, MICHAEL RAMON, EMANUEL TUTUC, SANJAY BANERJEE, The University of Texas at Austin — We study the tunneling between two overlapped, independently contacted graphene monolayers. We use micromechanical exfoliation to deposit graphene monolayers on separate substrates. Using electron beam lithography (EBL) patterning and etching we isolate the two monolayers and remove the multilayer graphene in their close proximity. Once patterned, one monolayer was removed from the substrate and manually aligned to the other monolayer with an overlap region of a few square micrometers. EBL and metal deposition were used to define hall bars on the two separate monolayers. This design allows the extraction of each sheet's mobility and density using standard four-point resistance measurements. Using a finite element model, we calculate the current flow in each layer, as well as in between the two layers. The tunneling resistance is modeled as a contact resistance between the two graphene layers in this overlap region. We extract an upper limit for the specific tunneling resistance between the two graphene layers of 1.4E-4 Ohms*cm^2. We discuss the current density and potential dependence on the shape of the overlap region.

12:27PM Q37.00005 Electron Hole Asymmetry in Graphene Coupled to an SiO2 Substrate , ROBERT HIGGINBOTHAM, University of Notre Dame, NAN SUN, GERALD ARNOLD, STEVEN RUGGIERO — The conductance of graphene generally exhibits an asymmetry in the electron and hole branches. We propose a contribution to this asymmetry that is based upon the coupling between the graphene and an SiO2 substrate. Treating the coupling in the tight-binding approximation, we calculate an exact Green's function for the coupled graphene/SiO2 system.

12:39PM Q37.00006 Electron-hole interference in graphene[1] , ATIKUR RAHMAN, JANICE WYNN GUIKEMA, SOO HYUNG LEE, NINA MARKOVIC, Johns Hopkins University — The crystal symmetry of graphene gives rise to massless Dirac low-energy quasiparticles which are described by a two-component spinor that has contributions from two interpenetrating sublattices. As a result, the electron and hole states are interconnected, in sharp contrast to conventional semiconductors. Through the Aharonov-Bohm effect, we demonstrate that the electrons and holes in graphene exhibit quantum interference with each other. Our device is made of a graphene ring in contact with gold leads. A top gate on one arm of the ring independently controls the carrier type and concentration in that arm, while the back gate acts on both arms. We observe clear Aharonov-Bohm oscillations (overall visibility $\sim$10%) in the magnetoresistance when the charge carriers are holes in one arm and electrons in the other arm. This indicates phase coherence between the electrons and holes in the two arms of the interferometer. Phase coherence is further substantiated by our observations of $T^{-1/2}$ temperature dependence of the oscillation amplitude.

[1]This work is supported in part by NSF DMR 0547834 (CAREER) and DMR 0520491 (MRSEC).

12:51PM Q37.00007 Measurements of the energy gap in biased bilayer graphene[1] , CONOR PULS, YING LIU, Physics Department, The Pennsylvania State University — The application of bilayer graphene in logic-based electronics necessitates the demonstration of reliable bandgap opening, a matter complicated by charge inhomogeneity and midgap states due to local impurities and other disorder. We use dual-gated field effect transistor (FET) and planar tunnel junction devices prepared on mechanically exfoliated bilayer graphene flakes to probe the temperature dependent resistivity and density of states near the charge neutrality point. In both devices, the Fermi level and theoretical bandgap width are simultaneously controlled with a perpendicular displacement field. We report that at high displacement fields and with the Fermi level at the charge neutrality point, the temperature dependence of the resistivity follows a simple thermal activation across a gap width of up to 110 meV at high temperatures. Low temperature transport is dominated by hopping channels whose presence also increase conductivity at high temperatures, reducing the achievable σ_{ON}/σ_{OFF} ratio, a value of great interest for FET devices. We explore the role of charged impurities found in the deposited dielectric in limiting FET performance in this respect.

[1]Work supported by DARPA under the CERA program.

1:03PM Q37.00008 A Unified Description of the DC Conductivity of Monolayer and Bilayer Graphene Based on Resonant Scatterers , AIRES FERREIRA, J. VIANA-GOMES, University of Minho, Portugal, JOHAN NILSSON, University of Gothenburg, Sweden, EDUARDO R. MUCCIOLO, University of Central Florida, USA, NUNO M.R. PERES, University of Minho, Portugal, ANTONIO H. CASTRO NETO, Boston University, USA, and National University of Singapore — We show that a coherent picture for the dc conductivity of monolayer and bilayer graphene emerges from considering that strong short-range potentials are the main source of scattering in these two systems. The origin of the strong short range potentials may lie in adsorbed hydrocarbons at the surface of graphene. The equivalence between results based on the partial wave description of scattering, the Lippmann-Schwinger equation, and the T-matrix approach is established. Scattering due to resonant impurities close to the neutrality point is investigated via a numerical computation of the Kubo formula using a kernel polynomial method. We find that realistic adsorbates originate impurity bands in monolayer and bilayer graphene close to the Dirac point. In the midgap region, a plateau of minimum conductivity of about e^2/h (per layer) is induced by the resonant disorder. In bilayer graphene, a large adsorbate concentration can develop an energy gap between midgap states and high energy states. As a consequence, the conductivity plateau is supressed near the edges and a "conductivity gap" takes place.

1:15PM Q37.00009 Dynamic Screening and Spectral Functions in Bilayer Graphene[1] , RAJDEEP SENSARMA, EUYHEON HWANG, SANKAR DAS SARMA, Condensed Matter Theory Center, University of Maryland, College Park — We study the dynamic screening of Coulomb interactions in a bilayer graphene system within Random phase approximation. We derive an analytic expression for the dielectric function of the system and study the dispersion and damping of low energy plasmon modes. The quadratic dispersion and chirality of bilayer graphene systems lead to a plasmon dispersion which is distinct both from 2D electron gas and monolayer graphene plasmons. We also look at the effects of dynamic screening on the single particle spectral function of the system. We determine the quasiparticle weight, the effective mass and the damping of quasiparticles, which give a complete description of the low energy spectral function of the system.The compressibility of the system is also obtained from the self-energy renormalization of the chemical potential. We find that the presence of the second band leads to a well screened effective interaction, leading to much smaller renormalization of the Fermi liquid parameters in comparison to a 2D electron gas. However, the dynamic nature of the screening is very important in obtaining the single particle properties of this system.

[1]The authors acknowledge support from CNAM, Univ. of Maryland, and US-ONR MURI

1:27PM Q37.00010 Electron transport properties of bilayer graphene , KOSTYANTYN BORYSENKO[1], [1] Department of Electrical and Computer Engineering, North Carolina State University, Raleigh, NC 27695-7911, JEFFREY MULLEN[2], [2] Department of Physics, North Carolina State University, Raleigh, NC 27695-8202, XIAODONG LI[1], YURIY SEMENOV[1], JOHN ZAVADA[1], MARCO BUONGIORNO NARDELLI[2,3], [3] CSMD, Oak Ridge National Laboratory, Oak Ridge, TN 37831, KI WOOK KIM[1] — We investigate the role of different phonon scattering mechanisms in determining the electron transport properties of bilayer graphene (BLG). The ever-present electron-phonon interaction imposes the limitations on transport characteristics of any device and thus, must be always taken into account. However, in a realistic device setup, when BLG is laid (or epitaxially grown) on the top of a substrate, extrinsic scattering mechanisms (due to charged impurities, surface polar phonons, etc.) will dominate. The electron coupling with surface polar phonons of the substrate is always present and this scattering mechanism can be dominant. Using first principles approach (density functional perturbation theory) we calculate the electron-phonon matrix elements of BLG and estimate the intrinsic electron scattering rates. We show that the transport properties of the free-standing BLG resemble those of the bulk graphite. Using the Monte Carlo simulation we estimate the low-field mobility and saturation velocity of the free-standing BLG, as well as BLG on various substrates (SiC, SiO_2, HfO_2).

1:39PM Q37.00011 Dual Gating of Suspended Graphene Devices via Contactless Gates , JAIRO VELASCO JR., LEI JING, GANG LIU, PHILIP KRATZ, YONGJIN LEE, WENZHONG BAO, JEANIE LAU — Monolayer and Bilayer graphene devices with local electrostatic gates present a rich platform for both academic and application driven inquiry. Realization of the veselago lensing effect and band gap engineering are a few of the most dazzling and promising physical phenomena that these systems are predicted to host. However, a major roadblock in this quest is the strict requirement of exceedingly clean samples. We have developed a method to fabricate suspended top gates above a freestanding graphene flake to address this challenge. Using this technique we demonstrate dual gating of a suspended graphene flake. We will discuss the latest experimental progress towards the electrical transport of such a device in the zero-magnetic field regime, as well as in the quantum Hall regime.

1:51PM Q37.00012 Current Annealing of Suspended Graphene Atomic Membranes , FENGLIN WANG, UCR Department of Physics and Astronomy, JAIRO VELASCO JR., ZENG ZHAO, HANG ZHANG, PHILIP KRATZ, LEI JING, WENZHONG BAO, CHUNNING LAU — Using a multi-level lithographical technique, we are able to suspend graphene membranes coupled to vast majority of electrode materials. The device's mobility is significantly improved upon current annealing. By combining transport measurement with in-situ SEM imaging, we are able to monitor morphological changes in graphene and correlate with its current-voltage characteristics, thus optimizing the current annealing process.

2:03PM Q37.00013 Pulsed current-voltage measurements of GFETs[1] , INANC MERIC, CORY DEAN, ANDREA YOUNG, PHILIP KIM, KENNETH SHEPARD, Columbia University — Pulsed current-voltage measurements are used to measure high-bias characteristics of graphene field-effect transistors (GFET). In contrast to standard DC measurements, current saturation for channel lengths as small as 100 nm is observed when measured by this method. Our results indicate that hot carrier injection into traps in the gate oxide masks saturating characteristics in standard DC measurements. Devices exhibit constant transconductance and output conductance with scaling channel length, despite a variation in low field mobility, supporting a velocity saturation model due to optical phonon scattering.

Wednesday, March 23, 2011 11:15AM - 2:03PM –

Session Q38 DMP DPOLY GERA: Focus Session: Organic Electronics and Photonics – Morphology in polymer-based solar cells A130/131

11:15AM Q38.00001 Structural measurements of polymer-fullerene blend films for organic photovoltaics , DEAN DELONGCHAMP, NIST — Organic photovoltaic (OPV) technology has the potential to greatly lower the cost of solar cell fabrication by enabling ink-based deposition of active layers. In bulk heterojunction (BHJ) OPV devices, the power conversion efficiency critically depends on the distribution of the polymer absorber and the fullerene electron acceptor (e.g., the blend morphology). I will describe measurement methods to probe the structure of OPV devices, with a focus on the morphology of the BHJ layer. For example, the vertical distribution of absorber and electron acceptor in BHJ films follows segregation behavior similar to that of miscible polymer blends. The top (air) interface becomes rich in the polymer absorber, whereas the bottom interface composition depends on the substrate surface energy. Thin film transistors fabricated from BHJs can therefore exhibit ambipolar or hole-only transport depending on the dielectric, because of different interfacial segregation. We extend these results to practical photovoltaic devices by comparing BHJs cast upon hole transport layers that have similar work functions but different surface energies. This study includes the application of variable angle spectroscopic ellipsometry (VASE) to BHJ films, and emphasizes the importance of absorber anisotropy and vertical heterogeneity in the optical model. Additional results will describe the nanometer-scale structure in the BHJ interior. The application of solid-state nuclear magnetic resonance (SS-NMR) can reveal details about the segregation of absorber and acceptor in a BHJ film. Nanoscale BHJ morphology information can also be collected using tomographic transmission electron microscopy (TEM). Together these measurements allow us to reveal a detailed picture of BHJ morphology, explain how the morphology originates from materials and processing choices, and relate the morphology to device performance and stability.

11:51AM Q38.00002 Tuning Rod-Rod Interactions in Poly(3-alkylthiophene) Derivatives , BRYAN BOUDOURIS, VICTOR HO, RACHEL SEGALMAN, University of California, Berkeley — Poly(3-alkylthiophene) (P3AT) derivatives are used commonly in polymer semiconducting applications. However, during the coating of P3AT thin films strong intermolecular interactions generally lead to the formation of semiconducting fibers. This prevents the formation of long-range ordered domains and complicates analysis of structure-property relationships in P3AT-containing devices (e.g., organic photovoltaic cells). Here, we show rod-rod interactions can be controlled by rational polythiophene side chain design. The effects of side chain passivation are evidenced by a depressed melting temperature and the presence of a liquid crystalline region. We show also that while the rod-rod interactions are lowered significantly in a polythiophene derivative with a branched side chain relative to straight chain P3ATs, the optoelectronic properties remain approximately constant. Importantly, this reduced melting temperature allows for the real-time evolution of a P3AT crystal structure at room temperature to be monitored on an experimentally convenient time scale. These structural data correlate well with field-effect charge carrier mobility measurements and provide a path for studying the mechanism of ordering in plastic electronics.

12:03PM Q38.00003 Polymer/Polymer Heterojunctions for Ambipolar Charge Transport in Organic Electronics , FELIX KIM, SELVAM SUBRAMANIYAN, SAMSON JENEKHE, University of Washington — Understanding of charge transport in polymer semiconductor heterojunctions is of basic interest in developing high-performance organic optoelectronic devices based on multicomponent polymer semiconductors. We report ambipolar charge transport in thin films of layered heterojunctions and bulk heterojunctions of solution-processable unipolar polymer semiconductors. Selective solubility of the polymer semiconductors, poly(thiazolothiazole)s and ladder-type poly(benzobisimidazo-benzophenanthroline), in organic and acidic solvents enabled the sequential deposition or blending of the polymer semiconductors. Charge carrier mobilities of 0.001-0.01 cm2/Vs were observed for both electrons and holes in the polymer/polymer heterojunction field-effect transistors. Thin film deposition and processing with various solvents are effective to improve charge-carrier mobilities by a factor of 100-1000. We have investigated the effects of the processing methods on morphology, and photophysical and charge transport properties of the polymer semiconductor heterojunctions. Integrated circuits and solar cells based on the polymer semiconductor heterojunctions are also demonstrated.

12:15PM Q38.00004 The role of donor-acceptor intermixing in the performance of polymer-polymer OPVs , ELENI PAVLOPOULOU, STEPHANIE LEE, CHANG SU KIM, YUEH-LIN LOO, Department of Chemical and Biological Engineering, Princeton University, ZHIHUA CHEN, ANTONIO FACCHETTI, Polyera Corporation, MICHAEL F. TONEY, Stanford Synchrotron Radiation Lightsource — We investigated the effect of donor-acceptor intermixing in bulk-heterojunction active layers on device performance of polymer-polymer organic photovoltaics (OPVs). Poly(3-hexylthiophene) (P3HT) was blended with poly{[N,N'-bis(2-octyldodecyl) -naphthalene-1,4,5,8-bis(dicarboximide)-2,6-diyl]-alt-5,59-(2,29-bithiophene)} (PNDI) and P3HT/PNDI films were spin-cast from dichrolobenzene, a good solvent for PNDI; chlorobenzene, a good solvent for P3HT; and xylene, a bad solvent for both. The short-circuit current densities and device efficiencies vary with casting solvent quality; devices with active layers cast from xylene exhibit the highest efficiencies while those cast from dichlorobenzene the lowest. Grazing Incidence X-ray Diffraction show that intermixing on a molecular scale increases with decreasing dissolution of the polymers in the parent solutions. Accordingly, increasing intermixing enhances device efficiencies.

12:27PM Q38.00005 Phase purity in organic solar cells , BRIAN COLLINS, ELIOT GANN, LEWIS GUIGNARD, North Carolina State University, XIAOXI HE, CHRISTOPHER MCNEILL, University of Cambridge, HARALD ADE — To date, the device function of organic bulk heterojunction solar cells has been commonly interpreted to arise from two interpenetrating, phase-separated donor and acceptor materials with charge separation of excitons occurring at discrete interfaces. However, little attention has been paid to phase purity and the consequences of a mixed phase on the operation of devices. To probe this possibility and its implications, the miscibility of common fullerenes in (3-hexylthiophene) (P3HT) and a number of new low bandgap polymers including PCDTBT have been measured directly via x-ray absorption spectroscopy in a scanning transmission x-ray microscope on films brought to thermodynamic equilibrium. A mixed amorphous phase is always observed, along with a fullerene-rich phase and possibly a pure crystalline polymer phase if the polymer is able to crystallize. For example, grazing incidence x-ray scattering shows no intercalation of fullerenes into P3HT crystallites, while amorphous portions of the polymer contain ∼20 wt.% of the fullerene. In fact, all systems tested to date have failed to exhibt a pure amorphous polymer phase, suggesting that the device paradigm of pure phases and discrete interfaces requires modification.

12:39PM Q38.00006 Diffusion rates and crystallization of phenyl-C61-butyric acid methyl ester in poly(3-hexylthiophene)[1] , L. GUIGNARD, B. COLLINS, J. SEOK, H. ADE, North Carolina State University — Bulk heterojunction (BHJ) solar cells based on poly(3-hexylthiophene) (P3HT) and phenyl-C61-butyric acid methyl ester (PCBM) are an important model system for studying organic solar cell operation. Recent experiments reveal that PCBM is partially miscible in the amorphous regions of P3HT [1-3], implying that P3HT:PCBM devices have three phases. The miscibility depends on temperature and regioregularity of the P3HT. To better understand the influence of P3HT regioregularity and molecular weight on the the P3HT:PCBM system, diffusion rates of PCBM are determined as a function of regioregularity of P3HT and temperature with visible light microscopy by analyzing the growth of the PCBM depletion region near PCBM crystals or agglomerates. Lower diffusion constants are found for less crystalline regiorandom P3HT than highly regioregular P3HT. The shape and growth behavior of PCBM crystal or agglomerate is also found to vary greatly.

12:51PM Q38.00007 Structural evolution in polythiophene-fullerene mixtures , ENRIQUE GOMEZ, DEREK KOZUB, KIARASH VAKHSHOURI, The Pennsylvania State University — The morphology of organic semiconductor mixtures employed as the active layer of organic solar cells is a result of the complex interplay between the crystallinity of the constituents and the chemical incompatibility. Given that device performance can depend critically on the morphology of the active layer, efforts aimed identifying at the critical parameters for the structure formation process are important for the development of high-performance devices. We demonstrate that polythiophene-fullerene mixtures are partially miscible and that the crystallization of the electron donor drives the characteristic length scales of the structure. By modeling fullerene as a solvent for polythiophene, we have estimated the Flory-Huggins interaction parameter from measurements of the melting point depression of polythiophene. The miscibility between poly(3-hexylthiophene) (P3HT) and fullerene at P3HT volume fractions greater than 0.4 leads to a severe suppression of the crystallization of fullerene. Our efforts have enabled us to develop a hypothesis for the structure formation process in polythiophene/fullerene mixtures.

1:03PM Q38.00008 Miscibility Study of PCBM/P3EHT Organic Photovoltaics via Small Angle Neutron Scattering , WEN YIN, Department of Chemistry, University of Tennessee, BRYAN MCCULLOCH, RACHEL SEGALMAN, Department of Chemical Engineering, University of California , Berkeley, MARK DADMUN, Department of Chemistry, University of Tennessee — Organic photovoltaics (OPV) attracted considerable interest as lightweight, inexpensive, and easily processable replacement of inorganic photovoltaics. Current results indicate that the morphology of these photovoltaic materials is essential to their solar energy conversion efficiency but a detailed and fundamental understanding is absent. In this paper, the miscibility and structure of P3EHT/PCBM composites with varying PCBM loading level are investigated via small angle neutron scattering (SANS). With P3EHT having a melting temperature below 100°C, SANS experiments of the blends are conducted above the melting point to unequivocally determine the miscibility of PCBM and P3EHT without the added complexity of polymer crystals. Our SANS results show that blends with 20 and 50 wt% PCBM exhibit dramatically larger scattering at low-Q regime relative to 10 and 15wt% PCBM samples. This result implies that the miscibility limit of PCBM and P3EHT lies between 15:85 and 20:80. Further analysis is underway to correlate these results to OPV efficiency.

1:15PM Q38.00009 Characterization and Improvement on the Morphology in Polymer-Based Solar Cells , HAO SHEN, WENLUAN ZHANG, BRETT GURALNICK, MICHAEL MACKAY, University of Delaware, BRIAN KIRBY, CHARLES MAJKRZAK, National Institute of Standards and Technology — Polymer-based solar cells are promising for their cost-effective solar energy, yet this technology is still far from practical application owing to its low energy conversion efficiency. It has been known that the morphology in the active layer, or the nano-scaled intermixing between the polymer and fullerene derivative, is critical to the device performance. We have quantitatively measured the morphology in one of the most-studied polymer-based solar cells consisting of poly(3-hexylthiophene) (P3HT) and [6,6]-phenyl-C61-butyric acid methyl ester (PCBM), by means of neutron and x-ray scattering techniques. In particular, the effects of thermal and co-solvent-assisted annealing on the PCBM cluster formation and vertical distribution are characterized. Basing on the observations, we are proposing a new design of solar cell architecture to approach a more controlled morphology in the active layer, by utilizing a thermodynamically-driven assembly of fullerenes onto the surface of silica microspheres. This presentation will focus on its application in the P3HT:PCBM system.

1:27PM Q38.00010 Investigation of fullerene concentration profile in polymer based solar cell by using magnetic contrast neutron reflectivity , WENLUAN ZHANG, Department of Materials Science and Engineering, University of Delaware, BRIAN KIRBY, National Institute of Standards and Technology Center for Neutron Scattering, MICHAEL MACKAY, Department of Materials Science and Engineering, University of Delaware, DEPARTMENT OF MATERIALS SCIENCE AND ENGINEERING, UNIVERSITY OF DELAWARE COLLABORATION, NATIONAL INSTITUTE OF STANDARDS AND TECHNOLOGY CENTER FOR NEUTRON SCATTERING COLLABORATION — Poly(2,5-bis(3-tetradecyllthiophen-2-yl)thieno[3,2-b] thiophene) (pBTTT) has recently caused great interest as the electron donor in organic photovoltaics. It was demonstrated that fullerene molecules intercalate between side-chains of this semiconducting polymer creating a stable crystalline structure, so, a large concentration of fullerene must be used relative to the polymer to promote phase separated electron conductive pathways. We used state-of-the-art neutron reflectivity methods, with the application of magnetic contrast variation, to investigate the concentration profile of [6,6]-phenyl-C_{71}- butyric acid methyl ester($PC_{71}BM$) in order to understand the internal structure within the active layer. The $PC_{71}BM$ concentration profile greatly depends on the weight ratio of polymer to fullerene. XRD and other data are also used to show the morphology change of active layer.

1:39PM Q38.00011 Correlation of Structure and Roughness with Fabrication Conditions of P3HT-PCBM Bilayer Interfaces with X-Ray Reflectometry[1] , STUART KIRSCHNER, MING-LING YEH, NATHANIEL SMITH, HOWARD KATZ, DANIEL REICH, Johns Hopkins University — Organic semiconductors, including poly(3-hexylthiophene) (P3HT) and polymer-phenyl-C61-butyric acid methyl ester (PCBM), are considered as promising materials for applications such as photovoltaics, transistors, sensors, thermoelectrics, optoelectronics, and magnetoelectronics. In many cases, the interface plays a crucial role in device performance and in determining the origins of many effects. In this research, neat bilayers of P3HT-PCBM, and PCBM blended with polystyrenes, were studied with X-ray reflectometry (XRR), atomic force microscopy, and ultraviolet-visible spectroscopy. A polymer with a high atomic number element was included to improve the scattering length density contrast, and provided improved XRR resolution. A mobility of order 10^{-4} cm^2/V*s was maintained. The effect of different annealing, solvent, spin coating, and other fabrication conditions, was explored. Applicability of XRR to study interface characteristics, in these systems, will be discussed.

1:51PM Q38.00012 Polymer Solar Cells, Deconstructed , YUEH-LIN LOO, JONGBOK KIM, HE WANG, STEPHANIE LEE, Chemical and Biological Engineering Department, Princeton University, ZELEI GUAN, ANTOINE KAHN, Electrical Engineering Department, Princeton University — Soft-contact lamination and delamination has enabled us to construct polymer solar cells for testing, and deconstruct them subsequently for structural characterization of the active layers and electronic characterization of relevant charge transfer interfaces. We have thus been able characterize buried active layers and interfaces that are otherwise inaccessible. Structural characterization post-device fabrication and testing reveals simultaneous crystallization of the polymer donor and the electron acceptor in the once-buried bulk-heterojunction active layers to be responsible for photocurrent enhancement in these devices. Electronic characterization of the active layer-bottom electrode interface reveals an electronic band gap of 1.5 eV, attributable to the difference between the ionization potential of the polymer donor and the electron affinity of the electron acceptor. This value is significantly larger than the band gap predicted by examining the energy levels of the individual constituents, likely due to the presence of interfacial dipoles when the polymer donor and the electron acceptor are intimately mixed.

Session Q39 GSNP DBP: Information Processing in Biological Systems A124/127

11:15AM Q39.00001 TBD , YUHAI TU, IBM T J Watson Res Ctr — This abstract not available.

11:51AM Q39.00002 Adaptive processing of natural signals in the fly peripheral visual system , LIMING ZHOU, Indiana University Dept. of Physics, ROB DE RUYTER VAN STEVENINCK, Indiana University Bloomington Dept. of Physics — For modest light intensity variations, fly photoreceptors and their postsynaptic targets, the Large Monopolar Cells (LMCs) behave approximately linearly. In this linear and stationary regime, signal transmission is described by a combination of impulse response and noise autocorrelation function. But natural visual signals often show fast and large intensity variations, and cells adapt to cope with such strong variations. As a result, responses to small contrast perturbations are still linear, but the system is no longer stationary. We study signal transfer under these conditions by measuring responses to small pseudorandom contrast perturbations that ride on large cyclically repeated intensity fluctuations. Those measurements allow us to describe signal transmission by matrices representing nonstationary analogs of the impulse response and the noise autocorrelation function. This description makes it possible to quantify information transmission as the system is continuously adapting to large intensity fluctuations, and to study trade off in adaptation and reliable information transmission in a natural context.

12:03PM Q39.00003 Optogenetic dissection of neural circuit underlying locomotory decision-making in Caenorhabditis Elegans[1] , ASKIN KOCABAS, Harvard University, ZENGCAI GUO, SHARAD RAMANATHAN — Despite the knowledge of the physical connectivity of the entire nervous system of C.elegans, we know little about how neuronal dynamics results in decision-making. Detailed understanding of functional and dynamic relations of the neural circuitry requires spatiotemporal control of the neuronal activity. Recent discoveries of light gated ion channels have allowed temporal optical control of neural activity. However, excitation of a specific neuron from among many expressing the channel has been a challenge. By combining optogenetic tools, micro mirror array technology and fast real time image processing, we have developed a technique to activate specific single or multiple neurons in an intact crawling animal while tracking its behavior. Using this setup we traced the neural pathway controlling the gradual turning of the animal during the locomotion. We found that the activity of a specific neuronal circuit that receives inputs from sensory neurons is coordinated with head movement. This coordination allows the animal to turn left or right based on the variation of sensory stimulus during head movement. By directly modulating the activity of the neural circuit, we can force the animal to turn in a specific direction independent of sensory stimuli.

12:15PM Q39.00004 Physical limits to concentration sensing in biochemical signaling[1] , NICHOLAS LICATA, SIMA SETAYESHGAR, Indiana University — In many biological systems, signals are carried by changes in the concentration of diffusable molecules which are transduced by receptors. It has been demonstrated experimentally that many signaling systems, from regulation of gene expression during development to bacterial chemotaxis, operate with remarkable sensitivity as indicated by a reliable response to small fractional changes in concentration. This sensitivity has contributions from an irreducible noise arising from the inherent random nature of the diffusing input signal, as well as from the chemical measurement process. By explicitly evaluating these theoretically derived contributions for the experimentally well- characterized bacterial chemotaxis network and motor response, we show that they are comparable to within factors of order unity, consistent with the observation that the measurement error approaches the physical lower limit set by diffusion. We extend our analysis to a class of ligand-gated ion channels, demonstrating the generality of this result where accuracy is especially important for the signaling system.

12:27PM Q39.00005 Spatial phase patterns in locally coupled Kuramoto oscillators with repulsive interactions , ZAHERA JABEEN, MICHAEL GIVER, DAPENG BI, BULBUL CHAKRABORTY, Martin A. Fisher School of Physics, Brandeis University — Recent experiments in microfluidic arrays of interacting Belousov-Zhabotinsky droplets, which belong to the class of active emulsions, show a rich variety of spatial patterns [J. Phys. Chem. Lett. 1, 1241-1246 (2010)]. The predominant coupling between these droplets is inhibitory. Motivated by this experimental system, we study repulsively coupled Kuramoto oscillators with nearest neighbor interactions on a triangular lattice in two dimensions. We show that the geometry of the lattice constrains the phase difference between two neighboring oscillators to $2\pi/3$. We report the existence of domains with either clockwise or anticlockwise helicity, leading to defects in the lattice. We study the time dependence of these domains and show that at large coupling strengths the domains freeze due to frequency synchronization. A variant of this model, in which amplitude variations are introduced by an additional Ising-like coupling between the oscillators, explores the strong coupling limit phenomenon in the experimental system. We discuss these results in the context of the experiments.

12:39PM Q39.00006 Monte-Carlo Study of Axonal Transport in a Neuron[1] , UTTAM SHRESTHA, CLARE YU, ZHIYUAN JIA, ROBERT ERICKSON, STEVEN GROSS, University of California, Irvine — A living cell has an infrastructure much like that of a city. A key component is the transportation system that consists of roads (filaments) and molecular motors (proteins) that haul cargo along these roads. We will present a Monte Carlo simulation of intracellular transport inside an axon in which motor proteins carry cargos along microtubules and are able to switch from one microtubule to another. The breakdown of intracellular transport in neurons has been associated with neurodegenerative diseases such as Alzheimer's, Lou Gehig's disease (ALS), and Huntingdon's disease.

12:51PM Q39.00007 Phase and frequency entrainment in locally coupled phase oscillators with repulsive interactions , MICHAEL GIVER, ZAHERA JABEEN, BULBUL CHAKRABORTY, Martin A. Fisher School of Physics, Brandeis University — Recent experiments in one and two-dimensional microfluidic arrays of droplets containing Belousov - Zhabotinsky reactants show a rich variety of spatial patterns [J. Phys. Chem. Lett. 1, 1241-1246 (2010)]. These experiments provide the first steps towards creating easily reproducible model active emulsion systems. Motivated by this experimental system, we study repulsively coupled Kuramoto oscillators with nearest neighbor interactions on a linear chain as well as a ring in one dimension. We show using linear stability analysis as well as numerical study, that the stable phase patterns depend on the geometry of the lattice and that a transition to the ordered state does not exist in the thermodynamic limit. We will also present results comparing our Kuramoto model with finite element simulations of the Brusselator model in geometries similar to those of the experiment.

1:03PM Q39.00008 Simulation studies of creeping flexible nematogens: flocking and rectifying barriers[1] , ADAM NICHOLAS, Beloit College, ROBIN SELINGER, Kent State Univ. — Recent simulation studies of active nematics have focused on rigid rods or swimming bacteria undergoing collisions via simple rules. Here we present a more physically detailed model of self-propelled creeping flexible nematogens. Each segmented "worm" is represented as nine interaction sites connected by springs. The springs' equilibrium length is modulated, causing each worm to elongate and contract periodically. Each worm alternately grips the substrate at its leading or trailing end, producing creeping locomotion. Inter-worm interactions are described via the Weeks-Chandler-Anderson potential between nearby interaction sites. Random forces and damping are also added. For worms that reverse crawling direction at random intervals, we observe a homogeneous nematic phase, and study its behavior in the presence of a rectifying barrier. For worms that move only in a single direction, we observe flocking behavior characterized by evolving stripes of densely crowded particles interspersed with low-density regions. We compare these results with relevant experiments and related theory/simulation approaches.

1:15PM Q39.00009 ABSTRACT WITHDRAWN –

1:27PM Q39.00010 Glass-like dynamics in collective cell migration , THOMAS ANGELINI, University of Florida, DAVID WEITZ, Harvard University — The collective movement of tissue cells is essential to fundamental biological processes in both health and disease, and occurs throughout embryonic development, during wound healing, and in cancerous tumor invasion. Most knowledge of cell migration, however, comes from single cell studies. Single cells migrate by executing cyclic processes of extension, adhesion, and retraction, during which the cell body fluctuates dramatically and the cell changes direction erratically. These sub-cellular motions must be coupled between neighbors in confluent layers, yet the influence of this coupling on collective migration is not known. In this talk we present a study of motion in confluent epithelial cell sheets. We measure collective migration and sub-cellular motions, covering a broad range of length-scales, time-scales, and cell densities. We find that that collective cell migration exhibits many behaviors characteristic of classical supercooled particulate fluids, including growing dynamic heterogeneities in the migration velocity field, non-Arrhenius relaxation behavior, and peaks in the density of states analogous to the Boson peak. These results provide a suggestive analogy between collective cell motion and the dynamics of supercooled fluids approaching a glass transition.

1:39PM Q39.00011 Active Chemical Thermodynamics promoted by activity of cortical actin , BHASWATI BHATTACHARYA, Jawaharlal Nehru Centre for Advanced Scientific Research, Jakkur, Bangalore-560064, India, ABHISHEK CHAUDHURI, KRIPA GOWRISHANKAR, Raman Research Institute, C.V. Raman Avenue, Bangalore 560080,India, MADAN RAO, Raman Research Institute, C.V. Raman Avenue, Bangalore 560080/National Centre for Biological Sciences (TIFR), Bellary Road, Bangalore 560065, India — The spatial distribution and dynamics of formation and breakup of the nanoclusters of cell surface proteins is controlled by the active remodeling dynamics of the underlying cortical actin. To explain these observations, we have proposed a novel mechanism of nanoclustering, involving the transient binding to and advection along constitutively occuring "asters" of cortical actin. We study the consequences of such active actin-based clustering, in the context of chemical reactions involving conformational changes of cell surface proteins. We find that the active remodeling of cortical actin, can give rise to a dramatic increase in efficiency and extent of conformational spread, even at low levels of expression at the cell surface. We define a activity temperature (τ_a) arising due to actin activities which can be used to describe chemical thermodynamics of the system. We plot TTT (time-temparature-transformation) curves and compute the Arrhenius factors which depend on τ_a. With this, the active asters can be treated as enzymes whose enzymatic reaction rate can be related to the activity.

1:51PM Q39.00012 Brown movement in complex asymmetric periodic potential under the influence of colored noise , MIKHAIL SVIRIDOV, SERGEY GUZ, Moscow Institute of Physics and Technology — The idea of the molecular motor in an asymmetric periodic potential is a well-known problem. The motion of a Brownian particle is often studied when the system is subjected to the action of white noise. In practical situations noise is colored ("red") random process. The red noise is the Ornstein-Uhlenbeck process. In this work we consider noise when the spectral density of the external noise is equal to zero on the zeroth frequency. In our previous works such a noise is been called as "green" noise. For the analytical study of green noise action, we use an approach based on a Krylov-Bogoliubov averaging method which is modified to study the action of noise with arbitrary intensity. A certain effective potential can be built which determines the basic features of the system dynamics. Further, we compare two numerical cases. The first one is the time-derivative of the Ornstain-Uhlenbeck process (green noise). The complex potentials when the system does not work as a molecular motor in the case of red noise, i.e. the average motion of the particle does not exhibit a drift in a given direction. If green noise operates on the same system, it turn out the effective molecular motor. We demonstrate this fact by a histograms for realizations of these processes.

Wednesday, March 23, 2011 11:15AM - 2:03PM –

Session Q40 DCP: Theoretical Methods and Algorithms for Chemical Physics A122/123

11:15AM Q40.00001 Primordial Particles; Collisions of Inelastic Particles , GEORGE SAGI, George S. Sagi Research — Three-dimensional matter is not defined by Euclidian or Cartesian geometries. Newton's and Einstein's laws are related to the motions of elastic masses. The study of collisions of inelastic particles opens up new vistas in physics. The present article reveals how such particles create clusters composed of various numbers of particles. The Probability of each formation, duplets, triplets, etc. can be calculated. The particles are held together by a binding force, and depending upon the angles of collisions they may also rotate around their center of geometry. Because of these unique properties such inelastic particles are referred to as primordial particles, Pp. When a given density of Pp per cubic space is given, then random collisions create a field. The calculation of the properties of such primordial field is very complex and beyond the present study. However, the angles of collisions are infinite in principle, but the probabilities of various cluster sizes are quantum dependent. Consequently, field calculations will require new complex mathematical methods to be discovered yet.

11:27AM Q40.00002 Aggregation of Thermal Particles in Simulation[1] , IAT NENG CHAN, University of Macau — Based on the Schrodinger Equation, energy levels are evaluated for charged particle or atom surrounded by few atoms imitated to atomic cavity situations under multipole or Lennard-Jones interactions. To examine the states of corresponding eigenvalues, the associated wave functions from simulation are plotted in three-dimension to elucidate the space distribution of particles. In cases for testing on effect of different adjacent atomic structures, concentration region of distribution is revealed from a series of results. The range of localization shown also is affected by the type and strength of interactions between particles and atoms, besides the number and position of surrounding atoms. The thermal effect considered in the computation is modeled by average over results from random fluctuation of atom positions for a given heating grade. Moreover, analysis with fuzzy conditions is applied to reduce the complicated and time-consumption approach, also for the training in science education. Even the investigation is limited and tentative, qualitative studies on different parameters and structures can provide the influence of factors and approximate information to compare with the experience evidences.

11:39AM Q40.00003 Many Body Density Matrix Theory[1] , C.J. TYMCZAK, Texas Southern University — One fundamental limitation of quantum chemical methods is the accuracy of the approximate many-body theoretical framework. Accurate many-body formalisms for quantum chemical methods do exist, but these methods are computationally very expensive. Methods also exist that are much less computationally expensive such as Hatree-Fock, Density Functional and the Hybrid Functional theories, but at a reduced representation of the exact many-body ground state. This severely limits either the system size that can be addressed accurately, or the accuracy of the representation. What is needed is a method that represents the many-body ground states accurately, but with a low computational cost. Recently, a method for determining the response, to any order of the perturbation, within the density matrix formalism has been discovered. This method opens up the possibility of computing the variational many-body ground states to unprecedented accuracy within a simplified computational approach. We report on the theoretical development of this methodology, which we refer to as Many Body Density Matrix Theory. This theory has many significant advantages over existing methods. One, its computational cost is equivalent to Hartree-Fock or Density Functional theory. Two it is a variational upper bound to the exact many-body ground state energy. Three, like Hartree-Fock, it has no self-interaction. And four, it is size extensive.

11:51AM Q40.00004 Probing the Surface-to-Bulk Transition: A Closed-Form, Constant-Scaling Algorithm for Computing Subsurface Green Functions , MATTHEW REUTER, Department of Chemistry, Northwestern University, TAMAR SEIDEMAN, MARK RATNER — A closed-form algorithm for computing subsurface Green functions—the blocks of a material's Green function between the surface and the bulk—is presented, where we assume the system satisfies a common principal layer approximation. By exploiting the block tridiagonal and nearly block Toeplitz structure of the Hamiltonian and overlap matrices, this method scales independently of the system size (constant scaling), allowing studies of large systems. As a proof-of-concept example, we investigate the decay of surface effects in an armchair graphene nanoribbon, demonstrating the persistence of surface effects hundreds of atomic layers ($\sim$0.5 μm) away from a surface. We finally compare the surface-to-bulk transitions of finite and semi-infinite systems, finding that finite systems exhibit amplified surface effects.

12:03PM Q40.00005 Projecting the phase-space trajectory of multidimensional non-equilibrium systems onto a discrete set of states: a Projective Dynamics approach , KATJA SCHAEFER, M.A. NOVOTNY, Department of Physics and Astronomy, Mississippi State University — Phase-space trajectories, which are either continuous or possess small discontinuities, can be projected onto a discrete set of states with nearest neighbor coupling. The pointwise projection leads for non- equilibrium system to a non-Markovian process, even if the dynamics of the original system is Markovian. However, using time-averaged transition-rates a Markov process can be obtained, which has the same overall properties as the original dynamics of the system. The projected process defines a new dynamics, which only in the limit $t \to \infty$ obtains the property on the time-scale of the averaging procedure. We demonstrate the Projective Dynamics method in theory and applications to absorption processes, which in general are not describable through equilibrium or steady-state models. We show the discrete set of states $\{\zeta_k\}$ can be chosen arbitrarily (with slight restrictions) for all systems.

12:15PM Q40.00006 Finding lowest saddle point , QING LU, Department of Mechanical Engineering and Division of Materials Science and Engineering, Boston University, MINGHAI LI, Gustaf H. Carlson School of Chemsitry and Biochemistry, Clark University, AKIHIRO KUSHIMA, Department of Materials Science and Engineering, University of Pennsylvania, XI LIN, Department of Mechanical Engineering and Division of Materials Science and Engineering, Boston University — A history-penalized basin filling algorithm is presented in this work which identifies the lowest saddle point starting from any given initial state on any given potential energy hypersurface. The natural analogy of this algorithm is filling a barrel with water; by monitoring the location where leakage occurs one identifies the lowest opening on the wall of the barrel. The successful implementation of this algorithm relies on insightful choices of the penalty function, penalty function combination, and peak refinement. Several types of penalty functions are implemented to study two classical systems, the ad-cluster surface diffusion and supercooled binary Lennard-Jones liquid, and one quantum system of the topological soliton migration. The most efficient penalty function is found to be a triangle penalty function with uniform forces and large 3N+1-dimensional volume. The combination of penalty functions dramatically improves the computational efficiency. The lowest saddle point can be precisely located by the basin filling algorithm coupled with a few standard peak-refinement methods.

12:27PM Q40.00007 The Reaction of Carbon Dioxide with Water Clusters: an Ab Initio Metadynamics Study , GREGOIRE GALLET, FABIO PIETRUCCI, CECAM EPF Lausanne (CH), WANDA ANDREONI, CECAM and Institut de Théorie des Phénomènes Physique EPF Lausanne (CH) — Simulations are often invoked as aid to understand and optimize carbon capture and sequestration processes. The hydration of carbon dioxide (CO_2) offers an excellent test case for assessing the reliability of computational schemes. We present a density-functional-theory study of the reaction of CO_2 with water clusters. The first step was to validate DFT results in different approximations of the exchange and correlation functional with respect to quantum chemical methods for the structure, binding energies and vibrational frequencies of several isomers. Next, simulations of the reactions leading to the formation of carbonic acid were performed using metadynamics as accelerating procedure. This method allows us both to identify the reaction mechanisms and to obtain an estimate of the free energy barriers via the reconstruction of the free energy profiles. Comparisons were drawn with previous static calculations of the barriers. As reference, a similar calculation in liquid water will be presented.

12:39PM Q40.00008 Triplet Pairing and Odd-Electron Densities in Constrained-Pairing Mean-Field Theory , JASON K. ELLIS, Department of Physics and Astronomy and Department of Chemistry, Rice University, CARLOS A. JIMENEZ-HOYOS, Department of Chemistry, Rice University, GUSTAVO E. SCUSERIA, Department of Chemistry and Department of Physics and Astronomy, Rice University — Describing strong (also known as static or non-dynamical) correlation caused by degenerate or nearly degenerate orbitals near the Fermi level remains a theoretical challenge, particularly in molecular systems. Constrained-pairing mean-field theory (CPMFT) has been quite successful capturing the effects of static correlation in bond formation and breaking in closed- shell molecular systems. This method uses singlet electron entanglement to model static correlation at *mean field* cost. The present work extends the previous formalism to include triplet pairing, allowing a description of same-spin correlation and open-shell species. Additionally, a spin-orbital extension of the "odd-electron" formalism of Yamaguchi and co-workers is presented as a method for understanding triplet radical character in molecules. Results from representative systems are presented.

12:51PM Q40.00009 Dynamical Mean-Field Theory for Quantum Chemistry[1] , NAN LIN, Department of Physics, Columbia University, 538 West 120th Street, New York, NY 10027, USA, CHRIS MARIANETTI, Department of Applied Physics, Columbia University, New York, NY 10027, USA, ANDREW MILLIS, Department of Physics, Columbia University, 538 West 120th Street, New York, NY 10027, USA, DAVID REICHMAN, Department of Chemistry, Columbia University, 3000 Broadway, New York, NY 10027, USA — The dynamical mean-field concept of approximating an unsolvable many-body problem in terms of the solution of an auxiliary quantum impurity problem, introduced to study bulk materials with a continuous energy spectrum, is here extended to molecules, i.e. finite systems with a discrete energy spectrum. Application to chains and small clusters of hydrogen atoms yields ground state energies which are competitive with leading quantum chemical approaches at intermediate and large interatomic distances, and provides good approximations to the excitation spectrum. The method is a promising approach to the strong correlation problems of quantum chemistry.

1:03PM Q40.00010 Constrained Active Space Unrestricted Mean-Field Approaches for Controlling Spin-Contamination , TAKASHI TSUCHIMOCHI, GUSTAVO E. SCUSERIA, Department of Chemistry, Rice University — We have recently shown that unrestricted Hartree-Fock (UHF) variationally reduces to high-spin restricted open-shell Hartree-Fock when constraints are imposed on the eigenvalues of the spin density matrix [T. Tsuchimochi and G. E. Scuseria, J. Chem. Phys. **133**, 141102 (2010)]. We here generalize these ideas and propose to control spin-contamination in UHF by releasing the constraints in an active space while imposing them elsewhere. If the active space is properly chosen, our constrained UHF (CUHF) method greatly benefits from a controlled broken-symmetry effect while avoiding the massive spin contamination arising in the traditional UHF. We apply Löwdin's projection operator to CUHF and obtain multireference wave functions with moderate computational cost. We report results on singlet-triplet energy gaps to show that our constrained scheme outperforms fully unrestricted methods. This constrained approach can be readily used in Kohn-Sham (KS) density functional theory with similar favorable effects, provided that spin-contamination is given by the KS orbitals as in UHF.

1:15PM Q40.00011 Nuclear quantum effects using selective mode excitation in water , SRIRAM GANESHAN, MARIVI FERNANDEZ-SERRA, Stony Brook university — Recently, Ceriotti et. al. [1] introduced a comprehensive framework to use a custom-tailored Langevin equation with correlated-noise in the context of MD simulations. One of the interesting applications of these thermostats is that, such a framework can be used to selectively excite normal modes whose frequency falls within a prescribed, narrow range [2]. The general idea of this work is to understand whether, the selective excitation of modes in some systems like water is enough to reproduce the necessary nuclear quantum effects at a given temperature. Ceriotti et. al has also implemented their colored noise thermostat (Langevin) to the PIMD of TIP4P/F model [3]. In this work we study how the TIP4P/f responds to the selective mode excitation using the delta-thermostats. We apply this delta thermostat to the molecular dynamics of TIP4P/F [4] water force field, a model explicitly fitted with the lack of zero point ionic vibrations. TIP4P/F provides us an ideal platform to study the effect of selective mode excitation on water. We address the question of whether selective mode excitations are enough to generate the nuclear quantum effects in water. This work will also provide a way to identify the dominant modes for which the quantum effects are important. [1] Chem. Theory Comput.6, 1170 (2010) [2] Proc. Comp. Sci. 1, 1601 (2010), [3] J. Chem. Phys. 131, 024501 (2009), [4] J. Chem. Phys 133, 124104 (2010).

1:27PM Q40.00012 *Ab Initio* Composite Methods , ANGELA WILSON, WANYI JIANG, GBENGA OYEDEPO, MARIE LAURY, University of North Texas — In this brief presentation, we highlight recent developments of the *ab initio* composite method, the correlation consistent Composite Approach (ccCA). Recent work has enabled ccCA to be utilized for 3d transition metals, as well as for species for which a multireference wavefunction is required. We overview the development, as well as applications of the method to the prediction of spectroscopic and thermodynamic properties of molecules.

1:39PM Q40.00013 Distortion of scanning-tunnelling-spectroscopy images of isolated molecules induced by electron correlation , MASSIMO RONTANI, DIMITRIOS TOROZ, STEFANO CORNI, CNR-NANO S3, Modena, Italy — Scanning tunnelling spectroscopy (STS) visualizes electron states in both extended systems and nano-objects, as quantum dots and molecules. Whereas bulk quantum states are insensitive to electron number fluctuations, an energy gap opens each time a new electron is injected by the STS tip into a sufficiently small system. This gap originates from the interaction of the next incoming electron with the others already present in the system. In this Coulomb blockade regime a fundamental question is whether the wave function of the "quasi-particle" added to the system -imaged by the STS tip- is sensitive to electron-electron interaction. Here we show that the STS images of single planar molecules with metal centres predicted by ab initio many-body calculations differ qualitatively from their uncorrelated counterparts. We find in the maps resolved at the Fermi energy that correlation significantly removes spectral weight from the metal atom, as well as the overall weight is remarkably reduced. This change may be measured and compared with STS images of molecules without the metal center, whose many-body and uncorrelated versions are alike.

1:51PM Q40.00014 Maximizing the hyperpolarizability poorly determines the potential , ROLFE PETSCHEK, TIMOTHY ATHERTON, JOSEPH LESNEFSKY, GREG WIGGERS, Case Western Reserve University — Increasing the non-linear response of materials to an electric field, characterized by quantities such as the first hyperpolarizibility β, is a mattter of importance for applications. We optimized the zero frequency β of a one-dimensional potential well containing a single electron by freely adjusting the shape of that potential. It is shown that with careful optimization the maximum hyperpolarizability converges quickly with increasing numbers of parameters in the potential to approximately 0.708951 of the proven upper bound. The Hessian of β at the maximum makes it clear that there is a very wide range of nearby, nearly optimal potentials: with several measures of differences between potentials, this Hessian has only two large eigenvalues with the others diminishing quickly. The optimum potentials are substantially different and more affected by small eigenvectors than the wavefunctions. Thus, wavefunctions are superior for describing the conditions that optimize the hyperpolarizability. Prospects for a concise description of the two important constraints on near-optimum potentials and wavefunctions are discussed.

Session Q41 DCP: Focus Session: Fundamental Issues in Interfacial Charge Transport for Energy Applications II A115/117

11:15AM Q41.00001 First principles simulations of materials and processes in photo- and electro-catalysis , ANNABELLA SELLONI, Princeton University — I shall discuss applications of electronic structure calculations and molecular dynamics simulations to understand materials properties and reaction mechanisms in photo- and electro-catalysis. Examples will include studies of the interface between water and titanium dioxide (TiO_2), a widely used photocatalyst capable of splitting water in $O_2 + H_2$, and the cycle of H_2 production from water by the active site of an enzyme of hydrogen-producing bacteria, the di-iron hydrogenase, linked to a pyrite electrode.

11:51AM Q41.00002 Theoretical studies on a new pattern of laser-driven systems: towards elucidation of direct photo-injection in dye-sensitized solar cells[1] , KENJI MISHIMA, KOICHI YAMASHITA, The University of Tokyo — We theoretically and numerically investigated a new type of analytically solvable laser-driven systems inspired by electron-injection dynamics in dye-sensitized solar cells. The simple analytical expressions were found to be useful for understanding the difference between dye excitation and direct photo-injection occurring between dye molecule and semiconductor nanoparticles. More importantly, we propose a method for discriminating experimentally dye excitation and direct photo-injection by using time-dependent fluorescence. We found that dye excitation shows no significant quantum beat whereas the direct photo-injection shows a significant quantum beat.

[1]This work was supported by Funding Program for World-Leading Innovative R&D on Science and Technology (FIRST) "Development of Organic Photovoltaics toward a Low-Carbon Society," Cabinet Office, Japan.

12:03PM Q41.00003 Investigation of the Potential Difference between C60 and TiOPc on Ag(111) by Local Probe Techniques , KRISTEN BURSON, YINYING WEI, WILLIAM CULLEN, JANICE REUTT-ROBEY, University of Maryland-College Park — One challenge for increasing efficiency of organic photovoltaics is to understand the barrier to exciton separation that exists at the interface between organic molecules. Here we report a local probe measurement of the potential barrier at the interface between submonolayer C60, a good electron acceptor, and honeycomb phase TiOPc, an organic with high hole mobility, on Ag(111). We employ UHV AFM (atomic force microscopy) and KPFM (Kelvin probe force microscopy) to obtain simultaneous images of the potential and topographic landscapes. This technique allows for high spatial resolution of both the potential and the topography. In addition to reporting the work function difference between C60 and TiOPc, we investigate the work function for C60 on Ag(111).

12:15PM Q41.00004 Ultrafast proton coupled charge transfer dynamics in photocatalysis , HRVOJE PETEK, University of Pittsburgh — In this talk I will present our experimental and theoretical studies on the nature of electron and hole acceptor states and their dynamics for protic solvent molecule (H_2O, CH_3OH) covered TiO_2 surfaces. Electron-hole pair generation by band gap excitation can introduce charges into protic solvent/TiO_2 interface, which can drive photocatalytic processes. By time resolved two-photon photoemission and DFT electronic structure calculations we identify the partially solvated or "wet" electron accepter states, and their proton-coupled electron transfer (PCET) dynamics. Because holes are through to be the primary reagents for photocatalysis on TiO_2, we also explore possible hole driven PCET dynamic pathways.

12:51PM Q41.00005 First-principles study on Ru(4,4',4"-tricarboxy-2,2':6',2"-terpyridine)$(NCS)_3$ sensitizer on TiO_2 anatase(101) surface: Adsorbed structures and electronic states for dye-sensitized solar cells[1] , KEITARO SODEYAMA, MASATO SUMITA, YOSHITAKA TATEYAMA, National Institute for Materials Science MANA — Dye-sensitized solar cells are expected as a cost effective solar-to-electricity energy conversion devices. The efficiency of the power conversion is greater than 10% when Ru(II) polypyridyl sensitizers are used. For further improvement of the efficiency, we need to understand the adsorbed structures at atomistic level in detail. In this study, we investigated the adsorbed structures of Ru(4,4',4"-tricarboxy-2,2':6',2"-terpyridine)$(NCS)_3$ sensitizer on TiO_2 anatase(101) surface. For four possible adsorbed structures (two candidates have one adsorbed carboxyl group(one-leg) and the others have two adsorbed groups(two-leg)), we found the adsorption energies are quite similar within 0.4 eV. This is attributed to the presence of the hydrogen bond between the hydrogen of carboxyl group and the oxygen of the surface in the one-leg structure. We also calculated the excited states of the four structures of the sensitizer by TDDFT and found that the UV spectrum shift depending on the structure differences.

1:03PM Q41.00006 Reverse-engineering the atomic-scale structure of the TiO2/N3 interface in dye-sensitized solar cells using O1s core-level shifts , CHRISTOPHER PATRICK, FELICIANO GIUSTINO, Department of Materials, University of Oxford — Dye-sensitized solar cells employing mesoporous titania films sensitized with ruthenium-based dyes have shown consistently good performance over the past two decades. Understanding the process of charge injection in these devices requires accurate atomistic models of the interface between the light-absorbing dye and the semiconducting substrate. Despite considerable efforts devoted to the experimental and theoretical investigation of such interfaces, their atomistic nature remains controversial. In this work we pursue a novel computational approach to the study of the semiconductor/dye interface which does not rely on the calculated adsorption energies. In our approach we reverse-engineer photoemission data through the first-principles calculation of O1s core-level spectra for a number of candidate interface models. Our calculations allow us to discard some of the adsorption geometries previously proposed and point to an interface model which reconciles conflicting assignments based either on photoemission or infrared data.

1:15PM Q41.00007 Studies of Interfacial Electronic Processes in Nanoporous TiO2 Thin-Films[1] , VICTOR BATISTA, Yale University — Metal-oxide nanoparticles sensitized to visible light by covalent attachment of molecular adsorbates have attracted considerable attention in recent years due their central role in technologies for solar energy conversion, including dye-sensitized solar cells (DSSCs) and solar photocatalysis. However, the mechanisms of interfacial electron transfer and subsequent electron transport induced by photoexcitation of the molecular adsorbates remain only partially understood. We report recent progress in studies of nanoporous TiO2 thin-films functionalized with molecular adsorbates, with emphasis on interfacial electron injection, molecular rectification and the mechanism of electron transport through sintered TiO2 nanoparticles in thin-films relevant to DSSCs.

[1]The author acknowledges support from DOE (grants DE-FG02-07ER15909 and ANSER EFRC Award Number DE-PS02-08ER15944) and NSF (grants ECCS-0404191 and CHE 0911520).

1:51PM Q41.00008 Efficient adsorbate transport by electron wind: The role of resonant photoexcitation , KIRILL VELIZHANIN, DMITRY SOLENOV, Los Alamos National Laboratory — We study the surface electromigration force acting on an organic molecule at a conducting (metal) surface. The dominant contribution to the force comes from the scattering of metallic electrons off the molecule, as they tunnel to and from nearby molecular orbitals. When metal carries non-zero current, the net force is directed with the current flow. This force, however, is often too small for efficient transport of adsorbed molecules and only reveals itself through a contribution to the metal resistivity. We show that surface-molecule electron wind force can be substantially enhanced and controlled by exploiting appropriate resonances between molecular and metallic states activated by coherent light. This effect opens a path to new surface-molecule functionality, including high resolution spatially controlled force patterns, controlled molecule motion, etc.

2:03PM Q41.00009 Real-time observation of bond-by-bond interface formation during oxidation of H-terminated (111)Si by second-harmonic generation , BILAL GOKCE, North Carolina State University, ERIC J. ADLES, Johns Hopkins University, DAVID E. ASPNES, KENAN GUNDOGDU, North Carolina State University — Structure of solids is typically determined at the atomic level by techniques such as X-ray and electron diffraction, which are sensitive to positions of atomic nuclei. However, structure is determined by bonds between atoms, which are difficult to measure directly. We combine second-harmonic generation and the bond-charge model of nonlinear optics to probe, in real time, the dynamics of bond-by-bond chemical changes during the oxidation of H-terminated (111)Si, a surface that has been well characterized by static methods. Oxidation is activated by applied macroscopic strain, and exhibits anisotropic kinetics with one of the three equivalent back- bonds of on-axis samples reacting differently from the other two. This also leads to transient changes in bond directions. Strain is known to increase oxidation rate of Si for thermal oxides, however its affects at the microscopic scale has not been studied at the bond level. By comparing results for surfaces strained in different directions, we show that in-plane control of surface chemistry is possible. The use of nonlinear optics as a bond-specific characterization tool is readily adaptable for studying structural and chemical dynamics in many other condensed-matter systems.

Session Q42 DPOLY: Polymer Composites A302/303

11:15AM Q42.00001 Dispersion and composite processing of polymer coated graphene , SRIYA DAS, AHMED WAJID, JOHN SHELBURNE, ABEL CORTINAS, MICAH GREEN, Texas Tech University — Liquid phase exfoliation and dispersion of graphene, i.e. single layer graphite, is a critical challenge for bulk processing of graphene into advanced materials and devices. We demonstrate a suite of techniques for dispersing pristine graphene using polymer coatings for the purpose of liquid-phase nanocomposite processing. First, we illustrate a unique in situ polymerization technique to develop localized polymer coatings on the surface of dispersed pristine graphene sheets in solution. These polymer coatings do not disrupt the pristine structure or superior properties of the graphene sheets; instead, these coatings allow for stable, aggregation resistant graphene dispersions, as characterized through rheology, SEM, and AFM. We also demonstrate that certain polymers naturally wrap and stabilize pristine graphene in various organic solvents. We use this technique to prepare epoxy and PVA nanocomposites loaded with polymer-wrapped graphene as filler.

11:27AM Q42.00002 Fabrication of Graphene Oxide/Polypropylene Nanocomposites and Their Electrical Conductivity Study , JINYONG DONG, Institute of Chemistry, Chinese Academy of Sciences — Graphene oxide (GO) /polypropylene nanocomposites were fabricated via in situ polymerizing propylene monomer over a GO that had been treated with a Grignard reagent and $TiCl_4$ successively when GO was not only catalytically activated but also largely reduced to an almost O- free state. The polymerization led to the in situ formation of the PP matrix, which was synchronized by the nanoscale exfoliation of the reduced GO as well as its gradual dispersion. Morphological examination of the ultimate GO/PP nanocomposites by TEM and SEM techniques revealed effective dispersion in nanoscale of GO in PP matrix. High electrical conductivity was discovered with thus prepared GO/PP nanocomposites, e.g. at a GO loading of 4.9 wt%, σ_c was measured at 0.3 S·m^{-1}

11:39AM Q42.00003 Controlling nanorod self-assembly in polymer thin film composites , MIGUEL MODESTINO, University of California, Berkeley, JEFFREY URBAN, Molecular Foundry, Lawrence Berkeley National Laboratory, RACHEL SEGALMAN, University of California, Berkeley — Semiconducting nanorods are of particular interest for use in polymer composites due to their anisotropic physical properties; however such properties can only be harnessed in systems with orientational order. Here, we demonstrate control over nanorod self-assembly in solution which leads to arrays of vertically aligned nanorods in polymer thin films over large areas (>1 cm^2). Transmission electron microscopy and X-ray scattering techniques were used to determine the structure of composites and probe the nanorod self-assembly mechanism. This work demonstrates that strong interactions between alkane-covered colloidal nanorods can enable the formation of hexagonally packed arrays of nanorods in a wide range of polymer matrices. Kinetic effects during the casting process are shown to affect the final morphology of the composites, leading to reduced array sizes for systems with increasing polymer molecular weight and nanorod concentration. The results presented show that thin film confinement as well as surface segregation of the nanorod arrays enhance the orientational order of nanorods in composites.

11:51AM Q42.00004 Multi-Walled Carbon Nanotube Network Formation in Extruded High Density Polyethylene/MWNT Composites[1] , FRANK YEPEZ CASTILLO, BRIAN P. GRADY, DANIEL E. RESASCO, The University of Oklahoma — Multi-walled carbon nanotube (MWNT) / high density polyethylene (HDPE) composites with varying amounts of carbon nanotubes were investigated and the effect of MWNT weight fraction on their electrical conductivity, crystallinity and mechanical properties is presented here. Samples were prepared by melt dilution of a HDPE masterbatch containing 20 wt% MWNT with varying amounts of neat HDPE. Conductivity measurements on compression molded samples showed that electrical percolation occurs at 4.5 wt% MWNTs. The effect of processing conditions on the formation of a MWNT network in extruded samples was assessed by the addition of a low-shear annealing zone (shear rate 1-10 s^{-1}) before final extrusion through a die. The time in the low shear zone was varied from almost zero to 90 sec. Extruded samples above the compression-molded percolation threshold were tested, and electrical conductivity did not develop. However, a significant increase in electrical conductivity was observed in these samples when annealed for 5 minutes at the same temperature.

12:03PM Q42.00005 Effect of Nanowire Size Dispersity on the Electrical Conductivity in Polymer Nanocomposites , ROSE MUTISO, MICHELLE SHERROTT, JU LI, KAREN WINEY, University of Pennsylvania — In this simulation study, we model the percolation threshold and electrical conductivity of three-dimensional networks containing finite, conductive cylinders with experimentally typical (Gaussian) and engineered (Bidisperse) distributions in their length and/or diameter. We have previously used this approach to explore the effects of cylinder orientation and aspect ratio. Preliminary results suggest that narrow Gaussian distributions do not affect the threshold concentration or electrical conductivity significantly in both isotropic and oriented networks, while the addition of a small fraction of longer rods in a bidisperse system can improve the electrical properties considerably. Additionally, polydispersity in the filler length has a more pronounced effect on the electrical percolation behavior than that in filler diameter. This implies that the separate effects of length and diameter should be decoupled from the overall filler aspect ratio when probing the effects of size dispersity in conducting polymer nanocomposites with elongated fillers.

12:15PM Q42.00006 Simulating the Effect of Flame Retardant Materials on Heat Diffusion in Polymers , JOSEPH ORTIZ, Stony Brook University, ARPON RAKSIT, Commack High School, DILIP GERSAPPE, Stony Brook University — Many commonly used polymers have low ignition temperatures, presenting the dangers of combustion and thermal degradation. Simulating the effect of flame retardants on the spread of heat throughout a polymer may provide a better understanding on how to effectively manipulate and make use of flame retardant materials. Using the lattice Boltzmann method, a simulation of heat diffusion from a heat source to sink was implemented in three dimensions. The polymer and flame retardant material were incorporated into the system by implementing ignition within the particles of the polymer and by adding heat absorbing microscale filler particles within the polymer matrix, while allowing for reduced-rate heat transfer between interspecies particles. Flame retardant particles were given various volume fractions and morphologies in order to simulate the addition of a variety of particles such as carbon nanotubes. By manipulating the flame retardant particles' ability to absorb heat, and their efficiency in removing heat from the system, different degrees of polymer heat transport were simulated while polymer systems ranged from single polymer systems to multi-component blends.

12:27PM Q42.00007 Diffusion of small molecules in polymer nanocomposites: relationship between local free volume dynamics and penetrant diffusivity , VICTOR PRYAMITSYN, VENKAT GANESAN, University of Texas at Austin — Polymer membranes are widely used as barrier or gas/vapors separation materials. Recent experiments have demonstrated that the barrier properties of the polymer nanocomposites (PNC) dramatically different from pure polymer. Usually such properties are quantified by the permeability P of the material to a penetrant which consists of two contributions: the penetrant solubility S and diffusivity D: $P = S\ D$ In present work we only discuss term D. We use the Bond Fluctuation Model, which allows us to model the diffusivity of the penetrant, the dynamics of the polymer and the dynamics of the polymer free volume in a single framework. We modeled PNC's at different particle load and the penetrant size and found that addition of nanoparticles increseses the penetrant diffusivity and selectivity to the penetrant size. This increase is attributed to the free volume increase and the acceleration of the free volume relaxation in PNC relatively to the pure polymer. We have compared the penetrant diffusivity in a rubbery and glassy PNC's and found than the effect of the PNC load on diffusivity and selectivity is much stronger for the glassy system which is due to rubbery system D is controlled by the rate of matrix free volume relaxation and in glassy regime it is controlled by the static free volume percolation, which is more sensitive to the PNC load.

12:39PM Q42.00008 Nanoparticle Size Dependence of a Polymer's Mechanical Properties[1] , JOSEPH MOLL, Columbia University, SHUSHAN GONG, The Pennsylvania State University, SANAT KUMAR, Columbia University, RALPH COLBY, The Pennsylvania State University — Nanoparticle size critically affects the properties of polymer nanocomposites. We use a silica/poly(2-vinyl) pyridine (P2VP) polymer nanoparticle composite to investigate these effects by varying the nanoparticle sizes from 2nm to a micron. Since silica and P2VP are miscible, we obtain uniform nanoparticle spatial distribution in all cases. Rheology is employed to measure the macroscopic mechanical properties. X-ray photon correlation spectroscopy is used to probe nanoparticle dynamics. We rationalize our search for an optimal nanoparticle size (with regards to composite mechanical properties) by using thermogravimetric analysis to determine particle bound layer thickness as a function of particle size.

[1]NSF DMR-1006659

12:51PM Q42.00009 Preparation and Characterization of Electrospun Poly(Methyl Methacrylate)-QDs NanoComposite Fibers[1] , SUYING WEI, Lamar University, JAYANTHI SAMPATHI, DAN RUTMAN, ASHWINI KUCKNOOR, ZHANHU GUO — In this talk, we describe the simple electrospinning method to fabricate PMMA-CdSe/ZnS Quantum Dots (QDs) nanocomposite fibers followed by property analysis using a variety of techniques. The parameters that affect the electrospinning process including concentration, feed rate, applied voltage and working distance between the needle tip and the fiber collector are investigated and optimized to acquire uniform and defect-free polymer nanocomposite fibers. The surface morphology of the fiber was characterized by scanning electron microscopy, while the fluorescence emission characteristics were analyzed with fluorescence microscopy. In addition, the PMMA-QDs nanocomposite is thermally more stable than the pristine PMMA fibers as determined by the thermal-gravimetric analysis technique. The glass transition temperature and the melting temperature of the polymer are also altered due to the incorporation of QDs. This can be attributed to the interaction between the included QDs and the polymer structure, as disclosed by the surface analysis techniques attenuated total reflectance-infrared spectroscopy (ATR-IR) and X-ray photoelectron spectroscopy (XPS).It showed new vibration bands in the composite fiber in the ATR-IR spectra while the binding energy of both C1s and O1s shifted in their corresponding high-resolution XPS spectra.

[1]the Welch Foundation (V-0004)

1:03PM Q42.00010 Improvement of the dispersion of silica nanoparticles in PMMA[1] , KEREM GOREN, OSMAN B. OKAN, LIMENG CHEN, LINDA S. SCHADLER, RAHMI OZISIK, Rensselaer Polytechnic Institute — Creating well-dispersed polymer nanocomposites is an important part of controlling composite properties. Nanoparticles have been shown to demonstrate quite beneficial electrical and thermo-mechanical properties when they are added to polymers. In the current study, the effects of foaming on de-aggregation of nanoparticles in silica/PMMA nanocomposites are investigated. It was found that the saturation of polymer nanocomposite with supercritical carbon dioxide and subsequent rapid de-pressurization is successful in improving the dispersion of nanoparticles in polymer matrix. In addition, by varying saturation pressure, the degree of dispersion improvement can be controlled. Controlled saturation pressure experiments demonstrated that a decrease in saturation pressure led to decreased improvement of nanoparticle dispersion in polymer matrix. By monitoring the inter-nanoparticle distance using transmission micrographs, a quantitative comparison via radial distribution function (RDF) was constructed for before and after each saturation pressure.

[1]Supported by the NSF (CMMI-0500324).

1:15PM Q42.00011 Dispersion of Magnetic Brushes in Polymer Melts , YANG JIAO, PINAR AKCORA, Stevens Institute of Technology — It is now known that polymer grafted amphiphilic spherical silica nanoparticles can self-assemble into anisotropic nanostructures. In this study, we will show how dipolar interactions can affect the self-assembly mechanism of magnetic nanoparticles in polymer composite melts. Hydrophobic iron oxide nanoparticles of 6nm in size are synthesized and then decorated with poly(styrene) by reversible addition fragmentation chain transfer (RAFT) polymerization at various grafting densities and brush lengths. Dispersion of these magnetic brushes are examined in poly(styrene) matrices in TEM. Structures obtained from the balance of attractive dipolar interactions and repulsive forces between polymer chains are investigated. The influence of grafting densities and grafted chain lengths on the dispersion of magnetic nanoparticles and formation of the "equilibrium" structures will be discussed.

1:27PM Q42.00012 Modeling nanoparticle aggregation in nanocomposites , TANYA CHANTAWANSRI, Army Research Laboratory, LEE TRASK, ERIC COCHRAN, Iowa State University, JAN ANDZELM, Army Research Laboratory — A hybrid self-consistent field theory model (H-SCFT) was utilized to model the morphology of nanocomposities composed of cylinder forming ABA triblock copolymer and large nanoparticles (radius on the order of 10 nm). In this system, the size of the nanoparticles is comparable to the cylindrical domains such that nanoparticle segregation into this otherwise compatible phase would cause a significant loss in conformational entropy. To reduce this loss, the nanoparticles could instead macrophase separate out to form aggregates. To capture this particle aggregation in the H-SCFT model, we incorporated a Lennard-Jones potential into the framework. The incorporation of this interaction into the model can significantly alter the observed phase morphology since aggregation can prevent the nanoparticles from swelling and distorting the compatible block copolymer domain. We will demonstrate how the morphology of this nanocomposite varies as a function nanoparticle volume fraction and functionalization. Results will be compared to experimental findings when available.

1:39PM Q42.00013 Effect of Silicon Dioxide Nanoparticles on the Morphology and Interphase Structure of Electrospun PET Nanofibers[1] , QIAN MA, BIN MAO, PEGGY CEBE, Department of Physics and Astronomy, Tufts University — Poly(ethylene terephthalate), PET, nanofibers containing silicon dioxide nanoparticles were electrospun from solutions in hexafluoro-2-propanol. Various fill fractions of silicon dioxide nanoparticles in PET were used, ranging from 0-2.0% by weight. The morphologies of both the electrospun (ES) nanofibers and the SiO2 powders were investigated by scanning and transmission electron microscopies. The phase structure of the non-woven, nanofibrous composite mats was investigated with differential scanning calorimetry and real-time wide-angle X-ray scattering. The amount of immobilized layer, the rigid amorphous fraction (RAF), was obtained based on measurement of the specific reversing heat capacity for both as-spun amorphous and isothermally crystallized PET/silica nanocomposite fibers. For the first time, existence of rigid amorphous phase in the absence of crystallinity was verified for electrospun nanocomposite fibers, and two locations of the rigid amorphous fraction are proposed. The effect of interaction between the filler and polymer matrix on the mechanical properties of single fiber is also investigated using atomic force microscopy.

[1]This research was supported by the National Science Foundation, through grant DMR-0602473.

1:51PM Q42.00014 Flexible Polymer Nanocomposite Hydrogen Sensors by Solution Processes[1] , HOWARD WANG, YAYONG LIU, LIWEI HUANG, KAIKUN YANG, LIANFENG ZOU, State University of New York, Binghamton, CHEOL PARK, National Institute of Aerospace — Using solution processes such as flow coating and inkjet printing, flexible hydrogen sensors arrays have been fabricated on thin polymer nanocomposite films containing dispersed palladium nanoparticles (Pd-NPs). Composite films were annealed at temperatures from 150 °C to 200 °C to allow Pd-NPs to sinter and form a conductive network. An optimal processing temperature is found to yield the most sensitive sensors due to a good balance between the electrical resistance and connectivity of the Pd-NP network. As-fabricated hydrogen sensors can detect a hydrogen level of ca. 200 ppm or lower with a response time of less than 1 second upon the exposure to hydrogen gas, and a recovery time of *ca*. 5 min upon the removal of hydrogen. The sensitivity, repeatability and linearity of sensor arrays are shown to depend on the processing history, the morphology of sensing films, and the geometry of sensor layout.

[1]NSF CMMI- 0928865 & 0928839

2:03PM Q42.00015 Thermal Properties of PEO-anatase nanocomposites , MIRCEA CHIPARA, The University of Texas Pan American, HE HUANG, University of New Orleans, KAREN LOZANO, The University of Texas Pan American, DAVID HUI, XU HAILAN, University of New Orleans, RAFAEL VILLEGAS, THOMAS MION, The University of Texas Pan American — Polyethylene-oxide (PEO) - anatase composites containing various amounts of anatase ranging between 0 and 20 % wt. have been prepared. The as obtained samples have been investigated by Thermogravimetric Analysis at different heating rates ranging from 5 to 40 K/min. This study was focused on the effect of nanofillers on the activation energy and overall reaction order as well as on the temperature at which the mass loss rate is maxim. The first derivative of the as obtained thermogram has been fitted by using an extended Wigner-Breit-Fano function. The effect of the concentration of anatase nanoparticles on the parameters of the Wigner-Breit-Fano are discussed in detail. Non-isothermal differential scanning calorimetry measurements have been performed in order to determine the effect of anatase nanoparticles on the melting and crystallization of PEO. Isothermal crystallization at various temperatures ranging from 303 to 320 K have been also performed. The study aimed to correlate isothermal crystallization data with non-isothermal results and to determine the effect of anatase nanoparticles on the melting and crystallization of PEO. The crystallization process has been investigated within Avrami and Ozawa approaches.

Wednesday, March 23, 2011 11:15AM - 2:03PM –

Session Q43 DPOLY DBP: Focus Session: Translocation through Nanopores I A306/307

11:15AM Q43.00001 A Coupled-Dynamics Model for Polymer Translocation , TIMO IKONEN, TAPIO ALA-NISSILA, Aalto University School of Science, Finland, ANIKET BHATTACHARYA, University of Central Florida, WOKYUNG SUNG, Pohang University of Science and Technology, South Korea — We study a coarse-grained model of driven translocation of biopolymers, which comprises coupled equations of motion for the translocation coordinate s and the spatial coordinates for the first and the last bead of the translocating chain. We use Langevin dynamics simulations to solve the equations of motion and to study the dynamics of translocation through a nanopore, including the residence time distribution of the individual monomers and the average translocation time. In addition, we consider the time evolution of the spatial coordinates of the first and last bead, which underline the asymmetry of the dynamical chain conformations on the cis and $trans$ sides.

11:27AM Q43.00002 A new approach to polymer translocation , JOHAN DUBBELDAM, Delt University of Technology, VAKHTANG ROSTIASHVILI, Max Planch Institute for Polymer Research, ANDREY MILCHEV, Bulgarian Academy of Sciences, THOMAS VILGIS, Max planck Institute for Polyme Research — Polymer translocation is ubiquitous in nature. It plays a role in phenomena like virus infections and in trafficking of proteins through pores in a cell membrane. Many theoretical models have been developed to explain scaling properties of simple polymer chains through tiny nanopores. This has not resolved the controversies in this field, however. In this paper we employ novel methods to shed light on the results that were obtained using the different models that are in use today. We use, for example fractional Brownian motion to explain the scaling of the variance in the translocation length with time and find good agreement between simulation results and theoretical predictions. An extension of the theory to nanopores with more complex geometries are discussed.

11:39AM Q43.00003 Stepping dsDNA through a solid-state nanopore one basepair at a time[1] , ANTHONY HO, JEFFREY COMER, ALEKSEI AKSIMENTIEV, Department of Physics, University of Illinois at Urbana-Champaign — Solid-state nanopores hold great promise for single-molecule detection and manipulation, including low-cost, high-speed DNA sequencing. In a typical experiment, single molecules of DNA are driven through a nanopore by applying an electric potential difference across the membrane. As DNA passes through the pore, it modulates the ionic current, which potentially can be used to determine the DNA sequence. However, the typical rate of DNA transport in experiment is too high for detection of DNA sequences by ionic current measurement. It has been shown that it is possible to slow and weakly trap dsDNA in solid-state nanopores with diameters smaller than that of dsDNA [Nanotechnology 21:395501]. Using all-atom molecular dynamics simulations, we demonstrate that such pores can be used not only to trap but also to displace dsDNA in discrete steps using nanosecond-long pulses of electric field. Specifically, we have identified the pore geometry and pulse profiles that impel dsDNA by one basepair when the pulse is on and retain dsDNA in the same position when the pulse is off. Such nanopore traps may offer new means for manipulating single molecules in biophysics experiments.

11:51AM Q43.00004 Universal and Non-Universal Translocation Dynamics of Coarse-Grained Biopolymers , TAPIO ALA-NISSILA, Aalto University School of Science — I will discuss recent progress on the dynamical scaling of coarse-grained models of (bio)polymers under spontaneous and forced translocation.

12:27PM Q43.00005 DNA translocation through grapheme nanopores , CHRISTOPHER A. MERCHANT, University of Pennsylvania, KEN HEALY, MENI WANUNU, VISHVA RAY, NEIL PETERMAN, JOHN BARTEL, MICHAEL D. FISCHBEIN, KIM VENTA, ZHENGTANG LUO, A.T. CHARLIE JOHNSON, MARIJA DRNDIC — We report on DNA translocations through nanopores created in graphene membranes. Devices consist of nanometer-thick graphene membranes with electron-beam sculpted nanopores. Due to the thin nature of the graphene membranes, we observe larger blocked currents than for traditional solid-state nanopores. Unlike traditional solid-state nanopore materials that are insulating, graphene is an excellent electrical conductor. Use of graphene as a membrane material opens the door to a new class of nanopore devices in which electronic sensing and control are performed directly at the pore.

12:39PM Q43.00006 Characterization of DNA Translocation and Detection in Functionalized Nanopores , YALING LIU, Lehigh University, ABHIJIT RAMACHANDRAN, QINGJIANG GUO — Functionalized nanopores have been used in selective detective of DNA. While the interaction between a bare nanopore and a DNA has been analyzed extensively, little is know for that of a functionalized nanopore. This work focuses on studying the DNA translocation dynamics and mechanism of DNA sequencing in a functionalized nanopore through a coarse-grained molecular dynamics model. Physical properties of chemically modified nanopores, i.e., the effective pore diameter under different bias voltages are characterized. The DNA translocation dynamics under different nanopore coatings and different bias voltages are studied. The simulation results reveal that molecular selective translocation larges lies on the flexibility and orientation of the coating molecules and their interaction with the translocating DNA. This research supports rational designs of DNA transportation- and manipulation-based diagnostic systems.

12:51PM Q43.00007 Direct observation of DNA motions into solid state nanopore under applied electrical potentials on conductive surface , YOSHITAKA HAYASHI, GENKI ANDO, ICHIRO IDUTSU, TOSHIYUKI MITSUI, Aoyamagakuin University — Solid state nanopore is one of emerging methods for rapid single DNA molecule detection because the translocation of the DNA though nanopore produces ionic current changes. One of issues in this method is clogging long DNA molecules. Once DNA molecules clogged, the molecules are rarely removed by varying or switching the polarity of applied bias voltages across the nanopore. We develop a modified nanopore by 50nm Au coating on top of the nanopore surface to be able to remove the clogged DNA molecules during the DNA translocation experiment. Fluorescence microscopy was implemented for observation of stained DNA molecules. The nanopores with diameters near 100 nm can be used initially. DNA translocation rates changes dramatically by tuning the applied electrical potentials on surface higher or lower than the potentials across the nanopore. Furthermore, the Au potentials modifies IV characteristic of the ionic current across the nanopore which is similar to the gate voltages controlling the SD current in FET. We will discuss the influence of surface potential on DNA motion and translocation and clogged DNA molecules. Finally, we will present the recent results of DNA translocation into the SiN-Au-SiO2 nanopore and discuss the effect of applied voltages on Au.

1:03PM Q43.00008 Polymer Translocation through a Nanopore in the Presence of a Viscosity Gradient[1] , HENDRICK W. DE HAAN, GARY W. SLATER, University of Ottawa — Of interest for both biological and technological applications, the translocation of a polymer across a membrane through a nanopore has been studied via simulations under a great variety of conditions. In this work, results will be presented from Langevin Dynamics (LD) simulations of polymer translocation where the viscosity on the cis side of the membrane is different from the viscosity on the $trans$ side - a scenario both applicable to biological instances of translocation and replicable with artificial nanopores. Starting with the polymer halfway through the pore, the establishment of a preferential direction for large viscosity differences is observed. To investigate the origin of this effect, a simple model of the system as a 1D biased random walker in a viscosity gradient is explored by Monte Carlo and LD simulations. Good agreement between the simple model and the full polymer simulations for both the preferential direction and mean first passage time indicate that the effects that a viscosity difference across the membrane may have on translocation arise in the general case of a particle at a viscosity interface.

1:15PM Q43.00009 Ionic Coulomb Blockade in Nanopores[1] , MATT KREMS, MASSIMILIANO DI VENTRA, University of California, San Diego — Understanding the dynamics of ions in nanopores is essential for potential applications in molecule detection, DNA sequencing, and other technologies [1]. We show both analytically and by means of molecular dynamics simulations that ion-ion interactions in nanopores leads to the phenomenon of ionic Coulomb blockade, namely the build-up of ions inside a nanopore with specific capacitance impeding the flow of additional ions due to Coulomb repulsion. This is the classical counterpart of electronic Coulomb blockade in mesoscopic systems. We discuss the analogies and differences with the electronic case as well as experimental situations in which this phenomenon could be detected.

1:27PM Q43.00010 Modeling polyelectrolyte translocation through protein channels , JYOTI MAHALIK, JING HUA, YANBO WANG, MURUGAPPAN MUTHUKUMAR, University of Massachusetts, Amherst — We will present results from Brownian Dynamics simulations of translocation of polyelectrolyte chains through alpha-hemolysin and MspA protein channels. Comparisons will be made between these two pores in terms of the various characteristics of translocation events. Specifically, we will discuss the distribution functions of blocked ionic current and translocation time. The critical roles played by the charge decorations and the geometries of these two protein pores will be presented. The sequence of the polymer will also be addressed.

1:39PM Q43.00011 Polyelectrolyte translocation through a spherical cavity with tunable charge , ALEXANDER ELISEEV, MURUGAPPAN MUTHUKUMAR, University of Massachusetts, Amherst — We will present theoretical results on the free energy barrier for a translocating polyelectrolyte through a charge-decorated hole from a confining spherical cavity. Our results are based on self-consistent-field theory for the combined system of polyelectrolyte chain, counterions, electrolyte ions, and the dielectric mismatch between the cavity and the enclosing space. The effects of degree of ionization of the polymer and the net charge of the hole on the translocation barrier will be presented.

1:51PM Q43.00012 Polymer translocation facilitated by Chaperones , ANIKET BHATTACHARYA, University of Central Florida, Orlando, TAPIO ALA-NISSILA, Aalto University School of Science, Finland, WOKYUNG SUNG, Pohang University of Science and Technology, South Korea — We study translocation of biopolymers through a nanopore in a membrane facilitated by attractive binding particles (Chaperones) using Langevin dynamics simulation. Specifically we study how the density and attractive strength of these bindings particles affect the chain conformations at the $trans$ side and mean first passage time (MFPT). We also consider model larger chaperone that can bind reversibly on the multiple units of the translocating chain. Finally, we consider translocation of heteropolymers and how a specific sequence affect the translocation process. We discuss relevance of our studies in biological translocation processes.

Session Q44 DPOLY: Focus Session: Dynamics of Polymers-Phenomena due to Confinement

A309

11:15AM Q44.00001 The effect of pattern dimensions on the thermal decay of polymer patterns created by nanoimprint lithography , KENNETH KEARNS, Saginaw Valley State University, H.W. RO, HEATHER J. PATRICK, THOMAS A. GERMER, CHRISTOPHER SOLES, National Institute of Standards and Technology — Spectroscopic ellipsometry, combined with rigorous coupled wave modeling, is used to characterize the thermal decay of polymeric patterns prepared by nanoimprint lithography. When the residual layer is on the order of 10 nm, the pattern decay kinetics of patterns with a 420 nm periodicity near their glass transition temperatures are nearly an order of magnitude slower than patterns sitting on a thick residual layer. Pattern decay is not observed when the periodicity increased to 800 nm for the 10 nm residual layers. Polystyrene, poly(methyl methacrylate), and poly(4-t-butyl styrene) all show this behavior suggesting that changes in entanglement density are not important. The difference in the radius of curvature for the two different pattern periodicities is the likely origin for the pattern decay. The sensitivity of the technique to thin residual layers and nanoscale patterns is enhanced with an optical cavity of SiO_2 between the polymer and Si substrate. The SiO_2 layer enhances the changes in the ellipsometric parameters alpha and beta, which are related to psi and delta. The model dependent scatterometry data is corroborated by atomic force microscopy.

11:27AM Q44.00002 Capillary levelling as a probe of rheology in polymer thin films[1] , JOSHUA D. MCGRAW, NICK M. JAGO, KARI DALNOKI-VERESS, Department of Physics and Astronomy and the Brockhouse Institute for Materials Research, McMaster University — While measuring the rheology of bulk polymer systems is routine, when the size of a system becomes comparable to the molecular size, flow properties are poorly understood and hard to measure. Here, we present the results of experiments that are easily performed and can probe the rheological properties of polymer films that are mere tens of nanometres in thickness. We prepare glassy bilayer polymer films with height profiles well approximated by a step function. Upon annealing above the glass transition, broadening of the height profiles due to gradients in the Laplace pressure is observed. By validating the technique as a probe of the rheology with a range of molecular weights, we will show that this robust technique can be used to investigate the effects of confinement and interfaces on the rheology of ultrathin polymer films.

[1]Financial support from NSERC of Canada is gratefully acknowledged.

11:39AM Q44.00003 Direct evidence of heterogeneous dynamics within ultrathin polystyrene melt films[1] , TAD KOGA, NAISHENG JIANG, PETER GIN, MAYA ENDOH, Stony Brook University, SURESH NARAYANAN, Argonne National Laboratory, LARRY LURIO, Northern Illinois University, SUNIL SINHA, University of California San Diego — We report heterogeneous dynamics associated with cooperative motions of polymer chains within single polystyrene (PS) films at temperatures far above its glass transition temperature. The technique used was a marker x-ray photon correlation spectroscopy technique using "dilute" gold nanoparticles embedded in PS films in conjunction with resonance-enhanced x-rays scattering which intensifies the probing electrical field in the regions of interest within the films. We found that as the thickness decreased below around 60 nm, the diffusive motions of the markers were significantly suppressed both at the free surface and the center of the film relative to those for the thicker films (>100 nm thickness). It is attributed to the long-range effects on the polymer dynamics induced by an immobile layer at the substrate interface.

11:51AM Q44.00004 Anisotropic Dependence of Capillary Dynamics of Confined Polymer Liquid Films , YELING DAI, OLEG SHPYRKO, Department of Physics, University of California, San Diego, KYLE ALVINE, Pacific Northwest National Lab, SURESH NARAYANAN, ALEC SANDY, Argonne National Lab — We experimentally investigate the effect of highly anisotropic confinement on the capillary dynamics of polymer liquid films. Polystyrene films confined laterally within line-space silicon grating patterns of varying channel width represent a highly anisotropic liquid. The capillary fluctuation modes of such system can be expected to persist along the direction of the channels, while fluctuations perpendicular to the channels are likely to be suppressed. We utilized X-ray Photon Correlation Spectroscopy (XPCS) to access this capillary wave dynamics. In addition to the channel-width dependence of the capillary relaxation times, we also observe the anisotropic dependence of the capillary wave fluctuations on the confined polymer surface. I will discuss how XPCS can access the directional dependence of capillary dynamics and comment on the role played by interfacial pinning in suppressing capillary fluctuations.

12:03PM Q44.00005 Surface Dynamics of Macrocyclic Polystyrene Films , SHIH-FAN WANG, MARK D. FOSTER, Dept. of Polymer Science, The University of Akron, Akron OH 44325-3909, ZHANG JIANG, SURESH NARAYANAN, X-ray Science Division, Argonne National Laboratory, Argonne, IL 60439 — Thermally stimulated fluctuations of the surface of a melt of macrocyclic polymers have been studied for the first time. The surface fluctuations of macrocyclic polystyrene (cPS) of 2k, 7k, 17k, and 37k molecular weight (M) were probed using x-ray photon correlation spectroscopy (XPCS), a recently-developed technique that has already been applied to study surfaces of linear PS melts. The surface fluctuations for the cPS films are slower than those of linear chain analogs for all M. However, the glass transition temperatures (Tg) of the cyclic chains are higher than those of the linear analogs, with the discrepancy decreasing with increasing M. A continuum hydrodynamic theory of thermally stimulated capillary waves with a nonslip boundary condition is adequate to rationalize the behavior of the cPS films. When results from cPS of different M are plotted as a function of T/Tg the data nearly collapse to a single curve, indicating that Tg is a key parameter for the surface dynamics of macrocyclics in the temperature range studied. 12:15PM Q44.00006 Surface dynamics of micellar diblock copolymer films[1] , SANGHOON SONG, WONSUK CHA, HYUNJUNG KIM, Sogang University, ZHANG JIANG, SURESH NARAYANAN, Advanced Photon Source — We studied the structure and surface dynamics of poly(styrene)-b-poly(dimethylsiloxane) (PS-b-PDMS) diblock copolymer films with micellar PDMS surrounded by PS shells. By 'in-situ' high resolution synchrotron x-ray reflectivity and diffuse scattering, we obtained exact thickness, electron density and surface tension. A segregation layer near the top surface was appeared with increasing temperature Surface dynamics were measured as a function of film thickness and temperature by x-ray photon correlation spectroscopy. The best fit to relaxation time constants as a function of in-plane wavevectors were analyzed with a theory based on capillary waves with hydrodynamics with bilayer model Finally the viscosities for the top segregated layer as well as for the bottom layer are obtained at given temperatures

12:27PM Q44.00007 Polymer Transport Near Rough Surfaces , MOSES BLOOM, Northwestern University, JONATHAN WHITMER, University of Illinois, ERIK LUIJTEN, Northwestern University — The rheology of dilute polymer solutions under confinement is important in biology, medicine, microfluidic device design, synthetic polymer processing, and even geologic porous media. However, the solution's specific interactions with the confining surface are poorly understood. This situation is exacerbated for composite nanoparticles, such as polymer/metallic hybrids. Using multi-particle collision dynamics, we find a rich array of transport regimes depending on small-scale surface roughness and the specific surface/solute interactions. These factors couple to hydrodynamic conditions, including flow strength and confinement geometry in unexpected ways. Our findings may be relevant to transport phenomena in certain rough-walled capillaries, such as the distribution of various nanoconjugates in vivo.

12:39PM Q44.00008 Molecular dynamics simulation study of slip flows over surfaces with periodic and random anisotropic textures , NIKOLAI PRIEZJEV, Michigan State University — The influence of surface patterns on slip flow of a Lennard- Jones fluid is investigated using molecular dynamics simulations. We consider a situation when the typical pattern size is smaller than the channel width. First, anisotropic slip lengths are reported at low shear rates for flows over periodic stripes of different wettability when the shear flow direction is misaligned with respect to the stripe orientation. The results of MD simulations are compared with continuum predictions. Second, in case of random chemical patterning, the slip length depends sensitively on the total area of wetting texture. Finally, we found that at sufficiently high shear rates the slip length is anisotropic even for atomically flat crystalline surfaces; and, in particular, the slip length is enhanced when the shear flow is oriented along the crystallographic axis of the wall lattice. The simulation results indicate that the onset of the nonlinear regime between the slip length and shear rate is determined by the diffusion of fluid monomers within the first layer.

12:51PM Q44.00009 Glass Transition Dynamics and Surface Layer Mobility in Unentangled Polystyrene Films , ZHAOHUI YANG, Boston University, YOSHIHISA FUJII, F.K. LEE, C.H. LAM, DONGDONG PENG, OPHELIA TSUI — Most polymers solidify into a glassy amorphous state, accompanied by a rapid increase in the viscosity when cooled below the glass transition temperature (Tg). There has been an ongoing debate on whether the Tg changes with decreasing polymer film thickness and the origin of the changes. We measured the viscosity of unentangled, short-chain polystyrene (2.4kg/mol) films on silicon at different temperatures and found that the transition temperature for the viscosity decreases with decreasing films thickness, in agreement with the changes in the Tg of the films observed by thermal expansion measurements. By applying the hydrodynamics equations to the films, we are able to explain the data fully by assuming that a highly mobile layer is present within the top 2.3 nm thick region of the films and follows an Arrhenius dynamics while the remaining of the films is bulk-like.

1:03PM Q44.00010 Fingering Instability of Debonding Soft Elastic Adhesives , ELIE RAPHAEL, CNRS ESPCI — We study the crack-front fingering instability of an elastic adhesive tape that is peeled off a solid substrate. Our analysis is based on an energy approach using fracture mechanics and scaling laws and provides simple physical explanations for (i) the fact that the wavelength depends only on the thickness of the adhesive film and (ii) the threshold of the instability, and (iii) additionally estimates the characteristic size of the fingers. The scaling laws for these three observables are in agreement with existing experimental data.

1:39PM Q44.00011 Effect of molecular weight on surface mobility of polystyrene films , DONGDONG PENG, ZHAOHUI YANG, OPHELIA TSUI, Boston University — There have been mounting experimental results showing that a two-layer model is appropriate for describing the dynamics of polymer films. The model postulates that a surface mobile layer exists at the free surface and can modify the dynamics of the entire film. In a recent study, we measured the viscosity of unentangled, short-chain polystyrene (Mw=2.4kg/mol) films supported by silicon at different temperatures including the bulk Tg, and found that the data could be fully explained by assuming a surface mobile layer with a constant thickness exists and sits atop a bulk-like layer. In this talk, I will report the result we obtained by measuring the viscosity of polystyrene films with a wide range of molecular weights from 6.4 to 2316 kg/mol supported by silicon. Our result shows that the same two-layer model is applicable in describing the data if the mobility of the surface layer assumes a molecular weight dependence that differs from either the Rouse or Reptation model.

1:51PM Q44.00012 Scaling of confined and interacting comb polymers , CATHERINE YEH, PHILIP PINCUS, University of California, Santa Barbara — We study the scaling of polymer chains grafted to a line, i.e. a 1-D brush or comb polymer, on a repulsive plane in good solvent using classical molecular dynamics. The grafting density is large enough to cause chain stretching. The confined comb geometry is motivated by intermediate filaments where the unstructured monomer c-termini form annular rings that can be modeled as a confined comb bent into a ring. We find that the scaling of brush size as a function of the number of monomers per chain is the same for a comb with and without confinement by a repulsive plane. We also consider the transition of a line of parallel interacting combs to the planar brush geometry as they are compressed from isolated combs; we present results for the dependence of brush height on the distance between combs.

2:03PM Q44.00013 Geometry and molecular architecture effects in nanobubble inflation measurements , SHANHONG XU, Texas Tech University, SYLVIE CASTAGNET, Laboratoire de Mecanique et Physique des Materiaux, Poitiers, France, GREGORY MCKENNA, Texas Tech University — Confinement effects on the mechanical properties of ultrathin polymer films were investigated by a bubble inflation technique developed in our lab. Prior studies of ultrathin films of poly(vinyl acetate) (PVAc) and linear polystyrene (PS) were performed on circular bubbles of different diameters. Here the creep behaviors of ultrathin films of linear PS were investigated on rectangular bubbles. The modulus of the thin film rectangular bubbles was analyzed by approximation methods. The inflation of rectangular bubbles was simulated by finite element analysis (FEA). The mechanical properties of the thin films with the same thickness for circular and rectangular bubbles are compared and we find that the rubbery plateau compliance is geometry independent. We also investigated the creep behaviors of ultrathin films of 3-arm star PS on circular bubbles. We find the rubbery plateau compliance is molecular architecture independent.

Session Q45 DAMOP: Non-equilibrium Physics with Cold Quantum Gases II A310

11:15AM Q45.00001 Quenched dynamics in interacting one-dimensional systems: Appearance of current carrying steady states from initial domain wall density profiles[1] , JARRETT LANCASTER, New York University, EMANUEL GULL, Columbia University, ADITI MITRA, New York University — Dynamics arising after an interaction quench in the quantum sine-Gordon model is studied for the case of a system initially prepared in a spatially inhomogeneous domain wall state. The time-evolution of the density, current and equal time correlation functions are studied using the truncated Wigner approximation (TWA) to which quantum corrections are added in order to set the limits on its validity. For weak to moderate strengths of the back-scattering interaction, the domain wall is found to spread out ballistically with the system within the light cone reaching a non-equilibrium steady-state characterized by a net current flow. A steady state current is also found to exist for a quench at the exactly solvable Luther-Emery point. The magnitude of the current decreases with increasing strength of the back-scattering interaction. The two-point correlation function of the variable canonically conjugate to the density reaches a steady state which is spatially oscillating at a wavelength which is inversely related to the current.

[1]This was was supported by NSF-DMR (Award no. 1004589).

11:27AM Q45.00002 Quantum quenches and off-equilibrium dynamical transition in the infinite dimensional Bose Hubbard model , GIULIO BIROLI, BRUNO SCIOLLA, IPhT CEA Saclay — We study the off-equilibrium dynamics of the infinite dimensional Bose Hubbard Model after a quantum quench. The dynamics can be analyzed exactly by mapping it to an effective Newtonian evolution. For integer filling, we find a dynamical transition separating regimes of small and large quantum quenches starting from the superfluid state. This transition is very similar to the one found for the fermionic Hubbard model by mean field approximations.

11:39AM Q45.00003 Optimal control for unitary preparation of many-body states: application to Luttinger liquids[1] , ARMIN RAHMANI, CLAUDIO CHAMON, Boston University — Many-body ground states of local Hamiltonians can be prepared via unitary evolution in cold atomic systems. Given the initial state and a fixed time for the evolution, how close can we get to a desired ground state if we can tune the Hamiltonian in time? Here we study this optimal control problem focusing on Luttinger liquids with tunable interactions. We show that the optimal protocol can be obtained using the simulated annealing method. Rather surprisingly, we find that in the Luttinger liquid case the interaction strength in the optimal protocol can have a *non-monotonic* time-dependence. We find a marked difference in the behavior of the system when the ratio τ/L of the preparation time to the system size exceeds a critical value around 1/8. In this regime, the optimal protocol can prepare the states with almost perfect accuracy. Finally, we argue that the time-scale of the optimal evolution defines a dynamical measure of distance between quantum states.

11:51AM Q45.00004 Dissipative Transport of Trapped Bose-Einstein Condensates through Disorder , SATYAN BHONGALE, George Mason University, PAATA KAKASHVILI, NORDITA, CARLOS BOLECH, University of Cincinnati, HAN PU, Rice University — After almost half a century since the work of Anderson [Phys. Rev. **109**, 1492 (1958)], at present there is no well established theoretical framework for understanding the dynamics of interacting particles in the presence of disorder. Here, we address this problem for interacting bosons near $T = 0$, a situation that has been realized in trapped atomic experiments with an optical speckle disorder. We develop a theoretical model for understanding the hydrodynamic transport of *finite-size* Bose-Einstein condensates through disorder potentials. The goal has been to set up a simple model that will retain all the richness of the system, yet provide analytic expressions, allowing deeper insight into the physical mechanism. Comparison of our theoretical predictions with the experimental data on large-amplitude dipole oscillations of a condensate in an optical-speckle disorder shows striking agreement. We are able to quantify various dissipative regimes of slow and fast damping. Our calculations provide a clear evidence of reduction in disorder strength due to interactions. The analytic treatment presented here allows us to predict the power law governing the interaction dependance of damping. The corresponding exponents are found to depend sensitively on the dimensionality and are in excellent agreement with experimental observations.

12:03PM Q45.00005 Mesoscopic Transport of Ultracold Atoms in Optical Lattices[1] , MARTIN BRUDERER, WOLFGANG BELZIG, Fachbereich Physik, Universität Konstanz, D-78457 Konstanz, Germany — Transport of quantum gases is attracting considerable attention, both on a theoretical and experimental level, in part because ultracold atoms confined to optical lattices can be coherently manipulated and detected on microscopic scales. In particular, substantial technological progress has opened the way for a bottom-up approach to mesoscopic transport in optical lattices, in which case the coherence in certain parts of the system is deliberately destroyed. We show based on a specific setup, namely two incoherent atomic reservoirs connected by a short optical lattice, that mesoscopic phenomena such as, e.g., phonon assisted transport, coherent suppression of tunneling and non-adiabatic quantum pumping can be realized with ultracold atoms. For our analysis in the tight-binding regime we use the non-equilibrium Green's functions formalism extended to include the time dependence of the reservoirs.

12:15PM Q45.00006 Detecting Paired and Counterflow superfluidity via dipole ocsillations , ANZI HU, LUDWIG MATHEY, Joint Quantum Institute, University of Maryland and National Institute of Standard and Technology, Gaithersburg, MD 20899, IPPEI DANSHITA, Department of Physics, Faculty of Science, Tokyo University of Science, Shinjuku-ku, Tokyo 162-8601, Japan, CARL WILLIAMS, CHARLES CLARK, Joint Quantum Institute, University of Maryland and National Institute of Standard and Technology, Gaithersburg, MD 20899 — We study the dynamic response of the paired superfluid (PSF) and counterflow superfluid (CFSF) states in a binary mixture of ultra-cold bosonic atoms following an abrupt displacement of the trapping potential. In the PSF and CFSF states, the pairing and anti-pairing orders lead to novel transport properties and distinctive dynamic responses to the abrupt displacement. The findings provide a clear experimental procedure to detect these orders and give an intuitive insight into the dynamics of paired and counterflow superfluidity.

12:27PM Q45.00007 ABSTRACT WITHDRAWN –

12:39PM Q45.00008 Adiabatic Quantum Transport of Bosonic Atoms in Double Well Optical Lattices[1] , YINYIN QIAN, CHUANWEI ZHANG, Department of Physics and Astronomy, Washington State University, Pullman, Washington, 99164 USA — Quantum charge pump, where the amount of pumped charges is controlled precisely through the quantized adiabatic charge transport in periodic crystals, has many important applications in electronics. The quantum pump of cold neutral atoms may play a similar significant role in atomtronics. Neutral atoms can be bosons, and their transport properties can be very different from electrons (fermions). We study the adiabatic quantum transport of bosonic atoms in double well optical lattices where the lattice parameters are adiabatically and periodically tuned. The effects of the interaction between atoms on the transport properties are characterized. In the strong interacting regime, the bosonic atoms behave similarly as fermions with quantized atom transport. In the weak interacting regime, the atom transport depends strongly on the paths in the lattice parameter space and the quantized transport may be destroyed. The effects of harmonic traps and disorder potentials are also studied. The investigation is based on the numerical simulation of the exact quantum dynamics of cold atoms in double well optical lattices using the time evolving block decimation algorithm.

[1]This work is supported by the ARO (W911NF-09-1-0248).

12:51PM Q45.00009 Schwinger-Keldysh approach to the Bose-Hubbard model with time varying hopping[1] , MALCOLM P. KENNETT, Simon Fraser University, DENIS DALIDOVICH, Perimeter Institute; Simon Fraser University — Cold bosonic atoms confined in an optical lattice potential give a realization of the Bose Hubbard model, and it is possible to study the phase transition between a superfluid and a Mott insulator as the depth of the optical lattice is varied. We study the real time dynamics of the Bose Hubbard model at zero and finite temperature in the presence of time-dependent hopping using the Schwinger-Keldysh technique. Using a strong-coupling approach, we determine the effective action in the vicinity of the zero-temperature transition between superfluid and Mott insulating phases. We then study the solutions of the resulting saddle-point dynamical equations as the hopping is varied to sweep across the phase transition from the superfluid to insulating phase.

1:03PM Q45.00010 Optimal loading for a Tonks-Girardeau gas , CLAUDIA DE GRANDI, ANATOLI POLKOVNIKOV, Boston University — We analyze the process of loading a one-dimensional system of hard-core bosons, i.e. a Tonks-Girardeau gas, into a commensurate optical lattice. We consider different loading protocols (e.g. linear, quadratic or sudden ramp in time, or cyclic loading). We discuss possible ways of optimization to minimize the heating and the excitations rate of the system due to the loading process. Combining analytical and numerical methods we analyze the problem under experimentally realistic conditions and we compare the results with earlier scaling predictions.

1:15PM Q45.00011 Weakly interacting bosons in a periodic optical lattice[1] , QINQIN LU, KELLY R. PATTON, DANIEL E. SHEEHY, Louisiana State University — We study an interacting boson gas in a periodic optical potential, with the goal of understanding the properties of such a gas away from the Mott insulating regime at large optical lattice depth. In particular, we analyze the density dependence of the transition temperature as a function of optical lattice depth and the response to a dynamical modulation of the optical lattice.

[1]This work was supported by the Louisiana Board of Regents

1:27PM Q45.00012 Pairsuperfluid in Dynamically Constraint Bose-Hubbard Models , LARS BONNES, University of Stuttgart, STEFAN WESSEL — We consider ultra-cold atoms loaded into a two-dimensional optical lattice with strong three-body losses, i.e. three bosons sharing one lattice site scatter inelastically and dissipate from the system. This process dynamically stabilizes a three-body on-site repulsion in analogy to the quantum Zeno effect. The system studied here is described by a Bose-Hubbard model on a square lattice with on- site attraction. The maximal number of particles per lattice site is restricted to two in order to take the three-body repulsion into account. Field theoretical considerations and numerical simulations using Matrix Product States in one dimension suggest the existence of a dimer superfluid phase for small tunneling rates that is effectively described by the condensation of boson pairs and the absence of an atomic condensate. In this work we explore the ground state and finite-temperature phase diagram for our model using large-scale quantum Monte- Carlo simulations. Our main emphasis is the detection of the dimer superfluid phase and we address the issue of extrapolating our finite-temperature data to the thermodyanmic limit at $T = 0$. Furthermore, we explore the possibility of adding an explicit dimer hopping term that drastically changes the behavior of our system.

1:39PM Q45.00013 Beyond mean-field dynamics in open Bose-Hubbard chains[1] , HOLGER HENNIG, Max Planck Institute for Dynamics and Self-Organization (MPIDS), Goettingen, Germany and Department of Physics, Harvard University, Cambridge (USA), DIRK WITTHAUT, MPIDS, Goettingen, Germany, FRIEDERIKE TRIMBORN, Institute for Theoretical Physics, University of Hannover, Germany, GEORGIOS KORDAS, Institute for Theoretical Physics and Center for Quantum Dynamics, University of Heidelberg, Germany, THEO GEISEL, MPIDS, Goettingen, Germany, SANDRO WIMBERGER, Institute for Theoretical Physics and Center for Quantum Dynamics, University of Heidelberg, Germany — We investigate the effects of phase noise and particle loss on the dynamics of a Bose-Einstein condensate in an optical lattice. Starting from the many-body master equation, we discuss the applicability of generalized mean-field approximations in the presence of dissipation and methods to simulate quantum effects beyond mean-field by including higher-order correlation functions. It is shown that localized particle dissipation leads to surprising dynamics, as it can suppress decay and restore the coherence of a Bose-Einstein condensate. These effects can be applied to engineer coherent structures such as stable discrete breathers and dark solitons.

1:51PM Q45.00014 Strong local-field effect on dynamics of a dilute atomic cloud irradiated by two counterpropagating optical fields: beyond standard optical lattices[1] , GUANGJIONG DONG, JIANG ZHU, WEIPING ZHANG, State Key Laboratory of Precision Spectroscopy, East China Normal University, Dongchuan Rd. 500, Shanghai, 200241, China, MIKHAIL SHNEIDER, MAE Department, Princeton University, NJ 08544 — We study a recent experiment (K. Li et al., Phys. Rev. Lett. 101, 250401 (2008)) on diffracting a Bose-Einstein condensate by two counterpropagating optical fields. Including the local field effect, we explain asymmetric momentum distribution and self-imaging of the BEC in a self-consistent way, and find that the self-imaging is not dependent on the intensity difference of the two optical fields, but on the light-condensate interaction time. We show further that the local field effect leads to deformation of an optical lattice, and thus is essential for getting better quantitative analysis of other current optical lattice experiments of cold atoms. Moreover, intensity imbalance of the two optical fields could be applied as a new means to tailor both cold atom dynamics and optical propagation.

2:03PM Q45.00015 Quenched dynamics in a spin-1/2 chain prepared in a sharp domain wall state , LEA SANTOS, Yeshiva University, ADITI MITRA, New York University, EMIL PRODAN, Yeshiva University — Using exact diagonalization and Expokit, we study the time evolution of current, magnetization and correlation functions in an isolated spin-1/2 chain initially prepared in a domain wall state. The domain wall consists of spins pointing up in the first half of the chain and down in the other half. Integrable and nonintegrable regimes are reached by adjusting the parameters of the Hamiltonian, which allows for the comparison of behaviors in both limits. In a chain with nearest- neighbor couplings, chaos is induced by adding on-site disorder or by adding next-nearest-neighbor couplings. The magnitude of the current decreases with interaction for the clean integrable system and for the chaotic disordered case. For the chaotic clean system with next-nearest-neighbor couplings, a non- monotonic behavior in the current is found as the interaction strength is increased.

S1.00002 Scaffolding of peptides using a coarse-grained representation of residues with side chain and backbone nodes[1] , RAS PANDEY, University of Southern Mississippi, BARRY FARMER, Air Force Research Laboratory — Monte Carlo simulations are performed to study scaffolding of peptides (KSL) on a cubic lattice. A residue is represented by three backbone nodes (C-terminal, C-alpha, N-terminal) and a side node connected to the central C-alpha node each connected by fluctuating bond. A peptide is a chain of residues. A solvent constituent is represented by a particle of the same size as that of a node. Peptides and solvent are distributed randomly in the cubic box with concentration C_p and C_w respectively. Each residue interacts with other residues and solvent particles via its side chain with the Lennard-Jones (LJ) potential where a knowledge-based interaction matrix is used for the residue-residue interaction. We examine local and global physical quantities such as mobility and energy of each residue, radial distribution function, and structure factor. We find that the scaffolding of peptides depends on the interaction strength and concentration of the solvent. The structure factor shows multi-scale structure of the aggregates.

S1.00003 Ion tunable of rheology of supramolecular metallogels , NIGEL CLARKE, JONATHAN STEED, MARC-OLIVER PIEPENBROCK, Durham University — A bis(pyridylurea) ligand forms metallogels in methanol in the presence of up to 0.5 equiv of copper(II) chloride. The addition of further copper(II) chloride gives an unusual crystalline 4:3 coordination polymer, whereas in the presence of 0.5 equiv of copper(II) nitrate, a 2:1 crystalline coordination polymer arises. The latter represents a possible model for supramolecular gelators and highlights key interactions with counteranions that suggest a means to tune gel properties using anion binding. The influence of chloride and acetate anions on the rheological properties of the copper(II) chloride metallogels are investigated [1]. The rheology of the anion-containing mixtures shows complex behavior with the gel structure evolving over time. We also observe shear-induced gelation [2], where vigorous shaking, rather than sonication, transforms a weak jelly like aggregate into a robust gel, exhibiting clear structural changes within the gel fibres. Reversible anion tuning allows these compounds to as responsive soft materials.

S1.00004 Amine-sulfonyl hydrogen bonding forms β-strand mimics , JUSTIN BARONE, KATHERINE HARVEY, Virginia Tech — Ethyl vinyl sulfone (EVS)-substituted amino acids have the ability to form β-strand mimics that can then continue to aggregate into larger structures such as sheets. The β-strand forms from a sulfonyl-amine hydrogen bond. Here, we show that EVS-substituted lysine forms β-structures similar to protein β-structures as measured with x-ray diffraction. The β-structures can aggregate into macroscopic sheets with the ability to roll under the influence of the amino acid chirality. Microtubules form from sheets rolling left (L-lysine) or right (D-lysine).

S1.00005 Relationship between Hydrophilicity of PEO-PPO-PEO Copolymers and Their Ability to Protect Liposomes from Peroxidation , JIA-YU WANG, The Univeristy of Chicago, CHI-YUAN CHENG, SONG-I HAN, University of California, Santa Barbara, KA YEE LEE, The University of Chicago, THE UNIVERISTY OF CHICAGO COLLABORATION, UNIVERSITY OF CALIFORNIA, SANTA BARBARA COLLABORATION — It is known that PEO-PPO-PEO triblock copolymers interact with lipid membranes but can have opposing effects on membrane integrity - they can behave either as membrane sealants or as permeabilizers depending on their architecture. To understand the origin of their biomedical functionality, interactions between PEO-PPO-PEO triblock copolymers and biomimetic phospholipid vesicles were investigated by evaluating the effect of hydrophilicity of the triblock copolymers on their ability to protect liposomes from oxidative stress, a stress source used to disrupt lipid vesicles. Our results show that while highly hydrophilic triblock copolymers exhibit no apparent insertion into lipid membranes, they are most effective in protecting liposomes from oxidation, indicating that the protective effect of triblock copolymers comes from their physical adsorption onto, rather than their insertion into the membrane. Gaining a better understanding of polymer-membrane interactions could lead to a better design of polymeric cell membrane sealants.

S1.00006 The effect of ion beam sculpted nanopore size and shape on DNA translocation[1] , RYAN ROLLINGS, University of Arkansas, EDWARD GRAEF, University of Texas at Dallas, DENIS TITA, SANTOSHI NANDIVADA, MOURAD BENEMARA, JIALI LI, University of Arkansas — Solid state nanopore based devices can sense single biomolecules in their native environment. Nanopore thickness plays a crucial role in the signal to noise ratio of current blockades caused by biomolecule translocation and ultimately limits the spatial resolution of the nanopore device when discriminating small features on DNA and protein molecules. Low energy ion beam irradiation can create nanometer size pores in very thin membranes 10-20 nm thick, but to date ion beam sculpted nanopores have shown current blockades smaller than predicted from pores of this thickness. We use electron energy loss spectroscopy and energy filtered transmission electron microscopy to study ion beam sculpted nanopore geometry in detail and determine its effect on conductance blockades and I-V curves. Current blockades from pores thinned by chemical etching and ion beam sputtering will also be presented.

S1.00007 Detection of SPM tip-attached DNA molecules with solid state nanopores[1] , CHANGBAE HYUN, ZHEXUE LU, BRADLEY LEDDEN, JIALI LI, University of Arkansas — Using an apparatus that combines solid-state nanopores with a scanning probe microscope (SPM), we studied ionic current reduction due to the SPM tip. The experiment was performed at different KCl concentrations, SPM tip probing heights, and several bias voltages. The same experiment was also performed with DNA molecules attached to the SPM tip. The current blockage signal through solid-state nanopores with and without luDNA molecules attached to the SPM tip was analyzed. We also present the current blockage and electrical field profile simulation using finite element analysis software (Multiphysics, COMSOL Inc).

[1]We acknowledge the funding support provided by NHGRI/NIH R21HG00477 and NSF/MRSEC 080054

S1.00008 Micro-phase assembly of active sites in a coarse-grained model of chromatin by Monte Carlo simulation[1] , YANG ZHANG, DIETER HEERMANN, University of Heidelberg, Germany, BARRY FARMER, Air Force Research Laboratory, RAS PANDEY, University of Southern Mississippi — A coarse-grained model is used to study the self-assembly of active sites in a DNA (chromatin) chain. The chromosome is described by a bond-fluctuating chain of two types of nodes A (interacting) and B (non-interacting), distributed randomly with concentration C and $1-C$ respectively. Active nodes interact with a Lennard-Jones (*LJ*) potential and execute their stochastic motion with the Metropolis algorithm. The depth of the *LJ* potential (f), a measure of interaction strength and the concentration (C) of the active sites are varied. A number of local and global physical quantities are studied such as mobility (M_n) profile of each node, their local structural profile, root mean square (RMS) displacement (R), radius of gyration (R_g), and structure factor $S(q)$. We find that the chain segments assemble into microphase of blobs which requires higher concentration of active sites at weaker interaction. These findings are consistent with that of a dynamic loop model of chromatin on global (large) scale but differ at small scales.

S1.00009 Single-molecule studies of DNA self-diffusion in entangled linear and circular DNA blends , COLE D. CHAPMAN, UCSD, MICHAEL HARLANDER-LOCKE, University of San Diego, DOUGLAS E. SMITH, UCSD, RAE M. ROBERTSON-ANDERSON, University of San Diego, UCSD PHYSICS TEAM, USD PHYSICS TEAM — Here, we use single-molecule fluorescence and particle-tracking to measure self-diffusion coefficients of single DNA molecules in varying blends of entangled linear and circular DNA. We have previously shown that the self-diffusion of entangled circular and linear DNA differ from each other and are strongly dependent on the topology of the background DNA. This phenomenon can be attributed in part to the tendency of linear polymers to thread their circular counterparts, leading to constraint release, as well as reptation. Previous rheological studies have shown a complex relationship between the ratio of linear to circular polymers and viscosity, however, conflicting results have been reported and the molecular dynamics that lead to this behavior remain unclear. Using single-molecule methods, we can directly measure self-diffusion coefficients for individual DNA molecules within concentrated solutions of linear and circular DNA, and thus determine for both topologies the dependence of self-diffusion on: the ratio of linear and circular species, the overall solution concentration, and the molecular length.

S1.00010 Dual-Function Epi-fluorescence Optical Tweezers to Characterize Single Polymer Interactions in Complex Polymeric Fluids , KENT LEE, USD, COLE D. CHAPMAN, UCSD, RAE M. ROBERTSON-ANDERSON, USD, USD TEAM, UCSD TEAM — Intermolecular interactions within entangled polymeric fluids are highly complex and not well understood. Previously, we investigated these interactions on a single-molecule level by using optical tweezers and fluorescence microscopy to measure interaction forces between DNA molecules and self-diffusion of DNA, respectively. To better characterize these interactions, we have developed an epi-fluorescence optical tweezers which combines an epi-fluorescence microscope with a dual-trap, force-measuring optical tweezers. One of the optical traps is moveable enabling different DNA lengths to be stretched across the two traps. Forces on both traps are measured allowing us to probe the force exerted on a trapped DNA molecule by surrounding entangling DNA. Fluorescence capabilities allow us to directly visualize polymer interactions and dynamics while take force measurements. By fluorescently-labeling either the trapped DNA or a select number of surrounding DNA, we can determine both the conformational changes that the measured force induces on the DNA as well as the various molecular configurations that produce each force. These studies will provide a much needed link between single-molecule dynamics and conformations and intermolecular forces in complex polymeric fluids.

S1.00011 Dynamics of a linear polymer in a microchannel creeping flow[1] , PRASENJIT BOSE, MIRON KAUFMAN, PETRU FODOR, Cleveland State University — An understanding of the dynamics of a polymer in a microchannel could be used to design the technology for high throughput molecular analysis and manipulation. We simulate the motion of a linear polymer advected by a fluid in a rectangular microchannel. We consider the creeping laminar flow, i. e. zero Reynolds number. The model polymer is made up of beads connected by elastic springs. The dynamics of this nonlinear mechanical system is studied as a function of model parameters: the spring equilibrium distance, the mass of a bead, and the spring constant.

S1.00012 Glassy dynamics in thin layers of polystyrene and polyisoprene[1] , EMMANUEL URANDU MAPESA, MARTIN TRESS, FRIEDRICH KREMER, University of Leipzig — Broadband Dielectric Spectroscopy (BDS), Spectroscopic vis-Ellipsometry (SE), X-Ray Reflectometry (XRR), Alternating (ACC) and Differential Scanning Calorimetry (DSC) are combined to study glassy dynamics and the glass transition temperature in nanometric thin ($\geq$5 nm) layers of polystyrene (PS) having widely varying molecular weights (27,500 to 8,090,000 g/mol). For the dielectric measurements two sample geometries are employed, the common technique (capped) using evaporated electrodes and a recently developed approach (uncapped) taking advantage of highly-insulating silica nanostructures as spacers. *All* applied methods deliver the concurring result that deviations from glassy dynamics and from the glass transition temperature of the bulk never exceed margins of $\pm$3K *independent* of the layer thickness and the molecular weight, indicating that the length scale of interfacial interaction is restricted to less than 5 nm. We also show preliminary BDS results where thin layers of cis-1,4-polyisoprene (PI) are measured in both geometries; there are indications that the confinement-induced mode is absent when the layers are uncapped.

[1]Financial support from DFG (SPP 1369) is gratefully acknowledged.

S1.00013 Dynamics of Silica Particles Grafted with Polymer Brush in Polystyrene Matrix , TAIKI HOSHINO, MORIYA KIKUCHI, JST, ERATO, DAIKI MURAKAMI, JST,ERATO, KOJI MITAMURA, JST, ERATO, YOSHIKO HARADA, JST,ERATO, KIMINORI ITO, YOSHIHITO TANAKA, RIKEN SPring-8 Center, SONO SASAKI, Graduate School of Science and Technology, Kyoto Institute of Technology, MASAKI TAKATA, RIKEN SPring-8 Center, ATSUSHI TAKAHARA, JST, ERATO, Institute for Materials Chemistry and Engineering, Kyushu University — Nanoparticles (NPs) in soft materials near the glass transition temperature sometimes show fast diffusive behavior, called hyperdiffusion. In this study the dynamics of polystyrene (PS)- grafted silica NPs in PS matrix have been investigated by X-ray photon correlation spectroscopy (XPCS). XPCS system was setup at 27-m-long undulator beamline BL19LXU, SPring-8 (Japan). Detectors, a direct-illuminated CCD camera with a pixel size of 20$\times$20 μm^2 and a two-dimensional hybrid pixel array detector PILATUS, whose pixels were covered with a mask with $\sim$50 μm diameter holes for enhancement of the spatial resolution, were located about 3.2 m downstream of the sample. By XPCS measurements, autocorrelation functions, expressed by $g(q,t) = \exp(-2(\Gamma t)^{\beta}) + 1$ were obtained. At much higher temperature than the glass transition of PS matrix, g(q,t) with $\beta \leq 1$ were observed, but at decreased temperature, $beta > 1$ were observed. These behaviors can originate from hyperdiffusion. The detail of the measurements and the results will be presented.

S1.00014 New methods to characterize the confinement effects in epoxy nanocomposites[1] , LIYUN REN, MICHAEL GOODMAN, RAHMI OZISIK, Rensselaer Polytechnic Institute — Properties of epoxy can be improved/controlled via the addition of nanofillers. However, use of nanofillers leads to confinement and interfacial effects and the exact nature of these two effects on the properties are not yet clearly understood. In this study, the glass transition temperature of epoxy nanocomposites was investigated. The changes in the glass transition temperature were analyzed as a function of nanofiller content (confinement) and epoxy-nanofiller interface. In addition to these, the distribution and dispersion of nanoparticles also influences the properties. We applied two different methods to characterize the interparticle distance and compare the dependence of glass transition temperature on the nanofiller content and interparticle spacing. We found that our model provides a new understanding of the effect of interparticle spacing on glass transition phenomenon in polymeric nanocomposites.

[1]This work is supported by a grant from IBM.

S1.00015 Defect structures and coarsening in spherical shells of asymetric block copolymer systems , NICOLÁS GARCÍA, LEOPOLDO R. GÓMEZ, ALDO D. PEZZUTTI, DANIEL A. VEGA, Dep. de Fisica-IFISUR- Universidad Nacional del Sur. Conicet, MARCELO A. VILLAR, Dep. de Ing. Química-PLAPIQUI- Universidad Nacional del Sur. Conicet — We use a Brazovskii model to numerically investigate the defect structures and coarsening process of spherical shells of asymmetric block copolymers. It was found that the configurations of defects are dictated by the ratio between the radius of the spherical shell and the average lattice constant. For small system sizes most configurations of defects are in good agreement with the results for the Thomson problem and simply exhibit 12 well ordered disclinations. As the size of the system increases, in addition to the 12 disclinations the structure of defects is characterized by a varying number of dislocations arranged in grain boundary scars.

S1.00016 Nanoconfinement Effect on Polymerization , MAITRI VADDEY, SINDEE SIMON — Ring-opening metathesis polymerization of endo-dicyclopentadidene (DCPD) with second generation Grubbs catalyst is carried out under nanoscale constraint. Differential scanning calorimetry is used to study the polymerization reaction both in the bulk and in the nanopores of controlled pore glass as a function of heating rate; the Tg of the resulting reaction product is also determined. In 110 nm-diameter pores, DCPD undergoes incomplete polymerization followed by the reverse Diels-Alder reaction to form pentadiene. Decreasing the heating rate shifts both reactions towards lower temperatures but does not avert the side reaction. In the bulk unconfined case, the reverse Diels-Alder reaction only occurs in the absence of catalyst. The glass transition temperature of the nanoconfined polymerization product is 164 $^{\circ}$C, approximately 20 $^{\circ}$C higher than the polymer prepared under bulk conditions. Reaction kinetics in bulk and nanoconfined cases will also be discussed.

S1.00017 Molecular Dynamics Simulations of Grafted Layers of Bottle-Brush Polyelectrolytes[1] , DANIEL RUSSANO, JAN-MICHAEL CARRILLO, ANDREY DOBRYNIN, Department of Physics, University of Connecticut — Using molecular dynamics simulations, we study the effect of the brush grafting density and degree of polymerization of the side chains on conformations of brush layers made of charged bottle-brush macromolecules. The thickness of the brush layer first decreases with increasing brush grafting density; then, it saturates and remains constant in the wide interval of the brush grafting densities. The brush layers consisting of the bottle-brush macromolecules with longer side chains have a larger layer thickness. The elongation of the side chains of the bottle-brush macromolecules decreases with increasing brush grafting density. This contraction of the side chains is due to counterion condensation inside the volume occupied by bottle-brushes. Our simulations showed that counterion condensation is a multiscale process reflecting different symmetries of the bottle-brush layer.

[1]NSF: DMR-1004576

S1.00018 Influence of Ionic Strength on Chain Dimension in Polyelectrolyte Brushes at Aqueous Solution Interface[1] , KOJI MITAMURA, MOTOYASU KOBAYASHI, JST, ERATO & Kyushu Univ., MAYUMI TERADA, JST, ERATO, NORIFUMI L. YAMADA, KEK, ATSUSHI TAKAHARA, JST, ERATO & Kyushu Univ. — Polyelectrolyte brush on a solid surface in water generally has a swollen structure and provides high lubricity on the surface. Previously, we have reported that friction force on a cationic poly(2-(methacryloyloxy)ethyltrimethylammonium chloride) (PMTAC) brush in an aqueous medium increased with NaCl concentration, of which reason was not clear but probably due to a shrinkage of the swollen brush with the addition of salt. In this study, we investigated the salt concentration dependency of the chain dimension in PMTAC brush at the aqueous solution interfaces by neutron reflectometry. We also estimated how polydispersity in molecular weight of the brush influences the chain dimension.

[1]The present work was supported in S-type research project in KEK (2009S08).

S1.00019 Densely grafted brushes of gradient copolymers: an effective Flory-Huggins parameter approach[1] , SERGEY VENEV, IGOR POTEMKIN, Department of Physics, Moscow State University, Moscow 119992, Russian Federation; Department of Polymer Science, University of Ulm, 89069 Ulm,Germany — Manufacturing of gradient copolymers becomes cheaper and easier nowadays. There is a wide spectrum of experimental applications for such polymers. In this work, densely grafted gradient copolymer (monomers distribution function $g(n)$ along the chain is assumed to be a power law) brushes in a selective solvent are considered. Equilibrium thermodynamic properties of the system are investigated within the frames of a simple mean-field approach and an effective Flory-Huggins parameter $\chi_{eff}(n)$ approximation. Constructed profiles for polymer concentration demonstrate non-linear behavior, however the brush thickness varies in direct proportion to the molecular weight of copolymer. Coil-Globule transition properties in such a system are investigated as well.

S1.00020 Fast Lattice Monte Carlo Simulations of Inhomogeneous Polymers , QIANG WANG, Department of Chemical and Biological Engineering, Colorado State University, PENGFEI ZHANG, Institute of Physics, Nankai University, XINGHUA ZHANG, DELIAN YANG, Department of Chemical and Biological Engineering, Colorado State University, BAOHUI LI, Institute of Physics, Nankai University — Fast lattice Monte Carlo (FLMC) simulation with multiple occupancy of lattice sites and Kronecker δ-function interactions gives orders of magnitude faster/better sampling of the configurational space of multi-chain systems than conventional lattice MC simulations with self- and mutual- avoiding walks and nearest-neighbor interactions.[1] It also enables direct comparisons with the corresponding polymer field theories based on the same Hamiltonian (thus without any parameter-fitting) to unambiguously and quantitatively reveal the effects of fluctuations and correlations neglected or treated only approximately in the theories. Here we present our FLMC simulations of inhomogeneous polymeric systems including grafted and confined polymers, as well as the comparisons with lattice self-consistent field theory and Gaussian fluctuation theory to quantitatively reveal the consequences of approximations in these theories.

[1]Q. Wang, **Soft Matter, 5**, 4564 (2009).

S1.00021 Structure and Swelling Behavior of Weak Polyelectrolyte Brushes , CHAITRA DEODHAR, ERICK SOTO-CANTU, University of Tennessee, DAVID UHRIG, JOHN ANKNER, S. MICHAEL KILBEY II, Oak Ridge National Laboratory — In this work we describe the structure and swelling behavior of polyelectrolyte brushes consisting of poly(methacrylic acid) (PMAA) homopolymer brushes and random copolymer brushes made by a surface initiated copolymerization to create poly(MAA-co-2-hydroxyethyl methacrylate) brushes P(MAA-co-HEMA). To create dense polyelectrolyte brushes and alleviate problems with polymerization of the reactive electrolytic form of the monomer MAA, these brushes were made by chemical conversion of neutral, precursor brushes comprised of t-butyl methacrylate (tBMA). Neutron reflectivity (NR) was used to investigate the chemical conversion to "deprotected" form. Insight into the swelling behavior of PtBMA and PMAA brushes was obtained by ellipsometry and neutron reflectometry measurements. The responsive behavior of PMAA-containing brushes in different pH environments is evident from in situ ellipsometry and neutron reflectometry measurements, which in particular show significant sensitivity to the amount of water present in the layer as pH is changed. Current efforts to manipulate responsiveness through copolymerization to make P(MAA-co-HEMA) brushes will also be described.

S1.00022 Molecular dynamics simulations of interactions and friction between bottle-brush layers[1] , DANIEL RUSSANO, JAN-MICHAEL CARRILLO, ANDREY DOBRYNIN, University of Connecticut — Experiments on tethered polyelectrolyte bottle-brush-like macromolecules consisting of glycoproteins display fascinatingly low friction properties of biological tissues such as cartilage. To understand the role of the electrostatic interactions in lubricating properties of brush layers we have performed MD simulations of charged and neutral bottle-brush macromolecules tethered to substrates. In the case of charged bottle-brush layers the compression force per unit area F between two brush layers in salt-free solutions increases with decreasing the distance D between substrates as $F \propto D^{-2}$. A stronger dependence of the compression force F on the surface separation D was observed for neutral bottle-brushes, $F \propto D^{-4.7}$, in the same interval of compression forces. This strong dependence of the compression force F on the distance D is due to excluded volume interactions between monomers belonging to two overlapping bottle-brush layers. The weaker dependence observed in polyelectrolyte bottle-brushes is due to interaction between counterion clouds surrounding the bottle-brush layers. The charged bottle-brush layers have lower friction coefficient than neutral layers at the same interval of the compression and shear forces.

[1]NSF: DMR-1004576

S1.00023 Surface Dynamics of Partially Tethered Polymer Films , JIN KUK LEE, Dept. of Polymer Science, The University of Akron, Akron, OH 44325, BULENT AKGUN, NIST Center for Neutron Research, NIST, Gaithersburg, MD 20899, ZHANG JIANG, SURESH NARAYANAN, X-ray Science Division, Argonne National Laboratory, Argonne, IL 60439, SUSHIL SATIJA, NIST Center for Neutron Research, NIST, Gaithersburg, MD 20899, MARK D. FOSTER, Dept. of Polymer Science, The University of Akron, Akron, OH 44325 — The surface dynamics of "partially tethered" thin films have been studied using X-ray photon correlation spectroscopy (XPCS). Polystyrene (PS) chains have been grafted to substrates with low grafting densities, untethered deuterated PS (dPS) chains spun cast on the tethered chains and the films annealed to create layers containing both tethered and untethered chains. The extent of mixing between the tethered PS and untethered dPS chains has been measured by neutron reflectivity. The relaxation of surface height fluctuations for these films depends on the density of grafting, molecular weight of tethered chains, and extent to which tethered chains extend into the layer. When the tethered chains are able to stretch to the top surface, the relaxation time is slowed most remarkably.

S1.00024 A mechanistic study of a thermo-responsive polymer in a liquid crystal solvent , TIMOTHY BUNNING, MICHAEL MCCONNEY, JENNIFER HURTUBISE, VINCENT TONDIGLIA, TIMOTHY WHITE, Materials and Manufacturing Directorate, Air Force Research Laboratory — Thermo-responsive polymers are highly promising for a variety of applications including tailored drug release, gene delivery, and chromatography. Typical swelling/de-swelling polymer phase transitions involve isotropic liquids and disordered polymers. Here, we present a unique swelling/de-swelling polymer transition involving structured polymers and ordered liquids crystals. The polymers in this study have a degree of order that is imparted by polymerizing in the presence of a liquid crystal. The study focuses on helicoidal structured polymers templated by cholesteric liquid crystals because the optical properties are a simple indicator of the material structure properties. The mechanism of the swelling/de-swelling transition of this unique system were studied with differential scanning calorimetry, polarized optical microscopy, white light interferometery and visible/near-infrared spectroscopy. Differences in the dynamic optical changes with polymer structure are explored.

S1.00025 Formation of Liquid Crystal Elastomer Microparticles , CHANJOONG KIM, HUAN YAN, SOUPTIK MUKHERJEE, PAUL LUCHETTE, PETER PALFFY-MUHORAY, Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University, Kent, OH 44242, USA — Liquid crystal elastomer (LCE) combines the properties of rubber elasticity and anisotropic properties of liquid crystalline materials. In particular, LCE has a potential to exhibit interesting properties like electric polarization, ferroelectricity and piezo-electricity. Thin films, fibers and even balloons of LCE using techniques such as spin coating, electro-spinning and in cells have been reported by many groups before. Using microfluidics technique followed by photo-polymerization, we produce uniform spherical LCE microspheres with diameter of 20 - 85 μm. Compression of the LCE microspheres generates a characteristic director configuration. The elastomers may also reveal interesting magnetic and electrical properties due to the intrinsically anisotropic nature of liquid crystalline materials.

S1.00026 Coupling of Smectic Liquid Crystalline Order of iPP to Carbon Nanotube Alignment under Melt-Shear[1] , GEORGI GEORGIEV, Assumption College, ROBERT JUDITH, Tufts University, ERIN GOMBOS, MICHAEL MCINTYRE, Assumption College, PEGGY CEBE, Tufts University, ASSUMPTION/TUFTS TEAM, ASSUMPTION/TUFTS COLLABORATION — Carbon nanotubes (CNTs) exhibit liquid crystalline order and their nematic director couples to the one of low molecular weight liquid crystals. Here we explore the interactions between CNTs and the smectic liquid crystal phase of a polymer and the possibility for a similar coupling in this system. The pure iPP and iPP/CNT films were sheared in the melt state at 200 °C and 1Hz. The sheared samples were analyzed using polarized optical microscopy, Two Dimensional Microscopic Transmission Ellipsometry (2D-MTE) and Two Dimensional Wide Angle X-Ray Scattering (2D-WAXS). During shearing we detected a sudden increase of birefringence at 151 °C in the samples, higher than the iPP crystallization temperature, indicating liquid crystalline ordering. We measured anisotropic 2D-WAXS patterns of the samples that contained CNTs, indicating strong ordering of the crystals. Our results indicate that CNTs couple to the smectic phase of iPP, improve its order upon shearing and the crystals created after the formation of the oriented smectic phase are strongly aligned parallel to the direction of shearing.

S1.00027 Magnetic fields for the long-range ordering of amphiphilic block copolymers and surfactant mesophases[1]

, PAWEL MAJEWSKI, MANESH GOPINADHAN, CHINEDUM OSUJI, Yale University — We present a diamagnetic interactions-based approach to impose long range order in self-assembled soft materials. We discuss two chemically different systems which have been successfully aligned with the use of a magnetic field. The orientation and the degree of alignment are quantified by small-angle X-ray scattering, polarized optical microscopy and electrical impedance spectroscopy. We focus on Li ion-conducting liquid crystalline diblock copolymers. Our technique allows us to control the orientation of hexagonally packed PEO channels within a non-conducting liquid crystalline matrix that is responsive to the field. The electrical conductivity of the cylindrical samples with PEO domains aligned perpendicular to electrodes is an order of magnitude greater than for samples featuring randomly orientated domains. Our second system consists of non-ionic surfactants forming lamellar or cylindrical mesophase in water. The method which we term "rotational annealing", is successfully used to obtain highly ordered mesophases which can be further utilized as a template for nanomaterials synthesis.

[1]This work is funded by the NSF under DMR-0847534.

S1.00028 Morphology and Proton Conductivity of Ionic Liquid Containing Sulfonated Block Copolymers

, SUNG YEON KIM, MOON JEONG PARK, POSTECH — Proton exchange membrane fuel cells (PEMFC) offer the prospect of supplying clean electrical power for a wide variety of systems such as portable electronic devices and vehicles. Although, significant effort has been devoted to improvement of the transport properties of PEMs which is operated relatively lower temperature below 80°C, it suffers from a CO poisoning at Pt catalysis, complexity of water and heat management in the system. Herein, we report unique block copolymer electrolyte membrane systems containing ionic liquid. Due to the nonvolatile property of ionic liquid the systems exhibit effective proton transport above 100°C without humidification. In present study, sulfonated block copolymers, i.e., poly(styrenesulfonate-b-methylbuthylene) (SnMBm), are utilized for matrix materials by varying the ion contents and molecular weight. Imidazolium based ionic liquids are selectively incorporated into polystyrenesulfonate phases, which results in various morphological transitions as a function of the amount of the ionic liquid. The effect of counter ions on the observed morphologies is significant yielding concurrently different values of conductivity. Small angle x-ray scattering and transmission electron microscopy have been employed to determine various morphologies of the ionic liquid containing sulfonated block copolymer membranes and impedance spectroscopy is used for the conductivity measurements.

S1.00029 The Role of Neutralizing Ion Type on the Dynamics of Sulfonated Polystyrene Ionomers

, ALICIA CASTAGNA, The Pennsylvania State University, WENQIN WANG, KAREN I. WINEY, University of Pennsylvania, JAMES RUNT, The Pennsylvania State University — Sulfonated polystyrene (SPS) ionomers neutralized with Na, Cs, and Zn were investigated using scanning transmission electron microscopy (STEM), X-ray scattering, and dielectric relaxation spectroscopy. The role of the neutralizing ion on the structure and molecular dynamics will be discussed as a function of sulfonation level. STEM and X-ray scattering revealed the presence of spherical aggregates 2 nm in diameter. Successful fitting of the scattering data to the Kinning-Thomas modified hardsphere model provides additional information on aggregate size, number density and radius of closest approach. The dynamics of these materials, as revealed by DRS, are highly sensitive to the neutralizing ion, in particular, the character of the segmental relaxation, i.e. relaxation time, breadth and number of relaxations. Additionally, the relaxation time of the Maxwell-Wagner-Sillars interfacial polarization process at high temperatures is also highly dependent on neutralization and ion character.

S1.00030 Mixed-salts effect on the ionic conductivity of PEO-containing block copolymers

, WEN-SHIUE YOUNG, ALLEN SCHANTZ, THOMAS EPPS, University of Delaware — Salt-doped poly(ethylene oxide)-based block copolymers have attracted significant interest, as nanoscale ordered structures offer ideal platforms for the design of electrolytes for lithium battery membranes. However, the room temperature conductivities of these polymer electrolyte membranes are too low for many applications due to the crystallization of the PEO or the PEO:salt complex. In this study, a mixed-salt system, $LiClO_4$/LiTFSI, was adopted to decrease the crystallinity of PEO:salt complex and improve the relative conductivity at room temperature. Small-angle X-ray scattering and transmission electron microscopy were used to determine the microstructures of the copolymer electrolytes, while differential scanning calorimetry and AC impedance studies were used to examine the crystallinities of PEO:salt complexes and ionic conductivities of electrolyte membranes. Our results show that the 50%-50% $LiClO_4$/LiTFSI-doped PS-PEO with [EO]:[Li]=6:1 has no crystalline phase above room temperature and exhibits a higher conductivity than corresponding $LiClO_4$-doped and LiTFSI-doped PS-PEOs at low temperatures.

S1.00031 Time Scales of Ion Transport in Imidazolium-based Polymers

, U. HYEOK CHOI, Penn State University, YUESHENG YE, Drexel University, MINJAE LEE, HARRY GIBSON, Virginia Polytechnic Institute and State University, YOSSEF ELABD, Drexel University, JAMES RUNT, RALPH COLBY, Penn State University — We synthesize and characterize ionic polymers with imidazolium cations covalently attached to the polymer chain and various ionic liquid counterions for ionic actuators. The imidazolium cations are attached to the polymers with flexible alkyl spacer chains and also have a variety of alkyl and alkyl ether termini. The anionic counterions are also varied; tetrafluoroborate (BF_4), hexafluorophosphate (PF_6) and bis(trifluoromethanesulfonyl)imide (TFSI) were mainly used in this study. Dielectric relaxation spectroscopy (DRS) is utilized to measure the dielectric constant and conductivity, as a function of temperature. The 1953 Macdonald model is applied to estimate the number density of conducting ions and their mobility, from electrode polarization at low frequencies in DRS. The 1988 Dyre model is used to determine ion hopping times from the frequency-dependent conductivity at higher frequencies. The consequence of polymer structural variations will be elucidated for these vital characteristics.

S1.00032 Ionic Aggregation and Microphase Separation in Sulfonated Polyester Multiblock Copolymers and Ionomers

, MICHAEL O'REILLY, University of Pennsylvania, GREGORY TUDRYN, RALPH COLBY, Pennsylvania State University, KAREN WINEY, University of Pennsylvania — Polyethylene oxide (PEO) has been copolymerized with polytetramethylene oxide (PTMO) using a sulfonated phthalate ionic linker between blocks. The product is a linear multiblock copolymer, which is neutralized with lithium and sodium. We used X-ray scattering to investigate the morphology from 25 °C to 200 °C. The results show that this copolymer exhibits three distinct morphology characteristics. First, microphase separation exists between the PEO and PTMO phases. Second, ionic aggregates occur in the PEO microdomains. Finally, the appearance of better defined ionic aggregates occurs in the PTMO microdomains. Ion aggregation and microphase separation are studied as functions of temperature and copolymer molar composition. DRS analysis confirms that ionic aggregation is independent of copolymer composition.

S1.00033 Ion Conduction in Perfectly Aligned Block Copolymer-Ionic Liquid Mixtures

, JAE-HONG CHOI, Department of Materials Science and Engineering, University of Pennsylvania, YOSSEF A. ELABD, Department of Chemical and Biological Engineering, Drexel University, KAREN I. WINEY, Department of Materials Science and Engineering, University of Pennsylvania — Our earlier work to correlate the transport measurements in diblock copolymer-ionic liquid mixtures was limited by our bulk samples that have only partial alignment. Here, thin films with perfect alignment of lamellar microdomains from mixtures of a poly(methyl methacrylate-*b*-styrene) diblock copolymer and an ionic liquid, 1-ethyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide, have been studied. The morphologies will be characterized by cross-sectional transmission electron microscopy. Ion conduction will be presented within and through the thin film.

S1.00034 Modification of Aqueous Peptide-based Block Copolymer Morphologies through Addition of Ionic Liquid , ASHLEY JOHNSON, JACOB RAY, SANDEEP NAIK, LAURA BULLOCK, DANIEL SAVIN, School of Polymers and High Performance Materials — The self assembly of block copolymers in aqueous solution is a synthetically tunable behavior. Varying composition and the size of the block lengths, a range of morphological structures can be obtained each having diverse characteristics. Polypeptide blocks incorporate pH responsiveness due in part to the helix-coil transition. In these studies, we use light scattering to explore the morphology and pH responsiveness of PPO-P(Lys) diblock and triblock copolymers. While these materials have limited solubility for pH>8, the addition of a small amount of ionic liquid extends the phase range to pH above 10. Similar behavior is observed in Pluronic copolymers, which are solubilized in the presence of ionic liquid. Through use of dynamic light scattering (DLS), transmission electron microscopy (TEM), circular dichroism (CD), and Fourier Transform IR (FTIR), we seek to obtain a molecular-level understanding of the peptide interactions in water/ionic liquid solutions and how this translates to pH responsiveness.

S1.00035 Phase behavior of the blend of rod-coil block copolymer with the corresponding coil homopolymer , CHIA-SHENG LAI, National Tsing Hua University, CHUN-CHIH HO, WEI-FANG SU, National Taiwan University, HSIN-LUNG CHEN, National Tsing Hua University — We investigated the self-assembly behavior of the blends of a rod-coil block copolymer DEH-PPV-*b*-PMMA with the PMMA homopolymers (h-PMMA) with various molecular weights to clarify how the rigidity and self-organization of the rod block would affect the morphologies and the phase behavior comparing with those of coil-coil block copolymer blending. SAXS/WAXS along with TEM were used to reveal the nanostructure in detail. In the case of the blends with h-PMMA with lower molecular weight, the morphology was strongly dependent on the interplay between microphase separation and nematic interaction. The h-PMMA tended to localize into the middle of PMMA nanodomain and formed a lamellar structure irrespective of the volume fraction of h-PMMA. At high volume fraction of h-PMMA, a sponge phase was found to coexist with the lamellar structure. The interdomain spacing increased with the overall PMMA content. Macrophase separations became dominate in the blends with h-PMMA of high molecular weight. WAXS studies of the blends indicated the amorphous h-PMMA reduced the correlation of the rod-rod ordered packing. Upon heating, the lamellar structure transformed into a disordered state, and the T_{ODT} was found to be reduced by adding h-PMMA with lower molecular weight.

S1.00036 Threaded molecular wires as building blocks for advanced polymer blends: WPLEDs, ultra-broadband optical amplifiers, multi color lasers , SERGIO BROVELLI, MARTA MROZ, GIUSEPPE SFORAZZINI, TERSILLA VIRGILI, FRANCO MEINARDI, ALBERTO PALEARI, HARRY L. ANDERSON, GUGLIELMO LANZANI, FRANCO CACIALLI — The ability to produce semiconducting polymer blends with white emission spectra, large emission cross sections and broad optical gain is critical to their application in white PLEDs, lasers and broadband amplifiers. Cyclodextrin-encapsulation is an effective means of suppressing detrimental intermolecular interactions, and energy transfer (ET) channels in polymer blends, thus enabling fabrication of white-PLEDs. We show that all such properties combine into a high impact photonic application: ultra-broad optical gain and two-color lasing in a binary polyrotaxane blend. We study the ultrafast photophysics of a blend of a conventional and an encapsulated polyfluorene. The morphology is investigated by microRaman imaging, AFM, and fluorescence lifetime microscopy. We ascribe the ultra-broad optical gain (>850 meV), and the simultaneous ASE for both constituents, to the dual effect of reduced polaron formation and suppressed ET. Our results demonstrate that polyrotaxanes could realistically represent the building blocks for advanced polymer blends with highly controlled optical properties, for applications in solid state lightning, lasers and photovoltaic technologies.

S1.00037 Measurements of Thermally Stimulated Luminescence in Gamma-Irradiated Ultra-High Molecular Weight Polyethylene in the Presence of Vitamin E[1] , DEREJE ABDI, MUHAMMED JAHAN, BENJAMIN WALTERS, University of Memphis — Thermally stimulated luminescence (TSL) was detected in medical grade ultra-high molecular weight polyethylene (UHMWPE) GUR 1020 (Ticona) after gamma irradiation at room temperature (22°C) in air or nitrogen and subsequent heating from 22°C to 399°C using a commercial TSL apparatus (Thermec). A typical TSL glow curve exhibits two major glow peaks near 116°C and 200°C with a weak shoulder near 250°C. Additional glow peak is observed near 140°C in GUR 1020E (UHMWPE containing 0.1% vitamin E (alpha-tocopherol (α-T)). Full-width-at-half-max (FWHM) and activation energy for each peak were found as follows. 116°C: 40°C, 1.2 eV; 140°C: 40°C, 1.3 eV; 200°C: 64°C, 1.0 eV; 250°C: 56°C, 1.5 eV. The glow peaks seem to follow a kinetic order of 1.5. While the 116-°C glow is produced in all irradiated samples, the 200°- and 250-°C peaks are produced when irradiation is performed in air, suggesting that these latter glow peaks are associated with the oxygen-centered species and the former (at 116°C) with polyethylene (PE) radicals. The 140-°C peak could result from thermal breakdown of vitamin E radical (α-T-O*). Irradiation dose, 30, 65 or 100 kGy, simply changes the TSL intensity without affecting the TSL characteristic. Vitamin E, which is used as an antioxidant, does not seem to affect the TSL in UHMWPE.

S1.00038 Confocal Raman Microscopy on in-situ Structural Evolution of Polyolefin Blends[1] , WANSOO CHANG, BYUNGHO JEON, JONG-WON LEE, CHANG Y. RYU, Rensselaer Polytechnic Institute — Polyolefins account for more than half of world-wide consumption of plastic materials, and are typically blended with fillers and other types of polymers in applications. In particular, understanding the miscibility and phase behaviors of polyolefin blends is important for the advancement of a wide array of new applications in medicine, packaging, and other fields. We have used Confocal Raman Microscopy to take the advantages of it capability to locally probe the transformation of physical states in polymeric materials and to characterize morphology of polyolefin blends in-situ for lateral and in-depth imaging with a micron-scale spatial resolution. Upon distinct changes of Raman spectra associated with the melting of semicrystaline polyolefins, we report the in-situ morphological changes upon heating and cooling of polyethylene-polyethylene and polypropylene-polyethylene using confocal Raman microscopy with heating stage.

[1]NSF MRI-0722563

S1.00039 Polymer Blends for Proton Exchange Membranes[1] , TINA LOVATO, National Technical Institute for the Deaf, RIT, KELLY MCNABB, RIT, Mechanical Eng, JASON MEYERS, National Technical Institute for the Deaf, RIT, GABER RUPNIK, Gallaudet, Chemistry, QIAN MA, Tufts, Physics, MENG ZHAO, JINGJING PAN, JOEL WALKER, THOMAS SMITH, RIT, Chemistry, PEGGY CEBE, Tufts, Physics — In the present research, the crystal structure of PVDF in semicrystalline composite films composed of poly(vinylidene fluoride) (PVDF) and poly[4(5)-vinylimidazole/vinylimidazolium trifluoro-methyl-sulfonyl-imide] (PVIm/VIm$^+$ TFSI$^-$) were studied. In these composites, conditions such as choice of solvent, drying conditions, and thermal treatment can affect the crystal phase, crystallite size and degree of crystallinity of PVDF as well as the distribution of the minor component, poly[4(5)-VIm/VIm$^+$ TFSI$^-$]. Such composites may have potential in fuel cells as high-temperature proton-exchange membranes. PVDF imparts mechanical strength to the blend, and because of its high crystal melting point ($T_m > 160^\circ$C), should improve the high temperature stability of resulting fuel cell membranes. The long range goal is to make a thin, high strength membrane that will exhibit substantial proton conductivity at high temperature and low relative humidity. Thin PVDF/PVIm-PVIm$^+$ composite films have been fabricated and the nature of the PVDF crystalline polymorph and % crystallinity have been evaluated as a function of the HTFSI content.

S1.00040 Diffusion Studies of Compatibilizers in Immiscible Polymer Blends , CANDICE HALBERT, JOHN ANKNER, JAMES BROWNING, Oak Ridge National Laboratory, HASKELL BECKHAM, DAVID BUCKNALL, Georgia Institute of Technology — Much is known about how linear polymers and oligomers modify polymer interfaces, and this knowledge forms the basis for some very important commercial processes and products, including impact modifiers and immiscible blend compatibilizers. However, little is known about cyclic polymers at interfaces, despite evidence that indicates that loops are far better at improving interfacial fracture toughness than linear chain entanglements. Generally, polymer films strongly adhere to one another when there is efficient chain interpenetration and entanglement at the interface. When such reinforcement does not exist, as with immiscible polymers, the interfacial fracture toughness is rather weak (< 20 J/m^2), but even in these cases the adhesion strength can be correlated with interfacial entanglements. Neutron reflectivity measurements have been used to correlate the interfacial width of homopolymer interfaces with fracture toughness measurements. We have performed NR experiments to elucidate the interfacial activity of linear versus cyclic poly(oxyethylene). During our experiments at SNS we studied the effect of surface segregation in poly(methyl methacrylate) films as well as the effects of interfacial segregation in PMMA/polystyrene films. The results from these diffusion studies will be presented.

S1.00041 Synthesis of Functional Nanoparticles by Amphiphilic Star-like Block Copolymer as Template , XINCHANG PANG, ZHIQUN LIN, NANOFM TEAM — New strategies for materials fabrication are of fundamental importance in the advancement of science and technology. Organometallic and other organic solution phase synthetic routes have enabled the synthesis of functional inorganic nanoparticles (NPs). However, much research needs to be done to find a simple and unified approach to synthesize nanoparticles with different chemistry and properties. Here we report a novel approach to produce a variety of nanoparticles with different chemistry, properties and controllable diameters, including metallic NPs, ferroelectric NPs, superparamagnetic ion oxide nanoparticle (SPION), semiconducting NPs. These NPs capped with polymer as surface ligand are synthesized using a series of amphiphilic star-like diblock copolymer (forming single component NPs) and triblock copolymer (forming core/shell NPs) as templates.

S1.00042 Low temperature electrical conductivity of low-density polyethylene/carbon black composites , TAREK TAWALBEH, NMSU, SUBHI SAQ'AN, SHADI YASIN, AWWAD ZIHLIF, GIUSEPPE RAGOSTA — The study deals with the electrical characteristics of carbon black/low-density polyethylene (CB/LDPE) composites of various CB filler concentrations (10, 15, and 20% wt.). DC-electrical conductivity was studied as a function of filler concentration in the low temperature range 25–285K. It was found that the composites exhibit a negative temperature coefficient of resistivity (TCR) at low temperatures and a high enhancement in electrical conductivity with both temperature and carbon black concentration. The observed increase of conductivity with the filler concentration was interpreted through percolation theory. The dependence of the electrical conductivity of the given composites on temperature (25–285 K) was analyzed in terms of a formula consistent with the Mott hopping mechanism.

S1.00043 Effect of Grain Size on the AC Electrical Properties of Kaolinite/Polystyrene Composites , LINA ABDALLAH, NMSU, AWWAD ZIHLIF — Impedance spectroscopy has been used to study the effect of kaolinite grain sizes on the AC electrical properties of kaolinite/polystyrene composites under different temperatures and applied frequencies. Impedance measurements were performed on prepared composites containing 20% kaolinite mineral of grain sizes 63, 106, 212, and 300 μm in addition to neat polystyrene. The measured electrical quantities such as impedance, phase angle, dielectric constant and loss, AC conductivity, and thermal activation all showed a temperature and frequency dependence. The dielectric constant and loss increases with both grain size and temperature. The AC conductivity increases with decreasing kaolinite grain sizes. The 63 μm grain size composite has higher electrical conduction under applied frequencies and temperatures. A statistical model is presented to explain the dependence of the AC electrical properties on the filler grain size. The study concludes that the overall electrical behavior is influenced by some processes such as electron hopping, ion diffusion, and space charge polarization that take place in the composite microstructure.

S1.00044 Domain Structure Formation in Swollen Side-Chain Liquid Crystal Elastomers[1] , CHRISTOPHER GRABOWSHI, PAUL LUCHETTE, PETER PALFFY-MUHORAY, Liquid Crystal Institute - KSU — Liquid crystal elastomers (LCEs) are soft materials consisting of a crosslinked polymer network that incorporates mesogenic groups, allowing for orientational order in a solid rubber. Maintaining uniaxial strain on a swollen nematic polymer gel will fix the direction of average orientation of mesogens along the strain axis, yielding a monodomain LCE. Failure to strain the swollen gel within $\sim$30 minutes of formation will produce an opaque polydomain LCE that possesses no long-range nematic order unless stretched. Polarized laser light scattering has been previously employed to monitor the size of liquid crystal domains in fully-formed LCEs; however, no studies have focused on the initial stages of domain formation. We have recorded the time evolution of the far-field scattering patterns produced by swollen polymer gels under varying levels of applied strain. These scattering patterns provide dynamical information of domain behavior during synthesis and processing of monodomain and polydomain LCEs.

[1]This work was supported by the NSF under grant DMR 0606357.

S1.00045 Molecular Alignment and Temperature Effects on Photodriven, Mulitidimensional Oscillation of Azobenzene Liquid Crystalline Polymer Networks[1] , KYUNG MIN LEE, MATTHEW SMITH, HILMAR KOERNER, RICHARD VAIA, TIMOTHY BUNNING, TIMOTHY WHITE, Air Force Research Laboratory — The photodriven oscillation of uniaxially aligned monodomain azo-LCNs was investigated as a function of molecular alignment and temperature spanning a range of +/- 40 of the glass transition temperature (T_g). Monodomain azo-LCNs were synthesized between glass slide cells coated with Elvamide with an anti-parallel rubbing direction. In this work, multidimensional oscillations that include in plane bending and out of plane twisting are observed when the orientation of the axis is at intermediate angles to the long axis of the cantilever. The added dimensionality to the previously reported in plane oscillation is a result of a photoinduced shear gradient that causes twisting. The degree of twisting is shown to be dependent on both the polarization of the illuminating 442 nm light, and the orientation of the director to the cantilever geometry. Comparatively, rubbery azo-LCNs (e.g. systems heated $> T_g$) show higher amplitude than glassy azo-LCN cantilevers. The relationship between the critical laser intensity and the concentration of azobenzene monomer for the photodriven oscillation behavior of azo-LCNs will also be discussed.

S1.00046 The role of uniaxial deformation on microstructure and dynamics of a bulk-polymerized polyurea[1] , JAMES RUNT, TAEYI CHOI, The Pennsylvania State University, DANIEL FRAGIADAKIS, C. MICHAEL ROLAND, Naval Research Laboratory — Polyureas, formed by the rapid reaction between isocyanates and diamines are attractive for various applications due to their outstanding mechanical properties, which can be tuned by varying component chemistry, molecular weight and stoichiometry. Polyureas synthesized from a modified methylene diphenyl diisocyanate (Isonate 143L) and polytetramethylene oxide-di-p-aminobenzoate (Versalink P1000) are widely utilized and investigated for energy absorbing applications such as impact mitigation and ballistic protection. In order to develop a more complete understanding of their mechanical response, we explore the effect of uniaxial strain on the phase separated microstructure and molecular dynamics. We utilize wide- and small-angle X-ray scattering to investigate amorphous segment and hard domain orientation and broadband dielectric spectroscopy for interrogation of the dynamics Uniaxial deformation was found to significantly perturb the phase separated microstructure and chain orientation, and result in a considerable slowing down and broadening of the polyurea soft phase segmental relaxation.

S1.00047 Characterization of a Poly(styrene-block-methylacrylate-random-octadecylacrylate-block-styrene) Shape Memory ABA Triblock Copolymer , PENGZHAN FEI, KEVIN CAVICCHI — A new ABA triblock copolymer of poly(styrene-block- methylacrylate-random-octadecylacrylate-block-styrene) (PS-b- PMA-r-PODA-b-PS) was synthesized by reversible addition fragmentation chain transfer polymerization. The triblock copolymer can generate a three-dimensional, physically crosslinked network by self-assembly, where the glassy PS domains physically crosslink the midblock chains. The side chain crystallization of the polyoctadecylacrylare (PODA) side chain generates a second reversible network enabling shape memory properties. Shape memory tests by uniaxial deformation and recovery of molded dog-bone shape samples demonstrate that shape fixities above 96% and shape recoveries above 98% were obtained for extensional strains up to 300%. An outstanding advantage of this shape memory material is that it can be very easily shaped and remolded by elevating the temperature to 140°C, and after remolding the initial shape memory properties are totally recovered by eliminating the defects introduced by the previous deformation cycling.

S1.00048 Structure and dynamics of of solution polymerized polyureas[1] , TAEYI CHOI, YOUMI JEONG, JAMES RUNT, The Pennsylvania State University — Polyureas consisting of alternating soft and hard (urea containing) segments exhibit physical properties that are closely related to their microphase separated structure, which consist of rigid (high Tg and sometimes crystalline) hard domains embedded in a matrix dominated by flexible polyether segments. Polyurea properties can be controlled over a rather broad range by varying the chemical structures, molecular weight of the components, and reaction stoichiometry. In the present study, we focus primarily on linear polyureas synthesized using methylene diphenyl diisocyanate and polytetramethylene oxide-di-p-aminobenzoate using a solution polymerization method. Soft segment (diamine) molecular weights were varied from 460 to 860 to 1200 g/mol and characterize their morphology, hydrogen bonding, mechanical behavior and dielectric properties upon varying molecular weight of diamines. This presentation will focus on our latest findings, particularly details of the microphase separated morphology and molecular dynamics as measured using dielectric relaxation spectroscopy

S1.00049 The elastic Maier-Saupe-Zwanzig model and some properties of nematic elastomers[1] , DANILO LIARTE, SILVIO SALINAS, CARLOS YOKOI, University of Sao Paulo — We introduce a simple mean-field lattice model to describe the behavior of nematic elastomers. This model combines the Maier-Saupe-Zwanzig approach to liquid crystals and an extension to lattice systems of the Warner-Terentjev theory of elasticity, with the addition of quenched random fields. We use standard techniques of statistical mechanics to obtain analytic solutions for the full range of parameters. Among other results, we show the existence of a stress-strain coexistence curve below a freezing temperature, analogous to the P-V diagram of a simple fluid, with the disorder strength playing the role of temperature. Below a critical value of disorder, the tie lines in this diagram resemble the experimental stress-strain plateau, and may be interpreted as signatures of the characteristic polydomain-monodomain transition. Also, in the monodomain case, we show that random-fields may soften the first-order transition between nematic and isotropic phases, provided the samples are formed in the nematic state.

S1.00050 The Effect of Multiple Parallel Bonds on the Self-healing of Labile Crosslinked Nanogel Networks , ISAAC G. SALIB, GERMAN V. KOLMAKOV, CHET N. GNEGY, Chemical Engineering Department, University of Pittsburgh, KRZYSZTOF MATYJASZEWSKI, Department of Chemistry, Carnegie Mellon University, ANNA C. BALAZS, Chemical Engineering Department, University of Pittsburgh — We develop a hybrid computational approach to examine the mechanical properties and self-healing behavior of nanogel particles that are crosslinked primarily by highly reactive bonds that can break and readily remake (labile bonds). The individual nanogels are modeled via the lattice spring model (LSM). The crosslinks between the nanogels are simulated via a modified Hierarchical Bell Model (HBM), which allows us to capture both the rupturing and reforming of multiple, parallel bonds due to an applied force. Using our hybrid HBM/LSM, we simulate the behavior of the crosslinked nanogels under a tensile deformation. In these simulations, each labile linkage between the nanogels contains at most N parallel bonds. We reveal that while numerous parallel bonds within a linkage enhance the strength of the material, these bonds diminish the ductility and the ability of the material to undergo the structural rearrangements that are necessary for self-repair.

S1.00051 Characterization of hybrid hydrogel with different shape of particles after gamma-ray radiation , DONGHYUN KIM, HOIK LEE, HYEMI PARK, DAEWON SOHN, Department of Chemistry, Hanyang University, Seoul 133-791, Korea — Due to high specific surface area and the ability to absorb organic molecules, inorganic particles such as silica particle (spherical), imogolite (rodlike), and clay (fan shape) could be used as precursors for hydrogels. The hydrogel which had 3-D network structure was directly prepared by polymerization with acrylic acid (AA) on hydroxide surface of inorganic particles that was irradiated by gamma-ray at ambient condition. Surface of inorganic particles was used as sites of initiator and cross-linker to make hydrogel, so we don't need any additional additives to make hydrogel. The properties of hydrogel were characterized by small angle x-ray scattering (SAXS), universal testing machine (UTM), and Raman spectroscopy. By changing the inorganic particles/monomer ratio, the mechanical strength was significantly changed. The synthesized hydrogel can be elongated maximum 1800%. 2D SAXS pattern was different depending on the shape of inorganic particles. And the hydrogel swelled only in basic solutions at pH $>$ 7.

S1.00052 A State-of-Ease Analysis of Shape Memory Elastomers[1] , CHRISTOPHER LEWIS, JIAHUI LI, MITCHELL ANTHAMATTEN, University of Rochester — A state-of-ease model is developed to predict the time-dependent mechanical behavior of a shape memory elastomer. The model assumes continuous mechanical equilibrium between applied stress and stresses of entropic origin arising from a permanent network and a second, independent network composed of reversible bonds. Bonds forming the reversible network are assumed to rearrange at a constant rate, and newly formed bonds are created in a stress-free state. This gives rise to a time-dependent distribution of bond ages and corresponding stresses, and both are accounted for in the model using a delay integral approach. The model is capable of describing creep, stress relaxation, and shape memory responses. The model will be fit to experimental data for a poly(butyl acrylate) shape memory elastomer, and results will be compared to a simpler dashpot-spring model.

S1.00053 Real time small angle X-ray scattering from cyclically stretched nanoparticle-filled siloxane elastomers , ARTHUR K. SCHOLZ, University of California, Santa Barbara, CA, HUAN ZHANG, ESPCI Paris Tech, Paris, France, ELAINE R. CHAN, ALEXANDER HEXEMER, Advanced Light Source, Lawrence Berkeley Labs, Berkeley, CA, EDWARD J. KRAMER, University of California, Santa Barbara, CA — The origin of the cyclic softening and hysteresis (the well known "Mullins effect") observed in nanoparticle-filled elastomers is still debated. To probe this question we used synchrotron-based, time resolved, small angle x-ray scattering (SAXS) to observe changes in the structure of silica-filled siloxane elastomers with different filler loading and surface treatments under step cycle tensile deformation. We perform reverse Monte Carlo (RMC) simulations using graphical processing units (GPUs) to infer the real space configuration of the filler network that gives rise to the SAXS pattern and we compute the scattering invariant to quantify any void formation. We observe that the deformation is non-affine on length scales corresponding to the filler particles. The particles collect in "rafts" perpendicular to the tensile axis such that most of the deformation occurs in the elastomer-rich regions between rafts. At the largest deformations a scattering streak appears in a direction normal to the tensile axis at very small diffraction vectors (0.01 nm-1) which we attribute to the formation of elliptical voids whose long axis lies in the tensile direction.

S1.00054 Investigating Heterogeneous Microenvironments in Hydrogels by Single Quantum Dot Tracking , CHEOL HEE LEE, TODD EMRICK, ALFRED CROSBY, RYAN HAYWARD — Single particle tracking provides a powerful means to locally characterize physical properties within heterogeneous media. We have employed CdSe/ZnS core/shell quantum dots (QDs) as probes to characterize the heterogeneous microstructures within covalently- crosslinked polyacrylamide (PAAm) hydrogels. For appropriate gel compositions, the QDs show periods of caged motion within trapping sites, interspersed by nearly free diffusion. We analyze the trajectories of single QDs using a variety of statistical approaches to elucidate the distribution of trapping site strengths within gels of different average pore size.

S1.00055 Effects of AC Electrical Field on the Dielectrophoresis Force of Dielectric Elastomers and Blends , ANUVAT SIRIVAT, RUKSAPONG KUNANURUKSAPONG, The Petroleum and Petrochemical College, Chulalongkorn University — The effects of frequency and amplitude of AC electric field on the deflection and the dielectrophoresis force of an acrylic elastomer (AR71), styrene copolymers (SAR and SBR), and the blends of doped PPP and AR71 are investigated. The dielectrophoresis forces of the dielectric elastomers and blends were measured by using a vertical cantilever fixture at various frequencies (0.3 to 60 Hz) and at AC electric field strengths of 200-800 V_{pp}/mm. The effects of the thicknesses of the specimens and the particle concentration are studied. The doped PPP particles are embedded in the AR71 with concentrations of 1, 10, and 20 %vol. The dielectrophoresis forces and deflection distance of the dielectric elastomers and blends generally increase with increasing amplitude but slightly decrease with increasing frequency; and they dramatically drop at the cut-off frequency. The cut-off frequencies are 7.84, 1.45, and 0.74 Hz for AR71, SAR, and SBR, respectively, at E of 800 V_{pp}/mm and a thickness of 0.7 to 0.8 mm. After blending the AR71 with doped PPP, the cut-off frequencies of the 1 %vol, 10 %vol and 20 %vol of doped PPP are 18.51, 15.28, and 10.67 Hz, respectively, at an E of 800 V_{pp}/mm and a thickness of 0.2 to 0.3 mm. The conductive polymer particles are shown here to improve the electromechanical responses at high frequency.

S1.00056 Effects of Annealing on the Photovoltaic Performance of All-Conjugated Poly(3-alkylthiophene) Diblock Copolymer , MING HE, WEI HAN, YULIANG YANG, FENG QIU, ZHIQUN LIN — The effects of thermal annealing and solvent annealing on the photovoltaic performance of all-conjugated poly(3-butylthiophene)-b-poly(3-hexylthiophene) diblock copolymer, [6,6]-phenyl-C_{71}-butyric acid methyl ester (P3BHT:$PC_{71}BM$) based devices were investigated using the single diode model. Thermal annealing placed a better balance between the crystallization of P3BHT chains and the nanoscale phase separation with $PC_{71}BM$ domains, while solvent annealing under chloroform vapor induced a significant improvement in the crystallinity of P3BHT as well as enlarged P3BHT crystalline domains, thereby leading to unbalanced charge transport and increased charge recombination in the blend films. The physical meanings of the parameters in the equivalent single diode model were also discussed in terms of crystallinity and phase separation to gain the fundamental understanding of the mechanism that account for the annealing effects.

S1.00057 Role of Succinonitrile in a Poly(ethylene oxide)/LiTFSI membrane for lithium batteries , MAURICIO ECHEVERRI, THEIN KYU, Dept. of Polymer Engineering, University of Akron, Akron, Ohio — In designing novel flexible lithium battery membranes, high conductivity, peel strength and processability are the main targets for a successful product. Crystallinity of poly(ethylene oxide) (PEO) and lithium salts represent an obstacle to accomplish each of these specifications. We present a systematic study of ternary phase diagrams of PEO, bis(trifluoromethane) sulfonimide (LiTFSI) and succinonitrile (SCN) (i.e., solid plasticizer/co-solvent) mixtures by using DSC and polarized optical microscopy and map out various coexistence regions bound by the liquidus and solidus lines. The eutectic phase diagram of PEO/SCN system was calculated self-consistently using Flory-Huggins theory in conjunction with Landau-type phase field free energy for crystal solidification. Specific interactions such as hydrogen bonding were examined by FTIR. In lieu of PEO, poly(ethylene glycol) diacrylate (PEGDA) were used to completely eliminate all crystals. Further, photopolymerization of PEGDA affords a solid network containing LiTFSI and SCN that shows promising improvements with a conductivity value of 10^{-4}S/cm at 25°C.

S1.00058 Synthesis and Photovoltaic Properties of a New Class of Donor-Acceptor Alternating Copolymers Containing Pechmann-Dye Derivatives , JAE WOONG JUNG, WON HO JO, Department of Materials Science and Engineering, Seoul National University — Over the last decade, various low bandgap copolymers that exhibit over 5% power conversion efficiency have been developed. However, the synthesis of most low-bandgap polymers is complicated with relatively long synthetic routes and low yield. In this work, a new series of novel alternating copolymers composed of thiophene and Pechmann-dye derivatives were synthesized and used as an electron donor material of bulk heterojunction polymer solar cells. Two Pechmann-dye derivatives, 5,5'-bis-(3-octyl-thiophen-2-yl)-[3,3']bifuranylidene-2,2'-dione and 3,7-bis-(3-octyl-thiophen-2-yl)-pyrano[4,3-c]pyran-1,5-dione which have high molar absorption coefficient, strong electron-deficient core, and planar structure, were easily synthesized via simple three steps with high yield. The use of the Pechmann-dye derivatives as a building block for copolymers results in promising optical, electrochemical, and photophysical properties. Morphology, charge transport, and photovoltaic characteristics of the new copolymers will be discussed.

S1.00059 Nanostructured photovoltaic materials using conjugated block copolymer assemblies

, SARAH E. MASTROIANNI, THOMAS H. EPPS, III, University of Delaware, Chemical Engineering Department — Block copolymers containing a conjugated block offer attractive possibilities for creating nanostructured organic photovoltaic (OPV) devices. Current OPV materials suffer from efficiency losses primarily due to a size-scale discrepancy between exciton diffusion length and domain sizes; excitons that do not reach the interface between electron and hole-conducting materials recombine, preventing charge carrier separation. The inherent nature of block-copolymers to self-assemble into well-defined nanoscale structures with domain spacings on the order of exciton diffusion length offers a potential solution for reducing exciton recombination. In this work, allyl-terminated poly(3-hexyl thiophene) or poly(3-decyl thiophene) acting as electron donors are incorporated into the block copolymer chain via a coupling reaction with poly(styrene) or poly(isoprene-*b*-styrene) derivatives synthesized by anionic polymerization. The resulting block copolymer morphologies are characterized by small angle X-ray scattering and transmission electron microscopy.

S1.00060 Structure-performance analysis of donor/acceptor low band gap polymers: Effect of different acceptors

, LOUIS PEREZ, JAMES ROGERS, KRISTIN SCHMIDT, GUILLERMO BAZAN, EDWARD KRAMER, Materials Department UC-Santa Barbara, MATERIALS DEPARTMENT UC-SANTA BARBARA COLLABORATION — A well established method of designing low band gap polymers for bulk heterojunction solar cells employs what is known as a 'donor-acceptor' (D/A) motif. A D/A polymer is an alternating copolymer consisting of a covalently bound electron deficient unit as an electron acceptor and an electron rich component as an electron donor group. A notable D/A polymer, poly[2,6-(4,4-bis-(2-ethylhexyl)-4H-cyclopenta[2,1-b;3,4-b']-dithiophene)-alt-4,7-(2,1,3-benzothiadiazole)], (PCPDTBT) was the first to achieve device efficiencies over 5%. Device performance is predicted to improve by changing the acceptor to tune the energy level offsets between the polymers and the fullerene derivative to increase the driving force for exciton dissociation and the internal potential, (Voc). If the BT acceptor is changed to benzooxadiazole (BO) the Voc increases, however the current drops significantly, producing devices with efficiencies less than 2%. In order to understand the current drop, GIWAXS, NEXAFS, DSIMS, and TEM have been employed to elucidate structural and composition differences.

S1.00061 PCBM Functionalized Block Copolymer films for Photovoltaic Applications[1]

, ABUL M.A. HUQ, MANISH M. KULKARNI, ALAMGIR KARIM, Department of Polymer Engineering, University of Akron, USA — For efficient charge separation we examine block copolymer thin films as model nanoscale templates that can be utilized for OPV applications. If one can incorporate acceptor and donor in two different blocks, efficient charge separation can be possible. Microphase separation in block-copolymer (BCP) systems, a result of chemical incompatibility of the constituent polymer blocks can be used to control the nanoscale domain sizes. Here, Polystyrene-b-Polyethyleneoxide (PS-PEO) block copolymer, with the PEO being the cylinder forming phase was used because of its robust structural nature to form vertical nanomorphology of cylinders. The acceptor material, PCBM was incorporated into the block-copolymer at different concentration levels up to high levels (∼30%). Both TEM and AFM study showed that PCBM was well dispersed at up to 3:10 (PCBM:PS-PEO) in the block copolymer matrix. This amount is close to percolation threshold of PCBM at which independent donor and acceptor path is expected to be achieved. Further investigations by neutron scattering methods for possible numerous electronic applications including OPV are underway.

[1]Funding from Department of Energy Grant # DE-SC0005364.

S1.00062 Mixing Behavior of a Molecular Acceptor and Polymeric Donors in Organic Solar Cell Blends

, M.A. BRADY, N.D. TREAT, L.A. PEREZ, J.E. COCHRAN, UCSB, M.F. TONEY, Stanford Synchrotron Radiation Lightsource, C.J. HAWKER, M.L. CHABINYC, E.J. KRAMER, UCSB — Organic photovoltaics represent potentially low-cost, solution-processable materials for sustainable energy generation. The concept of a bulk heterojunction relies on the belief that separated domains of donor and acceptor exist to maximize interfacial area for exciton dissociation, while pathways are retained for charge transport to each electrode. Although phase-pure domains are believed to exist due to phase separation of acceptor (PCBM) and donor (P3HT) components, our results suggest otherwise. In this work, the rapid interdiffusion of PCBM and P3HT is investigated using dynamic secondary ion mass spectrometry and grazing-incidence wide angle X-ray scattering, illustrating the significant miscibility of PCBM within P3HT amorphous regions, especially at temperatures (150 °C) at which devices are often annealed to improve performance. The solubility of PCBM in the P3HT-rich phase decreases at lower temperatures. This mixing behavior is contrasted with that of PCBM with PBTTT, a poly(thiophene) of reduced side chain density.

S1.00063 Photophysical Study of Novel Perylene Analogues for Biophysical Applications[1]

, JORGE PALOS-CHÁVEZ, MARK PENICK, GEORGE NEGRETE, LORENZO BRANCALEON — Perylene and perylene derivatives have been shown to be useful in a variety of photoinitiated applications, such as molecular dyes, organic solar cells, etc. Recently we started the characterization of novel 3,9-perylene analogues which could potentially lead to the synthesis of novel molecules with improved ability to separate charges. We have characterized the basic photophysical properties of these molecules, and we are currently investigating the photochemistry that leads to photoproducts in chlorinated compounds. Spectroscopic measurements show the substantial changes in photophysical parameters consistent with the conversion of the original compounds into photoproducts. SEM and AFM imaging show that these photoproducts form ordered particles. Mass spectrometry studies have confirmed the presence of these photoproducts as well. Additional studies are underway concerning the use of these novel perylene analogues in binding to biological structures such as proteins. It is hoped that these compounds will prove useful for biophysical applications, specifically in studying the manipulation of protein conformation via physical methods.

[1]Supported by NIH/NIGMS MBRS RISE GM-60655.

S1.00064 Synthesis and Characterization of Quinoxaline-Based Low-Bandgap Copolymers for Bulk Heterojunction Solar Cells

, YOONKYOO LEE, WON HO JO, Department of Materials Science and Engineering, Seoul National University — A series of low-bandgap alternating copolymers consisting of quinoxaline derivatives and electron-donating carbazole or fluorene were synthesized via the Suzuki coupling reaction. For the purpose to improve the molecular packing of polymer chains and to enhance the charge carrier mobility in the packing direction, a new quinoxaline derivative, 5,8-dithien-2-yl-dibenzophenazine which has perfectly planar polycyclic structure, was synthesized and introduced as a new building block for alternating copolymers instead of frequently-used 5,8-dithien-2-yl-2,3-diphenylquinoxaline. The use of planar quinoxaline derivative exhibited better optical, electrochemical, and structural properties of the resulting copolymers as compared to those of polymers with less planar quinoxaline derivatives. Charge transport and photovoltaic properties of these two classes of copolymers are compared and discussed.

S1.00065 PL enhancement in MEH-PPV stretched films by suppression non-radiative relaxations

, JUI-HUNG HSU, Dept. of Materials & Opt-electronic Science, National Sun Yat-sen University, JONATHON DAVID WHITE, Dept. of Photonics Engineering, Yuan Ze University, ARNOLD C.-M. YANG, Dept. of Materials Science & Engineering, National Tsing-Hua University — Due to the strong electro-phonon coupling, excitation in conjugated polymer is easily relaxed through non-radiative decay channels, and the luminescence yield is lowering. It would be crucial to reduce the non-radiative relaxations for the high performance light-emitting applications. We report the study of stretched MEH-PPV blending films by fluorescence lifetime imaging microscopy. Polymer in the stretched region is fully aligned, and the emission yield is improved by 40%. The improvement is well-agreed with the lifetime studies. Our results indicate that the PL enhancement is due to the suppression of non-radiative relaxations while stretching. Comparing the lifetime imaging and the morphology by AFM, molecular strain distribution is provided. The investigation would be useful in the device application and the basic understanding of electronic excitation relaxation in conjugated polymers.

S1.00066 Classification of Semiconducting Polymeric Mesophases to Optimize Device Post-Processing , CHAD SNYDER, RYAN NIEUWENDAAL, LEE RICHTER, R. JOSEPH KLINE, DEAN DELONGCHAMP, NIST, MARTIN HEENEY, IAIN MCCULLOCH, Imperial College of London — Semiconducting polymers form a variety of phases and mesophases that respond differently to post-deposition solvent or thermal treatments. Here it is shown that classification of these materials into their appropriate mesophases can be a useful tool to optimize their post-deposition treatments. Calorimetry is used to quantify differences between very similar materials, using a well-established framework based on the kinetics and thermodynamics of phase changes. By way of example, this classification scheme is used to identify differences in three polymers, poly(3-hexylthiophene) and two isomeric bithiophene-thiophene copolymers (pBTTT and pATBT). It is demonstrated that poly(3-hexylthiophene) is a conformationally disordered (condis) crystal, and that the two bithiophene copolymers are liquid crystals. The condis state is used to help explain the wide range of reported values for poly(3-hexythiophene), as two separate glass transitions are clearly resolved. The diverse phase structure is notable in light of the molecular similarity of the three polymers, and it has impact on optimum post-processing conditions for maximum electrical performance in thin film transistor devices.

S1.00067 Solution processed organic microarray with inverted structure[1] , PATRICK TOGLIA, JASON LEWIS, EVAN LAFALCE, XIAOMEI JIANG, Department of Physics University of South Florida — We have fabricated inverted organic microarray using a novel solution-based technique. The array consists of 60 small (1 square mm) solar cells on a one inch by one inch glass substrate. The device utilizes photoactive materials such as a blend of poly(3-hexylthiophene) (P3HT) and [6,6]-phenyl-C61-butyric acid methyl ester (PCBM). Manipulation of active layer nanomorphology has been done by choice of solvents and annealing conditions. Detailed analysis of device physics including current voltage characteristics, external quantum efficiency and carrier recombinations will be presented and complimented by AFM images and glazing angle XRD of the active layer under different processing conditions. The procedure described here has the full potential for use in future fabrication of microarrays with single cell as small as 0.01 square mm for application in DC power supplies for electrostatic Microelectromechanical systems (MEMS) devices.

S1.00068 Subpicosecond photonic switching based on bacteriorhodopsin , PAL ORMOS, LASZLO FABIAN, ZSUZSANNA HEINER, Institute of Biophysics, Biological Research Centre, Hung. Acad. Sci., MARK MERO, HAS Research Group of Laser Physics, MIKLOS KISS, Department of Optics and Quantum Electronics, University of Szeged, ELMAR WOLFF, Institute for Applied Biotechnology and System Analysis at the University of Witten/Herdecke, KAROLY OSVAY, Department of Optics and Quantum Electronics, University of Szeged, ANDRAS DER, Institute of Biophysics, Biological Research Centre, Hung. Acad. Sci. — All-optical data processing is the most promising approach for further improvement in data trafficking. We present a subpicosecond photonic switch where the active role is performed by the chromoprotein bacteriorhodopsin. The changes in the refractive index that accompany the steps of the photocycle of bacteriorhodopsin are used for all optical switching in appropriate integrated optical devices. We use grating coupled planar waveguides and the coupling is modulated by the light induced refractive index changes of bacteriorhodopsin. The switching is demonstrated in ultrafast pump-probe experiments. Different transitions of the photocycle are explored for switching applications. We show that by using the bR to I transition subpicosecond switching can be readily achieved. The approach is a basis for protein-based integrated optical devices, eventually leading to a conceptual revolution in telecommunications technologies.

S1.00069 Efficient blue PhOLEDs using host materials of lower triplet energy than the emitter , JAMES SWENSEN, EVGUENI POLIKARPOV, AMBER VONRUDEN, LIANG WANG, ASANGA PADMAPERUMA, Pacific Northwest National Laboratory — It is a commonly held view that the host material for a phosphorescent emitter in an organic light emitting device (OLED) must have a triplet energy higher than that of the phosphorescent emitter in order to obtain high quantum efficiencies. We show that a combination of HTL, ETL and host with appropriate energy levels can provide high external quantum efficiency (EQE), even with a host triplet energy smaller than that of the emitter. Specifically, we report results for a new host material, 4-(di-p-tolylamino)phenyl)diphenylphosphine oxide, with a triplet energy lower than FIrpic that demonstrate improved OLED performance. Our results suggest modified design rules for the development of new, high performance host materials. Molecular design strategies, device design and OLED data will be discussed.

S1.00070 Simulation of DNA Electrophoresis by Coarse-Grained Hybrid Molecular Dynamics Approach[1] , RONG WANG, Department of Polymer Science and Engineering, Nanjing University — Simulation of DNA electrophoresis facilitates the design of DNA separation devices. Various methods have been explored for simulating DNA electrophoresis and other processes using implicit and explicit solvent models. Explicit solvent models are highly desired but their applications may be limited by high computing cost in simulating large number of solvent particles. In this work, a coarse-grained hybrid molecular dynamics (CGH-MD) approach was introduced for simulating DNA electrophoresis in explicit solvent of large number of solvent particles. CGH-MD was further applied to the simulation of DNA electrophoresis in polymer solution and in a well-studied nanofluidic device. Simulation results are consistent with observations and reported simulation results, suggesting that CGH-MD is potentially useful for studying electrophoresis of macromolecules and assemblies in nano-fluidic, micro-fluidic, and microstructure array systems that involve extremely large number of solvent particles, non-uniformly distributed electrostatic interactions, bound and sequestered water molecules.

S1.00071 Examining Adsorbed Polymer Conformations with Fluorescence Imaging , MARIA PARKES, Student Graduate, MOURAD CHENNAOUI, JANET WONG, TRIBOLOGY GROUP, DEPT. OF MECHANICAL ENGINEERING TEAM — The conformation of adsorbed polymers can have significant impact on their properties such as dynamics and elasticity as well as their ability to take part in reactions with other molecules. Experimental research to determine adsorbed polymer conformation has relied mainly on atomic force microscopy (AFM) studies. During an AFM scan, the contact between the scanning probe and the polymer could affect the polymer conformation, particularly where parts of the polymer might have formed projected loops and tails. In this work, conformations of model polymers are examined with total internal reflection fluorescence microscopy (TIRFM). The advantage of TIRFM over AFM is that TIRFM is a non contact technique. Lambda DNA labelled along its length with fluorescent probes was adsorbed in a projected 2D – 3D state. With TIRFM, the relationship between intensity and depth was used as a basis to determine how the conformation of the adsorbed polymers evolved with time using our custom algorithm.

S1.00072 Study of pluronic F68 molecules on silicon with Atomic Force Microscopy (AFM) , M.J. RETAMAL, U.G. VOLKMANN, Pontificia Univ. Catolica de Chile, V.D. SAMITH, Univ. Andres Bello, Chile — The triblock copolymer pluronic F68 belongs to a class of amphiphilic nonionic surfactants, relevant for applications in medicine, which includes transport of drugs to selective targets in the human body. In the present work, pluronic F68 films have been deposited on Si/SiO2 substrates. Previous to deposition, Si/SiO2 substrates were cleaned in acid and afterwards rinsed with ultra pure water. This cleaning method leaves intact the silicon oxide layer and provides a hydrophilic surface. The aliquots were prepared from aqueous solutions, obtaining different concentrations, which were deposited on the substrates and dried at room temperature. Each of these dispersions is in the range from 0.5 x 10-4 M to 10.0 x 10-4 M. Atomic force microscopy (AFM) shows changes in the morphology of the films, caused by the gradual increase of concentration. These changes occur in a narrow range of concentrations, attributed to the critical micelle concentration (CMC). Supramolecular structures (clusters) coexist at the CMC and above, forming 3D structures such as "dendritics." The percentage of F68 coverage on the substrate depends on the increase in molar concentration. In a "coverage vs. molar concentration" plot we obtain a curve with an inflection point that coincides with the CMC reported for a variety of techniques and conditions.

S1.00073 Hierarchical self-assembly of spider silk-like block copolymers , SREEVIDHYA KRISHNAJI, WEN-WEN HUANG, PEGGY CEBE, DAVID KAPLAN, Tufts University — Block copolymers provide an attractive venue to study well-defined nano-structures that self-assemble to generate functionalized nano- and mesoporous materials. In the present study, a novel family of spider silk-like block copolymers was designed, bioengineered and characterized to study the impact of sequence chemistry, secondary structure and block length on assembled morphology. Genetic variants of native spider dragline silk (major ampullate spidroin I, Nephila clavipes) were used as polymer building blocks. Characterization by FTIR revealed increased ?-sheet content with increasing hydrophobic A blocks; SEM revealed spheres, rod-like structures, bowl-shaped and giant compound micelles. Langmuir Blodgett monolayers were prepared at the air-water interface at different surface pressures and monolayer films analyzed by AFM revealed oblate to prolate structures. Circular micelles, rod-like, densely packed circular structures were observed for HBA6 at increasing surface pressure. Exploiting hierarchical assembly provide a promising approach to rationale designs of protein block copolymer systems, allowing comparison to traditional synthetic systems.

S1.00074 Tunable surface properties from bioinspired polymers , WENDY VAN ZOELEN, ADRIANNE ROSALES, HANNAH MURNEN, University of California, Berkeley, RONALD ZUCKERMANN, Lawrence Berkeley National Laboratory, RACHEL SEGALMAN, University of California, Berkeley — Anti-fouling properties can be derived from patterned or "ambiguous" surfaces displaying multiple surface properties. Biological polymers with precisely controlled chain shapes and self-assembled structures are attractive materials for these applications, in which tunability is of great importance. We have investigated the surface properties of polypeptoids, a class of non-natural biomimetic polymers based on an N-substituted glycine backbone, that combine many of the advantageous properties of bulk polymers with those of synthetically produced proteins. Polypeptoids are of particular interest as they can be made in a sequence controlled fashion with functionalities already known to impart fouling-resistance (ethers, zwitterions, hydrophobicity, and nanoscale patterning). We demonstrate their surface stability and processibility from the standpoint of coating performance and also discuss controlled self-assembly of these materials. Used strategies include mediation of crystallization by incorporating chain defects and specific interactions.

S1.00075 Synthesis and Characterization of Thermally Responsive Polysaccharide Nanoparticles , KRISTA FREEMAN, SEAN SHERIDAN, IMAAN BENMERZOUGA, JOHN MCKENNA, KIRIL STRELETZKY, Cleveland State University — Environmentally-manipulable nanoparticles (microgels) have been synthesized from the amphiphilic polymer hydroxypropyl-cellulose and characterized using dynamic and static light scattering spectroscopies. Careful synthesis studies have revealed dependences of microgel size and structure on polymer molecular weight, polymer concentration, salt concentration, and crosslinker density. An understanding of these dependences has allowed the synthesis of stable, largely spherical, and relatively small (about 100nm) and monodisperse microgels. The synthesized microgels exhibit a volume phase transition between temperatures of 40 and 41C, under which particles undergo a reversible 15-50-fold change in volume. The microgel structure, dynamics, and longevity have been systematically studied by light scattering both below and above the transition temperature.

S1.00076 Uniform Yeast Cell Assembly Based on Microfluidic Microgels , YA-WEN CHANG, PENG HE, Artie McFerrin Department of Chemical Engineering, Texas A&M University, College Station, TX, MANUEL MARQUEZ, YNano LLC, 14148 Riverdowns South Dr., Midlothian, Virginia 23113-3796, ZHENGDONG CHENG[1], Artie McFerrin Department of Chemical Engineering, Texas A&M University, College Station, TX, SAMANTHA M. MARQUEZ, Maggie L. Walker Governor's School for Government and International Studies, Richmond, VA — We present a novel microgel templated Yeastosome® (Yeast-Celloidosome®) based on self-assembly of yeast cells onto liquid-gel interfaces. To organize living cells onto the surface of the gel particles, strong positive charges were first introduced via LbL (layer by layer) polyelectrolyte decoration on monodisperse agarose microgel templates fabricated with a microfluidic flow focusing device. Native yeasts, bearing negative surface charges can then be driven electrostatically to form a monolayer shell around the gel core. Surface coverage/packing density of the yeast biofilm on varying microgel-to-yeast size ratio assemblies is evaluated with optical microscopy. Mechanical properties of the corresponding shells are characterized with buckling or collapse behavior during drying-hydrating cycle. We demonstrate the capability to fabricate narrow size distribution Yeastosome® with a soft hydrogel core. The combination of microfluidic fabrication with cell assembly offers excellent control over inner core properties and could enable further hierarchy bio-structures.

S1.00077 Clay platelets in a matrix of amino acids (of a clay binding peptide M1) homopolymer: binding, unbinding, dispersion, and self-assembly by a coarse-grained Monte Carlo simulation[1] , BARRY FARMER, LAWRENCE DRUMMY, SHARON JONES, RICHARD VAIA, RAJESH NAIK, Air Force Research Laboratory, HENDRIK HEINZ, University of Akron, RAS PANDEY, University of Southern Mississippi — Monte Carlo simulations are performed to study binding and distribution of a stack of clay platelets in a matrix of homo-polymers of residues. The set of residue monomers is selected from a clay binding peptide $(M1)$[1]. The length of homopolymer is same as that the peptide $M1$. Clay platelet and amino acid polymer (AAP) are described by a bond-fluctuation model[2] where specificity of each residue interaction is incorporated. Each node (of clay platelets and AAP) performs their stochastic motion via Metropolis algorithm subject to steric and excluded volume constraints. We examine the mobility of AAP and platelets and their density profiles. We find that dispersion and binding of each AAP is unique and differ from that of the clay platelets in peptide $M1$ matrix.

S1.00078 Diffusion-driven looping provides a consistent framework for chromatin organization , DIETER HEERMANN, MANFRED BOHN, University of Heidelberg — Chromatin looping seems to play a dominant role both in transcriptional regulation as well as in chromatin organization and has been assumed to be mediated by long-range interactions in many polymer models. However, it remains a crucial question which mechanisms are necessary to make two chromatin regions become co-located, i.e. have them in spatial proximity. We demonstrate that the formation of loops can be accomplished solely on the basis of diffusional motion. The probabilistic nature of temporary contacts mimics the effects of proteins, e.g. transcription factors, in the solvent. We establish testable quantitative predictions by deriving scale-independent measures for comparison to experimental data. In this Dynamic Loop (DL) model, the co-localization probability of distant elements is strongly increased compared to linear non-looping chains. The model correctly describes folding into a confined space as well as the experimentally observed cell-to-cell variation. Most importantly, at biological densities, model chromosomes occupy distinct territories showing less inter-chromosomal contacts than linear chains. Thus, dynamic diffusion-based looping, i.e. gene co-localization, provides a consistent framework for chromatin organization in eukaryotic interphase nuclei.

S1.00079 Synthesis of a novel photopolymerized nanocomposite hydrogel for the treatment of acute mechanical damage to cartilage , KATHRYN SCHLICHTING, Department of Materials Science and Engineering, Iowa State University, TRISHELLE COPELAND-JOHNSON, Department of Chemical Engineering, University of South Florida, MATTHEW GOODMAN, Department of Materials Science and Engineering, Iowa State University, ROBERT LIPERT, Institute for Combinatorial Discovery, Iowa State University, TODD MCKINLEY, JAMES MARTIN, Department of Orthopaedic Surgery and Rehabilitation University of Iowa, SURYA MALLAPRAGADA, Department of Chemical and Biological Engineering, Iowa State University, ZHIQUN LIN, Department of Materials Science and Engineering, Iowa State University — Posttraumatic osteoarthritis is caused by a cascade of pathobiologic and pathomechanical events starting with intraarticular fractures in the cartilage. Currently, treatment of fractures is completely focused on restoration of the macroanatomy of the joint. The premise is that restoring the macroanatomy will prevent ongoing stresses and in turn prevent cartilage degeneration. However, current treatment ignores acute mechanical damage sustained by cartilage at the time of injury. This study describes the initial development of a novel nanocomposite photopolymerizing copolymer that has potential to restore local structural integrity to acutely injured cartilage, and subsequently act as a carrier for chondrocyte-enhancing bioactive agents.

S1.00080 Car–Parrinello Molecular Dynamics Study of Base-Catalyzed Hydrolysis Reactions[1] , SUFIAN ALNEMRAT, IGOR VASILIEV, HAOBIN WANG, NMSU — We apply the first principles metadynamics simulation technique implemented in the Car-Parrinello molecular dynamics package to study the base-catalyzed hydrolysis of N-methylacetamide in aqueous solution. Our calculations are carried out in the framework of density functional theory combined with the hybrid BLYP exchange-correlation functional The free energy surfaces and hydrolysis reaction pathways for N-methylacetamide are examined in the presence of a hydroxide ion, and 4, 32, and 64 water molecules. We find that at least 32 water molecules must be explicitly included in metadynamics simulations to accurately describe the mechanism of the hydrolysis reaction of N-Methylacetamide. Our theoretical estimate for the dissociation energy of N-Methylacetamide is in good agreement with the results of previous experimental and theoretical studies.

[1]Supported by LANL-NMSU MOU.

S1.00081 Silica-Based Janus Nanoparticles at the Water-Decane Interface[1] , HENG FAN, ALBERTO STRIOLO, The University of Oklahoma, School of Chemical, Biological and Materials Engineering — It is well known that solid particles adsorb at water-oil interfaces to reduce the contact area between the two immiscible phases. Stable emulsions are obtained when the particles strongly adsorb at the interfaces. We report herein all atom molecular dynamics simulation results for silica-based nanoparticles functionalized with hydrophobic moieties at the decane-water interface. The simulation results are quantified in terms of contact angle at the water-nanoparticle-decane interface, mobility of the nanoparticles, association of multiple nanoparticles at the interface, and free-energy landscapes that dictate the nanoparticle adsorption at the interface. The results are discussed based on the chemical features of the nanoparticle surface. Comparison with experimental data, including but not limited to TEM and cryo-TEM images of water-oil emulsions, are provided.

S1.00082 Synthesis of stable Au-PEG nanocomposite chains in a single step precursor free method and its formation mechanism and Di-electric behavior[1] , RAJESH KUMAR NEOGY, RAJIB NATH, S.N.Bose Centre, GAUTAM BASU, Bose Institute, ARUP KUMAR RAYCHAUDHURI, S.N.Bose Centre — We report a simple and effective one step and one-pot synthesis of stable assembly of Au nanoparticles (diameter 8-10nm) into chains in an Ethylene Glycol medium(MEG), using only a solid metallic Au target and a pulsed excimer laser. No use any external precursor, reducing agent or surfactant so it is a chemistry free synthesis route. The Au-PEG nanocomposite chains (with unbroken lengths often more than few microns) formed in liquid medium are mechanically and thermally stable and can be transferred unchanged into a solid substrate which can span a large surface area. The nanochains show a broad optical absorption near to visible spectrum. Hybrid of Au nanochains and separated nanoparticles can also be formed using a proper choice of the laser fluence and MEG/DI water concentration. The Au-PEG nanocomposite chains in the medium shows enhanced low frequency dielectric constant & electrical conductivity. NMR shows that due to the formation of dimer/trimers of MEG molecules that formed by the ablation process, attach to the Au nanoparticles and facilitate the nanocomposite chain formation.

S1.00083 Assembly of carbon nanotube/polymer hybrids at liquid/liquid interface , WENDA WANG, ERIC LAIRD, Graduate Student, CHRISTOPHER LI, Associate Professor — Carbon nanotube (CNT)-templated polymer crystallization has led to controllable patterns on individual CNTs. Previous work has demonstrated that crystalline block copolymers (BCP) can be uniformly patterned on CNTs and the mechanism was attributed to CNT-induced BCP phase separation. Herein, we report that at liquid/liquid interface, CNTs can be bent into nanoscale rings. The structure and morphology of these intriguing CNT rings were investigated using electron microscope and Raman spectroscopy. Furthermore, these CNT rings were used as a template for polymer crystallization. Homopolymer, BCP and gold nanoparticles have been successfully patterned on sub-200 nm CNT rings. These unique hybrids are of great interest in various areas of nanoelectronics and single-electron devices.

S1.00084 Nucleation and Growth of Hydroxyapatite on Hierarchically Ordered Polymer Nanofibers , XI CHEN, BIN DONG, Drexel University, BINGBING WANG, CHRISTOPHER LI, Drexel University — The hierarchically ordered polymer nanofibers, named as nanofiber shish kebabs (NFSKs), were constructed via combination of electrospinning polycaprolactone (PCL) (shish polymer) and controlled crystallization of polycaprolactone-b-poly acrylic acid (PCL-b-PAA) (kebab polymer). These NFSKs were then employed as a template to control the nucleation and growth of hydroxypatite nanocrystals. Electron microscopy and diffraction technique were used to characterize this novel hybrid structure. The growth of minerals starts on the surface of single crystal kebabs and eventually covers the surface of NFSKs. The formation mechanism of hydroxyapatite on NFSKs is of great interest because of the NFSKs' potential application as bone scaffold materials.

S1.00085 Direct nanoparticle assembly in block copolymer based supramolecules containing liquid crystal , MYUNG IM KIM, University of California, Berkeley, CLAYTON E. MAULDIN, JEAN M.J. FRECHET, TING XU, University of California, Berkeley — Block copolymer (BCP)-based supramolecules which combine the nanoscopic assembly of BCPs and molecular ordering can generate hierarchical structure with built-in functionality. Here, we investigated the phase behavior of BCP-based supramolecules containing cholesteric liquid crystal (LC) moieties and achieved directed assembly of nanoparticles. In bulk, we found that BCP-based supramolecules formed a cylinder-in-lamellar structure after solution casting. Upon heating, the order-order transition from cylinder-in-lamella to lamella-in-cylinder was observed. In thin films, supramolecules forming a parallel cylinder-in-lamella structure on silicon substrates were induced by solvent-annealing in chloroform vapor. In addition, we could achieve directed nanoparticle assembly in BCP-based LC supramolecules in bulk and in thin films with control of nanoparticle spatial distribution.

S1.00087 PS-*b*-PDMS Block Copolymer Thin Film: Pattern Formation and Phase Behavior , I-FAN HSIEH, STEPHEN Z.D. CHENG, DEPARTMENT OF POLYMER SCIENCE, THE UNIVERSITY OF AKRON TEAM — Recently, block copolymer thin films attract great attention due to their potential applications in surface nano-lithography. In our work, PS-*b*-PDMS with cylinder morphology is chosen due to extremely large χ value between two blocks. Besides, PS-*b*-PDMS can be transformed into silicon oxide under UV/O_3 exposure and a layer of silicon oxide with the self-assembled block copolymer patterns can be made. By utilizing the PGMEA as solvent, we can easily obtain sphere morphology in cylindrical composition block copolymer by preserved block copolymer solution morphology during film formation. Furthermore, in thermal annealing process, the phase behavior of the PS-*b*-PDMS thin film is strongly affects by molecular weight, film thickness and annealing temperature. In larger-molecular-weight PS-*b*-PDMS, we only observed spherical domains rearrangement and without morphology transition between sphere and cylinder due to high energy barrier, whereas, in the case of smaller-molecular-weight polymer, depending on the film thickness and annealing temperature, its thin film morphology transits between sphere and cylinder alternatively, which is similar to what we found in solvent annealing.

S1.00088 Directing morphology development in Triblock copolymers: A Self-Consistent Field Theory Study , MOUGEH MOHAGHEGHI, BAMIN KHOMAMI, Mrail — Using combinatorial screening method based on self-consistent-field theory for multicomponent polymers, we study ABC block copolymers melt confined between two parallel neutral walls separated by distance L in which the backbone consists of A and B and C is the graft. We analyze the behavior of the system as a function of film thickness. It is shown that confining walls can direct the assembly of thin films of block copolymers. Moreover, by judicious select of film thickness and the position of the graft point, a number of novel morphologies that have not been experimentally realized to date can be created. Overall, These results demonstrate a promising strategy for fabrication of complex nanostructure materials for a variety of important applications such as organic photovoltaic materials.

S1.00089 How Fast Liposomes Diffuse in the Extracellular Matrix , JAMES KUO, BO WANG, SUNG CHUL BAE, STEVE GRANICK, UIUC — Single-particle tracking is used to compare the diffusivity of soft spheres (liposomes) with that of hard spheres of the same size, when they are embedded within gels whose mesh size is smaller than the particle size. The comparison is made in model systems and also in cell extracts of closer biological relevance. In both environments, the diffusivity of liposomes is systematically faster than that of hard spheres.

S1.00090 COMPLEX STRUCTURED MATERIALS III —

S1.00091 Preparation and Magnetic Properties of Co2Z Hexaferrite From Annealed Mixtures of BaM and Co2Y Hexaferrite Precursor Powders , MARC DOYLE, Drexel University, BRIAN KELLY, THOMAS EKIERT, KARL UNRUH, University of Delaware — The transformation of fine mixtures of BaM and Co2Y hexaferrite powders to Co2Z hexaferrite has been studied by scanning electron microscopy (SEM), x-ray diffraction (XRD), and vibrating sample magnetometry (VSM) measurements. The precursor hexaferrites were prepared by a solution-phase auto-combustion method and subsequently mixed in a low energy rolling mill. The BaM/Co2Y mixtures were annealed at temperatures between 800 and 1300 $^\circ$C in air for 2 hours. Over this temperature range a rapid decrease in the measured coercivity from a value of about 4 kOe, characteristic of the hard BaM component of the mixture, to a value of about 50 Oe, characteristic of the magnetically soft Co2Z phase, was observed. The coercivity reduction was accompanied by a modest increase in the saturation magnetization to a value of about 60 emu/g.

S1.00092 A High Energy X-Ray Diffraction Study of the Atomic-Scale Structure of Novel Vitreous Rare Earth Phosphates[1] , ERANDI S. GUNAPALA, G.K. MARASINGHE, Department of Physics and Astrophysics, University of North Dakota, Grand Forks, ND 58202, CHRIS J. BENMORE, Advance Photon Source, Argonne National Laboratory, Argonne, IL 60439 — The magneto-optical properties of rare earth phosphate glasses make them good candidates for numerous potential applications including high-energy/high power ($\sim 10^{15}$ watt) lasers. Because, properties of these materials depend heavily on their atomic structure, a detailed study can facilitate development of additional applications. A series of $(Pr_2O_3)_x(P_2O_5)_{1-x}$ glasses where $0.05 \leq x \leq 0.25$ had been characterized by high energy X-ray diffraction. Coordination parameters for nearest coordination neighbors were obtained by Gaussian fitting. The P-O coordination number, N_{PO}, and the P-O, O-O, P-P distances were found to be insensitive to the Pr_2O_3 content. Coordination numbers N_{PrO} decreased from $\sim$ 8.0 to $\sim$ 7.5 with increasing Pr_2O_3 content from 0.12 to 0.23. Pr-O distance did not seem to vary with Pr_2O_3 content in the x range that we studied.

S1.00093 ABSTRACT WITHDRAWN —

S1.00094 Characterizing the Structure and Porosity of Organic Molecules of Intrinsic Microporosity by Molecular Simulations and Experiment[1] , LAUREN J. ABBOTT, AMANDA G. MCDERMOTT, Penn State University, ANNALAURA DEL REGNO, University of Manchester, KADHUM J. MSAYIB, MARIOLINO CARTA, RUPERT TAYLOR, NEIL B. MCKEOWN, Cardiff University, FLOR R. SIPERSTEIN, University of Manchester, JAMES RUNT, CORAY M. COLINA, Penn State University — Organic molecules of intrinsic microporosity (OMIMs) are amorphous, glassy solids that contain interconnected pores of sizes smaller than 2 nm. The philosophy behind OMIMs is similar to that of polymers of intrinsic microporosity (PIMs); rigid, awkwardly shaped molecules frustrate packing and form low density materials with intrinsically porous structures. Atomistic simulations were performed on OMIMs using our recently developed packing and compression procedure to study the effect of structure on packing behavior. The structure and porosity of the simulated samples were characterized, such as by surface areas and structure factors, and compared to experimental results. The presented computational procedure will further understanding of structure-property relationships and aid in the design of novel materials with high surface areas.

S1.00095 Long-Range Potential Fluctuations in GST Chalcogenide Glasses , RAJEEV GUPTA, Department of Physics and Materials Science Programme, IIT Kanpur, India, CH. BAPANAYYA, Materials Science Programme, IIT Kanpur, India, S.C. AGARWAL, Department of Physics, IIT Kanpur, India — Ge-Sb-Te (GST) alloys are widely used for data recording based on the rapid and reversible amorphous to crystalline phase transformation that is accompanied by an increase in the optical reflectivity and electrical conductivity. However, their application in advanced memory technology is limited by their endurance; $Ge_2Sb_2Te_5$ (GST225) switch has the longest life. Search for more efficient materials has been on, but has not been fully successful so far. This is primarily because one does not know the algorithm to prepare such a material. In this paper, electrical transport properties - electrical conductivity and thermopower of GST alloys are studied and the widths of long-range spatial potential fluctuations present in thin films are estimated. The study shows that amorphous GST225 has the smallest potential fluctuations among all the alloys studied. This finding is correlated to the performance of the phase change materials. The presence of potential fluctuations increases the minimum free energy of the amorphous phase. This deteriorates the switching ability after a few cycles. This suggests that the material with smaller potential fluctuations is likely to be better suited as a switch with a longer life.

S1.00096 Extended X-ray Absorption Fine Structure (EXAFS) Analysis of Novel High Laser Media[1]

ARANWELA HEMANTHA, G.K. MARASINGHE, University of North Dakota, CARLO SEGRE, Illinois Institute of Technology, RICHARD BROW, Missouri University of Science and Technology — Rare earth-doped phosphate glasses are useful for a variety of optical and optoelectronic applications including high energy/high power ($\sim 10^{15}$ watt) Lasers. Binary $(R_2O_3)_x(P_2O_5)_{1-x}$ glasses can be prepared in the compositional range $0 \leq x \leq \sim 0.30$. Atomic-scale structure, especially the coordination environment of R^{3+} ions, play a major role in determining optical/physical characteristics. We have investigated the R^{3+} local environment of Praseodymium and Neodymium ultraphosphate and meta phosphate(REMP) glasses using extended X-ray absorption fine structure technique. For both Nd and Pr phosphate glasses, nearest neighbor (oxygen) coordination decreases with increasing RE concentration. For the first oxygen shell the RE-O distance ranges between 2.38-2.40 Å and 2.39-2.46 Å for Nd and Pr respectively. The second co-ordination shell around the RE ions consists of phosphorus ions, with RE-P distance about 3.4-3.5 Å and co-ordination numbers ranging from 1.5 to 3. There exists an Oxygen shell (third shell) about 4.1 Å from RE ion for both Nd and Pr phosphate glasses.

S1.00097 Dynamics of endohedral hydrogen in C_{60}: Infrared study[1]

MIN GE, U. NAGEL, D. HUVONEN, T. ROOM, Nat. Inst. of Chem. Phys. Biophys., Tallinn, Estonia, S. MAMONE, M.H. LEVITT, M. CARRAVETTA, Southampton Uni., UK, Y. MURATA, K. KOMATSU, Kyoto Uni., Japan, J.Y.-C. CHEN, N.J. TURRO, Columbia Uni., NY10027 — Infrared spectra of endohedral hydrogen isotopomers H_2, D_2, and HD were measured in the temperature range from 6 to 300 K. A model of a vibrating rotor in a spherical potential together with the translational motion induced dipole moment theory was used to explain the positions and intensities of IR absorption lines. By measuring spectra of a *para* enriched sample of $H_2@C_{60}$, we confirmed the assignment of lines to *ortho*- and *para*-H_2. Inside C_{60} cage the rotation of hydrogen is unhindered and the translation is quantized and coupled to the rotation. The isotropic and translation-rotation coupling part of the potential are anharmonic and depend on the vibrational states of hydrogen. The analysis of the isotopic effect on the IR transition intensities and interaction potential in the C_{60} cage is presented.

S1.00098 Interplay between structural and electronic properties of various fullerene derivatives, and their absorption spectra

SORA PARK, JEUNG SUN AHN, YOUNG-KYUN KWON, Kyung Hee University — Using density functional theory (DFT), we investigate the geometrical structures and electronic properties of various fullerene derivatives formed by attaching several kinds of addends on C_{60} through [2+2] cycloaddition. Various forms of such derivatives are modeled by considering different kinds, different positions and different numbers of addends to study how structural configurations will affect their electronic structures. Our results reveal that some derivatives with certain symmetries determined by the configuration of addends may have wider energy gap than that of pristine C_{60}. This suggests that absorption properties could be adjusted by controlling the addends configurations. To describe the excited state properties, such as absorption spectra, of various C_{60} derivatives more accurately, we performed time-dependent (TD) DFT calculations. We find the position and the intensity of the peak of absorption spectra of derivatives are affected by the specific symmetry of the derivatives defined by the configurations of the addends. To explore such peculiar effects, we analyze the charge distribution and orbital mixing characters.

S1.00099 Effective Shear Strain in Helical Rippled Carbon Nanotubes: A Unifying Concept for Understanding Electromechanical Response

TRAIAN DUMITRICA, DONG-BO ZHANG, University of Minnesota — Despite its importance, little is known about how complex deformation modes alter the intrinsic electronic states of carbon nanotubes. Here we consider the rippling deformation mode characterized by helicoidal furrows and ridges and elucidate that a new intralayer strain effect rather than the known bilayer coupling and σ-π orbital mixing effects dominates its gapping. When an effective shear strain is used, it is possible to link both the electrical and the mechanical response of the complex rippled morphology to the known behavior of cylindrical tubes. In combination with objective molecular dynamics, this concept may be useful for understanding the electromechanical characteristics of large scale carbon nanotube assemblies and other individual nanoscale forms of carbon.

S1.00100 Spin-dependent Tunneling through a Potential Barrier on a Nanotube

YONATAN ABRANYOS, GODFREY GUMBS, Hunter College at the City University of New York, PAULA FEKETE, United States Military Academy, West Point, New York — The electron spin effects on the surface of a nanotube have been considered through the spin-orbit interaction (SOI), arising from the electron confinement on the surface of the nanotube. This is of the same nature as the Rashba-Bychkov SOI at a semiconductor heterojunction. We estimate the effect of disorder within a potential barrier on the transmission probability. Using a continuum model, we obtained analytic expressions for the spin-split energy bands for electrons on the surface of nanotubes in the presence of SOI. First we calculate analytically the scattering amplitudes from a potential barrier located around the axis of the nanotube into spin-dependent states. The effect of disorder on the scattering process is included phenomenologically and induces a reduction in the transition probability. We analyzed the relative role of SOI and disorder on the transmission probability which depends on the angular and linear momentum of the incoming particle, and its spin orientation. We demonstrated that in the presence of disorder perfect transmission may not be achieved for finite barrier heights.

S1.00101 A First-Principles Study of SiGe Nanotubes[1]

PRABATH WANAGURU, ASOK K. RAY, Department of Physics, University of Texas at Arlington, Arlington, TX 76019 — A systematic study of the electronic structures of three types of SiGe armchair nanotubes from (3, 3) to (11, 11) using periodic boundary conditions has been performed. Geometries of the tubes have been optimized using the hybrid functional B3LYP, the double-zeta LANL2DZ basis set and the GAUSSIAN 03/09 software. Variations of the cohesive energies, band gaps, bond lengths, and Mulliken charges, among others, with the tube diameters will be presented in detail. The cohesive energies of all tubes, in general, increase as the diameters increase and appear to saturate at about 2.98eV for (11, 11) tubes. However, band gaps indicate an oscillatory pattern, with type 2 tubes, in general, with smaller band gaps. Results will be compared with previous results for SiGe tubes using the cluster approximation.[2]

S1.00102 Gas molecule adsorption on silicene nanoribbons: Conductance modulation and contact effects[1]

TIM OSBORN, AMIR FARAJIAN, Mechanical and Materials Engineering: Wright State University — We investigate the effects of adsorption of gas molecules on the quantum conduction of silicene nanoribbons with and without silver contacts, using ab initio methods and Green's function formalism. The adsorption positions and orientations are determined through energy calculations and structure optimizations for NO_2,CO_2, and CO gas molecules. The conduction change upon gas molecules adsorption is studied for isolated silicene nanoribbons and for silicene nanoribbons on silver side contacts for potential applications as ultrasensitive nanoelectrochemical sensors.

[1]This project is supported by the National Science Foundation grant ECCS-0925939.

S1.00103 A first principles study of the localized electronic states of noble metal atoms doped in Si nanocrystals , CEDRIC L. MAYFIELD, University of Texas at Arlington, M. SAIF ISLAM, University of California-Davis, MOWAFAK M. AL-JASSIM, National Renewable Energy Laboratory, MUHAMMAD N. HUDA, University of Texas at Arlington — The quest for a efficient energy conversion material has necessitated a detail study of semiconductors. Silicon is already playing important roles in many useful nano-applications. To optimize these nano-applications, electronically tailored nano-materials are needed. A number of semiconductor nanomaterials are synthesized using metal as catalysts contributing to various impurities into the nanomaterials. The solubility of a metal in nanomaterials is significantly higher than that in bulk materials. In this presentation, electronic and structural properties of noble metal atoms doping in silicon nano-crystals will be explored using density functional theory. The pristine nanocrystals are based on three different isomers of bulk silicon. We have identified the lower energy isomer and doped it with noble metals. Characterization of the structural changes is accomplished by studying the bonding near the impurity as a function of dopant site. Furthermore, energetic of these nano-structures, both doped and un-doped, such as binding energies, formation energies, and HOMO LUMO gaps will be compared along with their charge densities to identify localizations with respect to impurity site. Magnetism and surface terminations will also be addressed.

S1.00105 Anisotropic Electrical Properties of Nanostructured Metallic Thin Films , MO AHOUJJA, Physics Departrment, University of Dayton, Dayton, OH, PIYUSH SHAH, University of Dayton Research Institute, Dayton, OH, ANDREW SARAGAN, University of Dayton Electro-optics, Dayton, OH, SAID ELHAMRI, Physics Departrment, University of Dayton, Dayton, OH, ELENA GULIANTS, University of Dayton Research Institute, Dayton, OH — High surface area, porous, metallic (Ti, Cr) nanorod thin films with columnar microstructure can be deposited using conventional physical vapor deposition technique of E-beam evaporation. The technique relies on the physical vapor deposition onto a static substrate oriented in a position where flux from the source material (Ti, Cr) arrives at oblique angle. The adatoms provides geometrical shadowing which results in growth of nanorod columns in the direction of vapor source. Deposition conditions such as angle of the incoming vapor flux, substrate temperature, surface diffusion etc. have strong influence on the shape and arrangement of the columnar thin films. In this work, we demonstrate the growth and electrical characterization of these nanostructured thin films. Preliminary results on these films exhibit electrical resistivity anisotropy, when characterized by measuring their electrical resistivity using conventional van der pauw method. Origin and possible causes of this resistivity anisotropy is discussed.

S1.00106 An *Ab Initio* Study of SiC Double-Walled Nanotubes of Types 2 and 3[1] , KAPIL ADHIKARI, ASOK RAY, Department of Physics, University of Texas at Arlington — A hybrid density functional study of armchair SiC double walled nanotubes (DWNTs) of types 2 and 3 is presented. The geometries of individual DWNTs of types 2 and 3 have been spin optimized using the hybrid functional B3LYP (Becke's three-parameter exchange functional and the Lee-Yang-Parr exchange-correlation functional) and the basis set 3-21G* and the GAUSSIAN 09 software. A study of binding energies, Mulliken charge, density of states and HOMO-LUMO gaps has been performed for all nanotubes from (n,n)@(n+3,n+3) to (n,n)@(n+6, n+6) (n=3-6). Type 2 DWNTs do not conserve the coaxial geometry when the difference in chirality of outer and inner tube is 5 or less. For type 3, this occurs when the chirality difference of 4 or less. The gaps of types 2 and 3 DWNTs are less then the corresponding single-walled nanotubes and are significantly less than those of type 1 DWNTs.

[1]This work is supported by the Welch Foundation, Houston, Texas (Grant No. Y-1525).

S1.00107 Effects of NO_2 physisorption and chemisorption on the conduction of graphene nanoribbons[1] , AHMED HASSAN, CORY KNICK , AMIR FARAJIAN, Mechanical and Materials Engineering, Wright State University — Graphene nanoribbons have the potential of being used as the functional part of nanoelectronic gas sensors. This study focuses on the changes induced in the conduction of graphene nanoribbons upon adsorption of NO_2. Both chemisorption and physisorption situations, i.e., NO_2 adsorption with and without chemical bond formation, are studied. We use ab initio electronic structure calculations with MP2 correlation energy in order to optimize the structures of graphene nanoribbons, with hydrogen-terminated edges, in presence of NO_2. Subsequently, quantum conductance calculations are performed using Green's function implementation of the Landauer's approach. We explain different conductance modulation patterns in terms of charge transfer and dipole interactions. The results clarify some of the basic functionality issues of nanoelectronic-based gas sensors.

[1]This project is supported by the National Science Foundation grant ECCS-0925939

S1.00108 An *Ab Initio* Study of Atomic Hydrogen and Oxygen Adsorptions on Armchair Si Nanotubes[1] , HAOLIANG CHEN, ASOK RAY, Physics Department, University of Texas at Arlington, Arlington, Texas 76019 — First principles calculations based on hybrid density functional theory have been used to study the electronic and geometric properties of armchair silicon nanotubes from (3, 3) to (12, 12). Full geometry and spin optimizations have been performed without any symmetry constraints with an all electron 3-21G* basis set and the B3LYP functional. The largest silicon nanotube studied has a cohesive energy of 3.47eV/atom. Atomic hydrogen and oxygen adsorptions on a (6, 6) tube have been studied by optimizing the distances of the adatoms from both inside and outside the tube. The on-top external site is the most preferred site for hydrogen with an adsorption energy of 5.97eV and an optimized distance of 1.50 A. For oxygen, the external bridge site is the most preferred site with an adsorption energy of 11.36eV, the optimized distance being 1.66A.

[1]Work partially supported by the Welch Foundation.

S1.00109 Structural, Electronic and Transport Properties of Gd/Eu Atomic Chains Encapsulated in Single-walled Carbon Nanotubes , JING ZHOU, XIN YAN, GUANGFU LUO, RUI QIN, HONG LI, JING LU, ZHENGXIANG GAO, State Key Laboratory for Mesoscopic Physics and Department of Physics, Peking University, Beijing 100871, P. R. China, WAI NING MEI, Department of Physics, University of Nebraska at Omaha, Omaha, Nebraska 68182-0266 — Structural, electronic, and transport properties of Gd/Eu atomic chains encapsulated in single-walled carbon nanotubes (SWCNTs) are studied by using first-principles density functional theory and nonequilibrium Green's function method. We find that the linear single-atom Gd and Eu chains occupy an off-centered position when encapsulated in the (8,0), (10,0), and (6,6) SWCNTs and considerable electrons are transferred from the Gd and Eu chains to the SWCNTs. The resulting composites are all ferromagnetic metals, with conductivity significantly larger than those of the pristine SWCNTs and the free-standing Gd/Eu linear single-atom atomic chains. The spin polarization of the finite Gd linear single-atom chain at the Fermi level is 67% when encapsulated in the (8,0) SWCNT from the quantum transport calculation.

S1.00110 Anisotropic Conductivities of Magnetic Carbon Nanotubes Embedded in Epoxy Matrices , IL TAE KIM, ALLEN TANNENBAUM, RINA TANNENBAUM, Georgia Institute of Technology — Maghemite (γ-Fe_2O_3)/carbon nanotubes (CNTs) hybrid-materials were synthesized and their anisotropic electrical conductivities resulting from their alignment in a polymer matrix under a magnetic field were investigated. The tethering of γ-Fe_2O_3 nanoparticles on the surface of CNT was achieved by a modified sol-gel reaction. These hybrid-materials, specifically, magnetized carbon nanotubes (m-CNTs) were readily aligned parallel to the direction of a magnetic field even when using a relatively weak magnetic field. The conductivity of the epoxy composites formed in this manner increased with increasing m-CNT mass fraction in the polymer matrix. Furthermore, the conductivities parallel to the direction of magnetic field were higher than those in the perpendicular direction, indicating that the alignment of the m-CNT contributed to the enhancement of the anisotropic electrical properties of the composites in the direction of alignment.

S1.00111 Double Layer Charging for Conductivity Enhancement of Pure Metallic and Semiconducting Single Wall Carbon Nanotubes[1]

, NATHANAEL MAYO, ALEXANDER KUZNETSOV, ANVAR ZAKHIDOV, Nanotech Institute - University of Texas at Dallas — Injecting high electronic charge densities can profoundly change the optical, electrical, and magnetic properties of materials. Evidence suggests a possibility of significantly improving conductivity of carbon nanotubes through double layer charge injection. Double layer charge injection can prove to be a powerful method when applied to carbon nanotubes because of theirs high surface area and chemical stability. Investigation has commenced on the effect of charging on various types of carbon nanotubes, specifically 99% purified single wall semiconducting and single wall metallic tubes. An electrical double layer is electrochemically introduced upon a sheet of carbon nanotubes via application of potential (up to $\pm$5 volts) to a sample immersed in ionic-liquid-based electrolyte. Resistance of carbon nanotube as a function of applied charging voltage is recorded to determine the effects of charge injection. Results show that the electrical double layer considerably reduces the resistance across both samples. ESR/LFMA studies combined with low temperature magnetic and transport measurements are conducted to search for charge injection induced superconductivity in carbon nanotubes.

[1]Supported by AFOSR grant FA 9550-09-1-0384

S1.00112 Synthesis, micro and electronic structure investigation of diamond nanorod spherules by High resolution NEXAFS coupled PEEM and field emission performance[1]

, SWATHI IYER, PAUL MAGUIRE, NIBEC, University of Ulster — We report the synthesis of Diamond nanorods/flake Spherules (DNRS) predominantly consisting of UNCD enveloped by graphite in the form of flake or a rod with nanodimension, projecting randomly outward in all directions. The diamond nanoflake with a diameter of $\sim$2 nm has a central diamond (111) core encapsulated by graphitic (0002) lacing. The structure composition by High Resolution Transmission Electron Microscopy (HRTEM) and X ray Photoemission Electron Microscopy (XPEEM) revealed that the nanoflakes predominant with core sp^3 laced with sp^2, is embedded in carbon matrix consisting of other nanocarbon, such as the nanotubes, nanoonion and nanowires/sheets. High resolution localized XPEEM combined with XAS complimented the Raman and the XPS with a weak π* peak, a prominent exitonic and a second band dip, which are the signature of diamond. The congregated nanorod spherules exhibits a low-threshold, high current-density of 10 mA/cm^2 at 2.9 V/m which appears to be exceptional when compared to many other electron emitting nanostructures. Bias enhanced DNRS were also characterized by XPEEM and their FE's compared.

[1]VCRS Scholarship

S1.00113 Heat transfer through a dual-walled carbon nanotube[1]

, KHOA BUI, The University of Oklahoma, CEDRIC COUSIN, Blaise Pascal University, Clemont-Ferrand, HUONG NGUYEN, The University of Oklahomoa, ALBERTO STRIOLO, DIMITRIOS PAPAVASSILIOU, The University of Oklahoma — Molecular Dynamics simulations are used to investigate the resistance to heat tranfer between the walls of dual-walled carbon nanotubes (DWCNTs). Recent computional results have indicated that the carbon nanotube to carbon nanotube thermal boundary resistance (TBR) can be as high or higher than the TBR between a nanotube and the surrounding matrix (e.g., epoxy or octane) in thee case of composites. This generates the question of whether heat transfer in multi-walled carbon nanotubes occures through the outer nanotube only or not. We discuss here results for a DWCNT composed of a (5,5) nanotube inside a (10,10) nanotube, as well as the differences between this case and the case of a (6,6) inside a (19,0).

S1.00114 Aspect Ratio Dependant Buckling Mode Transition in Single-Walled Carbon Nanotubes under Compression[1]

, CHUN TANG, JEREMY FELICIANO, CHANGFENG CHEN, Department of Physics and Astronomy and High Pressure Science and Engineering Center, University of Nevada, Las Vegas, NV 89154 — We have conducted molecular dynamics simulations on compressing behaviors of single-walled carbon nanotubes (SWCNTs) with a large variaty of aspect ratios. It is found that SWCNTs with large aspect ratios experience column buckling behavior at low strain levels, in contrast to commonly observed shell buckling of short SWCNTs. Further compression leads to a transition to a shell buckling mode, which is distinct from those of short SWCNTs under compression. It originates from the column buckling induced bending loadings. We extract the scaling law with respect to the aspect ratio of SWCNTs based on an analytical model of bending buckling.

S1.00115 Intershell Interaction in a Double Wall Carbon Nanotube with Determined Chiral Indices under a Torsional Strain

, LETIAN LIN, Curriculum in Applied Sciences and Engineering, University of North Carolina at Chapel Hill, TAORAN CUI, SEAN WASHBURN, LU-CHANG QIN, Department of Physics and Astronomy, University of North Carolina at Chapel Hill — We have used a double wall carbon nanotube to build a torsional pendulum. The nanotube worked as a torsional bearing for a metal block. An external electric field was used to rotate the metal block to cause a fully elastic torsional deformation on the nanotube. Nano-beam electron diffraction patterns were taken before and while the nanotube was twisted. By analysis of the shift of the diffraction patterns, we were able to determine the nanotube chiral indices and measure the inner-shell torisonal responses to the torsional stress applied on the outer-shell. The inter-shell interactions and nanotube shear modulus were also calculated and discussed in connection to the theoretical estimations.

S1.00116 Large Band Gap in Graphene Induced by Inhomogeneous Mechanical Deformation

, IVAN NAUMOV, ALEXANDER BRATKOVSKY, Hewlett-Packard Laboratories, HEWLETT-PACKARD LABORATORIES COLLABORATION — Graphene is a prospective material for future electronics. However, in order to become useful and work in electronic chips, graphene should have a semiconducting energy gap. The seemingly simplest way to induce a gap is to subject the graphene to a strain. Recently, it was predicted within tight-binding approximation that by combining shear deformations and uniaxial strains one can open the gap up at moderate strains ($\sim$12%), well before the elastic limit of the material is reached. Here, we show with the help of ab-initio calculations that, in fact, the gap *cannot* be opened up by any kind of homogeneous deformations smaller that the graphene failure strain. The gap, however, can be opened up by *inhomogeneous* deformation, e.g. by the periodic out-of-plane atomic displacements with an "amplitude-to-wavelength" ratio on the order of 0.1, similar to Ref. [2], which translates roughly to only 10% elongation. The gap can be quickly pushed to values up to 1 eV by further increase of strain still far enough from the point of mechanical failure.

S1.00117 BIOLOGICAL PHYSICS —

S1.00118 Substrate Recognition of Histone H2B by DUBm , ELIZABETH HENDERSON, Hunter College, CHRISTOPHER BERNDSEN, CYNTHIA WOLBERGER, The Johns Hopkins University School of Medicine — The SAGA complex is a transcriptional coactivator that regulates gene expression in eukaryotes via histone acetylation and deubiquitination, which are crucial for transcription. Our lab is investigating the SAGA-dependent deubiquitination of histone H2B. The deubiquitinating module (DUBm) of SAGA is comprised of a ubiquitin-specific protease, Ubp8, and three other proteins. It is known that Ubp8 cleaves ubiquitin from histone H2B, however, the specific way in which the enzyme binds to the substrate remains elusive. In order to unravel this mechanism, we attempted to determine the crystal structure of the substrate binding complex. We obtained this substrate by exploiting the techniques of intein chemistry to artificially ubiquitinate a histone H2B peptide, which we then co-crystallized with DUBm. Additionally, we synthesized Ub-K63R-linked chains and Ub-K48-linked chains and co-crystallized them with DUBm.

S1.00119 pH Dependent Photoinduced Effects of Protoporphyrin IX to Human Serum Albumin , SARAH ROZINEK, JORGE PALOS-CHAVEZ, LORENZO BRANCALEON, University of Texas at San Antonio — Irradiation of the non-covalent complex between protoporphyrin IX (PPIX) and β-lactoglobulin (Blg), causes a modest unfolding of the protein localized to Trp19. That binding site is affected by pH of the solution. At physiological pH, PPIX is known to bind HSA in hydrophobic binding sites. However, no evidence is presented for the binding behavior of PPIX to HSA in non-physological pH confirmations, nor on the effects of irradiation on the bound system at any pH. The combination of spectroscopic data and molecular simulations suggests that distinct PPIX-compatible binding sites become available at each confirmation of HSA at pH 7.4, and 9 while the pH 3 conformation is unfavorable for binding. Photoinduced mechanisms produce changes in the ligand as well as the protein but they do not appear to be dependent on the presence of O_2 in solution. Therefore, the mechanism is not mediated by the formation of singlet oxygen and is likely the result of electron transfer between the porphyrin and amino acid residues.

S1.00120 Docking ellipticine to the V-VI transmembrane domain of the Kv11.1 potassium channel , DAWN LIPSCOMB, LORENZO BRANCALEON, Department of Physics and Astronomy, University of Texas at San Antonio, S. GENTILE, Department of Molecular Pharmacology and Therapeutics, Loyola University — Ellipticines such as 9-methoxy-N-2-methylellipticinium acetate (MMEA) and 9-hydroxy-N-2-methylellipticinium acetate (NMEA, Celiptium®) are antineoplastic drugs exerting their selective cytotoxicity against leukemia and endometrial carcinoma. Ellipticine's action is also related to severe physical side effects, but the link between undesired effects and pharmacological application is not well understood. We investigated the binding of Ellipticine derivatives with the Kv11.1 potassium ion channel using Autodock and revealed that hydroxyellipticinium derivatives provide binding configurations with Kv11.1, but the energy, location and estimated dissociation constant varied. The binding energy is as follows: Chloroceliptium (-6.60 kcal/mol) > Celiptium (- 6.37 kcal/mol) > Methoxyceliptium (- 6.20 kcal/mol) > Datelliptium (-6.08 kcal/mol). The data shows that some configurations enable these molecules to bridge among channel subunits, thus potentially inhibiting the flow of ions.

S1.00121 Effects of the range and strength of interparticle attraction on gelation , TONI PEREZ, JAMES GUNTON, Lehigh University, AMIT CHAKRABARTI, Kansas State University — Range and strength of interparticle attraction determine whether a complex assembly of particles will be ordered or disordered. For very short range interactions, the system seems to get trapped into a gel state as a result of arrested spinodal decomposition. On the other limit, for long range interactions, spinodal decomposition leads to phase separation. The nature of the gel transition at low volume fraction is still not well understood in between these two limits. Here, we study the dynamics of the gel transition at low volume fraction as a function of the range and strength of the attractive interparticle interaction. We perform Brownian dynamics simulations and study how gelation is affected as the range and strength of interparticle interaction are varied.

S1.00122 Explore the physical mechanism of Hofmeister series on protein structural dynamics , SANDIP KALEDHONKAR, LORAND KELEMEN, AIHUA XIE, Department of Physics, Oklahoma State University, Stillwater, OK 74078, XIE LAB TEAM — Hofmeister series, a classification of ions, are known to change the solubility and stability of proteins. We have found that Hofmeister series suppress functionally important structural dynamics of photoactive yellow protein (PYP). Here we investigate two possible mechanisms: (1) Hofmeister series increases the pK_a of Glu46, an active site proton donor to chromophore protonation of PYP, (2) Hofmeister series alter the energy landscape of surface exposed groups due to effective dehydration, making it difficult to change protein conformations. We will test these two hypotheses using strategic combination of protein engineering and time-resolved step-scan and rapid-scan FTIR difference spectroscopy. A variety of N-terminus tags are designed and employed to study the effect of effective dehydration of protein due to Hofmeister series. Time-resolved infrared structural biology will be used to capture light-triggered structural dynamic motions of PYP.

S1.00123 Time-resolved infrared structural biology: from active-site structural dynamics to proton transfer mechanism of photoactive yellow protein , SHUO DAI, LORAND KELEMEN, ZHOUYANG KANG, WOUTER HOFF, AIHUA XIE, Oklahoma State University, Stillwater, OK 74078 — Proton transfer is a fundamental process in biology. We employ photoactive yellow protein (PYP), a bacterial blue light receptor protein, as an ideal model system to study the physical mechanism of intra-molecular proton transfer in proteins. We employ time-resolved step-scan FTIR spectroscopy to detect functionally important structural changes in the active site of PYP before and after proton transfer from Glu46 to the negatively charged phenolic group of the p-coumaric acid chromophore in PYP, which occurs on a 250 microsecond time scale. In addition, we employ a combination of isotope editing and site-specific mutations to identify the vibrational modes and structural origins of infrared signals, and we develop and utilize vibrational structural markers to translate infrared signals to structural information. We will demonstrate the power of time-resolved infrared structural biology in structure-function studies of proteins and in proton transfer mechanism in photoactive yellow protein.

S1.00124 Exploring the effects of Hofmeister series ions on structural dynamics of water , NINGNING XU, THOMAS WRIGHT, SANDIP KALEDHONKAR, AIHUA XIE, Department of Physics, Oklahoma State University — Water is known as the lubricant of life. Most proteins lose their biological function upon dehydration. We found that in a variety of high concentration salt solutions, photoactive yellow protein, a blue light bacterial photoreceptor protein, loses its functionally important structural motions for receptor activation. We hypothesize that this effect is caused by reduced structural dynamics of water due to strong water-ion interactions. Here we report our experimental studies on the effects of salts on changes in structural dynamics of water at different time scales. The results are expected to provide deep insight regarding how Hofmeister series ions alter the structural dynamics of proteins.

S1.00125 Molecular Dynamics Simulations of Alpha-synuclein , MARIA SAMMALKORPI, CARL SCHRECK, ABHINAV NATH, DAVID DEWITT, ELIZABETH RHOADES, COREY O'HERN, Departments of Chemical Engineering, Physics, Mechanical Engineering and Materials Science, and Molecular Biophysics and Biochemistry, Yale University — We investigate the conformational dynamics of single alpha-synuclein proteins, which have been implicated in amyloid diseases such as Parkinson's and Alzheimer's disease, in solution using unconstrained and constrained all-atom, explicit solvent molecular dynamics simulations. The constraints on inter-residue separations are obtained from our single-molecule FRET measurements of eleven FRET pairs that span the protein. By comparing the simulation data satisfying different combinations of FRET constraints, we are able to identify those constraints that are most important in determining the radius of gyration and key features of the contact map of the protein.

S1.00126 InaD PDZs 4-5 Act as an Allosterically-Regulated Dynamic Scaffold , STEPHEN HELMS, UT Southwestern, PRASHANT MISHRA, Caltech, MICHAEL SOCOLICH, RAMA RANGANATHAN, UT Southwestern — The Drosophila scaffolding protein InaD is required for proper visual signaling. We previously identified that the fifth PDZ domain of InaD undergoes light-dependent PKC-mediated formation of a disulfide bond which disrupts the binding site. We investigated the interaction of this switch with the adjacent PDZ4 of InaD. We showed that PDZ4 destabilizes the disulfide bond and promotes binding of PDZ5 to its ligand, indicating a previously unidentified allosteric interaction between the two domains. We solved the structure of PDZ45 to 2.4Å, which revealed that PDZ4 forms an extensive interface with PDZ5 but does not alter its conformation. NMR HSQC spectra, however, indicated that nearly all of PDZ5 is in a different chemical environment in PDZ45. Finally, we identified that PDZ45 is phosphorylated by PKC in vitro at a site located near the domain interface. Intriguingly, the disulfide bond in PDZ5 is an evolutionary adaptation of just fast-flying flies, revealing the remarkable ability of evolution to rapidly build novel regulatory features into scaffolding proteins.

S1.00127 Tracking the Growth Transitions of A Solvent-Charged Model Globular Protein , JEREMIAH BABCOCK, JACOB FRIDAY, LORENZO BRANCALEON, University of Texas at San Antonio — Biophysical studies have shown that solutes like proteins undergo aggregation through specific pathways that often lead to long polymeric structures called fibrils. The knowledge of the size of early-stage protein aggregates (oligomers) has an important bearing on the elucidation of the dynamics of the process of protein unit combinations. In this study, bovine serum albumin, a well-characterized model protein known to polymerize in alkaline and acidic conditions in the normal (N) to basic (B) or (N) to (E) transition, was incubated at pH 9.0 and pH 3.1 for longer than eight days. Particle growth in solution was monitored by absorption, fluorescence and circular dichroism spectroscopy and concurrently measured by atomic force microscopy (AFM) methods to yield BSA oligomer size distributions. Results show that the BSA aggregation pathway is concentration-dependent and rapidly forms spherical aggregates, which preferentially come together to form flexible polymers.

S1.00128 Low frequency Raman study of the nucleosides , CRAIG KOONTZ, SCOTT LEE, University of Toledo — In both transcription and replication, the two helices of the DNA molecule move apart. Consequently, vibrations involving the relative motions of large portions of the molecule with respect to one another are of intrinsic interest. Such vibrations have relatively low frequencies because they involve weak bonds and large masses. Low frequency modes are difficult to observe in Raman spectroscopy because they are very close to the signal from the Rayleigh scattered light (which is very intense). In this poster, we will describe our results for the eight nucleosides: adenosine, deoxyadenosine, guanosine, deoxyguanosine, cytidine, deoxycytidine, uracil and deoxythymidine.

S1.00129 A temperature-dependent study of the low-frequency vibrational excitations in polynucleotides in solution , KRISTINA WOODS, Carnegie Mellon University, SCOTT LEE, Un. of Toledo — Far-infrared spectroscopy is a useful probe of low-frequency collective excitations of biomolecules, including DNA. These vibrational modes are believed to be related to conformational changes that occur in these molecules during their biological function and, therefore, are very important to study. In order to further our understanding of these modes, THz spectroscopy experiments were performed on solutions of polynucleotides between 20 to 100 cm^{-1} from room temperature to 90 $^{\circ}$C, covering the premelting and melting regimes. The samples studied include Poly(dA-dT), Poly(dA)-Poly(dT), Poly(dI-dC) and Poly(dI)-Poly(dC). Of particular interest, the intensity of a band at about 67 cm^{-1} is observed to increase as the melting proceeds.

S1.00130 Modification of DNA towards high conductance and transport measurements with mechanically controllable break junction electrodes , SHOUPENG LIU, Department of Physics, University of Konstanz, Germany, BENJAMIN BORNEMANN, SAMUEL WEISBROD, ZHUO TANG, ANDREAS MARX, Department of Chemistry, University of Konstanz, Germany, ARTUR ERBE, ELKE SCHEER, Department of Physics, University of Konstanz, Germany, DEPARTMENT OF PHYSICS, UNIVERSITY OF KONSTANZ, GERMANY TEAM, DEPARTMENT OF CHEMISTRY, UNIVERSITY OF KONSTANZ, GERMANY TEAM — The DNA molecule is proposed to be used as building block for molecular electronic devices by virtue of its unique recognition and self-assembling properties. However, electron transport properties of DNA are still not well established mainly because poor binding between DNA and gold electrodes. Here, we synthesized new DNA samples with terminal bases modified with a thiol group on its C5 atom and protected with Me3Si for better binding with gold electrodes and better conductivity because of better electron overlap. Its transport properties were measured with mechanically controlled break junction. Conductance with a current of 700 nA in 0.25V were obtained, which is higher than most of the former reports. We also measured conductance through DNA G-quadruple instead of double-stranded structure., which shows a more stable conductance when the distance between electrodes reversibly varied over a several nm.

S1.00131 QM/MM/3D-RISM study of solvation and electronic structure of DNA , NORIO YOSHIDA, FUMIO HIRATA, Institute for Molecular Science — It is well known that a DNA has high electronic conductivity in wet condition, while it doesn't in dry condition. Therefore, the solvent effects on the electronic properties of DNA got much attention in the field of biology, chemistry and physics. In the present study, we employ three-dimensional reference interaction site model method combined with quantum mechanics and molecular mechanics (QM/MM) method to treat the large DNA chain in solvent. By this theory, the electronic structure of DNA and solvent distribution around DNA can be determined simultaneously. The result shows the dramatic change of electronic structure of solute DNA molecule by solvation. The change strongly depends on the sequence of DNA.

S1.00132 The driving forces of membrane remodeling by non-intrinsically curved proteins , CHRISTOPHER J. RYAN, University of California, Berkeley, JEANNE C. STACHOWIAK, Sandia National Laboratories, EVA M. SCHMID, DANIEL A. FLETCHER, PHILLIP L. GEISSLER, University of California, Berkeley — Membranes are dynamically remodeled during numerous processes essential to cells. Among the most well-studied effectors of this remodeling are BAR family proteins, which are small and have a banana-like intrinsic curvature that senses, forms, and stabilizes curved membranes without expending energy as ATP or GTP. Recent experiments in reduced systems have shown, however, that small proteins that feature no such intrinsic curvature can similarly cluster at and dramatically remodel membranes. These proteins have no distinguishing features other than their size and their membrane-binding sites, and the dominant effect that is driving curvature is not well understood. Here, we present a coarse-grained simulation study that captures protein steric and binding effects as well as membrane fluctuations at large scales. We use this model to systematically test for the role that such attributes play in the resulting dynamics and equilibrium structures of remodeling processes that feature this motif.

S1.00133 Analysis of Striped Nanoparticle Complexation with Lipid Bilayers , REID VAN LEHN, ALFREDO ALEXANDER-KATZ, MIT — A recent study has shown that a new class of synthetic ligand-protected gold nanoparticles is able to penetrate the cell membrane without inducing poration or endocytosis. Furthermore, these nanoparticles fuse with pure lipid bilayers while retaining high solubility in biological conditions. This complexation behavior is related to the morphology of the ligand shell, which is composed of alternating ribbon-like domains of linear alkanes with either hydrophobic or charged end-groups. Spontaneous complexation is surprising given the large free energy barrier for moving charges through the hydrophobic bilayer core. In this work, we provide a thermodynamic analysis of bilayer complexation supported by multiscale simulations. We show that the key to bilayer complexation is the rearrangement of ligands by bending to maximize hydrophobic matching and minimize charge exposure. We believe this result will improve our understanding of transmembrane proteins and enable the design of nanoparticles for drug delivery and biosensing applications.

S1.00134 The Comparison of Lipid Compositional Uniformity of Giant Unilamellar Vesicles Synthesized From the Rapid Solvent Exchange liposomes with That From Dry Lipid Film , EDA BAYKAL-CAGLAR, JUYANG HUANG, Texas Tech University — Lipid bilayer, which is an important constituent of cell membranes, has been extensively studied. Cell membranes perform many vital cell functions such as signal transduction and transportation of materials needed for the functioning of the cell organelles. Understanding the dynamics of lipid bilayers is important for understanding the processes taking place in cell membranes. Giant Unilamellar Vesicles (GUVs) are cell-sized model systems that allow direct visualization of membrane-related phenomena using fluorescence microscopy. In this study, we synthesized DOPC/DSPC/cholesterol GUVs and diPhyPC/DPPC/cholesterol GUVs by the standard electroformation method using dry lipid film as well as by a modified method using liposomes made from Rapid Solvent Exchange (RSE) method. Second method has a potential of incorporating more varieties of membrane proteins to GUVs. We compare the uniformity of lipid composition of GUVs synthesized by the two methods by measuring the variation of phase transition temperature of individual GUVs through fluorescence microscopy; since a narrower distribution of transition temperature should correspond to a more uniform distribution in GUV lipid composition. We will present the results at several bulk lipid compositions and buffer ionic strengths.

S1.00135 Machanistic basis of rigidity sensing at biological interfaces , ALIREZA SARVESTANI, University of Maine — We have outlined a framework to investigate the thermodynamic equilibrium adhesion of a bio-membrane to a compliant substrate functionalized with immobilized bio-adhesive ligands. The membrane is modeled as a soft elastic shell, subjected to surface tension and reconstituted with mobile receptors and a repelling layer on the ventral side. The free energy function of the system is assumed to be comprised from the following contributions: the membrane–substrate non-specific interactions, stored elastic energy (in deformed membrane and substrate), binding enthalpy, and mixing entropy of mobile receptors. Assuming a van der Waals form for the interfacial non-specific potential, the equilibrium configuration of the system is studied in detail. We have shown that the equilibrium spread area of the adherent membrane is very sensitive to the rigidity of the underlying substrate and decreases as the surface compliance increases. This prediction is reminiscent of the experimental observations of spread area of cells attached to soft substrates. This is an interesting result considering the lack of contribution of intracellular signaling or actively regulated cytoskeleton in the proposed physical model for the adhesion. This suggests that the mechanistic pathways inherent to membrane–substrate thermodynamic interactions can be equally important as intracellular signaling pathways to mediate the process of rigidity sensing by cells.

S1.00136 Curved inclusions surf membrane waves , ROIE SHLOMOVITZ, UCLA Department of Chemistry, NIR GOV, Weizmann Institute of Science Dept. of Chemical Physics — There is mounting recent evidence for the existence and biological importance of a large family of curved membrane proteins (CMPs). In addition there is increasing interest in membrane waves, and the role they play in cell function. In this theoretical work, we examine the interaction between CMPs and membrane waves. We find that CMPs are advected on the cell surface by membrane waves. We calculate the relative drift velocity of the CMPs with respect to the wave velocity, for the case of sinusoidal waves. For relatively slow waves the CMPs move at the wave velocity, i.e. "surfing the wave." For fast waves the CMPs move back and forth with a Stokes drift that is inversely proportional to the quadrant of the wave velocity. For the more realistic case of decaying sinusoidal waves, we determine the equilibrium distribution of the CMPs, and find that such waves create a "hole" in the distribution of the CMPs on the cell membrane and calculate the size of that hole. Based on these calculations, we show how such proteins can be used in experiments to measure the properties of propagating membrane waves.

S1.00137 Chemotaxis and Autotaxis in Biofilm-Forming Systems , SHINJI STRAIN, SAMUEL BIENVENU, TRAVIS THATCHER, BENJAMIN COOLEY, VERNITA GORDON, University of Texas at Austin — Biofilms are multicellular, surface-bound communities of interacting unicellular organisms. In the initial stages of biofilm formation, discrete cells populate the surface and eventually form microcolonies (dense surface-bound clusters of cells). How much these microcolonies arise from clonal growth and how much they arise from attraction and active motility of non-clonal cells is not well-understood. One potentially important form of attraction is autotaxis, movement of cells toward like cells. Another is chemotaxis, movement of cells toward an attractive chemical, which could act to concentrate cells with no direct intercellular interaction. While both autotaxis and chemotaxis have been studied for three-dimensional, swimming, dense bacterial systems, they remain largely unstudied in sparse, surface-bound populations that initiate biofilms. Using microscopy and automated tracking and analysis algorithms, we will study how bacteria respond to each other and to chemoattractants, in a spatially-dependent manner. We will determine how variations in neighbor density and arrangement stimulate changes in the motility of E. coli and P. aeruginosa cells on a surface.

S1.00138 3D single molecule super-resolution imaging of cellular samples using MUM , ANDREA GROSSO, ANISH ABRAHAM, Department of Electrical Engineering, UT Dallas, JEFFREY KANG, JERRY CHAO, RAMRAJ VELMURUGAN, SRIPAD RAM, STEPHEN ANTHONY, ZHUO GAN, E. SALLY WARD, Dept. of Immunology, UT Southwestern Medical Center, Dallas, TX, RAIMUND J. OBER, Department of Electrical Engineering, UT Dallas — Localization based super-resolution imaging techniques (e.g., PALM, fPALM, STORM, etc.) represent a powerful tool to image single molecules at nanoscale resolution in two dimensions. However, the extension of these techniques to three dimensions poses several technical challenges, foremost being the poor depth discrimination inherent to conventional microscopes which is typically used by these techniques. Previously, we developed an imaging modality, multifocal plane microscopy (MUM), which overcomes the poor depth discrimination capability of conventional microscopes. We also introduced a 3D localization algorithm MUMLA and demonstrated experimentally that it provides the best possible accuracy with which the 3D position of single molecules can be determined. Here, we extend the application of MUM and MUMLA for super-resolution imaging and demonstrate 3D imaging of single molecules at nanometer scale resolution in a cellular sample.

S1.00139 Accuracy of single molecule localization using electron-multiplying charge-coupled device cameras , JERRY CHAO, Department of Electrical Engineering, University of Texas at Dallas, Richardson, Texas, E. SALLY WARD, Department of Immunology, University of Texas Southwestern Medical Center, Dallas, Texas, RAIMUND J. OBER, Department of Electrical Engineering, University of Texas at Dallas, Richardson, Texas — The electron-multiplying charge-coupled device (EMCCD) is an important technology for imaging under extremely low light conditions. Whereas a weak signal acquired under low light conditions can be overwhelmed by the readout noise of a conventional charge-coupled device (CCD), it is amplified in the case of an EMCCD such that the readout noise becomes insignificant. The EMCCD is therefore a commonly used image detector in applications such as single molecule microscopy. However, despite its wide use, there has been a lack of rigorous analyses to determine how accurately parameters of interest (e.g., location of a single molecule) can be estimated from an image it produces. Here, we model the EMCCD's stochastic multiplication of electrons as a geometrically multiplied branching process, and develop the theory for calculating the Fisher information for estimating parameters from an EMCCD image. A "noise coefficient" is also introduced which enables the comparison of a CCD and an EMCCD in terms of the best accuracy with which parameters can be estimated from the images they produce.

S1.00140 Simultaneous AFM force spectroscopy and FRET measurements on single biological molecules , HUI LI, CHI-FU YAN, SANJEEVI SIVASANKAR, Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011, DEPARTMENT OF PHYSICS AND ASTRONOMY, IOWA STATE UNIVERSITY, AMES, IOWA 50011 TEAM — Single Molecule Fluorescence Resonance Energy Transfer (FRET) and single molecule force measurements with the Atomic Force Microscope (AFM) are two powerful techniques that have facilitated much progress in the biological sciences. However each of these techniques suffers from limitations that can be overcome by the use of a combined single molecule AFM-FRET approach. Here, we describe an instrument that successfully combines single molecule AFM with FRET to apply forces on individual biological molecules and simultaneously monitor their conformational dynamics. To validate this technique, we measured the force induced shearing of dye-labeled, double stranded DNA. Single DNA molecules were sheared and mechanical transitions corresponding to DNA rupture were correlated with changes in FRET.

S1.00141 The Heterogeneity of Mutational Tolerance in a Protein is Dependent on the Strength of Selective Pressure Correlating with Sectors of Co-evolving Residues , MICHAEL STIFFLER, RAMA RANGANATHAN, UT Southwestern Medical Center — Proteins are capable of tolerating mutations at many positions while still maintaining fold and function. Previous studies have failed to consider how tolerance to random mutagenesis might depend on the strength of selective pressure. To examine this, we measured the fitness of every single point mutation of TEM-1 beta-lactamase across a range of ampicillin concentrations utilizing a novel application of deep-sequencing. We found that the relative mutational robustness between positions varied considerably with respect to ampicillin concentration: at a low ampicillin concentration only a few positions are intolerant of mutations, while at a higher ampicillin concentration many additional positions are as equally intolerant of mutations. Using an analytic method termed statistical coupling analysis (SCA) to measure the co-variation between all positions in a sequence alignment of beta-lactamases revealed sectors of co-evolving positions associated with groups of residues having increased sensitivity to mutagenesis at either low or high ampicillin concentrations. Our findings suggest that nature has "designed" proteins to be robust to random mutagenesis by loading the constraints for fitness on discrete networks of co-evolving positions depending on the strength of selective pressure.

S1.00142 The Evolutionary Design of Proteins , FRANK J. POELWIJK, Green Center for Systems Biology, UT Southwestern Medical Center, Dallas. Laboratory of Living Matter, Rockefeller University, New York, ARJUN S. RAMAN, Green Center for Systems Biology, UT Southwestern Medical Center, Dallas, STANISLAS LEIBLER, Laboratory of Living Matter, Rockefeller University, New York, RAMA RANGANATHAN, Green Center for Systems Biology, UT Southwestern Medical Center, Dallas — Proteins fold spontaneously into precise, well-packed 3D structures, and execute complex functions such as specificity in molecular recognition, and efficient catalysis. Despite this, many studies show that proteins are robust to random mutagenesis. Additionally, proteins are evolvable. What principles underlying the design of natural proteins explain these properties? Recent work examining correlated evolution of amino acid positions shows that many positions in proteins are nearly statistically independent while 10-20% are organized into groups of co-evolving positions – termed "protein sectors" – that underlie conserved, independently varying biological activities. These findings suggest that the basic design of natural proteins is fundamentally tied to the nature of fluctuations in the selection pressures during evolution. We propose to test this hypothesis using a system for high-speed laboratory evolution and determine how variation in selection pressures influences the architecture of amino acid interactions within a protein.

S1.00143 Laser-Neuron Interaction with Femtosecond Beat-Modulated 800-1200 nm Photon Beams, as the Treatment of Brain Cancer Tissue. Laser Neurophysics[1] , V. ALEXANDER STEFAN, Stefan University — I propose a novel mechanism for the brain cancer tissue treatment: nonlinear interaction of ultrashort pulses of beat-photon, $(\omega_1 - \omega_2)$, or double-photon, $(\omega_1 + \omega_2)$, [2] beams with the cancer tissue. The multiphoton scattering is described via photon diffusion equation. The open-scull cerebral tissue can be irradiated with the beat-modulated photon pulses with the laser irradiances in the range of a few mW/cm^2, and repetition rate of a few 100s Hz generated in the beat-wave driven free electron laser.[3] This highly accurate cancer tissue ablation removal may prove to be an efficient method for the treatment of brain cancer.

S1.00144 The effect of Ag nanoparticles on PC3 cells ultraweak bioluminescence , MARIUS HOSSU, XIAOJU ZOU, Univ Texas at Arlington, LUN MA, WEI CHEN, Univ Texas at Arlington — Ultraweak intrinsic bioluminescence of cancer cell is a noninvasive method of assessing bioenergetic status of the investigated cells. This weak emission generated by PC3 cell line was measured during various stages of growth with or without the presence of Ag nanoparticles. The comparison between nanoparticles concentration, bioluminescence and cell survival showed that even though Ag nanoparticles doesn't significantly affect cell survival at used concentration it affects cell metabolism, possibly making them more susceptible to other form of therapies.

S1.00145 Steinberg "AUDIOMAPS" Music Appreciation-Via-Understanding: Special-Relativity + Expectations "Quantum-Theory": a Quantum-ACOUSTO/MUSICO-Dynamics (QA/MD) , LEE FENDER, RUSSELL STEINBERG, FUZZYICS=CATEGORYICS(SON OF TRIZ)/CATEGORY-SEMANTICS, EDWARD CARL-LUDWIG SIEGEL, FUZZYICS=CATEGORYICS(SON OF TRIZ) — Steinberg wildly popular "AUDIOMAPS" music enjoyment/appreciation-via-understanding methodology, versus art, music-dynamics evolves, telling a story in (3+1)-dimensions: trails, frames, timbres, + dynamics amplitude vs. music-score time-series (formal-inverse power-spectrum) surprisingly closely parallels (3+1)-dimensional Einstein(1905) special-relativity "+" (with its enjoyment-expectations) a manifestation of quantum-theory expectation-values, together a music quantum-ACOUSTO/MUSICO-dynamics(QA/MD). Analysis via Derrida deconstruction enabled Siegel-Baez "Category-Semantics" "FUZZYICS"="CATEGORYICS ('TRIZ") Aristotle SoO DEduction , irrespective of Boon-Klimontovich vs. Voss-Clark[PRL(77)] music power-spectrum analysis sampling-time/duration controversy: part versus whole, shows QA/MD reigns supreme as THE music appreciation-via-analysis tool for the listener in musicology!!! Connection to Deutsch-Hartmann-Levitin[This is Your Brain on Music, (06)] brain/mind-barrier brain/mind-music connection is subtle/compelling/immediate!!!

S1.00146 CuS Nanoparticles for Photothermal Ablation of Tumor Cells , WEI CHEN, Department of Physics, University of Texas at Arlington, Arlington, TX 760190059, YUEBIN LI, Department of Physics, University of Texas at Arlington, TX, CHUN LI, WEI LU, QIAN HUANG, MIAO HUANG, The University of Texas M. D. Anderson Cancer Center, Houston, Texas 77030, UNIVERSITY OF TEXAS AT ARLINGTON, ARLINGTON, TX 76019-0059 TEAM, THE UNIVERSITY OF TEXAS M. D. ANDERSON CANCER CENTER, HOUSTON, TEXAS 77030 TEAM — Here, we report the photothermal ablation effects of 3-nm CuS nanoparticles. CuS nanoparticles exhibited strong absorption in the near infrared (NIR) region. Irradiation by a laser beam at 808 nm elevated the temperature of aqueous solutions of CuS nanoparticles as a function of exposure time and nanoparticle concentration. CuS nanoparticles mediated photothermal destruction of HeLa cells in a laser dose- and nanoparticle concentration-dependent manner, and displayed minimal cytotoxic effects with a profile similar to that of gold nanoparticles. Owing to their unique optical property, small size, low cost of production, and low cytotoxicity, CuS nanoparticles are promising new nanomaterials for cancer photothermal ablation therapy.

S1.00147 Characterization of Blood Flow in Capillaries by Numerical Simulation , TONG WANG, Department of Mathematics, Nanjing University of Aeronautics and Astronautics, Nanjing, Jiangsu, 210016, China, ZHONGWEN XING, Department of Materials Science and Engineering, Nanjing University, Nanjing, Jiangsu, 210093, China — We presents a numerical investigation of the axisymmetric, pressure driven motion of single file erythrocyte (i.e., red blood cell) suspensions flowing in capillaries of diameter 8-11μm. The governing Navier-Stokes equations are discretized using the operator splitting technique and solved by the finite element method. The study takes consideration the particulate nature of the blood. The red blood cell (RBC) is modeled as a closed membrane filled with a Newtonian fluid which has the same viscosity as the surrounding plasma. The cell membrane is described by a spring model so that the deformability of the cells can be considered. An immersed boundary method is also developed for dealing with the cell/fluid interaction in the flow. Our study successfully recreates several important in vivo hemodynamic and hemorheological properties of microscopic blood flow, such as parachute shape of the cells, blunt velocity profile, and the Fahraeus effect, and they have been shown to have strong dependence on cell deformability, hematocrit and vessel size.

S1.00148 Sensing Labeled and Immunocomplexed DNA with solid-state nanopores[1] , BRIAN THOMAS, DANIEL FOLOGEA, DAVID S. MCNABB, Department of Biological Sciences, University of Arkansas, Fayetteville, AR 72701, JIALI LI, Department of Physics, University of Arkansas, Fayetteville, AR 72701 — We report the detection of labeled and immunocomplexed DNA molecules using silicon nitride nanopores. We compared the characteristics of the current blockade signal measured from double-stranded DNA, biotinylated DNA, and immunocomplexed DNA samples. Single biotin-binding site Fab fragments as well as multiple-binding sites Monoclonal Biotin Antibodies were used to bind biotinylated DNA molecules. The electrical current blockage signature measured from the nanopores show that the current drop amplitude, time duration, and the integrated area of events can be used to discriminate DNA with and without labels, and the species of the labels. Our studies show that the single molecule nanopore measurement is more sensitive than bulk electrophoresis in detecting labeled DNA molecules.

[1]We acknowledge the funding support provided by NHGRI/NIH R21HG003290, NHGRI /NIH R21HG00477, NSF/MRSEC 080054, and ABI-111/710.

S1.00149 The translocation time of DNA and protein molecules in solid-state nanopores[1] , BRADLEY LEDDEN, RYAN ROLLINGS, DAVID TALAGA, Department of Chemistry and Biochemistry, Montclair State University, Montclair, NJ 07043, JIALI LI, Department of Physics, University of Arkansas. Fayetteville, AR 72701 — The time that a biopolymer takes to translocate through a nanopore contains the properties of the polymer including its size, conformation, electrical charge and charge distribution. We measured the dependence of the translocation times on the size, charge and charge distribution, voltage, and conformation states of DNA and protein molecules. To quantitatively fit the time distributions measured, 1-D Langevin and 1-D Fokker-Planck equations were used for DNA and native state proteins. Kramers reaction rate theory was used to fit the time distribution of unfolded proteins. It was observed that native-state protein and DNA translocation approximately follows simple one-dimensional biased diffusion of charged particles. Due to the heterogeneous charge sequence of polypeptides, unfolded proteins obey a coupled electrophoretic and thermally activated process that is sequence specific. Deviations between models and experimental results as well as future challenges for single molecule DNA and protein characterization using solid-state nanopores will be discussed.

S1.00150 Emission line shape of B850 band of light-harvesting complex II[1] , PRAVEEN KUMAR, SEOGJOO JANG, Department of Chemistry & Biochemistry, Queens College of the City University of New York, 65-30 Kissena Boulevard, Flushing, New York 11367 — A theoretical framework is developed for the emission line shape of the single complex spectroscopy (SCS). The quantum mechanical characteristics of the single complex emission line shapes for the model B850 band of the light harvesting complex 2 of purple bacteria are studied including both static and quasi-static disorders within the exciton Hamiltonian. The bath is modeled as an infinite sum of harmonic oscillators. For the Gaussian type of disorder, we examined the dependencies of the spectral line shapes on the temperature, polarization of the radiation, and on the type of exciton-bath coupling. Theoretically obtained emission profile is also compared with the absorption profile in the frequency domain. It is observed that emission profile contains an extra inhomogeneous term coming from the entanglement of the system and bath degrees of freedom in the initial equilibrium density operator. Contribution of this term to the overall emission line shape is studied in detail.

S1.00151 Quantum Mechanisms of Electronic Signal Propagation Along a Microtubule[1] , TRAVIS CRADDOCK, DOUGLAS FRIESEN, JACK TUSZYNSKI, University of Alberta — Evidence has been accumulating for the involvement of quantum coherence and entanglement in light harvesting photosynthetic complexes. This tests the adage that biological systems are too "warm and wet" to support quantum phenomena. Recent advancements in experiment and theory have allowed investigators to probe other warm systems for coherent phenomena including polymer chains, bacteriorhodopsin and ion channels. A debate has raged for over a decade regarding hypothetical quantum coherence/ entanglement in microtubules. Here we theoretically investigate coherent energy transfer in microtubules via dipole excitations coupled to the environment in networks of chromophoric amino acids. We present the spatial structure and Hamiltonian, containing localized site energies and couplings between aromatic amino acids, for the microtubule constituent protein tubulin. Energy transfer is discussed in terms of quantum walk formalism and energy transfer efficiency. Plausibility arguments are presented for the conditions favoring a quantum mechanism of electronic signal propagation along a microtubule.

S1.00152 An exactly solvable model for decoherence-assisted transport , ADRIANA MARAIS, ILYA SINAYSKIY, FRANCESCO PETRUCCIONE, Quantum Research Group, School of Physics and National Institute for Theoretical Physics, University of KwaZulu-Natal, Durban, 4001, SA, ARTUR EKERT, Centre for Quantum Technology, National University of Singapore, 2 Science Drive 3, 117542, Singapore, QUANTUM RESEARCH GROUP, SCHOOL OF PHYSICS AND NATIONAL INSTITUTE FOR THEORETICAL PHYSICS, UNIVERSITY TEAM, CENTRE FOR QUANTUM TECHNOLOGY, NATIONAL UNIVERSITY OF SINGAPORE, 2 SCIENCE DRIVE 3, 117542, SINGAPOR TEAM — The processes of energy and information transfer in quantum networks play an important role for quantum communication and quantum computation. Unavoidable interaction of the quantum system with the environment leads to decoherence and dissipation, processes typically associated with a destruction of quantum coherence in the system. However, recently the signature of long-lasting quantum coherence has been identified in conjugate polymers and in photosynthetic light harvesting complexes. Here we present an exactly solvable model where interaction with a decoherent environment plays a crucial role in assisting the transport in a quantum subsystem. Based on exact solution, we study different regimes of the parameters of the system, and identify the role of the correlations between the environments for assisting of the transitions in the quantum subsystem.

S1.00153 Circularly Polarized Light and Growth of Plants , PAVEL SHIBAYEV, ROBERT PERGOLIZZI, Bergen Academies, Hackensack, New Jersey — The influence of linearly polarized light on the direction of plants growth has been recently demonstrated. The state of circularly polarized (CP) light can also change when it is reflected from the surface of leaves and stems. However, the role of light handedness in the development of plants and CP light interaction with the complexes of chlorophyll molecules have still not been studied enough. In this work, the role of left CP light in the accelerated growth of lentil and pea plants is revealed and studied. The mechanism of such an enhancement is discussed in terms of the model considering transmission, absorption, and scattering of CP light on micro and macro levels of leaf organization. Theoretical modeling of light interaction with the interior of the leaf was conducted for a number of recently proposed models of organization of chlorophyll molecules and chloroplasts. All the calculations were performed by employing a 4x4 matrix method in solving Maxwell equations. It is shown that left-handed chiral organization of chlorophyll molecules can greatly enhance the absorption of light and therefore lead to the enhanced growth of the whole plant under CP light.

S1.00154 Design of Targeted Inhibitors of Polo-like Kinase 1 (Plk1) , D.S. DALAFAVE, The College of New Jersey — Computational design of small molecule inhibitors of Polo-like Kinase 1 (Plk1) is presented. Plk1, which regulates cell cycle, is often overexpressed in cancers. Its downregulation was shown to inhibit cancer progression. Most inhibitors of kinases' interact with the highly conserved ATP binding site. This makes the development of Plk1-specific inhibitors challenging, since different kinases have similar ATP sites. However, Plk1 also contains the polo-box domain (PBD), which is absent from other kinases. In this study, the PBD site was used as a target for designed Plk1 inhibitors. Common structural features of experimentally known Plk1 ligands were first identified. The information was used to design putative small molecules that specifically bonded Plk1. Druglikeness and possible toxicities of the designed molecules were determined. Molecules with no implied toxicities and optimal druglikeness were used for docking studies. The docking studies identified several molecules that made stable complexes with the Plk1 PBD site. Possible utilization of the designed molecules in drugs against cancers with overexpressed Plk1 is discussed.

S1.00155 DelPhi webserver: Comprehensive suite for electrostatic calculations of biological macromolecules and their complexes , SHAWN WITHAM, BRETT BOYLEN, BARR OWESEN, Clemson University, WALTER ROCCHIA, Italian Institute of Technology, EMIL ALEXOV, Clemson University — Electrostatic forces and energies are two of the major components that contribute to the stability, function and interaction of biological macromolecules. The calculations of the electrostatic potential distribution in such systems, which are comprised of irregularly shaped objects immersed in a water phase, is not a trivial task. In addition, an accurate model requires any missing hydrogen atoms of the corresponding structural files (Protein Data Bank, or, PDB files) to be generated in silico and, if necessary, missing atoms or residues to be predicted as well. Here we report a comprehensive suite, an academic DelPhi webserver, which allows the users to upload their structural file, calculate the components of the electrostatic energy, generate the corresponding potential (and/or concentration/dielectric constant) distribution map, and choose the appropriate force field. The webserver utilizes modern technology to take user input and construct an algorithm that suits the users specific needs. The webserver uses Clemson University's Palmetto Supercomputer Cluster to handle the DelPhi calculations, which can range anywhere from small and short computation times, to extensive and computationally demanding runtimes. The work was supported by a grant from NIGMS, NIH, grant number 1R01GM093937-01.

S1.00156 Using DelPhi capabilities to mimic conformational reorganization with amino acid specific dielectric constants[1] , LIN WANG, Clemson University, SUBHRA SARHAR, Clemson, WALTER ROCCHIA, Italian Institute of Technology, EMIL ALEXOV, Clemson University — Many molecular events are associated with small or large conformational changes occurring in the corresponding proteins. Modeling such changes is a challenge and requires significant amount of computing time. From point of view of electrostatics, these changes can be viewed as a reorganization of local charges and dipoles in response to the changes of the electrostatic field, if the cause is insertion or deletion of a charged amino acid. Here we report a large scale investigation of modeling the changes of the folding energy due to single mutations involving charge group. This allows the changes of the folding energy to be considered mostly electrostatic in origin and to be calculated with DelPhi assigning residue-specific value of the internal dielectric constant of protein in the range from 2 to 20. The predicted energy changes are benchmarked against experimentally measured changes of the folding energy on a set of 300 single mutations. The best fit between experimental values and predicted changes is used to find out the effective value of the internal dielectric constant for each type of amino acid.

[1]The work was supported by a grant from NIGMS, NIH, grant number 1R01GM093937-01.

S1.00157 Normal mode analysis with reduced Hessians for multi-scale modeling techniques , AN GHYSELS, University of California - Berkeley, BENJAMIN T. MILLER, National Institues of Health, MICHEL WAROQUIER, Center for Molecular Modeling, BERNARD R. BROOKS, National Institutes of Health — Normal mode analysis is a straight-forward technique to gain insight into the principal motions of molecular systems. Diagonalizing the mass-weighted second derivative matrix (Hessian) results in eigenfrequencies and eigenmodes which indicate the time scale and spatial shape of the vibrations. For large systems, it is often necessary to use Hessians of reduced size in order to limit the required computational resources as well as the amount of information. Methods such as coarse-grained multi-scale models, the Mobile Block Hessian approach, the Vibrational Subsystem Analysis, or the Partial Hessian Vibrational Analysis, focus on specific parts of the spectrum: localized and/or global modes with varying degrees of coupling with the environment. In this presentation, the link between the different approaches will be studied with size-independent metrics and overlap techniques.

S1.00158 Raman Spectroscopy Studies of Normal and Burned Biological Tissue , FARANAK ZARNANI, Department of Physics, University of Texas at Dallas, Richardson, TX 75080, DAVID MAASS, AHAMED IDRIS, Department of Surgery, University of Texas Southwestern Medical Center, Dallas, TX 75390, ROBERT GLOSSER, Department of Physics, University of Texas at Dallas, Richardson, TX 75080 — Burn injuries are a significant medical problem, and need to be treated quickly and precisely. Burned skin needs to be removed early, within hours (less than 24 hrs) of injury, when the margins of the burn are still hard to define. Studies show that treating and excising burn wounds soon after the injury prevents the wound from becoming deeper, reduces the release of proinflammatory mediators, and reduces or prevents the systemic inflammatory reaction syndrome. Also, removing burned skin prepares the affected region for skin grafting. Raman spectroscopy could be used as an objective diagnostic method that will assist burn surgeons in removing burned skin precisely. As a first step in developing a diagnostic tool, we present Raman spectroscopy information from normal and burned ex vivo rat skin, and a comparison of our findings. Raman spectroscopy is explored for its specificity and sensitivity.

S1.00159 Time-resolved infrared structural biology: Identification of Signature Vibrational Signals from the Active Site Tyrosine of Photoactive Yellow Protein , ZHOUYANG KANG, BEINING NIE, LORAND KELEMEN, Departments of Physics, Oklahoma State University, Stillwater, OK, 74078, RACHANA RATHOD, WOUTER D. HOFF, Department of Microbiology & Molecular Genetics, Oklahoma State University, Stillwater, OK, 74078, AIHUA XIE, Departments of Physics, Oklahoma State University, Stillwater, OK, 74078 — Hydrogen bond interactions are indispensable for protein structure and function. We are developing techniques for time-resolved infrared structural biology that offers high sensitivity to hydrogen bonding interactions, excellent time resolution, and a broad time window. Here we report the identification of signature vibrational signals from the active site Tyr42 of photoactive yellow protein for quantifying hydrogen bond interactions using a strategic combination of site-directed mutagenesis (Y76F, Y94F, Y98F, Y118F), specific Tyr isotope labeling, and time-resolved FTIR spectroscopy. These PYP mutants preserve functional activity, thus optimal for probing functionally important structural changes at the active site. This experimental approach is broadly applicable to other proteins, paving the way to transform time-resolved infrared spectroscopy to time-resolved infrared structural biology.

S1.00160 Fluorescence Measurement of Burned Skin Tissues , HECTOR MICHAEL DE PEDRO, CHUAN-I. CHANG, HUE NGUYEN, ANTON MALKO, FARANAK ZARNANI, ROBERT GLOSSER, Physics Department, University of Texas at Dallas, D. MAAS, A. IDRIS, Department of Surgery, University of Texas Southwestern Medical Center — Early removal of affected tissues from burn patients can significantly increase the success of their recovery, since burns continue to spread and damage surrounding tissues after hours of injury. The rationale behind this procedure is that burns trigger the body's immune system to overreact, causing additional damage. Therefore it is important to locate and identify the burn (area and thickness) so that it can be removed as quickly as possible. Our project explores the use of autofluorescence as a tool to identify the burned tissues from healthy ones. Here we present that our fluorescence results show differences between burned and normal skin in both its spectra and lifetime.

S1.00161 Point Spread Diffraction Patterns and Super-Resolution Particle Localization , STEPHEN ANTHONY, SRIPAD RAM, ANISH ABRAHAM, JERRY CHAO, E. SALLY WARD, Dept. of Immunology, UT Southwestern, RAIMUND OBER, Dept. of Electrical Eng., UT Dallas — Sub-diffraction limit localization of fluorophores depends upon fitting the observed photon distribution to the point spread function (PSF). As such, accurate knowledge of the PSF is important to super-resolution microscopy and critical to determining the trajectories and dynamics of molecules within cells. While simple geometrical optics serves well to represent light propagation on the macroscopic level, more elaborate wave representations are necessary to describe light propagation within a few wavelengths of focal points, such as single fluorophores imaged by microscope objectives. As a result, numerous theoretical approximations to experimental PSFs exist as the exact theoretical PSF is unknown. Further consideration must be given that for realistic experiments, frequently events of interest will not entirely match the design conditions of the microscope; most events of interest will not be perfectly in focus, nor can the index of refraction of a living cell be controlled. Additionally, a number of imaging modes explicitly rely upon out-of-focus images. Through serial sectioning microscopy, we explore the experimental PSF in comparison with various models, determining which models are robust and provide accurate sub-diffraction limit localization for realistic data.

S1.00162 Sensing calcium ions at high hydrostatic pressure using the dual-wavelength calcium-sensitive dye indo-1[1] , JORDAN RYAN, PAUL URAYAMA, Miami University — Because calcium often serves as a signaling ion in biological systems, accurate sensing of calcium-ion concentration under pressure is important in understanding cellular piezophysiologic effects. Indo-1 is a dual-wavelength fluorophore routinely used for calcium-ion sensing at ambient pressure, with an emission spectrum that changes upon calcium-ion binding. When subject to physiological pressures of up to 50 MPa, we observe piezochromic behavior in the excited-state emission which depends more on solvent polarity than on solvent viscosity. A two-state model is used to determine the thermodynamic volume change upon calcium dissociation from indo-1, which we find to be consistent with the value for other metal-ion chelators. Since, despite its piezochromicity, indo-1 continues to follow two-state binding-unbinding behavior, indo-1 remains useful under pressure as a probe for quantitative calcium-ion sensing.

S1.00163 DLS microrheology at the onset of weak elasticity during thermal denaturation of BSA , ULF NOBBMANN, CARLOS A. REGA, HANNA JANKEVICS, SAMIUL AMIN, Malvern Instruments, Grovewood Rd, Malvern, WR14 1XZ, UK — The ability to precisely detect the onset of protein aggregation to draw insights into microstructural characteristics plays a critical role in a variety of biotechnological applications such as therapeutic protein stability.[1] Rheological techniques are very sensitive to evolution of an aggregating network but have been limited in biotechnology, due to large sample volume and moderately high viscosity requirements in traditional mechanical rheometry. Dynamic Light Scattering (DLS) overcomes these limitations as experiments can be carried out on very dilute samples and small volumes. We present a method based on optical microrheology[2] to study the onset of bovine serum albumin (BSA) aggregation to develop an understanding of the evolving network structure. The exponent of the tracer mean squared displacement power law fit and the elastic modulus G' emerge as two key parameters. The impact of probe chemistry and probe size on the extracted microrheological response is discussed.

[1]A Saluja et al., "Ultrasonic rheology of a monoclonal antibody (IgG_2) solution: implication for physical stability of proteins in high concentration formulations" J. of Pharm. Sci. (2007) 96, 3181-3195.

S1.00164 Bacteria turn on surfaces by oversteering with Type IV pili , FAN JIN, University of California, Los Angeles, JACINTA C. CONRAD, University of Houston, MAXSIM L. GIBIANSKY, GERARD C.L. WONG, University of California, Los Angeles — Type-IV pili (TFP) are linear nano-actuators that enable bacteria to crawl on surfaces. Analysis of TFP-mediated crawling in *P. aeruginosa* reveals that it always alternates between two types of distinct movements: a linear translation of constant velocity is followed by a combined translation-rotation that is ∼10x faster in instantaneous velocity. The latter process can turn the cell body by over-steering so that the rear of the cell loses traction with the surface. Orientational distributions of these movements suggest that the former is due to pulling by multiple TFP, whereas the latter is mostly due to release by single TFP.

S1.00165 Automated detection and analysis of key transitions in biofilm formation , TRAVIS THATCHER, BENJAMIN COOLEY, VERNITA GORDON, Center for Nonlinear Dynamics and Department of Physics, University of Texas at Austin — Biofilms are cooperative, dynamic, multicellular systems made of interacting, surface-bound bacteria and/or yeast. The growth of biofilms is an inherently developmental process, characterized by changes in gene expression in response to cues from the environment and other cells. These changes in gene expression are associated with transitions in the behavior of bacteria in the developing biofilm. There are other transitions in behavior that may result from nongenetic influences, such as the conditioning of the surface with bacteria-produced extracellular materials. The early development of biofilms show several key transitions as bacteria move from discrete, swimming cells into surface-bound, dense microcolonies. Each of these transitions is associated with a loss of entropy and, therefore, must result from biological activity that compensates for this loss of entropy. We present a set of approaches for automatically identifying each of these transitions and localizing them in space and time.

S1.00166 Noise Induced Biological Adaptation Differs between Analogous Differentiation Circuits , MARK KITTISOPIKUL, Green Ctr. for Sys. Biology and Dept. of Pharm., UT Southwestern, Dallas, TX USA75390, ANDREW MUGLER, FOM Institute for Atomic and Molecular Physics (AMOLF), Science Park 104, Amsterdam, The Netherlands, ALEKSANDRA M. WALCZAK, Laboratoire Physique Theorique, Ecole Normale Supérieure & CNRS, 24 rue Lhomond, 75231 Paris Cedex 05, France, TOLGA ÇAGATAY[1], CHRIS H. WIGGINS, Dept. of Applied Physics and Applied Math., Ctr. for Comp. Biology and Bioinformatics, Columbia University, New York, NY 10027, GÜROL SÜEL[2] — Analogous genetic regulatory networks with alternate orders of activation and repression can have comparable functions and generate similar average dynamics but differ in terms of stochastic variability (noise). Here we examine if noise affects biological adaptation to stress by comparing the induction dynamics of the native *B. subtilis* competence differentiation network to a synthetic network implemented *in vivo* by Çagatay et al. that recapitulates mean dynamics but differs in noise. We use fluorescence microscopy to study the networks in live cells and stochastic models solved via the spectral method. The adaptability of the organism is affected by the circuit's ability to access different dynamic regimes as a function of stress.

S1.00167 CHEMICAL PHYSICS –

S1.00168 ABSTRACT WITHDRAWN –

S1.00169 Where the Periodic Table of Elements Ends? Additional Explanations

, ALBERT KHAZAN, IMET — Already 40 years ago, physicists claimed that the elements with number higher than 110 cannot exist. However at this day, Period 7 has been complete. Experiementalists syntesed 10 new syperheavy elements during only the last because. The method of synthesis is so finely developed that the experimentalists of Dubna tell about element No.150 as the higher limit of theTable of Elements (they do not provide a ground to the calculation). In contrast, our calculation are based neither on calculation of the stability of the electronic shells of the atoms, nor synthesis of the superheavy elements. Our caculation is based on study of the chemical processes, which give a new law of the Periodic Table (Albert Khazan. Upper Limit in Mendeleev's Periodic Table—Element No. 155. Svenska fysikarkivet, Stockholm, 2009). The core of the delusion of numerous scientists was that they, in their calculationsbased on Quantum Mechanics, initially set up the number of the elements (number of the protons) then calculated the atomic mass proceeding from the data. According to our theory, the atomic mass of the last element (411.66) should be calculated first, only then its number (155)!

S1.00170 Scaling of Nonclassical Nucleation Rates of Methanol

, GERALD WILEMSKI, FAWAZ HRAHSHEH, Missouri University of Science and Technology, Rolla MO, ABDALLA OBEIDAT, Jordan University of Science & Technology, Irbid, Jordan — Nonclassical gradient theory (GT) calculations of nucleation rates are presented for methanol, an associating vapor system. The calculations use the SAFT-0 equation of state (EOS) that accounts for the effects of molecular association based on the statistical association fluid theory (SAFT). Calculated rates were compared to the experimental rates of Strey, et al. [*J. Chem. Phys.* **1986**, 84, 2325]. The GT nucleation rates showed improved T and Sdependence compared to classical nucleation theory (CNT). The GT rates were also improved by factors of 100-1000 compared to CNT. Despite these improvements, GT does not describe the reported T and S dependence of the nucleation rates. To explore this further, the GT and experimental rates were analyzed using Hale's scaled model [*J. Chem. Phys.* **2005**, 122, 204509]. This analysis reveals an inconsistency between the predictions of GT, which scale relatively well, and the experimental data, which do not scale. It also shows that the measured rate data have an anomalous T and S dependence. A likely source of this anomaly is the inadequate thermodynamic data base for small cluster properties that was used originally to correct the raw rate data for the effects of association.

S1.00171 Hybrid Monte Carlo Method In Path Space

, PATRICK MALSOM, FRANK PINSKI, University of Cincinnati — We are interested in understanding the ways a collection of atoms are able to undergo conformational change, or change of state. In particular, we are studying atoms as they move under Brownian (over-damped Langevin) dynamics. In many cases, such transitions are blocked by an energy barrier and conformational changes become rare events when the thermal energy is small compared to the barrier height. Our technique attempts to sample these transition paths efficiently while preserving the sample's thermodynamic significance. Our approach is based on a Hybrid Monte Carlo scheme (Beskos *et al.*) that incorporates auxiliary variables. The relative probability of paths is computed using the Onsager-Machlup functional. This method correctly handles the fractal nature of the Brownian paths. We illustrate this method by investigating one of the low energy transitions in the 14-atom Lennard-Jones cluster. In addition, we will show preliminary results for the gas-to-liquid transition in a 2-dimensional Lennard-Jones system.

S1.00172 Small methanol cluster growth/decay rate constant ratios and application to nucleation data analysis

, BARBARA HALE, GERALD WILEMSKI, Missouri University of Science & Technology — The Bennett Monte Carlo technique is used to calculate growth/decay rate constant ratios for small methanol clusters using the model potential of van Leeuwen and Smit [J. Chem. Phys. **99**, 1831 (1995)] at temperatures of 220K, 240K and 260K. The resulting data are used to examine temperature scaling properties of the rate constant ratios and to illustrate how heat release from subcritical cluster formation affects the results of adiabatic nucleation rate measurements.

S1.00173 A Look at a Seires of Alkyl and Perfluoroalkyl Bromides

, BRITTANY LONG, GARRY GRUBBS, STEPHEN COOKE[1], University of North Texas, RADIO SPECTROSCOPY GROUP TEAM — The pure rotational spectrum of bromoperfluoroethane between 9.0-13.0 GHz has been measured on a chirped pulse Fourier transform microwave spectrometer. A total of 839 transitions were observed for the six isotopolouges. Only the $trans$ conformer was observed for which the rotational constants are reported. Nuclear electric quadrapole coupling constants have been determined and reported. Also, two dipole forbidden/quadrapole allowed $\Delta J = 2$ transitions were observed in the spectra.

S1.00174 Water-like Anomalous Properties and Polyamorphism in a Liquid with Smooth (Differentiable) Pair Interactions[1]

, JOEL ABRAHAM, NICOLAS GIOVAMBATTISTA, Department of Physics, Brooklyn College-CUNY, Brooklyn, NY 11210, USA — We perform molecular dynamics simulations of a system of particles interacting via a spherically symmetric, core- softened pair potential, which is a smooth version of the (non- differentiable) Jagla pair potential. Although liquid properties are extremely sensitive to the details of the pair interactions, we show that the smooth version of the Jagla potential preserves the main properties of the original model. Specifically, both pair potentials result in liquids that show (i) water-like thermodynamic and dynamical anomalous properties, as well as (ii) liquid and (iii) glass polymorphism (i.e., the presence of more than one liquid and glass form, respectively). The pressure-temperature phase diagram of our smooth potential shows, as observed in computer simulations using the Jagla model, a liquid-liquid first order transition line separating two liquid phases and ending in a critical point; such a critical point being accessible in equilibrium simulations.

[1]We thank the Research Foundation of CUNY for support (PSC-CUNY 40)

S1.00175 Modeling Adsorption on fcc(nnm) Surfaces[1]

, ALAIN PHARES, Villanova University, DAVID GRUMBINE, JR., St. Vincent College, FRANCIS WUNDERLICH, Villanova University — In general, fcc(*nnm*) surfaces consist of very long armchair (111) terraces separated by steps. The number M of atomic sites in the width of the terraces depends on the Miller indices (*nnm*). The model considers values of $M \leq 6$, with adsorbate-substrate interaction energy on step-sites different from those on bulk sites, takes into account first- and second-neighbor adsorbate-adsorbate interactions, and specializes to the case of attractive first-neighbors. We obtain the complete low temperature, 3-dimensional, energy phase diagrams. The occupational configurations of the phases exhibit features similar to those of the phases obtained in the infinite-width limit, or flat fcc(111) surfaces. This yields a classification of the phases into types, and, within each type, the phases are grouped into families. This suggests a number of generalizations for any value of M beyond 6, leading to a better understanding of the competing interaction energies and of the evolution of the phase diagrams with increasing width M of the terraces. The relevance of these results to experiments is discussed within the context of preferential adsorption on step sites, and applied to the adsorption of water on Pt(335).

S1.00176 Tethering Peptides to Functionalized Self-Assembled Monolayers on Gold Through Two Chemical Linkers Using the Huisgen Cycloaddition[1]

, IGNACIO GALLARDO, The University of Texas at Austin, LAUREN WEBB — A biocompatible platform has been made by tethering a helical peptide to a surface at two points. The presence of the peptide should be an ideal interface between inorganic substrates and proteins. The artificially synthetized alpha-helical peptide composed of alternating leucine and lysine residues, with two residues replaced with cyanophenylalanine to react with two neighboring surface-bound azide groups is linked to the azide-terminated self-assembled monolayer through a tetrazole made by a Husigen Cycloaddition. Surface analysis is done with ellipsometry, infrared spectroscopy and x-ray photoelectron spectroscopy. The cycloaddition and reaction conditions are supported by similar reactions of other smaller molecules like Methoxybenzonitrile and controls show no physisorption under our reaction conditions. Reaction yields from 80 to 98 percent are reported from the optimized reactions. The helical structure of the peptide in solution has been confirmed under our reaction conditions with circular dichroism and the peptide amide I and II modes studied by infrared spectroscopy and their comparison with a computational model of the peptide showed that the peptide is probably randomly oriented on the surface.

S1.00177 Size effect of silicon nanowires on their pH response

, SEONGJAE LEE, IN-BOK BAEK, XIANHONG LI, Hanyang University — The silicon nanowire is a promising material for the bio-chemical electronic sensors because the local change in the surface charge density can be easily transduced to the conductivity change of the nanowire due to its high surface-to-volume ratio. We investigated the pH-dependent electronic transport characteristics of FETs comprised of silicon nanowire channels of different sizes. Starting from the p-type SOI wafer with the top silicon layer of 40 nm thickness, we employed the conventional 'top-down' process to fabricate the FET devices with various silicon nanowires: 100, 135, 180, 220, 300 nm in width and 2, 5, 10, 20 μm in length. The devices were electrochemically characterized by I_D-V_G measurements with a reference electrode as a gate in the phosphate buffer solutions of a pH value ranging from 2 to11. The threshold voltages of all devices were extracted from the I_D-V_G curves and their relations to pH were compared with simulation results based on the Gouy-Chapman-Stern-Graham model. A good linear relation between the threshold voltage and pH was observed for all devices in the range of 4 $<$ pH $<$11 with a high sensitivity of 56 mV/pH which is much higher than the bulk devices and very close to the Nernst limit. However, the systematic increase of a threshold voltage shift as decreasing nanowire's dimension (width and length) was also observed and possible origins are discussed within the scope of the Gouy-Chapman-Stern-Graham model.

S1.00178 Role of Surfactant Molecular Structure on Self Assembly: Aqueous SDBS on Carbon Nanotubes[1]

, MANASWEE SUTTIPONG, Chulalongkorn University, JOHN R. THOMPSON, NAGA RAJESH TUMMALA, The University of Oklahoma, BOONYARACH KITIYANAN, Chulalongkorn University, ALBERTO STRIOLO, The University of Oklahoma — Stabilizing aqueous dispersions of carbon nanotubes mono-dispersed in diameter and chirality remains elusive. Surfactants have proven useful in deploying ultra-centrifugation techniques, but the molecular mechanism responsible for their effectiveness remains not fully understood. Based on a number of recent molecular simulation results, including those from our group, it appears that the morphology of the self-assembled surfactant aggregates on the carbon nanotubes strongly affects the effective potential of mean force between pairs of interacting carbon nanotubes. In this work we explore the effect of surfactant molecular structure on the properties of aqueous surfactant self-assembled aggregates. We employ equilibrium all-atom molecular dynamics simulations. We consider the surfactant SDBS (sodium dodecyl benzene sulfonate) with benzene ring located on the fifth or on the twelfth carbon atom in the tail, and the surfactant AOT [sodium bis(2-ethylhexyl) sulfosuccinate]. The simulations are conducted at room conditions for different surface coverages on (6,6), (12,12), and (20,20) single walled carbon nanotubes. These new results will help us identify the surfactant properties that allow us to manipulate nanotube-nanotube effective interactions.

S1.00179 Properties of Aqueous Electrolytes within Narrow Slit-Shaped Pores[1]

, TUAN A. HO, DIMITRIOS ARGYRIS, ALBERTO STRIOLO, The University of Oklahoma, School of Chemical, Biological and Materials Engineering — We report equilibrium molecular dynamics simulation results for structural and dynamic properties of aqueous electrolyte solutions confined within narrow pores. The slit-shaped pores are carved from cristobalite silica, corundum alumina, magnesium oxide, and other materials. The pore width is in the range 0.8 – 2.0 nm. The aqueous solutions contain NaCl, CsCl, $CaCl_2$, and $SrCl_2$ electrolytes at 1M concentration or larger. Equilibrium simulations are performed at ambient conditions within the NVT ensemble. The data suggest the formation of layered structures, which are consistent with results obtained for thin films of solution supported on free-standing surfaces. However, confinement enhances the differences in transport properties observed between those ions that are near the solid and those at the pore center. Because the self-diffusion coefficient is faster as the distance from the solid increases, the ions that are at the pore center diffuse more quickly through the pore than those adsorbed closer to the wall. Thus our results could be used to design membranes to separate, e.g., aqueous NaCl from CsCl solutions.

S1.00180 Chemisorption of Guanine on Cu(110)

, JERONIMO MATOS, ABDELKADER KARA, University of Central Florida — We use density functional theory (PBE) to calculate the adsorption of a guanine molecule on Cu(110). At saturation coverage, guanine adsorbs tilted with the oxygen atom strongly bound to one of the surface atoms at a height of 2.12 Å above this surface atom with a binding energy of 430 meV/molecule. The substrate top layer atoms show a buckling of 0.22 Å , while the molecule experiences a twist from the flat configuration in the gas phase. The dz^2 state of the copper atom -that is bound to the oxygen atom- presents an enhancement in its density near the Fermi level. We calculated a drop in the work function of 0.34 eV upon adsorption of guanine on Cu(110). These effects classify this system as chemisorption.

S1.00181 Proton transfer induced by receding water in Glycine—$(Water)_2$ Complex

, RAJEEV PATHAK, Department of Physics, University of Pune, India — We investigate molecular co-operativity in the zwitterionic configuration of Glycine (Gly) with two proximal water molecules, Gly—$(Water)_2$, by deliberately making one of the water molecules recede from the remaining complex. The consequent intra-molecular proton transfer that renders the zwitterionic configuration into a neutral one is viewed under two scalar field descriptors: Molecular Electrostatic Potential (MESP), reflecting the modifications in the environment and the HOMO (highest occupied molecular orbital) electron density. We quantify the process further by energetics, through a many-body analysis of the interaction energy as well as salient IR spectral signatures associated with the proton-transfer. While we employ the decent MP2/aug-cc-pvDZ level of theory to seek optimal structures, it is gratifying that a prescription within density functional theory (DFT) also provides a reliable description of this process.

S1.00182 Compositional-Dependent Structural Analysis of Cu_xPt_{38-x} Nanoparticles

, JOSAFAT GUERRERO-JORDAN, Posgrado en Ciencias (Fisica), Universidad de Sonora, ROY L. JOHNSTON, School of Chemistry, University of Birmingham, ALVARO POSADA-AMARILLAS, Dept. Inv. en Fisica, Universidad de Sonora — We present an exhaustive study of the lowest energy Cu_xPt_{38-x} clusters structures obtained through a genetic algorithm, which incorporates the Gupta potential to mimic interatomic bonding. A symmetric parameterization of the Gupta potential was used including a weighting factor (w) in order to search for different potential energy surfaces describing 38-atom Cu-Pt nanoparticles. This weighting factor was varied from 0 to 1 in steps of 0.1 to obtain a structure map which provides information on the structural distribution in terms of the composition. According to this structure map, the most abundant structural motif corresponds to the truncated octahedron. Atomic segregation was maximum for w = 1.0. We also present the plot of excess energy as a function of the weighting factor values for the complete compositional range. The most stable structures were found for w = 0.0. The most relevant structures were chosen to be reoptimized by using the DFT method. We found that the interatomic distances changed compared to those obtained with the genetic algorithm.

S1.00183 Evidences of Homogenous Nucleation in Nano Confined Secondary Alcohol[1] , SAMUEL AMANUEL, AMER KHRAISAT, JARGALSAIKHAN DULMAA, Department of Physics and Astronomy, Union College, Schenectady, NY 12308 — We have made comparative measurements to study the phase transition of physically confined 2-decanol in nano porous silica in the presences of excess bulk 2-decanol. We have systematically controlled the amount of excess bulk and studied how its existence influences freezing and melting temperatures. It appears that there is a lower limit in size, where freezing of the confined is not influenced by the presences or absence of the bulk. In our case this lower limit occurred with the average pore diameter of 100 nm. For 2-decanol confined in pore sizes larger than 100 nm, however, its freezing occurred at T = -23 $^\circ$C, which was triggered by the freezing of the excess bulk. In absence of the bulk, freezing occurred at a lower temperature depending on size. Melting of the confined 2-decanol, on the other hand, was not influenced by the presences or absence of the bulk. Generally, the melting of the confined 2-decanol preceded the melting of the bulk. These suggest that the nucleation of 2-decanol confined to pore sizes less than 100 nm is homogenous and controlled by its extent of supercooling.

S1.00184 Universal Patterns of Cluster Growth in Aqueous Sugars Observed by Dynamic Light Scattering[1] , TRI TRAN, DAVID SIDEBOTTOM, Creighton University — Dynamic light scattering was performed on aqueous sugar solutions to monitor the growth of sugar clusters as a function of sugar concentration and temperature. Three sugars (glucose, maltose and sucrose) were investigated. Analysis of the hydrodynamic radius of the diffusing clusters suggests a two-stage process of cluster growth. At low volume fractions of sugar, a cluster phase consisting of nearly monodisperse clusters forms with a mean cluster mass that increases in proportion to the volume fraction. A second stage of growth develops when clusters reach a size where they begin to overlap. In this later stage, cluster-cluster aggregation occurs and the cluster size grows in a common, but temperature dependent, power law fashion in advance of a percolation threshold near 83 wt% sugar.

S1.00185 Quantification of molecular topology using small angle scattering. , RAMNATH RAMACHANDRAN, DURGESH RAI, GREGORY BEAUCAGE, University of Cincinnati — A recent method to quantify molecular topology of various materials using small angle scattering will be presented. Small angle x-ray and neutron scattering has been used to characterize ceramic aggregates and polymer structures systems respectively. The structural differences in various systems arise from the competition between thermal and spacial constraints. The details in ceramic aggregates like branch fraction, number of segments in an aggregate and the short circuit path, coordination number, the number end groups *etc* are extracted. Amongst the polymer systems, details of topological quantification of polymer systems such as stars, cyclics and branched polymers like polyolefins will be presented. In polyolefins, the method provides a unique measure of the average long-chain branch length and the hyperbranched (branch-on-branch) characteristics. The quantification using scaling models are important in order to understand the structure-property relationship amongst materials.

S1.00186 Effects of Iridium interfacial nanolayers on stability and barrier hights of TCO/Si nano-holes Solar cell structures , BED SHARMA, MOHEMAD BOUANANI, University of North Texas — There is still a significant gap between currently achieved efficiencies and theoretical one. A fundamental understanding of physico-chemical and electronic properties as well as tuning and control of transparent conducting oxides (TCOs) and nano-structured semiconductor absorber material interfaces is critical. One of the many issues is the suspected formation of silicon oxides due to transport of oxygen from TCO to silicon that degrades the effectiveness of light generated charge transfer which eventually degrades final efficiency of solar cell. The fabrication of 3-D nano-holes in Si was obtained by electrochemical etching through anodic nano-porous alumina. The nano-porous alumina was prepared by depositing thick 1micrometer aluminum layer on RCA cleaned Si samples, annealing in Ar and using hard anodization process. One to few mono-layers of Ir were inserted at the TCO/Si interfaces to block the depletion of oxygen to stabilize the interface and tune its barrier height. Both ITO and ZnO were used as TCOs. The effect of Ir on the band alignment at these interfaces is evaluated by Ultraviolet Photoelectron Spectroscopy (UPS). The interface stability and chemical nature is evaluated by X-ray Photoelecton Spectroscopy (XPS).

S1.00187 Charge transfer energies of tetraphenyl-porphyrin-fullerene dyads[1] , RAJENDRA ZOPE, University of Texas at El Paso, MARCO OLGUIN, University of Texast at El Paso, TUNNA BARUAH, University of Texas at El Paso — Porphyrin-fullerene dyads are extensively studied for their photoinduced charge transfer properties. They form a donor-acceptor pair where the fullerene is the acceptor. Accurate theoretical estimate of the charge transfer energies in such systems has proven to be a challenge. In this study we examine the charge transfer energetics for such dyads using our recently developed density functional based excited state method which can yield reliable estimates of charge transfer energetics. In this study the effect of varying both the donor and acceptor components are studied by changing the tetra-phenyl-porphyrin (TPP) to Zn-TPP. Similarly the acceptor component is changed from C60 to C70. The structures were optimized using DFT-D3 theory at the all-electron level. Among the donor-acceptor pairs studied, we find that the ZnTPP-C60 has the lowest charge transfer energy (1.69 eV) and the TPP-C70 (2.13 eV) has the highest charge transfer energy.

S1.00188 Strong field DC slice imaging , LU YAN, Department of Chemistry, Wayne State University, Detroit, MI, 48202, MICHAEL DOYLE, YUNFEI LIN, WEN LI, ARTHUR SUITS — A new, "universal" variation of the DC slice ion imaging method is reported. This approach allows the central slice of the photofragment ion cloud to be recorded and the relevant speed and angular distributions for a molecular photodissociation to be obtained without any inversion methods, but does so using femtosecond non-resonant strong-field ionization. The probe laser is also implemented in a "raster imaging" approach that records only the central section of an expanded photofragment distribution and avoids interaction with the molecular beam itself. This is achieved by using the probe laser displaced off-axis from the molecular beam with application a narrow time gate to a multichannel plate detector. To avoid high background level and space charge effect, the detection region is in ultrahigh vacuum and we utilize a second differential stage to the molecular beam. Several examples will be presented illustrating the method.

S1.00189 FLUIDS AND SOFT MATTER –

S1.00190 Molecular Dynamics of Colloidal binary mixtures in an electric field , MANUEL VALERA, ATHULA HERAT, ETHAN CORLE, Slippery Rock University — We have studied a system of colloidal binary mixtures in an external electric field. The simulations were performed in the string fluid regime, low packing fraction, and high density regime under the influence of a strong electric field. In the dilute regime we studied the system structure for different concentrations and size ratios. For the high density regime we studied a 50:50 concentration with a size ratio or 1.2/1.0. We show the pair correlation function and diffusion coefficient. A partial phase diagram for the 50:50 concentration and 1.2/1.0 size ration is also presented.

S1.00191 Capillary Condensation: Novel Method for Patchy Particle Fabrication[1]

, NINA IVANOVA, NICOLE ZACHARIA[2], Texas A&M University — Patchy particles are patterned particles with at least one patch for anisotropic interaction. A novel route for their synthesis involves capillary condensation of a chemical species into the voids of an ordered colloidal sphere array. Polystyrene and silica particles ranging in diameter from 20 nanometers to 1 micron are assembled into crystalline arrays via evaporation induced self-assembly. The chemical condensed into the voids is then reacted with metal nanoparticles to produce novel patchy particles. The particles are characterized using FTIR, EDX and SEM. The size of these patches is quantitatively shown to reduce in size in proportion with increased particle radius. Surface Enhanced Raman Spectroscopy is explored as one of the possible applications for these novel particles.

S1.00192 Phase Equilibrium Model for Nanoparticle-Filled Nematic Liquid Crystals

, EZEQUIEL SOULE, Dept. of Chemical Engineering, McGill University,Montreal, Canada - Nanomaterials Group, Institute of Materials Science, Mar del Plata, Argentina, JONATHAN MILETTE, LINDA REVEN, Dept. of Chemistry, McGill University, 801 Sherbrooke St. W, Montreal, H3A2K6, Qc, Canada, ALEJANDRO REY, Dept. of Chemical Engineering, McGill University,3610 University St, Montreal, H3A2B2, Qc, Canada — This work presents an integrated characterization of phase transitions and structure formation in mixtures of nanoparticles (NP) and liquid crystals (LC), by means of a model for phase equilibrium and an experimental study on the system composed by 5CB and gold NPs. The model takes into account mixing, nematic ordering of the LC, crystalline ordering (self-assembly) of NPs, and LC-NP interactions. Generic features of phase diagrams for NP-LC mixtures are discussed. The model can explain some experimental observations, like the formation of NP aggregates and distinctive nematic textures, as a function of experimental parameters like NP concentration and the nature of the NP surface are changed. The parameters that produce these changes in phase behaviours can be directly correlated with experimental variables.

S1.00193 Observation of nematic/smectic liquid crystal configurations in a prolate spheroidal confinement

, JOONWOO JEONG, MAHN WON KIM, KAIST — Polymer-dispersed liquid crystal (PDLC) is a composite of dispersed LC droplets in a polymer matrix. The electro-optic properties of PDLCs, such as reorientation field strength and response time, are strongly related to the director configuration. Various factors including the intrinsic properties of LC/polymer and the size/shape of droplets affect the liquid crystal configuration. A balance between the bulk elastic energy and the surface anchoring energy determines the configuration. To study systematically the effect of size/shape of droplets on the configuration, we have prepared thin PDLC films with 4-Cyano-4'-pentylbiphenyl (5CB)/ 4-Cyano-4'-octylbiphenyl (8CB) and Polydimethylsiloxane (PDMS) elastomer. Using polarized optical microscopy, we have observed the change in the director configuration of LC droplets as a function of the aspect ratio up to 6 by stretching the film unidirectionally. We have also observed the effect of surface anchoring on the configuration.

S1.00194 Automation of Dielectric Characterization of Liquid Crystals

, SHANE DRYE[1], JOSAPHAT UVAH[2], CHANDRA PRAYAGA[3], University of West Florida — This report describes the complete automation of a setup for the dielectric characterization of liquid crystals (LC). A capacitor cell filled with the LC 8CB is housed in a temperature controlled environment. The temperature of the sample is varied between 25°C and 45°C with a stability and precision of 0.001K, with a PTC10 PID controller. The range covers the phase transitions of the LC. The purpose is to measure the dielectric properties of the liquid crystal near the phase transitions. The capacitance is measured with a SR830 lock-in amplifier and a Fluke4360 LCR meter upto 100kHz. An Agilent 4395A Network Analyzer is used to extend the frequency into the MHz range. In this work, the entire process is automated. All the instruments are connected to a computer through a GPIB (IEEE-488) interface. The program is designed using LabVIEW to control the instruments, send commands and inputs including temperature range and frequencies, receive data, calculate the capacitance, and plot the data automatically. Results of measurements will be presented.

S1.00195 Carbon nanotubes effects on the order parameter and crystal structure of 5CB liquid crystal

, GEORGI GEORGIEV, ERIN GOMBOS, MICHAEL MCINTYRE, Assumption College, PEGGY CEBE, Tufts University, ASSUMPTION / TUFTS TEAM — Carbon nanotubes (CNTs) are elongated anisotropic molecular size cylinders that can form a liquid crystal (LC) phase in lyotropic solutions. When dispersed in LCs their nematic directors couple. We have observed a large downshift in transition voltage during Freedericksz transition in LC/CNT nanocomposites. We are interested in the effect that CNTs have on the order parameter of LCs and their phase diagram and crystal structure. We measured using polarized UV/Vis absorption spectra a systematic increase of the order parameter of LC/CNT cells with increase of the CNTs content. The order parameter vs temperature slope decreases with increased CNTs content, which shows that CNTs support an increased order of the LCs to higher temperatures. This makes the Nematic-to-Isotropic transition sharper increasing its first order phase transition characteristics. The main mechanism for the strong nematic coupling is pi-pi stacking between the aromatic rings of the CNTs and LCs which we measure using FTIR and Raman difference spectroscopy. Through Polarized Microscopy, Ellipsometry and DSC we observed a change in crystalline order and an increase in nematic to crystal phase transition temperature with increasing CNTs concentration due to their crystal nucleation activity.

S1.00196 Brownian motion of particles in nematic fluids

, XUXIA YAO, KARTHIK NAYANI, JUNG PARK, MOHAN SRINIVASARAO, Georgia Institute of Technology — We studied the brownian motion of both charged and neutral polystyrene particles in two nematic fluids, a thermotropic liquid crystal, E7, and a lyotropic chromonic liquid crystal, Sunset Yellow FCF (SSY). Homogeneous planar alignment of E7 was easliy achieved by using rubbed polyimide film coated on the glass. For SSY planar mondomain, we used the capillary method recently developed in our lab. By tracking a single particle, the direction dependent diffussion coefficients and Stokes drag were measured in the nematic phase and isotropic phase for both systems.

S1.00197 Fluorescence of CdSe nanoparticles in the Liquid Crystal 8CB near the Phase Transitions

, JODIE GRAY, SHANE DRYE, DARREN NORTH, SAMUEL BECK, Undergraduate Physics Research, TIM ROYAPPA, Department of Chemistry, LASZLO UJJ, CHANDRA PRAYAGA, Department of Physics — The liquid crystal 4'octyl—4-cyanobiphenyl (8CB) doped with cadmium selenide nanoparticles was injected into a commercially available liquid crystal cell (INSTEC, Inc). The cell was housed in a temperature controlled environment constructed in the lab and exposed to light from a frequency doubled Nd: YAG laser. Fluorescence from the sample was filtered from the incident light and detected using a photodiode and measured with a lock-in amplifier. Measurements have been made over the temperature range 25° to 45°C. The sample was stabilized at each temperature, and the fluorescence intensity was measured at several temperatures. The results show a significant change in fluorescence near the nematic-isotropic phase transition. The temperature control and precision allowed more than 1000 data points to be taken between 25-50°C, with most of these clustered in the transition region between 38.5– 39.5°C, where the change in intensity was observed.

S1.00198 Spectral Measurements of Fluorescence of CdSe nanoparticles in Liquid Crystals near Phase Transitions

, SAMUEL BECK, JODIE GRAY, SHANE DRYE, DARREN NORTH, Undergraduate-Physics Research, TIM ROYAPPA, Department of Chemistry, CHANDRA PRAYAGA, LASZLO UJJ, Department of Physics — The liquid crystal 4'octyl-4-cyanobiphenyl (8CB) doped with cadmium selenide nanoparticles was injected into a commercially available liquid crystal cell (INSTEC, Inc). The cell was housed in a temperature controlled environment constructed in the lab and exposed to light from a frequency doubled Nd: YAG laser. The spectrum of fluorescence from the sample was measured at several temperatures over the range 250 to 450C, covering the smectic-nematic and nematic-isotropic phase transitions. The sample was held at each temperature with a precision and resolution of 1mK before taking the spectrum. It was therefore possible to approach very close to the phase transitions. The results show a significant change in the fluorescence spectrum near the nematic-isotropic phase transition.

S1.00199 Electro-optical properties of polymer-dispersed liquid crystals containing gold nanoparticles[1]

, ALFONSO HINOJOSA, SURESH SHARMA, UT Arlington — It is known that additions of relatively small concentrations of gold nanoparticles (Au NPs) can significantly change electro-optical properties of a polymer-dispersed liquid crystal (PDLC). For example, it has been shown that the addition of Au NPs to a PDLC microstructure lowers the operating voltage and increases transmission in a manner that depends on the concentration of the NPs and applied electric field.[2] We have extended these measurements to PDLCs synthesized with a different liquid crystalline material and doped with varying concentrations of the Au NPs. We discuss the electro-optical data on two different PDLCs as functions of the concentration of the Au NPs, as well as the polarization and intensity of the incident laser beam. We also present ideas to assess the role of the surface plasmon excitations in modifying the electro-optical properties of Au NPs containing PDLCs.

S1.00200 Fluorescence decay of CdSe nanoparticles in Liquid Crystals near Phase Transitions

, DARREN NORTH, SAMUEL BECK, JODIE GRAY, SHANE DRYE, Undergraduate Physics Research, CHANDRA PRAYAGA, LASZLO UJJ, Department of Physics, TIM ROYAPPA, Department of Chemistry — The liquid crystal 4'octyl-4-cyanobiphenyl (8CB) doped with cadmium selenide nanoparticles (Sigma-Aldrich) was injected into a commercially available liquid crystal cell (INSTEC, Inc). The cell was housed in a temperature controlled environment constructed in the lab and exposed to light from a frequency doubled pulsed Nd: YAG laser. The decay of fluorescence from the sample was measured at several temperatures over the range 25° to 45°C, covering the smectic-nematic and nematic-isotropic phase transitions. The sample was held at each temperature with a stability and resolution of 1mK before taking the measurement. The fluorescence was detected using a high-speed detector and the decay was measured using a boxcar averager. With the temperature control available, it was possible to approach very close to the phase transitions, with milliKelvin resolution. The results show a significant change in the decay of fluorescence near the nematic-isotropic phase transition.

S1.00201 Deformable viscoelastic cholesteric films with nanoparticles

, PETR SHIBAEV, CRISTINA SCHLESIER, Department of Physics, Fordham University, New York — Large spectral shifts of the selective reflection band and color changes are achieved in highly viscous mixture of cholesteric polymers and low molar mass liquid crystals filled with nanoparticles and subject to mechanical deformations. The color of the material changes instantaneously during deformation; the time for the color to be completely restored increased with the viscosity of the polymer mixture. The viscosity increases with increasing concentration of polymer or nanoparticles. This composite material was used to build highly sensitive mechanical sensor that was used to visualize both stress and deformation. The model describing the relation between the color and deformation is suggested. This model takes into account non-linear response to deformation and structural rearrangements inside the liquid crystalline matrix.

S1.00202 Specific heat at the micellization and phase transitions in a triblock copolymer-water system[1]

, LORENZO DUMANCAS, DAVID SIMPSON, D.T. JACOBS, The College of Wooster — The triblock copolymer ("unimer") of PPO-PEO-PPO (commercially known as 17R4) has hydrophobic ends and a hydrophilic center. When placed in water, a network of unimers can self-assemble at higher concentrations or temperatures to form micelles of different geometries. We have measured the micellization line marking the transition from only unimers in solution to some micelles. There is also a one- to two-phase transition at higher temperatures that is an Ising-like, LCST critical point. Specific heat measurements from our adiabatic calorimeter provide the enthalpy, entropy and free energy of micellization along the micellization line at different prepared compositions.

[1]We acknowledge the support from Research Corporation, NSF-REU grant DMR 0649112, and The College of Wooster.

S1.00203 Vesicle membrane fluctuations at nm resolution

, KEJIA CHEN, SUNG CHUL BAE, CHANG-KI MIN, STEVE GRANICK, University of Illinois at Urbana-Champaign, GRANICK GROUP TEAM — We measure membrane thermal fluctuations with nanometer spatial resolution and microsecond time resolution, extending a scattering technique used at the Curie Institute to study red blood cell dynamics (Timo Betz et al., Proc. Nat. Acad. Sci. USA 106, 15320, 2009). A laser beam is focused at the leading edge of a phospholipid vesicle membrane and the forward scattered light is detected by a quadrant photodiode. The measurements over 4 orders of magnitude of frequency allow quantification of more complete fluctuation spectra than competing methods, and therefore fuller understanding of the vesicle membrane mechanics. As a proof of concept, we quantify how adsorbed nanoparticles stiffen giant unilamellar vesicles (GUVs).

S1.00204 Interactions of End-Functionalized Nanotubes with Lipid Vesicles: Spontaneous Insertion and Nanotube Self-organization

, MEENAKSHI DUTT, OLGA KUKSENOK, University of Pittsburgh, MICHAEL NAYHOUSE, University of California at Los Angeles, STEVEN R. LITTLE, ANNA C. BALAZS, University of Pittsburgh — Via Dissipative Particle Dynamics (DPD) approach, we study the self-assembly of amphiphilic nanotubes into a lipid vesicle, which is immersed in a hydrophilic solvent. Individual lipids are composed of a hydrophilic head group and two hydrophobic tails. Each nanotube encompasses an ABA architecture, with a hydrophobic shaft (B) and two hydrophilic ends (A). To allow controlled transport through the nanotube, we also introduce hydrophilic tethers at one end of the tube. We show that nanotubes initially located in the outer solvent spontaneously penetrate the vesicle's membrane and assume a trans-membrane position, with the hydrophilic tethers extending from the surface of the vesicle. We add nanotubes one at a time after the previous nanotube has been inserted. We characterize the interactions among the nanotubes that have self-assembled into the vesicles' membrane and focus on their clustering within the membrane. We also show that the nanotube insertion and clustering within the vesicle strongly affects the vesicle shape in cases of a sufficiently large number of tubes. Ultimately, these nanotube-lipid systems can be used for making hybrid controlled release vesicles.

S1.00205 Electrospray fabrication and osmotic response of fluid core-viscoelastic shell microcapsules , ZHIYONG MENG, CHINEDUM OSUJI, Yale University — Microcapsules with fluid-core in viscoelastic shell is interesting partially because of their unusual elasticity/rigidity. Electrospray technique, more flexible and scalable than traditional bulk and microfluidic emulsification, was used to generate spherical microcapsules. In particular, sodium alginate fine droplets generated by electrospray was surface cross-linked by either Ca(II) or chitosan to form polyelectrolyte microcapsules. By adjusting the needle inner diameter, concentration of sodium alginate, and applied voltage, we can control the droplet size to the designated range. Furthermore, we can tune the thickness and thereby rigidity/elasticity of the viscoelastic shell by adjusting the residence time of microcapsules in gelation solution to control the rigidity/elasticity of microcapsules. These polyelectrolyte microcapsules were subject to the osmotic pressure of synthetic water-soluble polymers, such as poly(ethylene glycol), with progressively lower concentration to observe their osmotic swelling behavior.

S1.00206 Crossover Between 2D and 3D Fluid Dynamics in the Diffusion of Islands in Ultra-Thin Freely Suspended Smectic Films[1] , ZOOM NGUYEN, MARKUS ATKINSON, CHEOL PARK, JOSEPH MACLENNAN, MATTHEW GLASER, NOEL CLARK, University of Colorado-Boulder — fluid requires no force, leads, via the Einstein relation, to an infinite diffusion coefficient D for the disc. Saffman and Delbrück proposed that if the 2D fluid is a thin film immersed in a 3D viscous medium, then the film should behave as if it were of finite size, and $D \sim -\ln(a\eta')$, where a is the inclusion radius and η' is the viscosity of the 3D medium. By studying the Brownian motion of islands in freely suspended smectic films a few molecular layer thick, we verify this dependence using no free parameters, and confirm the subsequent prediction by Hughes, Pailthorpe and White of a crossover to 3D Stokes-like behavior when the diffusing island is sufficiently large.

S1.00207 Decoupling of ionic conductivity from the structural relaxation in ionic liquids , PHILIP GRIFFIN, Dept. of Physics and Astronomy, Univ. of Tennessee, ALEXANDER AGAPOV, Dept. of Polymer Science, Univ. of Akron, ALEXANDER KISLIUK, ALEXEI SOKOLOV, Dept. of Chemistry, Univ. of Tennessee and Chemical Sciences Division, ORNL — In numerous technological applications, notably battery technology, the need for a highly conductive ionic material is critical. Ionic liquids are well suited for these applications, but the fundamentals of their physical properties are still not well understood. To investigate the temperature dependence of the conductivity and structural relaxation in these systems, a combination of light scattering techniques as well as dielectric spectroscopy measurements were performed on the ionic liquid [C4mim][NTf2]. Combining these measurement techniques enables us to characterize the dynamics in a time window that spans more than twelve decades. Detailed analysis of our results shows that the temperature dependence of the conductivity decouples from that of the structural relaxation. Furthermore, the structural relaxation exhibits a dynamical crossover similar to that observed in many glass forming liquids, while the conductivity exhibits no sign of the crossover. Contrary to the traditional theory, these observations suggest that the mechanism controlling ionic conductivity in this system is different from the mechanism controlling structural relaxation.

S1.00208 Bistable Shear-Induced Alignment and Isotropy in Nematic Cylindrical Micelles , LOUIS MADSEN, KYLE G. WILMSMEYER, XIAOLIN ZHANG, Department of Chemistry and Macromolecules and Interfaces Institute, Virginia Tech, Blacksburg, VA 24061 — Wormlike micelles (WLMs), such as cetyltrimethylammonium bromide in water, are long flexible cylinders of surfactant molecules that self-assemble as a function of concentration and temperature. By placing a driven rheological cell into an NMR instrument, we use "rheo-NMR" to correlate molecular-scale to micron-scale details available by NMR with macroscopic behaviors, with precise control over the sample shear rate. We directly observe alignment of WLMs induced by shear and magnetic field, as well as anisotropic diffusion, providing us with a nematic phase diagram that is modulated by shear. Here we focus on conditions where WLMs do not spontaneously field align (at 9.4 T), but rapidly and stably field align after application of shear. This "bistable" fluid persists in either the isotropic state or the field aligned state (after shearing) for $>$ 12 hrs. We will further describe measurements of the nonlinear dynamics of director reorientation, with which we quantify anisotropic elastic constants and viscosities.

S1.00210 Measuring the Nonergodicity in Glasses by Ensemble-Averaged Photon Correlation Spectroscopy[1] , ERIC SVINGEN, DAVID SIDEBOTTOM, Creighton University — Although dynamic light scattering is used to monitor the dynamics of glass-forming liquids above the glass transition temperature, in the glass phase the absence of ergodicity results in a partial arrest of these dynamics and traditional time-averaged measures fail to monitor the remaining dynamics. Instead, scattering data must be processed in an ensemble-averaged manner by integrating the scattering from multiple regions by slowly translating the sample. We report studies of glass-forming 2Ca(NO3)2:3KNO3 (CKN) obtained below the glass transition temperature using a motorized translation system. Our findings will be used to assess the temperature dependence of the so-called nonergodic level that is predicted by certain mode-coupling theories to exhibit "cusp" near the mode coupling critical temperature.

S1.00211 Direct imaging of spatially and temporally heterogeneous two-state dynamics on metallic glass and amorphous silicon surfaces well below T_g[1] , SUMIT ASHTEKAR, GREGORY SCOTT, JOSEPH LYDING, MARTIN GRUEBELE, University of Illinois Urbana Champaign — Probing glassy dynamics of atomic glass formers with atomic resolution far below the glass transition has remained elusive due to the long waiting times and the small length scales involved. Here we report atomic resolution movies acquired using time-lapse scanning tunneling microscopy on metallic glass and amorphous silicon (a-Si) surfaces at room temperature well below their respective glass transition temperatures (Tg of glasses studied lie between 600-1000K). We find the clusters on metallic glass surfaces with size 2-8 atomic spacings exhibit dynamics which are almost exclusively two-state ($P_{3-state} \sim 0.06$) [1]. The two-state dynamics was found to be both spatially and temporally heterogeneous. We attribute the two-state dynamics to the secondary β relaxations which remains active well below the glass transition. Similar dynamics were found on amorphous silicon surfaces providing the first evidence for the existence of glass-like dynamics on pure a-Si surfaces at non-cryogenic temperature.

S1.00212 Frequency Dependence of Aging Dynamics in a Colloidal Glass , AJAY NEGI, CHINEDUM OSUJI, Yale University — The aging response of glassy particulate systems originates due to slow structural rearrangements of its constituent matter. It is reasonable to speculate that structural rearrangements on different length scales should manifest themselves in dynamical response on different timescales. Here we consider the frequency dependence of aging in a colloidal glassy system using parallel superposition bulk rheology. The aging behavior of the system is characterized by time evolution of the complex modulus in response to a sinusoidally varying probe stress of different frequencies superimposed on a steady background stress. Strikingly, the system displays more rapid aging when observed at smaller frequencies. This suggests that, by comparison, it is more arrested on shorter length scales (higher frequencies) than on the longer length scales where many-particle correlated motions are in effect. Such correlated motions are believed to be responsible for relaxation in glassy materials. The variation in the aging dynamics at different frequencies is more prominent at higher background stresses where the system is more fluidized.

S1.00213 Scaling, clustering and avalanches for steel beads in an external magnetic field[1] , ALYSE MARQUINEZ, INGRID THVEDT, S.Y. LEHMAN, D.T. JACOBS, The College of Wooster — We investigated avalanches using uniform 3mm steel spheres ("beads") dropped onto a conical bead pile within a uniform magnetic field. The bead pile is built by pouring beads onto a circular base where the bottom layer of beads had been glued randomly. Beads are then individually dropped from a fixed height after which the pile is massed. This process is repeated for thousands of bead drops. By measuring the number of avalanches of a given size that occurred during the experiment, the resulting avalanche size distribution was compared to a power law description as predicted by self-organized criticality. As the magnetic field intensity increased, the beads clustered to give a larger angle of repose and we measured the change in the avalanche size distribution. The moments of the distribution give a sensitive test of mean-field theory as the universality class for these bead piles.

S1.00214 Particle trajectories in 2D granular avalanches with imposed vibrations , NORA SWISHER, BRIAN UTTER, James Madison University — We study particle trajectories of photoelastic grains in a 2D circular rotating drum subjected to imposed vertical vibrations in order to characterize the jamming behavior of granular materials. Jamming appears in many systems (grain silos & chutes, landslides, mixing industrial materials, etc.) and vibration (granular temperature) is a primary factor in the jamming/unjamming transition. Images are taken and each particle's position is found for every frame then compared between frames to find the velocities. Particle tracking allows us to quantitatively measure the flow and mixing properties in our experiment. We present data on avalanching statistics, mean flow, the width of the shear band, and properties related to mixing (fluctuations and trajectories of neighboring grains). We find that vibrations induce more rearrangements of the grains and cause the pile of grains to become more compact over time. At constant peak acceleration we find that low frequency/high amplitude caused more grain movement than high frequency/low amplitude in both the stationary and rotating case.

S1.00215 Submerged granular flow of hydrophobic and hydrophilic sand , BEN FOLTZ, BRIAN UTTER, James Madison University — We experimentally investigate submerged granular flows of hydrophobic and hydrophilic grains in a rotating drum. While slurry and suspension flows are common in nature and industry, effects of surface chemistry on flow behavior have received little attention. The experiment consists of a cylindrical drum containing various concentrations of hydrophobic and hydrophilic grains of sand submerged in water and rotated at a constant angular velocity. Images of the resulting avalanches are taken and analyzed. While it is known that at slow speeds, submerged avalanches appear qualitatively similar to dry flows, our results suggest that the surface properties of the grains affect underwater flow significantly. High concentrations of hydrophobic grains result in the formation of aggregates. At concentrations larger than 75% hydrophobic sand, the avalanches do not behave in a manner which is typical for sand, but as the concentration decreases, the aggregates are smaller, the angle of repose decreases, and the grains start showing properties similar to those in regular sand. We present data on the size of the aggregates, slope, and avalanche statistics with changes in concentration.

S1.00216 Phase transition of colloidal particles on curved surfaces , GUANGNAN MENG, JAYSON PAULOSE, DAVID NELSON, Department of Physics, Harvard University, VINOTHAN MANOHARAN, Department of Physics and School of Engineering and Applied Sciences, Harvard University — Defects and disclinations have to appear in crystalline domains on a curved surface with non-zero Gaussian curvature. These geometrical frustrations can qualitatively change the physics of phase transition. We encapsulate micron sized polystyrene (PS) colloidal particles within emulsion droplets and use nanometer sized polyNIPAM hydrogel particles to introduce depletion attraction between PS particle and interface, as well as between PS particles. We use this experimental model system and confocal microscopy to study phase transitions on curved surfaces. We will present both experimental phenomena and theoretical analysis.

S1.00217 Self and Directed Assembly of Thin Metallic Films exposed to Pulsed Laser Irradiation , YUEYING WU, U. Tennessee, JASON FOWLKES, ORNL, PHILIP RACK, U. Tennessee, LOU KONDIC, NJIT, JAVIER DIEZ, UNCPBA — The synthesis and assembly of functional metallic nanomaterials is critical for realizing many important applications of nanoscience and nanotechnology. In this study, we investigate dewetting of metal films via pulsed nanosecond laser melting. We study film instabilities that result from the interplay of capillary forces and liquid-solid interaction, which can lead to thin film break-up and subsequent nanoparticle formation. We have also explored the dewetting and nanopattern formation of other liquid metal geometries, such as rings and lines. We will discuss how nano-lithographically defined features can be used to direct the assembly of nanoparticles with desired properties, concentrating in particular on the role of stochastic fluctuations.

S1.00219 Fabrication and Characterization of High Aspect Ratio Membranes and Microporous Filters made from PMMA , ALEX BURANT, Dept. of Physics and Astronomy, James Madison University, Harrisonburg, VA, BRIAN AUGUSTINE, Dept. of Chemistry and Biochemistry, James Madison University, Harrisonburg, VA, CHRIS HUGHES, Dept. of Physics and Astronomy, James Madison University, Harrisonburg, VA — This experiment shows a new way to create high aspect ratio membranes and microporous filters by curing a liquid monomer, methyl methacrylate (MMA), into poly(methyl methacrylate) (PMMA) structures. Holes were cut in 200 μm PMMA sheets by laser cutting. Membranes were made by filling these holes with wax and cooling until the wax solidified. The liquid monomer solution was flowed over the wax-filled holes and photopolymerized to make a thin membrane. The membrane thickness could be controlled by adding 3-10 μm, 30-50 μm, or 50-100 μm silica beads to the monomer solution. Filters were made by filling the holes with curing solution containing 3-10 μm beads, photopolymerizing, and etching the silica with hydrofluoric acid. The filter porosity could be controlled by varying the weight percentage of silica beads added to the monomer solution. Scanning electron microscopy was used as a method for characterizing both membrane thickness and filter porosity.

S1.00220 Enhanced shear separation for chiral magnetic colloidal aggregates[1] , CARLOS MENDOZA, Materials Research Institute, UNAM, CARLOS MARQUES, FABRICE THALMANN, Institute Charles Sadron — We study the designing principles of the simplest colloidal propeller, an architecture built from four identical spheres that can couple translation with rotation to produce controlled drift motion. By considering superparamagnetic beads, we show that the simultaneous action of a magnetic field and a shear flow leads to the migration of the cluster in the vorticity direction. We investigate the dependence of the migration velocity on the geometrical parameters of the cluster, and find that significant cluster separation can be achieved under the typical operation conditions of microfluidic devices. S1.00221 Numerical Analysis of Micromixers for Optimization of Mixing Action[1]

, YOGENDRA PANTA, PARAM ADHIKARI, Department of Mechanical Engineering, Youngstown State University — Micro-bio/chemical applications often require rapid and uniform mixing of a number of fluid streams that carries bio/chemical species in the solution. At microscale, fluid flow is highly laminar with low Reynolds number, fluids mixing mechanism is primarily by diffusion and free from any turbulence. Demand for highly efficient micromixers for microfluidic networks is due to slower mixing process for larger bio-molecules such as peptides, proteins, and nucleic acids compared to micro-scale molecules. Passive and active mixers are two basic mixers that are currently in use for these applications. Passive mixers often require very long mixing channels where are most active mixers require bulky moving parts to stir the fluids. In this study, electroosmotic effects orthogonally aligned with the fluid flowstream are utilized for optimum mixing effect in various micromixers. Cross-dependencies among several geometrical, electrical, and fluid parameters and their significance are studied in order to achieve an optimum mixing effect. It has been planned to optimize the mixer by non-moving stirring actions provided by an external magnetic field.

S1.00222 A multiscale model for nanoparticle binding dynamics under shear flow

, YALING LIU, JIFU TAN, Lehigh University, KYTAI NGUYEN, University of Texas at Arlington — Nanomedicine poses a new frontier in medical technology with the advantages of targeted delivery and patient specific design. In applications of nanoparticle targeted drug delivery, the delivery efficiency is controlled by the physical properties of the nanoparticle such as its size, shape, ligand density, as well as external environmental conditions such as blood flow rate, blood vessel diameter. Proper drug dosage choice relies on determination of the attachment and detachment rates of the nanoparticles at the active region and the understanding of the complex process of targeted drug delivery. A few particulate models have been proposed to study the adhesion probability of individual spherical or non-spherical nanoparticles. Meanwhile, continuum convection-diffusion-reaction models have been widely used to calculate the drug concentration, which usually assumes specific binding and de-binding constants. However, there has not been any study that links the particulate level nanoparticle size and shape information to the system level bounded particle concentration. A hybrid particle binding dynamics and continuum convection-diffusion-reaction model is presented to study the effect of shear flow rate and particle size on binding efficiency. The simulated concentration of bounded nanoparticles agrees well with experimental results in flow chamber studies.

S1.00223 Modeling spreading of nematic droplets[1]

, TE-SHENG LIN, LINDA CUMMINGS, LOU KONDIC, New Jersey Institute of Technology — Experiments by Poulard & Cazabat[2] on spreading droplets of nematic liquid crystal reveal a surprisingly rich variety of behavior, including at least two different emerging lengthscales resulting from a contact line instability. In earlier work[3] we modified a lubrication model for nematic liquid crystals due to Ben Amar and Cummings[4], and showed that, in a qualitative sense, it can account for much of the observed behavior. In the present work we propose a new approach, that allows us to explore the effect of anchoring variations on the substrate. This in turn gives a simple way to model the presence of defects, which are always present during such liquid crystal flows. The new model leads to additional terms in the governing equation. We first explore the influence of these additional terms for some simple flow scenarios, to gain a basic understanding of their influence, before extending our simulations to the experimental geometry and comparing our results to the experiments.

S1.00224 Drop evaporation and triple line dynamics

, BENJAMIN SOBAC, DAVID BRUTIN, Université de Provence, JEROME GAVILLET, CEA LITEN, UNIVERSITÉ DE PROVENCE TEAM, CEA LITEN TEAM — Sessile drop evaporation is a phenomenon commonly came across in nature or in industry with cooling, paintings or DNA mapping. However, the evaporation of a drop deposited on a substrate is not completely understood due to the complexity of the problem. Here we investigate, with several nano-coating of the substrate (PTFE, SiOx, SiOc and CF), the influence of the dynamic of the triple line on the evaporation process. The experiment consists in analyzing simultaneously the motion of the triple line, the kinetics of evaporation, the internal thermal motion and the heat and mass transfer. Measurements of temperature, heat-flux and visualizations with visible and infrared cameras are performed. The dynamics of the evaporative heat flux appears clearly different depending of the motion of the triple line

S1.00225 Nanoscale heterogeneity in alkyl-methylimidazolium bromide ionic liquids

, DAVID PRICE, BACHIR AOUN, MARIE-LOUISE SABOUNGI, ANDREAS GOLDBACH, MIGUEL A. GONZÁLEZ, SHINJI KOHARA — High-energy x-ray diffraction measurements on 1-alkyl-3-methylimidazolium bromide ionic liquids with ethyl, butyl and hexyl alkyl chains reveal a peak at low scattering vector Q that rises and moves to lower Q with increasing chain length. Atomic molecular dynamics simulations, which give results in excellent agreement with the x-ray data, show that this behavior is most pronounced in the partial structure factor for the tails of the alkyl chains but is also seen in those for the imidazolium ring centers and anions. The heterogeneity with a length scale of 1.9 nm established for the liquid with the hexyl chain is quantified by a density heterogeneity order parameter that shows a clustering of the tails. Our results are consistent with explanations in the literature of the increase in viscosity with alkyl chain length in terms of nanoscale segregation.

S1.00226 On segregation of noble gases in water-based Single Bubble Sonoluminescence

, MOGENS LEVINSEN, Niels Bohr Institute, Univ. of Copenhagen — A long-standing issue in the field of long time stable water based single bubble sonoluminescence has been the close similarity of the spectra to that of blackbody radiation. Looking for the effects of possible segregation of noble gases has been suggested as a means to investigate whether the similarity is just a weird coincidence with the bubbles being on the whole transparent to their own radiation. We have investigated spectra from bubbles seeded with various mixtures of helium and neon with xenon and argon using a novel transformation that allows for a single parameter characterization of the spectra, with the surprising result that although no trace of segregation is found, the radiation seems to be highly thermalized in all cases.

S1.00227 Generating a Pulsatile Pulmonary Flow after Fontan Operation by Means of Computational Fluid Dynamics (CFD)
