12:03PM W45.00005 Pulsed Counter-Rotating Source of Slow, Cold Molecules , IGOR LYUKSYUTOV, LES SHEFFIELD, MARK HICKEY, VITALIY KRASOVITSKIY, DAYA RATHNAYAKA, Department of Physics and Astronomy, Texas A&M University, DUDLEY HERSCHBACH, Department of Chemistry and Chemical Biology, Harvard University — We describe the performance of a new design of the counter-rotating source (CRS) of slow molecules introduced originally by Gupta and Herschbach. The CRS produces a supersonic expansion from a nozzle near the tip of a hollow rotor spun at high speed contrary to the exit beam velocity. Thereby the lab velocity can be markedly reduced. Introducing a pulsed feeding system, cryo-cooling, and shutter system has eliminated the main problem of the original CRS apparatus, in which continuous gas flow imposed high background pressure. The new version provides intense pulses, typically of duration 0.1 ms with lab speeds as low as 40 m/s and longitudinal temperature as low as 0.5 K. This device can, in principle, decelerate (or accelerate) any molecule available as a gas; we report experiments producing slow beams of krypton, oxygen, ammonia, and nitrogen dioxide.

12:15PM W45.00006 Nanofriction in Cold Ion Traps , ANDREA VANOSSI, ANDREA BENASSI, International School for Advanced Studies (SISSA), and CNR-IOM DEMOCRITOS, ERIO TOSATTI, International School for Advanced Studies (SISSA), CNR-IOM DEMOCRITOS, and ICTP — Sliding friction between crystal lattices and the physics of cold ion traps are so far non-overlapping fields. Two sliding lattices may either stick and show static friction or slip with dynamic friction; cold ions are known to form static chains, helices, or clusters, depending on trapping conditions. Based on simulations, we show that much could be learnt about friction by sliding (e.g., via an electric field) the trapped ion chains over a periodic corrugated potential. Unlike infinite chains where, according to theory, the classic Aubry transition to free sliding may take place, static pinning always shows up in trapped chains. Nonetheless we find that a properly defined static friction still vanishes Aubry-like at a symmetric-asymmetric structural transition, ubiquitous for decreasing corrugation in both straight and zig-zag trapped chains. Dynamic friction can also be addressed by ringdown oscillations of the ion trap. Long theorized static and dynamic one dimensional friction phenomena could thus become exquisitely accessible in future cold ion tribology.

12:27PM W45.00007 Pattern formation with trapped ions , TONY LEE, MICHAEL CROSS, California Institute of Technology — We propose an experiment to study collective behavior in a nonlinear medium of trapped ions. Using laser cooling and heating and an anharmonic trap potential, one can turn an ion into a nonlinear van der Pol-Duffing oscillator. A chain of ions interacting electrostatically has stable plane waves for all parameters. The system also behaves like an excitable medium, since a sufficiently large perturbation generates a travelling pulse. Small chains exhibit multistability and limit cycles. We account for noise from spontaneous emission in the amplitude equation and find that the patterns are observable for realistic experimental parameters. The tunability of ion traps makes them an exciting setting to study nonequilibrium statistical physics.

12:39PM W45.00008 Spontaneous emission modification via quantum interference with energy shifts remained , SHUAI YANG, Institute for Quantum Studies and Department of Physics, Texas A&M University, College Station, Texas 77843, USA, SHI-YAO ZHU, Beijing Computational Science Research Center, Beijing, 100084, China, M. SUHAIL ZUBAIRY, Institute for Quantum Studies and Department of Physics, Texas A&M University, College Station, Texas 77843, USA — Quantum interference in spontaneous emission from a four-level atom is investigated with the counter rotating terms and the energy shifts included. The atom has two upper levels coupled to a common lower level by the same vacuum modes and is driven by a coherent field to an auxiliary level. The effect of the counter rotating terms in coupling through the vacuum modes is taken into account by a unitary transformation method. We show how the quantum interference due to the energy shifts effects the spontaneous emission spectrum.

12:51PM W45.00009 Optical chirality and superchiral fields , YIQIAO TANG, Department of Physics, Harvard University — A chiral object is any material body whose mirror image may not be superimposed on the original. Electromagnetic (EM) fields may be chiral too, with circularly polarized light as the paradigmatic example. We propose a measure of the local chirality of EM fields, which we call optical chirality. Optical chirality determines the degree of chiral asymmetry in the interaction of light with small molecules. We predict the existence of superchiral forms of light which show larger bias for exciting a single chiral enantiomer, in some regions of space, than does circularly polarized plane waves. We performed a conceptually simple experiment to probe the interaction of superchiral light with a chiral biperylene derivative. We selected this molecule for its strong intrinsic optical activity and fluorescence in the visible. The regions of enhanced chiral selectivity are too thin to detect by absorption, so we used fluorescence instead. We demonstrated experimentally a 12-fold enhancement in the chiral selectivity of superchiral fields for these chiral compounds. The demonstrated chiral enhancement is not a fundamental limit. Larger enhancement may be obtained at the expense of lower overall excitation rate. These results establish that optical chirality is a fundamental property of the electromagnetic field, with possible applications ranging from plasmonic sensors to absolute asymmetric synthesis.

1:03PM W45.00010 Observation of a Red-Blue Detuning Asymmetry in Matter-Wave Superradiance , LU DENG, EDWARD W. HAGLEY, NIST, QIANG CAO, XIAORUI WANG, XINYU LUO, RUQUAN WANG, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, MARVIN G. PAYNE, NIST, FAN YANG, XIAOJI ZHOU, School of Electronics Engineering & Computer Science, Peking University, Beijing 100871, China, XUZONG CHEN, MINGSHENG ZHAN, State Key Laboratory of Magnetic Resonance and Atomic and Molecular Physics, Wuhan Institute of Physics and Mathematics, Chinese Academy of Sciences — We report the first experimental observation of strong suppression of matter-wave superradiance using blue-detuned pump light and demonstrate a pump-laser detuning asymmetry in the collective atomic recoil motion. In contrast to all previous theoretical frameworks, which predict that the process should be symmetric with respect to the sign of the detuning of the pump laser from the one-photon resonance, we find that for condensates the symmetry is broken. With high condensate densities and red-detuned pump light the distinctive multi-order, matter-wave scattering pattern is clearly visible, whereas with blue-detuned pump light superradiance is strongly suppressed. However, in the limit of a dilute atomic gas symmetry is restored.

1:15PM W45.00011 Large and rapidly-responding Kerr nonlinear phase shift using a four-level N-scheme with an active Raman gain core , KE LI, LU DENG, NIST — We report rapidly-responding Kerr nonlinear phase shift using a long pencil-shaped cold ^{85}Rb atom samples. Our system is a four-level N-scheme based on both the D1 and D2 transition lines of Rb atom. The nonlinear phase shift and nonlinear optical index of the cold medium are studied using an interferometric method for various pump and phase-inducing laser intensities.

1:27PM W45.00012 Experimental Observation of Carrier-Envelope Phase Effects in Multi-Cycle Pulses[1] , PANKAJ JHA, Texas A&M University, YURI ROSTOVTSEV, University of North Texas, HEBIN LI, VLADIMIR SAUTENKOV, Texas A&M University, MARLAN SCULLY, Texas A&M University and Princeton University — Using intense RF pulses interacting with the magnetic Zeeman sub-levels of Rubidium (Rb) atoms, we have experimentally and theoretically shown the CEP effects in the population transfer between two bound atomic states interacting with pulses consisting of many cycles (up to 15 cycles) of the field. It opens several exciting applications and interesting possibilities that can be easily transfer to optical range and enhance current and create new set of tools to control CEP of laser pulses. These tools allow researchers to improve laser systems that generate laser pulses with better reproducibility and accuracy and better controlled. Also the tools provide an additional handle to control the process of collisions, and the current approach of extending the duration of the pulses with measurable or controllable CEP allows researchers to extend the coherent control to a new level where they are able to study molecular collisions or electron collisions in nano-structures under the action of strong electromagnetic fields with known CEP. In particularly, the obtained results can be applied to control of chemical reactions.

1:39PM W45.00013 Counter-Propagating Coherent Stimulated Raman Spectroscopy for Remote Sensing in Air , LUQI YUAN, Texas A&M University, ANDREW TRAVERSO, DMITRI VORONINE, PANKAJ JHA, KAI WANG, ALEXEI SOKOLOV, MARLAN SCULLY — We analyze phase-matching conditions in various four-wave mixing schemes for coherent nonlinear optical spectroscopy in the counter-propagating beam configuration. Coherent stimulated Raman spectroscopy satisfies the conditions and gives a signal containing specific molecular spectroscopic information. A counter-propagating broadband and a narrowband pulses are used to measure the Raman spectrum with a single shot. In addition, the nonresonant background due to the nondegenerate four-wave mixing is suppressed. Using this technique we develop a new scheme for standoff spectroscopy in atmosphere by using nitrogen molecules in air as a gain medium for remote lasing.

1:51PM W45.00014 Efficient Backward Emission from Optically Pumped Air , ANDREW TRAVERSO, RODRIGO SANCHEZ-GONZALEZ, MICHAEL GRUBB, DMITRI VORONINE, KAI WANG, LUQI YUAN, Texas A&M University, ALEXEI ZHELTIKOV, Texas A&M University/Moscow State University, ARTHUR DOGARIU, JAMES MICHAEL, RICHARD MILES, Princeton University, VLADIMIR SAUTENKOV, ALEXEI SOKOLOV, SIMON NORTH, Texas A&M University, MARLAN SCULLY, Texas A&M University/Princeton University — We demonstrate the generation of backwards emitted coherent light in atmosphere via optical pumping. The backwards emitted light is narrow band centered at 845 nm and is generated from the dissociation of molecular oxygen and then subsequent two photon excitation of these newly dissociated oxygen atoms. Both the dissociation and excitation of oxygen are driven by a single 226 nm $\sim$10 nanosecond pulsed pump beam. The produced 845 nm light is a pulse approximately 10 nanosecond in duration and not only exhibits threshold characteristics, but is also nearly diffraction-limited. This optically-pumped mirror-less light source which propagates back towards the pump source presents a unique opportunity to develop new techniques for remote sensing.

2:03PM W45.00015 Quantum lithography beyond the diffraction limit via Rabi-oscillations[1] , ZEYANG LIAO, Institute for Quantum Studies and Department of Physics and Astronomy, Texas A&M University, College Station, TX 77843-4242, USA, MOHAMMAD AL-AMRI, The National Center for Mathematics and Physics, KACST, P.O.Box 6086, Riyadh 11442, Saudi Arabia, M. SUHAIL ZUBAIRY, Institute for Quantum Studies and Department of Physics and Astronomy, Texas A&M University, College Station, TX 77843-4242, USA — We propose a quantum optical method to do the sub-wavelength lithography. Our method is similar to the traditional lithography but adding a critical step before dissociating the chemical bound of the photoresist. The subwavelength pattern is achieved by inducing the multi-Rabi-oscillation between the two atomic levels. The proposed method does not require multiphoton absorption and the entanglement of photons. This method is expected to be realizable using current technology.

Session X1 DCMP: Quantum and Classical Phenomena in Josephson Junction Arrays Ballroom A1

2:30PM X1.00001 Quantum Coherence of the Fluxonium Superconducting Artificial Atom

, MICHEL DEVORET, Yale University — Artificial atoms built from superconducting tunnel junctions illustrate the problem of engineering a controllable electrodynamic quantum system, starting from basic elements. Can circuit architecture mitigate or even eliminate coherence limitations due to defects in the basic electrical constituents? This central question will be discussed from the perspective of recent experimental results of our group, obtained on the fluxonium[1], a novel superconducting quantum circuit. It consists of a Cooper-pair box junction which is shunted by a long array of larger junctions. Immunity to offset charge noise and only a weak sensitivity to flux noise is observed for the qubit transition. The combination of the very large inductance of the array, which has negligible parasitic resistance, and large phase fluctuations of the small junction, distinguishes fundamentally the fluxonium from the flux qubit. Significant improvement of the relaxation time has been obtained, when one compares with qubits of the same family. Finally, fluxonium displays the type of 3-level-atom physics which should prove useful for continuous, high-fidelity monitoring of a state. Work supported by the IARPA, ARO and NSF.

3:06PM X1.00002 Measurement of Quantum Phase-Slips in Josephson Junction Chains[1]

, WIEBKE GUICHARD, Joseph Fourier University — Quantum phase-slip dynamics in Josephson junction chains could provide the basis for the realization of a new type of topologically protected qubit [1] or for the implementation of a new current standard [2]. I will present measurements of the effect of quantum phase-slips on the ground state of a Josephson junction chain. We can tune in situ the strength of the phase-slips. These phase-slips are the result of fluctuations induced by the finite charging energy of each junction in the chain. Our measurements demonstrate that a Josephson junction chain under phase bias constraint behaves in a *collective* way [3]. I will also show evidence of coherent phase-slip interference, the so called Aharonov-Casher effect. This phenomenon is the dual of the well known Aharonov-Bohm interference.

3:42PM X1.00003 Coherent Terahertz Emission of Intrinsic Josephson Junction Stacks in the Hot Spot Regime[1]

, REINHOLD KLEINER, Physics Institute, University of Tuebingen, D72076 Tuebingen, Germany — Having small sized active and tunable devices operating at frequencies up to the Terahertz (THz) range is one of the goals of modern electronics. However, there is still a lack of good active or passive devices, often referred to as the "Terahertz gap." Intrinsic Josephson junctions formed by the layered crystal structure of high temperature superconductors such as $Bi_2Sr_2CaCu_2O_8$ have the potential to operate in this regime. While for a long time the research on THz generation with this type of junctions was carried out with perhaps only modest success, recently synchronous emission, with an estimated output power in the μW range, of stacks consisting of several hundred intrinsic Josephson junctions was achieved [1]. We report on the investigation of THz electromagnetic wave generation in intrinsic junction stacks (mesas) of different geometries, using a combination of transport measurement, direct electromagnetic wave detection and Low Temperature Scanning Laser Microscopy [2,3]. At high enough input power a hot spot (a region heated to above the superconducting transition temperature) coexists with regions being still in the superconducting state. In the "cold" regions cavity resonances can occur, synchronizing the ac Josephson currents and giving rise to strong and stable coherent THz emission. We discuss possible scenarios of the hot spot/wave interaction and its relation to the generation of coherent THz radiation.

4:18PM X1.00004 Vortex pinning in ferromagnet-superconductor bilayer with tunable domain patterns[1]

, MARTA Z. CIEPLAK, Institute of Physics, Polish Acad. Sciences — Ferromagnet superconductor hybrids provide a fascinating example of systems in which there is a rich interplay between two seemingly incompatible collective phenomena. Particularly interesting is the impact of the ferromagnet on the dynamics of vortices in the superconductor. The magnetic domains control the location of the vortices. Exquisite control of the dynamics can be achieved by careful tuning of the geometry of the magnetic domains. In this talk I will present the results of recent experiments on superconductor(S)-ferromagnet(F) bilayers with a focus on understanding the hitherto unexplained seemingly unpredictable dependence of the critical current density on the parameters of the experiment. In our experiments the S layer is made of niobium, the F layer is a Co/Pt multilayer with perpendicular magnetic anisotropy, and a thin insulating layer in-between eliminates proximity effect. We use various demagnetization procedures to define different domain patterns in the F layer. We show that some domain patterns produce highly inhomogeneous flux penetration and strong vortex confinement at the sample edge, while for others there is remerkable enhancement of the critical current density in excess of 15. This is the highest value reported to date. We have measured, for the first time in a single tunable structure, the dependence of the activation energy for vortex pinning on the domain width, temperature, and magnetic field. In collaboration with L.Y. Zhu, X. M. Cheng and C. L. Chien (Johns Hopkins), Z. Adamus (Polish Acad. Sci.) and M. Konczykowski (Ecole Polytechnique).

4:54PM X1.00005 Tuning superconductivity by carrier injection

, PAUL MÜLLER, Department of Physics, University of Erlangen, Germany — All high-T_c cuprates are stacking sequences of CuO_2 layers and charge reservoir layers consisting of metal oxides. Upon doping the CuO_2 layers, antiferromagnetic order is destroyed and metallic conductivity is established. Usually doping is achieved by a non-stoichiometric composition of the charge reservoir layer. However, we already have shown that we can change the carrier concentration of $Bi_2Sr_2CaCu_2O_{8+\delta}$ single crystals by current injection along the c- axis [1]. Critical temperature, c-axis resistivity and critical current of intrinsic Josephson junctions can be tuned in a large range from underdoping to extreme overdoping. This effect is persistent up to annealing temperatures of approximately 270 K. Using current injection at higher bias, we were able to reduce the carrier concentration again. We investigated in detail the superconducting properties by performing macroscopic quantum tunneling experiments of intrinsic Josephson junctions. The experiments have been carried out repeatedly on samples, whose properties were changed only by current injection. An exponential increase of the critical current density with hole concentration was observed. At the same time, the capacitance of intrinsic Josephson junctions increased significantly. Finally, only by current injection, we were able to convert into the superconducting state a nonsuperconducting, oxygen depleted sample. This work was done in collaboration with Y. Koval, X.Y. Jin, S. Probst, Y. Simsek, C. Steiner (Universität Erlangen), H. B. Wang (NIMS, Tsukuba), and G. Behr, B. Büchner (IFW Dresden).

Thursday, March 24, 2011 2:30PM - 5:30PM –

Session X2 DCMP: Coexistence Between Antiferromagnetism and Superconductivity in Fe-pnictides Ballroom A2

2:30PM X2.00001 Competing phases in the iron pnictides[1] , RAFAEL FERNANDES, Ames Laboratory and Iowa State University, Ames, IA 50011, USA — In this work, we present a theoretical model that consistently describes the interplay between the magnetic, elastic, and superconducting degrees of freedom of the iron pnictides, comparing our results to several experimental observations. First, we show that the outcome of the competition between the antiferromagnetic (AFM) and the superconducting (SC) order depends on the symmetry of the pairing state. In particular, we demonstrate that a conventional phonon-mediated superconducting state cannot coexist microscopically with the itinerant magnetic phase [1,2]. We also show that the magneto-elastic coupling in these materials is mediated by Ising-nematic degrees of freedom, which emerge from the degeneracy of the magnetic ground state. As a result, in the tetragonal phase, nematic fluctuations lead to the *softening* of the lattice in the normal state but to its *hardening* in the SC state, due to the competition between SC and AFM [3]. Accordingly, in the orthorhombic phase, nematic order is suppressed below the SC transition temperature, causing the suppression of the orthorhombic order parameter [4].

3:06PM X2.00002 Superconductivity and Magnetism in iron-pnictides: co-existence or not? , ANTON VORONTSOV, Montana State University — In this talk I will review the weak-coupling approach to describe the interplay of two electronic orders: superconductivity (SC) in the form of Cooper pairs, and magnetism in the form of the spin-density waves (SDW). The two orders, traditionally thought as incompatible, are close neighbors in magnetically-active Fe-based superconductors with surprisingly high T_c. Complex multi-band structure, multiple interactions and many families of these materials create a range of possible states of mingling between superconductivity and magnetism. I will present a list of different parameters, including (a) the Fermi surface shape, (b) the order parameter structure, (c) the relative strength of SC and SDW interactions, (d) the external magnetic field, and describe which properties, or their combinations, lead to co-existence or avoidance of SC and SDW orders, and how transition between the two orders occurs upon doping.

3:42PM X2.00003 Superconductivity and magnetism in 111 iron pnictides[1] , SERGEY BORISENKO, Institute for Solid State Research, IFW-Dresden, Helmholtzstrasse 20, 01069, Dresden, Germany — We study different 111 materials at ultra low temperatures by means of angle-resolved photoemission spectroscopy (ARPES). The measurements provide a direct access to the information on the low energy electronic structure, which includes the detailed knowledge of the Fermi surface, band renormalization, electronic self-energy and symmetry of the superconducting order parameter. The results suggest a direct correlation between the fermiology and fundamental physical properties throughout the phase diagram of 111 iron superconductors. In particular, the Van Hove singularity is identified as playing a primary role for the superconductivity.

[1]The project was supported, in part, by the DFG under Grant No. BO 1912/3-1 within the framework of the priority program SPP1458.

4:18PM X2.00004 Antiferromagnetic phase in iron-based superconductors: selection of magnetic order, spin excitations, competition with superconductivity , ILYA EREMIN, Institue for Theoretical Physics III, Ruhr-University Bochum — Recent discovery of superconductivity in the iron-based layered pnictides with Tc ranging between 26 and 56K generated enormous interest in the physics of these materials. The superconductivity has been discovered in oxygen containing RFeAsO (R=La, Nd, Sm) as well as in oxygen free AFe2As2 (A=Ba, Sr, Ca). Like the cuprates, the pnictides are quasi-two-dimensional systems, their parent material shows antiferromagnetic long-range order below 150K and superconductivity occurs upon doping of either electrons or holes into the FeAs layers. In my talk I will analyze the properties of the magnetically ordered state. In particular, I will discuss the selection of the stripe magnetic order in the unfolded BZ within itinerant description. Selecting one hole and two electron pockets we find that SDW order is highly degenerate if electron pockets are circular and interactions involved are between holes and electrons only. Repulsive charge interactions between two electrons as well as ellipticity of the electron pockets break the degeneracy and select metallic (0, π) [(π,0)] SDW state in the unfolded BZ – the same order as seen in the experiments. I will argue that the SDW state remains a metal even for the case of a perfect nesting because one combination of the two hole operators and one combination of two electron operators decouple from the SDW mixing. We also demonstrate that the quasi-one-dimensional nanostructure identified in the quasiparticle interference (QPI) is a consequence of the interplay of the magnetic (π, 0) spin-density wave (SDW) order with the underlying electronic structure. Finally, we address the salient experimental features of the magnetic excitations in the spin-density-wave phase of iron-based superconductors. We use a multiband random-phase approximation treatment of the dynamical spin susceptibility. Weakly damped spin waves are found near the ordering momentum and it is shown how they dissolve into the particle-hole continuum. We show that ellipticity of the electron bands accounts for the anisotropy of the spin waves along different crystallographic directions and the spectral gap at the momentum conjugated to the ordering one. *Work done with A. 4:54PM X2.00005 Optical Investigations of the Superconducting State in 122 Iron-Pnictides[1] , DAN WU, Physikalisches Institut, Unversitat Stuttgart, Germany — The new high-Tc iron pnictide superconductors have a pronounced multiband character, which complicates the electronic properties and allows for a variety of possible superconducting ground states. We have used the infrared spectroscopy–one of the most powerful tools to investigate the low-energy electrodynamic properties of superconductors–to study several pnictide families. We made a comparison between them with the aim to answer the following questions: (1) Is it possible to have more than one superconducting gap in iron pnictide? (2) Can their order parameters be distinct from each other? (3) How does the coupling between different bands influence the gap? (4) Do the gaps have a three-dimensional character? (5) Is the gap scenario universal for all the iron pnictides? We could show that the pairing condition depends sensitively on the similarity of geometry and dimension between hole and electron Fermi-surfaces.

[1]The work was done in collaboration with N. Barisic, J. Carbotte, G. H. Cao, P. Gegenwart, B. Gorshunov, B. Holzapfel, E. Schachinger and Z. A. Xu.

Session X3 DCMP: Topological Vortices in Magnets, Ferroelectrics, and Multiferroics Ballroom A3

2:30PM X3.00001 Magnetic vortices: From a hidden parameter to novel switching modes , YVES ACREMANN, Solid State Physics, Physics Dept., ETH Zurich — This abstract not available.

3:06PM X3.00002 Skyrmion Lattices in Chiral Magnets , CHRISTIAN PFLEIDERER, Physik-Department, Technische Universitaet Muenchen, D-85748 Garching, Germany — Skyrmions are topologically stable field configurations with particle-like properties. Using neutron scattering and measurements of the Hall effect we identified the formation of two-dimensional lattices of skyrmion lines, a new form of magnetic order, in metallic and semiconducting B20 compounds, namely MnSi [1,2], $Mn_{1-x}Co_xSi$ [3], $Mn_{1-x}Fe_xSi$ [3] and $Fe_{1-x}Co_xSi$ [4]. The existence of individual skyrmions and skyrmion lattices has recently been confirmed by Lorentz force microscopy for $Fe_{1-x}Co_xSi$ ($x = 0.5$) [5]. The skyrmion lattices in chiral magnets share remarkable similarities with vortex lattices in type II superconductors – they may be understood as vortex lattices of transverse spin supercurrents exhibiting domain formation and complex morphologies. Our studies establish magnetic materials lacking inversion symmetry as an arena for new forms of order composed of topologically stable spin configurations.

3:42PM X3.00003 Skyrmion crystal and topological Hall effect in B20-type transition-metal compounds , YOSHINORI ONOSE, University of Tokyo — Topological objects in solids such as domain walls and vortices have been attracting much attention for long. Among them the spin texture called skyrmion is an unusual topological object, in which the spins point in all the directions wrapping a sphere. The skyrmion hosts finite spin chirality, and therefore is anticipated to induce novel electromagnetic phenomena such as topological Hall effect. In B20-type transition metal compounds MnSi and $Fe_{1-x}Co_xSi$, the crystallization of skyrmions was observed by the neutron diffraction studies.[1,2] Recently, we have observed the real-space images of skyrmion crystal in thin films of related compounds ($Fe_{0.5}Co_{0.5}Si$ and FeGe) using Lorentz transmission electron spectroscopy.[3,4] We have observed the hexagonal arrangement of skyrmions including the topological defects (chiral domains and dislocations) under the magnetic field normal to the films, and found that the two dimensional skyrmion crystal phase is fairly stabilized by the thin film form of the samples. We have also studied the topological Hall effect caused by the spin chirality of the skyrmion crystal in a related material MnGe. In terms of the Hall measurement, they have shown the real space nature of the fictitious magnetic field caused by the magnetic configuration of the skyrmion crystal, in contrast with the momentum-space fictitious field in another spin chirality system, $Nd_2Mo_2O_7$.[5] This work was done in collaboration with X. 4:18PM X3.00004 Multiferroic vortices in hexagonal manganites[1] , WEIDA WU, Department of Physics and Astronomy, Rutgers University — Hexagonal rare earth manganites ($RE MnO_3$) show a unique improper ferroelectricity induced by structural trimerization. Extensive research on these systems has been carried out due to its potential application in memory and the intriguing multiferroicity (coexistence of ferroelectricity and antiferromagnetism). However, the true relationship between ferroelectric domains and structural domains has never been revealed. Using transmission electron microscopy (TEM) and conductive atomic force microscopy (cAFM), we observed an intriguing conductive "cloverleaf" pattern of six domains emerging from one point, all distinctly characterized by polarization orientation and structural antiphase relationships in hexagonal manganites.[2] The nanoscale electric conduction between a sharp tip and the surface is intrinsically modulated by the ferroelectric polarization.[3] The cloverleaf defects are structural vortices where the phase angle goes successively through all six phases.[4] In addition, we discovered that the ferroelectric domain walls and structural antiphase boundaries are mutually locked. Correlated with previous observation of coupled ferroelectric and antiferromagnetic domain walls,[5] our results suggest that these cloverleaf defects are indeed multiferroic vortices. These fascinating results reveal the rich physics of the hexagonal system with a semiconducting bandgap where structural trimerization, ferroelectricity, magnetism and charge conduction are intricately coupled.

4:54PM X3.00005 Ferroelectric vortices from atomistic simulations[1] , LAURENT BELLAICHE, University of Arkansas — In 2004, the use of a first-principles-based effective Hamiltonian [1] led to the prediction of a novel structure in zero-dimensional ferroelectrics, in which the electric dipoles organize themselves to form a vortex [2]. Such structure exhibits the so-called spontaneous toroidal moment, rather than the spontaneous polarization, as its order parameter [2]. Subsequently, various original phenomena, all related to vortices, were predicted in ferroelectric nanostructures. Examples of such phenomena are: (i) the existence of a new order parameter, denoted as the hypertoroidal moment, that is associated with many complex dipolar structures (such as double-vortex states) [3]; (ii) the possible control of single and double vortex states by electric fields, via the formation of original intermediate states [4-8]; (iii) the discovery of a new class of quantum materials (denoted as incipient ferrotoroidics), for which zero-point vibrations wash out the vortex state and yield a complex local structure [9]; (iv) the existence of chiral patterns of oxygen octahedral tiltings that originate from the coupling of these tiltings with the ferroelectric vortices [10]. The purpose of this talk is to discuss some of these striking phenomena, as well as, to reveal others (if time allows). These studies are done in collaboration with A.R. Akbarzadeh, H. Fu, I. Kornev, I. Naumov, I. Ponomareva, S. Prosandeev, Wei Ren and D. Sichuga.

Thursday, March 24, 2011 2:30PM - 5:30PM –
Session X4 DPOLY: Functional Gels Ballroom A4

2:30PM X4.00001 Micromechanical study of mitotic chromosome structure[1] , JOHN MARKO, Northwestern University — Our group has developed micromanipulation techniques for study of the highly compacted mitotic form of chromosome found in eukaryote cells during cell division. Each metaphase chromosome contains two duplicate centimeter-long DNA molecules, folded up by proteins into cylindrical structures several microns in length. Native chromosomes display linear and reversible stretching behavior over a wide range of extensions (up to 5x native length for amphibian chromosomes), described by a Young modulus of about 300 Pa. Studies using DNA-cutting and protein-cutting enzymes have revealed that metaphase chromosomes behave as a network of chromatin fibers held together by protein-based isolated crosslinks. Our results are not consistent with the more classical model of loops of chromatin attached to a protein-based structural organizer or "scaffold". In short, our experiments indicate that metaphase chromosomes can be considered to be "gels" of chromatin; the stretching modulus of a whole chromosome is consistent with stretching of the chromatin fibers contained within it. Experiments using topoisomerases suggest that topological constraints may play an appreciable role in confining chromatin in the metaphase chromosome. Finally, recent experiments on human chromosomes will be reviewed, including results of experiments where chromosome-folding proteins are specifically depleted using siRNA methods.

3:06PM X4.00002 A Molecular View of Liquid Crystalline Elastomers and Gels , JUAN DE PABLO, University of Wisconsin — A combination of Monte Carlo and molecular dynamics simulations is used to examine the order-disorder transitions that arise in model liquid crystalline elastomers and colloidal gels as a function of concentration and strain, respectively. Two models are considered. In the first, a lattice model is used to represent a colloidal gel of nematogens and nanoparticles. In the second, a cross-linked elastomer of Gay-Berne mesogens is adopted to examine the order-disroder transition that arises as a function of strain. The results of simulations are compared to those of recent experiments for these two classes of systems.

3:42PM X4.00003 Gelation of mucin: Protecting the stomach from autodigestion , RAMA BANSIL, Boston University — In this talk I will describe the molecular mechanisms involved in the remarkable ability of the mucus lining of the stomach for protecting the stomach from being digested by the acidic gastric juices that it secretes. These physical properties can be attributed to the presence of a high molecular weight glycoprotein found in mucus, called mucin. Rheology and other measurements show that gastric mucin forms a gel under acidic pH. A model of gelation based on the interplay of hydrophobic and electrostatic interactions will be discussed. Molecular Dynamics simulation studies of folding and aggregation of mucin domains provide further support for this model. The relevance of gelation to the motion of the ulcer causing bacterium H. pylori will be discussed.

4:18PM X4.00004 Responsive gels and membranes , MONICA OLVERA DE LA CRUZ, Northwestern University — We use computer simulations and analytical method to explore and analyze effects of composition heterogeneities in elastic membranes and gels. In particular, we focus on shape pattern formation in thin networks and elastic closed membranes driven by the presence of composition heterogeneities. We study the crumpling of multicomponent elastic membranes in response to changes in external conditions, as well as the spontaneous buckling transition of heterogeneous elastic shells into regular and irregular polyhedra.

4:54PM X4.00005 ABSTRACT WITHDRAWN –

Thursday, March 24, 2011 2:30PM - 5:30PM –
Session X5 FIAP: The Corporate Feel: Atomic Force Microscopy in Industry Ballroom C1

2:30PM X5.00001 Accelerated design and quality control of impact modifiers for plastics through atomic force microscopy (AFM) analysis , GUNTER MOELLER, Arkema Inc. — Standard polymer resins are often too brittle or do not meet other mechanical property requirements for typical polymer applications. To achieve desired properties it is common to disperse so called "impact modifiers", which are spherical latex particles with diameters of much less than one micrometer, into the pure resin. Understanding and control of the entire process from latex particle formation to subsequent dispersion into polymer resins are necessary to accelerate the development of new materials that meet specific application requirements. In this work AFM imaging and nanoindentation techniques in combination with AFM-based spectroscopic techniques were applied to assess latex formation and dispersion. The size and size distribution of the latex particles can be measured based on AFM amplitude modulation images. AFM phase images provide information about the chemical homogeneity of individual particles. Nanoindentation may be used to estimate their elastic and viscoelastic properties. Proprietary creep and nanoscale Dynamic Mechanical Analysis (DMA) tests that we have developed were used to measure these mechanical properties. The small size of dispersed latex inclusions requires local mechanical and spectroscopic analysis techniques with high lateral and spatial resolution. We applied the CRAVE AFM method, developed at NIST, to perform mechanical analysis of individual latex inclusions and compared results with those obtained using nanoscale DMA. NanoIR, developed by Anasys Inc., and principal component confocal Raman were used for spectroscopic analysis and results from both techniques compared.

3:06PM X5.00002 Scanning Probe Evaluation of Electronic, Mechanical and Structural Material Properties[1] , KUMAR VIRWANI, IBM — We present atomic force microscopy (AFM) studies of a range of properties from three different classes of materials: mixed ionic electronic conductors, low-k dielectrics, and polymer-coated magnetic nanoparticles. (1) Mixed ionic electronic conductors are being investigated as novel diodes to drive phase-change memory elements. Their current-voltage characteristics are measured with direct-current and pulsed-mode conductive AFM (C-AFM). The challenges to reliability of the C-AFM method include the electrical integrity of the probe, the sample and the contacts, and the minimization of path capacitance. The role of C-AFM in the optimization of these electro-active materials will be presented. (2) Low dielectric constant (low-k) materials are used in microprocessors as interlayer insulators, a role directly affected by their mechanical performance. The mechanical properties of nanoporous silicate low-k thin films are investigated in a comparative study of nanomechanics measured by AFM and by traditional nanoindentation. Both methods are still undergoing refinement as reliable analytical tools for determining nanomechanical properties. We will focus on AFM, the faster of the two methods, and its developmental challenges of probe shape, cantilever force constant, machine compliance and calibration standards. (3) Magnetic nanoparticles are being explored for their use in patterned media for magnetic storage. Current methods for visualizing the core-shell structure of polymer-coated magnetic nanoparticles include dye-staining the polymer shell to provide contrast in transmission electron microscopy. AFM-based fast force-volume measurements provide direct visualization of the hard metal oxide core within the soft polymer shell based on structural property differences. In particular, the monitoring of adhesion and deformation between the AFM tip and the nanoparticle, particle-by-particle, provides a reliable qualitative tool to visualize core-shell contrast without the use of additional contrast enhancing agents.

3:42PM X5.00003 Nanomechanical characterization of polypropylene-based materials with multifrequency atomic force microscopy (AFM)-based methods , DALIA YABLON, Exxonmobil Research and Engineering — Atomic force microscopy (AFM) is a powerful technique with broad applications to characterization of surfaces, primarily used for nanoscale quantitative topographic measurements and qualitatively distinguishing between material properties on the surface. We describe recent advances in our capabilities to quantify nanoscale mechanical measurements of surface properties using recently developed high frequency and multifrequency methods. Initial focus of this work is for polymeric materials (and specifically polypropylene based blends), where nanomechanical characterization is critical for effective understanding of structure-property relationships, especially for more complicated multi-component materials such as blends and composites. SPM techniques rely on complicated tip-sample interactions that must be effectively separated and understood if we are to ultimately identify and quantify specific materials and material properties at the nanoscale. We describe different approaches to this problem utilizing a number of AFM based techniques including force curves, bimodal imaging and contact resonance imaging. Ultimately, these techniques yield quantitative maps of conservative and dissipative tip-sample interactions that are then converted into elastic and viscous moduli maps. We describe initial applications of these methods to measure mechanical properties such as storage and loss moduli of model polypropylene containing blends including polypropylene/rubber and polypropylene/polystyrene blends. Finally, quantitative moduli values obtained by methods described above are compared to those obtained by bulk methods.

4:18PM X5.00004 Probing Photovoltaic Performance , DAVID GINGER, University of Washington — A wide range of nanostructured materials including organic bulk heterojunction blends, solution processed colloidal semiconductors, and hybrid organic/inorganic thin films are being explored for solar energy applications. These sytems typically exhibit nanoscale heterogenity in their electronic and optical properties. Scanning probes are critical for building a microscopic picture of the performance of new nanostructured and thin film photovoltaic materials–and may ultimately prove to be a valuable metrology tool for process control during production–because scanning probe microscopy provides a unique opportunity to correlate local charge generation, recombination and transport with local structure in these systems. In this talk I will focus on techniques developed and lessons learned during our group's study of thin film solar cell materials with a particular emphasis on nanostructured organic bulk heterojunction blends.

4:54PM X5.00005 Challenges and opportunities for probe-based information technology[1] , JEREMY LEVY, U. Pittsburgh — Scanning probe microscopes have become standard tools for characterization of materials and devices at the nanoscale. But what about "OEM" versions for information technology? The standard answer is that probe-based lithography or storage is not practical because it cannot scale-their cost and complexity will never allow useful devices to be made with probes. Such was not always the conventional wisdom in the industrial community. The Millipede Project,[2] pioneered by Gerd Binnig at IBM and pursued at other companies such as Hitachi and Seagate, sought to scale the number of probes to ∼1000. In fact, they were successful, but not enough to be competitive with FLASH memory. Since then, order of magnitude improvements have been made both in scaling up to the number of probes past ten million,[3] and in scaling down the minimum bit size below two nanometers.[4] Combining these two approaches may well justify the statement: "There's plenty of room for probes at the bottom."

Thursday, March 24, 2011 2:30PM - 5:30PM –

Session X6 DCOMP DAMOP: Pairing in Imbalanced Fermi Mixtures Ballroom C2

2:30PM X6.00001 Correlated phases in the Fermi Hubbard model with spin and mass imbalance , GIULIANO ORSO, Université Paris Diderot, Laboratoire Matériaux et Phénomènes Quantiques — One dimensional attractive fermions with unequal spin populations provide a direct realization of the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) superfluid state, in which Cooper pairs condense at finite momentum. The presence of an additional mass asymmetry between the two components gives rise to multi-particle bound states, including trimers made of one light and two heavy fermions. I first discuss the stability of these bound states through the exact solution of the three-body problem. Based on Density Matrix Renormalization Group simulations and bosonization theory, I then show that at finite and commensurate densities the ground state of the system is a Luttinger liquid of trimers. In this new phase superconducting FFLO correlations are exponentially suppressed. Finally I explain how the mass asymmetry changes the topology of the grand-canonical phase diagram of the Fermi Hubbard model. [GO, E. Burovski and T. Jolicoeur, PRL 104, 065301 (2010); E. Burovski, GO and T. Jolicoeur, PRL 103, 215301 (2009)]

3:06PM X6.00002 The phase diagram of imbalanced Fermi gases[1] , DANIEL E. SHEEHY, Louisiana State University — Recent experimental and theoretical research has focused on the phases of strongly interacting Fermi gases under an imposed population imbalance between the fermion species. The large difference in chemical potential between the majority and minority species disrupts conventional singlet s-wave pairing, yielding a rich phase diagram including regions of phase separation, Fulde-Ferrell-Larkin-Ovchinnikov superfluidity and magnetic superfluidity. I will discsuss these predicted phases, as well as the behavior at large imbalance where the minority species can induce an effective attraction among the majority fermions and a resulting instability towards p-wave superfluidity.

[1]Research supported by the Louisiana Board of Regents.

3:42PM X6.00003 Pair formation in Fermi systems with population imbalance in one- and two-dimensional optical lattices[1] , GEORGE BATROUNI, University of Nice, Institut Non-Linaire de Nice — I will discuss pairing in fermionic systems in one- and two-dimensional optical lattices with population imbalance. This will be done in the context of the attractive fermionic Hubbard model using the Stochastic Green Function algorithm in d=1 while for d=2 we use Determinant Quantum Monte Carlo. This is the first exact QMC study examining the effects of finite temperature which is very important in experiments on ultra-cold atoms. Our results show that, in the ground state, the dominant pairing mechanism is at nonzero center of mass momentum, i.e. FFLO. I will then discuss the effect of finite temperature in the uniform and confined systems and present finite temperature phase diagrams. The numerical results will be compared with experiments.

[1]With M. J. Wolak (CQT, National University of Singapore) and V. G. Rousseau (Department of Physics and Astronomy, Louisiana State University).

4:18PM X6.00004 Spin imbalanced Fermi gases in 1D and the crossover to 3D[1] , ANN SOPHIE RITTNER, Rice University — The search for the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) phase, a polarized superfluid with a spatially varying order parameter, has generated large interest in both condensed matter and cold atoms communities. To date, there has been only indirect experimental evidence of FFLO in the heavy fermion superconductor CeCoIn5. A strongly interacting 3D polarized Fermi gas exhibits three phases at low temperature: an unpolarized superfluid, a partially polarized and a fully polarized normal phase, which phase separate in an optical trap. There is no experimental evidence for an FFLO phase in the 3D system and theory predicts that it occupies only a small region in the phase diagram. In a 1D polarized Fermi gas, the FFLO phase is predicted to occupy a large region of the phase diagram. We have implemented a 2D optical lattice in order to explore the phase diagram of an imbalanced spin mixture of ^{6}Li. In in-situ density distributions, we observe in the center of the cloud a partially polarized region surrounded by an either fully polarized or an unpolarized superfluid shell depending on the spin imbalance. The density profiles are quantitatively well described by a finite temperature Bethe ansatz and can be used to extract the 1d phase diagram of the imbalanced 1d Fermi gas. Moreover, the quantitative agreement of experiment and theory paves the way for directly observing the elusive FFLO phase in the system.

[1]Supported by DARPA, NSF, ONR, and The Welch and Keck Foundations

4:54PM X6.00005 Universal Spin Transport in Strongly Interacting Fermi Gases[1] , MARTIN ZWIERLEIN, Massachusetts Institute of Technology — Ultracold gases of fermionic atoms have emerged as a unique platform to study strongly interacting fermion systems. Here we study spin transport in a two-state mixture of fermionic atoms near a Feshbach resonance. Starting with two separate spin domains in an atom trap, we observe the subsequent evolution of the spin mixture towards the eventual ground state, a superfluid of fermion pairs. Initially, the gas clouds of unlike spins almost perfectly bounce off each other, despite densities a million times thinner than air. Only over several seconds, about 100 000 collision times, the spins slowly diffuse into each other and, below a critical temperature, form a superfluid of fermion pairs. We determine the transport properties in this gas as a function of interaction strength and temperature. In particular, we find the spin diffusion coefficient in the strongly interacting, degenerate regime to take on the universal value for a "perfect fluid", $D \simeq \hbar/m = \frac{(100\mu\mathrm{m})^2}{\mathrm{s}}$, where m is the mass of the ^{6}Li atoms. At high temperatures, we find the universal law $D = \alpha \frac{\hbar}{m} (T/T_F)^{3/2}$ with a constant α. The ratio of spin conductivity and spin diffusion coefficient yields the spin susceptibility in these gases, showing the Curie law at high temperatures and a departure from the compressibility at low temperatures, that we interpret as a signature for entering the Fermi liquid regime. Our transport experiments near and far equilibrium have implications on other strongly interacting Fermi systems, suggesting a fundamental lower limit to the spin diffusion coefficient, in the absence of localization, on the order of $\hbar/m$ - a conjecture already made by Onsager. Our spin susceptibility measurements appear to exclude a ferromagnetic ground state on the repulsive side of the Feshbach resonance.

Thursday, March 24, 2011 2:30PM - 5:30PM –

Session X7 DBP: Quantitative Approaches to DNA Replication Ballroom C3

2:30PM X7.00001 Replication domains are self-interacting structural chromatin units of human chromosomes , ALAIN ARNEODO, CNRS — In higher eukaryotes, the absence of specific sequence motifs marking the origins of replication has been a serious hindrance to the understanding of the mechanisms that regulate the initiation and the maintenance of the replication program in different cell types. In silico analysis of nucleotide compositional skew has predicted the existence, in the germline, of replication N-domains bordered by putative replication origins and where the skew decreases rather linearly as the signature of a progressive inversion of the average fork polarity. Here, from the demonstration that the average fork polarity can be directly extracted from the derivative of replication timing profiles, we develop a wavelet-based pattern recognition methodology to delineate replication U-domains where the replication timing profile is shaped as a U and its derivative as a N. Replication U-domains are robustly found in seven cell lines as covering a significant portion (40-50%) of the human genome where the replication timing data actually displays some plasticity between cell lines. The early replication initiation zones at U-domains borders are found to be hypersensitive to DNase I cleavage, to be associated with transcriptional activity and to present a significant enrichment in insular-binding proteins CTCF, the hallmark of an open chromatin structure. A comparative analysis of genome-wide chromatin interaction (HiC) data shows that replication-U domains correspond to self-interacting structural high order chromatin units of megabase characteristic size. Taken together, these findings provide evidence that the epigenetic compartmentalization of the human genome into autonomous replication U-domains comes along with an extensive remodelling of the threedimensional chromosome architecture during development or in specific diseases. The observed cell specific conservation of the replication timing between the human and mouse genomes strongly suggests that this chromosome organization into self-interacting structural and functional units is a general feature of mammalian organisms.

3:06PM X7.00002 Thermal Replication Trap , DIETER BRAUN, Ludwig Maximilians University — The hallmark of living matter is the replication of genetic molecules and their active storage against diffusion. We have argued in the past that thermal convection can host the million-fold accumulation even of single nucleotides and at the same time trigger exponential replication [1]. Accumulation is driven by thermophoresis and convection in elongated chambers, replication by the inherent temperature cycling in convection. Optothermal pumping [2,3] allows to implement the thermal trap efficiently in a toroidal [4] or linear [5] geometry. Based on this method, we were in a position to combine accumulation and replication of DNA in the same chamber [5]. As we are missing a solid chemistry of prebiotic replication, we used as a proxy reaction for to replication the polymerase chain reaction. Convective flow both drives the DNA replicating polymerase chain reaction (PCR) while concurrent thermophoresis accumulates the replicated 143 base pair DNA in bulk solution. The time constant for accumulation is 92 s while DNA is doubled every 50 s. The length of the amplified DNA is checked with thermophoresis. Finite element simulations confirm the findings. The experiments explore conditions in pores of hydrothermal rock which can serve as a model environment for the origin of life and has prospects towards the first autonomous evolution, hosting the Darwin process by molecular selection using the thermophoretic trap. On the other side, the implemented continuous evolution will be able to breed well specified DNA or RNA molecules in the future.

3:42PM X7.00003 Single-molecule measurements of replisome composition and function reveal the mechanism of polymerase exchange , JOSEPH LOPARO, Harvard Medical School — A complete understanding of the molecular mechanisms underlying the functioning of large, multiprotein complexes requires experimental tools capable of simultaneously visualizing molecular architecture and enzymatic activity in real time. I will describe a novel single-molecule assay that combines the flow-stretching of individual DNA molecules to measure the activity of the DNA-replication machinery with the visualization of fluorescently labeled DNA polymerases at the replication fork. By correlating polymerase stoichiometry with DNA synthesis of T7 bacteriophage replisomes, we are able to quantitatively describe the mechanism of polymerase exchange. We find that even at relatively modest polymerase concentration (2 nM), soluble polymerases are recruited to an actively synthesizing replisome, dramatically increasing local polymerase concentration. These excess polymerases remain passively associated with the replisome through electrostatic interactions with the T7 helicase for 50 seconds until a stochastic and transient dissociation of the synthesizing polymerase from the primer-template allows for a polymerase exchange event to occur.

4:18PM X7.00004 Defects and DNA replication: a role for stochasticity[1] , JOHN BECHHOEFER, Simon Fraser University — When a cell replicates its DNA, each base must be copied once and only once per cell cycle. A failure to complete replication normally can lead to cell death, or worse. In this talk, I will discuss how ideas from statistical physics can help understand how replication is organized and controlled. In particular, we describe a formalism based on rate equations similar to those used to describe the kinetics of crystal growth and show how it can describe the normal course of DNA replication. In practice, replication must also deal with numerous kinds of problems. For example, the machinery of replication may stall or strands may be broken. We show how to extend our formalism to include the effects of such damage and conclude that there are two regimes: a normal regime, where the influence of defects is local, and an initiation-limited regime, where the influence of defects is long range. In the latter regime, defects have a global impact on replication. We show that normal, healthy cells have defect densities in the normal regime but cells with "problems" have defect densities that approach the crossover value. The overall conclusion is that passive stochastic control and physical effects such as diffusion are more relevant for DNA replication than had been believed until recently.

[1]Supported by HFSP and NSERC (Canada).

4:54PM X7.00005 Universal Temporal Profile of Replication Origin Activation in Eukaryotes , ARACH GOLDAR, CEA — The complete and faithful transmission of eukaryotic genome to daughter cells involves the timely duplication of mother cell's DNA. DNA replication starts at multiple chromosomal positions called replication origin. From each activated replication origin two replication forks progress in opposite direction and duplicate the mother cell's DNA. While it is widely accepted that in eukaryotic organisms replication origins are activated in a stochastic manner, little is known on the sources of the observed stochasticity. It is often associated to the population variability to enter S phase. We extract from a growing *Saccharomyces cerevisiae* population the average rate of origin activation in a single cell by combining single molecule measurements and a numerical deconvolution technique. We show that the temporal profile of the rate of origin activation in a single cell is similar to the one extracted from a replicating cell population. Taking into account this observation we exclude the population variability as the origin of observed stochasticity in origin activation. We confirm that the rate of origin activation increases in the early stage of S phase and decreases at the latter stage. The population average activation rate extracted from single molecule analysis is in prefect accordance with the activation rate extracted from published micro-array data, confirming therefore the homogeneity and genome scale invariance of dynamic of replication process. All these observations point toward a possible role of replication fork to control the rate of origin activation.

Thursday, March 24, 2011 2:30PM - 5:30PM –
Session X8 FHP FIP: Migrations of Physicists Ballroom C4

2:30PM X8.00001 Migration of scientists and the International Centre for Theoretical Physics – a Personal and Professional Perspective , KATEPALLI R. SREENIVASAN, New York University — Scientists migrate for a variety of reasons: political problems with their governments, lack of professional opportunities in their countries, the lure of better lives, financial security for them and their families, better education for their off-springs, and so forth. Migration usually occurs from poor and oppressed countries–the two categories are not one and the same–to the rich and the open. It has created, over time, a dilemma for the poor countries: in the midst of all their other problems, how to justify spending on higher education and research when that investment often results in the most enterprising of its citizens to leave their countries behind? (When migration has reversed direction occasionally, it is because of certain necessities of the scientists to be back in their countries or for opportunities that some individuals see for wielding greater scientific power.) The ideal of keeping the best scientists in their own countries, still ensuring that they remain scientifically productive and inspiring to the youth, is what provided the motivation for the creation of the International Centre for Theoretical Physics in Trieste, Italy, where I served as Director for some seven years. In this talk, I will present the story behind the formation of the Centre in 1964, explain its rationale, and analyze its evolution over time to accommodate the changing scene in world; I will discuss how some things have remained the same even as more of them have changed over time. Finally, I will remark on the broad needs of developing countries even though such needs are often very specific to a country.

3:06PM X8.00002 Physicists' Forced Migrations under Hitler , ALAN BEYERCHEN, Ohio State University — When the Nazis came to power in early 1933 they initiated formal and informal measures that forced Jews and political opponents from public institutions such as universities. Some physicists retired and others went into industry, but most emigrated. International communication and contact made emigration a viable option despite the desperate economic times in the Great Depression. Another wave of emigrations followed the annexation of Austria in 1938. Individual cases as well as general patterns of migration and adaptation to new environments will be examined in this presentation. One important result of the forced migrations was that many of the physicists expelled under Hitler played important roles in strengthening physics elsewhere, often on the Allied side in World War II.

3:42PM X8.00003 Migrations and the Rise of High Energy Physics in Brazil , ALBERTO SANTORO, State University of Rio de Janeiro, Brazil — There have been five phases in the development and evolution of High Energy Physics (HEP) in Brazil, that I review from a personal perspective. The Founding Phase (1938 - 1955) was followed by the Brasilia Phase that included an attempt by R. Salmeron, the first Brazilian physicist to work at CERN in its early years, to found an HEP institute at the University of Brasilia in 1960 - 1965. This was followed by my return from France during the redemocratization of 1985, after 21 years of miltary rule. The Expansion Phase (1984 - 1999) followed an ambitious plan that led to the spread of high energy physics to many key institutions throughout the country. The Evolutionary Phase (1984 - 2010), initiated with the strong help of Leon Lederman (Nobel Laureate, 1988) began with the strengthening of HEP groups and their participation in the major experimental collaborations, at the Tevatron at Fermilab and more recently at the LHC at CERN, with the strong support of the Brazilian funding agencies. The fifth Partnership phase (2011 -) has just begun, as the high energy physics community and its supporting agencies work to make Brazil an Associate Member of CERN, and in this way to make the Brazilian community a full partner in the global effort aimed at discoveries at the Energy Frontier.

4:18PM X8.00004 Russian, Soviet, and post-Soviet scientific migration: history and patterns , ALEXEI KOJEVNIKOV, University of British Columbia — Immigrant scientists from other European countries (predominantly German) were crucial in establishing the tradition of modern science in the Russian Empire of the 18th and 19th centuries. Since the 1860s, however, outgoing waves of scientific migration started originating in Russia, bringing important innovations to international science. The scale and patterns of migration varied greatly with the turbulent time. The talk will describe several landmark stages of the proceess and their cultural consequences: from opening higher education possibilities for women during the late 19th century, to post-1917 academic refugees and Soviet defectors, to the 1960s brain drain provoked by the launch of Sputnik, and to what can be called the first truly global scientific diaspora of Russophone scientists after 1990.

4:54PM X8.00005 Chinese/American Physicists: A Transnational History[1] , ZUOYUE WANG, Cal State Polytechnic Univ., Pomona — As part of a broader project on "Chinese/American Scientists: Transnational Science during the Cold War and Beyond," this paper examines the movements of American-trained Chinese physicists following the founding of the People's Republic of China in 1949. While a majority of these physicists chose to stay in the US (the "stayees"), a number went back to China in the 1950s (the "returnees") against many obstacles during the McCarthy era. After the reopening of US-China relations in the 1970s, the two groups joined hands in promoting China-US scientific and educational exchanges, leading eventually to the coming to the US of a new generation of Chinese physics students and the return to China of some of the original "stayees." This transnational history of Chinese/American physicists aims to illustrate the nature and extent of the Americanization of international science and the internationalization of American science in the post-World War II era.

Session X9 DFD: Coordination, Coherence and Synchronization through Hydrodynamic Interactions D220

2:30PM X9.00001 Collective motion and density fluctuations in swimming bacteria , HEPENG ZHANG, University of Texas at Austin and Shanghai Jiao Tong University — The emergence of collective motion such as in fish schools, mammal herds, and insect swarms is a ubiquitous self-organization phenomenon. Such collective behavior plays an important role in a range of problems, such as spreading of deceases in animal or fish groups. Current models have provided a qualitative understanding of collective motion, but progress in quantitative modeling in hindered by the lack of experimental data. Here we examine a model microscopic system, where we are able to measure simultaneously the positions, velocities, and orientations of up to a thousand bacteria in a colony. The motile bacteria form closely-packed dynamic clusters within which they move cooperatively. The number of bacteria in a cluster exhibits a power-law distribution truncated by an exponential tail, and the probability of finding large clusters grows markedly as bacterial density increases. Mobile clusters cause anomalous fluctuations in bacterial density as found in mathematical theories and numerical models. Our results demonstrate that bacteria are an excellent system to study general phenomena of collective motion.

3:06PM X9.00002 Collective behavior of spinning particles at fluid/fluid interface[1] , YAOUEN FILY, Syracuse University, APARNA BASKARAN, Brandeis University, M. CRISTINA MARCHETTI, Syracuse Biomaterials Institute and Syracuse University — Rotating particles in a viscous fluid can exhibit interesting behavior due to hydrodynamic interactions. When the particles are driven by an external torque, these interactions result in an effective azimuthal force, leading to swirling motion. It has been shown that small numbers of such particles form precessing atom-like structures. The behavior of large collections of spinning particles is, however, still relatively unexplored. We study the phase diagram of a collection of spinning particles in two dimensions using molecular dynamics simulations. The rotors interact via hydrodynamic interactions and short-range repulsion, in the presence of thermal noise. The repulsive interaction yields transitions from a solid to a liquid to a gas as the density of rotors is decreased. The azimuthal hydrodynamic interaction modifies each of these phases in a distinct way. Both long-range and screened hydrodynamic interactions are considered. Some properties of the various phases are shown to depend critically on the range of the interaction.

3:18PM X9.00003 ABSTRACT WITHDRAWN –

3:30PM X9.00004 Synchronization phenomena in systems with magnetodipolar interactions , ANDREJS CEBERS, MIHAILS BELOVS, University of Latvia — Rich pattern formation phenomena under the action of AC field for two dimensional systems of magnetic dipoles floating on the surface of liquid are observed and reproduced numerically by the first-principles model [1]. Here by the study of dynamics of two dipoles interacting with weak dipolar forces it is found that due to series of bifurcations the motion of dipoles in AC field is synchronized. If the dipoles orientation is confined to the plane the synchronous oscillation regime by infinite period bifurcation transforms to the regime of synchronous rotation. This regime is unstable for intermediate values of the field strength and the motion of dipoles is periodic or quasi-periodic. Above the critical value of field strength these regimes transform to rotational regime and the dipoles synchronously rotate in plane. Estimate of the critical parameters of the synchronization according to the dimensionless parameters used in the first-principles model [1] show that the synchronization of the dipoles rotation should be inherent in this model.

3:42PM X9.00005 Pattern Formation in a Rotating Suspension of Non-Brownian Buoyant Particles , PENGER TONG[1], Department of Physics, Hong Kong University of Science and Technology, MAKRAND KALYANKAR, BRUCE ACKERSON, Department of Physics, Oklahoma State University, W.R. MATSON, Department of Physics, DePaul University — This study examines concentration and velocity patterns observed in a horizontal rotating cylinder completely filled with a monodisperse suspension of non-Brownian buoyant particles. The unique patterns or phases are mapped by varying both the rotation rate and the solvent viscosity. Individual phases are identified using both frontal and axial views. Phase boundaries are compared to those obtained recently for suspensions of non-buoyant particles. Expressing the boundaries in terms of dimensionless parameters unifies the data for several samples at low rotation rates. When centrifugal force dominates, the behavior becomes quite different from previous studies.

3:54PM X9.00006 Shear-induced hydrodynamic diffusion of a flowing suspension of elastic capsules , MARCUS HWAI YIK TAN, DUC VINH LE, KENG-HWEE CHIAM, Mechanobiology Institute, National University of Singapore and A*STAR Institute of High Performance Computing — In flowing suspensions of soft and deformable elastic capsules, the shear flow causes hydrodynamic interaction among the capsules, resulting in an effective hydrodynamic diffusion that is not Brownian in origin. Recent experiments have suggested that hydrodynamic diffusion of red blood cells may play an important role in the pathophysiological processes of vasoocclusion and thrombosis. To study hydrodynamic diffusion further, we have developed accurate three-dimensional numerical simulations based on the immersed boundary method and thin shell theory to study the deformation of a large number of elastic capsules enclosed by thin shells moving in a shear flow. Using these simulations, we have calculated the effective hydrodynamic diffusion coefficient and showed how it varies with bulk flow velocity and capsule properties such as the volume fraction, size, and stiffness of spherical and biconcave capsules. We also compared them to scaling arguments and experimental measurements done for red blood cell suspensions.

4:06PM X9.00007 Artificial Microfluidic Squirmers , SHASHI THUTUPALLI, M.P.I. for Dynamics and Self Organisation, Gottingen, Germany, RALF SEEMANN, Physics Faculty, University of Saarlandes, Saarbrucken, Germany, STEPHAN HERMINGHAUS, M.P.I. for Dynamics and Self Organisation, Gottingen, Germany — While there is a growing consensus on the propulsion mechanisms of swimmers at low Reynolds' numbers, many questions remain open regarding the hydrodynamic effects on such swimmers, in particular the coupling between swimmers. Here we present experiments on artificial swimmers, where hydrodynamics is seen to be responsible for a wide range of collective behavior and interactions. Using droplet microfluidics with a surfactant laden continuous oil phase, we create monodisperse aqueous droplets containing chemicals that produce a steady source of Bromine ions. The surfactant (mono-olein) reacts at the droplet interface with the Bromine produced within the droplets, and a dynamic instability leads to gradients of interfacial tension at the droplet interface. These gradients set up Marangoni flows propelling the droplets, in a manner similar to the classical squirmer model of swimming. The flow around the swimmers as well as its effect on the droplet motion are measured using particle image velocimetry (PIV). The PIV analysis reveals the far field flows generated by the swimmers in the surrounding liquid, leading to the emergence of bound states and oriented clusters. We discuss the interaction mechanisms and compare it to previous theoretical work and simulations.

4:18PM X9.00008 Characterizing particle transport due to actuated cilia with adhesive tips , AMITABH BHATTACHARYA, Department of Chemical Engineering, University of Pittsburgh, GAVIN BUXTON, Department of Science, Robert Morris University, ALEXANDER ALEXEEV, Department of Mechanical Engineering, Georgia Institute of Technology, O. BERK USTA, Harvard Medical School, ANNA C. BALAZS, Department of Chemical Engineering, University of Pittsburgh — Biological tissues and organisms commonly utilize arrays of cilia to manipulate microparticles of different sizes. Motivated by biology, we use numerical simulations to study the interaction of microparticles with an array of actuated cilia, immersed in fluidic microchannel. For each cilium in the array, one end is tethered to the wall, while the other end is actuated by an external periodic force. Also, an adhesive force is introduced between the cilia tip and the microparticle. The simulations are performed using the Lattice Boltzmann Method for the flow, with a chain of point-forces, connected by springs, used to represent each cilium. We observe that a combination of hydrodynamic and adhesive forces can lead to size-specific control of microparticle transport. For instance, for certain adhesion strength and particle sizes, it is possible to trap and release particles by varying the actuation frequency. Also, for a given actuation frequency, the average particle speed is maximized at a particular adhesion strength. We will present the parameter range where we can observe the above behavior.

4:30PM X9.00009 Harnessing self-oscillating polymer gels to design active ciliated surfaces , PRATYUSH DAYAL, AMITABH BHATTACHARYA, OLGA KUKSENOK, ANNA C. BALAZS, University of Pittsburgh — Via theory and simulations, we design active surfaces capable of replicating characteristics of biological cilia. Our approach harnesses the use of polymer gels that undergo photosensitive Belousov-Zhabotinsky (BZ) reaction. Powered by internalized BZ reaction these polymer gels swell and de-swell autonomously due to the chemo-mechanical transduction and therefore are ideal materials for designing our system. We have successfully developed an efficient hybrid approach by combining our three dimensional gel lattice spring model (3D-gLSM) and Lattice Boltzmann Method (LBM) which allows us to capture the interactions between the cilia and the surrounding fluid. Using our gLSM-LBM hybrid model we determine the factors that govern the bending and beating of individual cilium and also their collective dynamic behavior. Our findings provide guidelines for designing ciliated surfaces that can exhibit biomimetic functionality.

4:42PM X9.00010 Designing active cilial sensors , YI YANG, ALEXANDER ALEXEEV, Georgia Institute of Technology — We employ a hybrid lattice Boltzmann / lattice spring computational model to simulate the three-dimensional hydrodynamic interactions among actuated and sensory elastic cilia tethered to a wall of a microfluidic channel. These actuated and sensory cilia are arranged a chessboard pattern on the channel wall. The actuated cilia are driven by a sinusoidal force applied to their free ends and induce periodic oscillations of a viscous fluid filling the microchannel. The passive, sensory cilia are used to measure the force arising due to fluid oscillations. We show that the combination of sensory and actuated cilia allows us to evaluate distances to solid objects located in a fluid-filled microchannel, thereby yielding a useful active sensor for microfluidic and biomedical applications.

4:54PM X9.00011 Nonlinear dynamics of flagellar bundling , PIETER JANSSEN, MICHAEL GRAHAM, University of Wisconsin - Madison — Flagella are long thin appendages of microscopic organisms used for propulsion in low-Reynolds environments. In many bacterial species, helical-shaped flagella driven by a molecular motor will bundle up. This bundling process is poorly understood, and the exact roles of hydrodynamic interactions, helix elasticity, and mechanical contact are unclear. To investigate the bundling, we consider two flexible helices next to each other, as well as several flagella attached to a spherical body. Each helix is modeled as several prolate spheroids connected by springs. For HI, we consider the flagella to made up of point forces, while the finite size of the body is incorporated via Faxén's laws. Before flagella can bundle, they must synchronize. Synchronization occurs fast relative to the bundling process. For flagella next to each other, the initial stage of bundling is governed by rotlet interactions generated by the rotating helices. At longer times, once bundling has occurred, we find that a sharp distinction can be made between "tight" and "loose" bundles, indicated by the local distance between the flagella. As function of the anchor point distance, a sharp transition from tight to loose is found when starting from the completely unbundled state. Incremental steps from stationary situations give multiple stationary for a single anchor distance. We show that the balance between elasticity and strong non-linear hydrodynamic interactions is responsible for this bifurcation behavior.

5:06PM X9.00012 Spontaneous transitions in the synchronisation states of a Chlamydomonas mutant , KIRSTY WAN, KYRIACOS LEPTOS, MARCO POLIN, University of Cambridge, IDAN TUVAL, IMEDEA, Mallorca, Spain, RAYMOND GOLDSTEIN, University of Cambridge — The mechanisms by which eukaryotic flagella are found to synchronise is poorly understood; the origins being dependent upon the hydrodynamics, as well as the underlying molecular biochemistry. Exemplifying how available phenotypic variations in a species may be exploited to extend our mathematical models for flagellar coupling, we turn to ptx1 - a non-phototactic mutant strain of the biflagellated alga *Chlamydomonas* with seemingly intact flagellar apparatus, which does not exhibit any gross motility defects. Intriguingly however, our high-speed imaging analysis of flagellar dynamics in ptx1 have revealed that rather unlike their wildtype predecessors, which beat mostly in synchrony interrupted by brief periods of drifts or slip [1], the two flagella of ptx1 are observed to consistently revert from synchrony to a state of stable, coupled, anti-phase beating dynamics. Incorporating the interpretation of the flagella pair as coupled noisy oscillators, we show how such behaviour corroborates readily with a secondary contribution to the coupling, which is further conjectured to be inherent in the wildtype.
[1] Polin M et al. *Science*, 487-490, **2009**.

5:18PM X9.00013 Emergence of synchronisation in flagella of variable length[1] , MARCO POLIN, DAMTP, University of Cambridge, IDAN TUVAL, IMEDEA, Mallorca, Spain, RAYMOND GOLDSTEIN, DAMTP, University of Cambridge — *Chlamydomonas reinhardtii* is a unicellular green alga that can swim by the concerted breaststroke-like beating of its two flagella. When the flagella are synchronised the organism moves along a straight helical path, while a large difference in the two beating frequencies induces sharp turns. Even in the synchronous state, however, the two flagella have slightly different intrinsic frequencies, and synchrony is guaranteed only by the presence of a sufficiently strong interflagellar coupling. Although the magnitude of this coupling is consistent with the value derived from a rough hydrodynamic estimate, no direct experimental test for the role of hydrodynamic in interflagellar coupling is available. In order to better understand the origin of interflagellar coupling, we employ high- speed imaging to study the dynamics of the two flagella of *Chlamydomonas* as they regrow after mechanically induced deflagellation. Our results show that the duration of synchronised motion is strongly dependent on flagellar length. We discuss this dependence in light of hydrodynamic models of flagellar synchronisation.

5:30PM X9.00014 Fluid dynamics and noise in bacterial scattering , JORN DUNKEL, KNUT DRESCHER, University of Cambridge, LUIS CISNEROS, University of Arizona, SUJOY GANGULY, RAYMOND GOLDSTEIN, University of Cambridge — Bacterial communication through chemical and physical channels is permanently challenged by internal and external noise. While the role of stochastic fluctuations in quorum sensing has been widely studied both theoretically and experimentally, our understanding of hydrodynamic interactions between bacteria is limited by the absence of empirical data. Here, we report the first direct measurement of the fluid flow generated by an individual bacterium far away from and near to a wall. The experiments show that the micro-hydrodynamics of E. coli are considerably different from that of more complex eucaryotes as, for example, Chlamydomonas algae. We discuss the implications of our results for bacterial cell-cell and cell-wall interactions.

Session X10 DMP: Focus Session: Growth, Structure, Dynamics, and Function of Nanostructured Surfaces and Interfaces – Organic Molecules D221

2:30PM X10.00001 Identification of the Atomic Scale Structures of the Molecule-Metal Interfaces of Single-Molecule Nanowires[1] , FIRUZ DEMIR, GEORGE KIRCZENOW, Simon Fraser University, Burnaby, Canada — We show theoretically how inelastic tunneling spectroscopy can identify the atomic scale structures of the molecule-metal interfaces of single-molecule nanowires bridging pairs metal electrodes, and thus resolve a long standing problem that is central to the field of single-molecule nanoelectronics. As an example we consider the propanedithiol (PDT) molecules bridging gold nanocontacts in the recent experiment of Hihath *et al.* [Nano Lett. **8**, 1673 (2008)]. Based on *ab initio* density functional and semi-empirical calculations we identify the features observed in the experimental inelastic tunneling spectra of these molecules at phonon energies near 46, 40 and 42 meV as arising from sulfur atoms (that have lost their thiol hydrogen atoms) bonding to the gold contacts in top site, bridge site and mixed bridge-top site geometries respectively. PDT molecules in which the sulfur atoms retain their thiol hydrogen atoms and bond strongly to gold in the top site geometry give rise to an IETS feature in the phonon energy range 54-57 meV.

2:42PM X10.00002 The adsorption geometries of C60 monolayer on Ag(111) and Au(111)[1] , RENEE DIEHL, HEEKEUN SHIN, Penn State University, KATARIINA PUSSI, Lappeenranta University of Technology — C_{60} films on metal surfaces are of particular interest as model van der Waals systems, and for applications such as molecular electronics. The electronic properties of these films are known to depend strongly on their structures and the relative molecular orientations of the C_{60} molecules, yet there are few detailed structure determinations for C_{60} films. When grown at room temperature and annealed to a sufficiently high temperature, C_{60} on Au(111) and Ag(111) form $(2\sqrt{3}\times 2\sqrt{3})$R30° structures with one C_{60} molecule per unit cell. We present a LEED study of their surface geometries, which are similar in some ways, but differ in others. They both form vacancy site structures that are thermally activated, they both form monolayers that are composed of a mixture of hex-down and 6:6 bond down molecules. The details of the 6:6 bond molecule geometries are different on both substrates, and the temperature dependence of the mixture is different.

2:54PM X10.00003 Mechanical Properties of a vdW molecular monolayer at a metal surface: Structural Polymorphism leading to facile compression , DEZHENG SUN, DAEHO KIM, UC Riverside, DUY LE, UC Florida, ØYVIND BORCK, Norwegian University of Science and Technology, KRISTIAN BERLAND, Chalmers University of Technology, KWANGMOO KIM, University of Maryland, WENHAO LU, YEMING ZHU, MIAOMIAO LUO, JON WYRICK, ZHIHAI CHENG, UC Riverside, T.L. EINSTEIN, University of Maryland, TALAT RAHMAN, UC Florida, PER HYLDGAARD, Chalmers University of Technology, LUDWIG BARTELS, UC Riverside — Intermolecular force plays an important role in self-assembly and surface pattern formation. Anthracene and similar unsubstituted arenes attach to a metallic substrate predominantly through van der Waals interaction leading. In this contribution we present images how anthracene on Cu(111) forms a large number of highly ordered patterns that feature a broad array of structural motifs. Density functional theory modeling including vdW interactions allows us to model the energetic of the pattern formation at high fidelity. Moreover, it allows us to deduce the strain energy associated with films of varying coverage. From this work, we obtain the Young's modulus and Poisson Ratio of a molecular monolayer, which resemble properties conventionally found for porous materials. These patterns are in marked contrast to those found after introduction of functional groups in the molecules, such as carbonyls or thiols.

3:06PM X10.00004 Monte Carlo Study of the Fish-like Patterns of Anthracenes on Cu(111)[1] , KWANGMOO KIM, T.L. EINSTEIN, University of Maryland, College Park, DEZHENG SUN, DAE-HO KIM, LUDWIG BARTELS, University of California, Riverside — Using Monte Carlo calculations of the two-dimensional triangular lattice with a 2-component 3-state Potts model, we demonstrate a mechanism for the spontaneous formation of fish-like patterns of anthracene (AC) molecules on Cu(111) by sputtering and annealing, then cooling to $\sim$ 80 K. The two components are an AC on a hollow site and another on a bridge site of Cu(111).[2] The liquid crystal model with two separate parts, positional and orientational, only explains a part of the fish-like pattern, not the whole regular pattern. Our model fixes the positional order of AC's into the triangular lattice and the orientational order into three angles as observed in the experiments. The variation of the coverages of AC's is reflected in the change of the ratio of two components in our model. We also try to understand the compression of AC's with the introduction of Gaussian dispersion of AC's about their triangular lattice sites.

3:18PM X10.00005 Self-assembly of metal phthalocyanines modulated by different substrates , WENDE XIAO, Institute of Physics, Chinese Academy of Sciences, YUHANG JIANG, JICHUN LIAN, LIWEI LIU, ZHIHAI CHENG, LI GAO, SHIXUAN DU, HONGJUN GAO — The self-assembly of organic molecules on solid surfaces has made tremendous progresses due to potential applications in organic nano-devices. Among the organic molecular building blocks, metal phthalocyanines (MPcs) have been attracting considerable interests because of their novel electronic and magnetic properties. The self-assembly and physical properties of MPcs on various surfaces have been investigated by scanning tunneling microscopy and spectroscopy (STM/STS). In this presentation, we will report on the self-assembly of iron phthalocyanine (FePc), manganese phthalocyanine (MnPc) and nickel phthalocyanine (NiPc) on Pb(111) and monolayer graphene (MG) epitaxy on Ru (0001) by means of low temperature (LT) STM. Highly ordered close-packed islands with square lattice are observed for all three kinds of MPcs growth on Pb(111), whereas regular dislocation lines are formed in the molecular islands of FePc on Pb(111). We find that the Kondo resonance of MnPc on Pb(111) is strongly location-dependant. For FePc, MnPc and NiPc growth on MG, dispersive single molecules, dispersive molecular lines and small patches of Kagome lattice are observed, respectively.

3:30PM X10.00006 Structural and electronic properties of polymer-silicon semiconductor heterojunctions using hybrid functionals , JOSEPH TURNBULL, North Carolina State University, WENCHANG LU, JERRY BERNHOLC, North Carolina State University, Department of Physics, Center for High Performance Simulation; Oak Ridge National Laboratory — Combining organic and inorganic components to form semiconductor heterostructures provides the basis for an enormous number of potential optoelectronic device designs. We report here on the use of hybrid-DFT calculations to study the structural and electronic properties of semiconductor interfaces between silicon and pi-conjugated polymers. Using large supercells and exact-exchange-corrected hybrid functionals, we explore different attachment motifs for polymer monolayers, as well as the role of screening, in particular in the context of predicting semiconductor band-offsets.

3:42PM X10.00007 Tuning Structural and Mechanical Properties of Two-Dimensional Molecular Crystals: The Roles of Carbon Side Chains , H.-J. GAO, H.Y. CUN, Y.L. WANG, S.X. DU, L. ZHANG, L.Z. ZHANG, W.A. HOFER, S.J. PENNYCOOK, INSTITUTE OF PHYSICS, CHINESE ACADEMY OF SCIENCES, PR CHINA TEAM, SURFACE SCIENCE RESEARCH CENTRE, UNIVERSITY OF LIVERPOOL, UK COLLABORATION, MATERIALS SCIENCE AND TECHNOLOGY DIVISION, OAK RIDGE NATIONAL LABORATORY, USA COLLABORATION — Organic-molecule based flexible electronics has been of significant interest due to its potential to challenge conventional silicon-based technologies. The crucial properties of these devices rely on the largely invariant physical properties of organic compounds or films when they are mechanically deformed. In this present work, by choosing quinacridone with flexible carbon chains as a model system, we developed a theoretical scheme to evaluate the contributions of various interactions to the molecular self-assembly process and find that such a process should be considered as a collective interaction between molecules and substrates rather than from the viewpoint of an isolated molecule. Importantly, the data provide insight into the origin and an estimate of the magnitude of the Young's modulus of the molecular film, which suggests that the elastic properties of molecular films can be tuned through control of side chain length.

3:54PM X10.00008 Formation of Molecular Networks: Tailored Quantum Boxes and Behavior of Adsorbed CO in Them[1] , JON WYRICK, DEZHENG SUN, DAE-HO KIM, ZHIHAI CHENG, WENHAO LU, YEMING ZHU, MIAOMIAO LUO, UC Riverside, YONG SU KIM, ELI ROTENBERG, LBL Berkeley, KWANGMOO KIM, T.L. EINSTEIN, U. Maryland, LUDWIG BARTELS, UCR — We show that the behavior of CO adsorbed into the pores of large regular networks on Cu(111) is significantly affected by their nano-scale lateral confinement and that formation of the networks themselves is directed by the Shockley surface state. Saturation coverages of CO are found to exhibit persistent dislocation lines; at lower coverages their mobility increases. Individual CO within the pores titrate the surface state, providing crucial information for understanding formation of the network as a result of optimization of the number N of electrons bound within each pore. Determination of N is based on quinone-coverage-dependent UPS data and an analysis of states of particles in a pore-shaped box (verified by CO's titration); a wide range of possible pore shapes and sizes has been considered.

4:06PM X10.00009 Origin of the Giant Honeycomb Network of Quinones on Cu(111)[1] , T.L. EINSTEIN, KWANGMOO KIM, U. Maryland, JON WYRICK, ZHIHAI CHENG, LUDWIG BARTELS, UC Riverside, KRISTIAN BERLAND, PER HYLDGAARD, Chalmers U. Tech. — We discuss the factors that lead to the amazing regular giant honeycomb network formed by quinones on Cu(111). Using a related lattice gas model with many characteristic energies, we can reproduce many experimental features. These models require a long-range attraction, which can be attributed to indirect interactions mediated by the Shockley surface state of Cu(111). However, Wyrick's preceding talk gave evidence that the network self-selects for the size of the pore rather than for the periodicity of the superstructure, suggesting that confined states are the key ingredient. We discuss this phenomenon in terms of the magic numbers of 2D quantum dots. We also report calculations of the effects of anthraquinones (AQ) in modifying the surface states by considering a superlattice of AQ chains with various separations. We discuss implications of these results for tuning the electronic states and, thence, superstructures.

4:18PM X10.00010 Tunneling and Time-Reversal Invariance in the Diffusion of Polyatomic Molecules at a Metal Surface , ZHIHAI CHENG, ERIC CHU, DEZHENG SUN, DAEHO KIM, YEMING ZHU, MIAOMIAO LUO, GREG PAWIN, KIN WONG, KI-YOUNG KWON, ROBERT CARP, MICHAEL MARSELLA, LUDWIG BARTELS, UCR — Rectangular molecules with 1 or 2 oxygen substrate linkers attached to each of their long sides diffuse in a uniaxial fashion, despite the threefold symmetry of the Cu(111) substrate. They achieve this by sequential placement of their substrate linkers and are hence dubbed "molecular walkers". VT-STM monitoring of their motion reveals a striking difference between the diffusion prefactors of the quadrupedal and bipedal species, with the latter being very low. DFT modeling of the diffusion barrier and WBK-based estimation of the potential for tunneling suggest that this discrepancy lies in the prevalence of tunneling for species, whose motion is only blocked by a barrier affecting one of their substrate linkers. In contrast, if the diffusion barrier affects two substrate linkers simultaneously, tunneling will not occur and conventional prefactors are observed. This finding may actually have far-reaching implications for the modeling of molecular motion in general, as it highlights that blocking of a single atoms is insufficient for confinement of molecular motion. We also investigated an asymmetric "molecular walkers", showing a symmetric diffusion in agreement with time-reversal invariance despite a saw-tooth shape of the diffusion barrier experienced.

4:30PM X10.00011 Hydrogen Bonding Controls the Dynamics of Catechol Adsorbed on a TiO_2(110) Surface , ULRIKE DIEBOLD[1], SHAO-CHUN LI, Department of Physics and Engineering Physics, Tulane University, New Orleans, LA 70118, USA, LI-NA CHU, XUE-QING GONG, Labs for Advanced Materials, Research Institute of Industrial Catalysis, East China University of Science and Technology, Shanghai, P. R. China — Direct studies of how organic molecules diffuse on metal oxide surfaces can provide insights into catalysis and molecular assembly processes. We studied individual catechol molecules, $C_6H_4(OH)_2$, on a rutile TiO_2(110) surface with scanning tunnelingmicroscopy. Surface hydroxyls enhanced the diffusivity of adsorbed catecholates. The capture and release of a proton caused individual molecules to switch between mobile and immobile states within a measurement period of minutes. Density functional theory calculations showed that the transfer of hydrogen from surface hydroxyls to the molecule and its interaction with surface hydroxyls substantially lowered the activation barrier for rotational motion across the surface. Hydrogen bonding can play an essential role in the initial stages of the dynamics of molecular assembly.

4:42PM X10.00012 Reversible rectification in sub-monolayer molecular heterojunctions[1] , JOE SMERDON, CHRIS GIEBINK, Center for Nanoscale Materials, Argonne National Laboratory, MATTHIAS BODE, Univ. Wuerzburg, NATHAN GUISINGER, JEFFREY GUEST, Center for Nanoscale Materials, Argonne National Laboratory — Pentacene and C_{60} are archetypal molecules for optically active acceptor-donor heterojunctions and have been used as the active materials in bilayer solar cells. We will discuss UHV STM and STS measurements on these bi-molecular films deposited sequentially to form heterojunctions on Cu(111). It is observed that rectification can be detected at the single-junction limit, and that the direction of rectification flips in accordance with the polarity of the heterojunction. The morphology of heterolayers will also be discussed. It is found that the density of a Pn monolayer can be affected by choice of growth conditions, and in turn can affect the overall morphology of the heterolayer and the rectification behavior of the heterojunctions. We will also briefly discuss progress towards probing the photophysical behavior of these systems. The correlation of atomic-scale structure and electronic behavior at the single-junction limit has important implications for applications of such heterojunctions, such as solar cells or OLEDs.

[1]This work was supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357 and "SISGR" Contract No. DE-FG02-09ER16109.

4:54PM X10.00013 Molecular self-assembly of dichloropentacene and C_{60} for a model organic solar cell heterojunction , JUN WANG, AMANDA BROWN, IRVINDER KAUR, JIAN-MING TANG, GLEN MILLER, KARSTEN POHL, Univ. of New Hampshire — Organic molecular self-assembly is a bottom-up approach to create molecular architectures that are suitable for a variety of applications including functional materials and molecular electronics. Specifically, the co-assembly of functionalized acenes (electron-donor materials) and fullerenes (electron-acceptor materials) on metal substrates provides a model for studying the structural and electronic properties for novel organic photovoltaic heterojunctions. Previously, we have fabricated a persistent self-assembled monolayer composed of single-domain 6,13-dichloropentacene (DCP) over large areas on the stepped Au(788) surface. Here we present the subsequent growth of C_{60} on a DCP monolayer covered gold surface by STM investigation and ab-initio calculations. After mild annealing C_{60} molecules are forced to the Au(788) step edges forming very long C_{60} chains, in contrast to the short C_{60} chains reported on bare vicinal gold steps. These final structure formations are attributed to the delicate intermolecular interactions and molecule-substrate interactions.

5:06PM X10.00014 BEEM Study of Interface Properties in PVDF-graphite Heterojunctions[1] , LE ZHANG, CLAY UPTON, ANDREI SOKOLOV, University of Nebraska - Lincoln — Since the prediction of giant electroresistance, tunnel junctions with ferroelectric (FE) barrier attract significant experimental and theoretical attention due to potential application as non-volatile data storage devices. The ferroelectric polymer, polyvinylidene fluoride (PVDF), is of particular interest thanks to its outstanding electromechanical, dielectric, and mechanical properties. However, direct experimental study of organic FE interface properties as a function of its polarization is extremely challenging. We employ ballistic electron emission microscope (BEEM) technique for nanometer size characterization of P(VDF-TrFE)/HOPG heterostructure. This method offers STM scale of spatial resolution and is immune to the contact quality of top electrode. By comparing the voltage dependence of ballistic current for different polarization states, we observe the change in tunnel barrier properties as the sign of FE polarization reverses. High-quality thin films of PVDF were fabricated using a Langmuir-Blodgett (LB) technique. Results will be also compared with thermally evaporated PVDF film and its isomorphic analog, polyethylene.

5:18PM X10.00015 Reverse self assembly: (111)-oriented gold crystallization at thiol monolayer templates[1] , AHMET UYSAL, BENJAMIN STRIPE, PULAK DUTTA, Physics and Astronomy, Northwestern University, BINHUA LIN, MATI MERON, CARS, The University of Chicago — Certain microorganisms can reduce gold ions from aqueous solutions to form gold nano/micro particles in a controlled way [1]. Understanding how biomolecules control the crystallization process may result in cheap and environment-friendly techniques in many different applications, including organic-inorganic hybrid molecular technologies and shape controlled gold nanoparticle production. To better understand the organic-inorganic interactions, we studied the crystallization of gold under octadecanethiol monolayers at the air-water interface. We used synchrotron x-rays in the grazing incidence geometry to determine the orientation of the gold crystals as well as the organic monolayer structure *in situ*. These x-rays also act as the gold reducing agent in this experiment. We see that the (111) faces of gold crystals are parallel to the monolayer surface. The monolayer structure changes with time and becomes commensurate with the gold (111) face, similar to a $\sqrt{3} \times \sqrt{3}$ self-assembled monolayer of thiol on gold.

Session X11 FIAP: Integer Quantum Hall Effect D222

2:30PM X11.00001 Imaging quantum Hall Coulomb islands inside a quantum ring , FREDERICO MARTINS, BENOIT HACKENS, SEBASTIEN FANIEL, VINCENT BAYOT, Universite catholique de Louvain, Louvain-la-Neuve 1348, Belgium, MARCO PALA, MINATEC, Grenoble, France, HERMANN SELLIER, SERGE HUANT, Institut Neel, Grenoble, LUDOVIC DESPLANQUE, XAVIER WALLART, IEMN, Villeneuve d'Ascq, France — In the quantum Hall regime near integer filling factors, electrons are transmitted through edge states confined at the borders of the device. In mesoscopic samples, however, edge states may be sufficiently close to allow electrons to tunnel, or to be transmitted through localized states ("Coulomb islands") [1]. Here, we use the biased tip of a low temperature scanning gate microscope to alter tunneling through quantum Hall Coulomb islands localized inside a quantum ring patterned in an InGaAs/InAlAs heterostructure. Simultaneously, we map the quantum ring resistance and observe different sets of concentric resistance fringes, due to charging/discharging of each Coulomb island. Tuning the magnetic field and the tip voltage, we reveal the rich and complex behaviour of these fringes [2].

2:42PM X11.00002 Emergent Dissipation in the $\nu = 1$ Quantum Hall Bilayer[1] , GANPATHY MURTHY, University of Kentucky, HERBERT FERTIG, Indiana University — Disorder is known to be central to the $\nu = 1$ bilayer [1]. Building on our previous study of the bilayer $\nu = 1$ system in a periodic potential [2] to capture the nonperturbative effects of disorder, we construct a $T = 0$ effective theory, in which the XY angle is coupled to an emergent Ising spin. We uncover a $z = 2$ quantum phase transition with emergent dissipation. Calculations of the interlayer tunnelling conductance and counterflow conductivity will be presented.

2:54PM X11.00003 Microwave induced electron heating in the regime of radiation-induced magnetoresistance oscillations in the GaAs/AlGaAs system[1] , A.N. RAMANAYAKA, R.G. MANI, Georgia State University, W. WEGSCHEIDER, Laboratorium fuer Festkoerperphysik, ETH Zurich — We examine the influence of microwave photoexcitation on the amplitude of Shubnikov-de Haas (SdH) oscillations at large filling factors in a two dimensional GaAs/AlGaAs electron system. A SdH lineshape analysis indicates that increasing the incident microwave power has a weak effect on the amplitude of the SdH oscillations, in comparison to the influence of modest temperature changes at liquid Helium temperatures on the dark-specimen SdH effect. The results indicate negligible electron heating under modest microwave photoexcitation, in good agreement with theoretical predictions for this regime.

3:06PM X11.00004 Transport study under microwave photoexcitation in epitaxial graphene[1] , RAMESH MANI, Georgia State University, JOHN HANKINSON, CLAIRE BERGER[2], WALT DE HEER, Georgia Institute of Technology — Single layers of carbon known as graphene are a promising new electronic material with potential for high frequency applications. For electronics, top-gated graphene field-effect transistors fabricated on large area epitaxial graphene wafers have already indicated switching cutoff frequencies up to 100 GHz [1]. Microwave and terahertz radiation-sensing constitutes another area of interest. Hence, we examine the electrical photo-response of graphene devices in the microwave band, and report transport measurements under microwave photo-excitation (f $<$ 120 GHz) carried out on micron sized Hall bars at liquid Helium temperatures.

3:18PM X11.00005 Quantized Anomalous Hall Insulator in a Nanopatterned Two-Dimensional Electron Gas , YONGPING ZHANG, CHUANWEI ZHANG, Department of Physics and Astronomy, Washington State University — We propose that a quantum anomalous Hall insulator (QAHI) can be realized in a nanopatterned two-dimensional electron gas (2DEG) with an in-plane magnetic field. The Berry curvatures originating from the in-plane magnetic field and Rashba and Dresselhaus spin-orbit coupling, in combination with a nanoscale honeycomb lattice potential modulation, lead to topologically nontrivial insulating states in the 2DEG. In the bulk insulating gaps, the anomalous Hall conductivity is quantized -e^2/h, corresponding to a finite Chern number -1. There exists one gapless chiral edge state on each edge of a finite size 2DEG.

3:30PM X11.00006 Remote sensing of transport in microwave photo-excited GaAs/AlGaAs heterostructure devices[1] , TIANYU YE, G. CHAND, A.N. RAMANAYAKA, R.G. MANI, W. WEGSCHEIDER, GEORGIA STATE UNIVERSITY COLLABORATION, ETH-ZURICH, SWITZERLAND COLLABORATION — The GaAs/AlGaAs two dimensional electron system (2DES) exhibits magnetoresistance oscillations under microwave and terahertz photo-excitation at liquid Helium temperatures. Such oscillations are understood in terms of the displacement and inelastic models for photo-excited transport in this system. In order to identify the relative physical contributions, we report on transport measurements and concurrent "remote" sensing of the 2DES. Hence, measurements under microwave photo-excitation were carried out on Hall bars fabricated from high mobility GaAs/AlGaAs single heterostructures, as a sensor above the specimen served to look for concurrent changes in response. We report here on the observed noticeable changes in the remote sensor and correlate the observations with the observed transport response of the photo-excited 2DES.

[1]Work has been supported by the ARO under W911NF-07-01-0158, and by the DOE under DE-SC0001762.

3:42PM X11.00007 Microscopic conductivity imaging of the quantum Hall edge states by a microwave impedance microscope , KEJI LAI, WORASOM KUNDHIKANJANA, MICHAEL KELLY, ZHI-XUN SHEN, Stanford University, JAVAD SHABANI, MANSOUR SHAYEGAN, Princeton University — Spatially resolved studies of the quantum Hall edge channels are usually challenging because most high mobility two-dimensional electron gas (2DEG) systems are buried underneath the surface. Using a cryogenic microwave impedance microscope, we demonstrate the conductivity mapping of the bulk and edge states in a GaAs/AlGaAs 2DEG. Narrow strips with either metallic or insulating screening properties are observed along edges of the 2DEG. The sizes and positions of these strips as a function of the magnetic fields agree with the self-consistent electrostatic picture. The quantitative local conductivity information provides a complete microscopic description of the evolution through the bulk filling factor $\nu = 2$. The imaging was performed without DC electrodes, vividly manifesting that the quantum Hall edges are equilibrium states and do not depend on externally supplied currents.

3:54PM X11.00008 Study of integer quantum Hall transition in long-ranged potentials[1] , RAVINDRA BHATT, Department of Electrical Engineering, Princeton University, Princeton, NJ 08544-5263, A. CHANDRAN, Princeton University, Princeton, NJ 08544 — We present results of a numerical study of a two-dimensional system of noninteracting electrons in a random correlated potential in the lowest Landau level in the presence of a perpendicular magnetic field. We use spatially uncorrelated and unbiased random gaussian potentials as well as potentials $V(r)$ with long-range, power-law correlations $\langle V(0)V(r)\rangle \propto r^{-\alpha}$ for different exponents α as models of disorder. We compute the Hall conductance σ_{xy} as well as the Thouless conductance as a function of size L of the sample, and use finite size scaling to determine the exponent ν characterizing the divergence of the localization length ξ at the quantum Hall transition. We also study the scaling of the diagonal conductivity as a function of L and compare our results to those obtained previously through different methods.

4:06PM X11.00009 High-Resolution Tunneling Spectroscopy of 2D Holes in the Quantum Hall Regime , B. HUNT, Dept. of Physics, MIT, O.E. DIAL, Dept. of Physics, Harvard, R.C. ASHOORI, Dept. of Physics, MIT, L.N. PFEIFFER, K.W. WEST, Department of Electrical Engineering, Princeton — We use Time-Domain Capacitance Spectroscopy (TDCS)[1], a method for extracting precise, high-resolution tunneling spectra, to determine the single-particle spectrum of the 2D hole system (2DHS) in the presence of high magnetic fields. The 2DHS has a variable density from zero to $3 \times 10^{11}\,\mathrm{cm}^{-2}$ and $T = 100\,\mathrm{mK}$. Owing to the heavy mass of holes in GaAs quantum wells, much higher values of r_s are attainable compared to 2D electron systems(2DES). Basic structure in the spectra appear very different from those observed in the 2DES[1]. For instance, a magnetic-field-induced Coulomb gap [1] appearing about the Fermi energy has a strong dependence on electron density (with a larger gap at low densities) that is not present for the 2DES. In addition, structure created by the exchange enhancement of spin splittings has an entirely different appearance from that seen in the 2DES. Ultimately, at lower temperatures, a high-resolution TDCS study of the 2DHS may show features related to the 2D metal-insulator transition.

4:18PM X11.00010 High quality two-dimensional hole system on hydrogen terminated silicon (111) surfaces , BINHUI HU, TOMASZ M. KOTT, ROBERT N. MCFARLAND, BRUCE E. KANE, University of Maryland — We have previously developed a novel field effect transistor structure, in which high mobility two-dimensional electrons are induced at a hydrogen-terminated Si(111) surface by a positive gate voltage through an encapsulated vacuum dielectric [1]. In this talk, we will demonstrate that a similar structure can also be used to define a high quality two-dimensional hole system (2DHS) at the H-Si(111) surface with a negative gate voltage. Hole concentrations up to 7.1×10^{11} cm^{-2} are obtained. The longitudinal and Hall resistivities are measured as functions of magnetic fields up to 12 T. Preliminary data show Shubnikov-de Haas (SdH) oscillations at B $>$ 3 T at T= 5 K. Until now the studies on 2DHSs on Si(111) surfaces are limited, primarily due to the lack of high quality 2DHSs on them. The high quality 2DHS here can provide some new opportunities.

4:30PM X11.00011 Microwave photo-voltaic oscillations in the GaAs/AlGaAs system[1] , GANESH CHAND, T. YE, A. RAMANAYAKA, R.G. MANI, Georgia State University, W. WEGSCHEIDER, ETH-Zurich — Microwave photo-excitation of the GaAs/AlGaAs system produces oscillations in the diagonal resistance that lead into novel zero-resistance states in the low temperature limit. Such photo-excitation also produces concomitant photo-voltage oscillations. Here, we examine this microwave photo-voltaic effect and correlate the results with observed magneto-transport over the frequency range $30 \leq f \leq 120GHz$ in Hall bars fabricatedfrom material characterized by n = 2x $10^{11}cm^{-2}$.

[1]Work has been supported by the ARO under W911NF-07-01-0158, and by the DOE under DE-SC0001762.

4:42PM X11.00012 Terahertz Coherent Control of Cyclotron Resonance in the Quantum Hall Regime , T. ARIKAWA, X. WANG, J. KONO, Rice University, D.J. HILTON, University of Alabama at Birmingham, J.L. RENO, W. PAN, Sandia National Laboratories — We report on the creation and coherent control of a superposition of many-electron quantum states (or a qubit) in a Landau-quantized GaAs two-dimensional electron gas (2DEG) using a sequence of coherent terahertz (THz) pulses. The first pulse excites electrons from the highest-filled Landau level (LL) to the lowest-unfilled LL, creating a superposition of the two LLs which re-emits a coherent THz wave. We found that the second THz pulse incident within the decoherence time stops or enhances the THz re-emission depending on its arrival phase. These results show that an arbitrary coherent control of the LL qubit is possible using THz pulses. We also performed a simulation within the framework of single-particle optical Bloch equations, which reproduced the experimental results surprisingly well. This agreement shows that the 2DEG behaves in the same way as a single-electron two-level system despite the fact that it contains a large density of interacting electrons. This finding extends the Kohn's theorem to a more general level of coherent dynamics.

4:54PM X11.00013 THz quantum Hall conductivity in a two dimensional electron gas , A.V. STIER, H. ZHANG, C.T. ELLIS, D. EASON, G. STRASSER, B.D. MCCOMBE, J. CERNE, University at Buffalo, The State University of New York — We investigate the THz Hall conductivity through measurement of the Faraday effect at 84 cm^{-1} near the cyclotron resonance (CR) in a two dimensional electron gas formed at a GaAs/(AlGa)As interface. Motivated by predictions of novel step-like features in the optical Hall conductivity (σ_{xy}) by Morimoto et.al. (Phys. Rev. Lett. 2009), we measure the THz σ_{xy} as a function of filling factor and temperature using polarization modulation techniques (Grayson, Phys. Rev. Lett. 2002). We observe plateaus in the Faraday rotation near integer filling factors of 1, 2 and 3 which we attribute to the THz integer quantum Hall effect. In electron density dependent studies, we observe a slight non-monotonic shift of the plateaus as a function of filling factor at magnetic fields above CR. A comparison of this effect with the shift in temperature shows that this cannot be explained by a simple electronic heating effect. This research was funded through NSF-DMR1006078.

5:06PM X11.00014 Superconducting Transport Mediated by Quantum Hall Edge Modes , STEPHANIE LAW, University of Illinois at Urbana-Champaign, MICHAEL VISSERS, ALLISON DOVE, NADYA MASON, JAMES ECKSTEIN — We report transport measurements between superconducting leads separated by a small gap consisting of quantum Hall edge modes. The NbTi superconducting layer is grown in-situ on top of the semiconducting heterostructure to allow good contact. The samples are then fabricated into Hall bars with narrow gaps between the superconducting leads. Differential resistance and IV characteristics are measured in two and four terminal setups at 300mK both on and off quantum Hall plateaus. We will show that in the smallest gaps when we are on a plateau, we see a chiral supercurrent the direction of which is controlled by the field. With larger gaps we see either a zero bias resistance minimum or maximum. Data taken on and off plateaus show marked differences, indicating that quantum Hall modes are crucial. Results for samples with different heterostructures will also be shown.

5:18PM X11.00015 In-plane Field Tuned Subband Quantum Hall Ferromagnetism , DAGIM TILAHUN, ALLAN MACDONALD — Motivated by the recent experimental work of Guo *et al.* (Phys. Rev. B 78, 233305 (2008)), we study the effects of an in-plane magnetic field on quantum Hall states in which subband, Landau level, and spin degrees of freedom compete. We find that the phase diagram identified by these authors can be explained qualitatively by using only single-electron properties, whereas the energy gap behavior can be explained only by considering electron-electron interactions. We predict a series of in-plane field tuned first order phase transitions in high-mobility samples.

Thursday, March 24, 2011 2:30PM - 5:30PM –

Session X13 GSNP: Focus Session: Continuum Description of Particulate Media D225/226

2:30PM X13.00001 A nonlocal enhancement to granular elasto-plasticity , KEN KAMRIN, MIT, GEORG KOVAL — A general, three-dimensional law to predict granular flow in an arbitrary geometry has been an elusive goal for decades. Recently, an elasto-plastic continuum model has shown the ability to approximate steady flow and stress profiles in multiple inhomogeneous flow environments. However, the model does not capture some of the characteristic phenomena observed in the slow, creeping flow regime. As normalized flow-rate decreases, granular stresses are observed to become largely rate-independent and a dominating length-scale emerges in the mechanics. This talk attempts to account for these effects with a nonlocal correction term that modifies the continuum law when the inertial number drops below a critical value. The correction depends on stress and strain-rate gradients and brings in a natural dependence on the particle diameter. We implement the modified law in multiple geometries and validate its predictions against discrete particle simulations.

2:42PM X13.00002 Effective temperature in elastoplasticity of amorphous solids[1] , IDO REGEV[2], Los Alamos National Laboratory, LAURENT BOUE, JACQUES ZYLBERG, ITAMAR PROCACCIA, The Weizmann institute of Science, GEORGE HENTSCHEL, Emory University — An effective temperature $T_{\rm eff}$ which differs from the bath temperature is believed to play an essential role in the theory of elasto-plasticity of amorphous solids. The definition of a measurable $T_{\rm eff}$ in the literature on sheared solids suffers however from being connected to a fluctuation-dissipation theorem which is correct only in equilibrium. Here we introduce a natural definition of $T_{\rm eff}$ based on measurable structural features without recourse to any questionable assumption. The value of $T_{\rm eff}$ is connected, using theory and scaling concepts, to the flow stress and the mean energy that characterize the elasto-plastic flow.

2:54PM X13.00003 Shock driven jamming and periodic fracture of particulate rafts , MAHESH BANDI, SEAS, Harvard Univeristy. CNLS & MPA-10, Los Alamos National Laboratory, TUOMAS TALLINEN, L. MAHADEVAN, SEAS, Harvard University — A tenuous monolayer of hydrophobic particles at the air-water interface often forms a scum or raft. When such a monolayer is disturbed by localized surfactant introduction, a radially divergent shock emanates and packs the particles into a jammed, compact, annular band that grows with time. The resulting two-dimensional, disordered, elastic solid locally has a packing fraction that saturates at random close packed density (ϕ_{RCP}) and fractures as it is driven radially outwards, to form periodic triangular cracks with robust geometrical features. We find that the number of cracks N varies monotonically with the initial particulate packing fraction ϕ_{init}, as does the compaction band radius R^* at fracture onset. However, its width W^* is constant across all ϕ_{init}. A simple geometric theory that treats the compaction band as an elastic annulus, and accounts for mass conservation allows us to deduce that $N \simeq 2\pi R^*/W^* \simeq 4\pi\phi_{RCP}/\phi_{init}$, a result that we experimentally verify over the range ($0.1 \leq \phi_{init} \leq 0.64$).

3:06PM X13.00004 Application of Classical Nucleation Theory to Cavitation in Metallic Glass , MICHAEL FALK, Departments of Materials Science and Engineering; Mechanical Engineering; and Physics and Astronomy, Johns Hopkins University — In order to predict the fracture toughness of amorphous solids such as metallic glasses it is necessary to understand the physics of the process zone. Theories of plastic deformation provide information about response to shear, but on their own these theories provide limited insight into the microscopic mechanisms that mediate the free surface generation critical to crack propagation. Previous molecular dynamics simulations indicate that cavitation likely plays this role. We have undertaken a series of molecular dynamics simulations of cavitation under hydrostatic tension in a binary metallic glass analog using pair-wise potentials. We compare the rate of cavity nucleation directly to homogeneous nucleation theory to examine the role of surface energy and irreversible deformation in the cavitation process. We find that both the reduction of the surface energy at small cavity size and the plastic deformation required for the cavity to grow play important roles in setting the strain-dependent free energy barrier to cavitation.

3:42PM X13.00005 Macroscopic transport and topological transitions in ordered suspensions in parallel-wall channels[1] , JERZY BLAWZDZIEWICZ, Texas Tech University, NIDHI KHURANA, Yale University, ELIGIUSZ WAJNRYB, IPPT, Warsaw, Poland — Our recent investigations of ordered suspensions in parallel-wall channels revealed complex nonlinear dynamics, including formation of defects in a particle lattice, dynamic order-disorder transitions, buckling of particle lattice, and fingering instabilities. We will describe hydrodynamic mechanisms that govern this collective particle behavior.

[1]Supported by NSF grant CBET–0931504

3:54PM X13.00006 Continuum Mean-Field Theories for Molecular Fluids, and Their Validity at the Nanoscale[1] , C.B. HANNA, Boise State University, F. PEYRONEL, University of Guelph, C. MACDOUGALL, St. Francis Xavier University, A. MARANGONI, University of Guelph, D.A. PINK, St. Francis Xavier University, AFMNET-NCE COLLABORATION — We present a calculation of the physical properties of solid triglyceride particles dispersed in an oil phase, using atomic- scale molecular dynamics. Significant equilibrium density oscillations in the oil appear when the interparticle distance, d, becomes sufficiently small, with a global minimum in the free energy found at $d \approx 1.4$ nm. We compare the simulation values of the Hamaker coefficient with those of models which assume that the oil is a homogeneous continuum: (i) Lifshitz theory, (ii) the Fractal Model, and (iii) a Lennard-Jones 6-12 potential model. The last-named yields a minimum in the free energy at $d \approx 0.26$ nm. We conclude that, at the nanoscale, continuum Lifshitz theory and other continuum mean-field theories based on the assumption of homogeneous fluid density can lead to erroneous conclusions.

4:06PM X13.00007 Coarse-Graining of a Physical Granular System , JIE ZHANG, Indiana University-Purdue University-Fort Wayne, ISAAC GOLDHIRSCH[1], Tel Aviv University, ROBERT BEHRINGER, Duke University — We present results, including particle displacements and rotations, as well as strain and stress fields, obtained by applying a resolution-controlled coarse-graining method to an experiment comprised of bidisperse disks subject to pure shear. We briefly review the experimental methods which involve determing inter-particle contact forces using the photoelastic properties of the disks. We then consider the philosophical and technical approaches of the coarse-graining methods used here. We particularly consider the emergence of shear bands, which are manifest in the displacements, rotations, and some strain fields, but not in the stress. Correlations of the displacement fluctuations decay on a very small scale, of the order of a few particle diameters, even close to jamming, which in this case, is induced by shear. We report an unexpected but simple correlation between particle rotation angles and the rotation field.

[1](deceased)

4:18PM X13.00008 Nonequilibrium Thermodynamics of Driven Disordered Materials , ERAN BOUCHBINDER, Weizmann Institute of Science — We present a nonequilibrium thermodynamic framework for describing the dynamics of driven disordered solids (noncrystalline solids near and below their glass temperature, soft glassy materials such as colloidal suspensions and heavily dislocated polycrystalline solids). A central idea in our approach is that the set of mechanically stable configurations, i.e. the part of the system that is described by inherent structures, evolves slowly as compared to thermal vibrations and is characterized by an effective disorder temperature. Our thermodynamics-motivated equations of motion for the flow of energy and entropy are supplemented by coarse-grained internal variables that carry information about the relevant microscopic physics. Applications of this framework to amorphous visco-plasticity (Shear-Transformation-Zone theory), glassy memory effects (the Kovacs effect) and dislocation-mediated polycrystalline plasticity will be briefly discussed.

4:54PM X13.00009 Breakdown of Granular Constitutive Relations for Flow through a Narrow Vertical Channel[1] , DONALD CANDELA, KEVIN FACTO, University of Massachusetts Amherst — We have used NMR/MRI techniques to study flow profiles and fluctuations in the dense, gravity-driven flow of a granular medium through a relatively narrow vertical channel (channel diameter approximately 20 grain diameters). Although the flow is macroscopically steady, the NMR experiments reveal large velocity fluctuations that can be characterized as random, short-lived jamming of the flow. Constitutive relations have been successfully developed for granular shear flows in constant pressure conditions, such as flow in open chutes or wide vertical channels. For the narrow-channel flow probed in our experiments, the constant-pressure constitutive relations are not appropriate. An alternative equation of state based on constant-volume conditions may be appropriate for the narrow-channel case, or it can be modeled using a piling-jamming model that abandons the constitutive-equation approach altogether.

5:06PM X13.00010 Dynamic Structure Factor and Transport Coefficients of a Homogeneously Driven Granular Fluid in Steady State[1] , KATHARINA VOLLMAYR-LEE, Bucknell University, USA, ANNETTE ZIPPELIUS, TIMO ASPELMEIER, Georg-August-Universitaet Goettingen, Germany — We study the dynamic structure factor of a granular fluid of hard spheres, driven into a stationary nonequilibrium state by balancing the energy loss due to inelastic collisions with the energy input due to driving. The driving is chosen to conserve momentum, so that fluctuating hydrodynamics predicts the existence of sound modes. We present results of computer simulations which are based on an event driven algorithm. The dynamic structure factor $F(q, \omega)$ is determined for volume fractions 0.05, 0.1 and 0.2 and coefficients of normal restitution 0.8 and 0.9. We observe sound waves, and compare our results for $F(q, \omega)$ with the predictions of generalized fluctuating hydrodynamics which takes into account that temperature fluctuations decay either diffusively or with a finite relaxation rate, depending on wave number and inelasticity. We determine the speed of sound and the transport coefficients and compare them to the results of kinetic theory.

5:18PM X13.00011 Discrete-continuum mapping for fiber network mechanics , CATALIN PICU, ALI SHAHSAVARI, HAMED HATAMI-MARBINI, Rensselaer Polytechnic Institute — Semi-flexible random fiber networks are the structural element of many biological and non-biological systems such as the cytoskeleton, artificial tissue and cellulose-based products. We have shown that in these systems the density, as well as mechanical fields (elastic moduli, strain energy etc), are long-range power-law correlated. The correlation length evolves during deformation. A procedure to map the elasticity of the discrete system to continuum representations is developed. The method is used to solve boundary value problems defined over large fiber network domains. However, the mapping can be performed only in some situations, limitations which are discussed in this talk.

Session X14 GSNP: Focus Session: Extreme Mechanics: Elasticity and Deformation IV D227

2:30PM X14.00001 Harnessing Instabilities in Polymers under Electric Fields , XUANHE ZHAO, Duke University — Subject to a voltage, a layer of a polymer reduces thickness and expands area, so the same voltage will induce an even higher electric field. The positive feedback may cause the polymer to thin down drastically, resulting in an electrical breakdown. This electromechanical instability has been long recognized in the electrical power industry as a major failure mode for polymer insulators. In this talk, we will present recent new observations and understandings of the electromechanical instability. For example, what will happen if the polymer is bonded on a rigid substrate to prevent the area expansion? We show that a new mode of instability will set in. Once the electric field reaches a critical value, the initially flat surface suddenly folds upon itself, deforming into a pattern of creases. As the electric field further rises, the creases increase in size and decrease in density, and strikingly evolve into holes in the polymer. The critical electric field for the creasing instability scales with square root of the polymer's modulus. We show that linear stability analysis overestimates the critical electric field for the instability. A theoretical model has been developed to predict the critical field by comparing the potential energies in the creased and flat states. The theoretical prediction matches consistently with experimental results. We further show that the instability can be harnessed with promising applications in many areas including high-breakdown-field organic capacitors, electrostatic lithography, dynamic pattern formations, fabrication of semi-permeable membranes, and energy harvesting.

3:06PM X14.00002 Ultrasoft Electronics for Hyperelastic Strain, Pressure, and Direct Curvature Sensing[1] , CARMEL MAJIDI, REBECCA KRAMER, ROBERT WOOD, Harvard University — Progress in soft robotics, wearable computing, and programmable matter demands a new class of ultrasoft electronics for tactile control, contact detection, and deformation mapping. This next generation of sensors will remain electrically functional under extreme deformation without influencing the natural mechanics of the host system. Ultrasoft strain and pressure sensing has previously been demonstrated with elastomer sheets (eg. PDMS, silicone rubber) embedded with microchannels of conductive liquid (mercury, eGaIn). Building on these efforts, we introduce a novel method for direct curvature sensing that registers the location and intensity of surface curvature. An elastomer sheet is embedded with micropatterned cavities and microchannels of conductive liquid. Bending the elastomer or placing it on a curved surface leads to a change in channel cross-section and a corresponding change in its electrical resistance. In contrast to conventional methods of curvature sensing, this approach does not depend on semi-rigid components or differential strain measurement. Direct curvature sensing completes the portfolio of sensing elements required to completely map hyperelastic deformation for future soft robotics and computing.

3:18PM X14.00003 ABSTRACT WITHDRAWN –

3:30PM X14.00004 Tensile shock waves in rubber , KRISHNASWAMY RAVI-CHANDAR, University of Texas, JOHNATHAN NIEMCZURA, Army Research Laboratory — We examine the propagation of waves of finite deformation in rubbers through experiments and analysis; in particular attention is focused on the propagation of one-dimensional tensile shock waves in strips of latex and nitrile rubber. Tensile wave propagation experiments were conducted at high strain-rates by holding one end fixed and displacing the other end at a constant velocity. A high-speed video camera was used to monitor the motion and to determine the evolution of strain and particle velocity in rubber strips. Shock waves have been generated under tensile impact in pre-stretched rubber strips; analysis of the response yields the tensile shock adiabat for rubbers. The propagation of shocks is analyzed by developing an analogy with the theory of detonation; it is shown that the condition for shock propagation can be determined using the Chapman-Jouguet shock condition.

3:42PM X14.00005 Kinetic features of pattern transformation and recovery in periodic hydrogel membranes , XUELIAN ZHU, RONG DONG, JI FENG, CHI-MON CHEN, SHU YANG, University of Pennsylvania, DEPT. OF MATER. SCI. & ENG., UNIV. OF PENNSYLVANIA TEAM — Pattern transformation triggered by mechanical instabilities is an attractive bottom-up method to create complex structures over a wide range of length scales. However, how to dynamically control the transformation and its recovery is yet to be studied. Here, we present a systematic study of the kinetic pattern transformation and its recovery using a model system from poly(2-hydroxyethyl methacrylate) hydrogel membrane with a square lattice of micron-sized cylindrical holes. The hydrogel membrane undergoes (1) a breathing mode (i.e. the hole reduces size but retains the shape) when exposed to DI-water; (2) a phase transition to a diamond plate pattern driven by capillarity during drying process; and (3) a recovery upon re-exposure to water. During drying, many antiphase boundaries (APBs) appear in the diamond plate pattern, which then act as embryos that determine the kinetic path for recovery. The boundary morphology (either random or aligned) can be manipulated by the moving speed of the waterfront. To reveal the underlying mechanism of pattern transformation and APB arrangement, as well as the role of APB in recovery, we utilized the dynamic Monte Carlo method to simulate the kinetic process of pattern transformation and recovery, which qualitatively matched well with the experiments.

3:54PM X14.00006 Cavitation in elastomeric solids: A defect-growth theory[1] , OSCAR LOPEZ-PAMIES, State University of New York at Stony Brook, MARTIN IDIART, TOSHIO NAKAMURA — A new theory is introduced to study the phenomenon of cavitation in soft solids that, contrary to existing approaches, simultaneously: (i) applies to large (including compressible and anisotropic) classes of nonlinear elastic solids, (ii) allows to consider general 3D loading conditions with arbitrary triaxiality, and (iii) incorporates direct information on the initial shape, spatial distribution, and mechanical properties of the underlying defects at which cavitation can initiate. The basic idea is to cast cavitation in elastomeric solids as the homogenization problem of nonlinear elastic materials containing random distributions of zero-volume cavities, or defects. In spite of the generality of the proposed approach, the relevant calculations amount to solving tractable Hamilton-Jacobi equations, in which the initial size of the cavities plays the role of "time" and the applied load plays the role of "space."

4:06PM X14.00007 The aerodynamics of jumping rope , JEFFREY ARISTOFF, HOWARD STONE, Department of Mechanical and Aerospace Engineering, Princeton University — We present the results of a combined theoretical and experimental investigation of the motion of a rotating string that is held at both ends (i.e. a jump rope). In particular, we determine how the surrounding fluid affects the shape of the string at high Reynolds numbers: the string bends toward the axis of rotation, thereby reducing its total drag. We derive a pair of coupled non-linear differential equations that describe the shape, the numerical solution of which compares well with asymptotic approximations and experiments. Implications for successful skipping will be discussed.

4:18PM X14.00008 Helical Root Buckling: A Transient Mechanism for Stiff Interface Penetration , JESSE SILVERBERG, Department of Physics, Cornell University, ROSLYN NOAR, UNCSU, Dept of Plant Pathology, MICHAEL PACKER, Department of Physics, Cornell University, MARIA HARRISON, Boyce Thompson Institute, Cornell University, ITAI COHEN, CHRIS HENLEY, Department of Physics, Cornell University, SHARON GERBODE, School of Engineering and Applied Sciences, Harvard University — Tilling in agriculture is commonly used to loosen the topmost layer of soil and promote healthy plant growth. As roots navigate this mechanically heterogeneous environment, they encounter interfaces between the compliant soil and the underlying compacted soil. Inspired by this problem, we used 3D time-lapse imaging of Medicago Truncatula plants to study root growth in two-layered transparent hydrogels. The layers are mechanically distinct; the top layer is more compliant than the bottom. We observe that the roots form a transient helical structure as they attempt to penetrate the bi-layer interface. Interpreting this phenotype as a form of buckling due to root elongation, we measured the helix size as a function of the surrounding gel modulus. Our measurements show that by twisting the root tip during growth, the helical structure recruits the surrounding medium for an enhanced penetration force allowing the plants access to the lower layer of gel.

4:30PM X14.00009 Increasing Digging Efficiency Using Two Biologically-Inspired Techniques[1] , DAWN WENDELL, PEKO HOSOI, MIT — The mechanics of digging through granular materials often neglect the inhomogeneities present in granular packings. This work reports on two biologically-inspired mechanisms that aim to increase the efficiency of digging through granular materials by taking advantage of the variety of forces found in granular packings. First, flexible diggers demonstrate that a slight increase in flexibility can lead to more efficient digging using a completely passive mechanism. Secondly, a digger with an actuated tip is investigated to find optimum parameters for energy efficient digging with actuated mechanisms.

[1]This work is funded by Schlumberger-Doll Research.

4:42PM X14.00010 Pattern switches in granular crystals , KATIA BERTOLDI, JONGMIN SHIM, Harvard University, FATIH GONCU, University of Twente, STEPHEN WILLSHAW, TOM MULLIN, University of Manchester, STEFAN LUDING, University of Twente — We report an experimental and numerical study of a pattern transformation in a regular array of macroscopic cylindrical particles with contrasting dimensions and stiffnesses. The initial structure is a square lattice with a pair of large (soft) and small (hard) particles at each lattice site. The application of a uniaxial compression produces a new periodic structure and the transformation principally depends on the size ratio of the particles. At small ratios it is homogeneous and approximately reversible i.e. the initial geometry is almost recovered after unloading. In contrast, when the size ratio is increased the final pattern is reached after a sudden rearrangement of the particles which involves the formation of a shear band. The structural reorganization of the granular crystal will have a significant effect on wave propagation properties and we suggest that this could have interesting applications in phononic and photonic crystals.

4:54PM X14.00011 Evidence for a mechanical instability, via folding, of the vein network in leaves , PILNAM KIM, Princeton University, MANOUK ABKARIAN, Universite Montpellier 2 / CNRS, HOWARD A. STONE, Princeton University — The venation pattern of leaves is the archetype of a self-organized transport network whose efficiency and robustness stems from the connectivity of its hierarchical branching structure, but whose underlying principles of formation are not understood. Here we propose that the folding instability of the inner tissues of the leaf provides such a hierarchical venation pattern. Using a multi-layered polymeric system under an equibiaxial compressive stress, which mimics both growth and the layered structure of a leaf tissue, we show that a repetitive wrinkling-to-folding transition can achieve a hierarchical network of folds by continual, local reorganization of the stress field. We find that the resulting network topology, including closed loops, is the result of a spontaneous evolution of both terminal and segmental branching of the fold network and shares basic topological properties with venation patterns. This folding transition gives new insights into the role of mechanical stress as a possible feedback mechanism for cell differentiation in early veins.

5:06PM X14.00012 Minimal resonances in annular non-Euclidean strips , BRYAN CHEN, Department of Physics and Astronomy, University of Pennsylvania, CHRISTIAN SANTANGELO, Department of Physics, University of Massachusetts, Amherst — Differential growth processes play a prominent role in shaping leaves and biological tissues. Using both analytical and numerical calculations, we consider the shapes of closed, elastic strips which have been subjected to an inhomogeneous pattern of swelling. The stretching and bending energies of a closed strip are frustrated by compatibility constraints between the curvatures and metric of the strip. To analyze this frustration, we study the class of "conical" closed strips with a prescribed metric tensor on their center line. The resulting strip shapes can be classified according to their number of wrinkles and the prescribed pattern of swelling. We use this class of strips as a variational ansatz to obtain the minimal energy shapes of closed strips and find excellent agreement with the results of a numerical bead-spring model. We derive and test a surprising resonance condition for strips with minimal bending energy along the strip center line to exist.

5:18PM X14.00013 Deflation of elastic surfaces , CATHERINE QUILLIET, Laboratory of Interdisciplinary Physics (ex "Spectro") — The deflation of elastic spherical surfaces has been numerically investigated, and show very different types of deformations according the range of elastic parameters, some of them being quantitatively understood through simple theoretical considerations. In particular, the role of the Poisson ratio is closely investigated. This work allowed to retrieve various shapes observed on hollow deformable shells (from colloidal to centimeter scale), on lipid vesicles, or on some simple biological objects. Conversely, it shows how high deformations can tell observers about mechanical properties of a body. Such investigations have been extended to other geometries, in order to provide clues to understand deformations of vegetal or animal tissues.

Session X15 DMP GMAG FIAP: Focus Session: Spins in Semiconductors - Manipulation of Dopant Spins D171

2:30PM X15.00001 Quantum information in silicon: Initialization, manipulation, storage and readout[1] , GAVIN W. MORLEY, London Centre for Nanotechnology and Department of Physics and Astronomy, University College London, UK — Spin qubits in silicon are exciting because of their long coherence times [1] and the electrical readout of the state of one electron spin [2]. In a single experiment we demonstrate initialization [3], manipulation, storage and electrical readout of quantum information with a small ensemble of phosphorus electronic and nuclear spins in silicon [4]. Our electrical readout does not destroy the electron spin coherence which is limited instead by naturally-occurring ^{29}Si nuclear spins. These experiments require a pulsed electron spin resonance spectrometer operating at high magnetic fields [5]. Silicon quantum computers would benefit from having a second dopant species which can be addressed selectively [6-8], and we find that bismuth atoms are well suited for this role [9]. They offer long spin coherence times [9,10] as well as new opportunities [11] when compared with phosphorus.

3:06PM X15.00002 Crystal orientation induced spin Rabi beat oscillations of point defects at the c-Si(111)/SiO_2 interface , SEOYOUNG PAIK, SANG-YUN LEE, CHRISTOPH BOEHME, University of Utah — Spin-dependent electronic transitions such as certain charge carrier recombination and transport processes in semiconductors are usually governed by the Pauli blockade within pairs of two paramagnetic centers. One implication of this is that the manipulation of spin states, e.g. by magnetic resonant excitation, can produce changes to electric currents of the given semiconductor material. If both spins are changed at the same time, quantum beat effects such as beat oscillation between resonantly induced spin Rabi nutation becomes detectable through current measurements [1]. Here, we report on electrically detected spin Rabi beat oscillation caused by pairs of ^{31}P donor states and P_b interface defects at the phosphorous doped Si(111)/SiO_2interface. Due to the g-factor anisotropy of the P_b center we can tune the intra pair Larmor frequency difference (so called Larmor separation) through orientation of the sample with regard to the external magnetic field. As the Larmor separation governs the spin Rabi beat oscillation, we show experimentally how the crystal orientation can influence the beat effect.

3:18PM X15.00003 Dynamic Response of the Kondo Resonance in a Single-Electron Transistor in the Presence of Magnetic Field , BRYAN HEMINGWAY, TAI-MIN LIU, ANDREI KOGAN, University of Cincinnati, STEVEN HERBERT, Xavier University, MICHAEL MELLOCH, Purdue University — We report a sharp peak in the differential conductance of a Single-Electron Transistor (SET) in the Kondo regime irradiated with microwaves, plotted as function of an external, in-plane magnetic field, B. The peak emerges at frequencies, hf, above $\sim T_K/2$ and shifts approximately linearly with the microwave signal frequency. At frequencies significantly below the Kondo scale, T_K/h (M. Hettler and H. Schoeller Phys. Rev. Lett. 74, 4907-4910 (1995)), no such peak is present and the conductance data agree with the predictions based on static measurements. In the Coulomb Blockade regime, we find good agreement with the photon-assisted resonant tunneling model and experiments (T.H. Oosterkamp et al., Phys. Rev. Lett. 78 (1997)) . Our SETs are fabricated lithographically using GaAs/AlGaAs heterostructure with sheet density 4.8×10^{11} cm^{-2} and mobility 5×10^5 cm^{2}V^{-1}sec^{-1} and have the lithographic dot size approximately 130 nm in diameter.

3:30PM X15.00004 Jahn-Teller induced multiple ferromagnetic exchange interactions in magnetic semiconductors[1] , HANNES RAEBIGER, TAKESHI FUJITA, Yokohama National University, Yokohama — Ferromagnetic interactions among $3d$ impurities in compound semiconductors (II-VI, III-V, etc) are usually rationalized via "double exchange", "p-d exchange", and "superexchange" type interactions, which ensue a description of the $3d$ impurity electronic configuration based on host symmetries. Obviously Jahn-Teller distortions break these symmetries and yield completely different, closed shell, electronic configurations for the impurities, which most theories [1] simply describe as magnetically inactive. Nonetheless, such Jahn-Teller distorted $3d$ impurities e.g. in the AlN host exhibit strong short range ferromagnetic interactions. Superexchange models may offer some insight to "closed shell" magnetic interactions, not applicable to the present case, however. We investigate such peculiar magnetic interactions via density-functional calculations, and find that a Jahn-Teller distortion can trigger the formation of a 3d-3d chemical bond that stabilizes ferromagnetism via direct exchange [2], and further facilitates a double exchange type interaction. This multiple exchange is what aligns parallel the spins of e.g. Cr impurities in AlN.

3:42PM X15.00005 Detecting excitation and magnetization of individual dopants in a semiconductor two-dimensional electron gas[1] , JENS WIEBE, Institute of Applied Physics, Hamburg University — Magnetic atoms doped into a semiconductor are the building blocks for bottom up spintronic and quantum logic devices. They also provide model systems for the investigation of fundamental effects. In order to correlate the dopant's atomic structure with its magnetism magnetically sensitive techniques with atomic resolution are a prerequisite. Here, I show electrical excitation and read-out [1] of single magnetic dopant associated spins in a two-dimensional electron gas (2DEG) confined to a semiconductor surface [2] using spin-resolved scanning tunneling spectroscopy [3]. I will review our real-space study of the quantum Hall transition in the 2DEG [2] and of the magnetic properties of the dopants [1]. Finally, I will demonstrate that the dopant serves as an atomic scale probe for local magnetometry of the 2DEG. This work was done in collaboration with A. A. Khajetoorians, B. Chillian, S. Schuwalow, F. Lechermann, K. Hashimoto, C. Sohrmann, T. Inaoka, F. Meier, Y. Hirayama, R. A. Römer, M. Morgenstern, and R. Wiesendanger.

4:18PM X15.00006 Coherent spin precession of multiple spins in an inhomogeneous environment , V. KORTAN, M.E. FLATTÉ, University of Iowa Department of Physics and Astronomy — Mn dopants in GaAs, whose core spins are bound anti-aligned to a hole, forming a J=1 ground state of the neutral acceptor, are very sensitive to their environment, including strain [1] and electric fields [2]. This sensitivity affects spin precession by broadening resonance lines and shifting/adding resonant frequencies. Using a low energy Hamiltonian developed for a single Mn ion-hole complex in GaAs [1,2] we have studied spin dynamics of a small collection of spins in the presence of bias electric fields and strain fields. Each Mn ion-hole complex is locally subject to a random electric field in addition to bias fields to determine if coherent spin precession persists. Using these calculations we predict the possible observation of coherent spin precession of small numbers of Mn spins via optical polarization measurements [3], and estimate the strength of the random field necessary to destroy the signal of coherent spin precession. This work supported by NRI through WIN.

4:30PM X15.00007 Study of spin interactions between InAs surface electrons and local magnetic moments by antilocalization measurements , YAO ZHANG, R.L. KALLAHER, V. SOGHOMONIAN, J.J. HEREMANS, Virginia Tech — Spin-orbit coupled electrons in the InAs surface accumulation layer can be used as a sensitive system to experimentally study the interactions and exchange between electrons and local magnetic moments in semiconductors. We use antilocalization measurements as a probe of quantum states, by comparing measurements on patterned InAs accumulation layers where Sm^{3+}, Gd^{3+} and Ho^{3+} have been deposited, with those where no magnetic species are deposited. The randomly distributed ions modify the spin-orbit scattering time and the magnetic spin-flip time, identified via the antilocalization signal and characterized over temperature. The magnetic spin-flip time carries information about magnetic interactions. Experiments indicate that the spin-orbit scattering times display a weak temperature dependence. The Sm^{3+} and Gd^{3+} cases yield temperature-independent magnetic spin-flip times, while Ho^{3+} shows a spin-flip time obeying $T^{-1/2}$ at low temperatures. Similar results as observed in the Ho^{3+} case have in the literature been attributed to Kondo-like behavior. We thus interpret the results as indicative of a Kondo interaction with a Kondo temperature considerably above 5 K, of which antilocalization measurements can identify the low-temperature tail (partial support from DOE DE-FG02-08ER46532).

4:42PM X15.00008 Spin relaxation dynamics for an electron gas with localized magnetic impurities near the ferromagnetic transition[1] , MATTHEW MOWER, GIOVANNI VIGNALE, University of Missouri — We study the spin relaxation dynamics of electrons in Mn-doped GaAs. Modeling the Mn as magnetic impurities embedded in an electron gas, we construct effective electron-electron and impurity-impurity interactions. This model exhibits a ferromagnetic transition as the temperature is lowered. Near the ferromagnetic transition, strong spin fluctuations cause an enhancement of the electron scattering rate, which affects the spin relaxation time of spin polarized electrons. This is especially notable in the D'yakonov-Perel' spin relaxation time which is proportional to the electron scattering rate. We will elucidate the behavior of the spin relaxation time and other spin-dependent kinetic coefficients near the ferromagnetic transition.

4:54PM X15.00009 Intrinsic Magnetism at Silicon Surfaces , STEVEN ERWIN, Naval Research Laboratory, FRANZ HIMPSEL, University of Wisconsin-Madison — It has been a long-standing goal to create magnetism in a nonmagnetic material by manipulating its structure at the nanometer scale. Many structural defects have unpaired spins; an ordered arrangement of such defects can give rise to a magnetically ordered state. Here we predict theoretically [1] that stepped silicon surfaces stabilized by adsorbed gold realize this goal by self-assembly, creating linear chains of polarized electron spins with virtually perfect structural order. The spins are localized at the silicon step edges, which have the form of graphitic hexagonal ribbons. The predicted magnetic state is indirectly supported by recent experimental observations, such as the coexistence of double- and triple-period distortions and the absence of edge states in photoemission. Ordered arrays of spins at a surface offer access to local probes with single spin sensitivity, such as spin-polarized scanning tunneling microscopy. The integration of structural and magnetic order is crucial for technologies involving spin-based computation and storage at the atomic level.

[1] S.C. Erwin and F.J. Himpsel, Nature Communications 1:58 (2010).

5:06PM X15.00010 Magnetic Si Atoms at the Step Edges of Si(553)-Au , PAUL SNIJDERS, ORNL, NATHAN GUISINGER, ANL, PHILLIP JOHNSON, UW-Madison, STEVEN ERWIN, NRL, FRANZ HIMPSEL, UW-Madison — A recent calculation predicts the possibility of magnetism at step edges of vicinal Si(111) surfaces decorated with gold [1]. Graphene-like Si ribbons are formed, which contain spin-polarized Si atoms at their edges. Those atoms form a six-fold superlattice at low temperature. Scanning tunneling spectroscopy (STS) of the magnetic broken bond orbitals reveals two peaks below 50 K. They match the calculated majority and minority spin states. The peaks merge into a single, broad peak at 300 K due to rapid spin fluctuations.

[1] Steven C. Erwin and F. J. Himpsel, Nature Communications 1:58 (2010).

5:18PM X15.00011 Electronic structure of Gd impurities in GaN on Ga, N and Ga-N adjacent sites and the role of N interstitials , TAWINAN CHEIWCHANCHAMNANGIJ, WALTER LAMBRECHT, Case Western Reserve University — Gd-doped GaN is one of the most interesting dilute magnetic semiconductors. However, the origins of its magnetic properties are still unclear. Previous studies have focused on the role of intrinsic defects, such as Ga vacancies and N or O interstitials. Here, we study Gd doped in pairs on adjacent Ga and N sites, which were suggested to be required to explain the X-ray linear dichroism signals in Gd L-edge spectra by Ney et al. JMMM 322, 1162 (2010). By using the FP-LMTO method in the LSDA+U, we find that the Gd on N site is pushed to the interstitial site after the relaxation and there is no extra magnetic moment besides the seven Bohr magneton from the 4f half-filled shell on each Gd atom. In spite of the relaxation, we find the energy of formation of this cluster to be of order 10 eV, which shows that the Gd doped on Ga-N adjacent sites is unlikely to occur. We also study Gd doped on a single N site and find an excess magnetic moment of 3 Bohr magneton which is spread over Gd, the nearest neighbor Ga atoms, and second nearest neighbor N atoms. However, its energy of formation is also large that this kind of impurity is unlikely to occur. We critically examine previous work on the role of N interstitials in the magnetism of Gd-doped GaN by studying the magnetic properties of the split interstitials, their interaction with each other and with Gd.

Session X16 GMAG DMP: Focus Session: Spins in Carbon-Based Materials – Graphene, CNT, and C60 D173

2:30PM X16.00001 Enhanced spin injection and spin lifetime in Graphene[1] , WEI HAN, KEYU PI, KATHLEEN MCCREARY, YAN LI, ROLAND KAWAKAMI — Graphene is an attractive material for spintronics due to the low intrinsic spin-orbit and hyperfine coupling, which should lead to excellent spin transport properties. Earlier studies on spin injection and transport in graphene present two major challenges: low spin injection efficiency and short spin lifetimes compared to the theoretical predictions. In our work, we utilized TiO2 Seeded MgO barriers and achieved tunneling spin injection into single layer. As a result, large nonlocal magnetoresistances were observed at room temperature, with high spin injection efficiency up to 30%. Surprisingly, enhanced spin lifetimes of graphene are obtained, which is due to reducing the contract-induced spin relaxation by inserting tunnel barrier between graphene and Co electrodes.

[1]Thanks to the support of ONR and NSF.

2:42PM X16.00002 Electrical Detection of Spin Transport in Epitaxial Graphene Grown on the Si-face of Hexagonal SiC(0001) , J. ABEL, A. MATSUBAYASHI, J. GARRAMONE, University at Albany, C. DIMITRAKOPOULOS, A. GRILL, C.Y SUNG, IBM T.J Watson Research Center, V. LABELLA, University at Albany — Graphene has great potential for use as a spin transport channel due to its low spin orbit coupling and high mobility. Spin diffusion lengths in the microns have been demonstrated on exfoliated graphene at room temperature[1]. We will present our measurements of spin relaxation in both exfoliated graphene and epitaxially grown graphene on SiC from IBM using non-local Hanle measurements as a function of temperature. The diffusion lengths on epitaxial graphene were comparable to those found in exfoliated flakes. The initial results show the diffusion length is limited by contact induced relaxation that occurs at the metal/graphene interface in agreement with results from exfoliated flakes.

2:54PM X16.00003 Room Temperature Spin Transport in C_{60}-based spin valves.[1] , LUIS HUESO, CIC nanoGUNE / IKERBASQUE, MARCO GOBBI, ROGER LLOPIS, FEDERICO GOLMAR, CIC nanoGUNE, FELIX CASANOVA, CIC nanoGUNE / IKERBASQUE — Carbon-based materials offer a unique playground for spin transport studies by merging relatively small spin relaxation mechanisms with the potential chemical versatility of some organic molecules. However, how the spin travels inside such materials is far from understood. In this work, we present magneto-transport studies in vertical spin valves containing a C_{60} non-magnetic spacer and simple ferromagnetic (Co and Py) electrodes. Large magnetoresistance values (up to 5%) are recorded at room temperature for fullerene thickness up to 30 nm. Remarkably, magnetoresistance is also present at relatively high bias (1 Volt), highlighting the robustness of the spin transport in this material. By choosing such a simple carbon system we are also able to introduce a simple multi-step tunneling model, which explain the electronic transport data and which is compatible with coherent spin transport over long distances.

3:06PM X16.00004 Spin-orbit coupling in graphene: from single layers to graphite[1] , JAROSLAV FABIAN, Institute for Theoretical Physics, University of Regensburg — The spin-orbit interaction in graphene is full of contrasts. First, this relativistic interaction destroys the ideal relativistic "touching cones" electronic dispersion at the K points. A finite, albeit small, gap appears, giving a finite mass to the electrons. Then, while the spin-orbit splitting in the carbon atom is about 10 meV, the electronic states at the K points have a gap of only about 24 micro eV. Finally, it turns out that this quintessential sp material has its spin-orbit coupling derived almost exclusively from d orbitals. In this talk I will give first-principles [1] and tight-binding [2] perspectives on the spin-orbit coupling in graphene in the presence of a transverse electric field. The field, which would normally come from the substrate or the gates, breaks the space inversion symmetry and gives the extrinsic (Bychkov-Rashba) splitting of the states. It also brings interesting band-structure topologies, from gapped at low electric fields (the topological insulator phase), through a mixture of genuine touching Dirac cones and parabolic bands (the intrinsic and extrinsic spin-orbit strengths equal), to gapples, dominated by the extrinsic effects [1]. The intrinsic coupling is dominated by d orbitals, while the extrinsic by the field induced hybridization of the s and p orbitals. It turns out that similar physics holds for bilayer and trilayer graphene, ultimately also in graphite. I will also discuss the problem of the spin relaxation in graphene. The main issue is that conventional theories predict microseconds for the spin relaxation time, while experiments seem to consistently yield 100 ps. One possibility [3] is that that spin relaxation in graphene is due to adatoms that pull out the carbon-like spin-orbit coupling of the p electrons and lead to the larger spin relaxation of the Dyakonov-Perel type.

3:42PM X16.00005 Ferromagnetism in Mn-implanted HOPG[1] , SAMARESH GUCHHAIT, The University of Texas at Austin, HENDRIK OHLDAG, Stanford Synchrotron Radiation Lightsource, DOMINGO FERRER, SANJAY BANERJEE, The University of Texas at Austin — 20 keV energy Mn ions were implanted on HOPG samples at 300°C. SQUID magnetometer measurements show ferromagnetic ordering and magnetic hysteresis at very low temperatures. Mn K-edge XAS spectra show presence of Mn and O in our sample and XMCD data shows ferromagnetic ordering of Mn at 14 K, but not at 300 K. SIMS data show presence of Mn and O with carbon, besides other elements. Raman spectroscopy results indicate disorder graphite phase and high resolution TEM images confirm amorphous Mn-implanted region with presence of nanocrystallites.

3:54PM X16.00006 Organic spin-valves based on fullerene C60[1] , RAN LIN, FUJIAN WANG, MARKUS WOHLGENANNT, University of Iowa, CHUNYONG HE, XIAOFANG ZHAI, YURI SUZUKI, University of California at Berkeley, MARKUS WOHLGENANNT TEAM[2], YURI SUZUKI TEAM[3] — Recent work suggests that the spin-transport length in organic semiconductors is limited by hyperfine coupling. Therefore, to potentially overcome this limitation, we fabricated spin-valves based on C60 for which the hyperfine coupling is minute. However, our devices do not show a significantly larger spin-diffusion length. This suggests that either a mechanism other than hyperfine coupling causes the loss of spin-polarization, or that in thick devices an increasing conductivity mismatch limits spin-injection.

4:06PM X16.00007 On the Role of Spin-Orbit Coupling in the Spin Response of C_{60}-based Spintronics Devices[1] , THO NGUYEN, FIJIAN WANG, Department of Physics & Astronomy, University of Utah, 115 South 1400 East, Salt Lake City, Utah 84112, USA, XIAO-GUANG LI, Hefei National Laboratory for Physical Sciences at Microscale, People's Republic of China, EITAN EHRENFREUND, Technion-Israel Institute of Technology, Israel, VALY VARDENY, Department of Physics & Astronomy, University of Utah, 115 South 1400 East, Salt Lake City, Utah 84112, USA — We report comprehensive studies of the spin response in C_{60}-based spintronics devices such as spin valves and diodes. The buckeyball C_{60} molecules are composed of ∼99% ^{12}C carbon atoms having spinless nuclei with zero hyperfine interaction. Therefore it was believed that the spin diffusion length in C_{60}-based spin-valves is large, and the magnetoresistance (MR) in C_{60} diodes is negligible small. Surprisingly, we obtained a small spin diffusion length which we believe to be due to a relatively strong spin-orbit (SO) coupling in the material. We also found that the MR in C_{60} diodes is relatively small, with characteristic magnetic field response dominated by the SO coupling with strength, $\xi \approx 1/2$ μeV, more than ten times larger than the HFI constant. This was verified by measuring the response of ^{13}C-rich C_{60} diodes.

4:18PM X16.00008 Kondo effect of magnetic impurities on nanotubes[1] , PIER PAOLO BARUSELLI, SISSA, Via Bonomea, 265 34136 Trieste (Italy), CNR-IOM Democritos, ALEXANDER SMOGUNOV, SISSA, CEA Saclay, MICHELE FABRIZIO, ERIO TOSATTI, SISSA, ICTP, CNR-IOM Democritos — The effect of magnetic impurities on the ballistic conductance of nanocontacts is, as suggested in recent work, amenable to ab initio study [1]. Our method proceeds via a conventional density functional calculation of spin and symmetry dependent electron scattering phase shifts, followed by the subsequent numerical renormalization group solution of Anderson models – whose ingredients and parameters are chosen so as to reproduce these phase shifts. We apply this method to investigate the Kondo zero bias anomalies that would be caused in the ballistic conductance of perfect metallic (4,4) and (8,8) single wall carbon nanotubes, ideally connected to leads at the two ends, by externally adsorbed Co and Fe adatoms. The different spin and electronic structure of these impurities are predicted to lead to a variety of Kondo temperatures, generally well below 10 K, and to interference between channels leading to Fano-like conductance minima at zero bias.

4:30PM X16.00009 Electric-field control of magnetism in graphene quantum dots: A route to spin field effect transistors[1] , LUIS AGAPITO, NICHOLAS KIOUSSIS, Department of Physics, California State University Northridge, EFTHIMIOS KAXIRAS, Department of Physics, Harvard University — Graphene is a promising candidate for all-carbon electronics because of its outstanding electrical, mechanical, and thermal properties. Also, the relentless drive for miniaturization leads to the use of ever smaller graphene fragments; at nanoscopic dimensions ($<$ 10nm), edge states become more relevant. Edge states are important because they lie in the vicinity of the Fermi level and hence are relevant to transport properties. Furthermore, edge states exhibit magnetism. We have employed ab-initio electronic structure and Landauer-Büttiker transport calculations to study the magnetoelectro effects of graphene patches. We will present results of (1) how specific geometries (such as "diamond" shape) favor specific magnetic states, (2) how those magnetic states can be controlled by an external electric field [1], and (3) we will demonstrate how a graphene fragment containing different edge geometries can be employed as a spin-polarized field effect transistor.

4:42PM X16.00010 Evidence for magnetic behavior in chemically modified graphene , JOEL THERRIEN, KYLE TWAROWSKI, ECE, U. Massachusetts Lowell, VAIBHAV MATHUR, Physics, U. Massachusetts Lowell, ANTONIO H. CASTRO-NETO, Physics, Boston University — Although graphene has exceptional electronic and structural properties, there is very little experimental evidence that graphene by itself shows strong electron-electron correlations. In fact, in spite of a large amount of theoretical work, recent experiments have shown that pure and clean graphene shows no signs of correlated many-body states such as magnetism or superconductivity. We will report on the observation of room temperature magnetism in mechanically exfoliated, chemically modified, graphene. The effect has been found using both magnetic force microscopy and magnetization tests. It was shown that the graphene can be brought back to a non-magnetized state by removing the surface chemistry. The search for correlated electronic states in graphene generates an enormous interest because of its low dimensionality, which is prone to strong quantum and thermal effects, and also because it would open up doors for a plethora of technological applications, from permanent two-dimensional magnets to spintronics.

4:54PM X16.00011 QMC study of molecules for spintronics and photoswitching[1] , MATUS DUBECKY, RENE DERIAN, LUCIA HORVATHOVA, Inst. of Physics, Slovak Academy of Sciences, Bratislava, Slovakia, LUBOS MITAS, Dept. of Physics, North Carolina State University, Raleigh, 27695, U.S.A., IVAN STICH, Inst. of Physics, Slovak Academy of Sciences, Bratislava, Slovakia — A combination of QMC and quantum chemistry (CAS-SCF) techniques are used to study two large molecules: azobenzene (AB) imporatnt as a photoswitch and vanadbenzene (VB), frequently used in spintronics [1]. In AB higher singlet state, S_2 the fingerprint of AB in excitation spectra has been calculated in addition to the low singlet states S and S_1 [2]. We have also calculated the lowest triplet T_1 vertical excitation, identified by EELS [3] as well as adiabatic T_1 excited state. All calculated energies are in excellent agreement with available experiments [3, 4]. In VB we focus initially on PES for dissociation and excited state of the vanadium cation.

Session X17 GMAG DMP: Focus Session: Magnetic Oxide Thin Films - Multiferroic Heterostructures and Europium Oxide D174

2:30PM X17.00001 Electric field control of magnetism in multiferroic heterostructures[1] , CARLOS A.F. VAZ, Paul Scherrer Institut, 5232 Villigen PSI, Switzerland — Much interest is being devoted to designing systems where magnetic and ferroelectric orders coexist (multiferroics), and where the presence of magnetoelectric coupling could enable the electrostatic control of magnetism in the solid state. In particular, proximity effects can be tailored to design novel electronic structures with enhanced magnetoelectric couplings in composite heterostructures [1]. A striking example of this approach is our recent demonstration of a large, charge-mediated, magnetoelectric coupling in epitaxial PZT/LSMO heterostructures [2], which explores the sensitivity of the magnetic properties of the doped manganites to charge. Through magnetic, electric, structural and spectroscopic characterization, we demonstrate that the magnetoelectric coupling in PZT/LSMO heterostructures is electronic in origin, and results from the modulation in the valency of the Mn upon switching the PZT ferroelectric polarization [3]. In particular, we conclude that the interfacial spin ordering is modified upon charge doping, which explains the large magnetoelectric response found in this system [4]. This ability to control spin via electric fields opens a new pathway for the development of novel spin-based technologies.

3:06PM X17.00002 Ferroelectric field effect modulation of magnetism in composite multiferroics , JASON HOFFMAN, CARLOS VAZ, YARON SEGAL, MATTHEW MARSHALL, FRED WALKER, CHARLES AHN, Yale University — This work harnesses the strong charge-driven magnetoelectric coupling in $Pb(Zr_{0.2}Ti_{0.8})O_3/La_{0.8}Sr_{0.2}MnO_3$ (PZT/LSMO) heterostructures to explore the sensitivity to charge of the electron transport and magnetic behavior of complex oxides. Epitaxial LSMO films that exhibit a highly ordered crystalline structure, as determined by *in situ* reflection high energy electron diffraction (RHEED) measurements and *ex situ* x-ray diffraction and transmission electron microscopy are grown by oxide molecular beam epitaxy. Off-axis RF magnetron sputtering is used to grow the PZT gate dielectric, which is characterized by square polarization-electric field hysteresis loops, with a large polarization and low leakage current. We use a combination of low-field magneto-transport and magneto-optic Kerr effect (MOKE) magnetometry to study the ferroelectric field effect induced changes in the magnetic coercive field in PZT/LSMO bilayers. A reversible shift in the coercive field is observed for the two polarization states of the ferroelectric, with a larger coercive field in polarization state that accumulates hole carriers at the PZT/LSMO interface. The reversible electrical control of magnetism in engineered heterostructures is opens new directions in the field of spintronics.

3:18PM X17.00003 Pulsed Laser Deposition of $Cr_{2-x}Fe_xTeO_6$ Thin Film[1] , JUNLEI WANG, KIRILL D. BELASHCHENKO, PETER A. DOWBEN, CHRISTIAN BINEK, Department of Physics & Astronomy, University of Nebraska-Lincoln — Promising spintronic concepts such as Cr_2O_3 based voltage-controlled exchange bias system [1] employ electric controlled boundary magnetization. Symmetry arguments reveal that equilibrium boundary magnetization is a generic property of magnetoelectric antiferromagnets [2]. However, experimental evidence of the boundary magnetization is scarce. Here we explore non-traditional growth of magnetoelectric oxides with tri-rutile structure using pulsed laser deposition (PLD) methodology. We grow and characterize structurally and magnetically various magnetoelectric thin films of the $Cr_{2-x}Fe_xTeO_6$ family starting from x=2 in order to take advantage of the reduced chemical complexity of Fe_2TeO_6 and the beneficial high temperature onset of antiferromagnetic order at 230K in comparison to 90K of Cr_2TeO_6. Our investigation aims on an experimental test of the predicted generality of the equilibrium boundary magnetization in magnetoelectric antiferromagnets.

3:30PM X17.00004 Properties of the Predicted Multiferroic $Ca_3Mn_2O_7$ - Experiment , R. MISRA, The Pennsylvania State University, University Park, PA, C. ADAMO, N.A. BENEDEK, Cornell University, NY, S.A. DENEV, A. SENGUPTA, The Pennsylvania State University, University Park, PA, J.A. MUNDY, Cornell University, NY, J.H. LEE, The Pennsylvania State University, University Park, PA, D.A. MULLER, Cornell University, NY, V. GOPALAN, The Pennsylvania State University, University Park, PA, C.J. FENNIE, D.G. SCHLOM, Cornell University, NY, P. SCHIFFER, The Pennsylvania State University, University Park, PA — We have studied the properties of epitaxial films of $Ca_3Mn_2O_7$, an $n = 2$ Ruddlesden-Popper phase. This material has been predicted to have novel multiferroic properties, including electric field switching of the magnetization [1]. 50 nm thick unstrained $Ca_3Mn_2O_7$ films were grown by reactive MBE on (110) $YAlO_3$ single crystal substrates. XRD shows that the $Ca_3Mn_2O_7$ films are single phase and epitaxial with (001) $Ca_3Mn_2O_7$ // (110) $YAlO_3$. Our films show a transition to a weakly ferromagnetic or canted antiferromagnetic state below 120K. The magnetic properties have strong anisotropy with a clear transition visible with an in-plane applied field, but none along the out of plane direction. Second harmonic generation results show that a weak polar order exists at room temperature and it persists until $\sim$700°C. We also report on the low temperature dielectric properties of the material.

3:42PM X17.00005 Robust isothermal electric control of exchange bias at room temperature[1] , CHRISTIAN BINEK, University of Nebraska-Lincoln — Voltage-controlled spintronics is of particular importance to continue progress in information technology through reduced power consumption, enhanced processing speed, integration density, and functionality in comparison with present day CMOS electronics. Almost all existing and prototypical solid-state spintronic devices rely on tailored interface magnetism, enabling spin-selective transmission or scattering of electrons. Controlling magnetism at thin-film interfaces, preferably by purely electrical means, is a key challenge to better spintronics. Currently, most attempts to electrically control magnetism focus on potentially large magnetoelectric effects of multiferroics. We report on our interest in magnetoelectric Cr_2O_3 (chromia). Robust isothermal electric control of exchange bias is achieved at room temperature in perpendicular anisotropic Cr_2O_3(0001)/CoPd exchange bias heterostructures. This discovery promises significant implications for potential spintronics. From the perspective of basic science, our finding serves as macroscopic evidence for roughness-insensitive and electrically controllable equilibrium boundary magnetization in magnetoelectric antiferromagnets. The latter evolves at chromia (0001) surfaces and interfaces when chromia is in one of its two degenerate antiferromagnetic single domain states selected via magnetoelectric annealing. Theoretical insight into the boundary magnetization and its role in electrically controlled exchange bias is gained from first-principles calculations and general symmetry arguments. Measurements of spin-resolved ultraviolet photoemission, magnetometry at Cr_2O_3(0001) surfaces, and detailed investigations of the unique exchange bias properties of Cr_2O_3(0001)/CoPd including its electric controllability provide macroscopically averaged information about the boundary magnetization of chromia. Laterally resolved X-ray PEEM and temperature dependent MFM reveal detailed microscopic information of the chromia (0001) surface magnetization and provide a coherent interpretation of our results on robust isothermal electric control of exchange bias. The latter promise a new route towards purely voltage-controlled spintronics and an exciting way to electrically control magnetism.

4:18PM X17.00006 Europium Chalcogenide Magnetic Semiconducting Nanocrystals , JAMES DICKERSON, Vanderbilt Univ — This abstract not available.

4:54PM X17.00007 First-principles analysis of magnetic interaction in electron-doped EuO , JOONHEE AN, KIRILL BELASHCHENKO, University of Nebraska, Lincoln, KIRILL BELASHCHENKO'S GROUP TEAM — Using linear response calculations within the linear muffin-tin orbital method, we analyze the exchange interaction in electron-doped EuO. The 4f shell is treated within the LDA+U method. Calculations in the virtual crystal approximation show that the RKKY interaction mediated by the conduction band qualitatively explains the observed doping dependence of the Curie temperature in EuO. Further, to understand the role of a particular rare earth dopant, we consider EuO supercells with a substitutional Gd atom, as well as with an oxygen vacancy. Important differences with the virtual crystal approximation are found. The behavior of the exchange interaction in real space is analyzed, and its mechanisms are sorted out. The applicability of the magnetic polaron picture to Gd-doped EuO is evaluated.

5:06PM X17.00008 Curie temperature of electron-doped EuO - is there an intrinsic limit? , A. SCHMEHL, T. MAIROSER, University of Augsburg, Augsburg, Germany, A. MELVILLE, T. HEEG, Cornell University, Ithaca, N.Y., USA, L. CANELLA, P. BÖNI, Technische Universitaet Muenchen, Garching, Germany, W. ZANDER, J. SCHUBERT, Forschungszentrum Juelich GmbH, Juelich, Germany, D.E. SHAI, E.J. MONKMAN, K. M. SHEN, D.G. SCHLOM, Cornell University, Ithaca, N.Y., USA, J. MANNHART, University of Augsburg, Augsburg, Germany — Increasing the Curie temperature (T_C) of the ferromagnetic semiconductor europium monoxide is the key problem to make this versatile material attractive for wide use. Its half-metallic behavior and its structural and electronic compatibility with Si, GaN and GaAs make EuO a promising material for semiconductor-based spintronics. By doping EuO with donor impurities, T_C can substantially be increased. This increase is attributed to an additional exchange interaction that is mediated via the conduction electrons. Here we report on Hall measurements on Gd doped EuO films grown over a wide range of doping concentrations and growth conditions. We demonstrate that only a small fraction of the introduced impurities actually act as donors even for optimized growth parameters. Too high growth temperatures even render the dopants completely inactive. These results open the exciting question, if further raising the charge carrier density will elevate the Curie temperature way above today's maximum value of 170 K.

5:18PM X17.00009 The Effect of Lu Doping on Ferromagnetic EuO , ALEXANDER MELVILLE, Cornell University, THOMAS MAIROSER, ANDREAS SCHMEHL, JOCHEN MANNHART, University of Augsburg, DARRELL SCHLOM, Cornell University, CORNELL UNIVERSITY TEAM, UNIVERSITY OF AUGSBURG COLLABORATION — Europium Oxide (EuO) is a poorly understood ferromagnetic semiconductor whose spin-ordering temperature (T_C) can be greatly influenced by the inclusion of dopants such as oxygen vacancies or one of several trivalent ions. The ability to grow high-quality crystalline and stoichiometric EuO by adsorption-controlled growth using molecular-beam epitaxy is imperative in separating the effect of oxygen vacancies from that of trivalent dopants. In this study, we have prepared 5% Lu-doped EuO and characterized the effects of this doping on the magnetic and electronic properties. We show for the first time that Lu is a viable dopant material for EuO, increasing the T_C up to 120K as a result of an increase in the carrier concentration to $1.8\text{x}10^{26}\text{m}^{-3}$ from $1.0\text{x}10^{23}\text{m}^{-3}$. This is on par with other EuO films grown in an adsorption-controlled environment and doped with La or Gd. Furthermore, we find that EuO maintains a high spin-polarization (>80%) at this doping level. As a result of the simultaneously high T_C and high spin-polarization, EuO can be considered for spintronic applications at much higher temperatures than possible for undoped EuO.

Thursday, March 24, 2011 2:30PM - 5:30PM –

Session X18 GMAG DMP: Focus Session: Low D/Frustrated Magnetism - Spin Chains & Ladders D172

2:30PM X18.00001 Quantum criticality, kink confinement, and emergent symmetries in coupled Ising chains and ladders , ALAN TENNANT, Helmholtz Center Berlin — In this talk I cover the physics in three of the central quantum phase transitions in 1D. First, the transverse Ising model which is realized in CoNb2O6. While this is perhaps the simplest textbook case of a quantum phase transition, a remarkable emergence of E8 symmetry arises close to the quantum critical point. This manifests itself in an octave of bound states. We observe these experimentally and in particular the interval of the first two resonances on this octave which are found to match the golden ratio 1.618... - just as predicted for the emergence of this extraordinary symmetry. I then plan to show with the example of the Heisenberg chain how we can probe the quantum critical volume experimentally and show the characteristic scaling behaviour in space and time. The third example is of a spin ladder CaCu2O3 which is near the long sought after Wess-Zumino-Novikov-Witten quantum critical point.

3:06PM X18.00002 Evidence for strong orbital fluctuations below the Jahn-Teller transition in $Sr_3Cr_2O_8$, J. DEISENHOFER, ZHE WANG, M. SCHMIDT, A. GÜNTHER, S. SCHAILE, N. PASCHER, F. MAYR, Y. GONCHAROV, H.-A. KRUG VON NIDDA, A. LOIDL, Experimental Physics V, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, D-86135 Augsburg, Germany, D.L. QUINTERO-CASTRO, A.T.M.N. ISLAM, B. LAKE, Helmholtz-Zentrum Berlin für Materialien und Energie, D-14109 Berlin, Germany — We report on the magnetic and phononic excitation spectrum of SrCrO determined by THz and infrared (IR) spectroscopy, specific heat, and electron spin resonance measurements. We identify the singlet-triplet excitations in the dimerized ground state and observe an extended temperature range $T^*(= 125\text{ K}) < T < T_{JT}(= 285\text{ K})$ below the Jahn-Teller transition, where the IR active phonons change only gradually with decreasing temperature. A clear anomaly in the specific heat marks the onset of orbital ordering at T_{JT}, but a detailed analysis of the orbital contribution to the specific heat shows the persistence of strong fluctuations down to T^* in agreement with the IR data. Due to these fluctuations we can observe electron spin resonance absorptions only below T^* with a linewidth $\propto \exp(-\Delta/k_BT)$ indicating an Orbach-type spin relaxation via the excited orbital state of the Cr e doublet split by $\Delta/k_B = 388$ K.

3:18PM X18.00003 NMR in the high-field magnetic phase of $LiCuVO_4$, WOLFGANG KRAETSCHMER, NORBERT BUETTGEN, ALOIS LOIDL, Center for Electronic Correlations and Magnetism, University of Augsburg, LEONID E. SVISTOV, LYUDMILA A. PROZOROVA, Kapitza Institute, Moscow, ANDREY PROKOFIEV, Institute for Solid State Physics, TU Vienna — $LiCuVO_4$ is a quasi-one-dimensional antiferromagnetic spin-$1/2$ system with strong magnetic frustration due to competing interactions within the Cu spin chain. Consequently, a complex magnetic phase diagram with three critical magnetic field values evolves [arXiv:1005.5668]. Furthermore, spiral spin order below T_N=2.7K induces ferroelectricity thus rendering $LiCuVO_4$ multiferroic. The ferroelectric polarization can be switched by reorienting the spin helix through application of external magnetic fields [PRB **77**, 144101 (2008)]. Above $H > H_{c2}$ $LiCuVO_4$ becomes paraelectric and the magnetic order changes to a collinear spin-modulated phase. Employing Nuclear Magnetic Resonance we study the nature of this high-field phase by analysis of ^{7}Li and ^{51}V spectra recorded around $H > H_{c2}$=7.5T. We find, together with simulations for different scenarios, that Cu-spins of neighboring planes along the c-axis have a random phase-relation thus implying a two-dimensional character of the spin order [PRB **77**, 144101 (2008)].

3:30PM X18.00004 Density Functional Study of the magnetic structure on spin frustrated $MnSb_2S_4$ and Sr_2MOsO_6 (M = Cu, Ni) , CHUAN TIAN, CHANGHOON LEE, ERJUN KAN, North Carolina State University, FANG WU[1], Nanjing Forestry University, MIKE WHANGBO, North Carolina State University — We explored the electronic structures of two spin-frustrated magnetic systems monoclinic $MnSb_2S_4$ and Sr_2MOsO_6 (M = Cu, Ni) on the basis of first principles DFT calculations. The spin exchanges of $MnSb_2S_4$ are frustrated within each MnS_4 chain and between adjacent MnS_4 chains, which explains the observed helical spin order of $MnSb_2S_4$. We predict that $MnSb_2S_4$ is multiferroic with ferroelectric polarization of $\sim$14 μC/m^2 along the chain direction, and a field-induced reversal of the ferroelectric polarization occurs by reversing the direction of the helical spin rotation. The ordered double perovskites Sr_2MOsO_6 (M = Cu, Ni), reported to be half-metallic, are found to be magnetic insulators. The magnetic structures of Sr_2MOsO_6 were probed by evaluating their spin exchanges.

3:42PM X18.00005 Ultra-slow Magnetic Order-Order Transition in the Spin Chain Antiferromagnet Ca3Co2O6

, O.A. PETRENKO, University of Warwick, Department of Physics, Coventry, CV4 7AL UK, S. AGRESTINI, C.L. FLECK, L.C. CHAPON, C. MAZZOLI, A. BOMBARDI, M.R. LEES — We report the observation of a highly unusual time-dependent magnetic phenomena in which a transition from one long-range magnetically ordered state to another occurs over a timescale of several hours. We have used powder neutron diffraction to investigate the magnetic structure of Ising spin chain compound $Ca_3Co_2O_6$. Our investigation focuses on the low-temperature regime ($T < 14$ K$<< T_N = 25$ K) where previous neutron diffraction studies have shown that there is an increasing instability in the spin density wave (SDW) order within this material. The results of the present work reveal that there is an order-order transition from the SDW structure to a new commensurate antiferromagnetic phase. The extraordinary time dependence of the magnetic reflections demonstrates that this transition occurs via a very slow transformation process. As the temperature is reduced the characteristic time of the transition process increases rapidly and at low temperatures the magnetic states become frozen. Calculations show that the commensurate AFM phase has a lower exchange energy than the SDW structure and is therefore expected to be ground state of $Ca_3Co_2O_6$. Our neutron data confirm the theoretical predictions, but also show that the SDW phase is preferred for 12 K $< T < T_N$.

3:54PM X18.00006 Magnetic structure and superexchange pathways in CsV_2O_5

, ANDRES SAUL, CINaM/CNRS (Marseille, France), GUILLAUME RADTKE, IM2NP (Marseille, France) — The study of low dimensional spin-1/2 quantum systems has been a very prolific field of condensed matter physics during the last decades. The family of vanadates, in particular, has provided a rich variety of compounds with different behaviours and topologies. Their magnetic structure and properties are primarily determined by the magnitude and the sign of the different exchange couplings arising between magnetic ions and therefore on the very details of their atomic and electronic structures. The sole consideration of the topology of a compound, based on idealized crystal structures, is often incomplete and even misleading. In this work, the magnetic properties of the layered compound CsV_2O_5 have been investigated using density-functional calculations. The results show that this compound is built from strongly dimerized alternating chains oriented along the **c** axis. Moreover, we demonstrate that the largest interaction along the chains direction arises *between* the structural dimers, involving a superexchange pathway through the covalently bonded $V^{(5+)}O_4$ bridging groups.

4:06PM X18.00007 Thermal Conductivity due to Magnon Heat Transport in $Ca_{2+x}Y_{2-x}Cu_5O_{10}$[1]

, RAHEEM BELLO, Department of Physics, Department of Astronomy University of Texas, ISAAC MANZANERA ESTEVE, JOHN MARKERT, Department of Physics, University of Texas — In the spin-chain structure $Ca_{2+x}Y_{2-x}Cu_5O_{10}$, the thermal conductivity in some samples is observed to exhibit two peaks attributed to the thermal transport contributions by phonons and magnons. We have built a thermal conductivity probe, with a 2D rotation stage, to study the magnon contribution to the thermal conductivity of ceramic samples over the range 4–300 K. We plan to measure changes in the magnon contribution by varying the orientation of the lattice with respect to the magnetic field. We have prepared a set of samples with small deviations in oxygen stoichiometry to examine the effects of the defects on magnon thermal transport.

4:18PM X18.00008 The origin of the incommesurate phase in the spin Peierls compound TiOCl

, ARIEL DOBRY, DIEGO MASTROGIUSEPPE, CLAUDIO GAZZA, Instituto de Física de Rosario — TiOX (X=Cl,Br) are recently characterized Spin-Peierls compounds. They are unusual due to the appearance of an intermediate incommensurate phase between the dimerized and the uniform ones. We show that the incommensurate phase is stabilized by a linear dependency of the phononic dispersion near the dimerized mode. A model based on antiferromagnetic chains with position dependent exchanges accounts for the evolution of the atomic coordinates with temperature within the incommensurate phase. The magnetic gap closes in the intermediate phase. Finally, we find that the magnetic static structure factor has incommensurate peaks situated at twice the wave vector of the structural ones. These peaks could be found in future elastic neutron scattering measurements.

4:30PM X18.00009 Singlet-Triplet Excitations in the Unconventional Spin-Peierls System TiOBr

, J.P. CLANCY, B.D. GAULIN, McMaster University, C.P. ADAMS, St. Francis Xavier University, G.E. GRANROTH, A.I. KOLESNIKOV, T.E. SHERLINE, Oak Ridge National Laboratory, F.C. CHOU, National Taiwan University — TiOBr belongs to a select group of quasi-one-dimensional materials which undergo a spin-Peierls (SP) phase transition and develop a dimerized singlet ground state at low temperatures. However, unlike conventional SP systems, TiOBr exhibits not one, but two successive phase transitions upon cooling: a continuous transition into an incommensurate SP state at $T_{C2} \sim 48$ K, followed by a discontinuous transition into a commensurate SP state at $T_{C1} \sim 27$ K. We have performed time-of-flight neutron scattering measurements on powder samples of TiOBr using the fine-resolution Fermi chopper spectrometer (SEQUOIA) at the Spallation Neutron Source. These measurements reveal two branches of magnetic excitations within the commensurate and incommensurate SP phases, which we associate with n = 1 and n = 2 triplet excitations out of the singlet ground state. This study represents the first direct measure of the singlet-triplet energy gap in TiOBr, which we have determined to be $E_g = 21.2 \pm 1.0$ meV.

4:42PM X18.00010 Field-Induced Gap in a Quantum Spin-1/2 Chain in a Strong Magnetic Field[1]

, S. ZVYAGIN, M. OZEROV, J. WOSNITZA, Dresden High Magnetic Field Laboratory (HLD/FZD), Dresden, Germany, E. ČIŽMÁR, CLTP/P.J. Safarik University, Košice, Slovakia, R. FEYERHERM, HZB, Berlin, Germany, S.R. MANMANA, JILA, Dept. of Physics, University of Colorado, Boulder, USA, F. MILA, Inst. for Theor. Physics, EPF Lausanne, Lausanne, Switzerland — Magnetic excitations in copper pyrimidine dinitrate, a spin-1/2 antiferromagnetic chain with alternating g-tensor and Dzyaloshinskii-Moriya interactions that exhibits a field-induced spin gap, are probed by means of pulsed-field electron spin resonance spectroscopy. In particular, we report on a minimum of the gap in the vicinity of the saturation field $H_{sat} = 48.5$ T associated with a transition from the sine-Gordon region (with soliton-breather elementary excitations) to a spin-polarized state (with magnon excitations). This interpretation is fully confirmed by the quantitative agreement over the entire field range of the experimental data with the DMRG investigation of the spin-1/2 Heisenberg chain with a staggered transverse field.

4:54PM X18.00011 Non-equlibrium energy dynamics in spin chains and ladders

, FABIAN HEIDRICH-MEISNER, STEPHAN LANGER, MARKUS HEYL, LMU Munich, Germany, IAN MCCULLOCH, U Queensland, Brisbane, Australia — We investigate the real-time dynamics of the energy density in spin-1/2 chains and ladders, starting from initial states with an inhomogeneous profile of bond energies, extending our previous work on the dynamics of spin-density wave packets [1]. These simulations are carried out using the adaptive time-dependent density matrix renormalization group algorithm. We analyze the time-dependence of the spatial variance of the bond energies which yields necessary criteria for ballistic or diffusive energy dynamics. In the case of the XXZ chain, our results are consistent with ballistic behavior, both in the massless and the massive phase. For the massless regime, we compare our numerical results to predictions from bosonization for, e.g., the velocity that the initial perturbation spreads with. In the case of ladders, we find an involved dynamics whose qualitative interpretation is still under scrutiny.

5:06PM X18.00012 Nonmagnetic impurities in a frustrated spin ladder[1] , ERIK WULF, SEBASTIAN MÜHLBAUER, TATIANA YANKOVA, VASILY GLAZKOV, ANDREY ZHELUDEV, ETH Zürich, Schafmattstr. 16, 8093 Zürich, Switzerland — Sul-Cu_2Cl_4 is a representative of the spin S=1/2 4-leg ladders. Due to weak interladder interactions it shows almost perfect 1D character. The singlet ground state is separated from the excited triplet state by a gap of Δ=0.52meV which can be closed by a critical field of H_c=3.7T. At H_c the disordered spin liquid undergoes a phase transition to chiral helimagnetic order. By replacing nonmagnetic chlorine atoms by nonmagnetic bromine atoms random bond disorder is introduced in Sul-$Cu_2(Cl_{1-x}Br_x)_4$. Measurements of the magnetization and the specific heat show a drastically changed behavior in an applied field even at low bromine concentrations. At T>0 the material exhibits an intermediate phase between the spin liquid phase and the helimagnetic ordered phase for x=0.01, while the phase transition to the helimagnetic order is suppressed already for x=0.025. Nevertheless, the critical field H_c to overcome the excitation gap is independent from the impurity concentration.

5:18PM X18.00013 Exotic gapless Bose metals and insulators on multi-leg ladders , RYAN V. MISHMASH, MATT S. BLOCK, UCSB, RIBHU K. KAUL, UK, Lexington, DONNA N. SHENG, CSU, Northridge, OLEXEI I. MOTRUNICH, Caltech, MATTHEW P.A. FISHER, UCSB — We present recent work establishing compelling evidence for the existence of quasi-1D descendants of the d-wave Bose liquid (DBL), a novel 2D quantum phase of itinerant bosons first discussed in [1]. In particular, we study a model of hard-core bosons moving on the N-leg ladder square lattice with frustrating four-site ring exchange. In this talk, we focus on two novel phases: an incompressible gapless Mott insulator on the 3-leg ladder and a compressible gapless Bose metal on the 4-leg ladder. The former is a fundamentally quasi-1D phase that is insulating along the ladder but has two 1D gapless modes and power law transverse density-density correlations at incommensurate wave vectors; extensions of this phase to full 2D will be discussed. The latter, on the other hand, is conducting along the ladder and has five 1D gapless modes, one more than the number of legs; this represents a significant step forward in establishing the existence of the DBL in two dimensions. In both cases, we can understand the nature of the phase using slave-particle-inspired variational wave functions consisting of a product of two distinct Slater determinants, the properties of which compare impressively well to a DMRG solution of the model Hamiltonian. [1] O. I. Motrunich and M. P. A. Fisher, PRB **75**, 235116 (2007).

Thursday, March 24, 2011 2:30PM - 5:06PM –
Session X19 DCOMP: Classical and Quantum Molecular Dynamics D170

2:30PM X19.00001 Structure and Dynamics of Shock-Induced Nanobubble Collapse in Water , MOHAMMAD VEDADI, AMIT CHOUBEY, KEN-ICHI NOMURA, RAJIV KALIA, AIICHIRO NAKANO, PRIYA VASHISHTA, University of Southern California, ADRI VAN DUIN, Pennsylvania State University — Structure of water under shock and shock-induced collapse of nanobubbles in water are investigated with molecular dynamics simulations based on a reactive force field. Shock induces dramatic structural changes, including an ice-VII-like structural motif at a particle velocity of 1 km/s. The incipient ice VII formation and the calculated Hugoniot curve are in good agreement with experimental results. In the presence of a nanobubble, we observe a focused nanojet at the onset of nanobubble shrinkage and a secondary shock wave upon nanobubble collapse. The secondary shock wave propagates spherically backwards and induces high pressure as it propagates. Both the propagation velocity and the induced pressure are larger than those of the primary shock. We explored effects of nanobubble radius and shock amplitude on nanojet formation. The nanojet size increases by increasing particle velocity but the effect of increasing radius is more significant. The jet length scales linearly with the nanobubble radius, as observed in experiments on micron-to-millimeter size bubbles. Shock-induced collapse of a nanobubble in the vicinity of a cell membrane creates a transient nanopore when the nanojet impacts the membrane. Transient cell poration has potential applications in drug delivery.

2:42PM X19.00002 Thermal conductivity of ultra high temperature ceramics (UHTC) ZrB_2 and HfB_2 from atomistic simulations , JOHN LAWSON, NASA Ames Research Center, MURRAY DAW, Clemson University, CHARLES BAUSCHLICHER, NASA Ames Research Center — Ultra high temperature ceramics (UHTC) including ZrB_2 and HfB_2 are characterized by high melting point, good strength, and reasonable oxidation resistance. These materials are of interest for use as sharp leading edges for hypersonic vehicles among other applications. Progress in computational modeling of UHTCs has been limited in part due to the absence of suitable interatomic potentials. Recently, we developed Tersoff style parametrizations of such potentials for both ZrB_2 and HfB_2 appropriate for atomistic simulations. As an application, Green-Kubo molecular dynamics simulations were performed to evaluate the lattice thermal conductivity for single crystals of ZrB_2 and HfB_2. The atomic mass difference in these binary compounds leads to oscilations in the time correlation function of the heat current, in contrast to the more typical monotonic decay seen in monoatomic materials. Results at room temperature and at elevated temperatures will be reported.

2:54PM X19.00003 A robust and monotonically convergent iterative algorithm for solving the Kohn-Sham equations in metallic systems[1] , JEAN-LUC FATTEBERT, Lawrence Livermore National Laboratory — We propose a new iterative algorithm to efficiently calculate the electronic structure in Density Functional Theory calculations of metallic systems and warm dense matter with high electronic temperature. This parameter-free algorithm directly searches for a set of wave functions and a compatible single particle density that minimizes the Mermin finite temperature functional. It is particularly useful for simulating physical systems considered difficult to converge, such as large systems with variable occupancies and presenting charge sloshing. We demonstrate the effectiveness of the proposed algorithm and its implementation by applying it to challenging large scale problem in First-Principles Molecular Dynamics simulations.

3:06PM X19.00004 Molecular Dynamics with Quantum Fluctuations , IONUT GEORGESCU, JASON DECKMAN, VLADIMIR MANDELSHTAM, University of California, Irvine — A new Quantum Dynamics approach, called Gaussian Molecular Dynamics (GMD), is introduced. As in the Centroid Molecular Dynamics (CMD), the N-body quantum system is mapped to an N-body classical system with an effective Hamiltonian arising within the Variational Gaussian Wave-packet approximation. The approach is exact for the harmonic oscillator and for the high-temperature limit, accurate in the short time limit and is computationally very efficient. GMD is furthermore used to estimate the diffusion constant and the spectrum of the velocity auto-correlation function of low pressure para-hydrogen at 14K and respectively 25K. The results are consistent with known experimental and theoretical results, such as CMD and RPMD.

3:18PM X19.00005 Biased Monte Carlo technique to accelerate Molecular Dynamics simulations of rare events , PRATYUSH TIWARY, AXEL VAN DE WALLE, Department of Applied Physics and Materials Science, Caltech — We propose a hybrid Monte Carlo (MC) -Molecular Dynamics (MD) technique to study temporally rare event dynamics. By using biased MC sampling (Metropolis-Hastings), we avoid actually visiting low energy states in the MD and instead carry out a quick estimate of the mean escape time to be added to the computer clock. The method does not assume anything about the nature of the transition surfaces separating basins in the energy surface. We then apply the method to the case of dislocation kink movement in BCC metals at low temperatures.

3:30PM X19.00006 Ab initio molecular dynamics simulations using a Chebyshev-filtered subspace iteration technique for modeling amorphous silicon dioxide[1] , MINJUNG KIM, KHOONGHONG KHOO, JAMES CHELIKOWSKY, University of Texas — Ab initio molecular dynamics simulations are a powerful tool for examining liquids and amorphous materials; however, such simulations are often computationally intensive. We present a molecular dynamics method that dramatically reduces the computational load using a new algorithm based on Chebyshev-filtered subspace iteration. We apply this method to amorphous silicon dioxide. Amorphous silicon dioxide has been intensively studied owing to its broad applications to electronic devices and photonics. We perform ab initio molecular dynamics simulations to obtain the amorphous structure of silicon dioxide. We employ implement several new procedures to investigate the effect of quenching rates and system sizes. The calculated structure factor for our amorphous structure is in good agreement with experimental data. We performed structural relaxations to calculate the hyperfine splitting constants. Our calculated hyperfine splitting constants of E'_γ oxygen defect centers show excellent agreement with electron paramagnetic resonance experiments. We will also discuss statistical results of oxygen-related defect centers.

3:42PM X19.00007 Molecular Dynamics simulations of Carbon-Oxygen mixtures in the Core of White Dwarf Stars , ANDRE DA SILVA SCHNEIDER, JOE HUGHTO, CHARLES HOROWITZ, DON BERRY, Indiana University — A White Dwarf will be the final evolutionary state of most of the stars in our galaxy. The core of these faint and compact stars is a mixture of ions immersed in a degenerate electron gas. The latent heat of fusion of this mixture is important for White Dwarf cooling from which the age of stellar systems can be inferred. Assuming Carbon and Oxygen to be the most abundant elements we studied the phase diagram of the mixture using large classical molecular dynamics simulations. The ion interactions were modeled by a screened Coulomb potential and the system was kept in a half-solid half-liquid state. Understanding the chemical separation that takes place helps estimate the central abundance of these elements and is important for observations of White Dwarfs in globular star clusters [1].

3:54PM X19.00008 Diffusion in Yukawa Crystals in White Dwarfs and Neutron Stars , JOSEPH HUGHTO, CHARLES HOROWITZ, ANDRE SCHNEIDER, Indiana University — Compact stars, white dwarfs and neutron stars, contain strongly interacting liquid and solid systems that we model using screened Yukawa interactions. Diffusion of impurities can release significant gravitational energy. We calculate diffusion constants using Molecular Dynamics (MD) simulations for both multicomponent liquid and single component solid systems. Diffusion in the solid depends strongly on the number and nature of crystal defects. We are not aware of previous direct calculations of diffusion in Yukawa crystals.

4:06PM X19.00009 MD Simulations of the Breaking Strain of Coulomb Crystals in Neutron Stars: Star mountains and gravitational waves[1] , CHARLES HOROWITZ, Indiana University, JOE HUGHTO, ANDRE SCHNEIDER, DON BERRY — Neutron stars — collapses stars half again as massive as the sun but with a 10-kilometer radius — have solid crusts made of dense coulomb crystals. We perform large-scale molecular dynamic simulations of the breaking strain (strength) of this crust including the effects of impurities, defects, and grain boundaries. We find neutron star crust to be the strongest material known, with a breaking stress 10 billion times stronger than steel [1]. This is because of the high density, high pressure, and the long-range nature of the coulomb interactions where each ion interacts with thousands of its neighbors. The crust can support massive mountains that, on a rapidly rotating neutron star, can radiate detectable gravitational waves. These oscillations of space and time, predicted by Einstein almost 100 years ago, should be detected in the next few years.

4:18PM X19.00010 Tracer Diffusion for Rough Hard Spheres , OLGA KRAVCHENKO, MARK THACHUK, UBC — We present a study of tracer diffusion in a rough sphere fluid. In such fluid collisions between particles exchange rotational and translational energy and momentum. As tracer particles grow in size, their diffusion constant is described by the Stokes-Einstein hydrodynamic result. In this limit, smooth hard spheres are shown to adopt "slip" boundary conditions. The current results show that rough hard spheres adopt boundary conditions proportional to their degree of roughness, defined by the radius of gyration. Spheres with maximum roughness adopt "stick" boundary conditions while those with intermediate roughness adopt values between the "slip" and "stick" limits. This dependence is found to be almost linear. Changes in the diffusion constants as a function of roughness are also examined and it is found that the dependence is stronger than suggested by the low-density, Boltzmann result. Rough hard spheres model the effect of inelasticity of a real collision and show that even without the presence of attractive forces, the boundary conditions for large particles can deviate from "slip" and approach "stick."

4:30PM X19.00011 Solvation and thermal effects on the optical properties of naturaldyes: a case study on the flavylium cyanin , ARRIGO CALZOLARI, CNR-IOM, BARIS MALCIOGLU, SISSA, Trieste IT, RALPH GEBAUER, ICTP, Trieste, IT, DANIELE VARSANO, Univ. "La Sapienza," Rome IT, STEFANO BARONI, SISSA, Trieste IT — We present a first-principles study of the effects of both hydration and thermal dynamics on the optical properties of a natural anthocyanin dye, namely, *cyanin* (Cya), in aqueous solution. We combine Car-Parrinello molecular dynamics and time-dependent density functional theory (TDDFT) [1] approaches to simulate the time evolution of UV-vis spectrum of the hydrated Cya molecule at room temperature [2,3]. The spectrum of the dye calculated in the gas phase [4] is characterized by two peaks in the red and in the blue, which would bring about a greenish hue incompatible with the dark purple coloration observed in nature. Describing the effect of the water solvent through a polarizable continuum model does not modify qualitatively the resulting picture. An explicit simulation of both solvent and thermal effects using ab-initio molecular dynamics results instead in a spectrum that is compatible with the observed coloration. This result is analyzed in terms of the spectroscopic effects of molecular distortions, induced by thermal fluctuations. [1] *turbo*-TDDFT, B. Walker, A. Saitta, R. Gebauer, S. Baroni, *Phys. Rev. Lett.* **2006**, 96, 113001. [2] A. Calzolari, et. al , *J. Chem. Phys.* **132**, 114304 (2010). [3] O.B. Malcioglu, A. Calzolari, R. Ghebauer, D. Varsano, and S. Baroni, preprint (2010). [4] A. 4:42PM X19.00012 ABSTRACT WITHDRAWN –

4:54PM X19.00013 Model inter-atomic potential for Cu-Zr system generated using a multi-canonical simulation combined with a first-principles calculation , YOSHIHIDE YOSHIMOTO, Department of Applied Mathematics and Physics, Graduate School of Engineering, Tottori University — We can obtain an accurate force field for a molecular dynamics simulation from a first principles calculation. However, the available physical time for a direct first-principles molecular dynamics simulation is often limited to ~ 10 ps because of its high computational cost. If we want to achieve much longer physical time, a possible approach is to build a model inter-atomic potential from a first-principles calculation. As a kind of this approach, Yoshimoto has proposed the "thermodynamic downfolding" method[1,2] which generates an inter-atomic potential based on a multicanonical simulation combined with a first-principles calculation. With this method, we can expect that the thermodynamics of the system is conserved to a maximum extent. In this presentation, application of the method to Cu-Zr system will be reported. This system is interesting because at an composition this system become a bulk metallic glass which has several technologically attracting properties. The melting properties of the system will be covered.

Session X20 DMP FIAP GERA: Focus Session: Thermoelectric Materials: Theory D168

2:30PM X20.00001 Atomistic simulations of heat transport in nanostructures , DAVIDE DONADIO, Max Planck Institute for Polymer Research — Engineering materials at the nanoscale allows for tuning several of their properties over a broad range. These holds particularly for thermoelectric performances of group IV semiconductors, such as silicon and germanium. Experiments [1,2] suggest that improvements of the thermoelectric figure of merit in nanostructured silicon are mostly related to a drop in the thermal conductivity of about two orders of magnitude with respect to the bulk. In spite of success of macroscopic empirical approaches, we argue that atomistic simulations are necessary to provide the correct physical behavior and achieve significant understanding of a complex phenomenon such as thermal transport at the nanoscale (~ 10nm). By means of atomistic simulation methods, we address the issue of lattice thermal transport in silicon and SiGe nanostructures and nanostructured materials, e.g. nanowires, nanoporous and amorphous silicon thin films. We have reviewed and compared several simulation approaches (equilibrium and non-equilibrium molecular dynamics and anharmonic lattice dynamics), and developed a new method for large scale simulations, based on the scattering approach. We have identified strength, weaknesses and possible artifacts for each method, and established reliable simulation procedures to compute thermal transport properties. Our results shed light on the cooperative effects of dimensionality reduction, nanostructuring and disorder, in reducing the thermal conductivity of silicon-based nanostructured materials, stemming from prominent changes of lattice vibrational properties and enhancement of phonon scattering [3].

3:06PM X20.00002 Thermoelectric performance of Si-Ge heterostructured nanowires from first-principles , ARASH MOSTOFI, MATTHEW SHELLEY, Imperial College London — We present calculations of the thermoelectric figure of merit ZT of both pristine and axially heterostructured Si/Ge nanowires as a function of their compositional disorder, growth direction and diameter. Our method is based on density-functional theory (DFT). Both charge and transport properties are calculated within the Landauer-Buttiker formalism. We compute ZT for realistic nanowires (ca. 10,000 atoms and 100 nm in length) by using maximally-localized Wannier functions to map large-scale DFT calculations onto short-ranged model Hamiltonians with negligible loss of accuracy. The approach is fully automated and robust, such that large numbers of configurations of the system can be explored with high throughput and efficiency. While we focus here on their application to thermoelectric nanowires, the algorithms we have developed are generally applicable to other classes of disordered quasi-one-dimensional nanostructures such as DNA, carbon nanotubes and graphene nanoribbons.

3:18PM X20.00003 Thermoelectric Properties of Ultra Narrow Silicon Nanowires from Atomistic Calculations , NEOPHYTOU NEOPHYTOS, HANS KOSINA, Institute for Microelectronics, Technical University of Vienna — The progress in nanomaterials' synthesis allows the realization of thermoelectric devices based on 1D nanowires (NWs). In these confined systems the electrical and thermal conductivities, and the Seebeck coefficient can be designed to some degree independently, providing enhanced ZT values as compared to the bulk material's value. We calculate the electrical conductivity, the Seebeck coefficient, and the electronic part of the thermal conductivity of scaled Si NWs. We use the atomistic sp3d5s*-spin-orbit-coupled tight-binding model and linearized Boltzmann transport. Our calculations include up to 5500 atoms, a task still computationally affordable within this model. We examine n-type and p-type NWs of diameters between 3nm and 12nm for [100], [110] and [111] transport orientations, at different doping levels. Using experimentally measured values for the lattice thermal conductivity, the expected ZT values of the nanowires are estimated. We further provide directions for power factor optimization with structure confinement.

3:30PM X20.00004 Interface scattering and thermal conductivity in Si/SiGe alloy superlattices[1] , ZLATAN AKSAMIJA, University of Wisconsin-Madison, IRENA KNEZEVIC, Univeristy of Wisconsin-Madison — $Si/Si_{1-x}Ge_x$ alloy superlattices (SLs) show promise for application as efficient thermoelectrics because of their low thermal conductivity, below that of the bulk $Si_{1-x}Ge_x$ alloy. Lattice thermal conductivity in these superlattices is dominated by scattering from the rough interfaces between layers, even at room temperature. Therefore, interface properties, such as roughness, orientation, and composition, are expected to play a significant role in thermal transport and offer additional degrees of freedom to control the thermal conductivity in semiconductor nanostructures based on superlattices. In this paper, we demonstrate the sensitivity of the lattice thermal conductivity in SLs to the interface properties, using a momentum-dependent model for scattering of phonons from rough material interfaces. Our results show excellent agreement with experimental data and explain the measured thickness and temperature dependence, as well as anisotropy of thermal conductivity in superlattices.

[1]This work has been supported by the Computing Innovation Fellows Project (NSF award No. 0937060 to the Computing Research Association, sub-award CIF-146 to the University of Wisconsin) and by the AFOSR YIP program (award No. FA9550-09-1-0230).

3:42PM X20.00005 Molecular dynamics simulation of the thermal transport across Si/Al interfaces , WOON IH CHOI, KWISEON KIM, SREEKANT NARUMANCHI, NREL — Efficient heat dissipation is critical for power electronics where the device package consists of several layers of different materials. Conventional thermal interface materials are bottlenecks in heat removal. Detailed understanding of interfacial heat resistance would benefit efforts to improve the device design. We have chosen Si/Al interfaces for this thermal transport study. We construct Si-Al MEAM interatomic potential parameters based on the density functional theory (DFT) calculations. We generate various interface structures using the first-principles molecular dynamics (MD) simulations. Using the direct method to compute the thermal conductance, we investigated various interface structures. We will discuss the effect of the inter-diffused layers and roughness of the interfaces on the thermal boundary conductance. We will also compare our result with limited data in the literature.

3:54PM X20.00006 Thermal Boundary Resistance at Ideal Gas Solid-Fluid Interfaces , SANG-HAMITRA NEOGI, GERALD MAHAN, Pennsylvania State University — We study the thermal boundary resistance at the interface between an ideal gas solid and another ideal gas fluid. In the solid side, heat is mostly carried by phonons, and thermal resistance occurs due to the partial reflection of phonons at the interface. In the fluid side, the sound waves can carry diffusive heat from the interface into the bulk of the liquid. We include both longitudinal and transverse sound modes of the fluid in the theory. The sound modes in the fluid and the reflected phonons in the solid have the same frequency as the phonon incident at the interface from the solid side. The wave vector for the sound modes is then calculated using the knowledge of the fluid pair distribution function in the bulk. The pair distribution function near the interface is modified due to the presence of the solid atoms. We solve coupled equations of motion for the atoms at the interface to obtain the phonon reflection coefficients. The Kapitza resistance is then obtained using the knowledge of these reflection coefficients. The calculation provides a method for extending the Young-Maris theory to the fluid-solid substances.

4:06PM X20.00007 Micro to Nano Scale Heat Conduction in Thermoelectric Materials , MARTIN MALDOVAN, MIT — Understanding and controlling heat transfer in solids is very important for increasing the efficiency of thermoelectric materials such as skutterudites, clatharates, superlattices, nanowires, and quantum dots. Although the mechanisms governing the thermal conductivity have been understood for years, a comprehensive theoretical method to calculate heat transfer, particularly at small scales, has not been available. This is mainly due to the complexity of anharmonic processes and phonon boundary scattering. We present a comprehensive theoretical model to calculate the thermal conductivity of thermoelectric materials at small length scales. The approach involves an exact calculation of the reduction of the phonon mean free paths due to boundary scattering and removes the need to solve the Boltzmann equation or to use adjustable terms as in the Callaway or Holland models. The analysis is based on the kinetic theory of transport processes and considers general expressions for dispersion relations, phonon mean free paths, and surface specularity parameters. The results show an excellent agreement with experiments for thin films, nanowires, and superlattices over a wide range of temperature and across multiple length scales. The theoretical approach can further be applied to a wide variety of problems involving the conduction of heat in micro/nanostructured thermoelectrics. This research was funded by the MIT Energy Initiative.

4:18PM X20.00008 Quantum Thermoelectric Effects on the Nanoscale , JUSTIN BERGFIELD, CHARLES STAFFORD, University of Arizona — An exact expression for the heat current in a nanostructure coupled to multiple metallic electrodes is derived, including both electron-electron and electron-phonon interactions. We use this formalism to investigate quantum effects on the flow of charge and entropy, and find an enormous quantum enhancement of thermoelectric effects in the vicinity of higher-order interferences in the transmission spectrum of a nanoscale junction. A nonequilibrium quantum analysis of a single-molecule junction based on 3,3'-biphenyldithiol demonstrates a maximum operating efficiency of 27% of the Carnot limit. Nonlocal quantum corrections to thermoelectric transport coefficients in multiterminal geometries are predicted.

4:30PM X20.00009 Thermal transport in Si-based disordered systems: amorphous silicon and silicon germanium alloys , YUPING HE, IVANA SAVIC, GIULIA GALLI, UC Davis, DAVIDE DONADIO, MPI for Polymer Research — Understanding and modeling heat transport in structurally and mass disordered semiconductors (e.g. amorphous silicon–a-Si and SiGe alloys) have long been a challenging problem in solid state physics. Using a combination of techniques (equilibrium and non- equilibrium molecular dynamics and lattice dynamics), we analyze the nature of vibrations and compute the thermal conductivities (k) of a-Si, bulk and nanoporous SiGe. We find that in amorphous and mass disordered systems, two types of modes are present, phonons and diffusive modes. In a-Si, phonons (who are only 3 % of the total vibrations) contribute to approximately half of k [1]. The value of k critically depends on the morphology of the system [2], for example it considerably dereases if thin films or samples with nano-holes are considered. A discussion of how mean free paths and lifetimes change as a function of morphology and disorder will be presented, together with results showing the effect,on k, of disorder at pores or film surfaces.Work supported by grant DOE DE-FC02-06ER25777.

4:42PM X20.00010 Atomistic study of heat transport in SiGe alloys[1] , IVANA SAVIC, YUPING HE, Department of Chemistry, University of California at Davis, Davis, California, USA, DAVIDE DONADIO, Max Planck Institute for Polymer Research, Mainz, Germany, GIULIA GALLI, Department of Chemistry and Department of Physics, University of California at Davis, Davis, California, USA — Semiconductor alloys, e.g. SiGe, are considered as promising materials to build efficient thermoelectric devices [1], and atomistic modeling of heat transport in these systems may help complement and guide experiments in optimizing their efficiency. We analyze strengths and weaknesses of several atomistic approaches in modeling the thermal conductivity of SiGe alloys, and we analyze in detail their range of validity. In particular, we focus on equilibrium molecular dynamics [2], an approach based on the solution of the Boltzmann transport equation [3] and Green function techniques [4]. Applications to both bulk and nanostructured SiGe will be presented.

4:54PM X20.00011 Scattering of charge carriers and phonons in thermoelectric devices , GIUSEPPE ROMANO, LEE JOO-HYOUNG, JEFFREY GROSSMAN, Massachusetts Institute of Technology — We investigate the effects of the scattering of charge carriers and phonons on the figure of merit of thermoelectric devices. Despite many efforts devoted to the optimization of the figure of merit ZT, the commercial diffusion of such systems is still limited due to their low efficiency. The main problem behind the engineering of ZT is the interdependency between the Seebeck coefficients, electrical conductivity and thermal conductivity. ZT could be maximized by either increasing the Seebeck coefficient or decreasing the thermal conductivity. While the first approach involves the distortion of the electronic density of states [1], the thermal conductivity can be lowered by inserting nonporous in the bulk materials [2]. Recent works have shown a detailed comparison between np-Ge and np-Si material and investigated the effect of the porosity on ZT [3]. Here we couple classical molecular dynamics and continuous simulation to study the phonon-phonon, phonon-pore, electron-phonon and phonon-boundary scattering and their effects on the electrical and thermal conductivities. The knowledge gained about material properties is then used to perform simulations of thermoelectric devices.

5:06PM X20.00012 Many-body effects in frequency-dependent charge and thermal transport[1] , JESUS CRUZ, JAMES FREERICKS, Georgetown University — Recently, Shastry has proposed that thermoelectric properties (thermopower, Lorenz number, and figure of merit) can be determined accurately in strongly correlated materials by examining their high frequency behavior. He also has derived a sum rule similar to the f-sum rule in optical conductivity, for the frequency dependent thermal conductivity. We examine these ideas within the context of an exactly solvable model (the Falicov-Kimball model) with dynamical mean-field theory. We see that the low-frequency and high-frequency limits are not so close in this system. We also discuss the thermal conductivity sum rule. These results are important in trying to understand strong electron correlation effects in thermoelectrics.

5:18PM X20.00013 Effective medium theory for thermoelectrics , PAUL HANEY, National Institute of Standards and Technology — We report on the application of effective medium theory to binary compound thermoelectric materials. We find a range of parameters for the conductivity and thermopower of the constituent elements such that the compound has an enhanced power factor. The results of effective medium theory are compared to full numerical simulations of an ensemble of disordered systems, and good qualitative agreement is found between the two calculations. The effect of various tailored geometries are explored in the direct numerical solution of the compound thermoelectrics.

Session X21 GIMS: Focus Session: Novel X-Ray Instrumentation and Measurement Techniques

D161

2:30PM X21.00001 Inelastic X-ray Scattering at Third Generation Synchrotron Sources: Present Activities and Future Plans[1] , JOHN HILL, Brookhaven National Laboratory — This talk will review present activities and future plans for utilizing inelastic x-ray scattering to study excitations in hard condensed matter systems. In particular, at current third generation sources it is now possible to observe the key elementary excitations in solids, including phonons, magnons, orbital excitations and electronic excitations such as plasmons and charge transfer excitations. The technique offers a number of advantages over existing methods for the study of these excitations, including especially, the ability to study very small sample volumes, the range of momentum and energy transfers available and the ability to work in disparate sample environments. A few recent illustrative examples are discussed. The first of these is a study of phonons in SmFeAs(O,F) which show an anomalous renormalization of certain phonons and for which momentum-dependent measurements of the electron-phonon coupling have been made. The second example will focus on work being performed at the Swiss Light Source in which spin waves in (La,Sr)CuO4 have been observed. Finally, the current and future state of inelastic x-ray scattering instrumentation in this country is discussed, including the upgrade plans at the Advanced Photon Source, and plans for new inelastic beamlines at the NSLS-II source currently under construction at Brookhaven National Laboratory

3:06PM X21.00002 The new X-ray absorption spectroscopy beamline at Diamond: B18 , SILVIA RAMOS, GIANNANTONIO CIBIN, STEPHEN PARRY, ANDY J. DENT, Diamond Light Source Ltd., Harwell Science and Innovation Campus, Didcot OX11 0DE, United Kingdom — The new core XAS spectroscopy beamline at Diamond (B18) has been designed to provide a reliable spectrometer for a broad scientific community. The instrument first became operational in April 2010 and is currently combining further commissining with a rapidly growing user programme. The main goal of the optics design of B18 was to achieve high stability in an instrument that can operate over a wide energy range (2.05 to 35.0 keV). XAS measurements can be carried out using several detection methods: transmission, electron yield and fluorescence (with a Ge detector, a Si drift detector or a gas microstrip). It is also possible to carry out combined absorption and diffraction measurements. The instrument offers several sample environments: a liquid nitrogen cryostat capable of loading over 40 samples, a pulse tube cryostat with base temperature of 1.6 K and an infrared furnace with a maximum temperature of 800^{o}C and can integrate a variety of specialised set-ups designed by the users. In this talk we will present the beamline and selected examples to show its capabilities.

3:18PM X21.00003 The soft x-ray materials research (SXR) instrument at the Linac Coherent Light Source , JOSHUA J. TURNER, Linac Coherent Light Source, SLAC National Accelerator Laboratory, Menlo Park, CA, OLEG KRUPIN, European XFEL, Hamburg, Germany, WILLIAM SCHLOTTER, Linac Coherent Light Source, SLAC National Accelerator Laboratory, Menlo Park, CA — The soft x-ray materials science research (SXR) instrument completed commissioning in June 2010 and began experimental user operations shortly afterwards. This instrument delivers intense, ultra-short soft x-ray pulses from the Linac Coherent Light Source, the free-electron laser at the SLAC National Accelerator Laboratory. These are fully coherent and can contain up to 10^{13} photons per pulse (or about 3 mJ per pulse) with bunch lengths from 300 femtoseconds down to sub-10 femtoseconds. The instrument includes a monochromator whose energy range spans energies from 480 eV - 2000 eV and a Kirkpatrick-Baez mirror system to create a focal spot of a few microns in diameter. The SXR instrument has a diverse set of end stations available to conduct a large variety of experimental techniques such as coherent imaging, resonant x-ray diffraction, photoelectron spectroscopy, and x-ray emission and/or absorption. First studies include fields spanning liquid femtosecond chemistry and time-resolved resonant inelastic x-ray scattering to ordering in solids and ultrafast magnetization. An overview of the instrument and its capabilities will be given.

3:30PM X21.00004 Polarization Depend Soft X-ray Scattering of Anisotropic Organic Thin Films[1] , H. ADE, E. GANN, B. COLLINS, H. YAN, NCSU, J. COCHRAN, M. CHABINYC, UCSB — Crystalline, semi-crystalline and liquid-crystalline organic materials have locally large anisotropic bond orientation statistics. This strongly impacts the mechanical, optical and electronic properties. For example, charge transport in organic thin films is often highly anisotropic and overall transport depends upon domain size, degree of order within domains, domain correlations, and the domain boundaries. Knowing the relative impact of all parameters is necessary for a detailed understanding of organic thin film transistors. - We demonstrate a novel scattering method to characterize such films: Polarization Dependent Soft X-ray Scattering (P-SoXS). In scattering, the linear dichroic absorption often exploited in x-ray microscopy is accompanied by strong linear dichroic dispersion, leading to large contrast based on bond orientation. This can not be achieved with hard x-rays or neutrons. We demonstrate P-SoXS on devices based on prototypical materials such as pentacene, poly(2,5-bis(3-tetradecyllthiophen-2-yl)thieno[3,2-b]thiophene) (pBTTT) and poly(3-hexylthiophene) (P3HT). The use of linear or circularly polarized x-rays allows the bond orientation contrast to be switched on and off, respectively, which is very useful to characterize the correlated and individual domain size.

3:42PM X21.00005 Probing buried interfaces by Index-Matched Soft X-ray Scattering[1] , E. GANN, J. SEOK, NCSU, J. COCHRAN, M. CHABINYC, UCSB, B. COLLINS, H. ADE, NCSU — Interfaces are often critical to function and performance in systems ranging from electronics to biology. Organic-organic interfaces are the location for charge transport in organic thin film transistors and exciton splitting in organic photovoltaics. Complete morphological characterization of buried interfaces is unfortunately difficult to achieve with conventional tools. We present a new method termed Index-Matched Soft X-ray Scattering (IM-SoXS). By matching the real part of the complex index of refraction of the top layer to that of vacuum through judicious choice of photon energy, we can minimize scatter from the top surface and substantially increase scatter from a buried interface, revealing both the spatial distribution and amplitude of the interfacial roughness. We demonstrate the method on samples with engineered and controlled interfacial roughness and provide examples of systems of scientific interest for which IM-SoXS should provide improved understanding of interface morphology and its relation to performance and function in systems.

[1]NSF DMR-0906457 and DMR-0906224

3:54PM X21.00006 Lensless x-ray imaging in reflection geometry , DANIEL PARKS, University of Oregon, SUJOY ROY, Lawrence Berkeley National Lab, KEOKI SEU, RUN SU, University of Oregon, JOSHUA TURNER, SLAC National Accelerator Laboratory, WEILUN CHAO, ERIK ANDERSON, Center for X-ray Optics Lawrence Berkeley National Laboratory, STEFANO CABRINI, Molecular Foundry Lawrence Berkeley National Laboratory, STEPHEN KEVAN, University of Oregon — We report on the development of a technique for lensless x-ray imaging in reflection geometry. In an approach similar to Fourier transform holography, we use a set of apertures to define object and reference waves from light which has already scattered from the sample. Back propagation from the apertures gives the image at the sample plane. This technique can be used with extended objects without additional masking, and can be used in reflection and transmission geometries. The extension of lensless x-ray imaging into reflection geometry opens the possibility of imaging surfaces in thin films, buried interfaces in multilayers, or Bragg planes in single crystals.

4:06PM X21.00007 Determination of Total X-ray Absorption Coefficient using Non-Resonant X-ray Emission , ANDREW ACHKAR, University of Waterloo, TOM REGIER, Canadian Light Source, ERIC MONKMAN, KYLE SHEN, Cornell University, DAVID HAWTHORN, University of Waterloo — Inverse partial fluorescence yield (IPFY) is a newly developed x-ray absorption spectroscopy (XAS) that utilizes non-resonant emission processes to measure the x- ray absorption of a material. Unlike XAS by traditional transmission, total electron yield and total fluorescence yield, IPFY is free of pinhole, saturation, and self-absorption effects. Moreover, IPFY exhibits a simple angle dependence that can be exploited to deduce the total x-ray absorption coefficient from a series of measurements performed with different experimental geometries. We quantitatively determine the total x-ray absorption coefficient of insulating NiO and $NdGaO_3$ single crystals at soft x-ray energies using this approach.

4:18PM X21.00008 Hard X-ray Microscopy with Multilayer Laue Lenses , HYON CHOL KANG, Chosun University — The possibility of imaging at near-atomic resolution using x-rays has been a dream ever since the short-wavelength nature of x-rays was demonstrated by von Laue and coworkers nearly a century ago. Even today the scientific impact of atomic-scale focusing of electromagnetic radiation would be deep and broad, because x-ray microscopy provides capabilities (ability to penetrate, sensitive and accurate elemental and structural information) that are complementary to other high-resolution microscopies. Although hard x-rays can in principle be focused to spot sizes on the order of their wavelength (0.1 nm), this limit has never been approached because of the difficulty in fabricating the optics. Multilayer Laue lens(MLL) is a novel diffractive optic for hard x-ray nano-focusing, which can be fabricated by sputter deposition of zone plate structure on flat substrate. According to the theoretical results, MLL is capable of focusing x-rays to well below 1 nm. We have demonstrated 2-dimensional focusing of hard x-rays with MLLs to a spot size of 25 nm x 27 nm with an efficiency of 2% at a photon energy of 12 keV, while 1-dimensional focus of 16 nm has been achieved. In this talk, we will present an overview of MLL microscopy and recent accomplishments for the determination of chemical composition in nanoscale systems. Lastly, we will give the capabilities of MLL microscopy that have the potential to significantly advance materials science, nanoscience, bio-medical science and environmental science.

4:54PM X21.00009 Dynamical diffraction effects on beam focusing for x-ray back reflection from curved multi-plate x-ray crystal cavity , YING-YI CHANG, SUNG-YU CHEN, Department of Physics, National Tsing Hua University, MAU-TSU TANG, National Synchrotron Radiation Research Center, M. YABASHI, Spring-8/RIKEN Mikazuki, Hyogo, Japan, YI-WEI TSAI, YU-HSIN WU, SHIH-CHANG WENG, CHIA-HUNG CHU, PO-YU LIAO, Department of Physics, National Tsing Hua University, SHIH-LIN CHANG, National Synchrotron Radiation Research Center — We have recently observed diffraction enhanced beam-focusing in curved multi-plate x-ray crystal cavities of silicon using (12 4 0) as the back reflection at 14.4388 keV. The measurement on the transmitted x-ray beam size through the crystal cavities shows a reduced focal length and an extremely long beam waist at the focal point. This effect could be understood according to the dynamical theory of x-ray diffraction. Based on the consideration of the excitation of the dispersion surface for each curved crystal surface involved in the crystal device, beam focusing and beam splitting occur, leading to the observed focusing feature. Detailed dynamical calculations on the transmitted intensities at different positions near the focal point will be discussed.

5:06PM X21.00010 High-Resolution Thermal Expansion Measurements of Single-Crystal Sapphire for Application as X-Ray Backscattering Monochromator[1] , JOHN J. NEUMEIER, Montana State University, I. SERGEEV, European Synchrotron Radiation Facility, D. BESSAS, R.P. HERMANN, Forschungszentrum Juelich — We report measurements of the thermal expansion of high-purity single crystal sapphire along the a and c directions. The data were acquired using a thermal expansion cell that is constructed of fused silica with a relative resolution of approximately $3x10^{-9}$. Comparison will be made to existing literature values determined from dilatometry and high-resolution x-ray diffraction. This project's main goal is the use of sapphire as x-ray backscattering monochromator for phonon spectroscopy using nuclear inelastic scattering. Tuning of the monochromator is done by varying the sapphire temperature, and the new thermal expansion values will improve the energy calibration.

Thursday, March 24, 2011 2:30PM - 5:18PM –
Session X22 DCMP: Metals: Bulk Properties and Nanostructures D163

2:30PM X22.00001 Phonon self energy in transition metals , LAURENT CHAPUT, IJL, UMR CNRS 7198, Nancy Universite, France, ATSUSHI TOGO, ISAO TANAKA, Department of Materials Science and Engineering, Kyoto University, Japan, GILLES HUG, LEM, UMR 104 ONERA-CNRS, ONERA, France — We present *ab initio* calculations of the phonon self energy of transition metals obtained using second order many body perturbation theory.[1] The code we have implemented[2] use the symmetry properties of the phonon-phonon interactions to express the self energy as a sum over irreducible triplets. It is analogous to the reduction of integration to the irreducible part of the Brillouin zone for one particle properties. The self energy of transition metals is then calculated. We show that the Peierls approximation[3] is in fact reasonable for *bcc* and *fcc* metals, but fails for the *hcp*. The decays paths of phonons producing the self energy is finally analyzed using surfaces of reciprocal space defined by conservation law.

2:42PM X22.00002 Observation of phonon softening in Cr near its Neel transition , RUQING XU, Argonne National Laboratory, TAI-CHANG CHIANG, University of Illinois at Urbana-Champaign — Chromium is a classic antiferromagnetic spin-density-wave system, with many unique properties yet to be fully understood despite the extensive experimental and theoretical efforts in the past. For instance, near its two magnetic transitions at 311K and 123K, the elastic constants of Cr have been observed to soften abruptly by ultrasonic experiments, indicating a strong lattice-spin interaction. However, such softening has never been confirmed in previous measurements of Cr's phonon dispersion relations. To address this issue we have carried out studies with inelastic x-ray scattering (IXS) as well as x-ray thermal diffuse scattering (TDS) at temperatures around the Neel transition (311K). While the IXS measurements did not find obvious changes in the overall phonon dispersion relations of Cr, abrupt changes in TDS intensities were clearly observed across the transition at wavevectors close to the Brillouin zone centers, unveiling a softening in the long-wavelength lattice excitations in Cr at the Neel transition.

2:54PM X22.00003 First-principles study of phonon-phonon interaction in FCC metals at high temperatures , XIAOLI TANG, CHEN W. LI, Department of Material Science and Applied Physics, California Institute of Technology, BRENT FULTZ, Material Science and Applied Physics, California Institute of Technology — Third-order lattice anharmonicity induced phonon broadening of FCC metals (including Al and noble metals Cu, Ag, Au) were calculated from first-principles density functional theory (DFT) using the second-order perturbation theory, where anharmonic force constants were obtained from supercell finite displacement method combined with DFT calculations. For aluminum, the good agreement between our calculations and prior measurement of phonon linewidth at 300K and our new measurement of phonon density of states to 750K indicates the third-order phonon-phonon interactions can account for the lifetime broadenings of phonons in aluminum to at least 80% of its melting temperature. A systematic study of noble metals further suggests that, despite of the similarity among these systems, scattering kinematics play an important role in determining the relative anharmonicity between the modes, while potential anharmonicity modulates the absolute phonon decay rate.

3:06PM X22.00004 Dynamical behavior of coherent phonons in semimetals: Measuring fast electron decoherence rates with slow pulses , JIAN CHEN, Stanford PULSE Institute, SLAC National Accelerator Laboratory, JINGJING LI, Department of Physics, University of Michigan, STEPHEN FAHY, Department of Physics, University College Cork, Ireland, ROBERTO MERLIN, Department of Physics, University of Michigan, DAVID REIS, Stanford PULSE Institute, SLAC National Accelerator Laboratory — Coherent light illumination of solids above the band-gap leads not only to a population of photoexcited carriers, but also to the generation of coherent electronic states of particular symmetries which can drive vibrations of the same symmetry. For A1g and Eg symmetry phonons in Bi and Sb, there has been some controversy regarding the generation mechanism of coherent vibrations. Here, we use a combination of ultrafast stimulated Raman scattering (RS) and cw spontaneous RS to determine the lifetime of electronic coherences of A1g and Eg symmetry. Their lifetime can be inferred from a comparison between pump-probe measurements of the amplitude of the corresponding coherent phonons, and a determination of the spontaneous RS cross sections. Our results represent a new approach to probe extremely fast electron decoherence rates using much slower (50-100fs FWHM) laser pulses. The Eg electronic coherence, resulting from a fragile unequal distribution of carriers in three equivalent regions of the band structure, is extremely short lived. Its temperature-dependent lifetime is in the range 2-12 fs in Bi and 5-12 fs in Sb.

3:18PM X22.00005 First-principles calculations of lattice stabilities in Mo , WESTON NIELSON, VIDVUDS OZOLINS, University of California, Los Angeles — The determination of accurate lattice stabilities is of great importance in producing phase diagrams of metallic alloys using the CALPHAD approach. Ab-initio molecular dynamics simulations in combination with thermodynamic integration are used to determine the lattice stabilities of fcc and bcc phases in Molybdenum at a range of temperatures. We employ the so-called fixed-cell-shape molecular dynamics approach, which involves the calculation of free energies over varying lattice strains. Our results also predict that at high temperatures fcc Mo is harmonically unstable.

3:30PM X22.00006 Competing orders in the Dirac-like electronic structure and the non-linear sigma model with the topological terms , POUYAN GHAEMI, LBNL and Department of Physics UC Berkeley, SHINSEI RYU, Department of Physics UC Berkeley — The Dirac-like electronic structure can host a large number of competing orders in the form of mass terms. In particular, two different order parameters, can be said to be dual to each other, when a static defect in one of them traps a quantum number (or "charge") of the other. The complementary nature of the pair of the order parameters shows up in their dynamical properties (correlation functions) in the following sense: When a quantum phase transition is driven by one type of fluctuations in order parameter, approaching the transition from the disordered (paramagnetic) side, the order parameter correlation function at the critical point is reduced. On the other hand, such fluctuations enhances the correlation of the dual order parameter. Such complementary behaviors in the correlation function can be used to diagnose the nature of quantum fluctuations that is the driving force of the quantum phase transition.

3:42PM X22.00007 Concentration dependence of the electron-phonon coupling from metals to semiconductors , ANDREI SERGEEV, MICHAEL REIZER, VLADIMIR MITIN, SUNY at Buffalo — We study dependence of the deformation potential (DP) on concentration of carriers in the wide range from metals to semiconductors. DP in metals and semiconductors has a different nature. In metals, DP is due to electron gas compressibility, while in semiconductors this contribution is negligible due to small carrier concentrations. DP in semiconductors originates from a shift of the conduction band edge under the deformation, while in metals such contribution is small because of strong screening. We investigate DP in the transition region and found that the electron-phonon coupling has a significant minimum at intermediate concentrations. The effects of disorder on the coupling are also investigated. Theoretical conclusions are compared with available data on semi-metals and highly-doped semiconductors.

3:54PM X22.00008 Investigation of the electronic structure of $TiTe_2$ using ARPES , JIANQIAO MENG, GEY-HONG GWEON, ANDREW LAFORGE, SRIRAM SHASTRY, Department of Physics, UC Santa Cruz, ARTHUR PENN RAMIREZ, Baskin School of Engineering, UC Santa Cruz, ZACK SCHLESINGER, Department of Physics, UC Santa Cruz, KAI ROSSNAGEL, Institute for Experimental and Applied Physics, University of Kiel, DEPARTMENT OF PHYSICS, UC SANTA CRUZ TEAM, BASKIN SCHOOL OF ENGINEERING, UC SANTA CRUZ COLLABORATION, INSTITUTE FOR EXPERIMENTAL AND APPLIED PHYSICS, UNIVERSITY OF KIEL COLLABORATION — $TiTe_2$ is considered a model Fermi liquid material in the field of angle-resolved photoelectron spectroscopy (ARPES). Over the years, many groups have contributed to improving the quality of the ARPES data on $TiTe_2$, helping to understand the connection between the ARPES data and the transport properties. However, some key questions remain unanswered, the most outstanding one being the anomalous temperature dependence in the Hall coefficient R_H. Here, we present a detailed high resolution ARPES data set in a wide range of temperature and momentum. This reveals some new features: temperature dependence in the band width, temperature dependence of the Ti 3d and Te 5p occupancies, and subtle features in the line shapes as the peak crosses the Fermi level. We discuss these new features in comparison with previous ARPES studies and known transport properties.

4:06PM X22.00009 Anomalous Ordering in Inhomogeneously Strained Materials: Surface Critical Behavior in the Bulk[1] , KEVIN E. BASSLER, University of Houston, CHARO I. DEL GENIO, Max Plank Institute for Physics of Complex Systems, BO LI, University of Houston — We study a continuous quasi-two-dimensional order-disorder phase transition that occurs in a simple model of a material that is inhomogeneously strained due to the presence of dislocation lines. Performing Monte Carlo simulations of different system sizes and using finite size scaling, we measure critical exponents describing the transition of $\beta = 0.18 \pm 0.02$, $\gamma = 1.0 \pm 0.1$, and $\alpha = 0.10 \pm 0.02$. Comparable exponents have been reported in a variety of physical systems. These systems undergo a range of different types of phase transitions, including structural transitions, exciton percolation, and magnetic ordering. In particular, similar exponents have been found to describe the development of magnetic order at the onset of the pseudogap transition in hightemperature superconductors. Their common universal critical exponents suggest that the essential physics of the transition in all of these physical systems is the same as in our simple model. We argue that the nature of the transition in our model is related to surface transitions although our model has no free surface.

[1]This work is supported by the NSF through Grant No. DMR-0908286.

4:18PM X22.00010 Finding saddle points using Gentlest ascent dynamics , AMIT SAMANTA, XIANG ZHOU, Applied and Computational Mathematics, Princeton University, WEINAN E, Department of Mathematics and Program in Applied and Computational Mathematics, Princeton University — We present dynamical equations for determining transition states and escape paths from basins of attraction of a stable system on a potential energy landscape. It is shown that the stable fixed points of such dynamical systems are the index-1 saddle points. The method relies on determining the smallest eigenvalue of the Hessian matrix. The formalism is easy to extend to systems of higher dimensions and can be used to explore the free energy landscapes of systems whose large time scale separation makes the standard molecular dynamics inefficient. The utility of the algorithm is demonstrated by evaluating the activation parameters for homogeneous and heterogeneous dislocation nucleation.

4:30PM X22.00011 An efficient method to treat low barriers in kinetic ART simulations , PETER BROMMER, NORMAND MOUSSEAU, Département de physique, Université de Montréal, Québec, Canada — In kinetic Monte Carlo (KMC) the time scale of the simulation is dominated by the height of the lowest energy barrier separating two states. Rapid back-and-forth movements across very low barriers called flickers are a major limitation of the technique, as they can cost considerable CPU time without advancing the simulation. To accelerate KMC simulations, an energy basin finding algorithm has been presented [1]. In the kinetic Activation-Relaxation technique (kART) [2], KMC events are constructed during the simulation, taking full care of elastic deformations while avoiding the need for complete event search at every step. To account for low energy barriers located in this package, we implement a basin identification scheme that works on the fly as well. We apply this method to interstitial diffusion in bcc iron. There, rapid diffusion paths with low barriers for properly aligned interstitial clusters limit the simulated time. With our method, we can prevent unproductive oscillations in this diffusive basin while maintaining an appropriate distribution of exit states. This considerably extends the time scales accessible to simulation.

4:42PM X22.00012 ABSTRACT WITHDRAWN –

4:54PM X22.00013 Is the Debye-temperature a useful concept at the nanometer scale? Insights from *ab initio* free energy calculations of $Au_{13}$and $Au_{12}Fe$ nanoclusters , GHAZAL S. SHAFAI, MARISOL ALCANTARA ORTIGOZA, TALAT S. RAHMAN, University of Central Florida — We have calculated the phonon density of states, specific heat, and mean-square vibrational amplitudes of the five lowest-lying isomers of Au_{13} and two of $Au_{12}Fe$ nanoparticles, as dictated by their Helmholtz free energy. We find the vibrational entropic contributions to not affect the energy ordering of the isomers. We show that the highest phonon frequencies shift to slightly higher energies in the hybrid clusters: a signature of alloying. As expected the density of vibrational states differs significantly from the Debye model for bulk systems. The definition of the "Debye temperature" for the nanocrystal thus becomes ambiguous and depends very much on how it is calculated. In particular it neither correlates uniquely with atomic bond strengths nor does it relate to the maximum phonon frequency. The discrete phonon spectrum of nanoparticles is thus needed to describe the *exact* mean square displacement or the temperature dependency of the heat capacity. Work supported by DOE Grant DE-FG02-07ER46354

5:06PM X22.00014 Insights on the anomalously soft and stiff modes of metal nanoparticles , MARISOL ALCANTARA ORTIGOZA, TALAT S. RAHMAN, Department of Physics, University of Central Florida, Orlando FL, USA, ROLF HEID, KLAUS-PETER BOHNEN, Institut für Festkörperphysik, Karlsruher Institut für Technologie, Germany — The low- and high-energy tails of the phonon density of states (PDOS) of transition-metal nanoparticles is enhanced with respect to that of their bulk counterparts. For particles in the sub-nanometer scale, we propose a rationale for this fact based on ab initio calculations of their charge density and of the frequency and displacement pattern of their vibrational modes. We find that the radial breathing and non-radial vibrations – analogous to the pulsations observed in variable stars – correspond to the highest and lowest frequencies, respectively. This result is traced to the radial atomic distribution and the charge density distribution particular to the low-coordinated atoms, both of which give rise to modes that have no counterpart in the bulk. We find that the enhanced PDOS at low frequencies is at least partly due to the relatively small number of modes that nanoparticles can sustain and that clusters with bulk-like ordering render fewer and less stiff modes above the bulk limit.

Session X23 DMP DCOMP: Focus Session: Iron Based Superconductors – Gap Symmetry D165

2:30PM X23.00001 Nodal and nodeless Superconductivity in Iron-Based Superconductors[1]

, RONNY THOMALE, Princeton University — The superconducting phase in Iron-based superconductors (pnictides) exhibits a variety of different properties depending on the doping regime and specific parameters such as band structure and interaction which describe the different compounds. The question of the symmetry of the superconducting order parameter combined with the role of interaction-induced anisotropies plays a decisive role to distinguish material-dependent effects from universal mechanisms in this family of compounds. In our talk we attempt to provide an overview of the superconducting phases currently discussed for different classes of pnictides. Specifically, we report on our work on functional renormalization group (FRG) calculations for the pnictides and how it can contribute to our understanding of the different compounds. We discuss from first principles why LaOFeAs shows nodeless while LaOFeP shows nodal anisotropic extended s-wave superconductivity, which we find to be dictated by the existence / non-existence of an additional hole pocket at $\mathrm{M} = (\pi, \pi)$ in the unfolded Brillouin zone. We also elaborate on the nodal phase in KFe_2As_2 as being of d-wave symmetry type and explain its microscopic origin related to the absence of electron pockets which are gapped out at large hole doping. In particular, we will draw a direct line from band structure and interaction parameter calculations to FRG which accomplishes to study Fermi surface instabilities from a truly ab initio starting point, and illustrate this approach for the LiFeAs compound.

[1]Support by a Feodor Lynen Scholarship of the Humboldt Foundation and DFG grant SPP 1458/1 is acknowledged.

3:06PM X23.00002 Do theoretical calculations really predict nodes in Fe-based superconductors?

, IGOR MAZIN, Naval Research Laboratory — It is well established that calculations based on the LDA band structure and the Hubbard model, with the parameters $U \sim 1.3 - 1.6$ eV, and $J \sim 0.2 - 0.3J$ (a "UJ" model), yield strongly anisotropic, and sometimes nodal gaps. The physical origin of this effect is well understood: the two leading terms in the model are $\sum U n_{i\uparrow} n_{i\downarrow}$ and $\sum{}' U n_i n_j$. The former ensures that the coupling to spin fluctuations proceeds only through the like orbitals, and the latter, not being renormalized by the standard Tolmachev-Morel-Anderson logarithm, tends to equalize the positive and the negative order parameters. Both these features are suspect on a general physics basis: the leading magnetic interaction in itinerant systems is the Hund-rule coupling, which couples every orbital with all the others, and the pnictides, with the order parameter less than 20 meV, should have nearly as strong renormalization of the Coulomb pseudopotential as the conventional superconductors. I will argue that, instead of the UJ model, in pnictides one should use the "I" model, derived from the density functional theory (which is supposed to describe the static susceptibility on the mean field level very accurately). The "I" here is simply the Stoner factor, the second variation of the LSDA magnetic energy. Unfortunately, this approach is very unlikely to produce gap nodes as easily as the UJ model, indicating that one has to look elsewhere for the nodes origin.

3:18PM X23.00003 Competing Pairing Symmetries in a Generalized Two-Orbital Model for the Pnictides

, A. NICHOLSON, W. GE, X. ZHANG, University of Tennessee and ORNL, J. RIERA, Universidad Nacional de Rosario, M. DAGHOFER, IFW Dresden, A. OLES, Max-Plank Institut fur Festkorperforchung, Heienberstrasse, G. MARTINS, Oakland University, A. MOREO, E. DAGOTTO, University of Tennessee and ORNL — An extended "t-U-J" two-orbital model [1] for the pnictides will be introduced that includes Heisenberg terms deduced from the strong coupling expansion of the Hubbard model. This extension allows us to enhance the strength of the $(\pi, 0)$-$(0, \pi)$ spin order and favors the presence of tightly bound pairing states even in the small clusters that are exactly diagonalized. The A_{1g} and B_{2g} pairing symmetries are found to compete in the realistic spin-ordered and metallic regime. The dynamical pairing susceptibility additionally unveils low-lying B_{1g} states, suggesting that small changes in parameters may render any of the three channels stable. These results contribute to understanding the puzzling results in pnictides where both nodeless and nodal states have been reported.

3:30PM X23.00004 What the magnitude of $2\Delta/T_c$ on the hole pockets can tell us about the structure of the gaps on electron pockets in Fe-based superconductors?

, SAURABH MAITI, ANDREY CHUBUKOV, University of Wisconsin — There is evidence from transport and penetration depth measurements that some Fe-based superconductors (pnictides) are nodal and some nodeless. Most notable example of nodal behavior is $BaFe_2(As_{1-x}P_x)_2$. But as of this date, there has been no direct probes of the gap structure in this material. ARPES is a direct probe to measure the gap evolution along the Fermi surfaces (FS), but in $BaFe_2(As_{1-x}P_x)_2$ accurate laser ARPES data are only available for hole FSs at Γ point, along which the gaps are nearly identical and are nearly angle-independent. We addressed the issue whether one can use ARPES data for $2\Delta_h/T_c$ on the hole FSs to predict the gap structure and magnitude along the two electron FSs. For this, we considered the non-linear gap equations in realistic 2D multi-pocket models. We found that, in the 4-pocket model, at least in certain limits, the electronic gaps have accidental nodes if $2\Delta_h/T_c$ is below a certain value close to the BCS result, and have no nodes if $2\Delta_h/T_c$ exceeds this value. This, combined with the experimental input on the $2\Delta_h/T_c$, allows us to predict the forms of the electronic gaps based on the ARPES data for the gaps on the hole pockets The verification of these results by the ARPES measurements along the electron FSs will be a crucial test for 2D itinerant multi-pocket models for Fe-pnictides.

3:42PM X23.00005 Observation of a ubiquitous three-dimensional superconducting gap function in optimally-doped $Ba_{0.6}K_{0.4}Fe_2As_2$

, Y.-M. XU, Lawrence Berkeley National Laboratory, Y.-B. HUANG, Chinese Academy of Sciences, X.-Y. CUI, E. RAZZOLI, M. RADOVIC, M. SHI, Swiss Light Source, G.-F. CHEN, Renmin University, P. ZHENG, N.-L. WANG, Chinese Academy of Sciences, C.-L. ZHANG, Oak Ridge National Laboratory, P.-C. DAI, The University of Tennessee, J.-P. HU, Purdue University, Z. WANG, Boston College, H. DING, Chinese Academy of Sciences — The knowledge of the quasi-three-dimensional (3D) superconducting (SC) gap is essential for understanding the superconducting mechanism of the iron-pnictides highlighted by their multiband and quasi-3D electronic structure. By using the k_z-capability of angle-resolved photoemission, we completely determined the SC gap on all five FSs in 3D on $Ba_{0.6}K_{0.4}Fe_2As_2$ samples. We found a significant k_z dispersion of the SC gap which can only derive from interlayer pairing. Remarkably, the SC energy gaps can be described by a single 3D gap function with two energy scales characterizing the strengths of intra-layer (Δ_1) and interlayer (Δ_2) pairing. The anisotropy ratio Δ_2/Δ_1, determined from the gap function, is close to the c-axis anisotropy ratio of the magnetic exchange coupling J_c/J_{ab} in the parent compound. The ubiquitous gap function for all the 3D FSs reveals that pairing is short-ranged and strongly constrain the possible pairing force in the pnictides.

3:54PM X23.00006 Field dependence of the zero energy density of states of an anisotropic $s_\pm$ superconductor

, YAN WANG, PETER HIRSCHFELD, Department of Physics, University of Florida, Gainesville, FL 32611, USA, SIEGFRIED GRASER, EKM, Institute of Physics, University of Augsburg, 86135 Augsburg, Germany — The pairing symmetry in iron-based superconductors (SC) is generally believed to be an $s_\pm$-wave state. Although ARPES suggests a mainly isotropic gap on all Fermi surface sheets, different thermodynamic and transport measurements are still inconclusive about the existence and orientation of gap nodes. Specific heat measurements in a magnetic field showing a square root like dependence of the Sommerfeld coefficient $\gamma(B)$ have been reported, contradicting the linear behavior expected for a fully gapped system. For a d-wave SC, $\gamma(B) \propto \sqrt{B}$ is well-known as Volovik effect. For a fully gapped $s_\pm$-wave SC with $\Delta_+ \neq \Delta_-$, a similar concave field dependence is expected. To distinguish these two effects we apply a two-band model using the Riccati parametrization of the Eilenberger equation to study the density of states around a single vortex and compare it with self-consistent calculations in the vortex lattice. Different models for the momentum dependence of the gap on each band relevant to the iron-based SC, ranging from isotropic to strongly anisotropic and nodal gaps are investigated. Partial support was provided by DOE DE-FG02-05ER46236 (PJH).

4:06PM X23.00007 Measurement of a sign-changing two-gap superconducting phase in $Ba(Fe_{1-x}Co_x)_2As_2$ single crystals using scanning tunneling spectroscopy (STS) , M.L. TEAGUE, G.K. DRAYNA, G.P. LOCKHART, T.P. WU, N.-C. YEH, Dept. of Physics, Caltech, Pasadena, CA 91125, USA, P. CHEN, B. SHEN, H.-H. WEN, Institute of Physics, Chinese Academy of Sciences, CHINA — We present STS studies of the iron pnictide superconductors $Ba(Fe_{1-x}Co_x)_2As_2$ (x=0.06, 0.08, 0.12). Studies on single crystals, cleaved at room temperature in a pure argon atmosphere, reveal direct spectroscopic evidence for predominantly two-gap superconductivity. These gaps decrease with increasing temperature and vanish immediately above the superconducting transition, T_C. Fourier transformation of the tunneling conductance demonstrates slight doping- and energy-dependent quasiparticle scattering interferences (QPI) near the nesting wave-vectors $(\pm\pi,0)/(0,\pm\pi)$ and also near $(\pm2\pi,0)/(0,\pm2\pi)$. The dominant QPI near $(\pm\pi,0)/(0,\pm\pi)$ and the two-gap nature are consistent with sign-changing s-wave superconductivity. The excess zero-bias conductance and the large gap-to-T_C ratios suggest significant unitary impurity scattering. Further studies of the magnetic field dependence will be discussed. This work was supported by NSF Grant DMR-0907251.

4:18PM X23.00008 Local measurement of the superfluid density in the pnictide superconductors $Ba(Fe_{1-x}Co_x)_2As_2$ across the superconducting dome , LAN LUAN, T.M. LIPPMAN, Stanford institute for materials and energy science, SLAC, C.W. HICKS, School of Physics and Astronomy, University of St Andrews, O.M. AUSLAENDER, Physics Department, Technion-Israel Institute of Technology, J.A. BERT, JIUN-HAW CHU, J.G. ANALYTIS, I.R. FISHER, K.A. MOLER, Stanford institute for materials and energy science, SLAC — We locally measure the superfluid density $\rho_s(T)$ in $Ba(Fe_{1-x}Co_x)_2As_2$ single crystals with magnetic force microscopy and scanning SQUID susceptometry. These high-precision, local-probe-based techniques enable us to measure both the zero temperature value of the superfluid density $\rho_s(0)$ and the temperature variation, to distinguish homogeneous from spatially varying responses, and to report systematic behavior as a function of Co doping across the superconducting dome. We find that $\rho_s(T)$ increases sharply with decreasing temperature below the superconducting transition temperature T_c of both optimally doped and underdoped compounds, and that $\rho_s(0)$ falls more quickly with T_c on the underdoped side of the dome than on the overdoped. These observations, as well as the increasing temperature induced change of $\rho_s(T)$ at low temperatures upon underdoping, are consistent with magnetic fluctuation mediated pairing and the coexistence of magnetism and superconductivity.

4:30PM X23.00009 A sign of change: pinning down the pairing symmetry of the iron-based superconductors , EREZ BERG, Harvard University, NETANEL LINDNER, TAMAR PEREG-BARNEA, California Institute of Technology — Understanding the structure of the order parameter of the iron-based superconductors is the key to unveil their pairing mechanism. Although there has been much theoretical and experimental indications that the order parameter changes its sign in momentum space, direct evidence is still lacking. The difficulty stems from the fact that the order parameter is likely to be of s-wave symmetry, and therefore designing a phase sensitive experiment that would clearly reveal the sign change is non-trivial. Here, we examine a contact between a sign-changing superconductor and an ordinary, uniform-sign superconductor. If the the barrier between the two superconductors is not too high, the frustration of the Josephson coupling between different portions of the Fermi surface across the contact can lead to surprising consequences, such as time-reversal symmetry breaking at the interface and unusual energy-phase relations with multiple local minima. We propose this mechanism as a possible explanation for the half-integer flux quantum transitions in niobium-iron pnictide loops, which were discovered in a recent experiment (C-T. Chen et. al., Nature Physics 6, 260 (2010)).

4:42PM X23.00010 Probing the Superconducting Order Parameter of $Ba(Fe_{1-x}Co_x)_2As_2$ by Josephson Interferometry[1] , J.M. ATKINSON, D.J. VAN HARLINGEN, University of Illinois at Urbana-Champaign, P. CANFIELD, N. NI, Iowa State University, J.D. STRAND, Syracuse University — Since the discovery of the first Fe-based superconductors in 2006, extensive effort has been directed toward characterizing and modeling the novel properties of these exotic materials, in particular, the symmetry of their superconducting order parameter. We probe the order parameter in Co-doped $BaFe_2As_2$ single crystals by fabricating Josephson junctions on polished faces orthogonal to the c-axis. It has been proposed that the Fe-pnictides form electron and hole pockets in the Fermi surface that have s-wave Cooper pair symmetry but opposite phases, the so-called s$\pm$ model. The modulation of the critical current I_C as a function of magnetic flux applied along the c-axis is different for junctions fabricated on a corner (between [100] and [110] faces) or on an edge (either [100] or [110]). In the same way, the product I_CR should be different for each type of junction. The combination of these effects may help us map the phase anisotropy and test for this pairing symmetry. We will present preliminary results of these studies and attempts to match them with existing theoretical models.

[1]Work supported by the Department of Energy grant BNL-150252 through the CES-EFRC.

4:54PM X23.00011 Robust nodal gap structure in $BaFe_2(As_{1-x}P_x)_2$ with P doping revealed by magnetic penetration depth measurements , KENICHIRO HASHIMOTO, RYO KATSUMATA, SHO TONEGAWA, SHIGERU KASAHARA, TAKAHITO TERASHIMA, TAKASADA SHIBAUCHI, YUJI MATSUDA, Kyoto University, ALESSANDRO SERAFIN, ANTONY CARRINGTON, University of Bristol — A number of experimental studies show that the non-universal superconducting gap structures with and without nodes is realized in iron pnictides, depending on the doping materials and its doping level. It has been suggested that in a framework of s++ wave symmetry, vertical nodal gap structure occurs during the crossover from s++ to s+- state due to the competition between the orbital and magnetic fluctuations as well as the impurity scattering effect. On the other hand, within the spin-fluctuation mediated pairing mechanism, three dimensional nodal structures is discussed. Therefore, it is important to uncover the doping dependence of the superconducting gap structure and its impurity effect. Here we report the magnetic penetration depth results measured down to 100 mK in the P-doped Ba122 system indicate robust nodal gap structure. We especially focus on doping evolution of the superfluid density with P doping. We also discuss the impurity effect introduced by Pb heavy ion beam respective to the in-plane.

5:06PM X23.00012 Two-Gap Paring of the Optimal Doped (M,K)Fe_2As_2 with M = Ba, Sr , FENGYAN WEI, Texas Center for Superconductivity at University of Houston and Department of Physics, BING LV, Texas Center for Superconductivity at University of Houston, FENG CHEN, YUYI XUE, Texas Center for Superconductivity at University of Houston and Department of Physics, CHINGWU CHU, Texas Center for Superconductivity at University of Houston and Department of Physics,Lawrence Berkeley National Laboratory — The gap structure revealed by the specific heat of iron pnictides remains unsettled. Not only do the reported characters vary for similar $Ba_{0.6}K_{0.4}Fe_2As_2$ and $Sr_{0.55}K_{0.45}Fe_2As_2$, single gap and two-gap pairings have also been suggested in the crystals with the same nominal composition of $Ba_{0.6}K_{0.4}Fe_2As_2$. It seems that either the gap structure is unusually sensitive to the sample details or some analysis procedures need to be refined Here we explored both the (Sr,K)Fe_2As_2 and (Ba,K)Fe_2As_2 systems, and different procedures were used to extract the phonon background. In the case of (Sr,K)Fe_2As_2, the phonon background seems to be insensitive to both the procedures and the potassium doping. For (Ba,K)Fe_2As_2, however, the data suggest a significant doping dependency of the soft phonons. The observations cast doubts on the previous procedures of using either $BaFe_2As_2$ or $Ba(Fe_{0.9}Co_{0.1})_2As_2$ to estimate the phonon background of $Ba_{0.6}K_{0.4}Fe_2As_2$. A new procedure, therefore, is developed. The result will be presented and discussed.

5:18PM X23.00013 Superconducting gap measurements on Co-doped SrFe2As2 single crystals by point contact spectroscopy[1] , CASSANDRA R. HUNT, H.Z. ARHAM, W.K. PARK, L.H. GREENE, University of Illinois at Urbana-Champaign, J. GILLETT, S. SEBASTIAN, University of Cambridge — We present point contact spectroscopy results on single crystal Co-doped $SrFe_2As_2$. Two sets of Andreev-like enhancements in conductance are seen with nominally c-axis contacts. For temperatures up to $T_c = 14.5$ K, the conductance is fit to a Blonder-Tinkham-Klapwijk (BTK) model extended to two independent bands with lifetime broadening [1]. We also consider recently proposed $s_{\pm}$-wave extensions to BTK [2,3]. Many recent reports claim multiple gaps in the 122 compounds, however care must be taken to distinguish the presence of Andreev peaks from other excitation modes. We find robust evidence of an SC gap at 6 meV and evidence of another conductance enhancement at 12 mV that tracks the inner gap. The origin of this feature, and of multi-gap features as measured by PCS, are discussed. [1] G. E. Blonder, M. Tinkham, and T. M. Klapwijk, PRB **25**, 45154532 (1982). [2] A. A. Golubov, *et al.* PRL **103**, 077003 (2009). [3] I. B. Sperstad, J. Linder, A. Sudbo, PRB **80**, 144507 (2009).

Thursday, March 24, 2011 2:30PM - 5:30PM –

Session X24 DCOMP: Focus Session: Quantum Transport Simulations and Computational Electronics – Molecular Junctions D167

2:30PM X24.00001 Efficient k.p method for first-principles calculation of Seebeck coefficient in quantum transport[1] , DAVID A. STRUBBE, Department of Physics, University of California, Berkeley, and Materials Sciences Division, Lawrence Berkeley National Laboratory, SU YING QUEK, Molecular Foundry, LBNL, HYOUNG JOON CHOI, Department of Physics and IPAP, Yonsei University, J.B. NEATON, Molecular Foundry, LBNL, STEVEN G. LOUIE, Dept. of Physics, University of California, Berkeley; Molecular Foundry and Materials Sciences Division, LBNL — Thermoelectric properties of molecular junctions reveal fundamental aspects of nanoscale charge transport at interfaces and are relevant to potential organic/inorganic hybrid thermoelectric materials. Quantum transport calculations typically evaluate the Seebeck coefficient S by finite differences of the transmission as a function of energy. However, in ab initio calculations this quantity is difficult to converge for realistic systems and can require very large k-grids. We derive a new analytic-derivative method to evaluate S via k.p perturbation theory, implement it in a DFT-based scattering-state transport code, and apply it to calculations of molecular junctions. This technique improves k-point convergence by avoiding critical points in the lead bandstructure and allows more efficient calculations of Seebeck coefficients.

[1]Support from DOE (DE-AC02-05CH11231), NSF (DMR10-1006184 and GRFP Fellowship), NERSC, TeraGrid.

2:42PM X24.00002 First-Principles Studies of Charge Dynamics in Single-Molecule Junctions at Finite Bias[1] , PIERRE DARANCET, Molecular Foundry, LBNL, HYOUNG JOON CHOI, Physics, Yonsei University, JONATHAN R. WIDAWSKY, SCOTT BERKLEY, LATHA VENKATARAMAN, Columbia University, JEFFREY B. NEATON, Molecular Foundry, LBNL — Extending well-established measurements of low-bias conductance of single molecule junctions, new experiments report IV characteristics of organic molecules for biases as high as 1V [1]. Such measurements provide a unique probe of electronic properties of well-defined metal-organic nanointerfaces when driven out-of-equilibrium, and an opportunity to examine a still-missing quantitative theory of out-of-equilibrium charge dynamics at the nanoscale. Here we will present first-principles transport calculations for several amine-Au and pyridine-Au linked junctions at different levels of approximation: first mean-field, and then including electron-electron correlations at equilibrium and out-of-equilibrium. We show that incorporating electronic correlations at equilibrium already leads to a very good agreement with experiments [1], and discuss how these corrections might change out of equilibrium.

2:54PM X24.00003 Understanding the Role of Direct Au-C Links to Electrodes in Single Molecule Junctions[1] , HECTOR VAZQUEZ, JONATHAN WIDAWSKY, ZHANG-LING CHENG, SEVERIN SCHNEEBELI, RACHID SKOUTA, RONALD BRESLOW, MARK S. HYBERTSEN, LATHA VENKATARAMAN — Recent experiments have shown that use of tri-methyl tin (SnMe3) link groups results in the formation of alkane single molecule junctions with measured conductance ∼100 times higher than found for any other link group previously used. Further evidence points to the in-situ formation of direct Au-C bonds to the electrode. In this work we use Density-Functional Theory based calculations to study the formation and structure of junctions based on direct Au-C link bonds. Transport calculations based on Non-Equilibrium Green's Functions for benzene and alkane molecules anchored through Au-C bonds show that the alkane backbone couples more strongly to the leads, resulting in a higher transmission as compared with other link groups. In the case of benzene, however, transport is primarily through the σ system, yielding a smaller conductance increase. Finally, we discuss corrections to the position of molecular resonances found in the DFT-based calculations and the implications for conductance.

3:06PM X24.00004 Phonon-assisted tunneling in two-level quantum dots or diatomic molecules[1] , KEVIN INGERSENT, U. Florida, EDSON VERNEK, GISELE IORIO, Fed. U. Uberlandia, Brazil — Electron-electron interactions in nanoscale systems can be significantly modified by coupling to bosonic modes (photons, phonons, and plasmons) that act as sources of dissipation and decoherence (dephasing). Photon-assisted tunneling can take place through ground and excited states of various types of quantum-dot system, while signatures of vibrational modes are seen in transport through single-molecule transistors in the Coulomb blockade and Kondo regimes. We report numerical renormalization-group results for a quantum dot or diatomic molecule that has two active levels, taking into account both intra-level and inter-level Coulomb interactions. We focus on how decoherence induced by phonon-assisted inter-level transitions affects the formation of the many-body Kondo singlet between the dot/molecule and the leads, and quantify the consequent modification of the zero-bias electrical conductance.

[1]Supported by NSF grant DMR-0710540

3:18PM X24.00005 Quantum current of a molecular photo-switch between two graphene sheets , G.P. BRIVIO, C. MOTTA, Università di Milano-Bicocca, Italy, M.I. TRIONI, CNR, ISTM, Milano (Italy), K.L. SEBASTIAN, Indian Institute of Science, Bangalore (India) — Light responsive materials that reversibly change shape under alternate UV and visible irradiation have attracted much interest because they can be used as optical switches, since the isomers show different features in the dimension, HOMO-LUMO gap and transmission spectrum. In view to integrate the photo-switch in the carbon based electronics devices, the conductance of a system constituted by a photochromic molecule between two graphene electrodes is investigated. In this work the conductance of the junction formed by diarylperfluorocyclopentene between two semi-infinite graphene sheets was computed using the non-equilibrium Green's function method combined with density functional theory via the TranSiesta code. The results emphasize the role of the graphene and the molecular electronic states in the switching behaviour of this hybrid system.

3:30PM X24.00006 Correlation between Raman scattering and conductance in a molecular junction , TAE-HO PARK, MICHAEL GALPERIN, Department of Chemistry and Biochemistry, University of California at San Diego — Raman spectroscopy of molecular junctions is a promising diagnostic and control tool. We present a model for non-resonant Raman spectroscopy, generalizing previous considerations to strong laser pulses of arbitrary time dependence. The model paves a way to realistic simulations of Raman spectroscopy experiments in molecular conduction junctions. We demonstrate within the model that the optical properties of molecular conduction junctions are strongly correlated with the electron transport properties. Feynman diagrams responsible for such similarity are analyzed for both processes, and possible explanation for observed (anti-)correlated behavior of Stokes signal and conductance is proposed.

3:42PM X24.00007 Towards *single-atom-controlled* device[1] , SUBHASISH MANDAL, RANJIT PATI, Dept. of Physics, Michigan Technological University — *Single-atom-controlled* device has been explored recently in the context of molecular junction. Here, by using a codoping model, where a cation and an anion are introduced simultaneously into the host to maintain charge neutrality, we have probed the electron transport characteristics in a strongly coupled single molecular junction. We have used 1, 12-dicarba-*closo*-dodecaborane inorganic molecule as a precursor and have replaced one of the vertex carbon atoms by a boron atom and simultaneously decorated it with an endohedrally doped alkali atom (Li/Na) to look into the role of dopant atoms on the conductivity. The commonly used thiolate anchoring groups are used to attach the molecule in between two gold electrodes, and a parameter free, first-principles, nonequilibrium Green's function approach is used to calculate the current-voltage characteristics. Charge transfer from the alkali atom to the host is found to have a profound effect on the electronic structure causing a dramatic change in the conductivity. Since the single alkali atom controls the behavior of electron flow in this circuit, we term this device as a *single-atom-controlled* device.

[1]NSF Grant No. 0643420

3:54PM X24.00008 Conformational and Voltage Gating in a Molecular Three Terminal Device , SAIKAT MUKHOPADHYAY, RAVINDRA PANDEY, Michigan Technological University, SHASHI KARNA, Army Research Laboratory — The effect of the conformational changes in the gate arm of a three terminal molecular device is investigated. The donor-acceptor molecular moieties connected through a ring describe the two arms, whereas a π-conjugated molecular wire is used as a gate in the proposed architecture. In the absence of the gate field, the device exhibits current switching between the non-planar and planar orientations of the π -electron moieties with respect to each other with maximum $I_{(ON)}/I_{(OFF)}$ =14. When the gate field is applied, $I_{(ON)}/I_{(OFF)}$ ratio decreases, thus suggesting that the effects of the conformational changes in the gate arm and the applied gate field oppose each other in the architecture considered. Furthermore, the tunneling current corresponding to conformational gating in two different directions appears to exhibit oscillatory nature with a phase factor of $\pi/2$ in presence of the gate field.

4:06PM X24.00009 Charge transport in strongly coupled molecular junctions: 'In-phase' and 'out of phase' contribution to electron tunneling[1] , PARTHA PRATIM PAL, RANJIT PATI, Michigan Technological University — We report a first principles study on the evolution of charge transport in a two-terminal molecular scale device with the increase in the length of the molecular wire build out of cubane oligomers. In particular, for wires of three different lengths, we look into the relative contribution of the 'in-phase' and the 'out-of-phase' components of the total electronic current under the influence of an external bias. In the low bias regime, the 'out-of-phase' contribution to total current is minimal and 'in-phase' or elastic tunneling of the electrons is responsible for the net electronic current. This is true irrespective of the length of the molecular spacer. In this regime, the I-V characteristics follow Ohm's law and the conductance of the wires is found to decrease exponentially with length which is in agreement with experimental results. However, after a certain 'off-set' voltage, the I-V characteristics become non-linear and the 'out-of-phase' tunneling starts to contribute substantially to the net current.

4:18PM X24.00010 Negative Differential Resistance at Low Bias: C60-Based Molecular Devices , WENCHANG LU, North Carolina State University, Raleigh, NC and CSMD, ORNL, TN, XIAOHONG ZHENG, NC State University, Raleigh, NC, T.A. ABTEW, NC State University, VINCENT MEUNIER, CSMD, ORNL, TN, JERRY BERNHOLC, NC State University, Raleigh, nC and CSMD, ORNL, TN — Unlike single-C60-based devices, molecular assemblies based on two or more C60 can exhibit negative differential resistance (NDR). We evaluate electron transport properties of molecular devices built from two C60 connected by an alkane chain, using a non-equilibrium Green function technique implemented within the framework of linear-scaling DFT. We find that electronic conduction in these systems is mediated by C60's lowest unoccupied molecular orbitals (LUMOs), as in the case of a single-C60-based device. However, as the LUMOs' positions are pinned to the chemical potentials of their respective electrodes, their relative alignment shifts with applied bias and leads to an NDR at a very low bias. Furthermore, the position and magnitude of the NDR can be tuned by chemical modification of the C60s and by changing the length of the alkane linker. The flexibility and richness of C60-based molecular electronics components point to a potentially promising route for the design of molecular devices and chemical sensors.

4:30PM X24.00011 Charge injection and transport across metal-C60 and C60-petacene interfaces: A first-principles study[1] , YONG-HOON KIM, Korea Advanced Institute of Science and Technology — Recent experiments demonstrated that [60]fullerene (C_{60}) molecules adsorbed on metal surfaces provide favorable energy level alignment for both electron and hole injections in the context of light-emitting diode applications [1,2]. The efficient hole injection across C_{60} layers is rather surprising, since C_{60}s are highly electron-accepting molecules and should behave as a hole blocking (rather than hole injection) layer. To provide a microscopic understanding of these seemingly contradictory finding, we consider Au–C_{60}–pentacene–C_{60}–Au molecular junctions using a first-principles computational approach. We find the Fermi level pinning at the Au–C_{60} interfaces and the strongly configuration-dependent charge transport efficiency at the C_{60}–pentacene interfaces. The former finding is in agreement with a recent experimental report [2] and our earlier conclusion from the study of polymerized C_{60} wires [3]. We will explain the latter observation based on the nature of charge tunneling across π–π orbitals [1] Lee, J.Y., Appl. Phys. Lett. **88**, 073512 (2006) [2] Wang, Z.B *et al.*, Appl. Phys. Lett. **95**, 043302 (2009). [3] Lee, G.I., Kang, J.K., & Kim, Y.-H., J. Phys. Chem. C **112**, 7029 (2008).

4:42PM X24.00012 Electron correlation enhancement of the diode property of asymmetric molecule , YOSHIHIRO ASAI, HISAO NAKAMURA, National Institute of Advanced Industrial Science and Technology (AIST), JOSHUA HIHATH, NONGJIAN TAO, Arizona State University — Stimulated by the giant diode property found in tetraphenlydithiol derivative including dipyrimidinil-diphenly diblock [1], a possible mechanism of the giant diode property was investigated theoretically based on electron correlation. We found that the mean field theory (MFT) fails in describing the giant diode property, as it was confirmed by first principle calculation of ballistic electronic current through the diode molecule using GGA. Electron correlation effect on electric current taken into account within the self-consistent GW approximation using Keldysh Green's function theory was found to give the fair account of the giant diode property. We conclude that elastic electron collision beyond MFT enhances the diode property quite a lot.

4:54PM X24.00013 First Principles Study and Theoretical Analysis of a Single Molecular Diode by $p-n$ di-block molecules , HISAO NAKAMURA, YOSHIHIRO ASAI, National Institute of Advanced Industrial Science and Technology, JOSH HIHATH, NONGJIAN TAO, Arizona State University — The concept of a single molecular diode was first proposed by Aviram and Ratner, and there have been many studies of synthesis D-σ-A or $p-n$ di-block molecules and measurements of the current-voltage $(I-V)$ characteristics for relating molecular junctions. Recently, the $I-V$measurement in a symmetric tetraphenyl junction and non-symmetric dipyrimidinyl -diphenyl diblock junction was performed, and clear rectification was found in the latter system, which resembles the $p-n$ junction by the covalent connection between electron-deficient bypyrimidinyl and electron-rich biphenyl moieties, though an applied bias is much lower than the resonant level. In this presentation, we performed the first principles calculations of electron transport for the above tetraphenyl and dipyrimidinyl -diphenyl diblock junctions by the self-consistent nonequilibrium Green's function theory with the use of our HiRUNE program module. We carried out the systematic analysis of the rectification behavior and identified the change of electron-pathway in the bridge molecule relating to $p-n$ junction based on the first principles data. The relation between the rectifying action and molecular conformation, particularly, the torsion of diblock, will be discussed.

5:06PM X24.00014 Temperature influence on a molecular switching under electric field: quantum transport ab initio calculation[1] , MAIA VERGNIORY, Donostia International Physics Center, JOSE GRANDINO-ROLDAN, University of Jaen, ARAN GARCÍA-LEKUE, Donostia International Physics Center, LIN-WANG WANG, Lawrence Berkeley National Labortaory, QUANTUM TRANSPORT TEAM — A molecular transistor based on torsion-angle conformation change driven by gate electric field is designed and studied using *ab initio* calculations. This transistor consists of a $\mathrm{SH-C_6H_2F(CH_3)C_6H_2(CH_3)F-SH}$ molecule sandwiched between two Au(111) electrodes, where the interaction between the molecular dipole and a gate voltage induced electric field will cause the molecule to twist along its c-axis. This twist changes the quantum conductivity of the molecule. The effect of thermal fluctuation on the molecular conformation is studied, so is the ability of the transistor to shut off its current. The advantages and challenges of using such molecular conformation change as a mechanism for transistor gating are discussed

[1]This work has been supported partially by the U.S. Department Of Energy BES/SC under contract No. DE-AC02-05CH11231 and and the Spanish MICINN (Grant No. FIS2010-19609-C02-02).

5:18PM X24.00015 Vibronic- and mechanical-spin control in spin-1 molecular devices[1] , DAVID RUIZ-TIJERINA, Ohio University, PABLO CORNAGLIA, CARLOS BALSEIRO, Centro Atomico Bariloche and Instituto Balseiro, Argentina, SERGIO ULLOA, Ohio University — Using numerical renormalization group calculations, we study the effect of a vibronic mode on the electronic transport through a deformable spin-1 molecular device. We analyze the experimental situation of Parks et. al. [Science 328 1370 (2010)], where it is observed that stretching the molecule introduces a static magnetic anisotropy. The device is modeled as an interacting two-level system with only one level coupled to metallic leads, in which the static anisotropy is modulated by a vibronic mode. We performed calculations of the local spectral density, which indicate that this dynamic magnetic anisotropy can counter the static effects and drive the ground state into a non Fermi-liquid phase with non-zero spectral density at the Fermi level. It also renormalizes the couplings between the molecule and the metallic leads in an anisotropic fashion, reducing the spin-1 Kondo temperature of the device.

Thursday, March 24, 2011 2:30PM - 5:18PM –

Session X25 DCMP: Superconductivity: Optical, Raman and Other Spectroscopies D166

2:30PM X25.00001 How can we relate the critical temperature and the superconducting gap amplitude in cuprate superconductors? , ALAIN SACUTO, SEABSTIEN BLANC, YANN GALLAIS, MAXIMILIEN CAZAYOUS, MARIE AUDE MEASSON, Laboratoire Matériaux et Phénomènes Quantiques, CNRS Université Paris Diderot - Paris 7, Paris Cedex 13, France, J.S. WEN, Z.J. XU, GENDA GU, Matter Physics and Materials Science, Brookhaven National Laboratory (BNL), USA — We explore the superconducting state of hole-doped cuprates by electronic Raman scattering as a function of both temperature and doping level. We observe a loss of coherent quasi-particles in the anti-nodal region and show that coherent Bogoliubov quasiparticles are confined around the nodes. This contrasts to conventional superconductors where superconductivity develops uniformly along the normal-state Fermi surface. We define the fraction of coherent Fermi surface, f_c around the nodes for which quasi-particles are well defined and superconductivity sets in. We establish that $T_c \propto f_c \Delta_{max}$. Δ_{max} is the maximum amplitude of the d-wave superconducting gap. This new relation differs from the standard BCS theory and gives us some clues for increasing T_c in the cuprates. S. Blanc et al. Phys. Rev. B **82**, 144516 (2010); S. Blanc et al. Phys. Rev. B **80**, 140502 (2009).

2:42PM X25.00002 Raman response in density wave materials , ELIZABETH NOWADNICK, ALEXANDER KEMPER, BRIAN MORITZ, THOMAS DEVEREAUX, Stanford University and SLAC — Raman spectroscopy, which uses different incoming and outgoing light polarizations to measure different areas of the Brillouin zone, allows researchers to probe the nature of charge and spin density wave gaps. We present calculations of the Raman response for two density wave materials: rare earth tri-tellurides in the charge density wave state and the iron pnictides in the spin density wave state. Both of these materials have phase diagrams which can be further understood by clarifying the nature of the density wave state. For example, in the tri-tellurides, either one or two charge density wave gaps are present depending on the type of rare earth element in the compound. In the pnictides, which we treat with a multiband model, superconductivity coexists with or is in close proximity to a spin density wave state. We discuss what can be learned from our calculations and compare to experimental results.

2:54PM X25.00003 Far-infrared spectroscopy of magnetic-field-induced pairbreaking in superconducting thin films[1] , XIAOXIANG XI, University of Florida, J. HWANG, Pusan National University, C. MARTIN, D.B. TANNER, University of Florida, G.L. CARR, Brookhaven National Laboratory — A magnetic field will break the time-reversal symmetry of the superconducting condensate pairing, giving rise to a pair-breaking effect. This pairbreaking has been confirmed by our recent far-infrared transmission and reflection measurement of a superconducting NbTiN thin film in an in-plane magnetic field. The complex optical conductivity was extracted, and the optical gap was obtained from its real part. Comparison with the pair-breaking theory of Abrikosov and Gor'kov yields good quantitative agreement, confirming directly the theory's validity for the optical conductivity.

[1]Supported by the US DOE through contracts DE-FG02-02ER45984 at UF and DE-AC02-98CH10886 at the NSLS. Access to the high-field magnet is courtesy of J.J. Tu (CCNY).

3:06PM X25.00004 Optical properties of the pseudogap state in deeply underdoped cuprates , ADAM POUND, University of Guelph, JULES CARBOTTE, McMaster University, ELISABETH NICOL, University of Guelph — Recent optical measurements of deeply underdoped cuprates have revealed that a coherent Drude response persists well below the end of the superconducting dome in the phase diagram[1]. We show that this observation is consistent with the resonating valence bond spin-liquid model proposed by Yang, Rice, and Zhang[2]. Within this model, we analyze the three elements that cause the overall reduction in optical conductivity in the approach to the Mott insulating state: a Gutzwiller factor associated with increased correlations, which causes a reduction in the coherent part of the carrier Green's function; a shrinking of the Fermi surface defining the hole Luttinger contours; and an increase in optical effective mass. We show that each of these elements yields qualitative agreement with various experimental observations. Finally, we show how the increased magnitude of the pseudogap at low doping modifies the microwave conductivity and the Wiedemann-Franz law.

3:18PM X25.00005 Point group sensitive probes of the pseudogap electronic structure in Bi2212 , J.P. HINTON, UC Berkeley, LBNL, J.D. KORALEK, LBNL, J. ORENSTEIN, UC Berkeley, LBNL, I. FIRMO, M. HAMIDIAN, K. FUJITA, LASSP Cornell U, CMPMS BNL, J.C. DAVIS, LASSP Cornell U, CMPMS BNL, SUPA U St. Andrews — We combine optical transient grating spectroscopy (TGS) and spectroscopic imaging scanning tunneling microscopy (SI-STM) to study the pseudogap electronic structure in the underdoped cuprate superconductor $Bi_2Sr_2CaCu_2O_{8+\delta}$. In TGS a pair of 50 fs pump pulses at 800 nm coincident on the sample surface generate a sinusoidal variation in the index of refraction. This index grating is phase sensitively probed, allowing us to clearly resolve two components in the optical response below Tc. We attribute one of the components to a coherent nonlinear optical process, whose properties are sensitive to the point group symmetry of the pseudogap electronic structure. We compare the results of these optical experiments with recent analysis of SI-STM data (M. J. Lawler *et al* **Nature 466**,347 (2010)) which measures the amplitude of peaks at various reciprocal lattice vectors in the Fourier transform of atomically resolved images of the pseudogap electronic structure. The symmetry properties of the SI-STM Bragg amplitudes provide additional evidence relevant to the point group of the pseudogap electronic structure.

3:30PM X25.00006 Evidence for symmetry breaking in the pseudogap phase of the single-layer Cuprate Pb-Bi2201 , J.D. KORALEK, J. HINTON, J. ORENSTEIN, LBNL/Berkeley, R.-H. HE, M. HASHIMOTO, Z.-X. SHEN, H. KARAPETYAN, A. KAPITULNIK, Stanford/SIMES, H. EISAKI, AIST — We use time-resolved optical spectroscopy, combined with angle resolved photoemission, and polar Kerr effect measurements, to study the single-layer Cuprate superconductor $Pb_{0.55}Bi_{1.5}Sr_{1.6}La_{0.4}CuO_{6+\delta}$ (Pb-Bi2201). Near optimal doping this material has convenient temperature scales with a T_c of 38K and T^* of 130K, allowing signals associated with the superconducting and pseudogap phases to be clearly separated in the raw data. The unusual time dependence of the pseudogap signal is suggestive of a coherent nonlinear optical process which is sensitive to changes in the electronic point group symmetry. This nonlinear signal turns on at T^* and persists to low temperature. Angle resolved photoemission and polar Kerr effect measurements performed on the same batch of samples reveal the opening of a particle-hole asymmetric gap and the onset of Kerr rotation, both with strikingly similar temperature dependence to the nonlinear optical signal.

3:42PM X25.00007 BCS-BEC Crossover Approach to the Optical Conductivity in high T_c Superconductors , DAN WULIN, HAO GUO, James Franck Institute and Department of Physics, University of Chicago, CHIH-CHUN CHIEN, Los Alamos National Laboratory, KATHRYN LEVIN, James Franck Institute and Department of Physics, University of Chicago — We address the finite frequency ω conductivity in the cuprates. We presume that the pseudogap arises from stronger-than-BCS attraction, which leads to non-condensed pairs above and below T_c. Our theoretical formalism, which is consistent with gauge invariance and the transverse f-sum rule, yields a mid infrared peak associated with the energy needed to break pairs. It also leads to a situation in which very high ω spectral weight participates in the formation of the condensate. These observations, along with others reported here are consistent with experiment.

3:54PM X25.00008 Kerr effect measurements in the pseudo-gap regime of LBCO and Pb-BSCO using high resolution Sagnac , HOVNATAN KARAPETYAN, VIKRAM NATHAN, RUIHUA HE, MAKOTO HASHIMOTO, ZHI-XUN SHEN, AHARON KAPITULNIK, Stanford University, HIROSHI EISAKI, Nanoelectronics Research Institute, AIST, Japan, JAKE KORALEK, JAMIE HINTON, JOE ORENSTEIN, Lawrence Berkeley National Laboratory, JOHN TRANQUADA, GENDA GU, MARKUS HUECKER, Brookhaven National Laboratory — Polar Kerr effect in several high-Tc superconductors systems was measured at zero magnetic field with high precision using a cryogenic Sagnac fiber interferometer with zero-area. We observed non-zero Kerr rotations of order $\sim 1\mu$rad appearing near the pseudogap temperature T^*, and marking what appears to be a true phase transition. In this talk we will review our work on $YBa_2Cu_3O_{6+x}$, $La_{1.875}Ba_{0.125}CuO_4$ and $Pb_{0.55}Bi_{1.5}Sr_{1.6}La_{0.4}CuO_{6+\delta}$. In particular, in Pb-BSCO we observe an emergence of Kerr signal that coincides with ARPES data showing an abrupt change at T^* from a relatively simple one- band metal into a state with profoundly-altered electronic structure.

4:06PM X25.00009 DC Transport in Pseudogapped Superconductors: The Role of the Fermi Arcs , HAO GUO, BENJAMIN M. FREGOSO, DAN WULIN, James Franck Institute and Department of Physics, University of Chicago, CHIH-CHUN CHIEN, Los Alamos National Laboratory, KATHRYN LEVIN, James Franck Institute and Department of Physics, University of Chicago — We examine the dc conductivity σ in a d-wave pseudogapped high T_c superconductor for a range of different hole doping concentrations and temperatures T. Our approach is based on treating the cuprates as mid-way between BCS and Bose Einstein condensation and our correlation functions are demonstrably consistent with gauge invariance and the transverse f-sum rule. Studies of the $\omega \to 0$ dc conductivity below T_c lead to a peak structure (observed experimentally) while above T_c we show that pseudogap effects manifest themselves in the resistivity primarily through a depression in the effective carrier number with decreasing T. We discuss related implications for resistivity vs $T > T_c$ experiments and demonstrate that the trends with hole doping are compatible with the data, while the role of the Fermi arcs appears overall to be secondary.

4:18PM X25.00010 Ultrafast transient grating and pump probe measurements in optimally doped $La_{2-x}Sr_xCuO_4$ thin films , DARIUS TORCHINSKY, FAHAD MAHMOOD, DAVID HSIEH, JAMES MCIVER, MIT, A. BOLLINGER, I. BOZOVIC, Brookhaven National Laboratory, NUH GEDIK, MIT — We have performed pump probe and transient grating measurements on high-T_c thin films of optimally doped $La_{2-x}Sr_xCuO_4$. In these experiments, a pair of femtosecond pulses are interfered on the sample generating a sinusoidal intensity modulation that in turn induces a density grating of photoexcitations. The resulting change in reflectivity allows time-resolved optical measurement of the separate effects of recombination and diffusion. We describe the temperature and excitation density dependence of these measurements and discuss their implications on the nature of superconductivity in the cuprates.

4:30PM X25.00011 Ultrafast quasiparticle dynamics of $La_{2-x}Sr_xCuO_4$ probed by time-resolved THz spectroscopy , ALEX FRENZEL, Massachusetts Institute of Technology / Harvard University, DANIEL PILON, Massachusetts Institute of Technology, ANTHONY BOLLINGER, IVAN BOZOVIC, Brookhaven National Laboratory, NUH GEDIK, Massachusetts Institute of Technology — We have studied picosecond quasiparticle recombination dynamics in the superconducting state of the cuprate superconductor $La_{2-x}Sr_xCuO_4$. After excitation by a 1.5 eV optical pulse, the optical conductivity in the range 0.5 - 2 THz is measured at varying time delays using coherent time-domain terahertz spectroscopy. We show that the conventional two-fluid model, which successfully describes the optical conductivity in YBCO, is unable to accurately reproduce our results. At optimal doping, we observe a weak dependence on excitation density in the recovery rate at low fluence. We comment on the recovery rate of the superconducting state in terms of the bimolecular recombination dynamics described by the phenomenological Rothwarf-Taylor model.

4:42PM X25.00012 Optical conductivity in dynamic Hubbard model , GIANG BACH, Department of Physics, University of Alberta, Edmonton, Alberta, Canada, T6G 2J1, JORGE HIRSCH, Department of Physics, University of California, San Diego, La Jolla, California, 92093-0319, FRANK MARSIGLIO, Department of Physics, University of Alberta, Edmonton, Alberta, Canada, T6G 2J1 — The Dynamic Hubbard model is a candidate to capture the physics of two-band Hubbard models, such as the enhancement of critical Hubbard U for the Mott transition. A pseudo-spin $1/2$ auxiliary field, which modifies the Coulomb U interaction based on the on-site occupancy of electrons, breaks the electron-hole symmetry normally associated with the Hubbard model. The dependence of optical conductivity on the number of particles also reveals the effect of the pseudo-spin on the spectral weight distribution as a function of frequency.

4:54PM X25.00013 Optical and DC conductivity in the two-dimensional $t-t'-t''$ Hubbard model near the antiferromagnetic quantum critical point[1] , DOMINIC BERGERON, ANDRÉ-MARIE S. TREMBLAY, Dept. de physique, RQMP, Universite de Sherbrooke — We calculate the conductivity of the two-dimensional Hubbard model with second and third nearest neighbor hoppings t' and t'' for dopings in the vicinity of the antiferromagnetic quantum critical point (QCP) using the two-particle self-consistent approach. This approach is non-perturbative and was benchmarked against quantum Monte Carlo calculations from weak to intermediate coupling. We include vertex corrections that are the analogs of the Maki-Thompson and the Aslamazov-Larkin terms in the theory of paraconductivity, but for antiferromagnetic fluctuations. With these corrections the f-sum rule is satisfied and important effects in DC and optical conductivity are obtained. In the pseudogap regime induced by antiferromagnetic correlations, the resistivity increases with vertex corrections. This effect is stronger on the hole-doped side where the system changes from metallic to insulating. This is opposite to what is observed when $t' = t'' = 0$. On the non-magnetic side of the QCP, the resistivity decreases with vertex corrections.

[1]NSERC (Canada), CRC (A.-M.T.), RQCHP and Compute Canada

5:06PM X25.00014 Exact nonequilibrium model for time-resolved photoemission spectroscopy of an electronic charge density wave insulator at zero temperature , WEN SHEN, JAMES FREERICKS, Georgetown University — We exactly solve the nonequilibrium problem of electrons moving in a lattice potential that corresponds to a checkerboard ordered charge density wave at zero temperature. The exact solution can be found in arbitrary dimensions by calculating a series of two-by-two evolution operators with the Trotter formula. We examine how the charge density wave responds to being excited into nonequilibrium by a large electric field femtosecond pulse. We find that the order parameter is rapidly reduced (but not to zero) and then rings with an oscillation frequency given by the potential scattering energy U. The density of states shows evidence of gap closing for short times, which then reforms for long times. We discuss the implications of the solution of this model for the nonequilibrium melting of charge density waves observed in recent experiments.

Thursday, March 24, 2011 2:30PM - 5:30PM –

Session X26 DMP DCOMP: Focus Session: Iron Based Superconductors – Fe(Se-Te) D162/164

2:30PM X26.00001 Evidence for local moment magnetism in superconducting $FeTe_{0.35}Se_{0.65}$, GUANGYONG XU, ZHIJUN XU, JINSHENG WEN, Brookhaven National Laboratory, SONGXUE CHI, NIST Center for Neutron Research, WEI KU, GENDA GU, JOHN TRANQUADA, Brookhaven National Laboratory — We investigate the temperature evolution (from 5 K to 300 K) of low energy spin fluctuations in Fe-based superconductor $FeTe_{0.35}Se_{0.65}$ ($T_c \sim 14$ K) via inelastic neutron scattering. The magnetic excitation spectrum in the superconducting phase appears qualitatively similar to those observed in other Fe-based superconductors, with a spin gap (at about 5 meV) and a resonance peak at $\hbar\omega \sim 6.5$ meV. At higher temperatures, the spectral weight of the low-temperature resonance is found to redistribute to lower energies below the spin gap. A significant moment ($\gtrsim 0.26\mu_B$/Fe) is found for the integrated spectral weight below merely $\hbar\omega \sim 12$ meV, with nearly no temperature dependence up to 300K, indicating existence of strong local moments.

2:42PM X26.00002 Low-energy magnetic excitations in the parent superconducting phases $Fe_{1+x}Te$ for $x = 0.07 - 0.18$, CHRIS STOCK, EFRAIN RODRIGUEZ, MARK GREEN, NIST Center for Neutron Research — We present inelastic neutron scattering measurements of the phases $Fe_{1+x}Te$ for varying amounts of interstitial iron in the lattice. The x in $Fe_{1+x}Te$ corresponds to interstitial iron located between the two-dimensional FeTe sheets, and the amount of x greatly affects the nature of the crystallographic transition and the magnetic ordering at lower temperatures in this system. The low energy spectrum of the magnetic excitations from 0.5 meV to 10 meV using the Multi-Axis Crystal Spectrometer (MACS) will be presented for both the incommensurate and commensurate phases. Neutron polarized diffraction experiments that detail the nature of the magnetic ordering will also be presented.

2:54PM X26.00003 Neutron Scattering Study of the Dependence of Magnetic Correlations on Se and Fe Content in the Fe(Te,Se) System , ZHIJUN XU, JINSHENG WEN, GUANGYONG XU, GENDA GU, JOHN TRANQUADA, Brookhaven National Laboratory — We have performed a series of neutron scattering and magnetization measurements on $Fe_{1+y}Te_{1-x}Se_x$ with different Fe and Se compositions to study the interplay between magnetism and superconductivity.[1] FeTeSe is rather unique for possessing two different types of spin configurations: one is a "bicollinear" or "E-type" structure that corresponds to the static order near (0.5,0), and the other is a "collinear" or "C-type" spin configuration that gives rise to spin excitations near (0.5,0.5). [2] Short-range static magnetic order near the (0.5,0) in-plane wave-vector (using the two-Fe unit cell) is found in all non-superconducting samples. The static order disappears and bulk superconductivity emerges, as the spectral weight of the magnetic excitations shift to the region of reciprocal space near the in-plane wave-vector (0.5,0.5) with Se doping. Besides Se doping, Fe also plays an essential role in superconductivity and the magnetic correlations. Our results suggest that spin fluctuations associated with the collinear magnetic structure appear to be universal in all Fe-based superconductors, and there is a strong correlation between superconductivity and the character of the magnetic order/fluctuations in this system. [1] Zhijun Xu *et al.*, Phys. Rev. **B** 82, 104525 (2010) [2] Wei-Guo Yin *et al.*, Phys. Rev. Lett. 105, 107004 (2010)

3:06PM X26.00004 Spin Excitations in Fe(Se,Te)[1] , MARK LUMSDEN, Oak Ridge National Laboratory — The full spectrum of magnetic excitations in both superconducting $FeTe_{0.51}Se_{0.49}$ (x=0.49) and non- superconducting $Fe_{1.04}Te_{0.73}Se_{0.27}$ (x=0.27) was studied using inelastic neutron scattering on single crystal samples. The magnetic excitations are two-dimensional in nature and are observed for energy transfers as high as 300 meV. The zero energy extrapolation of the measured dispersion shows incommensurate excitations emanating from a wavevector near (0.5,0.5), the location of the resonance in the superconducting material. For low energy transfers, the spectrum consists of a set of incommensurate spots, four-fold symmetric about the (1,0) (square lattice (π,π)) wavevector. At higher energies, these spots evolve into rings centered on Q=(1,0). These excitations are notably different than the cones of scattering expected from a long-range magnetically ordered material and likely reflect the itinerant nature of the magnetism. The qualitative evolution of the incommensurate excitation spectrum is similar that seen previously in the cuprates. Despite the incommensurate nature of the spectrum, the observed resonance in the x=0.49 sample remains peaked at the (0.5,0.5) wavevector as in other Fe-based superconductors. At low energies, the x=0.27 sample exhibits an additional feature in the excitation spectrum centered near Q=(0.5,0), the wavevector of magnetic order in $Fe_{1+y}Te$. This scattering persists for all energies below about 10 meV and forms the short range order observed for this concentration. This scattering is completely absent in the x=0.49 sample which contains no excess Fe.

3:42PM X26.00005 Chemical tuning of magnetism and superconductivity in Fe_{1+x}(Te,Se) , EFRAIN E. RODRIGUEZ, CHRIS STOCK, NIST Center for Neutron Research, NICHOLAS P. BUTCH, JOHNPIERRE PAGLIONE, Center for Nanophysics and Advanced Materials, U. of Maryland, MARK GREEN, NIST Center for Neutron Research — We present evidence demonstrating how the magnetism and superconductivity can be tuned for the phases $Fe_{1+x}Te$ and $Fe_{1+x}Te_{1+y}Se_{1+y}$. Through the use of iodine vapor as an oxidant, we can de-intercalate these materials to remove the interstitial iron, *i.e* the x in Fe_{1+x}(Te,Se). Our analysis of the neutron inelastic scattering indicates that paramagnetism from this interstitial iron is detrimental to superconducting properties, and magnetization measurements show that superconducting volume fraction is indeed increased as the amount of interstitial iron is removed. Diffraction results detailing changes in key structural parameters and magnetic ordering will also be presented.

3:54PM X26.00006 Local lattice dynamic correlation in $FeSe_xTe_{1-x}$, KEESEONG PARK, DESPINA LOUCA, University of Virginia, Charlottesville, Virginia 22904, USA., JON TAYLOR, ISIS Spallation Neutron Source, Rutherford Appleton Laboratory, Chilton, Didcot OX110QX, UK., JIAQIANG YAN, Division of Materials Science and Engineering, Ames Laboratory, Ames, IA 50011, USA. — With the use of inelastic neutron scattering, the local lattice dynamics were determined for the new Fe-based superconductors, $FeSe_xTe_{1-x}$ with x=0.1, 0.5 and 0.9. The nature of the dynamic pair correlations was characterized above and below the phase transitions. In the x=0.1 sample that is not superconducting(SC), the nearest Fe-Te and Fe-Fe pair correlations gradually disappear with increasing energy by 35 meV. The same energy dependence is observed above and below the magnetic transition. This energy corresponds to the cut-off frequency of the phonon vibrational modes. On the other hand, in the SC x=0.5 and 0.9, the Fe-Fe correlations gain weight just above the elastic, only to be quickly suppressed by 15 meV. This effect is stronger below the transition than above. The Fe-Te correlations that overlap with the Fe-Fe bonds persist in x=0.5 (possibly in x=0.9 as well but are too weak). On the other hand, the Fe-Se correlations persist beyond this energy, and eventually disappear by 30 meV. These differences in the local lattice dynamics between the non-SC and SC might provide a clue towards understanding the phonon contribution to the mechanism of superconductivity in this system.

4:06PM X26.00007 Magnetic field dependence of spin fluctuations in superconducting FeSe0.4Te0.6[1] , V. THAMPY, Institute of Quantum Matter, Dept. of Physics, Johns Hopkins Univ, Y. ZHAO, NIST Center for Neutron Reseach, W. BAO, Dept. of Physics, Renmin Univ. of China, Z. MAO, Dept. of Physics, Tulane Univ., J. RODRIGUEZ, NIST Center for Neutron Reseach, D. ARGYRIOU, Helmholtz-Zentrum Berlin für Materialen und Energy, Germany, A. SAVICI, G. GRANROTH, Oak Ridge National Lab, A. HIESS, Institut Max von Laue-Paul Langevin, France, C. BROHOLM, Institute of Quantum Matter, Dept. of Physics, Johns Hopkins Univ — Spin fluctuations may play a key role in metals where superconductivity appears as a magnetic phase is suppressed under pressure or with chemical substitution. The suppressed magnetism is manifested as a gap in the spin fluctuation spectrum and a spin resonance to which the spectral weight is shifted. We have studied the effect of high magnetic fields on this resonance. While fine structure is observed, these features do not shift with field and persist in zero field and in the normal state. Temperature difference spectra are however, significantly broadened in high fields.

[1]Work at JHU supported by DoE through DE-FG02-08ER46544.

4:18PM X26.00008 Neutron study of spin fluctuations in iron chalcogenide , SONGXUE CHI, Oak Ridge National Lab, TANER YILDIRIM, JEFFREY LYNN, NIST Center for Neutron Research, CHENGLIN ZHANG, University of Tennessee, Knoxville, JOSE RODRIGUES, NIST Center for Neutron Research, PENGCHENG DAI, University of Tennessee, Knoxville, DANIEL PHELAN, DEEPAK SINGH, RICK PAUL, NIST Center for Neutron Research — The incommensurate spin excitations in the nonsuperconducting $FeTe_{0.72}Se_{0.28}$ have been studied using both cold and thermal neutron spectroscopy. At low energies spectrum weight shifts from (1/2,0) commensurate excitations to the incommensurate quartets about the (1,0) point, which disperse outward before the inward dispersion at higher energies. The steep dispersion is disturbed in the energy range between 20 meV and 32 meV, resulting in abnormal excitations that are also observed in the superconducting $FeTe_{0.62}Se_{0.38}$. Polarized neutron measurements were carried out and the origin of these abnormal excitations is discussed.

4:30PM X26.00009 ARPES study of FeTe single crystal and $FeTeO_x$ films[1] , YUEFENG NIE, Department of Physics, University of Connecticut, Storrs, CT 06269, MARTIN MANSSON[2], YASMINE SASSA, CHRISTOF NIEDERMAYER, Laboratory for Neutron Scattering, ETH Zäurich and Paul Scherrer Institute, PSI, Switzerland, GENDA GU, Condensed Matter Physics and Materials Science, Brookhaven National Laboratory (BNL), Upton, NY 11973, JOSEPH BUDNICK, BARRETT WELLS, Department of Physics, University of Connecticut, Storrs, CT 06269 — We have performed an ARPES investigation of FeTe single crystals, films, as well as the novel superconducting film FeTeOx. Our results from the single crystals reflect the previously reported Fermi surface pocket around the X-point [(π,0)], possibly connected to a spin-density wave (SDW) order [Y. Xia, PRL 103, 037002 (2009)] . Unlike this previous report, our results also reveal the presence of an energy gap which would be expected from the SDW order. The temperature dependence shows that the gap closes in the rough vicinity of the magnetic transition temperature, supporting it's interpretation as reflecting the SDW state. We were able to produce an ARPES quality surface by cleaving films of FeTe and $FeTeO_x$, with the FeTe films showing similar features as the bulk.

4:42PM X26.00010 ARPES Study of the Phase Diagram of $Fe_{1+y}Te_{1-x}Se_x$, ZHONGKAI LIU, MING YI, Stanford University, YULIN CHEN, SLAC National Laboratory, RUIHUA HE, Stanford University, DONGHUI LU, ROB MOORE, SLAC National Laboratory, JIN HU, TIJIANG LIU, ZHIQIANG MAO, Tulane University, ZHI-XUN SHEN, Stanford University, STANFORD UNIVERSITY TEAM, SLAC NATIONAL LABORATORY COLLABORATION, TULANE UNIVERSITY COLLABORATION — Iron chalcogenide $Fe_{1+y}Te_{1-x}Se_x$ is a unique member among the iron-based superconductor family due to its simplicity in structure and richness in physics. The end member $Fe_{1+y}Te$ has an antiferromagnetic order with Neel temperature $\sim$72K. Substitution of Se for Te suppresses this long-range magnetic order and enters a "spin-glass" phase where (π,0) short-range magnetic order contributes to weak charge carrier localization. Superconductivity emerges by further substitution of Se and suppression of the short-range magnetic order. Here we present ARPES study on this system, providing evidence of the underlying physics in the phase diagram by analyzing electronic structure information. The comparison of iron chalcogenide and other iron-based systems help us identify the governing physics in this new family of superconductors.

4:54PM X26.00011 ARPES studies on $FeTe_{1-x}Se_x$ iron chalcogenides epitaxial thin films , DAVIDE INNOCENTI, Advanced Light Source and University of Rome "Tor Vergata", LUCA MORESCHINI, ALS, YOUNG JUN CHANG, ANDREW WALTER, ALS and Fritz-Haber-Institut, AARON BOSTWICK, ALS, DANIELE DI CASTRO, ANTONELLO TEBANO, PIER GIANNI MEDAGLIA, University of Rome "Tor Vergata", EMILIO BELLINGERI, ILARIA PALLECCHI, CARLO FERDEGHINI, CNR-SPIN Genova, GIUSEPPE BALESTRINO, University of Rome "Tor Vergata", ELI ROTENBERG, ALS — The physics of iron-based chalcogenides raises fundamental questions on the interplay of magnetic order and electron pairing at the origin of the superconducting state. We have performed angle-resolved photemission spectroscopy (ARPES) studies on high-quality epitaxial thin films of $FeTe_{1-x}Se_x$, grown by *in situ* pulsed laser deposition (PLD) on beamline 7.0.1 at the ALS. Specifically, we are able to show the evolution of the band structure as a function of x. We discuss our experimental results in comparison to the available theoretical band calculations.

5:06PM X26.00012 ARPES Studies on $FeTe_{1-x}Se_x$[1] , HONGBO YANG, ZHIHUI PAN, GENDA GU, PETER JOHNSON, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, MICHAEL WEINERT, Department of Physics, University of Wisconsin - Milwaukee — Angle-resolved Photoelctron Spectoscopy (ARPES) is used to study the electronic structure of Fe based superconductor, $FeTe_{1-x}Se_x$. Detailed comparisons are made between the measured Fermi surfaces and first principles FLAPW calculations. In particular we explore the origin of a Dirac like cone at the center of the Brillouin zone.

Session X27 GQI: Quantum Computing and Simulation II C155

2:30PM X27.00001 Analysis of quantum Monte Carlo dynamics for quantum adiabatic evolution in infinite-range spin systems[1] , JUN-ICHI INOUE, Hokkaido University — We analytically derive deterministic equations of order parameters such as spontaneous magnetization in infinite-range quantum spin systems obeying quantum Monte Carlo dynamics. By means of the Trotter decomposition, we consider the transition probability of Glauber-type dynamics of microscopic states for the corresponding classical system. Under the static approximation, differential equations with respect to macroscopic order parameters are explicitly obtained from the master equation that describes the microscopic-law. We discuss several possible applications of our approach to disordered spin systems for statistical-mechanical informatics. Especially, we argue the ground state searching for infinite-range random spin systems via quantum adiabatic evolution.

[1]We were financially supported by Grant-in-Aid for Scientific Research (C) of Japan Society for the Promotion of Science, No. 22500195.

2:42PM X27.00002 Ramsey numbers and adiabatic quantum computing , FRANK GAITAN, Laboratory for Physical Sciences, LANE CLARK, Southern Illinois University — The graph-theoretic Ramsey numbers are notoriously difficult to calculate. In fact, only nine Ramsey numbers are currently known, with knowledge of other Ramsey numbers limited to bounds on their possible value. We describe a quantum algorithm for the computation of Ramsey numbers. We show how the problem of computing a Ramsey number can be mapped to a combinatorial optimization problem whose solution can be found using adiabatic quantum evolution (AQE). We numerically simulate this adiabatic quantum algorithm and show that it correctly determines the Ramsey numbers R(3,3) and R(2,s) for s $\leq$ 6. We also discuss experimental implementation of an adiabatic quantum computation of R(3,3).

2:54PM X27.00003 Two-particle quantum walks applied to the graph isomorphism problem[1] , JOHN KING GAMBLE, MARK FRIESEN, DONG ZHOU, ROBERT JOYNT, S.N. COPPERSMITH, University of Wisconsin-Madison — We show that an algorithm based on the dynamics of interacting quantum particles is more powerful than the corresponding algorithm for non-interacting particles. Specifically, our algorithm attempts to determine whether two graphs are isomorphic. We focus on strongly regular graphs (SRGs), a class of graphs with particularly high symmetry. By studying the dynamical evolution of two-particle quantum walks on pairs of non-isomorphic SRG's, we show that interacting particles can distinguish non-isomorphic graphs that noninteracting particles cannot. First, we prove that quantum walks of two noninteracting particles cannot distinguish pairs of non-isomorphic SRG's. Next, we demonstrate numerically that two interacting bosons are more powerful, in that their quantum walks distinguish all non-isomorphic pairs of SRGs we tried, including those with up to 64 vertices. Finally, we find a set of operators that determine these evolutions.

3:06PM X27.00004 Quantum Walks on Trees with Disorder , STEVEN JACKSON[1], TENG JIAN KHOO[2], FREDERICK STRAUCH, Williams College — Quantum walks on trees have the potential for exponential speedup compared to classical algorithms. It has been argued that disorder may limit this potential, due to Anderson localization. We report on an extensive numerical analysis of quantum walks with disorder and find evidence of a localization transition for large disorder, but a quantum-to-classical transition for intermediate disorder. These results suggest that quantum walks may yet retain their speedup for high-dimensional graphs with weak disorder.

[2](now at Cambridge University)

3:18PM X27.00005 Numerical investigations of quantum walks with hard-core bosons and the graph isomorphism problem[1] , MARK WELLONS, JOHN GAMBLE, ERIC BACH, MARK FRIESEN, ROBERT JOYNT, KENNETH RUDINGER, DONG ZHOU, SUSAN COPPERSMITH, University of Wisconsin-Madison — Gamble et al. investigated quantum walks of two hard-core bosons on a class of highly symmetric graphs called strongly regular graphs (SRGs) and showed that these walks will distinguish nonisomorphic graphs from the same family. However, J. Smith (arXiv:1004.0206) has shown that pairs of nonisomorphic graphs exist that cannot be distinguished by such quantum walks. Here we construct explicit counterexample graph pairs for 2 and 3-particle interacting and non-interacting walks. We also describe an algorithm that, given k particles, generates two graphs indistinguishable by a k-boson quantum walk. We find that these indistinguishable graph pairs generated by our algorithm scale in size quadratically with the number of particles. It follows that distinguishing graphs via simulating quantum walks with classical computers will likely require exponential time in the size of the graph, while leaving open the possibility that a quantum computer could distinguish the graphs in polynomial time.

3:30PM X27.00006 Simulating Quantum Dynamics On A Quantum Computer , NATHAN WIEBE, University of Calgary, DOMINIC BERRY, IQC, PETER HOYER, BARRY SANDERS, University of Calgary — We develop an efficient quantum algorithm for simulating time-dependent Hamiltonian evolution of general input states on a quantum computer. Given conditions on the smoothness of the Hamiltonian, the complexity of the algorithm is close to linear in the evolution time, and therefore is comparable to algorithms for time-independent Hamiltonians. In addition, we show how the complexity can be reduced by optimizing the time steps. The complexity of the algorithm is quantified by calls to an oracle, which yields information about the Hamiltonian, and accounts for all computational resources. In contrast to previous work, which allowed an oracle query to yield an arbitrary number of bits or qubits, we assign a cost for each bit or qubit accessed. This per-bit or per-qubit costing of oracle calls reveals hitherto unnoticed simulation costs. We also account for discretization errors in the time and the representation of the Hamiltonian. We generalize the requirement of sparse Hamiltonians to being a sum of sparse Hamiltonians in various bases for which the transformation to a sparse Hamiltonian may be performed efficiently.

3:42PM X27.00007 Preparing Ground States of Many-Body Systems by Simulated Cooling , DVIR KAFRI, University of Maryland, College Park, Department of Physics, JACOB TAYLOR, University of Maryland, College Park, Department of Physics; National Institute of Standards and Technology, Gaithersburg, MD — Computational problems, such as satisfiability, can be rephrased in terms of the preparation of the ground state of a many-body Hamiltonian. More generally, a quantum simulator could provide information on many-body systems if the ground state can be appropriately prepared. Adiabatic preparation is a common technique for obtaining the ground state of a quantum mechanical system, by slowly varying the system Hamiltonian. A principle disadvantage is that its timing scales with the gap energy of the intermediate Hamiltonian, for which a gap may not be promised, rather than the final Hamiltonian which may be known to be gapped. We present an alternative approach, in which an arbitrary system of qubits is cooled to an effective many-body ground state, through the algorithmic interaction with a small number of "bath" qubits. We specify bounds for the parameters of the algorithm, show that cooling time scales with the system's gap, and present simulated results on a frustrated few-spin system. We further discuss possible experimental applications.

3:54PM X27.00008 An Open-System Quantum Simulator with Trapped Ions , JULIO T. BARREIRO, MARKUS MUELLER, PHILIPP SCHINDLER, DANIEL NIGG, THOMAS MONZ, MICHAEL CHWALLA, MARKUS HENNRICH, CHRISTIAN F. ROOS, PETER ZOLLER, Universitaet Innsbruck, RAINER BLATT — The control of quantum systems is of fundamental scientific interest and promises powerful applications and technologies. Impressive progress has been achieved in isolating the systems from the environment and coherently controlling their dynamics, as demonstrated by the creation and manipulation of entanglement in various physical systems. However, for open quantum systems, engineering the dynamics of many particles by a controlled coupling to an environment remains largely unexplored. Here we report the first realization of a toolbox for simulating an open quantum system with up to five qubits. Using a quantum computing architecture with trapped ions, we combine multi-qubit gates with optical pumping to implement coherent operations and dissipative processes. We illustrate this engineering by the dissipative preparation of entangled states, the simulation of coherent many-body spin interactions and the quantum non-demolition measurement of multi-qubit observables. By adding controlled dissipation to coherent operations, this work offers novel prospects for open-system quantum simulation and computation.

4:06PM X27.00009 Discrete quantum walk on a binary tree , ZLATKO DIMCOVIC, IAN MILLIGAN, DAN ROCKWELL, ROBERT M. BURTON, THINH NGUYEN, YEVGENIY KOVCHEGOV, Oregon State University — We have recently constructed a framework for quantum walks, based on classical walks with memory. This framework reproduces known walks, while it can be used to build walks in systems that are difficult for current approaches. As our first example of its utility, we study a symmetric discrete quantum walk on the infinite binary tree. For a walk starting from a pure state at a given level in the tree, we compute the amplitude at the root, as a function of time and starting level. The result is strikingly different from the classical case, as its amplitude spans an order of magnitude, with a power law tail, while the classical one decays exponentially. (For example, for a delayed walk this property yields a polynomial vs. exponential speed up over the classical walk, in delay time.) The breadth of the probability peak indicates that any restriction of the extent of the tree, such as a matching tree, sinks or boundaries, would likely yield algorithms superior to classical. The calculation utilizes a variety of analytical techniques (memoried stochastic processes, combinatorics and path counting, transforms, steepest descent, orthogonal polynomials). This study also brings up interesting general questions about quantum processes on such structures.

4:18PM X27.00010 Quantum Random Walks of Non-Interacting Bosons on Strongly Regular Graphs[1] , KENNETH RUDINGER, JOHN KING GAMBLE, MARK WELLONS, MARK FRIESEN, DONG ZHOU, ERIC BACH, ROBERT JOYNT, S.N. COPPERSMITH, University of Wisconsin- Madison — We investigate the quantum dynamics of particles on graphs ("quantum walks"), with the aim of developing quantum algorithms for determining if two graphs are isomorphic and show that there are fundamental differences between the distinguishing power of two-particle and three-particle non-interacting quantum walks. We investigate quantum walks on strongly regular graphs (SRGs), a class of graphs with high symmetry. We show analytically that the two-particle walk always fails to distinguish non-isomorphic members of the same SRG family. We show numerically that the three-boson walk is able to distinguish 99.6% of 70,712 SRG comparisons made and that this distinguishing power comes from different multiplicities of certain graph substructures in non-isomorphic graphs. We identify certain distinguishing substructures and examine ones that appear in the four-boson walk, discovering they are able to distinguish almost all of the graphs that the three-boson walk failed on. This indicates a positive correlation between number of bosons in the walk and distinguishing power.

4:30PM X27.00011 Real-time Simulations of Quantum Spin $\frac{1}{2}$ Particles Coupled to Multiple Spin Baths , MARTA L. GUERRA, M.A. NOVOTNY, Mississippi State University, HANS DE RAEDT, University Groningen — We present simulations in real time for one and two spin $\frac{1}{2}$ particles coupled to one or more baths of $\frac{1}{2}$-integer quantum spins. The simulations were performed using the algorithm and code of Prof. De Raedt [1,2]. We first simulated one spin coupled to one or two spin-baths with no interactions between the bath spins, as has been calculated theoretically [3]. We find in agreement with [3], that the quantum purity $\mathcal{P}(t)$ decays in both cases, exponentially for a single bath and algebraically for two baths. We extend these simulations by introducing random interactions between the bath spins in an attempt to reach the asymptotic decay rate at earlier times and for fewer spins in the baths. We also have performed similar studies for two spin $\frac{1}{2}$ quantum particles coupled to one, two, or more spin baths. The time- dependent quantum density matrix and $\mathcal{P}(t)$, as well as other quantities, are calculated in these simulations.

4:42PM X27.00012 Effects of Decoherence in Quantum Simulations , NAYELI ZUNIGA-HANSEN, MARK S. BYRD, YU-CHIEH CHI — We investigate the effects of decoherence in quantum simulations by observing the evolution of the system when the Quantum Information Processor is coupled to the environment. We simulate the noise as the interactions between the particles of the processor itself and observe the effects of varying the strength of the couplings. We perform these calculations for different quantum systems and compare the results of those that interact with the environment to the same system when it's completely isolated from it to observe the effects of the noise on the simulation and investigate ways to prevent the adverse effects of the noise.

4:54PM X27.00013 Computational codes for simulating the Schrödinger equation and the Master equation[1] , NAGENDRA DHAKAL, MICHAEL LEUENBERGER, University of Central Florida — We developed new codes for simulating the Schrödinger equation. We compared the codes with the FDTD codes and codes based on Quantum Monte Carlo method in 1, 2 and 3 dimensions. In addition, we simulated the Master equation for the purpose of studying the spatial and time evolution of the decoherence. Our main focus is to investigate the scalability of the codes and we found the Quantum Monte Carlo method is the most suitable for the simulation of the Master equation because it reduces the dimension of the problem to the dimension of Hilbert space, with the benefits of speeding up the process of calculation and at the same time reducing the memory. Our results are important for the implementation of quantum computing, quantum communication, and spintronics.

[1]We acknowledge support from NSF Grant No. ECCS-0901784 and AFOSR Grant No. FA9550-09-1-0450.

5:06PM X27.00014 Experimental photonic quantum simulation of frustrated Heisenberg spins , PHILIP WALTHER, University of Vienna, XIAO-SONG MA, Austrian Academy of Sciences, BORIVOJE DAKIC, University of VIenna, WILLIAM NAYLOR, ANTON ZEILINGER, Austrian Academy of Sciences — Quantum simulators are controllable quantum systems that can reproduce the dynamics of the system of interest, which are typically unfeasible for classical computers. The recent developments of quantum technology enable the precise control of individual quantum particles as required for studying complex quantum systems. In particular, quantum simulators capable of simulating frustrated Heisenberg spin systems provide a platform for understanding exotic matter such as high-temperature superconductors. Here we report the analog quantum simulation of arbitrary Heisenberg-type interactions among four spin-1/2 particles. This spin-1/2 tetramer is the two-dimensional archetype system whose ground state belongs to the class of valence-bond states. Depending on the interaction strength, frustration within the system emerges such that the ground state evolves from a localized to a resonating valence-bond state. This spin-1/2 tetramer is created using the polarization states of four photons. The precise single-particle addressability and a tunable measurement-induced interaction allows us to obtain fundamental insights into entanglement dynamics among individual particles by observing the frustration of entanglement, governed by quantum monogamy.

5:18PM X27.00015 A realistic topological quantum computation platform using hole-doped semiconductor nanowires and s-wave superconductors , MING GONG, LI MAO, Department of Physics and Astronomy, Washington State University, Pullman, Washington, 99164 USA, SUMANTA TEWARI, Department of Physics and Astronomy, Clemson University, Clemson, South Carolina, 29634, USA, CHUANWEI ZHANG, Department of Physics and Astronomy, Washington State University, Pullman, Washington, 99164 USA, ZHANG TEAM, TEWARI TEAM — We show that two majorana fermions exist at the two ends of a hole-doped semiconductor nanowire that is in proximity contact with an s-wave superconductor. The required experimental parameters (carrier density, g-factor, spin-orbit coupling effect, magnetic field, etc.) for the observation of the Majorana fermions are within the experimentally reachable regime of InSb and InAs nanowires and the mini gap that provides the topological protection for the Majorana zero energy states is of the order of the s-wave superconducting gap. The Majorana zero energy states can be observed through the zero bias peak in the STM signal. The Josephson effects between two nanowire are studied. The proposed model provides a realistic experimental platform for observing non-Abelian statistics and performing topological quantum computation. This work is supported by DARP-MTO (FA955-10-1-0497), and DARPA-YFA (N66001-10-1-4025).

Thursday, March 24, 2011 2:30PM - 5:30PM –

Session X28 DCMP: Carbon Nanotubes and Related Materials: Theoretical and Computational Studies C156

2:30PM X28.00001 Electron-phonon renormalization of the electronic structure of diamond , FELICIANO GIUSTINO, Department of Materials, University of Oxford, STEVEN G. LOUIE, MARVIN L. COHEN, University of California at Berkeley and Lawrence Berkeley National Laboratory — The calculation of band structures from first-principles has reached a high level of accuracy. Calculations combining density-functional theory with many-body perturbation theory often are in good agreement with measurements by photoemission, tunneling, and other spectroscopic probes. While significant efforts have been devoted to improving the description of electron-electron interactions in these calculations, the effect of lattice vibrations has largely been overlooked so far. In this work we study from first principles the electron-phonon renormalization of the band gap of diamond. The calculated temperature dependence of the gap and the broadening of the absorption edge are in excellent agreement with spectroscopic ellipsometry data. Interestingly we find a gap renormalization due to zero-point vibrations as large as 0.6 eV. We discuss the implications of our findings for the electronic structure of other carbon-based bulk materials and nanostructures.

2:42PM X28.00002 Intrinsic Twisting and Electronic Properties of Carbon Nanotubes : A First-Principles Study , KOICHIRO KATO, TAKASHI KORETSUNE, SUSUMU SAITO, Department of Physics, Tokyo Institute of Technology — We report the energetics and electronic structures of twisted single-walled CNTs in the framework of the density functional theory (DFT) with the local density approximation. As for very thin CNTs, we use conventional plane-wave DFT computational code. In order to utilize the periodic boundary condition implemented in the plane-wave DFT code, we study CNTs under several discretized twisting conditions. On the other hand, in the case of thicker nanotubes including experimentally abundant nanotube sizes, we use a real-space DFT computational code which can deal with twisted CNTs with only two atoms per "helical" unit cell. As a result, it is found that chiral CNTs become more stable in slightly twisted geometry. Our results suggest that chiral nanotubes would possess the intrinsic twisting. We also report the twisting-level dependence of the electronic structures. It is found that the fundamental gaps of most kinds of CNTs sensitively depend on twisting level. Importantly, the directions of the intrinsic twisting are the same as the directions of enlarging the fundamental gap except for very thin CNTs.

2:54PM X28.00003 Excitonic Hierarchies in Gapped Carbon Nanotubes , ROBERT KONIK, Brookhaven National Lab — We present evidence that the strong electron-electron interactions in gapped carbon nanotubes lead to a hierarchy of excitons within a given nanotube subband. We study these hierarchies by employing a field theoretic reduction of the gapped carbon nanotube permitting electron-electron interactions to be treated exactly. We analyze this reduction by employing a Wilsonian-like numerical renormalization group. We are so able to determine the gap ratios of the one-photon excitons as a function of the effective strength of interactions. We also determine within the same subband the gaps of the two-photon excitons, the single particle gaps, as well as a subset of the dark excitons. The strong electron-electron interactions in addition lead to strongly renormalized dispersion relations where the consequences of spin-charge separation can be readily observed.

3:06PM X28.00004 Biexcitonic Non-Linearities in Semiconducting Carbon Nanotubes[1] , TOROS TOROSYAN, IGOR BONDAREV, North Carolina Central University — We obtained an analytical expression for the biexciton binding energy as a function of the inter-exciton distance and binding energy of constituent quasi-one-dimensional excitons in single-wall semiconducting carbon nanotubes. This allows one to trace biexciton energy variation and relevant non-linear absorption under external conditions whereby the exciton binding energy varies. In particular, we show the biexciton-plasmon coupling tunability by means of the quantum confined Stark effect, both for the ground-ground state and for the ground-excited state biexcitonic configurations. The non-linear absorption lineshapes calculated exhibit characteristic asymmetric Rabi splitting as the exciton energy is tuned to the nearest interband plasmon resonance. These results are useful for tunable optoelectronic device applications of optically excited semiconducting carbon nanotubes, including the strong excitation regime with optical non-linearities.

[1]NSF (ECCS-1045661, HRD-0833184), NASA (NNX09AV07A), and ARO (W911NF-10-1-0105) support acknowledged.

3:18PM X28.00005 Spin manipulation in carbon nanotubes: All electrical spin filtering through spin-orbit interactions[1] , G. S. DINIZ, Ohio University, Athens-OH - USA, A. LATGÉ, Instituto de Fisica, Universidade Federal Fluminense, Niteroi - Brazil, S. E. ULLOA, Ohio University, Athens-OH - USA — Carbon nanotubes (CNTs) are known to exhibit interesting physical properties, such as metallic or insulating behavior for different chiral vectors. Application of external electric fields and the presence of spin-orbit interaction (SOI) result in modification of the energy level structure of CNTs and their conductance profiles. SOI couples spin and orbital degrees of freedom in these nanostructures, and we explore this effect in this work. We present calculations of the electronic transport of different single-wall CNTs in the presence of SOI. Our calculation uses a single-orbital tight-binding Hamiltonian representation and the equilibrium surface Green's function formalism [1] to calculate electronic transport. We consider the effects of both Rashba and intrinsic SOIs. Our results show possible implementations of carbon nanotubes as spin filtering devices for spatially asymmetric electric fields. We further discuss the spin polarization for different CNT size, chirality, field strength, and the spatially varying fields induced by the adsorption of DNA on their surface.

3:30PM X28.00006 Substantial reduction of thermal conductivity of defected carbon nanotubes , CEM SEVIK, Artie McFerrin Dept of Chemical Engineering, Laboratory of Computational Engineering of Nanomaterials Texas A&M University, College Station, TX , HALDUN SEVINCLI, Institute for Materials Science and Max Bergmann Center of Biomaterials, Dresden University of Technology, 01062 Dresden, Germany, JUSTIN B. HASKIN, ALPER KINACI, Artie McFerrin Dept of Chemical Engineering, Laboratory of Computational Engineering of Nanomaterials Texas A&M University, College Station, TX , GIANAURELIO CUNIBERTI, Institute for Materials Science and Max Bergmann Center of Biomaterials, Dresden University of Technology, 01062 Dresden, Germany, TAHIR CAGIN, Artie McFerrin Dept of Chemical Engineering, Laboratory of Computational Engineering of Nanomaterials Texas A&M University, College Station, TX , TEXAS A&M UNIVERSITY TEAM, DRESDEN UNIVERSITY OF TECHNOLOGY TEAM — The influence of the structural details and defects on the thermal transport properties of carbon nanotubes (CNTs) are explored by molecular dynamics and real-space Kubo methodologies. A variety of randomly oriented and distributed defects, (mono- and di-vacancies, Stone Wales defects) on lattice thermal conductivity and anharmonic phonon mean free paths are studied for model systems in sizes up to 1000 nm. Substantial reduction in thermal conductivity, up to $\sim$80% reduction compared to the pristine CNTs, is observed for $\sim$0.5\% defect concentrations. Additionally, nearly the same saturation value of lattice thermal conductivity for CNTs with different type of defects is predicted.

3:42PM X28.00007 All About Chlorinated Carbon Nanotubes[1] , DOGAN ERBAHAR, SAVAS BERBER, Gebze Institute of Technology — The halogens are viable alternatives to harsher chemicals in the post-process of purification of carbon nanotube production. However the chlorine is known to bind less agresively to carbon nanotubes than fluorine and hydrogen. Therefore, in principle the residual Cl left after the halogen gas treatment of the nanotubes can be removed without damaging the nanotube walls easier. We report ab initio density functional calculation results about pure and defective carbon nanotubes of various diameters interacting with single and multiple chlorine atoms. We first focus on pure nanotubes and investigate the adsorption of additional Cl atoms near the first adsorbtion site, investigate the clustering tendency and most favourable configurations. We report the energetics results as well as the alteration of electronic properties. We then focus on monovacancy and divacancy defects on carbon nanotubes. It is a known fact that the defective site to be more active in this case. We apply the same procedure as in the pure nanotubes but also investigate the effect of chlorination on reconstruction process and also electronic transport properties.

3:54PM X28.00008 The origins of nanotube chirality: Is the edge-catalyst in control? , EVGENI PENEV, YUANYUE LIU, BORIS YAKOBSON, Rice University — The chance for a nanotube of a chiral angle c to emerge from the "primordial soup" of carbon atoms on the catalyst is determined by their relative energies. Massive computations allow one to evaluate the "elastic" energies of the caps, and the energies of their edges [1], G(c+C), which appears to be dominating. Importantly, the latter contains a "chemical phase shift" C, so that the probability of different chiralities is determined by the chemical conditions at the edge. Preference for specific chirality can be achieved by tuning chemical potential of edge terminating chemical. This offers a rational way to control the tube chiral symmetry, a tantalizing yet so far elusive goal.

4:06PM X28.00009 Laser-Shot-Induced Chemical Reactions inside Nanotubes: a TDDFT investigation , HONG ZHANG, Sichuan University, China, YOSHIYUKI MIYAMOTO, NEC, Japan, ANGEL RUBIO, University of the Basque Country, Spain — We present the application of the time-dependent density functional theory (TDDFT) on ultrafast laser pulse which induces dynamics in molecules encapsulated by a nanotube. A strong laser pulse polarized perpendicular to the tube axis induces a giant bond-stretch of an HCl molecule inside both C and BN nanotubes. Depending on the initial orientation of the HCl molecule, the subsequent laser-induced dynamics is different [1]. We also observed a radial motion of the nanotube and vacancies appear on the tube wall when the HCl is perpendicular to tube axis. Furthermore, the disintegration of HCl molecules took place when their molecular axis tilted to tube axis. These simulations are important to analyze light-induced nanochemistry and manipulation of nanostructures encapsulated in organic and inorganic nanotubes. The computational scheme used in present work was a combination of the molecular dynamics and real-time propagation of electron wave functions under presence of strong optical field [2,3]. The energy conservation rule was checked to monitor the numerical stability. [1] Y. Miyamoto, H. Zhang, and A, Rubio, submitted., [2] O. Sugino and Y. Miyamoto, Phys. Rev. B59, 2579 (1999). [3] A. Castro, E. Rasanen, A. Rubio and E. K. U. Gross, Eur. Phys. Lett. 87, 53001 (2009).

4:18PM X28.00010 Ab initio study of the dependence of the reactivity upon carbon nanotube diameter , JONATHAN LAFLAMME JANSSEN, JASON BEAUDIN, MICHEL CÔTÉ, Département de physique, Université de Montréal, Canada, NICHOLAS D.M. HINE, PETER D. HAYNES, Imperial College, London, United Kingdom — One of the main research efforts of the recent years has been the development of an efficient way to select desired carbon nanotubes according to their size and their electronic properties. This selectivity would allow easier fabrication of field effect transistor and light-emitting diode devices with appropriate nanotubes. An appealing approach to assess this problem is to use the dependence of chemical functionalization thermodynamics on the material's properties. In this talk, ab initio studies of carbon nanotubes functionalized with bromophenyl will be presented. The radius dependence of the binding and activation energies of this functionalization will be reported. The purpose of this presentation is also to demonstrate the performance of linear-scaling density-functional theory code ONETEP, which provides the possibility carrying out large system simulations (up to several tens of thousands of atoms). Furthermore, the diameter dependence of the oxidation of carbon nanotubes by carbon dioxide will be presented.

4:30PM X28.00011 Electric field response on hybrid C/BN nanostructures , MIGUEL ALONSO-PRUNEDA, CIN2 (CSIC) — Synthesis of hybrid C/BN nanotubes [1] and nanosheets [2] offer a unique route for material engineering, by combination of the exciting properties of graphene with those of insulating polar BN. First principles (DFT) calculations of the zigzag-terminated edges between C and BN nanodomains will be presented, proving that unconventional physical effects similar to those observed at insulating oxide interfaces [3], can also exist in lower dimensions, opening alternative routes for tuning electronic properties at nanointerfaces. In particular, it will be shown that the magnetic character of the edge states in zigzag shaped graphene nanoribbons, and the polar BN edge, team up to give a spin asymmetric screening that induces half-semimetallicity at the interface [4]. This property is also observed in tubular geometries, where potential magnetoelectric effects will be discussed.

4:42PM X28.00012 Study of Singlet-Triplet Gaps in π-Conjugated Polymers versus Graphene Nanoribbons and Single-Walled Carbon Nanotubes. The Effect of Dimensionality[1] , KARAN ARYANPOUR, SUMIT MAZUMDAR, Department of Physics, University of Arizona, HONGBO ZHAO, School of Physics and Telecommunication Engineering, South China Normal University — We compute and compare the gap between the optical singlet and lowest triplet excitons in poly (para-phenylenevinylene) (PPV) with semiconducting graphene nanoribbons (GNRs) and single-walled carbon nanotubes (SWCNTs) within Coulomb correlated model Hamiltonian. The singlet-triplet gaps in semiconducting GNRs and SWCNTs are more than one order of magnitude smaller that in PPV. We ascribe this to two-dimensionality. Spatial distribution of the electron-hole separation in excitons reveals significant localization of the triplet state wave function compared to singlet state in PPV. In GNRs and SWCNTs however, singlet and triplet wave functions exhibit comparably extended spatial distributions. Singlet-triplet gap size is an indicator of the effective Coulomb interaction strength which in turn controls the exciton binding energies of these systems. Exciton binding energy plays a deciding role in light emission and device performance in photovoltaics.

4:54PM X28.00013 Carbon-Based Zero-Bandgap Tunnel Transistors[1] , YOUNGKI YOON, SAYEEF SALAHUDDIN, University of California, Berkeley — Tunnel field-effect transistors (TFET) have been proposed as a means of breaking the classical limit of voltage requirement and energy dissipation in electronic devices. However, a tunnel barrier severely reduces the current and hence the speed at which the transistor can be operated. In this work, by performing an atomistic quantum simulation, we propose a novel transistor involving a unique interface between a graphene nanoribbon (GNR) and a metallic carbon nanotube (CNT), such that (i) at low voltages it acts exactly like a tunnel transistor reducing voltage requirement below the classical limit and (ii) at a larger voltage the tunnel barrier is dramatically diminished, resulting in a large flow of current [Appl. Phys. Lett. **97**, 033102 (2010)]. Indeed, experimental fabrication of such an interface could be possible using recently demonstrated methods where carbon nanotubes are unzipped to open up narrow graphene ribbons. Our results show that orders of magnitude improvement in ON current can be obtained in this structure.

5:06PM X28.00014 Josephson current in carbon nanotube quantum dots , RAMON AGUADO, CSIC, JONG SOO LIM, ROSA LOPEZ, Universitat de les Illes Balears, Spain, MAHN-SOO CHOI, Korea University — We study theoretically the Josephson current through a carbon nanotube quantum dot coupled to superconducting leads. Due to the interplay between the curvature-induced spin-orbit effect and external magnetic fields, we find a rich $0-\pi$ phase diagram in various transport regimes ranging from noninteracting to Coulomb Blockade, cotunneling and the Kondo limit.

5:18PM X28.00015 Kinetics of Gas Adsorption in Nanopores: A Computer Simulation Study , CHRISTOPHER E. PUEBLO, Southern Illinois University Carbondale, M. MERCEDES CALBI, University of Denver — Motivated by a variety of experimental results concerning gas adsorption in open-ended carbon nanotubes, we present a series of results for the kinetics of adsorption of a gas inside a nanopore. The study is based on a Kinetic Monte Carlo simulation in combination with a lattice model of adsorption. This allows us to monitor the change in coverage with time and extract corresponding adsorption rates or equilibration times. Adsorption in nanopores presents several distinctive features when compared to open surfaces. The adsorption process is mainly controlled by the energy states close to the ends of the pore; we analyze the consequences of this effect on the equilibration times of the system and also on temperature programmed desorption spectra.

Session X29 GQI: Focus Session: Quantum Information for Quantum Foundations - Information Measures, Entanglement, and Entropies C148

2:30PM X29.00001 ABSTRACT WITHDRAWN –

2:42PM X29.00002 Uncertainty Relation for Smooth Entropies

, MARCO TOMAMICHEL, RENATO RENNER, ETH Zurich — Uncertainty relations give upper bounds on the accuracy by which the outcomes of two incompatible measurements can be predicted. While the established uncertainty relations apply to cases where the predictions are based on purely classical data (e.g., a description of the system's state before the measurement), an extended relation which remains valid in the presence of quantum information has been proposed recently [Berta et al., Nature Physics 6, 659 (2010)]. Here we generalize this uncertainty relation to one formulated in terms of smooth entropies. Since these entropy measures are related to operational quantities, our uncertainty relation has various applications. As an example, we show that it directly implies security of quantum key distribution protocols.

2:54PM X29.00003 Inadequacy of von Neumann entropy for characterising extractable work

, OSCAR DAHLSTEN, Singapore Centre for Quantum Technology, National University of Singapore, and Clarendon Laboratory, University of Oxford, RENATO RENNER, ETH Zurich, ELISABETH RIEPER, Singapore Centre for Quantum Technology, National University of Singapore, VLATKO VEDRAL, Singapore Centre for Quantum Technology, National University of Singapore, and Clarendon Laboratory, University of Oxford — The lack of knowledge an observer has about a system limits the amount of work it can extract. This lack of knowledge is normally quantified using the Shannon/von Neumann entropy. We show that this standard approach is, surprisingly, only correct in very specific circumstances. In general one should use the recently developed smooth entropy approach. For many common physical situations, including large but internally correlated systems, the resulting values for the extractable work can deviate arbitrarily from those suggested by the standard approach. (For details see arXiv:0908.0424)

3:06PM X29.00004 Interpreting quantum discord through quantum state merging[1]

, VAIBHAV MADHOK, University of New Mexico, ANIMESH DATTA, Clarendon Laborartory, University of Oxford — We present an operational interpretation of quantum discord based on the quantum state merging protocol. Quantum discord is the markup in the cost of quantum communication in the process of quantum state merging, if one discards relevant prior information. Our interpretation has an intuitive explanation based on the strong subadditivity of von Neumann entropy. We use our result to provide operational interpretations of other quantities like the local purity and quantum deficit. Finally, we discuss in brief some instances where our interpretation is valid in the single copy scenario.

[1]NSF Grant Nos. 0903953 and 0903692

3:18PM X29.00005 The thermodynamic meaning of negative entropy

, LIDIA DEL RIO, RENATO RENNER, JOHAN AABERG, ETH Zurich, OSCAR DAHLSTEN, VLATKO VEDRAL, entre for Quantum Technologies, National University of Singapore — Landauer's erasure principle states that all irreversible operations, like the erasure of data stored in a system, have an inherent work cost. This work cost depends on our knowledge of the system: the less we know about its state, the more it costs to erase it. Here, we analyse erasure in a general setting, where our information about a system can be quantum mechanical. We show that the work cost of erasure is bounded by the entropy of the system conditioned on that quantum information. Our result implies that conditional entropies, originally introduced in the context of information theory, have a direct thermodynamic significance. Since these entropies can become negative, a particular consequence is that an observer who is strongly correlated to a system may gain work while erasing it.

3:30PM X29.00006 Operational interpretations of quantum discord[1]

, MARCO PIANI, University of Waterloo, DANIEL CAVALCANTI, National University of Singapore, LEANDRO AOLITA, ICFO-Institut de Ciencies Fotoniques, SERGIO BOIXO, California Institute of Technology, KAVAN MODI, National University of Singapore, ANDREAS WINTER, University of Bristol — Quantum discord quantifies non-classical correlations going beyond the standard classification of quantum states into entangled and unentangled ones. Although it has received considerable attention, it still lacks any precise interpretation in terms of some protocol in which quantum features are relevant. Here we give quantum discord its first information-theoretic operational meaning in terms of entanglement consumption in an *extended quantum state merging* protocol. We further relate the asymmetry of quantum discord with the performance imbalance in quantum state merging and dense coding.

3:42PM X29.00007 Measures of non classical correlations

, MATTHIAS LANG, Center for Quantum Information and Control, University of New Mexico, ANIL SHAJI, School of Physics, Indian Institute of Science Education and Research, CARLTON CAVES, Center for Quantum Information and Control, University of New Mexico — To quantify non classical correlations in a quantum state, much effort has been put into the investigation of entanglement and its properties. It is known, however, that entanglement does not capture all quantum correlations. Several entropic measures of non-classical correlations beyond entanglement have been proposed, quantum discord being the most popular amongst them. We have developed an entropic framework for formulating such measures. We discuss new measures that emerge from this framework, and relations among the various measures, and we present numerical results for the measures for two-qubit states.

3:54PM X29.00008 Redundant imprinting of information in non-ideal environments: Quantum Darwinism via a noisy channel[1]

, MICHAEL ZWOLAK[2], Los Alamos National Laboratory, HAITAO QUAN, University of Maryland, College Park, WOJCIECH ZUREK, Los Alamos National Laboratory — Quantum Darwinism provides an information-theoretic framework for the emergence of the classical world from the quantum substrate. It recognizes that we - the observers - acquire our information about the "systems of interest" indirectly from their imprints on the environment. Objectivity, a key property of the classical world, arises via the proliferation of redundant information into the environment where many observers can then intercept it and independently determine the state of the system. While causing a system to decohere, environments that remain nearly invariant under the Hamiltonian dynamics, such as very mixed states, have a diminished ability to transmit information about the system, yet can still acquire redundant information about the system [1,2]. Our results show that Quantum Darwinism is robust with respect to non-ideal initial states of the environment.

4:06PM X29.00009 Quantum Darwinism in an Everyday Environment: Huge Redundancy in Scattered Photons[1] , CHARLES RIEDEL, University of California, Santa Barbara, WOJCIECH ZUREK, Los Alamos National Laboratory — We study quantum Darwinism—the redundant recording of information about the preferred states of a decohering system by its environment—for an object illuminated by a blackbody. In the cases of point-source, small disk, and isotropic illumination, we calculate the quantum mutual information between the object and its photon environment. We demonstrate that this realistic model exhibits fast and extensive proliferation of information about the object into the environment and results in redundancies orders of magnitude larger than the exactly soluble models considered to date. We also demonstrate a reduced ability to create records as initial environmental mixedness increases, in agreement with previous studies.

[1]This research is supported by the U.S. Department of Energy through the LANL/LDRD program and, in part, by the Foundational Questions Institute (FQXi).

4:18PM X29.00010 Quantum systems as embarrassed colleagues: what do tax evasion and state tomography have in common? , CHRIS FERRIE, Institute for Quantum Computing, University of Waterloo, ROBIN BLUME-KOHOUT, Theoretical Division, Los Alamos National Laboratory — Quantum state estimation (a.k.a. "tomography") plays a key role in designing quantum information processors. As a problem, it resembles probability estimation – e.g. for classical coins or dice – but with some subtle and important discrepancies. We demonstrate an improved classical analogue that captures many of these differences: the "noisy coin." Observations on noisy coins are unreliable – much like soliciting sensitive information such as ones tax preparation habits. So, like a quantum system, it cannot be sampled directly. Unlike standard coins or dice, whose worst-case estimation *risk* scales as $1/N$ for all states, noisy coins (and quantum states) have a worst-case risk that scales as $1/\sqrt{N}$ and is overwhelmingly dominated by nearly-pure states. The resulting optimal estimation strategies for noisy coins are surprising and counterintuitive. We demonstrate some important consequences for quantum state estimation – in particular, that adaptive tomography can recover the $1/N$ risk scaling of classical probability estimation.

4:30PM X29.00011 Quantum networks reveal quantum nonlocality , DANIEL CAVALCANTI, CQT-Centre for Quantum Technologies, MAFALDA ALMEIDA, VALERIO SCARANI, ANTONIO ACIN, CQT-ICFO COLLABORATION — The results of local measurements on some composite quantum systems cannot be reproduced classically. This impossibility, known as quantum nonlocality, represents a milestone in the foundations of quantum theory. Quantum nonlocality is also a valuable resource for information processing tasks, e.g. quantum communication, quantum key distribution, quantum state estimation, or randomness extraction. Still, deciding if a quantum state is nonlocal remains a challenging problem. Here we introduce a novel approach to this question: we study the nonlocal properties of quantum states when distributed and measured in networks. Using our framework, we show how any one-way entanglement distillable state leads to nonlocal correlations. Then, we prove that nonlocality is a non-additive resource, which can be activated. There exist states, local at the single-copy level, that become nonlocal when taking several copies of it. Our results imply that the nonlocality of quantum states strongly depends on the measurement context.

4:42PM X29.00012 A generalization of Noether's theorem and the information-theoretic approach to the study of symmetric dynamics[1] , IMAN MARVIAN, Perimeter Institute, IQC, ROBERT SPEKKENS, Perimeter Institute — Information theory provides a novel approach to study of the consequences of symmetry of dynamics which goes far beyond the traditional conservation laws and Noether's theorem. The conservation laws are not applicable to the dissipative and open systems. In fact, as we will show, even in the case of closed system dynamics if the state of system is not pure the conservation laws do not capture all the consequences of symmetry. Using information theoretic approach to this problem we introduce new quantities called asymmetry monotones, that if the system is closed they are constant of motion and otherwise, if the system is open, they are always non-increasing. We also explain how different results in quantum information theory can have non-trivial consequences about the symmetric dynamics of quantum systems.

[1]I.M. is supported by Mike and Ophelia Lazaridis scholarship.

4:54PM X29.00013 Closed Systems that Measure Particles , MICHAEL STEINER, RONALD RENDELL, Inspire Institute — The Measurement Problem has been of fundamental concern since the discovery of Schrödinger's equation. We have been developing a framework for which this problem can be considered under the assumption that the particle and detector are jointly considered a closed system. The framework is based on imposing conditions on quantum state evolution that such a closed system meet, including conservation of energy and momentum, no-cloning and no-signaling, gauge invariance, and relativity constraints. Another requirement will be presented, which is a quantum mechanical generalization of Newton's first law. Based on these conditions, we will derive and present several new results.

5:06PM X29.00014 Quantum Theory for a Total System with One Internal Measuring Apparatus , WEN-GE WANG, Univ of Sci & Tech of China — We propose a quantum theory for a total system including one internal measuring apparatus. The theory is based on three basic assumptions and a principle termed the principle of compatible description (PCD). The assumptions are: (i) Physical states of the total system can be associated with vectors in the Hilbert space. (ii) Dynamical evolution of a state vector obeys Schrö dinger equation. (iii) For a physical state of the total system described by a pure vector, in which a subsystem may play the role of an internal measuring apparatus, when certain stable condition is satisfied, the pure-vector description may be given a Born-type ensemble interpretation. The PCD states that different descriptions for the same state of the total system must give consistent predictions for results of measurements performed by the internal measuring apparatus. The proposed theory lies at a meeting point of Copenhagen, Everett's relative-state, and consistent-histories interpretations of quantum mechanics. While, it provides something new: For example, the PCD imposes a restriction to vectors that can be associated with physical states, which may effectively break the time-reversal symmetry of Schrödinger equation. As an application of the theory, we derive a condition under which a two-level quantum system may have definite properties, such that it may play the essential role of a measuring apparatus.

Thursday, March 24, 2011 2:30PM - 5:30PM –
Session X30 DCMP: Nanowires: Electronic Transport, Experimental C147/154

2:30PM X30.00001 Resistivity of Endotaxial Silicide Nanowires Measured with UHV-STM Nanoprobe[1] , SAM TOBLER, PETER BENNETT, Arizona State University — We have measured the resistivity of endotaxial silicide nanowires on silicon using a UHV STM nanoprobe in a 2-point configuration, which allows separation of intrinsic resistivity from contact resistance using a variable probe spacing. A fixed contact is provided by a thin metal film deposited by shadow evaporation with an edge profile 100nm wide and sheet resistance 500 ohms, while the second contact is provided by the STM tip. A controlled approach with 15 Ang displacement beyond the tunneling position allows for reliable and repeatable electrical contact without damage to the tungsten STM tip. Using this method, we have obtained resistivity values of 30 micro-ohm-cm and 120 micro-ohm-cm for CoSi2 nanowires of width 40nm and 20nm, respectively, on Si(110). The increase of resistivity with decreasing width is attributed to boundary scattering along the sidewalls of the nanowires.

[1]Supported by NSF Grant DMR0503705

2:42PM X30.00002 Field Effect Transistor based on Single Crystalline InSb Nanowire[1] , JIA LU, YENNAI WANG, KARAN BANERJEE, USC, HUIJUN YAO, Juelich Intitute, THOMAS SCHAEPERS, Juelich Institute, NAMI COLLABORATION, IBN COLLABORATION — Semiconductor nanowires have attracted substantial scientific and technological interests due to their unique properties arising from the size confinement effects. Among III-V group, indium antimonide (InSb) has the smallest bandgap energy (170 meV) at room temperature and possess an extremely high bulk electron mobility. It has been widely used in infrared optoelectronics and high-speed devices, and has inspired significant interest for fundamental studies in their nanostructure form. In this work, InSb nanowires with precise stoichiometry and zincblende crystal structure are synthesized via pulsed-laser chemical vapor deposition. Raman spectroscopy shows stoke and anti-stoke peaks of transverse-optical mode with asymmetric broadening. The nanowire demonstrates n-type semiconductor behavior. Enhanced surface scattering due to size confinement leads to reduced electron mobility.

[1]DAAD

2:54PM X30.00003 Realizing lateral wrap-gated nanowire FETs: Controlling gate length with chemistry rather than lithography , ADAM MICOLICH, School of Physics, University of New South Wales, Sydney NSW 2052, Australia, KRISTIAN STORM, GUSTAV NYLUND, LARS SAMUELSON, Solid State Physics/Nanometer Structure Consortium, Lund University S-211 00 Lund, Sweden — An important consideration in miniaturizing transistors is maximizing the coupling between the gate and the semiconductor channel. A semiconductor nanowire with a coaxial metal gate represents the optimum in gate-channel coupling, but has only been realized for vertically-oriented nanowire transistors. We report a method for producing laterally oriented fully wrap-gated nanowire field-effect transistors that provides exquisite control over the gate length via a single wet etch step, eliminating the need for additional lithography beyond that required to define the source/drain contacts and gate lead. Our design allows the contacts and nanowire segments extending beyond the wrap-gate to be controlled independently by biasing the doped substrate, significantly improving the sub-threshold electrical characteristics. Our devices provide stronger, more symmetric gating of the nanowire, operate at temperatures between 300 to 4 Kelvin, and offer new opportunities in applications ranging from studies of one-dimensional quantum transport through to chemical and biological sensing.

3:06PM X30.00004 Transport studies of ultrathin YSi_2 nanowires , SABAN M. HUS, HAO HU, VIOLETA IANCU, HANNO H. WEITERING, The University of Tennessee, AN-PING LI, Center for Nanophase Material Sciences, Oak Ridge National Laboratory — Extremely long YSi_2 nanowires have been fabricated via self-assembly during epitaxial growth of Y on the Si (100) 2x1 surface. The thinnest YSi_2 nanowires have a cross section of $\sim$0.4 x1.1 nm^2 and can grow up to 2 μm long. They are among the closest realizations of a one-dimensional conductor. Their electrical transport properties have been investigated with a variable-temperature four-tip scanning tunneling microscope (STM) using ex-situ fabricated contact pads. These ex-situ investigations indicated that the electrical conductivity of single nanowires is thermally activated, following an inverse Arrhenius law. In-situ contact fabrication has been accomplished via a field-induced atomic emission process from a gold STM tip. Details of the in-situ fabrication method and preliminary transport results will be presented. The research at Oak Ridge National Laboratory's Center for Nanophase Materials Sciences was sponsored by the Division of Scientific User Facilities, US Department of Energy.

3:18PM X30.00005 Experimental observation of very large magnetoconductance in microbial nanowires[1] , NIKHIL MALVANKAR, Depts. of Physics and Microbiology, University of Massachusetts, Amherst MA 01003, MADELINE VARGAS, DEREK LOVLEY, Dept. of Microbiology, University of Massachusetts, Amherst MA 01003, MARK TUOMINEN, Dept. of Physics, University of Massachusetts, Amherst MA 01003 — Microbial nanowires are 2-5 nm-wide conductive proteinous pili filaments secreted by some bacteria, which can grow tens of micrometers long and may serve as a conduit for long-distance electron transport. Our previous studies demonstrated that pili of Geobacter sulfurreducens exhibit properties akin to disordered metals, and indicated a temperature-driven crossover from the regime of weak localization (WL) to strong localization (SL). Here we report a very large positive magnetoconductance (MC), up to 10,000 %, at 300K. MC increased exponentially with magnetic field. A crossover from positive MC (WL regime) to negative MC (SL) was observed at $\sim$ 280K when the localization and the phase-breaking lengths are expected to become comparable. We attribute positive MC to destruction of the quantum interference of delocalized electron wavefunctions and negative MC to shrinkage of the localized electron wavefunctions due to applied magnetic field, which is consistent with the temperature dependence of conductivity.

[1]Funded by U.S. DOE Genomic Sciences and Office of Naval Research

3:30PM X30.00006 Electron Transport in Gold Nanowires: Stable 1-, 2- and 3-Dimensional Atomic Structures and Non-Integer Conduction States , DOUGLAS SMITH, FRANCESCA TAVAZZA, LYLE LEVINE, JON PRATT, ANNE CHAKA, National Institute of Standards and Technology — We report experimental conductivity measurements made during highly stable tensile deformation of Au nanowires showing a rich variety of behaviors, including non-integer quantum conductance plateaus, transitions and slopes. Using tight binding conductance calculations on simulated nanowires previously deformed using density functional theory calculations, we demonstrate that all of these phenomena can arise from structural transitions between highly stable ordered atomic configurations that self-organize during tensile deformation.

3:42PM X30.00007 Gate-induced Fermi level tuning and ambipolar conduction control in InP nanowires , KRISTIAN STORM, GUSTAV NYLUND, MAGNUS BORGSTRÖM, JESPER WALLENTIN, CARINA FASTH, CLAES THELANDER, LARS SAMUELSON, Lund University — Semiconducting nanowires are an interesting platform for studies of fundamental material transport properties in one dimension as well as for building blocks for various types of devices. Most conventional semiconductor devices are based upon doping for its operation, but as device dimensions are decreased, the random position of a few incorporated impurity atoms may come to dominate device characteristics. We present measurements of InP nanowires in which the Fermi level is tuned at efficiency close to the theoretical limit using semi-wrapped gates. Furthermore, we present ambipolar devices in which the Fermi level can be tuned across the entire bandgap of the semiconductor. We believe this will be of considerable importance and serve as a foundation for producing nanowire devices where the device behavior is induced by sequential gates wrapped around the nanowire channel, replacing the need for doping in certain types of devices. This way, the properties can be dynamically tuned using wrapgates, as opposed to statically set using the doping level.

3:54PM X30.00008 Transport Measurements on Sb doped Silicon Nanowires , PRATHYUSHA NUKALA, Dept. of Electrical Eng. University of North Texas, MARZIEH ZARE, GOPAL SAPKOTA, Dept. of Physics University of North Texas, PRADEEP GALI, USHA PHILIPOSE, Dept. of Electrical Eng. University of North Texas — Semiconductor nanowires (NWs) present an alternative approach for device scaling. N-type Si NWs are generally grown with silane as source with phosphine and arsenic as dopants, all of which are toxic in nature. We present a safe, cost-effective approach for synthesis of n- doped Si NWs using Sb. Structural and compositional characterization using electron microscopy and X-ray spectroscopy will be presented for crystallographic information on the quality and morphology. Ohmic contacts established to a single and on an array of doped and undoped NWs in an FET type of device configuration will provide information on several parameters such as type of majority carriers, mobility and concentration. We will highlight the promise of Sb doped Si NWs for electronic applications such as nano-scale field effect transistors and sensors.

4:06PM X30.00009 Role of defect states in charge transport in semiconductor nanowires[1] , DONGKYUN KO, XIANWEI ZHAO, KONGARA REDDY, WOLFGANG WINDL, NITIN PADTURE, NANDINI TRIVEDI, FENGYUAN YANG, EZEKIEL JOHNSTON-HALPERIN — Charge transport characteristics are investigated in Se-doped InP nanowires in order to determine the nature of the defect states. I-V curves indicate that transport is limited by trapped space charges rather than by Schottky at high bias. In addition, mobility calculations show that hopping between defect states plays an important role at low bias. A transition between hopping mechanisms as a function of temperature can be determined from the behavior of the temperature-dependent resistance R(T). Nearest neighbor hopping (NNH) is dominant in the high temperature regime (>158K) , $R \sim exp(T_0/T)^{1.03}$, and Efros-Shklovskii variable range hopping (ES-VRH) is dominant in the low temperature regime (<158K), $R \sim exp(T_{ES}/T)^{0.49}$. Gate-bias dependence of the transition temperature and hopping parameters are also investigated: these results suggest that applying positive gate-bias changes the strength of electron correlations in these quasi-1D systems.

4:18PM X30.00010 InAs Nanowire Transistors as Gas Sensor: the Role of Surface States[1] , DONG LIANG, JUAN DU, HAO TANG, XUAN P.A. GAO, Department of Physics, Case Western Reserve University — Utilizing the large surface-to-volume ratio, sensors of quasi one-dimensional semiconductor nanowires based electronic devices have been shown high sensitivity to the adsorption gaseous molecules or the binding of biomolecules in liquid, enabling a label-free sensing modality with high sensitivity and direct electrical readout. We report a study of the response of InAs nanowire field-effect transistor sensor devices to various gases and alcoholic vapors. It is concluded that the change in conductance of the device in response to chemical vapors is a combined result of both the charge transfer and modified electron mobility effects. In particular, we found that surface adsorption of most chemical molecules can reduce electron density in nanowires from $\sim 10^4$ to $\sim 10^3/\mu$m and enhance the electron mobility greatly (from tens to a few hundred of $cm^2/(V\ s)$) at the same time. These effects are attributed to the interactions between adsorbed molecules and the electron accumulation layer and rich surface states on the InAs nanowire surface. Journal reference: Nano Letters 9, 4348 (2009).

4:30PM X30.00011 Surface passivated pure Indium Oxide nanowires for gas sensors , PRADEEP GALI, Department of Electrical Electrical Engineering, University of North Texas, KIRAN SHRESTHA, Department of Physics, University of North Texas, FANG LINGKUO, NIGEL SHEPHERD, Department of Materials science, University of North Texas, USHA PHILIPOSE, Department of Physics, University of North Texas — Indium oxide (In_2O_3) nanowires have applications in semiconductor electronics and gas sensing. We report on growth of stoichiometric In_2O_3 nanowires with diameter ranging from 40 to 80nm and lengths over 10 μm. Structural characterization done with SEM, XRD and TEM shows that the nanowires exhibits BCC structure and grow along the (100) direction. Energy Dispersive X-ray spectroscopy shows stoichiometric composition. Transport measurements on a single nanowire shows ohmic behavior and a resistance of about 100 KΩ. Photoluminescence spectrum at room temperature shows strong emission peaks at 370nm and 415nm, corresponding to near band edge and defect related emission respectively. We present a technique of post-growth annealing of these nanowires to eliminate the defect induced emission and enhance band edge emission. Passivating the surface of these nanowires enhances their gas sensing abilities.

4:42PM X30.00012 Synthesis and Characterization of InAs / InSb Nanowire Heterojunctions[1] , MINKYUNG JUNG, MICHAEL SCHROER, JASON PETTA, Princeton University — InSb is a very promising material for both electronic and optoelectronic devices due to its unique features, including a very small band gap, large bulk mobility, enormous electronic g- factor and strong spin-orbit interaction. In particular, the small effective mass of InSb makes it straightforward to fabricate devices that display effects due to quantum confinement [1,2]. Here InAs/InSb nanowire heterostructures were grown by metal-organic vapor-phase epitaxy on InAs (111)B substrates. We investigated morphology changes of InAs/InSb nanowires with varying growth temperature and V/III ratio. The samples were characterized using scanning electron microscopy and high resolution transmission electron microscopy. In order to study the transport properties of InAs/InSb nanowires, field effect transistors were fabricated on SiO_2/Si substrates and characterized at room temperature and 4.2 K.

4:54PM X30.00013 Measurement of minority carrier diffusion length in individual silicon nanowires with an in-situ grown p-n junction , A.D. MOHITE, D.E. PEREA, S. SINGH, S.A. DAYEH, S.T. PICRAUX, H. HTOON, LANL, CENTER FOR INTEGRATED NANOTECHNOLOGIES TEAM, CHEMISTRY DIVISION, LOS ALAMOS NATIONAL LABORATORY TEAM — We report a scanning photocurrent microscopy study across a p-n junction of individual in-situ doped Si nanowires (NWs). The measured photocurrent decreases exponentially as the laser spot is scanned away from the p-n junction in both directions. The photocurrent peak widens with increasing reverse bias, indicating the increase of depletion width. For a 40nm diameter NW, the fit of photocurrent decay to an exponential function gives minority carrier diffusion lengths of L_n=1.842 μm and L_p=1.45 μm for electrons and holes, respectively. Such relatively long minority carrier diffusion lengths are consistent with the low dopant incorporation we expected for our growth condition. This result further suggests that the diffusion length scales with doping concentration despite the impact of surface states of a 1D system. We will further discuss the dependence of the minority carrier diffusion length on diameter, doping concentrations, and back-gating.

5:06PM X30.00014 Andreev tunneling enhanced by Coulomb oscillations in superconductor-semiconductor hybrid Ge/Si nanowire devices , XIAOJIE HAO[1], Key Laboratory of Quantum Information, CAS, University of Science and Technology of China, Hefei, China; University of Michigan, USA, TAO TU, HAI-OU LI, CHENG ZHOU, GANG CAO, GUANG-CAN GUO, GUO-PING GUO, Key Laboratory of Quantum Information, CAS, University of Science and Technology of China, Hefei, China, WAYNE FUNG, ZHONGQING JI, WEI LU, Department of Electrical Engineering and Computer Science, The University of Michigan, Ann Arbor, USA — We explore the magneto-conductance of Ge/Si core/shell nanowire quantum dot devices contacted by superconducting leads. Significant magneto-conductance peaks around zero field are observed and show a periodic modulation with gate voltage as discrete states of the quantum dot are turned on- and off-resonance with the Fermi energy in the superconducting electrodes. The ability to create and control coherent transport in superconductor-semiconductor hybrid nanostructures allows for new opportunities in the study of various fundamental competing effects such as superconductivity and electron-electron interactions.

[1]Now at University of California, Los Angeles

5:18PM X30.00015 Minority Carrier Lifetimes and Surface Effects in VLS-Grown pn Junction Silicon Nanowires , YEONWOONG JUNG, ALEKSANDAR VACIC, Yale University, DANIEL PEREA, TOM PICRAUX, Los Alamos National Laboratory, MARK REED, Yale University, YALE UNIVERSITY COLLABORATION, LOS ALAMOS NATIONAL LABORATORY COLLABORATION — We study the minority carrier lifetimes and surface effects of pn junction Si nanowires. Axial pn junction Si nanowires with alternating p-n doped segments are grown based on the Au-catalyzed VLS process by an in-situ exchange of gas-phase dopants. As-grown nanowires display strong current rectification only after surface etching processes. By utilizing the reverse recovery transient of minority carriers, we directly characterize the minority carrier lifetimes and observe the decrease of the lifetimes with a decrease of nanowire diameters. Investigation of the diameter-dependent device ideality factor and current density strongly suggests that the surface recombination with an enhanced surface-to-volume ratio significantly governs the carrier transport. We also characterize the carrier lifetimes of nanowires with and without surface passivation layers, and observe an enhancement of the lifetimes in the surface-passivated ones. These studies elucidate the carrier transport mechanism in VLS pn junction Si nanowires and emphasize the importance of the surface passivation for efficient photovoltaic applications.

Thursday, March 24, 2011 2:30PM - 5:18PM –
Session X31 DCMP: Amorphous Solids, Glasses & Liquids I C145

2:30PM X31.00001 Evidence of Fatigue Damage in the Local Structure of Zr-based Bulk Metallic Glasses , DESPINA LOUCA, PENG TONG, University of Virginia, PETER LIAW, GONGYAO WANG, The University of Tennessee, YOSHIHIKO YOKOYAMA, Tohoku University, ANNA LLOBET, Los Alamos National Laboratory, RICK SPENCE, Argonne National Laboratory — Bulk metallic glasses (BMG) are particularly vulnerable to fatigue damage, where catastrophic failure may occur without observable macroscopic changes. The local atomic structure of two BMGs with compositions of $Zr_{50}Cu_{40}Al_{10}$ and $Zr_{60}Cu_{30}Al_{10}$was investigated by synchrotron X-ray and neutron diffraction via the pair density function analysis. Under a load of 1600 MPa, the number of compression cycles ranged from 0 – 10^7 at 10 Hz. At room temperature, a subtle but irreversible change is observed in the local structure due to fatigue. Upon cooling down to 10 K, however, a significant structural re-organization is observed especially in the short range that is proportional to the number of fatigue cycles. The effect becomes more pronounced with increasing the number of loading cycles. The changes are beyond the usual narrowing from reducing thermal vibrations. The results indicate that hardening occurs after fatigue.

2:42PM X31.00002 Analysis of Amorphous Iron Surface Energies and Bulk Properties using DFT[1] , CHARLES NEWNAM, U.S. Naval Academy, MICHAEL MEHL, U.S. Naval Research Laboratory, DANIEL FINKENSTADT, U.S. Naval Academy — From Ab Initio calculations, we compare the energy of amorphous Iron to bcc and fcc Iron structures, both at zero pressure and high pressure. From these calculations we draw conclusions on the properties of metallic glass structures over a range of pressure. Additionally, we address the adsorption energy of Oxygen on amorphous surfaces versus the structure's cell size and compared against bcc and fcc Iron structures. The adsorption energies allow us to evaluate the corrosion potential of an amorphous structure versus a typical crystalline surface.

2:54PM X31.00003 Super-localization of atomic dynamics in liquid Iron[1] , MADHUSUDAN OJHA, DAVID J. KEFFER, The University of Tennessee, DON M. NICHOLSON, Oak Ridge National Laboratory, TAKESHI EGAMI, The University of Tennessee and Oak Ridge National Laboratory — Lattice dynamics in crystals is well described in terms of phonons. However, phonons cannot give precise description of the atomic dynamics in liquids because they are highly damped. We carried out MD simulations of liquid iron at high temperatures. The results are presented in terms of the dynamic pair-density function (DPDF), which describes the atomic correlation, or the distribution of atomic distances over time, at the angular frequency ω. Our analysis shows that the atomic dynamics in liquid iron above the boson mode (BM) is confined to only the nearest neighbors, resulting in super-localization of atomic dynamics. The dynamics of nearest neighbor shells is well described in terms of atomic level stresses. This super-localization of atomic dynamics in liquid iron implies that the dynamics of the local atomic level stresses represents the normal modes in liquids at high temperatures, and justifies the equipartition law observed for the atomic level stresses [1].

3:06PM X31.00004 Data-mining for hidden order in metallic liquids and glasses , XIAOWEI FANG, Ames Laboratory - USDOE and University of Science and Technology of China, C.Z. WANG, Y.X. YAO, Ames Laboratory - USDOE, Iowa State University, Z.J. DING, University of Science and Technology of China, K.M. HO, Ames Laboratory - USDOE, Iowa State University — Although metallic liquids and glasses look quite homogenous macroscopically, most of them exhibit structural and chemical orders at the atomic scale. This short-range (SRO) or medium-range order (MRO) occurs on a length scale of 5-20 Å. However, they are generally difficult to discern at the macroscopic scale due to random orientations of the ordered units. In this paper, we develop an efficient computational algorithm to align the neighborhood cluster around each atom to reveal the hidden symmetry and order contained in the system. In our alignment algorithm, we put the center atoms into a common origin and rigidly rotate the clusters to maximize their common registry to reveal any existing SRO or MRO. The results determine what are the major competing orders and the strengths of various orders in the system. Such atomic scale information are very difficult to acquire by experiments and are critical for understanding the mechanism of glass formation and phase selections during the rapid solidification from the metallic liquids.

3:18PM X31.00005 Metallic States of Multicomponent Glasses , TERRENCE JACH, NIST, Gaithersburg, MD — The $K\alpha_3$ and $K\alpha_4$ satellite lines in x-ray fluorescence result from two-electron shake-up transitions. The ratio of these lines in some solids is known to be highly sensitive to the valence band of the material and a well-defined indicator of metallic vs. oxide states. The good energy resolution of a microcalorimeter x-ray detector allows us to determine the ratio in the fluorescence x-ray spectrum of glasses. An investigation of the satellite ratios of Mg and Al $K\alpha$ lines in a multi-component glass used as a NIST Standard Reference Material shows that these elements appear to be in a metallic state, despite the original constituents of the glass. This result would be hard to determine by x-ray photoemission spectroscopy because of charging effects in the glass. It remains to be determined whether the effect is due merely to incomplete oxidation of the atoms or actual nanoparticle-sized metallic phases in the glass.

3:30PM X31.00006 An NMR study of homogenous deformation-induced ordering in $La_{50}Ni_{15}Al_{35}$, MAGDALENA SANDOR, YUE WU, HAIBO KE, WEI HUA WANG — The mechanism of mechanical deformation is currently an unresolved issue of fundamental importance. ^{27}Al NMR nutation experiments in $La_{50}Ni_{15}$ Al_{35} bulk metallic glasses (BMG) were carried out to probe local structural changes induced by elastostatic compression at room temperature. It was observed that compression enhances local symmetry at Al sites with compression time. Modulated differential calorimetry studies were also performed to understand how free volume changes with compression time. Results provide insight into the nature of homogenous deformation and the interplay of free volume with local structural changes.

3:42PM X31.00007 Understanding intrinsic ductility from Poisson's ratio for amorphous solids through force-field tuning , YUNFENG SHI, JIAN LUO, Rensselaer Polytechnic Institute — This work is motivated by recently observed empirical relationship between the Poisson's ratio and the fracture energy for a range of metallic glasses and oxide glasses. Glassy solids with low Poisson's ratio are brittle and vice versa, with a critical Poisson's ratio of about 0.31. Here we used a force-field tuning scheme to investigate how a near-equilibrium elastic constant determines far-from-equilibrium fracture behavior. By modifying a well-studied binary Lennard-Jones system, we obtained a family of glassy systems with different Poisson's ratio ranging from 0.2 to 0.4. Interestingly, the model glasses with low Poisson's ratio exhibit brittle fracture in tension and vice versa, which agrees with experimental observations. Finally, we will discuss how ductility of amorphous solids can be comprehended in terms of the structure and bonding of the amorphous solids, both of which also dictate the Poisson's ratio.

3:54PM X31.00008 Universal Sound Attenuation in Amorphous Solids , DERVIS CAN VURAL, University of Illinois at Urbana Champaign — A large class of amorphous materials, including glasses, polymers, disordered crystals and in some cases quasi-crystals and proteins, show a striking degree of universality in their low temperature acoustic and thermal properties. Among the least understood is the dimensionless acoustic mean path $l/\lambda \sim 150$. Although many theories have been proposed to explain the universality of this constant, they rely on detailed phenomenological assumptions, such as the existence of tunneling two-state systems. In this talk, I present the many-body acoustic response of elastically coupled random matrices to demonstrate that the universality is a property of a general class of theories, and emerges regardless of the detailed assumptions regarding the constituents of the amorphous solid.

4:06PM X31.00009 Finite-temperature critical point of a glass transition , YAEL ELMATAD, University of California, Berkeley, ROBERT JACK, University of Bath, JUAN GARRAHAN, University of Nottingham, DAVID CHANDLER, University of California, Berkeley — We generalize the simplest kinetically constrained models of a glass-forming liquid by softening kinetic constraints, allowing them to be violated with a small rate. We demonstrate that these models support a first-order dynamical (space-time) phase transition between active (fluid) and inactive (glass) phases. The first-order phase boundary in these softened model ends in a finite-temperature dynamical critical point, which may be present in natural systems. In this case, the glass phase has a very large but finite relaxation time. We discuss links between the dynamical critical point and quantum phase transitions, showing that dynamical phase transitions in d dimensions map to quantum transitions in the same dimension, and hence to classical thermodynamic phase transitions in $d+1$ dimensions.

4:18PM X31.00010 Nonequilibrium relaxation and aging scaling properties of the Coulomb glass[1] , MATTHEW T. SHIMER, UWE C. TÄUBER, MICHEL PLEIMLING, Department of Physics, Virginia Tech — Using Monte Carlo simulations, we analyze the two-time density autocorrelation function for the two- and three-dimensional Coulomb glass with various long-range interaction potentials. A full aging scaling ansatz is sufficient to describe the nonequilibrium relaxation properties of these highly correlated disordered systems. By investigating the trends of the scaling exponents, we find that they are non-universal, and depend on temperature, charge density, and interaction strength.

4:30PM X31.00011 Vibrational excitations and elastic phases in Sodium Borate Glasses[1] , K. VIGNAROOBAN, P. BOOLCHAND, University of Cincinnati, M. MICOULAUT, University of Paris VI — Glass Transition temperatures (T_gs) and non-reversing enthalpy (ΔH_{nr}) at T_g of dry $(Na_2O)_x(B_2O_3)_{100-x}$ glasses across the $0\% < x < 44\%$ soda range are measured. Trends in $\Delta H_{nr}(x)$ show a reversibility window in the $20\% < x < 40\%$ range, and fix the Intermediate Phase (IP). IR and Raman vibrational modes including Boson modes are also examined. At low x ($< 20\%$), the Raman active 808 cm^{-1} mode of boroxyl rings steadily lowers in scattering strength and red-shifts with increasing x, suggesting that the stressed-rigid quasi 2D network of B_2O_3 glass at $x = 0$, steadily softens with a characteristic optical elastic power-law ($p_1 = 0.85(2)$). In the $26\% < x < 40\%$ range, a mode near 770 cm^{-1} rapidly grows in strength and red shifts with increasing x with a power- law of $p_2 = 1.05(5)$ characteristic of IPs observed earlier[a] in other 3D covalent and ionic networks. In addition, many other modes are observed, some blue-shift, some red-shift and some remain unchanged with x. These data will be discussed in relation to glass structure evolution with composition.

4:42PM X31.00012 Accelerated kinetics of amorphous silicon using an on-the-fly off-lattice kinetic Monte-Carlo method , JEAN-FRANCOIS JOLY, Universite de Montreal, FEDWA EL-MELLOUHI, Texas A&M University at Qatar, LAURENT KARIM BELAND, NORMAND MOUSSEAU, Universite de Montreal — The time evolution of a series of well relaxed amorphous silicon models was simulated using the kinetic Activation-RelaxationTechnique (kART), an on-the-fly off-lattice kinetic Monte Carlo method [1]. This novel algorithm uses the ART nouveau algorithm to generate activated events and links them with local topologies. It was shown to work well for crystals with few defects but this is the first time it is used to study an amorphous material. A parallel implementation allows us to increase the speed of the event generation phase. After each KMC step, new searches are initiated for each new topology encountered. Well relaxed amorphous silicon models of 1000 atoms described by a modified version of the empirical Stillinger-Weber potential [2] were used as a starting point for the simulations. Initial results show that the method is faster by orders of magnitude compared to conventional MD simulations up to temperatures of 500 K. Vacancy-type defects were also introduced in this system and their stability and lifetimes are calculated.

4:54PM X31.00013 ABSTRACT WITHDRAWN –

5:06PM X31.00014 Properties of fluids under strong confinement: a mode coupling approach , SAROJ NANDI, Centre for Condensed Matter Theory, Department of Physics, Indian Institute of Science, Bangalore - 560012, India, SARIKA BHATTACHARYA, Solid State and Structural Chemistry Unit, Indian Institute of Science, Bangalore - 560012, India, SRIRAM RAMASWAMY, Centre for Condensed Matter Theory, Department of Physics, Indian Institute of Science, Bangalore - 560012, India — We extend the mode coupling theory (MCT) of glass transition in bulk fluids to the case of confinement, which enhances the feedback mechanism to drive the system to a glassy state. Confinement enters the theory in terms of an external potential that produces an inhomogeneous density background, which in turn forces the fluid to relax diffusively. Below a certain density, the MCT transition becomes continuous and the critical density of continuous to discontinuous transition depends on the nature of the external potential. If the control parameters are in the proper region of phase space, the fluid shows a three-step relaxation scenario. We also incorporate shear in our theory and thereby show that the fluid, when confined, shows shear thinning at much lower shear rate compared to a bulk fluid.

Thursday, March 24, 2011 2:30PM - 4:30PM –

Session X32 FIAP DCOMP: Focus Session: Frontiers in Computational Thermodynamics of Materials II C144

2:30PM X32.00001 Low temperature phase transition predicted in the compound B13C2/B4C[1] , MICHAEL WIDOM, Carnegie Mellon University — The experimental phase diagram of boron-carbon exhibits the compound boron-carbide over a broad composition range that extends to low temperatures, in seeming contradiction to the third law of thermodynamics. First principles total energy calculations suggest the presence of two energy-minimizing structures in the boron-carbon phase diagram, B13C2 and B4C. Both distribute boron and carbon atoms on the same 15-atom rhombohedral unit cell (hR15), consisting of 12-atom icosahedra at cell vertices plus three-atom chains at cell centers. However, only B13C2 respects the rhombohedral symmetry, while B4C breaks the symmetry by replacing one of the icosahedral boron atoms with carbon. Because B4C is incompatible with the experimentally observed rhombohedral symmetry, it must lose thermodynamic stability at elevated temperatures. We report a study of the configurational ensemble obtained by substitution of boron or carbon on different sites using a semi-grand canonical ensemble. Varying chemical potential at low temperature, we find sharp transitions from beta-rhombohedral boron to B13C2 then to B4C and finally to graphitic carbon. Only the rhombohedral-symmetry phase B13C2 survives at high temperature while the symmetry-broken phase B4C loses stability around room temperature.

3:06PM X32.00002 Thermodynamic modeling of Pt-Al and Pd-Al , DEREK CARR, Brigham Young University — Pure platinum and pure palladium are too soft for typical jewelry applications. Adding small amounts of other metals can significantly increase their performance. However, international hallmarking standards require the alloys to be 95% pure by weight. How does one achieve significant improvements in performance adding only small amounts (5 wt-%) of other metals? Significant improvements are possible even with small additions if precipitate hardening can be induced. Using a combination of first-principles, cluster expansion, and Monte Carlo modeling, we have identified new Pt-rich/Pd-rich phases in Pt-Al and Pd-Al that should be useful in precipitate hardening. Thermodynamical modeling indicates that the phases are experimentally feasible (not kinetically inhibited).

3:18PM X32.00003 Equation of State and Viscosity of Tantalum and Iron from First Principles , LJUBOMIR MILJACIC, STEVEN DEMERS, AXEL VAN DE WALLE, California Institute of Technology — To understand and model at continuum level the high-energy-density dynamic response in transition metals like Tantalum and Iron, as it arises in hypervelocity impact experiments, an accurate prediction of the underlying thermodynamic and kinetic properties for a range of temperatures and pressures is of critical importance. The relevant time scale of atomic motion in a dense gas, liquid, and solid is accessible with *ab-initio* Molecular Dynamics (MD) simulations. We calculate EoS for Ta and Fe via Thermodynamical Integration in 2D (V,T) phase space throughout different single and two-component phases. To reduce the *ab-initio* demand in selected regions of the space, we fit available gas-liquid data to the Peng-Robinson model [1] and treat the solid phase within the Boxed-quasi-harmonic approximation [2]. In the fluid part of the 2D phase space, we calculate shear viscosity via Green-Kubo relations, as time integration of the stress autocorrelation function.

3:30PM X32.00004 Binary Magnesium Alloys: Searching for Novel Compounds by Computational Thermodynamics , RICHARD TAYLOR, STEFANO CURTAROLO, Duke University, GUS HART, Brigham Young University — Magnesium alloys are among the lightest structural materials and are of considerable technical interest. We use the high-throughput framework AFLOW to make T = 0 K ground state predictions by scanning a large set of known candidate structures for thermodynamic minima. The study presented here encompasses 34 Mg-X systems of interest (X=Al, Au, Ca, Cd, Cu, Fe, Ge, Hg, Ir, K, La, Pb, Pd, Pt, Mo, Na, Nb, Os, Rb, Re, Rh, Ru, Sc, Si, Sn, Sr, Ta, Tc, Ti, V, W, Y, Zn, Zr). Avenues for further investigation revealed by this study include stable phases found in addition to experimental phases and compound forming systems thought to be either immiscible or non-compound forming. The existence of potentially novel ordered phases presents new opportunities for materials design.

3:42PM X32.00005 High-throughput combinatorial search of novel topological insulators , KESONG YANG, WAHYU SETYAWAN, SHIDONG WANG, Department of Mechanical Engineering and Materials Science and Department of Physics, Duke University, JEFFREY MULLLEN, MARCO BUONGIORNO-NARDELLI, Department of Physics, North Carolina State University, STEFANO CURTAROLO, Department of Mechanical Engineering and Materials Science and Department of Physics, Duke University, CURTAROLO GROUP @ DUKE: COMPUTATIONAL MATERIALS SCIENCE TEAM, BUONGIORNO-NARDELLI GROUP @NCSU: ERMES GROUP TEAM — In recent years, topological insulators (TIs) have attracted lots of attentions not only because of their interesting electronic characteristics induced by spin-orbit coupling but also their potential applications. So far, experimentally observed topological insulators mainly include HgTe/CdTe quantum well structure, semiconducting alloy $Bi_{1-x}Sb_x$, and so-called second-generation TI materials, i.e., the family of Bi_2Se_3, Bi_2Te_3, and Sb_2Te_3. Later theoretical simulations predict more TIs such as $TlBiQ_2$ and $TlSbQ_2$ (Q=Te, Se, and S), $LaBiTe_3$ as well as half-Heusler alloys, LuPtSb and ScPtBi. Numerous attempts are being made to look for more TIs. In this presentation, we will introduce our high-throughput combinatorial approach to find novel TI materials based on the AFLOW framework and distributed libraries.

3:54PM X32.00006 Classification of the ICSD by crystal Prototype , JUNKAI XUE, WAHYU SETYAWAN, STEFANO CURTAROLO, Duke University — An efficient way to determine the prototypes of the ICSD database has been implemented within our high-throughput formalism. This presentation illustrates how we use this tool to search for structure/properties correlations in an automatic fashion.

4:06PM X32.00007 Novel Occurences of $L1_1$ and $L1_3$ found using the synnergy between High Throughput and Cluster Expansion , LANCE NELSON, GUS HART, Brigham Young University, STEFANO CURTAROLO, Duke University — Despite their geometric simplicity, $L1_1$(CuPt) and $L1_3$ ($CdPt_3$) fail to appear as groundstates in experimental systems. ($L1_1$ appears in CuPt only) Are these crystal structures actually energetically unfavorable, or have they simply been overlooked in experimental studies? Here we investigate, using computational methods, the energetic stability of these phases in all binary inter-metallic systems. We combine the results of two techniques,namely High Throughput (HT) and Cluster Expansion (CE), to maximize efficiency and ensure thoroughness. HT results show $L1_1$($L1_3$) to be stable in the following systems: AgPd, AgPt, CuPt, PdPt(CdPt,CuPt,PdPt,LiPd,LiPt). Cluster expansions constructed for these systems verify the HT findings in all cases, with the exception of the HT groundstate PdPt-$L1_1$.(D_4 is found to be energetically more favorable) Monte Carlo simulations, which are used to identify order-disorder transition temperatures, were performed for all occurences of these two phases. While the transition temperatures for some systems are found to be extremely low, others appear to be physically realizable.

4:18PM X32.00008 Ab Initio Insights on the Shapes of Nanocrystals[1] , ROMAN CHEPULSKYY, STEFANO CURTAROLO, Duke University — Catalytic, chemical, optical and electronic properties of nanocrystals are strongly influenced by their faceting. A variational approach based on quantum mechanical energies is introduced to evaluate stable and metastable shapes of nanocrystals. The method leads to a nanoscale equation of state, which is solved self-consistently. Using platinum as example, it is found that the surface energy dependence on the lattice parameter is the key factor controlling the equilibrium stability of the crystal shapes. The energies of different surfaces versus lattice parameter are calculated from first principles in high-throughput fashion. Considering several crystal shapes and using Wulff's construction, the transitions between stable and metastable shapes are predicted below 3 nm in diameter. Our variational approach explains experimental results and establishes a direction to search for better catalysts.

Session X33 DCMP: Quantum Fluids and Solids I C143/149

2:30PM X33.00001 Characterization of MEMS Devices for the Study of Superfluid Helium Films[1] , MIGUEL GONZALEZ, BYOUNG HEE MOON, PRADEEP BHUPATHI, PAN ZHENG, GEORGE LING, ERIK GARCELL, Department of Physics, University of Florida, Gainesville, FL 32611, USA, HO BUN CHAN, Department of Physics, The Hong Kong University of Science and Technology, Hong Kong, China, YOONSEOK LEE, Department of Physics, University of Florida, Gainesville, FL 32611, USA — Measurements on the mechanical attributes of MEMS resonators were performed at room and low temperatures. Specially devised resonators which can be actuated for shear motion were designed and fabricated using a state-of the-art multi-user MEMS process. The devices consist of a pair of parallel plates with a well-defined gap whose size can be controlled with high accuracy down to the sub-micron range. A full study of resonance properties at various pressures was performed at room temperature. Details of design, fabrication, and operation will be presented along with results from a preliminary study of a resonator immersed in liquid ^{4}He. The devices show potential for use in low temperature experiments and to investigate novel phenomena in quantum fluids at the micro/nano scale such as superfluid ^{3}He films.

2:42PM X33.00002 Interplay of Aerogel Anisotropy and Textures in Superfluid ^{3}He , JIA LI, JOHANNES POLLANEN, CHARLES COLLETT, WILLIAM J. GANNON, WILLIAM P. HALPERIN, Department of Physics and Astronomy, Northwestern University — We have performed pulsed NMR on ^{3}He-B in 98.1% porosity aerogel with different anisotropy. The aerogel anisotropy was characterized with an optical, cross-polarization technique [1]. In the isotropic aerogel sample at P = 26 bar and $T < 1.2mK$, we find a single peak with a positive frequency shift relative to the Lamor frequency indicating an n-texture that is predominately perpendicular to the field. Upon warming, we find a crossover at $T \approx 1.2mK$ from $n \perp \mathbf{H}$ to a texture where n is predominately parallel to the field. Near the crossover the NMR intensity is distributed among two components indicating an inhomogeneous texture. We have also studied an anisotropic aerogel which was compressed along its cylinder axis by 22.5%. At the same pressure, we find a homogeneous texture for all T and a similar textural crossover from $n \perp \mathbf{H}$ to $n \parallel \mathbf{H}$, but for this sample the textural crossover happens near $T_{caerogel}$. We have introduced a model to account for the interplay of aerogel anisotropy and n-textures. Currently we are studying the tip angle dependence of NMR frequency shifts in these aerogels. This work was supported by the National Science Foundation, DMR-0703656.

2:54PM X33.00003 Equal-Spin Pairing Superfluid State of ^{3}He in Radially Compressed Aerogel , J. POLLANEN, J. LI, C. COLLETT, W.J. GANNON, W. P. HALPERIN, Northwestern University — Anisotropic quasiparticle scattering has been predicted to stabilize anisotropic superfluid states of ^{3}He [1,2]. We have performed pulsed nuclear magnetic resonance (NMR) experiments on ^{3}He in a homogeneously anisotropic 97.5% porosity aerogel. From the NMR frequency shifts on warming at P = 26 bar we find a single superfluid state exists between $0.7mK$ and $T_{caero} = 1.67mK$. Susceptibility measurements indicate this phase is an equal-spin pairing (ESP) state. The anisotropy of our cylindrical aerogel sample was induced during the growth and drying stages in the form of 14.3% radial compression. The sample was characterized with an optical, cross-polarization technique [3] to confirm the presence of a homogeneous optical axis aligned with the cylinder axis. Similar experiments and characterization have been performed on a homogeneously isotropic 98.1% aerogel and, in this case, we find the non-ESP aerogel B-phase is the stable state. We are currently studying the tip angle dependence of the NMR frequency shift to identify which of the ESP states we have observed and to explore the full P-T phase diagram of superfluid ^{3}He in these aerogels. This work was supported by the National Science Foundation, DMR-0703656. [1] C.L. Vicente, et al., PRB 72, 094519 (2005). [2] K. Aoyama and R. Ikeda, PRB 73, 060504(R) (2006). [3] J. Pollanen et al., JNCS 354, 4668 (2008).

3:06PM X33.00004 Moderate Magnetic Field Transverse Acoustics in Superfluid ^{3}He-B , C. COLLETT, S. SASAKI, J.P. DAVIS, J. POLLANEN, W.J. GANNON, J. LI, W.P. HALPERIN — We present the results of transverse acoustics studies in superfluid ^{3}He-B at fields up to 0.1 T. Using acoustic cavity interferometry, we observe the acoustic Faraday effect[1,2] for a transverse sound wave propagating along the magnetic field, and we measure Faraday rotations of the polarization of the sound up to 990°, significantly more extensive than has been previously reported. We use these results to extend previous calculations of the Landé g factor. We also find the field dependence of cavity interference oscillations resulting from coupling to the imaginary squashing mode (ISQ), a collective mode of the order parameter with total angular momentum $J = 2$. Measurements in large magnetic fields were performed at frequencies up to the pair breaking threshold, where there has been a recent report[3] of a new collective mode with $J = 4$. The discovery of Faraday rotations coming from this new mode is reported, along with their intersection with rotations from the ISQ. Support for this work from the NSF, grant DMR-0703656, is gratefully acknowledged.

3:18PM X33.00005 Lévy Flights and Anomalous Diffusion in Liquid ^{3}He-Aerogel[1] , JAMES SAULS, Northwestern University — The transport of heat by liquid ^{3}He impregated into silica aerogel is limited at low temperatures by elastic scattering of quasiparticles by the aerogel. The gossamer structure of silica aerogel is a realization of a random fractal - a solid with no long-range order, but power-law scaling of the density correlation function. Complementary to fractal scaling of the particle-particle correlation function is the appearance of a power law distribution of *free flight paths*. The open structure shown in the DLCA simulations of low-density aerogel leads to a distribution of exceedingly long flight paths governed by a Lévy distribution. I describe a theory for anomalous diffusion of quasiparticles in which the Lévy distribution of long free paths is interrupted by inelastic collisions between quasiparticles. These rare events lead to finite temperature corrections to the thermal diffusion coefficient of the form, $\kappa/T = K_0 - K_1\,(T/T^\star)^\beta$, where $T^\star$ is the temperature at which the elastic and inelastic mean free paths are equal and β is related to the fractal dimension of the Lévy distribution.

3:30PM X33.00006 Signatures of Crystalline Phases and Domain Walls in Superfluid ^{3}He Thin Films[1] , ANTON VORONTSOV, Montana State University, JAMES SAULS, Northwestern University — Thin films of superfluid ^{3}He may spontaneously break translation symmetry in the plane of the film.[2] Near a critical film thickness, $D_{c_1} \approx 13\,\xi_0$, a one-dimensional "stripe phase" develops as a periodic array of domain walls separating degenerate, but inequivalent B-phases, $(\Delta_{||}, \Delta_{||}, +\Delta_\perp)$ and $(\Delta_{||}, \Delta_{||}, -\Delta_\perp)$. These defects have a unique spectrum of topological excitations bound to the domain wall. We present results for the order parameter and Fermionic spectrum, and their observable signatures, for a single domain wall and for the stripe phase. The combination of particle-hole asymmetry and broken translational symmetry of the order parameter leads to a weak modulation of the density, $\delta n \sim \ln\left(E_f/k_BT_c\right)\left(k_BT_c/E_f\right)^2\,\bar{n}$, where $\bar{n}$ is the mean particle density. This leads to a modulation of the van der Walls attraction, and thus a small, static modulation of the film thickness. We report theoretical results for the density modulation, film thickness profile and optical reflectivity for the crystalline phases of superfluid ^{3}He.

3:42PM X33.00007 Visualization of counterflow dynamics using frozen nanoparticles[1] , ENRICO FONDA, University of Trieste - University of Maryland, College Park, MATTHEW S. PAOLETTI, University of Texas at Austin, KATEPALLI R. SREENIVASAN, New York University, DANIEL P. LATHROP, University of Maryland, College Park — We study the dynamics of quantized vortices and quantum turbulence utilizing a particle tracking visualization technique. This is accomplished by using sub-micron and micron-sized hydrogen or atmospheric ice particles injected into He^4 flows that get trapped on the vortices. This technique has been used to observe and characterize reconnection of quantized vortices and thermal counterflow. We present the latest results using nano-sized ice particles. These sub-micron particles are superior to larger particles in a number of ways. In particular, being less affected by Stokes drag, they stay trapped on faster moving vortices and remain trapped closer to the lambda transition. Using these particles, we have made additional observations of counterflows at higher heat fluxes to shed light on the particle-vortex interaction mechanism. The technique has also been extended for visualization for fluid dynamics experiments using liquid nitrogen.

3:54PM X33.00008 Numerical Real Space Renormalization of a 2D Random Boson Model , SHANKAR IYER, GIL REFAEL, California Institute of Technology — Interest in the random boson problem originated in experiments on Helium adsorbed in Vycor, but the problem arises in many contexts, including Josephson junction arrays and disordered cold atom systems. Recently, Altman, Kafri, Polkovnikov, and Refael have studied a rotor model description of interacting bosons subjected to quenched disorder in one dimension. Using a real space renormalization approach, they have identified a random fixed point that marks the transition between superfluid and Mott-glass phases. Here, we describe work that numerically extends their approach to the random boson problem in two dimensions. We first test the validity of the real space renormalization by comparison to exact diagonalization of small systems. Then, we move to larger systems and explore what the renormalization scheme can tell us about the nature of the insulating and superfluid phases.

4:06PM X33.00009 Third Sound in Superfluid ^{4}He Films Adsorbed on Packed Multiwall Carbon Nanotubes[1] , EMIN MENACHEKANIAN, GARY A. WILLIAMS, University of California, Los Angeles — An investigation of third-sound propagation is carried out with thin ^{4}He films adsorbed on multiwall carbon nanotubes. At an average diameter of 12 nm and a length of several microns, the powder of nanotubes is lightly packed into a cylindrical resonator, with a resistor bolometer at the cylinder end to detect the temperature oscillations accompanying the waves. The lowest standing-wave mode in the cavity is excited by mechanical vibrations, with FFT analysis allowing measurement of the sound speed as well as the dissipation. The Kosterlitz-Thouless onset transition is observed with increasing film thickness for temperatures between 1.3 and 1.7 K. At higher thicknesses capillary condensation becomes important, probably at connection points where the nanotubes touch. Layering effects in the third-sound velocity, associated with the relatively strong van der Waals coupling between helium and carbon, are not observed, and measurements below 1 K may be necessary to see this. There is also no indication of any effect of superfluidity attributable to the adsorption of helium on the inner surfaces of the nanotubes.

4:18PM X33.00010 ABSTRACT WITHDRAWN –

4:30PM X33.00011 Vortex-Loop Thermodynamics of Superfluid ^{4}He Under Pressure[1] , ANDREW FORRESTER, GARY A. WILLIAMS, UCLA — The thermodynamic quantities of pressurized superfluid ^{4}He near the λ-transition are calculated using a vortex-loop renormalization method. The superfluid density, specific heat, vortex core size, and vortex core energy are determined as functions of pressure and temperature, and compared with experiments. The theory predicts exponents describing the critical behavior of the superfluid density and specific heat that are in agreement with recent high-precision theoretical simulations. The vortex core size is found to increase with pressure, while the core energy decreases, the behavior found experimentally for both parameters. The specific heat, though strongly dependent on both of these parameters, is found to scale with pressure in agreement with experimental measurements.

4:42PM X33.00012 Topological and geometrical interactions between quantum vortices near zero temperature , RAN CHENG, XIAO LI, QIAN NIU, University of Texas at Austin — With new velocity-dependent term discovered, various types of interactions between quantum vortices in 2-d superfluid Helium and BEC near zero temperature are unified via Berry Phase theory. Originated from the finite compressibility of the fluid, the topological statistical gauge field of an vortex breaks down to geometrical gauge field mediating local interactions. This new interaction modifies the cyclotron motion of a pair of identical vortices, and changes the pattern of orbits of a pair of vortex-antivortex. Damping effect due to finite temperature is treated phenomenologically, which does not invalidate our essential conclusions.

4:54PM X33.00013 Semiclassical dynamics of vortices in superfluid helium thin films , XIAO LI, RAN CHENG, QIAN NIU, The University of Texas at Austin — Based on the Berry phase theory, we consider the case of two vortices in Bosonic superfluids and try to extract the interaction between them. Under the adiabatic approximation, we use semiclassical Lagrangian formalism to describe the system and found that in addition to the universal background "magnetic field" which results in the Magnus force, there exists a new interaction mediated by the density profile of the background fluid due to its finite compressibility. Finally, numerical solutions from the nonlinear Schrodinger equation were employed to gain better insight into this problem.

5:06PM X33.00014 Theory of the Bose-glass states in Br-doped Nickel-Tetrakis Thiourea (DTN) , RONG YU, Rice University, STEPHAN HAAS, University of Southern California, TOMMASO ROSCILDE, Ecole Normale Superieure de Lyon - France — We present extensive Quantum Monte Carlo calculations on bond-disordered coupled spin chains with strong single-ion anisotropy, modeling the behavior of Br-doped Nickel-Tetrakis Thiourea (DTN). Our model quantitatively describes the phase diagram of the experimental compound - in particular the low-temperature magnetization curve and the critical temperature for magnetic Bose-Einstein condensation as a function of the field. Hence it provides fundamental insight into the nature of the Bose-glass phases appearing at low temperature close to the two critical fields for condensation. Br-doped bonds act as nucleation centers of magnetic quasiparticles in the low-field Bose glass, while at high fields the Br-doped bonds represent the localization centers of magnetic quasiholes. The quantitative understanding of Br-doped DTN opens the way to a detailed investigation of Bose-glass physics in quantum magnets.

Session X34 DCMP: Nanostructures: Assembly, Growth, and Characterization C141

2:30PM X34.00001 Vapor-Liquid-Solid Glancing Angle Deposition (VLS-GLAD): A New Approach to Fabricate Crystalline Semiconductor Nanowires , ARIF SINAN ALAGOZ, TANSEL KARABACAK, Department of Applied Science, University of Arkansas at Little Rock — Vapor-liquid-solid (VLS) method has become one of the few and most powerful bottom-up single crystal nanowire growth techniques. On the other hand, control of growth direction and crystal orientation of semiconductor nanowires stand as major issues in VLS technique. In order to overcome these challenges, we developed a new vapor-liquid-solid glancing angle deposition (VLS-GLAD) fabrication approach for the growth of semiconductor nanowire arrays with a controlled geometry and crystal orientations. VLS-GLAD is a physical vapor deposition nanowire fabrication approach based on selective deposition of nanowire source atoms onto metal catalyst nanoislands placed on a crystal wafer. In this technique, collimated obliquely incident flux of source atoms selectively deposit on catalyst islands by using "shadowing effect". Geometrical showing effect combined with conventional VLS growth mechanism leads to the growth of tilted crystalline semiconductor nanowire arrays. In this presentation, we show the morphological and structural properties of tilted single crystal Si and Ge nanowire arrays fabricated by utilizing a conventional thermal evaporation system for VLS-GLAD.

2:42PM X34.00002 LEEM and STM observations of Growth of Nanowires of Ag on Ge(110) and Surface Structural Phases of Ir on Ge(111)[1] , CORY MULLET, MARSHALL VAN ZIJLL, EMILIE HUFFMAN, SHIRLEY CHIANG, University of California, Davis — We have used both low energy electron microscopy (LEEM) and scanning tunneling microscopy (STM) to characterize the growth of silver on Ge(110) and iridium on Ge(111) as a function of coverage, deposition temperature, and annealing temperature. We observed 1D island growth along [-110] as Ag is deposited onto Ge(110) above 430 C. Island dimensions varied with deposition temperature. At 480 C, Ag islands are $\sim$100nm wide and 1-20 μm long for 9 ML coverage. Between 380 C and 430 C, we observed two novel low coverage phases, with the higher coverage phase completing at 0.12 ML. Ir deposited onto the Ge(111) c(2x8) above 400 C forms a $(\sqrt{3}x\sqrt{3})R30^o$ phase, with island size dependent upon substrate temperature during deposition. Deposition at 400-425 C produces Ir islands, which are 1-20 nm in diameter at 0.5 ML coverage. Island heights range from one to several atomic layers, and exhibit a unique growth mode with islands connected by "streamers" of Ir. We observed Stranski-Krastanov growth in LEEM at 670 C. Ir desorbs from Ge(111) at 870 C, beginning from areas of high step density.

2:54PM X34.00003 ABSTRACT WITHDRAWN –

3:06PM X34.00004 Alignment of Gold Nanorods in Thermoresponsive Hydrogels[1] , HEUNG-SHIK PARK, OLEG LAVRENTOVICH, Kent State University — The unique optoelectronic properties of the anisotropic metallic nanorods (NRs) are of great interest because of their potential applications in biomedical science, transformative optics and materials science. In order to utilize metallic NRs for the practical devices, the control of orientation and immobilization of NRs in bulk materials are essential. We report an experimental study of gold NR embedded in thermoresponsive gels which can align NRs by volume-contraction transition. When temperature increases, an NR hydrogel stripe experiences an abrupt shrinkage in two lateral (x,y) directions; in the third z-direction, the size remains fixed as the stripe is clamped. The shrunk stripes show high birefringence and anisotropic absorption associated with alignment of the NRs. The alignment of NRs in anisotropically shrunk hydrogels can be achieved also when one uses aggregates of side-by-side preassembled NRs rather than individual NRs. These aggregates can be transferred into a polymer hydrogel preserving their structural and optical features. The hydrogel stripes with preassembled NRs show optical anisotropy opposite to that one of stripes with isolated NRs.

[1]AFOSR FA9550-10-1-0527 and MURI FA9550-06-1-0337

3:18PM X34.00005 Programmable Nanofabrication of Nanoparticle Assemblies of arbitrarily Shapes on DNA Templates , MAURICIO PILO-PAIS, SARAH GOLDBERG, Duke University, ENRIQUE SAMANO, CNyN-UNAM, Ensenada, B.C., México, HENOK MEBRAHTU, THOMAS LABEAN, GLEB FINKELSTEIN, Duke University, GLEB FINKELSTEIN TEAM, THOMAS LABEAN TEAM — We present a method for producing metallic structures with nanoscale dimensions and programmable design. Rectangular "DNA origami" structures ($\sim$90x70nm) were modified to have uniquely coded binding sites and adsorbed onto silicon dioxide substrates. Gold nanoparticles functionalized with a complimentary DNA sequence were attached to these binding sites in a highly controllable fashion. The seed nanoparticles were then enlarged (and even fused, if desired) by a silver reduction chemistry. Using this method we constructed a variety of metallic structures, including parallel wires, H-shapes, and rings. Due to the flexibility of the design and the multiply parallel nature of the method, these structures may offer great promise for plasmonic applications.

3:30PM X34.00006 Controlling Nanostructure Self-assembly for Design of Three-dimensional Semiconductor Heterostructures[1] , SANTINO D. CARNEVALE, J. YANG, P.J. PHILLIPS, M.J. MILLS, R.C. MYERS, Dept. of Materials Science and Engineering, Ohio State University — We examine the control of vertical and coaxial growth in self-assembled GaN/AlN nanowires grown on Si (111) by plasma assisted molecular beam epitaxy. To grow nanowires vertically and not radially a two-step growth method is used. Nanowires are nucleated at low temperatures and grown vertically at high temperatures, allowing for independent control of density and height and constant radius. A second method is used to promote radial growth. GaN nanowire cores are formed, then growth temperature is reduced and growth continues. Vertically and coaxially oriented AlN/GaN heterostructures grown using these methods are presented. We discuss the structural and optical properties of these GaN/AlN quantum disk and core-shell heterostructures using scanning electron microscopy, scanning transmission electron microscopy, and temperature dependent photoluminescence measurements.

[1]Work supported by the Office of Naval Research.

3:42PM X34.00007 Preparation of monodisperse silicon nanocrystals through density-gradient unltracentrifugation in organic solvents[1] , JOSEPH B. MILLER, AUSTIN VAN SICKLE, SWATHI IYER, NDSU, REBECCA A. ANTHONY, UWE R. KORTSHAGEN, University of Minnesota, ERIK K. HOBBIE, NDSU — Monodisperse colloidal suspensions of ligand-coated silicon nanocrystals, synthesized through a nonthermal low-pressure plasma reaction, have been prepared through density-gradient ultracentrifugation in mixed organic solvents. Density-gradient profiles of mixed chloroform and m-xylene are used to tune and control the settling speed of the nanoparticles and hence optimize their transient separation by size along the depth of polyoxymethylene ultracentrifuge tubes. The mean size and polydispersity of the extracted fractions are characterized through photoluminescence spectroscopy and transmission electron microscopy, and the self-assembly of fractions into close-packed crystal lattices is achieved using an immiscible two-fluid evaporation scheme. The photophysical properties of the nanocrystal lattices are compared with those of the starting materials and suspensions, and the influence of atmospheric oxygen on the stability of the nanocrystal photoluminescence is measured.

[1]Supported by the DOE through DE-FG36-08GO88160

3:54PM X34.00008 Self-assembled Au Nanoparticle Arrays with Engineered Hot Spots for SERS , A. CHEN, U. WELP, V. VLASKO-VLASOV, Material Science Division, Argonne National Laboratory, A.E. DEPRINCE III, A. DEMORTIERE, A. JOSHI-IMRE, E.V. SHEVCHENKO, S.K. GRAY, Center for Nanoscale Materials, Argonne National Laboratory — We demonstrate a cost-effective bottom-up self-assembly of 80 nm Au nanoparticles (NPs) with controllable regular arrays of hot spots for high-fidelity and high-sensitivity sensor applications. The self-assembly of gold NPs is implemented using solvent evaporation techniques. By careful control of surface stabilizers on NPs and optimization of assembly conditions, we fabricated hcp arrays of NPs extended over more than 200 μm. Electromagnetic hot spots localized in the nanometer gaps between Au NPs are well defined and reproducible over large areas of the arrays. UV-Vis-NIR extinction spectra of our 2D plasmonic crystals exhibit unique resonances due to strong particle-particle interactions, in a good agreement with results of our finite-difference-time-domain (FDTD) simulations. We experimentally demonstrate large enhancements of both photoluminescence and surface enhanced Raman scatterings of 5nm CdSe quantum dots coated on 80nm Au NP arrays. High-resolution SEM imaging of quantum dots gave a precise estimate of their density and positions and allowed direct evaluation of the enhancement factors.

4:06PM X34.00009 Fine tuning nanoparticle spacing in freestanding membranes through ion and electron beams , PONGSAKORN KANJANABOOS, The University of Chicago, ALEXANDRA JOSHI-IMRE, XIAO-MIN LIN, Argonne National Laboratory, HEINRICH JAEGER, The University of Chicago — Freestanding membranes of ligated nanoparticles can be assembled in a one-step drying-mediated process. These 2D sheets have remarkable mechanical properties, in particular extreme bending flexibility coupled with effective Young's moduli in the range of 1-20GPa, depending on the nanoparticle and ligand types and sizes. We report on experiments in which used a focused Ga ion beam to strategically place cuts into freestanding monolayer membranes. Exposed to electron beams, the cuts expand and the membranes act as if additional strains were deposited. Given that the exposed membranes behave like strained elastic sheets, we can easily design various strain patterns. With calibration, the electron beam dose serves as a knob to fine-tune interparticle distances in these patterns.

4:18PM X34.00010 Mechanics of colloidal nanoparticle arrays , JIE YIN, MARKUS RETSCH, EDWIN L. THOMAS, MARY C. BOYCE, Massachusetts Institute of Technology, BOYCE TEAM, THOMAS TEAM — Hollow colloidal nanoparticles have become a focal point of studies for applications in drug delivery and nanostructured materials. The mechanical properties of individual nanoparticle and the collective behavior of colloidal nanoparticle arrays are of great importance. In this paper, the mechanics of colloidal arrays of hollow amorphous silica spherical nanoparticles during microindentation are explored. The study reveals that the consecutive contact process of nanoparticles during indentation results in highly nonlinear indentation load-displacement curves. The contacted nanoparticles successively become flattened and locally bend and buckle to form a localized dimple as the indentor encounters each particle. By using the contact mechanics model of single hollow particle, the indentation load-displacement formula is obtained for indentation on hollow spherical nanoparticle arrays and the Young's modulus of an individual particle is extracted from the measured load-displacement behavior of an array. The reduced Young's modulus is consistent with the measurement of single hollow amorphous silica nanoparticle by using AFM.

4:30PM X34.00011 Au/Fe nanoparticles prepared by multilayers annealing[1] , AIDA SERRANO, Institute for Ceramic and Glass- CSIC, OSCAR RODRIGUEZ DE LA FUENTE, Dpt. Material Physics - University Complutense at Madrid, MIGUEL ANGEL GARCIA, Institute for Ceramic and Glass- CSIC — Metallic nanoparticles supported onto a substrate can be obtained by thin film deposition and subsequent annealing. The stress relief after the thermal annealing due to the difference of thermal expansion coefficient between the metal and the substrate promotes hillock formation and subsequent hole nucleation, growth and percolation leading to the formation of nanoparticles layers. The nanoparticle size and inter-particle distance can be tuned by controlling the initial film thickness and the annealing time, temperature and atmosphere, providing a simple and low cost method to prepare NPs layers over large areas. The method has been successfully applied to obtain nanoparticles from a single metallic layer in the past. We report here the formation of complex nanoparticles ensembles by deposition and annealing of Au-Fe multilayers. The optical properties of gold nanoparticles (surface plasmon resonance absorption) and the magnetic properties of Fe/Fe oxide ones as well as cross-over effects are studied as a function of multilayers structure and annealing conditions.

4:42PM X34.00012 Effects of ligand binding strength and facet coverage on the morphology of nanocrystal superlattices[1] , CLIVE BEALING, RICHARD HENNIG, Cornell University — Nanocrystals (NCs) of lead-salt have been proposed for a number of photovoltaic applications. These NCs consist of an inorganic core, in the rock salt structure, whose surface is usually passivated by oleate ligands. The self-assembly of NCs from colloidal solutions into mesoscale superlattices provides a path to materials with tunable electronic, physical and chemical properties that are promising for applications. The self-assembly is controlled by the NC shape and by ligand-mediated interactions between NCs; to understand this, it is necessary to know the effect of the ligands on the surface energies, as well as the relative coverage of the different facets. Our density functional calculations of the binding energies of carboxylic acid-based ligands on PbSe and PbS show that the ligands exhibit a strong energetic preference to particular facets. The results suggest that the transformation of the NC superlattice structure from *fcc* to *bcc* in aged NC assemblies is caused by the preferential detachment of ligands from particular facets, leading to anisotropic ligand coverage. Combined with the experimental results, our calculations present a potential route to greater control over the morphology of the NC superlattice assembly.

4:54PM X34.00013 Scanning Tunneling Microscopy and Spectroscopy of Rare Earth-Monopnictide Nanostructures Embedded in a Semiconducting Matrix , JASON KAWASAKI, University of California Santa Barbara, RAINER TIMM, Lund University, TREVOR BUEHL, University of California Santa Barbara, EDVIN LUNDGREN, ANDERS MIKKELSEN, Lund University, ARTHUR GOSSARD, CHRIS PALMSTRØM, University of California Santa Barbara — The atomic and electronic structure of molecular beam epitaxy (MBE)-grown rare earth-monopnictide nanostructures embedded within a III-V semiconductor matrix are examined via scanning tunneling microscopy (STM) and spectroscopy (STS). We examine several systems, including ErSb nanoparticles embedded in GaSb, ScAs nanoparticles embedded in GaAs, and ErAs nanoparticles and nanorods embedded in GaAs. Tunneling current I(V) and differential conductance dI/dV spectra show that for both ErAs nanoparticles and nanorods the local density of states (LDOS) exhibits a sharp but finite minimum at the Fermi level, demonstrating that both the particles and rods are semimetallic and not semiconducting. This observation lies in contrast to previous models of quantum confinement in ErAs. We also use STS to measure the LDOS across the ErAs/GaAs interface and discuss the formation of interface states and band bending at the interface. Finally, we discuss possible changes in the LDOS with varying nanoparticle size and varying levels of doping in the semiconductor matrix.

5:06PM X34.00014 *Ab Initio* Studies of Si_mGe_n(m+n $\leq$ 5) Nanoclusters[1] , SARAH DUESMAN, ASOK RAY, University of Texas at Arlington — Electronic and geometric structure properties of Si_mGe_n(m+n $\leq$ 5) nanoclusters have been investigated using hybrid density functional B3LYP, 6-311G (3df, 3pd) basis set, and the GAUSSIAN 03 software. For the Si atom, the computed values of the ionization potential and electron affinity are 8.11 and 1.10eV, and for the Ge atom, the values are 7.90 and 1.14eV. The experimental values are 8.15, 1.39, 7.90, and 1.23eV, respectively. Various possible geometries have been spin-optimized to determine the global minimum for each nanocluster. We will present the electronic and geometric structures of the isomers of each nanocluster, including bond length, symmetry group, electronic state, binding energy, HOMO-LUMO gap, ionization potential, and electron affinity. In addition, the harmonic frequencies, fragmentation energies, average coordination number and Mulliken atomic charges will also be discussed for the ground states of the nanoclusters.

5:18PM X34.00015 Competition of Nonlinear Optical Properties in ZnO Nanoparticles , JIE LIN, ANTONIO LLOPIS, BENNY URBAN, University of North Texas, YASUHISA FUJITA, Shimane University, ARUP NEOGI, University of North Texas — ZnO nanoparticles have attracted increased attention due to its large exciton binding energy. Moreover it has enhanced nonlinear optical properties due to its noncentrosymmetric crystal structure which results in a second order nonlinearity. The presence of oxygen vacancy and modified surface states also yields third order nonlinearity such as two photon absorption which yield significant two-photon emission. However, the presence of high second order nonlinearity in a system can result in the retardation of the third order nonlinearity. We thereby present the relative efficiencies of the second and the third-order nonlinear processes in ZnO nanoparticle system. Using tunable femtosecond laser irradiation the recombination lifetime due to single and two-photon induced electron-hole recombination process has been studied. Our results show that the second harmonic generation (SHG) process compete with the two photon emission(TPE) process in the region 700nm—900nm. The TPE process is more efficient in 700 nm-740nm whereas the SHG process is more efficient from 745-900nm) region. We also observed the increase of the two photon emission with excited energy is caused by the increased life of its virtual state.

Thursday, March 24, 2011 2:30PM - 5:42PM –
Session X35 DCMP: Topological Insulators: Theory III C140

2:30PM X35.00001 Search for New Topological Insulators , HSIN LIN, Northeastern U., L.A. WRAY, S.-Y. XU, M.Z. HASAN, Princeton U., T. DAS, Y.J. WANG, R.S. MARKIEWICZ, ARUN BANSIL, Northeastern U. — Topological insulators (TIs) host a novel quantum phase of electrons which is characterized by topologically protected surface states originating from the effects of spin-orbit and time-reversal symmetries. While several families of TIs have already been found, the intense world-wide search for new classes of TIs continues unabated. This interest is driven by the need for materials with greater structural flexibility and tunability to enable viable applications in spintronics and quantum computing. We have used first-principles band theory computations in combination with angle-resolved photoemission experiments to successfully predict many new classes of topologically interesting materials, including Bi2Se3 series, the ternary half-Heusler compounds, thallium-based chalcogenides, and the Li2AgSb and $Ge_nBi_{2m}Te_{3m+n}$ families. [1-5] Work supported by the Office of Basic Energy Sciences, US DOE.

2:42PM X35.00002 Spin-texture of three-dimensional topological insulators: Bi_2Te_3, Bi_2Se_3 and Sb_2Te_3 , SUSMITA BASAK, HSIN LIN, Northeastern University, L.A. WRAY, S.-Y. XU, M.Z. HASAN, Princeton University, A. BANSIL, Northeastern University — We have investigated the nature of surface states in the Bi_2Te_3, Bi_2Se_3 and Sb_2Te_3 family of 3D topological insulators using first-principles calculation as well as $k \cdot p$ scheme [1]. Recent spin-resolved photoemission experiments suggest that electrons on the surface of a topological insulator behave as massless relativistic particles with an intrinsic angular momentum (spin) which is locked to their translational momentum [2,3]. We have computed the in-plane spin-textures of all three aforementioned compounds to demonstrate the 'spin-helical' nature of the 2D fermions. In addition, the spin must acquire a finite out-of-the-plane component to preserve the bulk topological invariant [1]. We study this quantity in particular since there are possibilities of observing new quantum effects. Work supported by the US DOE.

2:54PM X35.00003 First principles analysis of quantum transport in Bi2Se3 3D topological insulators , YONGHONG ZHAO, YIBIN HU, LEI LIU, YU ZHU, HONG GUO — By carrying out density functional theory (DFT) within the Keldysh nonequilibrium Green's function formalism (NEGF), we have investigated quantum transport properties of the Bi2Se3 topological insulator from atomistic first principles without any phenomenological parameters. Using the scattering states, our results vividly reveal the surface Dirac fermions and helical edge spin states in the momentum space. We have also determined the real-space distribution of the helical edge spin states which provide the penetration depth of the surface topological conducting channels into the bulk Bi2Se3 crystal. Our first principles calculations take into account the full non-collinear spin structure and spin-orbit interaction, the details of these technical advances within the NEGF-DFT quantum transport formalism will also be briefly discussed.

3:06PM X35.00004 Electrically controllable surface magnetism on the surface of topological insulator[1]

, JIA-JI ZHU, SKLSM, Institute of Semiconductors, Chinese Academy of Sciences, DAO-XIN YAO, School of Physics and Engineering, Sun Yat-sen University, SHOU-CHENG ZHANG, Department of Physics, Stanford University, KAI CHANG[2], SKLSM, Institute of Semiconductors, Chinese Academy of Sciences — We study theoretically the RKKY interaction between magnetic impurities on the surface of a three dimensional topological insulator, mediated by the massless and massive helical Dirac electrons. Exact analytical expression of RKKY interaction shows that the spin- spin interaction consists of the Heisenberg-like, Ising-like and Dzyaloshinskii-Moriya (DM)-like terms caused by the helicity of the topological surface states. It provides us a new way to realize various spin models, e.g., DM model, XXZ model and XZ model, and control surface magnetism by tuning the Fermi energy, and/or the distance between the two local spins. The gap opened by doped magnetic ions can lead to a short-range Bloembergen- Rowland interaction via the virtual interband interaction when the Fermi energy is located in the gap. The competition among the Heisenberg, Ising and DM terms leads to rich spin configurations and anomalous Hall effect on different lattices.

3:18PM X35.00005 Ordering of magnetic impurities and tunable electronic properties of topological insulators[1]

, DMYTRO PESIN, The University of Texas at Austin, Austin, TX, DMITRY ABANIN, Princeton University, Princeton, NJ — We study collective behavior of magnetic adatoms randomly distributed on the surface of a topological insulator. As a consequence of the spin-momentum locking on the surface, the RKKY- type interactions of two adatom spins depend on the direction of the vector connecting them, thus interactions of an ensemble of adatoms are frustrated. We show that at low temperatures the frustrated RKKY interactions give rise to two phases: an ordered ferromagnetic phase with spins pointing perpendicular to the surface, and a disordered spin-glass-like phase. The two phases are separated by a quantum phase transition driven by the magnetic exchange anisotropy. Ferromagnetic ordering occurs via a finite-temperature phase transition. The ordered phase breaks time-reversal symmetry spontaneously, driving the surface states into a gapped state, which exhibits an anomalous quantum Hall effect and provides a realization of the parity anomaly. We find that the magnetic ordering is suppressed by potential scattering. Our work indicates that controlled deposition of magnetic impurities provides a way to modify the electronic properties of topological insulators.

3:30PM X35.00006 Possible Strong Topological Insulator Phase in Li_2IrO_3

, HEUNG SIK KIM, CHOONG HYUN KIM, Department of Physics and Astronomy and Center for Strongly Correlated Materials Research, Seoul National University, Seoul 151-747, Korea, HOSUB JIN, Department of Physics and Astronomy, Northwestern University, Evanston, Illinois 60208, USA, JAEJUN YU, Department of Physics and Astronomy and Center for Strongly Correlated Materials Research, Seoul National University, Seoul 151-747, Korea — Recently Na_2IrO_3, a layered $5d$ transition metal oxide compound, was suggested to be a possible topological insulator (TI) based on the $j_{eff} = 1/2$ states induced by the strong spin-orbit coupling of Ir $5d$ states, but its realization has not been clarified yet. In search of the TI phase in transition metal oxides, we propose Li_2IrO_3 to be a candidate for the three-dimensional strong TI. By carrying out Wannier function analysis based on first-principles calculations, we constructed a low energy effective Hamiltonian, which leads to a three-dimensional extension of the Kane-Mele model with third-nearest-neighbor hopping within the Ir honeycomb layer and a significant inter-layer coupling. The nature of spin-orbit coupled states near the Fermi level depends on the change of the trigonal crystal field driven by the lattice deformations. A competition between the third next-nearest-neighbor hopping parameter and the trigonal crystal field is found to play a key role in determining the topological character of Li_2IrO_3.

3:42PM X35.00007 Half-Heusler Topological Insulators: A First-Principle Study with the Tran-Blaha Modified Becke-Johnson Density Functional[1]

, WANXIANG FENG, Institute of Physics, Chinese Academy of Sciences, DI XIAO, Oak Ridge National Lab, YING ZHANG, Beijing Normal University, China & University of Texas, YUGUI YAO, Institute of Physics, Chinese Academy of Sciences & University of Texas — We systematically investigate the topological band structures of half-Heusler compounds using first-principles calculations. The modified Becke-Johnson exchange potential together with local density approximation for the correlation potential (MBJLDA) has been used here to obtain accurate band inversion strength and band order. Our results show that a large number of half-Heusler compounds are candidates for three-dimensional topological insulators. The difference between band structures obtained using the local density approximation (LDA) and MBJLDA potential is also discussed.

3:54PM X35.00008 Toplogical electronic structure in half-Heusler topological insulators[1]

, WAEL AL-SAWAI, HSIN LIN, ROBERT MARKIEWICZ, Northeastern University, L. WRAY, Y. XIA, S. XU, M. HASAN, Princeton University, A. BANSIL, Northeastern University — We investigate the details of electronic band structure of a series of 28 ternary half-Heusler compounds MM′X of MgAgAs-type where M = (Lu, La, Sc, Y) and M′X=(PtBi, AuPb, PdBi, PtSb, AuSn, NiBi, PdSb). Our results show that the Z_2 topological order is due to a single band inversion at the Γ-point. Half-Heusler compounds can be either topologically nontrivial semimetals, nontrivial metals, or trivial insulators. Our analysis reveals a straightforward relationship between the band inversion strength (extent of deviation from the critical point), the atomic charge of constituents, and the lattice parameter. Our findings suggest a general method for identifying Z_2 topological insulators in nonmagnetic ternary compounds.

4:06PM X35.00009 Topological insulating behavior in conducting property of crystalline Ge-Sb-Te

, JEONGWOO KIM, JINWOONG KIM, SEUNG-HOON JHI, Physics, POSTECH — Phase-change random access memory (PRAM) is one of the most promising materials for data storage application. Especially, Ge-Sb-Te(GST) is considered as the best candidates for next generation nonvolatile memories because of the rapid and reversible cycles between the crystalline and amorphous structures. GeTe and $Sb_2Te_3$are the main components of GSTs, and have finite band gaps in the bulk phase. Sb_2Te_3 is topological insulator that has gapless edge states while maintaining bulk energy gap. These surface states are robust to external perturbations because they are protected by time-reversal symmetry. We report a discovery, through first-principles calculations, that crystalline GST phase-change materials exhibit the topological insulating property. Our calculations show that the materials become topological insulator or develop conducting surface-like interface states depending on the layer stacking sequence. It is shown that the conducting interface states originate from topological insulating Sb_2Te_3 layers in GSTs and can be crucial to the electronic property of the compounds. These interface states are found to be quite resilient to atomic disorders but sensitive to the uniaxial strains. We presented the mechanisms that destroy the topological insulating order in GSTs and investigated the role of Ge migration that is believed to be responsible for the amorphorization of GSTs.

4:18PM X35.00010 Ab initio study of topological order induced by symmetry breaking in PbTe , JINWOONG KIM, Department of Physics, POSTECH, SEUNG-HOON JHI, Department of Physics and Advanced Materials Science Division, POSTECH — Topological insulator (TI) is a new class of materials that have an energy gap in bulk phase but contain linear and chiral band dispersions on their surface. The topological insulating order can be initiated by parity inversion in time-reversal symmetric momenta. We studied the topological insulating properties of PbTe under uniaxial strain using first-principles methods. PbTe is a narrow-gap semiconductor with trivial topological insulating order. While it is known to have band inversion under pressure at a time-reversal symmetric k-point, the degeneracy at the k-point prevents the overall parity inversion which is needed to induce the TI order. In this presentation, we show that uniaxial strain can break the symmetry and thus induce topologically nontrivial order in PbTe.

4:30PM X35.00011 Electronic structure of the side surface of Bi_2Se_3[1] , CHANG-YOUN MOON, JINHEE HAN, HYUNGJUN LEE, HYOUNG JOON CHOI, Department of Physics and IPAP, Yonsei University, Korea — We investigate the electronic band structure of a side surface geometry, other than the conventional [111] surface, of the topological insulator Bi_2Se_3 using the first-principles pseudopotential calculations. As Bi_2Se_3 is known to be a strong topological insulator, it is expected that an arbitrary surface would have the topological surface state characterized by Dirac-cone-like band dispersion and spin-momentum coupling. Here we indeed obtain surface states with linear band dispersion around the Gamma point, but with a strong anisotropy with different group velocities along different k-directions. Low energy effective hamiltonian is proposed, and physical implications of the anisotropic Dirac fermions are also discussed.

4:42PM X35.00012 Spatial characters of metallic surface states of topological insulators , JINHEE HAN, HYUNGJUN LEE, HYOUNG JOON CHOI, Department of Physics and IPAP, Yonsei University — We study the electronic structure of metallic surface states in Bi_2Se_3, Bi_2Te_3, and Sb_2Te_3 using an ab-initio pseudopotential density-functional method. We implemented the spin-orbit interaction into the SIESTA in a form of additional fully non-local projectors. For surface states on (001) surface, we used a supercell containing 10 quintuple layers. We obtained bulk and surface electronic structures of topological insulators Bi_2Se_3, Bi_2Te_3, and Sb_2Te_3, which are close to previous theoretical results and consistent with Dirac-cone band dispersions measured by angle-resolved photoemission spectroscopy. Then, we analyzed the wavefunctions of the metallic surface states near the Fermi level to find out spatial distributions of the surface-state wavefunctions, which turn out to be localized in the surface region with a typical spread of about 2 quintuple layers, and the shapes of the wavefunctions around Bi (or Sb) atoms close to the surface. This work was supported by the NRF of Korea (Grant No. 2009-0081204) and KISTI Supercomputing Center (Project No. KSC-2008-S02-0004).

4:54PM X35.00013 Chern-Simons orbital magnetoelectric coupling in generic insulators , SINISA COH, DAVID VANDERBILT, Rutgers University, ANDREI MALASHEVICH, UC Berkeley, IVO SOUZA, Centro de Fisica de Materiales, San Sebastian — The isotropic Chern-Simons coupling θ is a component of the orbital contribution to the magnetoelectric coupling.[1] In a generic insulator it can have any value, while it must be exactly π in a strong Z_2 topological insulator. The results of our first-principles density-functional calculations for the ordinary magnetoelectrics Cr_2O_3, $BiFeO_3$ and $GdAlO_3$ confirm that the Chern-Simons contribution is quite small in these materials.[2] We discuss various strategies for finding insulators for which θ is large but not equal to π. For example, we show that if the spatial inversion and time-reversal symmetries of the Z_2 topological insulator Bi_2Se_3 are broken by hand, large induced changes appear in the Chern-Simons magnetoelectric coupling. We also perform an analysis based on space-group representation theory to determine the simplest possible magnetic structures which allow for a non-zero and possibly large value of θ.

5:06PM X35.00014 Theoretical prediction of new topological insulators in filled skutterudites , BINGHAI YAN, Department of Physics, McCullough Building, Stanford University, Stanford, CA 94305-4045, LUKAS MUECHLER, Institut fuer Anorganische Chemie und Analytische Chemie, Johannes Gutenberg - Universtitaet, 55099 Mainz, Germany, XIAO-LIANG QI, Department of Physics, McCullough Building, Stanford University, Stanford, CA 94305-4045, CLAUDIA FELSER, Institut fuer Anorganische Chemie und Analytische Chemie, Johannes Gutenberg - Universtitaet, 55099 Mainz, Germany, SHOU-CHENG ZHANG, Department of Physics, McCullough Building, Stanford University, Stanford, CA 94305-4045 — We have reported a unique class of topological insulators, filled skutterudite (FS) compounds, using ab initio calculations. We find that several FSs are not only two-dimensional topological insulators as quantum wells like HgTe, but also three-dimensional topological Kondo insulators. Different from previously reported topological insulators, they have unique band inversion feature in band structures. Their advantages are discussed to realize superconductivity proximity and other topological phenomena.

5:18PM X35.00015 Three-Dimensional Topological Insulators in I-III-VI_2 and II-IV-V_2 Chalcopyrite Semiconductors[1] , DI XIAO, Oak Ridge National Lab, WANXIANG FENG, JUN DING, YUGUI YAO, Institute of Physics, Chinese Academy of Sciences — Using first-principles calculations, we investigate the band topology of the ternary chalcopyrite family. Our method is based on the adiabatic continuity of the Hamiltonian combined with direct calculation of the Z2 topological invariants in inversion-symmetry breaking systems. We show that a large number of these compounds are candidates for three-dimensional topological insulators. Moreover, The topological order can be tuned and controlled by lattice strain. The excellent physical properties of these compounds make them an appealing platform for novel quantum phenomena.

5:30PM X35.00016 Edge states and the bulk-boundary correspondence in Dirac Hamiltonians , VASUDHA SHIVAMOGGI, ROGER MONG, University of California, Berkeley — We present an analytic prescription for computing the edge dispersion $E(k)$ of a tight-binding Dirac Hamiltonian terminated at an abrupt crystalline edge. Specifically, we consider translationally invariant Dirac Hamiltonians with nearest-layer interaction. The result is a geometric formula that relates the existence of surface states as well as their energy dispersion to properties of the bulk Hamiltonian. We give examples of how the formula can be used to find the edge state dispersion in various topologically ordered systems. We further prove the bulk-boundary correspondence between the Chern number and the chiral edge modes for quantum Hall systems within the class of Hamiltonians studied here. Our results can be extended to the case of continuum theories which are quadratic in momentum, as well as other symmetry classes.

Thursday, March 24, 2011 2:30PM - 5:30PM –
Session X36 DCMP: Graphene: Quantum Hall Effect C142

2:30PM X36.00001 Graphene in a periodically alternating magnetic field: an unusual quantization of the anomalous Hall effect , PATRICK BRUNO, ESRF, Grenoble, France, MATHIEU TAILLEFUMIER, University of Oslo, Norway, VITALII K. DUGAEV, Rzeszow University of Technology, Poland, BENJAMIN CANALS, CLAUDINE LACROIX, Institut Néel, CNRS, Grenoble, France — We study the energy spectrum and electronic properties of graphene in a periodic magnetic field of zero average with a symmetry of triangular lattice. The periodic field leads to formation of a set of minibands separated by the gaps, which can be manipulated by external field. The Berry phase, related to the motion of electrons in k space, and the corresponding Chern numbers characterizing topology of the energy bands are calculated analytically and numerically. In this connection, we discuss the anomalous Hall effect in the insulator state, when the Fermi level is located in the minigap. The results of calculations show that in the model of gapless Dirac spectrum of graphene the anomalous Hall effect can be treated as a sum of fractional quantum numbers, related to the nonequivalent Dirac points.

2:42PM X36.00002 Quantum Hall Edge States in Bilayer Graphene Ribbons[1] , HERBERT FERTIG, Indiana University, VICTORIA MAZO, EFRAT SHIMSHONI, Bar-Ilan University — We study the low energy edge states of bilayer graphene ribbons subject to a strong perpendicular magnetic field B, and show that they can be described within a continuum model (the Dirac equation). We are mainly interested in investigating the energy- band structure of ribbons with a zigzag termination. At the zero Landau Level there are eight degenerate bands, whose degeneracy can be broken and controlled by an external inter- layer voltage bias V. This leads to the opening of a gap in the bulk. On the edges, due to a mixture of hole- and particle- like bands (from the same valley), an avoided crossing occurs which can be understood within a perturbative expansion in the inter-layer hopping. On the other hand, edge states from different valleys are protected from mixing by a long-range disorder potential. Hence, hole- and particle-like states can cross without mixing, and the system has properties of a topological insulator. In the presence of interactions, the rich behavior of crossing single-electron edge states may lead to a variety of collective edge-modes, whose properties dominate the transport behavior of this system.

[1]US-Israel Binational Science Foundation

2:54PM X36.00003 Hofstadter's Fractal Energy Spectrum in Twisted Bilayer Graphene[1] , ZHENGFEI WANG, School of Physics, Georgia Institute of Technology. Department of Materials Science and Engineering, University of Utah, FENG LIU, Department of Materials Science and Engineering, University of Utah, M.Y. CHOU, School of Physics, Georgia Institute of Technology — Hofstadter butterfly, the fractal spectrum of 2D lattice electrons in a magnetic field, has been studied theoretically for a few prototypical systems. However, due to the small unit cell in traditional materials, it is difficult to directly observe such a structure in the experiment. In this work we demonstrate that the Hofstadter butterfly structure can be detected in twisted bilayer graphene with a reasonable strength of the magnetic field. Based on the recursive tight-binding method, we have systematically studied the landau level dependence on the magnetic field as a function of the twist angle, with the underlying electronic structure ranging from the parabolic dispersion of Bernal bilayer graphene to the linear dispersion of decoupled graphene layers. The signature of transition is characterized by some low-lying landau levels in slightly twisted bilayer graphene, which are related to the flat bands induced in the layer decoupling process.

3:06PM X36.00004 Multi-Domain Model of Bilayer Graphene with Broken Time Reversal Symmetry[1] , GILAD BEN-SHACH, AMIR YACOBY, BERTRAND I. HALPERIN, Harvard University — Recent experiments suggest strange new states for bilayer graphene at zero electric and magnetic fields [1]. We consider recent models for the ground state of bilayer graphene with interactions [2,3]. These models predict domains with non-zero local Hall conductance but an expected overall average Hall conductance of $\sigma_{xy} = 0$, and should exhibit broken time reversal symmetry. We examine theoretical models for random four-probe measurements for various domain geometries in bilayer graphene at zero electric and magnetic fields. We find non-zero Hall conductance of magnitude dependent on domain geometry and network structure.

3:18PM X36.00005 Fractional quantum Hall effect in graphene: multicomponent states and tunable interactions[1] , ZLATKO PAPIC, Department of Electrical Engineering, Princeton University, DMITRY ABANIN, Princeton Center for Theoretical Science, Princeton University, NICOLAS REGNAULT, Laboratoire Pierre Aigrain, Ecole Normale Superieure, CNRS, MARK GOERBIG, Laboratoire de Physique des Solides, CNRS, Universite Paris-Sud, Orsay — We study the fractional quantum Hall (FQH) states in graphene using exact diagonalization and taking into account the multicomponent degrees of freedom and the possibility of tuning the interaction potential. The recently observed graphene FQH state at a filling factor $\nu_G = 1/3$ is found to be adiabatically connected to the $1/3$ Laughlin state in the upper spin branch, with SU(2) valley-isospin ferromagnetic ordering and a completely filled lower spin branch. At the experimentally relevant values of the Zeeman field, however, the state possesses characteristic low-energy spin-flip excitations (different from the magneto-roton expected at large Zeeman fields) that may be unveiled in inelastic light-scattering experiments. We also discuss the possibility of realizing other Abelian and non-Abelian FQH states in graphene by modifying the effective interaction potential using a combination of insulating substrates.

[1]This work was supported in part by DOE grant DE-SC 000 2140.

3:30PM X36.00006 Decomposition into half-integer quantum Hall numbers from Dirac cones in a graphene-related lattice model , HARUKI WATANABE, Department of Physics, University of Tokyo, HATSUGAI YASUHIRO, Institute of Physics, University of Tsukuba, HIDEO AOKI, Department of Physics, University of Tokyo — In field theory it is well-known that the Hall conductivity of a massive Dirac particle is equal to $1/2\ \mathrm{sgn}\,(m)$ (in units of $-e^2/h$) when the Fermi energy lies in the mass gap. By contrast, any lattice model must have an integer quantum Hall number when we consider noninteracting electrons, as dictated by the TKNN formula arising from the periodicity in the Brillouin zone. Usually, this is understood to be consistent with the fact that in lattice models such as graphene honeycomb lattice Dirac dispersions tend to appear in pairs (as dictated by the Nielsen-Ninomiya theorem for chiral cases), but this does obscure a half-integer contribution from each Dirac cone. To resolve this, here we show that it is possible to identify half-integer contributions by constructing a lattice model with systematically shifted Dirac points [1]. Edge-state spectrum also confirms this.

[1] H. Watanabe, Y. Hatsugai and H. Aoki, arXiv:1008.0130, to appear in Phys. Rev. B (R).

3:42PM X36.00007 Lattice Theory of Pseudospin Ferromagnetism in Bilayer Graphene: Competing Orders and Interaction Induced Quantum Hall States , JEIL JUNG, FAN ZHANG, ALLAN MACDONALD, Department of Physics, University of Texas at Austin — In mean-field-theory bilayer graphene's massive Dirac fermion model has a family of broken inversion symmetry ground states with charge gaps and spin-valley flavor dependent spontaneous charge transfers between layers. We use a lattice Hartree-Fock model to explore some of the physics which controls whether or not this type of broken symmetry state, which can be viewed as a pseudospin ferromagnet, occurs in nature. We find that inversion symmetry is still broken in the lattice model and estimate that transferred areal densities are $\sim 10^{-5}$ per carbon atom, that the associated energy gaps are $\sim 10^{-2}$eV, the ordering condensation energies are $\sim 10^{-7}eV$ per carbon atom and the energy differences between competing orders at the neutrality point to be of the order of $\sim 10^{-9}eV$ per carbon atom. We explore the quantum phase transitions between different states induced by external magnetic fields and by externally controlled electric potential differences between the layers. We find, in particular, that in an external magnetic field coupling to spontaneous orbital moments favors broken time-reversal-symmetry states that have spontaneous quantized anomalous Hall effects. Our theory predicts a non monotonic behavior of the band gap as a function of electric field in qualitative agreement with recent experiments.

3:54PM X36.00008 $\nu = 0$ quantum Hall ferromagnet in a monolayer graphene: bulk ground states and charged edge excitations[1] , MAXIM KHARITONOV, Department of Physics and Astronomy, Rutgers University — The $\nu = 0$ quantum Hall state in a defect-free graphene sample is studied within the framework of the quantum Hall ferromagnetism. Starting from the low-energy electron Hamiltonian, in which all allowed by symmetry sublattice- and valley-anisotropic terms due to the Coulomb and leading electron-phonon interactions are taken into account, the energy functional for the quantum Hall ferromagnet is derived. Paying special attention to the signs of anisotropies, we find that the anisotropy due to the repulsive Coulomb interactions always favors the spin-polarized pseudospin-singlet state. On the other hand, the anisotropy due to the phonon-mediated attractive interactions favors the XY pseudospin-polarized spin-singlet state. It is then demonstrated that, in the case of the XY pseudospin bulk order and armchair boundary, the Skyrmion-type charged excitations are gapped at the edge, which makes the whole sample insulating. These findings suggest that the experimentally observed insulating $\nu = 0$ state is an XY pseudospin ferromagnet favored by electron-phonon interactions.

4:06PM X36.00009 Disorder-induced magnetooscillations in bilayer graphene at high bias , MIKHAIL RAIKH, VAGHARSH MKHITARYAN, Department of Physics and Astronomy, University of Utah, Salt Lake City, UT 84112, USA — Energy spectrum of biased bilayer graphene near the bottom has a "Mexican-hat"-like shape. For the Fermi level within the Mexican hat we demonstrate that, apart from conventional magnetooscillations which vanish with temperature, there are additional magnetooscillations of capacitance and conductance which are weakly sensitive to temperature. These oscillations are also insensitive to a long-range disorder. Their period in magnetic field scales with bias, V, as V^2. The origin of these oscillations is the disorder-induced scattering between electron-like and hole-like Fermi-surfaces, specific for Mexican hat. At low temperatures, oscillations transform into quantum Hall plateaus in σ_{xy}. We predict that evolution of σ_{xy} with magnetic field is highly non-trivial. This is because the contributions to σ_{xy} from electron-like and hole-like Landau levels have opposite signs.

4:18PM X36.00010 Dynamical scaling analysis of the optical Hall conductivity in the quantum Hall regime , TAKAHIRO MORIMOTO, University of Tokyo, YSHAI AVISHAI, Ben Gurion University, HIDEO AOKI, University of Tokyo — We study the optical Hall conductivity $\sigma_{xy}(\varepsilon_F, \omega)$ in two-dimensional electron gas (2DEG) and in graphene in the quantum Hall regime, which is measurable by the Faraday rotation. It was previously demonstrated that both conductivities retain their plateau structure at finite frequency, up to the optical frequency regime. Physically, the robustness of the plateau structure in the ac optical regime can be attributed to the localization of electrons in the QHE. To quantify this picture, a dynamical scaling analysis of $\sigma_{xy}(\varepsilon_F, \omega)$ is performed for the $n = 0$ Landau level in graphene as well as for the conventional quantum Hall system. This analysis examines whether the system size dependence of $\sigma_{xy}(\varepsilon_F, \omega)$ can be captured with a universal scaling function that involves the localization exponent ν and the dynamic critical exponents z. Based on exact diagonalization of these systems with potential disorder, employing the Kubo formula, it is shown that $\sigma_{xy}(\varepsilon_F, \omega)$ obeys a well-defined dynamical scaling behavior. For both systems, the static exponents ν are similar and the dynamical exponents z are found to be ≈ 2. Our quantitative analysis indicates that the plateau structure in the ac Hall conductivity should be robust and experimentally testable in the THz regime.

4:30PM X36.00011 Disorder Effect of Quantum Anomalous Hall effect in Graphene , ZHENHUA QIAO, SHENGYUAN A. YANG, WANG-KONG TSE, The University of Texas at Austin, YUGUI YAO, Institue of Physics, Chinese Academy of Sciences, China, JIAN WANG, The University of Hong Kong, QIAN NIU, The University of Texas at Austin — We investigate the possibility of realizing quantum anomalous Hall effect in graphene. We show that a bulk energy gap can be opened in the presence of both Rashba spin-orbit coupling and an exchange field. We calculate the Berry curvature distribution and find a nonzero Chern number for the valence bands and demonstrate the existence of gapless edge states. Inspired by this finding, we also study, by first-principles method, a concrete example of graphene with Fe atoms adsorbed on top, obtaining the same result. We further study the disorder effect of this quantum anomalous Hall effect and show how this state is localized in the presence of strong disorders.

4:42PM X36.00012 Multiferroïc-like behavior in the quantum Hall ferromagnetic states of a graphene bilayer , RENE COTE, JULES LAMBERT, Universite de Sherbrooke — In a quantizing magnetic field, a graphene bilayer has an octet of degenerate states in the Landau level $N = 0$. An electron in this level must be described by three quantum numbers: its spin, its valley index K or K' and an orbital quantum number $n = 0, 1$. In the Hartree-Fock approximation, the ground states of the graphene bilayer at integer filling factors $\nu \in [-3, 4]$ can be described as different kinds of quantum Hall ferromagnets (QHF's) with finite interlayer, inter- orbital, or inter-spin coherence. In this talk, we present the phase diagram of the two-dimensional electron gas (2DEG) in $N = 0$ when the filling factor or a finite interlayer voltage, Δ_B is varied. A finite density of $electric$ dipoles is either spontaneously present in the QHF phases with inter-orbital coherence or can be generated by applying an external electric field in the plane of the layers. We show that by changing the strength of this electric field, and so the coupling with the electric dipoles, it is possible to control the degree of $magnetic$ polarisation of the 2DEG.

4:54PM X36.00013 Longitudinal Conductivity of Bilayer Graphene in the Integer Quantum Hall Regime , ROHIT HEGDE, ALLAN MACDONALD, University of Texas at Austin — We investigate the frequency dependent conductivity of disordered bilayer graphene near neutral filling, in a strong magnetic field. Absent Zeeman coupling, and with two independent valleys, a graphene bilayer's lowest Landau level is eightfold-degenerate, comprising two Landau orbitals of equal energy. Its spectral properties are altered by an inter-layer bias potential, which can open a gap between the constituent orbitals. We establish the dependence of the one and two-particle disorder-averaged Greens' functions on inter-layer bias, and show that the longitudinal conductivity exhibits the signature of disorder-induced Landau orbital mixing.

5:06PM X36.00014 Transverse Thermoelectric Conductivity of Bi-layer graphene in quantum Hall Regime[1] , WEI-LI LEE, CHANG-RAN WANG, WEN-SEN LU, Institute of Physics, Academia Sinica, INSTITUTE OF PHYSICS, ACADEMIA SINICA TEAM — We performed electric and thermoelectric transport measurements of bilayer graphene in a magnetic field up to 15 Tesla. The transverse thermoelectric conductivity α_{xy}, determined from four transport coefficients, attains a peak value of $\alpha_{xy,peak}$ whenever chemical potential lies in the center of a Landau level. The temperature dependence of $\alpha_{xy,peak}$ is dictated by the disorder width W_L. For $k_BT/W_L \leq 0.2$, $\alpha_{xy,peak}$ is nominally linear in temperature, which gives $\alpha_{xy,peak}/T = 0.19 \pm 0.03 nA/K^2$ independent of the magnetic field, temperature and Landau Level index. At $k_BT/W_L \geq 0.5$, $\alpha_{xy,peak}$ saturates to a value close to the predicted universal value of $4 \times (\ln 2) k_B e/h$ according to the theory of Girvin and Jonson. We remark that an anomaly is found in α_{xy} near the charge neutral point, similar to that in single-layer graphene.

5:18PM X36.00015 Interface Landau levels in graphene monolayer-bilayer junction , MIKITO KOSHINO, Department of Physics, Tohoku University, TAKESHI NAKANISHI, Nanotube Research Center, AIST, TSUNEYA ANDO, Department of Physics, Tokyo Institute of Technology — Electronic structure of graphene monolayer-bilayer junction in a magnetic field is studied within an effective-mass approximation. The energy spectrum is characterized by interface Landau levels, i.e., the locally flat bands appearing near the boundary region, resulting in a series of characteristic peaks in the local density of states. Their energies are independent of boundary types such as zigzag or armchair. In the atomic scale, the local density of states shows a Kekulé pattern due to the valley mixing in the armchair boundary, while does not in the zigzag boundary.

Session X37 DMP: Focus Session: Graphene Structure, Dopants, and Defects: Magnetism and Nanoribbons C146

2:30PM X37.00001 Oxygen- and Sulfur- driven Ferromagnetism in Graphitic Fragments: Ab-Initio Study , IVAN NAUMOV, Hewlett-Packard Laboratories, YAKOV KOPELEVICH, Instituto de Física "Gleb Wataghin," Universidade Estadual de Campinas, UNICAMP 13083-970, Campinas, São Paulo, Brasil, ALEXANDER BRATKOVSKY, Hewlett-Packard Laboratories, HEWLETT-PACKARD LABORATORIES COLLABORATION — We study the origins of high-temperature ferromagnetic behavior in graphite by means of unbiased ab-initio calculations and compare them with our data. The experimental results show that oxygen/sulfur-induced edges of graphitic fragments (via unzipping effect) play an essential role in this phenomenon, and that the finite magnetic moment appears if edges in a graphitic ribbon are occupied asymmetrically by either oxygen or sulphur. In particular, our ab-initio calculations performed within the LDA and GGA approximations showed that in the case of pure graphene ribbon, its zig-zag edge carbon atoms carry large magnetic moment ($\sim 1\ \mu_B$/C). In an oxidized or sulfurized graphene, however, the magnetic moment at the edge with absorbed atoms gets considerably reduced, leading to effective ferromagnetic (more precisely, ferri-magnetic) behavior of the sample.

2:42PM X37.00002 Defect Induced Resonances and Magnetic Patterns in Graphene , YI CHEN CHANG, Department of Physics and Astronomy, University of southern California — We investergate the effects of point and line defects in monolayer graphene was investigated within the framework of the Hubbard model, using a self-consistent mean field theory. These defects are found to induce characteristic patterns into the electronic density of states and cause non-uniform distributions of magnetic moments in the vicinity of the impurity sites. Specifically, defect induced resonance bound states in the local density of states are observed at energies close to the Dirac points. The magnitudes of the frequencies of these resonance states are shown to decrease with the strength of the scattering potential, whereas their amplitudes decay algebraically with increasing distance from the defect. Furthermore, non-trivial impurity induced magnetic patterns are observed in the presence of line defects: zigzag line defects are found to introduce stronger-amplitude magnetic patterns than single line defect and armchair line defects. When the scattering strength of these topological defects is increased, the induced patterns of magnetic moments become more strongly localized.

2:54PM X37.00003 Theory of Magnetic Edge States in Chiral Graphene Nanoribbons , RODRIGO CAPAZ, Instituto de Fisica, Universidade Federal do Rio de Janeiro, OLEG YAZYEV, STEVEN LOUIE, Department of Physics, U. C. Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory — Using a model Hamiltonian approach including electron Coulomb interactions, we systematically investigate the electronic structure and magnetic properties of chiral graphene nanoribbons. We show that the presence of magnetic edge states is an intrinsic feature of any smooth graphene nanoribbons with chiral edges, and discover a number of structure-property relations. Specifically, we describe how the edge-state energy gap, zone-boundary edge-state energy splitting, and magnetic moment per edge length depend on the nanoribbon width and chiral angle. The role of environmental screening effects is also studied. Our results address a recent experimental observation of signatures of magnetic ordering at smooth edges of chiral graphene nanoribbons and provide an avenue towards tuning their properties via the structural and environmental degrees of freedom. This work was supported by National Science Foundation Grant No. DMR10-1006184, the U.S. Department of Energy under Contract No. DE-AC02-05CH11231 and the ONR MURI program. RBC acknowledges financial support from Brazilian agencies CNPq, FAPERJ and INCT-Nanomateriais de Carbono.

3:06PM X37.00004 Spin-orbit interactions in graphene nanoribbons : Effects of the edge profile , JUN-WON RHIM, KYUNGSUN MOON, Yonsei University, CONDENSED MATTER THEORY TEAM — In graphene, it has been shown by Kane and Mele that the spin orbit coupling (SOC) connects the Dirac particles to the low- lying p_x and p_y orbitals so that the quantum spin Hall effect(QSHE) arises at the edges of the graphene. Their theory has drawn considerable attention as a realization of Haldane's idea of quantum Hall effect without magnetic field and as a trigger for the surging field of topological insulator. In the work, we study the band structure of the zigzag nanoribbons with the spin-orbit interaction and argue that the role of graphene edge should be considered more carefully since the realization of the QSHE is found to be largely dependent on the edge profile such as the kinds of molecules passivated. When the edge p_x, p_y and s orbitals are dangling without any passivation, the Dirac states at the edges seem to be no longer chiral for each spin species and the QSHE is not guaranteed to occur. We notice that upon the hydrogen passivation at the edges, the spin filtered chiral edge states become available. We will explain that these are due to the interaction between π-edges states and σ-edge states. The similar calculations are also performed for the armchair nanoribbons and compared with those of zigzag nanoribbons.

3:18PM X37.00005 Quantum Monte Carlo Study of Edge Magnetism in Nanoribbons of Graphene , Z.Y. MENG, Institut für Theoretische Physik III, Universität Stuttgart, H. FELDNER, IPCMS Université de Strasbourg France, Institut für Theoretische Physik, Georg-August-Universität Göttingen, T.C. LANG, Institut für Theoretische Physik und Astrophysik, Universität Würzburg, S. WESSEL, Institut für Theoretische Physik III, Universität Stuttgart, A. HONECKER, Institut für Theoretische Physik, Georg-August-Universität Göttingen, F. ASSAAD, Institut für Theoretische Physik und Astrophysik, Universität Würzburg — We study the electronic and magnetic properties of graphene nanoribbons, employing projective quantum Monte Carlo simulations within the Hubbard model description of electrons in graphene. We also compare our numerical results to a self-consistent mean field approximation in the weak coupling regime. Motivated by recent STM experiments about electronic resonance around atomic vacancies on multilayer graphene and graphene nanoisland, we in particular examine the local density of states throughout the sample. From this, we verify that interacting zig-zag ribbons develop an insulating ground state with a finite single particle gap from the localized edge modes observed in the non-interacting limit. In addition, we observe a drastic increase of the spin-spin correlation length along the zig-zag edge with the ribbon width. Effectively, on our finite samples ferromagnetic edges appear already for moderately wide zig-zag ribbons. This ferromagnetism is accompanied by an essentially gapless edge magnon mode, that we identify in the spin excitation spectrum.

3:30PM X37.00006 First principles study of edge effects in electronic structures of graphene nanoflakes and nanoribbons , CHENGBO HAN, WENCHANG LU, JERRY BERNHOLC, North Carolina State University, Raleigh, NC, CENTER FOR HIGH PERFORMANCE SIMULATION (CHIPS) TEAM — Graphene is a promising material for future nanoelectronics. Understanding of the edge effects on the electronic structure of graphene nanoflakes and nanoribbons is important for its nanoscale applications. Using the real space multigrid method within density functional theory, we systematically simulate STM images of nanoflakes and nanoribbons with both zigzag and armchair edges. Our results explain several STM patterns seen in experiments [1], such as triangular and hexagonal lattices for different shapes of flakes. We also find that localization of edge states in zigzag flakes depends on the interior angle between two edges. Furthermore, we show that the influence of Si(001)-2x1-H substrate on the local density of states of graphene nanoflakes is not significant when the graphene layer is 0.3 nm above the substrate.

3:42PM X37.00007 Spin states in graphene quantum dots , KLAUS ENSSLIN, ETH Zurich — Graphene quantum dots [1,2], douple dots [3], rings [4] and nanoribbons [5] have been fabricated by electron beam lithography and dry etching. The orbital [1] properties of graphene quantum dots have been investigated in perpendicular magnetic fields and the details of the electron-hole crossover in graphene leads to a situation where electron (hole) states move down (up) in magnetic field opposite to what has been observed in standard semiconductor based quantum dots. Graphene quantum dots are thought to be good candidates for spin-based quantum information processing since spin-orbit interactions and hyperfine coupling are both expected to be weak. We investigated graphene quantum dots in the single-level transport regime in in-plane magnetic fields where orbital effects are expected to have a minor effect [6]. The g-factor is found to be $g \approx 2$ and the spin filling sequence of orbital levels can be understood in view of the strength of the exchange interaction which is independent of carrier density in graphene.

4:18PM X37.00008 Complex edge effects in graphene nanoribbons due to hydrogenation[1] , BIPLAB SANYAL, Associate Professor, Uppsala University, Sweden, SUMANTA BHANDARY, Ph.D. student, Uppsala University, Sweden, MIKHAIL KATSNELSON, Professor, Radboud University Nijmegen, The Netherlands, OLLE ERIKSSON, Professor, Uppsala University, Sweden — We have performed density-functional calculations as well as employed a tight-binding theory, to study the effect of hydrogenation of zigzag graphene nanoribbons (ZGNR). We show that each edge C atom bonded with 2 H atoms open up a gap and magnetism collapses for small widths of the nanoribbon. However, a re-entrant magnetism accompanied by a metallic electronic structure is observed from eight rows and thicker nanoribbons. The electronic structure and magnetic state are quite complex for this type of termination, with sp^3 bonded edge atoms being nonmagnetic whereas the nearest neighboring atoms are metallic and magnetic. We have also evaluated the phase stability of several thicknesses of ZGNR and demonstrate that sp^3 bonded edge atoms with 2 H atoms at the edge can be stabilized over 1 H atom terminated edge at high temperatures and pressures.

4:30PM X37.00009 Magnetism in bulk and finite size graphene multilayers and its effect on the band gaps[1] , BHAGAWAN SAHU, HONGKI MIN, SANJAY BANERJEE, ALLAN MACDONALD, University of Texas at Austin — In this talk, we will address the edge state magnetism and the resulting modulation of band gaps induced by quantum confinements in multilayer graphene ribbons and flakes. The magnetism arising from random point defects such as vacancies in bulk graphene layers will also be presented. The robustness of magnetism with respect to the edge disorder and the saturating agents in finite size graphene layers and with respect to the defect concentrations in bulk graphene layers will be discussed. A numerical approach based on density functional theory which uses plane-wave basis set and pseudopotentials for ion-electron interactions will be used for elucidating the complex interplay of magnetism, external electric field applied perpendicular to the layers and the resulting band gaps.

[1]Financial support from SRC-NRI SWAN center is acknowledged.

4:42PM X37.00010 Exploring the Structure of Graphene Nanoribbons Using Scanning Tunneling Microscopy , YEN-CHIA CHEN, JUANJUAN FENG, CHENGGANG TAO, LIYING JIAO, XIAOWEI ZHANG, OLEG YAZYEV, RODRIGO CAPAZ, ALEX ZETTL, STEVEN LOUIE, HONGJIE DAI, MICHAEL CROMMIE — The confined dimension and edges of graphene nanoribbons (GNRs) are predicted to result in novel magnetic edge states and tunable energy gaps. Such properties should be strongly dependent on GNR nanoscale structure. Here we report a scanning tunneling microscopy (STM) study of the structure of GNRs derived from unzipped carbon nanotubes that are deposited onto different substrates. These GNRs are found to have different chiralities and widths, and show some unexpected geometrical structure near the edges. We will also present new results obtained from GNRs with disordered edges.

4:54PM X37.00011 STM and STS studies of CVD grown graphene nanoribbons , XIAOTING JIA, MIT, MINGHU PAN, CNMS, ORNL, SREEKAR BHAVIRIPUDI, MIT, VINCENT MEUNIER, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, JING KONG, MILDRED DRESSELHAUS, MIT — Graphene nanoribbons (GNRs) are quasi one dimensional structures which have unique transport properties, and have a potential to open a bandgap at small ribbon widths. They have been extensively studied in recent years due to their high potential for future electronics applications. We have experimentally found some GNRs in our CVD grown graphene layers. In this work, we investigated the morphology and electronic properties of the GNRs on top of a graphene layer transferred to a SiO_2 substrate by using scanning tunneling microscopy. Our results suggest that these GNRs have a surprisingly high crystallinity with one side folded. Atomic resolution images were obtained on the folded layer and the bottom layer of the GNR, which enables clear identification of the chirality for both layers. By combining with theoretical modeling we conclude that a (5,7) line defect exists at the zone of maximum curvatures to help reducing the strain energy of the folding. Low temperature spectroscopic measurements suggest that different electronic states may exist at GNR edges, when compared to the ribbon interior regions.

5:06PM X37.00012 ABSTRACT WITHDRAWN –

5:18PM X37.00013 Large intrinsic energy band gaps in annealed nanotube-derived graphene nanoribbons[1] , J. HARUYAMA, T. SHIMIZU, Aoyama Gakuin University, D.C. MARCANO, D.V. KOSINKIN, J.M. TOUR, Rice University, K. HIROSE, K. SUENAGA, AIST, Japan — The usefulness of graphene for electronics is diminished by an absent energy bandgap. While graphene nanoribbons have non-zero bandgaps, lithographic fabrication methods introduce defects which decouple the bandgap from electronic properties and compromise performance [1]. Here, we present direct measurements of a large intrinsic energy bandgap of approximately 50 meV in 100 nm-width level nanoribbons fabricated by high-temperature annealing of unzipped carbon nanotubes [2]. The activation energy is seven times greater than those in [1], and is close to the width of the transport gap in the differential conductance. This similarity suggests that the activation energy is in fact the intrinsic bandgap. High-resolution TEM and Raman spectroscopy, along with an absence of hopping conductance and stochastic charging effects, suggest a low defect density. [1] M.Y. Han, P. Kim et al., PRL 104, 056801 (2010) [2] J.Haruyama, J.M.Tour, et al., Nature Nanotech. (December 2010)

Session X38 DCP DBP: Focus Session: Non-Equilibrium Insights into Single Molecules and Cell Function I A130/131

2:30PM X38.00001 The Statistical Mechanics of Trajectories and Weights: Applications to Gene Expression , ROB PHILLIPS, California Institute of Technology — Many fascinating questions concerning the behavior of systems ranging from chemical reaction patterns to the patterns of gene expression in living systems do not concern their terminal states, but rather the various microscopic trajectories connecting those states. Some of the most intriguing examples of these kinds of phenomena center on the time evolution of the many molecular machines that populate living cells. Motivated by studies of the time evolution of gene expression, this talk will review both classic approaches to time evolution using rate equations (but couched in the language of trajectories and weights) and more controversial ideas based upon the principle of maximum entropy.

3:06PM X38.00002 Challenges in Characterizing and Controlling Complex Cellular Systems[1] , JOHN WIKSWO, Vanderbilt University — Multicellular dynamic biological processes such as developmental differentiation, wound repair, disease, aging, and even homeostasis can be represented by trajectories through a phase space whose extent reflects the genetic, post-translational, and metabolic complexity of the process - easily extending to tens of thousands of dimensions. Intra- and inter-cellular sensing and regulatory systems and their nested, redundant, and non-linear feed-forward and feed-back controls create high-dimensioned attractors in this phase space. Metabolism provides free energy to drive non-equilibrium processes and dynamically reconfigure attractors. Studies of single molecules and cells provide only minimalist projections onto a small number of axes. It may be difficult to infer larger-scale emergent behavior from linearized experiments that perform only small amplitude perturbations on a limited number of the dimensions. Complete characterization may succeed for bounded component problems, such as an individual cell cycle or signaling cascade, but larger systems problems will require a coarse-grained approach. Hence a new experimental and analytical framework is needed. Possibly one could utilize high-amplitude, multi-variable driving of the system to infer coarse-grained, effective models, which in turn can be tested by their ability to control systems behavior. Navigation at will between attractors in a high-dimensioned dynamical system will provide not only detailed knowledge of the shape of attractor basins, but also measures of underlying stochastic events such as noise in gene expression or receptor binding and how both affect system stability and robustness. Needed for this are wide-bandwidth methods to sense and actuate large numbers of intracellular and extracellular variables and automatically and rapidly infer dynamic control models. The success of this approach may be determined by how broadly the sensors and actuators can span the full dimensionality of the phase space.

3:42PM X38.00003 Maximizing efficiency of molecular machines , GAVIN CROOKS, Lawrence Berkeley Natl. Lab. — I will discuss how to locate protocols that minimize dissipation in non-equilibrium, molecular scale processes, adapting ideas from finite-time thermodynamics.

4:18PM X38.00004 Autonomous Boolean models for logic, timing, and stability in regulatory networks[1] , JOSHUA E.S. SOCOLAR, Physics Department and Center for Systems Biology, Duke University — The dynamics of gene expression in a cell is controlled by a dizzying array of biochemical processes. Natural selection, however, has created regulatory systems with a level of logical organization that can be modeled without detailed knowledge of the biochemistry. In cases where graded responses are not relevant, autonomous Boolean network (ABN) models can effectively represent the logic of gene regulation. These are models in which Boolean logic governs the output value of each node and the timing of updates is determined according to delay parameters associated with each link. An advantage of ABNs over synchronous or random asynchronous Boolean networks is that noise associated with molecular concentrations or transport times can be represented through fluctuations in the timing of updates. We have used ABN models to investigate the stability of oscillations in a model of transcriptional oscillations in yeast and the parameter constraints in a model of segment polarity maintenance in the fly embryo, and also to characterize chaotic dynamics observed in a free–running digital electronic circuit. The yeast study highlights architectural and dynamical features of oscillators that rely on pulse transmission rather than a frustrated feedback loop; the fly study reveals timing constraints that are hidden in ODE models; and the electronics study shows that Boolean chaos can occur if and only if time delays are history dependent.

4:54PM X38.00005 Maximum Caliber Analysis of Ion-Channel Gating , ROY CAMPBELL, Walla Walla University — The principle of maximum caliber, MaxCal, is a generalization to nonequilibrium statistical mechanics of the principle of maximum entropy, MaxEnt. E. T. Jaynes introduced the MaxEnt approach to equilibrium statistical mechanics in 1957 and its MaxCal generalization in 1980. MaxCal has recently been used to derive dynamical laws of transport, analyze single particle two-state dynamics, and study few state models of non-equilibrium processes. We use MaxCal to analyze ion-channel gating data and make logical inferences concerning the underlying dynamics. The inferred trajectory probabilities are used to calculate the fluctuations responsible for channel noise.

5:06PM X38.00006 Driving denaturation: Nanoscale thermal transport as a probe of DNA melting , YONATAN DUBI, School of Physics and Astronomy, Tel-Aviv University, Tel-Aviv, Israel, KIRILL VELIZHANIN, CHIH-CHUN CHIEN, MICHAEL ZWOLAK, Los Alamos National Laboratory — The microscopic dynamics of DNA denaturation have long been a subject of intense study but many aspects of this phenomenon remain poorly understood. Experiments typically measure the degree of denaturation versus temperature which, unfortunately, introduces only a relatively weak constraint: Although many existing models reproduce this denaturation transition well, they give, e.g., incorrect time scales for fluctuations in base pair unbinding. Here, we propose a critical test of DNA models based on driving DNA out of thermal equilibrium via two heat reservoirs. Contrary to what might be expected, we find that the preeminent model of denaturation predicts the thermal conductance to increase substantially as DNA melts. Furthermore, we show that different models can possess qualitatively different thermal transport properties. Measuring the thermal conductance of DNA will thus shed new light on the nonlinear physics of this important molecule and may lead to novel thermal technologies, such as a DNA thermal switch.

Thursday, March 24, 2011 2:30PM - 5:30PM –

Session X39 DBP DCOMP: Biomechanics: From Subcellular to Multicellular Scales A124/127

2:30PM X39.00001 Simple, Voltage Dependent Statistics Governing Cell-Substrate Contact Times , BRET N. FLANDERS, Department of Physics, Kansas State University — The distribution of contact times between a nanofilament-based contact sensor and individual pseudopods of *D. discoideum* have been measured as a function of voltage applied to the filament. The distributions are well described by exponential distributions. The average duration of the pseudopod-filament contact was found to increase across the +20 mV to -50 mV range of filament-voltages. These results are consistent with the predictions of a simple model based on rather general considerations of energy usage by the cell. This analysis indicates that the exponential functionality (of the contact time distributions) results from competition between a large number of cellular processes for the available energy. The evolution of these distributions across the +20 mV to -50 mV voltage range suggests that the negatively biased filament enhances adhesion to the filament by activating additional adhesion molecules to bind to its surface. These results will be discussed in the context of recent findings on the coupling of voltage gated ion channels and cellular adhesion.

3:06PM X39.00002 Multiscale modeling of the dynamics of multicellular systems[1] , IOAN KOSZTIN, University of Missouri - Columbia — Describing the biomechanical properties of cellular systems, regarded as complex highly viscoelastic materials, is a difficult problem of great conceptual and practical value. Here we present a novel approach, referred to as the Cellular Particle Dynamics (CPD) method, for: (i) quantitatively relating biomechanical properties at the cell level to those at the multicellular and tissue level, and (ii) describing and predicting the time evolution of multicellular systems that undergo biomechanical relaxations. In CPD cells are modeled as an ensemble of cellular particles (CPs) that interact via short range contact interactions, characterized by an attractive (adhesive interaction) and a repulsive (excluded volume interaction) component. The time evolution of the spatial conformation of the multicellular system is determined by following the trajectories of all CPs through integration of their equations of motion. Cell and multicellular level biomechanical properties (e.g., viscosity, surface tension and shear modulus) are determined through the combined use of experiments and theory of continuum viscoelastic media. The same biomechanical properties are also "measured" computationally by employing the CPD method, the results being expressed in terms of CPD parameters. Once these parameters have been calibrated experimentally, the formalism provides a systematic framework to predict the time evolution of complex multicellular systems during shape-changing biomechanical transformations. By design, the CPD method is rather flexible and most suitable for multiscale modeling of multicellular system. The spatial level of detail of the system can be easily tuned by changing the number of CPs in a cell. Thus, CPD can be used equally well to describe both cell level processes (e.g., the adhesion of two cells) and tissue level processes (e.g., the formation of 3D constructs of millions of cells through bioprinting).

3:42PM X39.00003 Theoretical estimation of the breakage intensity of microtubules at resonance using ultrasound waves , ABDORREZA SAMARBAKHSH[1], JACK TUSZYNSKI[2], Department of Oncology, University of Alberta — Microtubules (MTs) are protein filaments forming a major part of the cytoskeleton of all eukaryotic cells which directly contribute to the process of cell division by forming mitotic spindles and providing force for the segregation of chromosomes. In this work first we show the resonance condition for MTs subject to ultrasound wave by solving the beam equation for MT analytically. Then we estimate the required minimum intensity of the ultrasound at the location of the MT in order to break it. We have shown that this intensity is of the order of 100KW per unit of area which corresponds to 170 dB.

3:54PM X39.00004 Flexural Rigidity of MCF-7 Microtubules Measured from Thermal Fluctuations in Shape , MITRA SHOJANIA FEIZABADI, Physics Department, Seton Hall University, KIRYAKO MUTAFOPULOS, Biology Department, Seton Hall University, ADAM BEHR, Physics Department, Seton Hall University — Microtubules play a key role in the mechanical and elastic properties of eukaryotic cells. For this reason, measuring the flexural rigidity of bovine brain microtubules have been extensively investigated through different methods of measurement. Beta tubulin isotypes, a noticeable trait to consider as we transfer from mammalian neural microtubules to mammalian non-neural microtubules, are assembled differently in distributions among various types of microtubules. Different studies have shown that microtubules made from different beta-tubulin isotypes express unique polymerization and dynamic behavior. This study focuses on measuring mechanical properties of one of non-neural microtubules, MCF-7. We will discuss the structure differences between brain bovine microtubules and MCF-7, along with the rigidity of single microtubules polymerized from MCF-7 tubulin through monitoring the curvature of microtubule due to thermal fluctuations.

4:06PM X39.00005 ABSTRACT WITHDRAWN –

4:18PM X39.00006 Persistence Length of Stable Microtubules[1] , TAVIARE HAWKINS, University of Massachusetts Amherst, MATTHEW MIRIGIAN, National Institutes of Health, M. SELCUK YASAR, JENNIFER ROSS, University of Massachusetts Amherst — Microtubules are a vital component of the cytoskeleton. As the most rigid of the cytoskeleton filaments, they give shape and support to the cell. They are also essential for intracellular traffic by providing the roadways onto which organelles are transported, and they are required to reorganize during cellular division. To perform its function in the cell, the microtubule must be rigid yet dynamic. We are interested in how the mechanical properties of stable microtubules change over time. Some "stable" microtubules of the cell are recycled after days, such as in the axons of neurons or the cilia and flagella. We measured the persistence length of freely fluctuating taxol-stabilized microtubules over the span of a week and analyzed them via Fourier decomposition. As measured on a daily basis, the persistence length is independent of the contour length. Although measured over the span of the week, the accuracy of the measurement and the persistence length varies. We also studied how fluorescently-labeling the microtubule affects the persistence length and observed that a higher labeling ratio corresponded to greater flexibility.

4:30PM X39.00007 Modeling actin waves in dictyostelium cells , VAIBHAV WASNIK, RANJAN MUKHOPADHYAY, Clark University — Actin networks in living cells demonstrate a high capacity for self-organization and are responsible for the formation of a variety of structures such as lamellopodia, phagocytic cups, and cleavage furrows. Recent experiments have studied actin waves formed on the surface of dictyostelium cells that have been treated with a depolymerizing agent. These waves are believed to be physiologically important, for example, for the formation of phagocytic cups. We propose and study a minimal model, based on the dendritic nucleation of actin polymers, to explain the formation of these waves. This model can be extended to study the dynamics of the coupled actin-membrane system.

4:42PM X39.00008 ABSTRACT WITHDRAWN –

4:54PM X39.00009 Force Generated by Actin Array , KONSTANTINOS TSEKOURAS, Institut Curie, DAVID LACOSTE, Ecole Superieure de Physique et Chimie Industrielles, KIRONE MALLICK, CEA Saclay, JEAN-FRANCOIS JOANNY, Institut Curie — We study a theoretical model for a group of parallel filaments growing against a barrier held by a constant force. An array of N filaments nucleate on a fixed surface and grow towards a rigid barrier which is held in place by a constant force. Filaments are coupled only by mechanical contact against the barrier. We obtain the filament density distribution in terms of the distance from the barrier, and force-velocity curves. We apply our model to the case of an array of actin filaments. All results are validated by extensive Monte-Carlo simulations. For a small value of N we find the stall force to be N times the stall force of a single filament ($f_{stall} \approx N f^1_{stall}$). For large N we find that the velocity *appears* to be considerably smaller, an effect due to its exponential decrease as the theoretical stall force is approached.

5:06PM X39.00010 BSDB: the Biomolecule Stretching Database[1] , MAREK CIEPLAK, MATEUSZ SIKORA, Institute of Physics, Polish Academy of Sciences, JOANNA I. SULKOWSKA, UCSD, BARTLOMIEJ WITKOWSKI, Institute of Physics, Polish Academy of Sciences — Despite more than a decade of experiments on single biomolecule manipulation, mechanical properties of only several scores of proteins have been measured. A characteristic scale of the force of resistance to stretching, F_{max}, has been found to range between ∼10 and 480 pN. The Biomolecule Stretching Data Base (BSDB) described here provides information about expected values of F_{max} for, currently, 17 134 proteins. The values and other characteristics of the unfolding proces, including the nature of identified mechanical clamps, are available at www://info.ifpan.edu.pl/BSDB/. They have been obtained through simulations within a structure-based model which correlates satisfactorily with the available experimental data on stretching. BSDB also lists experimental data and results of the existing all-atom simulations. The database offers a Protein-Data-Bank-wide guide to mechano-stability of proteins. Its description is provided by a forthcoming Nucleic Acids Research paper.

5:18PM X39.00011 The nonequilibrium thermodynamics and kinetics of focal adhesion dynamics , KRISHNA GARIKIPATI, JOSEPH OLBERDING, MICHAEL THOULESS, ELLEN ARRUDA, University of Michigan — We consider a focal adhesion (FA) to be made up of molecular complexes consisting of ligands, integrins, and associated plaque proteins. Free energy changes drive the binding and unbinding of these complexes, thus controlling the FA's dynamic modes of growth, treadmilling and resorption via the following mechanisms: (i) work done during the addition of molecular complexes, (ii) the chemical free energy of addition of a molecular complex, (iii) the elastic free energy of deformation of FAs and the cell membrane, and (iv) the work done on a molecular conformational change. We have developed a treatment of FA dynamics as a nonlinear rate process driven by out-of-equilibrium thermodynamic driving forces, and modulated by kinetics. The mechanisms governed by the above four effects allow FAs to exhibit a rich variety of behavior, predicting growth, treadmilling and resorption. Treadmilling requires symmetry breaking between the ends of the focal adhesion, and is achieved by driving force (i) above. In contrast, the remaining mechanisms cause symmetric growth or resorption. These findings hold for a range of conditions: temporally-constant force or stress, and for spatially-uniform and non-uniform stress distribution over the FA. This treatment of FA dynamics can be coupled with models of cytoskeleton dynamics and contribute to the understanding of cell motility.

Session X40 DBP: Biological Networks and Systems Biology A122/123

2:30PM X40.00001 Computer Simulations of Loss of Organization of Neurons as a Model for Age-related Cognitive Decline[1] , LUIS CRUZ, ELENE FENGOMETIDIS, FRANK JONES, SRINIVAS JAMPANI, Physics Dept., 3141 Chestnut St., Drexel University, Philadelphia PA 19104 — In normal aging, brains suffer from progressive cognitive decline not linked with loss of neurons common in neurodegenerative disorders such as Alzheimer's disease. However, in some brain areas neurons have lost positional organization specifically within microcolumns: arrays of interconnected neurons which may constitute fundamental computational units in the brain. This age-related loss of organization, likely a result of micron-sized random displacements in neuronal positions, is hypothesized to be a by-product of the loss of support from the surrounding medium, including dendrites. Using a dynamical model applied to virtual 3D representation of neuronal arrangements, that previously showed loss of organization in brains of cognitively tested rhesus monkeys, the relationship between these displacements and changes to the surrounding dendrite network are presented. The consequences of these displacements on the structure of the dendritic network, with possible disruptions in signal synchrony important to cognitive function, are discussed.

2:42PM X40.00002 Coupled feedback loops govern bistability properties in gene networks , ABHINAV TIWARI, OLEG IGOSHIN, Rice University — Positive feedback is a necessary component for network bistability - the simplest design being a positive autoregulatory circuit. Then why some biological systems have multiple feedback loops? We hypothesize that the presence of multiple additively or multiplicatively coupled feedback loops affects the net cooperativity of the system, thereby influencing the possibility of bistability. We find that additively coupled feedback loops in the MprAB-SigE-RseA network in mycobacteria do not lead to bistability. Only the inclusion of post-translational regulation of SigE by RseA makes the system robustly bistable. In general we find that if two one-feedback networks are individually monostable, then only multiplicative coupling can generate bistability in the combined circuit. We analytically perform pair-wise controlled comparisons between the autoregulation circuit, additively and multiplicatively coupled two-gene circuits that reveal neither of the circuits has an advantage with regards to bistability range. We numerically validate our results by employing Monte Carlo parameter sampling for the comparisons.

2:54PM X40.00003 Better Bet-Hedging with coupled positive and negative feedback loops , JATIN NARULA, OLEG IGOSHIN, Dept. of Bioengineering, Rice University — Bacteria use the phenotypic heterogeneity associated with bistable switches to distribute the risk of activating stress response strategies like sporulation and persistence. However bistable switches offer little control over the timing of phenotype switching and first passage times (FPT) for individual cells are found to be exponentially distributed. We show that a genetic circuit consisting of interlinked positive and negative feedback loops allows cells to control the timing of phenotypic switching. Using a mathematical model we find that in this system a stable high expression state and stable low expression limit cycle coexist and the FPT distribution for stochastic transitions between them shows multiple peaks at regular intervals. A multimodal FPT distribution allows cells to detect the persistence of stress and control the rate of phenotype transition of the population. We further show that extracellular signals from cell-cell communication that change the strength of the feedback loops can modulate the FPT distribution and allow cells even greater control in a bet-hedging strategy.

3:06PM X40.00004 Attractor Distribution in Random Biological Networks Described by ODEs and Diminished Order-Chaos Transition , ZHIYUAN LI, UCSF, Dept of Biophysics, CHAO TANG, UCSF — Ordinary Differential Equations (ODEs) are widely used to model biological network in a continuous manner. The state of an ODE system after infinitely long time is called attractor, which indicates the ultimate fate of the corresponding biological system. Even though the attractor behaviors of many biological systems have been understood, yet the distribution of attractors for networks followings biological reaction rules is in general unknown. In our work, we study the final state for all 3 nodes networks that follow transcriptional regulation or enzymatic reaction rules, under random parameter sets. Surprisingly, mono-stable behavior appears most frequently, while bi-stable and tri-stable behavior is less frequently observed. Oscillations are rarely seen, and chaos is almost never observed. We extend the study to random networks with a large number of nodes, and the outcome does not change qualitatively. Furthermore, with increased connectivity, the transition from order to chaos predicted by discrete models is not observed. Our results provide a null-distribution for attractors in bio-networks, and have important implication for cell fate decision.

3:18PM X40.00005 Beyond Critical Exponents in Neuronal Avalanches , NIR FRIEDMAN, Department of Physics, University of Illinois at Urbana-Champaign, TOM BUTLER, Massachusetts Institute of Technology, ROBERT DEVILLE, Department of Mathematics, University of Illinois at Urbana-Champaign, JOHN BEGGS, University of Indiana, KARIN DAHMEN, Department of Physics, University of Illinois at Urbana-Champaign — Neurons form a complex network in the brain, where they interact with one another by firing electrical signals. Neurons firing can trigger other neurons to fire, potentially causing avalanches of activity in the network. In many cases these avalanches have been found to be scale independent, similar to critical phenomena in diverse systems such as magnets and earthquakes. We discuss models for neuronal activity that allow for the extraction of testable, statistical predictions. We compare these models to experimental results, and go beyond critical exponents.

3:30PM X40.00006 Stochastic Modeling of Regulation of Gene Expression by Multiple Competing Small RNAs , CHARLES BAKER, TAO JIA, RAHUL KULKARNI, Virginia Polytechnic Institute and State University — A wealth of new research has highlighted the critical roles of small RNAs (sRNAs) in diverse processes such as quorum sensing and cellular responses to stress. The pathways controlling these processes often have a central motif comprised of a key protein regulated by multiple sRNAs. However, the regulation of stochastic gene expression of a single target gene by multiple sRNAs is currently not well understood. To address this issue, we analyze a stochastic model of regulation of gene expression by multiple sRNAs. For this model, we derive exact analytic results for the regulated protein distribution including compact expressions for its mean and variance. The derived results provide novel insights into the roles of multiple sRNAs in fine-tuning the noise in gene expression. In particular, we show that, in contrast to regulation by a single sRNA, multiple sRNAs provide a mechanism for independently controlling the mean and variance of the regulated protein distribution.

3:42PM X40.00007 The up and down states of cortical networks , MARYAM GHORBANI, ALEX J. LEVINE, MAYANK MEHTA, ROBIJN BRUINSMA, UCLA — The cortical networks show a collective activity of alternating active and silent states known as up and down states during slow wave sleep or anesthesia. The mechanism of this spontaneous activity as well as the anesthesia or sleep are still not clear. Here, using a mean field approach, we present a simple model to study the spontaneous activity of a homogenous cortical network of excitatory and inhibitory neurons that are recurrently connected. A key new ingredient in this model is that the activity-dependant synaptic depression is considered only for the excitatory neurons. We find depending on the strength of the synaptic depression and synaptic efficacies, the phase space contains strange attractors or stable fixed points at active or quiescent regimes. At the strange attractor phase, we can have oscillations similar to up and down states with flat and noisy up states. Moreover, we show that by increasing the synaptic efficacy corresponding to the connections between the excitatory neurons, the characteristics of the up and down states change in agreement with the changes that we observe in the intracellular recordings of the membrane potential from the entorhinal cortex by varying the depth of anesthesia. Thus, we propose that by measuring the value of this synaptic efficacy, one can quantify the depth of anesthesia which is clinically very important. These findings provide a simple, analytical understanding of the spontaneous cortical dynamics.

3:54PM X40.00008 Adiabatic and Non-Adiabatic Non-Equilibrium Stochastic Dynamics of Single Regulating Genes , HAIDONG FENG, BO HAN, JIN WANG, Department of Chemistry, State University of New York at Stony Brook — We explore the stochastic dynamics of self regulative genes from fluctuations of molecular numbers and of on and off switching of gene states due to regulatory protein binding/unbinding to the genes. We found when the binding/unbinding is relatively fast (slow) compared with the synthesis/degradation of proteins in adiabatic (non-adiabatic) case, the self regulators can exhibit one or two peak (two peak) distributions in protein concentrations. This shows even with the same architecture (topology of wiring), networks can have quite different functions (phenotypes), consistent with recent single molecule single gene experiments. We derive the non-equilibrium phase diagrams of mono-stability and bi-stability in adiabatic and non-adiabatic regimes. We study the stability and robustness of the systems through mean first passage time (MFPT) from one peak (basin of attraction) to another. In addition, using the new method for quantifying the paths and the associated weights for complex systems in discrete state space (Markov chains), we identified the dominant paths among all possible paths from the "off" basin to the "on" basin for self-activators, and observe turnover kinetic behavior of transitions and MFPT from non-adiabatic to adiabatic regimes.

4:06PM X40.00009 Steady state growth of *E. Coli* in low ammonium environment , MINSU KIM, BARRET DERIS, ZHONGGE ZHANG, TERRY HWA, UCSD — Ammonium is the preferred nitrogen source for many microorganisms. In medium with low ammonium concentrations, enteric bacteria turn on the nitrogen responsive (ntr) genes to assimilate ammonium. Two proteins in *E. coli*, Glutamine synthetase (GS) and the Ammonium/methylammonium transporter AmtB play crucial roles in this regard. GS is the major ammonium assimilation enzyme below 1mM of NH_4^+. AmtB is an inner membrane protein that transports NH_4^+ across the cell membrane against a concentration gradient. In order to study ammonium uptake at low NH_4^+ concentration at neutral pH, we developed a microfluidic flow chamber that maintains a homogenous nutrient environment during the course of exponential cell growth, even at very low concentration of nutrients. Cell growth can be accurately monitored using time-lapse microscopy. We followed steady state growth down to micro-molar range of NH_4^+ for the wild type and ΔamtB strains. The wild type strain is able to maintain the growth rate from 10mM down to a few uM of NH_4^+, while the mutant exhibited reduced growth below $\sim$20 uM of NH_4^+. Simultaneous characterization of the expression levels of GS and AmtB using fluorescence reporters reveals that AmtB is turned on already at 1mM, but contributes to function only below $\sim$30 uM in the wild-type. Down to $\sim$20 uM of NH_4^+, *E. coli* can compensate the loss of AmtB by GS alone.

4:18PM X40.00010 Threshold response and bimodality in non-cooperative auto-activation circuits[1] , RUTGER HERMSEN, DAVID ERICKSON, TERENCE HWA, Center for Theoretical Biological Physics, UC San Diego — In prokaryotes as well as in eukaryotes, many transcription factors (TFs) activate their own gene. For that reason the benefits of auto-activation have been studied extensively. However, little attention is paid to the fact that many TFs are modified by a signal, usually through phosphorylation or binding of a ligand. Typically only one version of the TF—the modified or the unmodified one—can activate transcription. Consequently the TF's expression level responds to changes in the signal. Here, we use stochastic models to study the response properties of such circuits. In real examples the auto-activation is often mediated by a single binding site. Surprisingly, in that case we find that an arbitrarily sensitive threshold response can be obtained, while the bistability and hysteresis associated with multiple cooperative binding sites are avoided. Also, we find that the steady-state probability distributions of the TF expression level can be bimodal even though the system is not bistable. This is not caused by slow TF–DNA binding kinetics or bursty protein production, as in earlier studies, but by strongly reduced production and degradation rates at low expression levels.

4:30PM X40.00011 Inferring Complex Network Topology from Spatio-Temporal Spike Patterns , FRANK VAN BUSSEL, BIRGIT KRIENER, MARC TIMME, Max Planck Institute for Dynamics and Self-Organization, Goettingen, Germany — The problem of reconstructing or reverse-engineering the connectivity of networks consisting of dynamically interacting units has become an active area of study in fields such as genetics, ecology, and neuroscience. The collective dynamics of such networks is often sensitive to the presence (or absence) of individual interactions, but there is commonly no direct way to probe for their existence. We present an explicit method for reconstructing neuronal networks from their spiking activity. The approach works well for networks in simple collective states, but is also applicable to networks exhibiting complex spatio-temporal spike patterns. In particular, stationarity of spiking time series is not required.

4:42PM X40.00012 ABSTRACT WITHDRAWN –

4:54PM X40.00013 Temporal competition between differentiation programs determines cell fate choice , ANNA KUCHINA, UT Southwestern Medical Center, LORENA ESPINAR, Universitat Politècnica de Catalunya, TOLGA CAGATAY, ALEJANDRO BALBIN, ALMA ALVARADO, UT Southwestern Medical Center, JORDI GARCIA-OJALVO, Universitat Politècnica de Catalunya, GUROL SUEL, UT Southwestern Medical Center — During pluripotent differentiation, cells adopt one of several distinct fates. The dynamics of this decision-making process are poorly understood, since cell fate choice may be governed by interactions between differentiation programs that are active at the same time. We studied the dynamics of decision-making in the model organism *Bacillus subtilis* by simultaneously measuring the activities of competing differentiation programs (sporulation and competence) in single cells. We discovered a precise switch-like point of cell fate choice previously hidden by cell-cell variability. Engineered artificial crosslinks between competence and sporulation circuits revealed that the precision of this choice is generated by temporal competition between the key players of two differentiation programs. Modeling suggests that variable progression towards a switch-like decision might represent a general strategy to maximize adaptability and robustness of cellular decision-making.

5:06PM X40.00014 Comparison of Control Approaches in Genetic Regulatory Networks by Using Stochastic Master Equation Models, Probabilistic Boolean Network Models and Differential Equation Models and Estimated Error Analyzes , MEHMET UMUT CAGLAR, RANADIP PAL, Texas Tech University — Central dogma of molecular biology states that "information cannot be transferred back from protein to either protein or nucleic acid" . However, this assumption is not exactly correct in most of the cases. There are a lot of feedback loops and interactions between different levels of systems. These types of interactions are hard to analyze due to the lack of cell level data and probabilistic - nonlinear nature of interactions. Several models widely used to analyze and simulate these types of nonlinear interactions. Stochastic Master Equation (SME) models give probabilistic nature of the interactions in a detailed manner, with a high calculation cost. On the other hand Probabilistic Boolean Network (PBN) models give a coarse scale picture of the stochastic processes, with a less calculation cost. Differential Equation (DE) models give the time evolution of mean values of processes in a highly cost effective way. The understanding of the relations between the predictions of these models is important to understand the reliability of the simulations of genetic regulatory networks. In this work the success of the mapping between SME, PBN and DE models is analyzed and the accuracy and affectivity of the control policies generated by using PBN and DE models is compared.

Session X41 DCP: Focus Session: Electronic Structure and Applications to Energy Conversion II A115/117

2:30PM X41.00001 Fundamental understanding and computational design of thin-film photovoltaics materials , JEFFREY C. GROSSMAN, Massachusetts Institute of Technology — The search for abundant and clean energy sources has placed photovoltaics at the focus of research over a variety of disciplines spanning physics, chemistry and materials science. However, the quest for more cost-efficient photovoltaics is challenged by limitations in efficiency of charge excitation and collection in the materials and their interfaces. We will present our recent *ab initio* calculations aimed at understanding important microscopic mechanisms in solar photovoltaic materials. Our goal is to predict accurately key properties that govern the efficiency in these materials, including structural and electronic effects, interfacial charge separation, electron and hole traps, excited state phenomena, band level alignment, and binding energies. Examples of our work in the areas of organic and other thin-film photovoltaics will be presented. We use these examples to illustrate how accurate electronic structure approaches can improve our understanding and lead to more efficient materials.

3:06PM X41.00002 Effect of environment and long range behaviour of exchange functional on polaron formation in π-conjugated polymers , IFFAT NAYYAR, Theoretical Div, Los Alamos National Lab, NM and NanoScience Technology Center, Dept. of Physics, University of Central Florida, Orlando, FL, ENRIQUE BATISTA, SERGEI TRETIAK, AVADH SAXENA, DARRYL SMITH, RICHARD MARTIN, Theoretical Division, Los Alamos National Lab, NM — Organic conjugated polymers find a variety of applications in devices such as solar cells, light emitting diodes and lasers. An accurate understanding of the role of nonlinear excitations as polarons in charge carrier transport is critical to improve the efficiency of these devices. PPV and MEH-PPV are the candidates of choice for the extensive experimental data and relative simplicity compared to other polymers. This motivated us to perform a density functional theory study to describe the charge defects in these systems. We emphasize on the role of surrounding dielectric medium and the amount of long range orbital exchange in the density functional to predict the polaron localization in agreement with experiment. The particle-hole symmetry observed in trans-geometries is broken by introducing certain cis defects.

3:18PM X41.00003 Photo-induced modulation in the dipole moment of a donor-acceptor pair of organic molecules[1] , YOSHIYUKI MIYAMOTO, National Institute of Advanced Industrial Science and Technology, Japan, MINA YOON, ORNL, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der Max-Planck-Gesellschaft — We have investigated the photo-induced electron dynamics in donor-acceptor pairs of organic molecules. Specifically we will discuss TTF and TCNQ molecules and study their electron dynamics under illumination by means of time-dependent density functional theory within the local-density approximation. In their stable molecular structure, we find that these molecules align in parallel and show maximum optical oscillator strength with an optical polarization parallel to their molecular axis. Without illumination, a dipole moment from TTF to TCNQ directs perpendicular to the molecular axis. This dipole-moment is further increased upon illumination with an optical polarization parallel to the molecular axis at resonant excitation energies of 2.00 eV and 3.55 eV. The light-induced increase of the dipole moment, which reflects the separation of electron and hole pair, is caused by the internal electric field between these molecules. Therefore, these molecules may have a high potential as building blocks of future organic photovoltaic devices.

3:30PM X41.00004 Exciton transport and dissociation at organic interfaces , DAVID BELJONNE, University of Mons — This paper focuses on modeling studies of exciton transport and dissociation at organic interfaces and includes three parts: 1) Experiments have shown that the values of exciton diffusion length L_D in conjugated polymers (CPs) are rather low, in the range of 5-10 nm, apparently regardless of their chemical structure and solid-state packing. In contrast, larger L_D values have been reported in molecular materials that are chemically more well-defined than CPs. Here we demonstrate that energetic disorder alone reduces the exciton diffusion length more than one order of magnitude, from values typically encountered in molecules (>50nm) to values actually measured in CPs (<10nm). 2) A number of organic crystals show anisotropic excitonic couplings, with weak interlayer interactions between molecules that are more strongly coupled within the layers. The resulting energy carriers are intra-layer 2D excitons that diffuse along the interlayer direction. We model this analytically for infinite layers and using quantum-chemical calculations of the electronic couplings for anthracene clusters. We show that the exciton hopping rates and diffusion lengths depend in a subtle manner on the size and shape of the interacting aggregates, temperature and the presence of energetic disorder. 3) The electronic structure at organic/organic interfaces plays a key role, among others, in defining the quantum efficiency of organic-based photovoltaic cells. Here, we perform quantum-chemical and microelectrostatic calculations on molecular aggregates of various sizes and shapes to characterize the interfacial dipole moment at pentacene/C60 heterojunctions. The results show that the interfacial dipole mostly originates in polarization effects due to the asymmetry in the multipolar expansion of the electronic density distribution between the interacting molecules. We will discuss how the quadrupoles on the pentacene molecules produce direct electrostatic interactions with charge carriers and how these interactions in turn affect the energy landscape around the interface and therefore also the energy barrier for exciton dissociation into free carriers.

4:06PM X41.00005 Correlating First-Principles Electronic Structure with Device Performance of Organic Photovoltaic Cells , ERIC B. ISAACS, SAHAR SHARIFZADEH, BIWU MA, JEFFREY B. NEATON, Molecular Foundry, Lawrence Berkeley National Laboratory — Organic photovoltaic cells (OPVs) are promising candidates for low-cost solar energy conversion. Here, we employ static and time-dependent density functional theory calculations to predict the excitation energy of the donor-acceptor charge transfer state (E_{CT}) at the interface between C_{60} and several boron(subphthalocyanine)- and azadipyrromethene-based donor moieties, comparing to measured open-circuit voltage (V_{oc}) in bilayer heterojunction OPVs [1]. When E_{CT} is approximated as the difference between the ionization potential and electron affinity of the isolated donor and acceptor molecules, respectively, we observe no apparent correlation between E_{CT} and V_{oc}. Both bulk polarization and excitonic effects at the interface are found to influence the energetics significantly, the latter being strongly morphology dependent. We demonstrate that a linear relationship between V_{oc} and E_{CT} may be obtained once the interface morphology is considered. We acknowledge support from DOE, NSF-NCN, and NERSC.

[1] C. E. Mauldin *et al.*, ACS Appl. Mater. Interfaces **2**, 2833 (2010).

4:18PM X41.00006 Photo-induced Charge Separation in Nanoscale Donor-Bridge-Acceptor Systems: Theory and Experiment , PETER DOAK, Molecular Foundry, LBNL; Department of Chemistry, UC-Berkeley, PIERRE DARANCET, Molecular Foundry, LBNL, KASPER MOTH-POULSEN, Department of Chemical and Biological Engineering, Chalmers U. of Technology, JESSE JENKINS, Department of Chemistry, UC-Berkeley, RACHEL SEGALMAN, Department of Chemical Engineering, UC-Berkeley, DON TILLEY, Department of Chemistry, UC-Berkeley, JEFF NEATON, Molecular Foundry, LBNL — Understanding and control of light-harvesting processes at the molecular-scale remains a fundamental challenge in solar energy conversion. Donor-bridge-acceptor molecules (DBAM), with atomically-defined interfaces made by a covalently bound bridge between donor and acceptor moieties, allow probing of excited states relevant to optical absorption and charge separation. In close collaboration with experiment, we use first-principles many-body perturbation theory, within the GW approximation and the Bethe-Salpeter equation approach, to compute excited states for six DBAMs. We compare with experiments, and quantitative agreement is obtained. Implications of our results for nanoscale light-harvesting are thoroughly discussed. Support: DOE via the Molecular Foundry and Helios SERC, and NSF via NCN. Computational support provided by NERSC.

4:30PM X41.00007 Exciton Scattering in Branched Conjugated Molecules: Towards Photoinduced Dynamics and Energy Transfer , VLADIMIR CHERNYAK, Wayne State University — The exciton scattering (ES) approach attributes excited electronic states in quasi-one-dimensional (branched) conjugated molecules with perfect geometry to standing waves on the linear segments of a molecule formed by scattering of quantum quasi-particles (excitons). We extract their dispersion and frequency-dependent scattering matrices at termini, including donor/acceptor substitutions, joints, and branching centers from time-dependent density functional theory (TD-DFT) calculations, with applications to for conjugated phenylacetylene-based molecules. This allows electronic spectra for any structure of arbitrary size within the considered molecular family to be obtained with insignificant numerical effort. To extend the capability of the ES approach to treating photoinduced dynamics, including absorption and fluorescence lineshapes and energy transfer, the methodology should be modified to account for non-ideal molecular geometry. Geometry distortions break down translational symmetry of the linear segments, and excitations are not represented by perfect standing waves anymore. To overcome this difficulty we associate electronic excitations with the eigenstate of a quantum particle on an irregular lattice (graph), referred to as a tight-binding model. The morphology of the underlying lattice, together with the tight-binding parameters, can be identified by studying the topological and analytical properties of excitons at molecular termini, joints, and branching centers. The dependence of the tight-binding parameters on geometry distortions that controls effects of disorder and coupling to vibrational modes can be extracted from quantum chemical calculations by studying exciton scattering on localized geometry distortions, the latter considered as scattering centers.

5:06PM X41.00008 NA-ESMD modeling of photoinduced dynamics in conjugated molecules , TAMMIE NELSON, Los Alamos National Laboratory, SEBASTIAN FERNANDEZ-ALBERTI, Universidad Nacional de Quilmes, VLADIMIR CHERNYAK, Wayne State University, ADRIAN ROITBERG, University of Florida, SERGEI TRETIAK, Los Alamos National Laboratory — The evolution of electronic excitations in optically active molecules can generally be defined by non-adiabatic (NA) dynamics. A number of fundamental and complex processes are associated with NA dynamics. To treat ultrafast excited state dynamics we have developed a non-adiabatic excited state molecular dynamics (NA-ESMD) framework incorporating quantum transitions. Our calculations combine the Collective Electronic Oscillator (CEO) package with the Tully's fewest switches algorithm for surface hopping, and the actual potential energy surfaces of the excited states are used. This method is applied to model the photoinduced dynamics of distyrylbenzene. Our analysis shows intricate details of vibronic relaxation and identifies specific slow and fast nuclear motions that are strongly coupled to the electronic degrees of freedom. Non-adiabatic relaxation of the highly excited mAg state is predicted to occur on a femtosecond timescale at room temperature and on a picosecond timescale at low temperature.

Session X42 DPOLY: Polymeric Glasses A302/303

2:30PM X42.00001 Molecular Mobility on the Surface of Glassy Tris-naphthylbenzene (TNB) , ZAHRA FAKHRAAI, University of Wisconsin-Madison, CHAD DALEY, University of Waterloo, STEPHEN F. SWALLEN, DANIEL SCIFO, University of Wisconsin-Madison, JAMES A. FORREST, University of Waterloo, MARK D. EDIGER, University of Wisconsin-Madison — Mechanical relaxation measurements on the surface of polymeric glasses show that as the bulk material falls out of equilibrium at Tg a thin layer at the surface behaves like a liquid with relaxation times that are orders of magnitude faster and more weakly temperature dependent compared to those of the bulk glass. However the origin of this phenomenon remains elusive. Recently exceptionally stable glasses of small organic molecules have been produced by physical vapor deposition at temperatures below Tg, suggesting that these glasses also exhibit enhanced surface mobility. In this study gold nanoparticles were used to probe micron size meniscus formation on the surface of organic glass former TNB below Tg, a direct evidence of surface mobility in this material. Neutron scattering measurements of inter-diffusion between stacks of d-TNB and regular TNB layers during the deposition suggest that the temperature dependence of the diffusion on the surface is very similar to what is observed on polymeric films.

2:42PM X42.00002 Tuning the Dynamics of Penetrant Transport in Glassy Polymers through Network Structure Modification , ADAM EKENSEAIR, NICHOLAS PEPPAS, Department of Chemical Engineering, The University of Texas at Austin — The relative rates of the diffusional and relaxational processes during the absorption of penetrant molecules in glassy polymers determine the nature of the transport process and lead to Fickian, Case II, and anomalous absorption behavior. While previous models account for anomalous behavior, there is still a disconnect between theory and experiment, as data must be fit to the model with previously determined independent parameters. With trends leading to smaller device scales and increasingly complex polymer structures, there is a need for a quantitative understanding of the manner in which a polymer's network structure alters both the rate and the mode of penetrant transport. To this end, the effects of the basic network parameters of PMMA, including the degree of crosslinking, polymer mesh size, and the crosslink interchain bridge length, on the integral sorption of methanol were studied utilizing gravimetric integral sorption studies. The effects of sub-T_g annealing/aging, temperature, and the presence of un-reacted monomer were also investigated. Controlling the relative timescale of the relaxational process by altering the polymer network structure was shown to directly influence the Case II front propagation velocity and control the overall nature of the observed transport behavior.

2:54PM X42.00003 A Surrogate for Debye-Waller Factors from Stokes Shifts[1] , MARCUS CICERONE, QIN ZHONG, MADHUSUDAN TYAGI, NIST — We show that short-time relaxation behavior characteristic of the intermediate scattering function at q near the peak in the static structure factor can be obtained from time-resolved Stokes shifts (TRSS) in glassforming materials. We extract Debye- Waller factor ($\langle u^2 \rangle$) analogs from the TRSS data from four glassforming liquids and apply these to a proposed relationship between α relaxation and the Debye-Waller factor; $\tau_\alpha = \tau_\infty \, Exp\left[\frac{a^2}{2\langle u^2\rangle} + \frac{\sigma_{a^2}^2}{8\langle u^2\rangle^2}\right]$. This putative relationship has previously been evaluated using experimental Debye-Waller factors obtained in the time range (40 to 2000) ps. We show that the relation yields physically meaningful fit values only when relaxation on a 1 ps timescale is considered. We also observe an unexpected dependence of short-time Debye-Waller factors on fragility.

3:06PM X42.00004 Comparison of the KWW and BSW Model Descriptions of the Dynamic Responses of Polymeric and Colloidal Glass Formers , BEN XU, GREGORY B. MCKENNA, Department of Chemical Engineering, Texas Tech University — In this work, we present the results of the KWW and BSW[1] descriptions of the dynamic data for a colloid and a polymer (PVAc) in their respective glass transition regions. It was found that the KWW function is not able to describe the dynamic data for the colloidal system, while BSW function, provides an acceptable description to the dynamic response of the polymer. The fitting parameters n_e and n_g in the BSW function, which indicate the slopes of the relaxation spectrum, remain constant at different temperatures consistent with the validity of the time-temperature superposition principle. We also used the G_g obtained from the KWW and BSW functions, where appropriate, to evaluate the Dyre shoving model.[2] Here, as is the case for small molecule glass formers, we found the temperature dependences of the G_g highly sensitive to the model chosen to describe the experimental data. This suggests that evaluation of the shoving model requires very broad frequency and temperature experiments beyond those normally performed in dynamic rheometry.

3:18PM X42.00005 Aging and structural recovery behaviors in epoxy films subjected to carbon dioxide plasticization jumps: Evidence for a new glassy state , GREGORY MCKENNA, SHANKAR SUBRAMANIAN, JING ZHAO, MATAZ ALCOUTLABI, LAMECK BANDA, Texas Tech University — Structural recovery and physical aging of glassy polymers after temperature jumps have been very well studied in the literature. On the contrary, there is only limited work available on the aging and recovery behaviors of glassy polymers subjected to plasticizer jumps. We have shown in our previous works, using strong and weakly polar plasticizers that qualitatively they mimic the behaviors of temperature jumps but quantitatively they are different [1, 2]. In this work, we further investigate this anomalous behavior by studying the structural recovery and physical aging of an epoxy film subjected to carbon dioxide pressure jumps and compare the results with temperature jump experiments such that the final conditions are identical. The results are surprising and we observe evidence for existence of a new glassy state.

3:30PM X42.00006 Effect of Quench Conditions on the Subsequent Physical Aging Rate of Polymer Glasses , LAURA GOLICK, PAUL YOON, ANDY PAHNER, CONNIE ROTH, Dept. of Physics, Emory University — We investigate the stability of polymer glasses when thermally quenched under different conditions. Ellipsometry is used to measure the physical aging rate of polystyrene (PS) films supported or transferred onto silicon wafers. The aging rate quantifies the time-dependent decrease in film thickness that results from the increase in average film density during aging. Although all films are subsequently aged in a supported state, we observe significant differences between films quenched in a free-standing compared to supported state. Films quenched in a free-standing state exhibit a strong thickness dependence to their physical aging rate at micron length scales, an order of magnitude or two larger than thicknesses where nanoconfinement effects on the glass transition and modulus are typically observed. In contrast, supported films do not display any film thickness dependence to their aging rate at this large length scale. This indicates that the physical aging of the material is strongly dependent on conditions during the formation of the glassy state. In an effort to determine the key factors underlying the aging dynamics, we have measured the physical aging rate of supported PS films quenched at various controlled rates. In addition, we have explored the effects of quenching free-standing films held on different frames such that either biaxial or uniaxial stress is applied.

3:42PM X42.00007 Low Temperature Flow of PVC Chains , WEI CHEN, GI XUE[1] — PVC is usually processed at temperature above 180 °C, however, it starts to degrade at 130 °C. If PVC can flow at temperatures below glass transition temperature (Tg), the manufacturing procedure will be energy-conserving and environment-friendly. We find that PVC powders with controlled inter-segment van der Waals attraction can be compressed into a transparent pellet with high modulus at low temperatures. The molecular mechanism underlying this phenomenon involves shear-induced unjamming transition. PVC chains are unjammed by cold-pressing freeze-dried powder with decreased packing density. Because the Tg of freeze-dried PVC is dramatically reduced to the test temperatures under compression, PVC chains are able to flow by applying pressure solely. These results help us better understanding glass transition and can possible to develop a theory for cold processes.

3:54PM X42.00008 Evolution of Entanglements During Crazing of Glassy Polymers[1] , TING GE, MARK O. ROBBINS, Johns Hopkins University, ROBERT HOY, Yale University, STEFANOS ANOGIANNAKIS, CHRISTOS TZOUMANEKAS, DOROS THEODOROU, National Technical University of Athens — Craze formation increases the fracture energy of glassy polymers by orders of magnitude. The polymer volume expands by an extension ratio which is assumed to be determined by the entanglement network. We test this assumption with molecular simulations that use the Contour Reduction Topological Analysis (CReTA) algorithm to follow topological constraints (TCs) associated with the entanglement network. The TCs are identified with contacts between chains after applying CReTA. Within systematic errors, crazing does not change the number of TCs or the distribution of chemical distances between them. Moreover, about 75% of the contacts remain between the same chains at nearly the same location. The 25% of contacts that change do not reflect a comparable loss of entanglements. Instead, small displacements within the tube change which chains contact after CReTA. This interpretation is tested by adding fixed crosslinks to a sparse entanglement network and crazing preoriented samples.

4:06PM X42.00009 Surface Softening in Polymers and Their Nanocomposites Determined by Surface Mechanical Properties through Spontaneous Particle Embedment , TASKIN KARIM, GREGORY MCKENNA, Texas Tech University — In the present work, we have used the particle embedment technique with sub-micron particles to estimate the surface modulus of epoxy/POSS composites at a temperature far below the glass transition temperature. The embedment of the particle is determined from atomic force microscope measurements and the modulus was determined using the elastic analysis of Johnson, Kendall and Roberts (JKR) with surface energy estimates of the work of adhesion as the driving force for embedment. The surface modulus values were found much smaller than the macroscopic modulus values. The maximum embedment depth obtained for all surfaces was low enough so that it did not cause plastic deformation on the surface. The maximum stress values on all surfaces induced by the particle embedment were estimated to verify the expected response in close to the linear regime.

4:18PM X42.00010 Effect of molecular weight on gold nanoparticle embedding into polystyrene films near and below the bulk glass transition temperature , CHAD DALEY, DONGPING QI, JAMES FORREST, University of Waterloo — We use gold nanoparticle embedding to probe the surface properties of glassy polystyrene films at temperatures ranging from a few degrees above to 10's of degrees below the bulk glass transition temperature (T_g). These studies employed monodisperse polymer samples with molecular weights (M_w) ranging from 3000-80000 kg/mol. A qualitative change in the surface response is observed between the high M_w and low M_w regimes. At low M_w a buildup of polymer material forms around the base of the nanoparticles similar to the observed behavior in molecular glasses. For the higher molecular weights this buildup is not observed and the system instead relaxes through nanoparticle embedding. We also observe changes in the complete embedding process observed only near the bulk T_g. These changes suggest that nanoparticle embedding can be used as a probe of polymer entanglements.

4:30PM X42.00011 Glass Transition and Free Volume Behavior in Epoxy-amine Network Glasses: Effect of Diiamine Isomers , SERGEI NAZARENKO, MUKUL KAUSHIK, MATTHEW JACKSON, JEFFREY WIGGINS, School of Polymers and High Performance Materials The University of Southern Mississippi, Hattiesburg, MS 39406 — A systematic investigation of the effect of meta and para isomers of diamino diphenyl sulfone (DDS) crosslinker on glass transition temperature (T_g) and free volume properties of DGEBF based epoxy-amine network was carried out. The pressure volume temperature (PVT) properties were measured experimentally from 0 to 120 MPa and 30 °C to 240 °C in a high pressure dilatometer-type PVT apparatus. It was observed that the glass transition temperature of epoxy system with para isomer is higher than the one consisting of meta isomer by 30 °C. PVT data were also fitted using Simha-Somcynsky, equation of state to calculate occupied and free volume. Positron annihilation lifetime spectroscopy (PALS) was used to calculate average hole free volume below and above glass transition temperature. The average free volume size in para isomer cured systems is larger than in meta isomer cured systems below their glass transition temperature, while in the melt state they are the same.

4:42PM X42.00012 Difference in the heat capacity and the coefficient of thermal expansion responses during thermal cycling , GRIGORI MEDVEDEV, EUN-WOONG LEE, JAMES CARUTHERS, Purdue University — An observation that different experimental methods give different values of Tg is part of the lore of the field of the glassy polymers. We report on a careful study of a series of polymeric systems both thermoplastic and thermoset, including PMMA, PC, PS, and 3,3' DDS Epon 825, conducted using DSC and TMA techniques. We found that for the same thermal history the heat capacity and the coefficient of thermal expansion (both measured upon heating) as functions of temperature transition from the glassy asymptote to the equilibrium asymptote at significantly different temperatures; this difference was in the range from 8 to 17 degrees, depending on the system. We argue that such a large difference in the enthalpy and volume responses during the same thermal history is inconsistent with the commonly used material clock models, but is consistent with the view of the glassy materials as containing dynamically heterogeneous regions.

4:54PM X42.00013 Formation of Glassy Polymer Films by Matrix Assisted Pulsed Laser Evaporation , RODNEY PRIESTLEY, YUNLONG GUO, Department of Chemical and Biological Engineering, Princeton University, CRAIG ARNOLD, Department of Mechanical and Aerospace Engineering, Princeton University — The properties of glasses strongly depend on the path to glass formation. The most common method of making polymer glasses is by cooling from the liquid state. Recently, it has been shown that alternative routes to the vitreous state can lead to dramatically improved glassy-state stability. In this talk, we present our initial work on the thermal and kinetic stability of glassy polymer films prepared by Matrix Assisted Pulsed Laser Evaporation (MAPLE). In comparison to glassy films prepared by spin coating, MAPLE-deposited glassy films can exhibit higher glass transition temperatures and greater kinetic stability.

5:06PM X42.00014 Characterization of pre-mature nanocomposite crazes , GREGORY N. TOEPPERWEIN, JUAN J. DE PABLO, University of Wisconsin Madison — Crazing is a unique mode of failure by which polymer strands are stretched into a periodic array of columns. It has been shown that these crazes follow cavitation under deformation. Inclusion of nanoparticles drastically alters the glass transition temperature and the globally measurable mechanical properties of these polymer glasses. However, limited literature exists to explain the behavior on the lengths scales of the heterogeneous domains within the glass in the context of nanocomposites. In this work, we investigate the nucleation and growth of voids that precede craze formation to elucidate the role these inclusions play in failure and further characterize the pre-mature craze itself. Extensive Molecular Dynamics and Monte Carlo simulations of highly entangled polymer nanocomposites allow for calculation of local densities, local elastic moduli, and local orientation of additives. We find that the site of void formation is inexorably linked to the local mechanical properties of polymer. This relationship is more evident upon the inclusion of reinforcing additives which induce a broader distribution of local moduli leading to the nucleation of more, smaller voids. Within the developing craze, larger additives resist incorporation, but those that do are subject to ordering.

5:18PM X42.00015 Structural Characterization of a Polymer of Intrinsic Microporosity: X-ray Scattering With Insight From Molecular Dynamics Simulations[1] , AMANDA G. MCDERMOTT, GREGORY S. LARSEN, Penn State University, PETER M. BUDD, University of Manchester, CORAY M. COLINA, JAMES RUNT, Penn State University — Polymers of intrinsic microporosity (PIMs) are high-T_g, amorphous materials exhibiting high gas permeability and a large concentration of pores smaller than 2 nm, arising from a combination of rigid segments and sites of contortion. Structures generated by molecular dynamics simulations accurately reproduce characteristic scattering features from PIM-1 at high q, allowing us to investigate their origin by examining partial structure factors. Unlike scattering patterns typical of nonporous amorphous polymers, broad q range PIM scattering patterns include a shoulder at the size scale corresponding to pore sizes measured by other techniques. We discuss the development of a model for extracting pore sizes from scattering patterns.

Session X43 DPOLY: Focus Session: Assembly, Structure, & Instabilities in Polymer Films, Network Films, & Interfaces II A306/307

2:30PM X43.00001 Hydrogels with Spatially and Temporally Controlled Properties to Control Cellular Interactions , JASON BURDICK, University of Pennsylvania — Stem cells (e.g., mesenchymal stem cells, MSCs) respond to many cues from their microenvironment, which may include chemical signals, mechanics, and topography. Importantly, these cues may be incorporated into scaffolding to control stem cell differentiation and optimize their ability to produce tissues in regenerative medicine. Despite the significant amount of work in this area, the materials have been primarily static and uniform. To this end, we have developed a sequential crosslinking process that relies on our ability to crosslinked functional biopolymers (e.g., methacrylated hyaluronic acid, HA) in two steps, namely a Michael-type addition reaction to partially consume reactive groups and then a light-initiated free-radical polymerization to further crosslink the material. With light exposure during the second step comes control over the material in space (via masks and lasers) and time (via intermittent light exposure). We are applying this technique for numerous applications. For example, when the HA hydrogels are crosslinked with MMP degradable peptides with thiol termini during the first step, a material that can be degraded by cells is obtained. However, cell-mediated degradation is obstructed with the introduction of kinetic chains during the second step, leading to spatially controlled cell degradability. Due to the influence of cellular spreading on MSC differentiation, we have controlled cell fates by controlling their spread ability, for instance towards osteoblasts in spread areas and adipocytes when cell remained rounded. We are also using the process of stiffening with time to investigate mechanically induced differentiation, particularly in materials with evolving mechanics. Overall, these advanced HA hydrogels provide us the opportunity to investigate diverse and controlled material properties on MSC interactions.

3:06PM X43.00002 Hydrogel Stamping of Polyelectrolyte Multilayers for Directed Cell Growth , NICOLE ZACHARIA, Texas A&M University, CHUNGYEON CHO, Texas A&M University, Materials Science and Engineering — The authors have recently introduced the use of hydrogel stamp materials to pattern polyelectrolyte multilayer (PEM) films. It has been demonstrated that using a stamp equilibrated in either low or high pH can cause local swelling in these films, leading to patterns. It has also been shown that stamps soaked in high ionic strength salt solutions are able to locally etch PEM films. This hydrogel stamping technique gives both lateral control of surface properties and depth control over the film's properties. This technique is a promising way to pattern chemical reactions within PEM, phase transformation, and physical properties such as film thickness, Young's modulus, and swelling. By using hydrogels for the stamp material, stamping becomes a process of continuously delivering aqueous reagent of interest to a film, instead of merely a single layer of material, as is the case when using hydrophobic stamp materials such as PDMS. While chemical modification of only the surface may be desirable in some cases, the hydrogel stamping technique is more versatile. By creating local variations in swelling, we are able to pattern mechanical stiffness, and in turn cell adhesion. We demonstrate the creation of gradients in mechanical stiffness which we are able to use to direct cell growth and adhesion on these films.

3:18PM X43.00003 Patterned Poly-N-isopropylacrylamide Surfaces for Culture and Harvest of Muscle Fibers , SAMUEL DUPONT, KRANTHI KUMAR ELINENI, NATHAN GALLANT, RYAN TOOMEY, University of South Florida — Swelling of surface confined poly-N-isopropylacrylamide (pNIPAAm) structures leads to non-uniform patterns that can be switched by a thermal cue. Based on the geometry of the surface confined patterns, various forms of structural instabilities arise such as bulk buckling, differential lateral swelling and edge buckling. Instabilities that arise from the swelling of patterned pNIPAAm surfaces present a unique platform for tissue engineering applications. Recent work has demonstrated the attachment, survivability, and alignment of fibroblasts grown atop rectangular pNIPAAm surface extrusions. Detachment of contiguous and aligned fibroblasts grown on these surfaces was observed when the geometry of the structure was such that a bulk buckling instability formed upon thermally induced gel swelling. Current work is aimed at utilizing this switchable platform to culture aligned myoblasts, which upon differentiation, form multicellular myotubes, an important structure in skeletal muscle. Myotubes for tissue engineering can then be harvested by non-enzymatic detachment facilitated by thermally induced non-uniform gel swelling.

3:30PM X43.00004 Controlled Release from Model Blended Polyelectrolyte Multilayer Films , BULENT AKGUN, NIST Center for Neutron Research, NIST, Gaithersburg, MD 20899, YEONGSEON JANG, School of Chemical and Biological Engineering, Seoul National University, Seoul, Korea , SUSHIL SATIJA, NIST Center for Neutron Research, NIST, Gaithersburg, MD 20899, KOOKHEON CHAR, School of Chemical and Biological Engineering, Seoul National University, Seoul, Korea — We propose a new concept of controlled release platforms based on the model blended multilayer films composed of positively charged weak polyelectrolyte (linear poly(ethylenimine),LPEI) layer and blended layer with negatively charged strong (poly(sodium-4-styrene sulfonic acid),PSS) and weak (poly(methacrylic acid),PMAA) polyelectrolytes. The blended multilayer films $((\text{LPEI/PSS:PMAA})_n)$ with well-defined internal structure are prepared by spin-assisted LbL deposition method, and their release behavior is systematically characterized with combined techniques of neutron reflectivity, ellipsometry, AFM, QCM and FT-IR. Since PSS provides the robust skeleton within the multilayer films independently on pH variation, the burst erosion of multilayer films is dramatically suppressed, and the release kinetics of PMAA can be precisely controlled by simply changing PSS contents within the multilayer films.

3:42PM X43.00005 Surface wrinkling driven by swelling and its applications , HYUN SUK KIM, ALFRED CROSBY, University of Massachusetts Amherst — The nature of reversible surface wrinkling offers great promise for designing responsive or adaptive materials. We experimentally explore the reversibility and geometry of surface wrinkles driven by swelling an elstically-supported stiff plate by solvent vapor and liquid. We use crosslinked polydimethylsiloxane (PDMS) substrates with surfaces modified by ultraviolet-ozone (UVO) processing, creating materials with rigid, surface films that swell differentially in comparison to the underlying substrates. We observe the dependence of the wrinkle wavelength on the UVO time and thickness of elastomers. Furthermore, we identify a critical length scale for the swelling region below which wrinkle formation is suppressed. Taking advantage of the reversibility and geometric relations, we demonstrate advanced applications such as smart windows with swichable optical transparency and responsive channels in microfluidics.

3:54PM X43.00006 Nanoporous Conductive Films Derived from Polymeric Bicontinuous Microemulsions , BRAD JONES, KAI-YUAN CHENG, RUSSELL HOLMES, Department of Chemical Engineering and Materials Science, University of Minnesota, TIMOTHY LODGE, Department of Chemistry and Department of Chemical Engineering and Materials Science, University of Minnesota — Ternary blends of two homopolymers and a diblock copolymer can self-assemble into interpenetrating, 3D-continuous networks with a characteristic length scale of 100 nm. These polymeric bicontinuous microemulsions (BμE) can be designed to serve as templates for the synthesis of nanoporous materials with 3D-continuous pore networks. We have investigated the behavior of BμE-forming blends of polyolefins as precursors to nanoporous polyethylene (PE) films. The effect of interfaces in these films can drastically disrupt the BμE structure, leading to a macro-phase separated morphology. Proper consideration of several factors, including substrate surface energy, film thickness, and annealing time, is necessary to retain a BμE structure in such films. Finally, we use the BμE-like, nanoporous PE films as templates in the synthesis of nanoporous films of the conducting polymer poly(3,4-ethylenedioxythiophene), having potential application in organic electronic devices.

4:06PM X43.00007 Particle Behavior at Anisotropically Curved Liquid Interfaces , KATHLEEN MCENNIS, CHUAN ZENG, BENNY DAVIDOVITCH, ANTHONY DINSMORE, THOMAS RUSSELL, University of Massachusetts Amherst — A particle bound to an anisotropically curved liquid interface, such as a cylinder or catenoid, cannot maintain a constant contact angle without deforming the interface. Theory suggests that the particles will experience a force that depends on the interfacial shape and migrate to minimize the total interfacial energy. To test these predictions, particles were deposited on top of liquid semi-cylinders of ionic liquid or melted polystyrene confined on chemically patterned surfaces. Particles were also deposited on liquid catenoid structures created by placing a melted polymer film under an electric field. The location of the particles on these structures was observed by optical, confocal, and scanning electron microscopy. The implications for the directed assembly of particles and stability of Pickering emulsions are also discussed.

4:18PM X43.00008 Hierarchically Ordered Block Copolymer Micelles Formed by Controlled Evaporative Self-Assembly , WEI HAN, MYUNGHWAN BYUN, ZHIQUN LIN, Iowa State University — Highly ordered gradient stripes of PS-b-P4VP block copolymer were obtained by combining the microscopic controlled evaporative self-assembly (CESA) of confined microfluid of PS-b-P4VP toluene solution in a "cylinder-on-Si" geometry with spontaneous self-assembly of micellar hexagonal arrays of PS-b-P4VP at the nanometer scale. The order of packed micelles within microstripes could be significantly improved by subsequent THF vapor annealing. The surface reconstruction of micelles led to the formation of nanoporous arrays when immersed in a selective solvent of the pore component. Gold nanoparticles were then selectively deposited into the core of micelles, and eventually forming the hexagonal arrays of gold nanoparticles after removal of polymer templates by oxygen plasma. The formation of gold particle arrays was verified by XPS measurement.

4:30PM X43.00009 Viscoelastic properties of ultrathin polymer films using the liquid dewetting technique , JINHUA WANG, GREGORY MCKENNA, Department of Chemical Engineering, Texas Tech University, Lubbock, Texas, 79409 — There is considerable interest in studying the behavior of polymers at the nanoscale. Here we describe experiments using the Bidiguel and Fretigny's liquid dewetting technique in which no great glass transition temperature (Tg) reduction or rubbery plateau compliance change for polystyrene (PS) films was observed [1]. These results are contrary to observations by others of Tg reductions on free standing polystyrene films and of large rubbery stiffening observed in our lab using a bubble inflation method [2,3]. Preliminary results of PS film dewetting are consistent with the Bidiguel and Fretigny's results. Also, annealing time and confinement effects on the creep behavior of polystyrene thin film were examined. Then, the range of investigated materials is being expanded to polycarbonate (PC) and poly(methyl methacrylate) PMMA with the ultimate goal to determine the reasons for the differences between the bubble inflation method and liquid dewetting technique of polymer film charicterization. 4:42PM X43.00010 Elastic Moduli of Nanoparticle-Polymer Composite Thin Films via Buckling on Elastomeric Substrates , HONGYI YUAN, ALAMGIR KARIM, Department of Polymer Engineering, The University of Akron, Akron, OH, USA, UNIVERSITY OF AKRON TEAM — Polymeric thin films find applications in diverse areas such as coatings, barriers and packaging. The dispersion of nanoparticles into the films was proven to be an effective method to generate tunable properties, particularly mechanical strength. However, there are very few methods for mechanical characterization of the composite thin films with high accuracy. In this study, nanometric polystyrene and polyvinyl alcohol films with uniformly dispersed cobalt and Cloisite nanoparticles at varying concentrations were synthesized via flow-coating and then transferred to crosslinked polydimethylsiloxane (PDMS) flexible substrates. The technique of Strain-Induced Elastic Buckling Instability for Mechanical Measurements (SIEBIMM) was employed to determine the elastic moduli of the films, which were calculated from the buckling patterns generated by applying compressive stresses. Results on moduli of films as a function of the concentrations of nanoparticles and the thicknesses of the composite films will be presented. *Corresponding author: alamgir@uakron.edu

4:54PM X43.00011 Effect of Chain Architecture on the Physical Aging of Thin Polymer Filims , BRADLEY FRIEBERG, EMMANOUIL GLYNOS, PETER GREEN, University of Michigan — Physical aging, glassy structural relaxations, is an important phenomenon that has an important influence on a range of physical properties, such as optical, mechanical and electrical, of polymeric materials properties. When a polymeric material is cooled below its glass transition temperature (Tg) it resides in a non-equilibrium state, and over time it attempts to return to equilibrium via a structural relaxation process. We have previously demonstrated that chain architecture can influence the Tg in supported thin films. Specifically, star-shaped molecules possessing sufficiently high functionality (f) and low molecular weight of the arm (Mw), exhibit significant differences in vitrification trends from their linear analogs. In this presentation we show that when f is sufficiently high, or Mw is sufficiently low, the physical aging rate is suppressed compared to linear chains. Moreover, the aging rates of thin, supported films of star shaped molecules are strongly thickness dependent.

5:06PM X43.00012 Perturbing the Tg of Polymers by 50-100 K in Nanoconfined Freely Standing Films and by the Presence of Neighboring Layers of Other Polymers , JOHN TORKELSON, SOYOUNG KIM, Northwestern University — We demonstrate via the temperature dependence of fluorescence intensity intrinsic to the polymer of interest or from dye labels that the glass transition temperature (Tg) of a polymer can be altered by 50-100 K by nanoconfinement in freely standing films and in multilayer systems in which the neighboring layers are different polymers. In the former case, Tg always decreases from bulk Tg; in the latter case, Tg decreases or increases depending on the Tg of the neighboring polymer layer and factors that may be related to fragility. We employ fluorescence to characterize the gradient in Tg from the perturbing interfaces. These studies reveal that the theory by de Gennes for the Tg reduction in freely standing films cannot be correct and that the perturbation to Tg by a neighboring layer of another polymer can extend as much as 100 nm into the layer of interest.

Session X44 DPOLY DFD: Focus Session: Polymer Colloids-Structure, Function, and Dynamics II A309

2:30PM X44.00001 Nanoparticle Organic Hybrid Suspensions: Structure and Rheology , SAMANVAYA SRIVASTAVA, LYNDEN ARCHER, Cornell University — Nanoparticle Organic Hybrid Materials (NOHMs) are a new class of tethered nanoparticle systems with high grafting densities and behave as model systems for studying spherical polymer brushes. Here we report rheology and scattering measurements of NOHMs with a silica core and PEG corona suspended in PEG oligomers at varying volume fractions. Our rheology results reveal a liquid-glassy transition at strikingly low core volume fractions in these suspensions and prominent stress overshoots in flow startups indicative of yielding in the high volume fraction suspensions. Further, we elucidate the form of particle interactions in the glassy suspensions and compare them with established models. Also, a negative first normal stress difference in the moderate volume fraction suspensions is reported, which is in agreement with recent theoretical and experimental findings. We also report small angle scattering measurements of these suspensions to reveal their equilibrium structure, which are in qualitative agreement with a recent theoretical study (Langmuir, 2010, 26, 16801).

2:42PM X44.00002 Measuring and Modeling the Interactions Between DNA-Functionalized Colloids , WILLIAM ROGERS, JOHN CROCKER, Department of Chemical and Biomolecular Engineering, University of Pennsylvania — DNA hybridization is an ideal tool to direct "bottom-up" assembly of complex materials and has been used to form crystalline assemblies of quantum dots, polymer microspheres and other materials made exclusively of DNA. In order to fully realize the potential of DNA-directed self-assembly, one must be able to quantitatively predict the binding energies and interaction potentials between the relevant "building blocks." In this work, we use a scanning-line optical tweezers instrument to measure DNA-induced interactions between colloidal microspheres. We then use well-known concepts in statistical mechanics to model the pair-potentials, whose functional form and energetics of binding are intimately related to the equilibrium configurations of grafted polymers and polymer bridges. By measuring and modeling the pair interaction energies as a function of the essential system parameters (solution hybridization free energies, DNA concentrations, temperature, interparticle separation, etc.), we are able to develop simple, numerical tools that can be used to guide both experiment and simulation.

2:54PM X44.00003 Rheological and scattering properties of cross-linker-free microgels , ZHIYONG MENG, CHINEDUM OSUJI, Yale University — Microgel suspensions are intriguing tunable systems in part due to their pH/temperature responsivity at the single particle level. Particle collapse during volume transitions is heavily mediated by the presence of cross-links in the system. Here we examine the rheology and light scattering of microgel suspensions based on poly(N-isopropylacrylamide-*co*-acrylic acid) (pNIPAm-AAc) in the limit of vanishing cross-linking density. One issue of concern is centered on the nature of these fluids – are they simple polymer solutions or real particulate suspensions? A combination of concentration-dependent viscometry and static light scattering demonstrates conclusively that these are particulate suspensions. The absence of cross-linkers provides a sharper volume collapse at the LCST in comparison with heavily cross-linked particles. Furthermore, at fixed mass content, cross-linker-free microgel suspersions display a much higher shear modulus than cross-linked counterparts due to their larger particle size, which implicates the use of these particles in rheological modification. We survey the frequency dependence and yielding response of these suspensions as a function of temperature and composition.

3:06PM X44.00004 Normal Modes and Density of States of Disordered Colloidal Solids , MOHAMMAD ISLAM, Department of Materials Science & Engineering, Carnegie Mellon University, Pittsburgh, PA 15213 — The normal modes and the density of states (DOS) of any material provide a basis for understanding its thermal and mechanical transport properties. In perfect crystals, normal modes take the form of planewaves, but they can be complex in disordered systems. I will show our recent experimental measurements of the normal modes, the DOS and dynamical structure factor (DSF) in disordered colloidal solids: disordered colloidal crystals composed of thermally sensitive micron-sized hydrogel particles at several different particle volume fractions, ϕ. Particle positions are tracked over long times using optical microscopy and particle tracking algorithms in a single two dimensional (2D) [111] plane of a 3D face-centered-cubic single crystal. The dynamical fluctuations are spatially heterogeneous while the lattice itself is highly ordered. At all ϕ, the DOS exhibits an excess of low frequency modes, a so-called boson peak (BP), and the DSF exhibits a crossover from propagating to non-propagating behavior, a so-called Ioffe-Regel (IR) crossover, at a common frequency somewhat below the BP for both longitudinal and transverse modes. As we tune ϕ from 0.64 to 0.56, the Lindemann parameter grows from $\sim$3% to $\sim$8%, however, the shape of the DOS and DSF remain largely unchanged when rescaled by the Debye level. This invariance indicates that the effective degree of disorder and the structure of the underlying normal modes remain essentially unchanged even in the vicinity of melting. This work was supported by NSF through grants DMR-0645596 & DMR-0619424, the Sloan Foundation and American Chemical Society Petroleum Research Fund.

3:42PM X44.00005 Signatures of Aging: Comparison between Colloidal and Molecular Glasses , XIAOJUN DI, Dept of ChE, Texas Tech Univ., K.Z. WIN, GREGORY MCKENNA, T. NARITA, F. LEQUEUX, S. PULLELA, Z. CHENG, DEPT OF CHE, TEXAS TECH UNIV TEAM, PPMD, UPMC-ESPCI-CNRS, FRANCE TEAM, DEPT OF CHE, TEXAS A&M UNIV TEAM — Colloids near to the glass concentration are often taken as models for molecular glass formers. Yet, one of the most important aspects of the dynamics of molecular glasses, structural recovery, remains to be examined in colloids. We use DWS to investigate structural recovery in a thermosensitive PNIPAM colloidal suspension in the glass concentration range. The three classical aging signatures observed in molecular glasses: intrinsic isotherms, asymmetry of approach and memory effect, are investigated with this colloid and the results are compared with those typical of molecular glasses. We find: 1 for the intrinsic isotherms, the colloid shows dramatic changes in relaxation time at equilibrium while the times required to reach the equilibrium state are nearly independent of the concentration; 2 for the asymmetry of approach, the observed nonlinearity is similar to that in molecular glasses; 3 for the memory experiment, while the memory effect is seen in the colloid, the response is qualitatively different than in the molecular glass.

3:54PM X44.00006 Packings of soft disks[1] , PRIMOZ ZIHERL, University of Ljubljana and Jozef Stefan Institute, MARIJA VIDMAR, University of Ljubljana — We explore the stability of 2D ordered structures formed by soft disks treated as isotropic solid bodies. Using a variational model, we compute the equilibrium shapes and the elastic energy of disks in regular columnar, honeycomb, square, and hexagonal lattice. The results reproduce the Hertzian interaction in the regime of small deformations. The phase diagram of elastic disks is characterized by broad regions of phase coexistence; its main feature is that the coordination number of the stable phases decreases with density. These results may provide an insight into structure of the non-close-packed lattices observed in certain nanocolloidal systems.

4:06PM X44.00007 Theory of effective interactions and dispersion of soft nanoparticles in polymer melts , JIAN YANG, KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — Integral equation theory is employed to investigate the consequences of nanoparticle softness (surface fluctuations) and corrugation (discrete roughness) on the equilibrium behavior of polymer-particle mixtures in the dilute filler limit. Monomer-particle pair correlations exhibit qualitatively different features relative to hard spheres which depend on both roughness and softness. Under athermal nonadsorbing polymer conditions, depletion effects on the interparticle potential-of-mean-force (PMF) are qualitatively modified by surface corrugation and/or fluctuations. As particle softness increases, monomer-scale PMF oscillations are destroyed, and the strongest attraction occurs at a particle separation and attraction depth that depends sensitively on surface fluctuation amplitude, as does the dependence on monomer-nanoparticle size asymmetry ratio (R). For corrugated particles, the most attractive nanoparticle separation does not occur at contact, and is far weaker and less sensitive to R than for hard spheres. Second virial coefficient calculations are performed to estimate how particle softness/roughness modifies miscibility in chemically matched blends. How surface corrugation and softness modifies bridging and sterically stabilized states has also been studied..

4:18PM X44.00008 Density functional theory for the structure and dynamics of solvent-free nanoparticle–organic hybrid materials , HSIU-YU YU, DONALD KOCH, Cornell University — Nanoparticle–organic hybrid materials consist of inorganic nanocores functionalized with oligomeric organic molecules. They exhibit fluid behavior in the absence of solvent with the fluidity provided by the attached oligomers. We present a density-functional theory for the equilibrium structure and transport properties of these materials based on an assumption that the intercore forces are mediated by entropic effects associated with the conformations of the hairs subject to the constraint that the oligomer fluid is incompressible. Because each core particle carries its share of the fluid phase, the structure factor at zero wave number is equal to zero. When the radius of gyration of the oligomers is large compared with the core radius, each core experiences weak interactions with many other cores residing in its neighborhood. Exploiting this limit, the transport properties can be determined in a quasi-analytical manner based on a solution of the non-equilibrium probability density for pairs of particles experiencing a non-pairwise-additive intercore potential.

4:30PM X44.00009 Yielding mechanisms and particle rearrangements in colloidal glasses and gels under shear , GEORGE PETEKIDIS, IESL-FORTH — Steady and oscillatory rheology was utilized to study the mechanical response of colloidal glasses and gels with particular emphasis in the way these are shear melted (yield) [1,2]. We used suspensions of hard sphere colloids with short-range depletion attractions induced by the addition of non-adsorbing linear polymer. The linear viscoelasticity and the yielding mechanisms at different regimes of colloid volume fraction and particle attractions are discussed. While hard sphere glasses exhibit a single step yielding due to cage breaking, attractive glasses show a two-step yielding reflecting bond and cage breaking respectively [1]. Here we present experimental data both along a line of equal attraction, varying the particle volume fraction, from an attractive glass to a low volume fraction gel as well as at intermediate and high volume fractions with increasing the attraction strength. In attractive gels yielding remains a two step process until very low ϕ's. The first yield strain is related with in-cage or inter-cluster bond braking while the second yield point is attributed to braking of cages or clusters into smaller constituents [3]. The latter increases as volume fraction is decreased due to enhancement of structural inhomogeneities. When the range of attraction was increased, both yield strains increase, scaling with the range of attraction and accompanied structural changes. Brownian Dynamics simulations and Dynamic Light scattering under shear (LS-echo) provide information on the microscopic particle rearrangements and structural changes during yielding and flow such as the size and structure of clusters that change under steady shear as a function of shear rate. Work in collaboration with: N. Koumakis, (FORTH), M. Laurati, S.U. Egelhaaf (U. Duesseldorf) and J. F. Brady (Caltech).

5:06PM X44.00010 Ridge formation of charged end group ligands grafted on faceted nanoparticle , PEIJUN GUO, RASTKO SKNEPNEK, MONICA OLVERA DE LA CRUZ, Northwestern University — We have investigated the conformations of charged end group ligands grafted on icosahedral nanoparticles, using a coarse-grained molecular dynamics approach. Due to a competition between the electrostatic repulsion and the hydrophobic ligand-ligand attraction, the ligand coatings form a variety of different conformations. These conformations have been compared with the case of non-charged grafted ligands. We have found that the electrostatic interaction between the charged ends drives the formation of a ridge-like structure of the ligands, which makes the nanoparticle surface highly anisotropic. We argue that the ridge-like ligand structure induces controllable directional interaction between the nanoparticles, and can drive the self-assembly of the nanoparticles into crystalline structures.

5:18PM X44.00011 Dynamics of Polymers in Colloidal Flows , HSIEH CHEN, ALFREDO ALEXANDER-KATZ, Massachusetts Institute of Technology — This research is motivated by recent studies on the von Willebrand factor (vWF), a large multimeric protein that plays an essential role in the initial stages of blood clotting in blood vessels. Recent experiments substantiated the hypothesis that the vWF is activated by shear stress in blood flow that causes its shape to transform from a compact globule to an extended state [1], and biological function is obtained only in the extended state. Simple simulations (which only consider a single polymer in bulk shear flow) have successfully reproduced the observed dynamics of the vWF [2]. However, a more refined model is still demanding for the better understanding of the behaviors of this biomolecule in the physiological environments. Here we refine the existing model by adding the drifting colloids into the flows to mimic the presence of the blood cells in the bloodstream. Preliminary result shows that colloids greatly influence the dynamics of the polymers. It is observed that the average extensions of polymers along and perpendicular to the shear flow direction are both increased with the presence of the colloids.

5:30PM X44.00012 Spontaneous asymmetry in coated spherical nanoparticles in solution and at liquid-vapor interfaces , J. MATTHEW D. LANE, GARY S. GREST, Sandia National Laboratories — Nanoparticles in solution are often stabilized with functional coatings to prevent aggregation. We'll present recent simulations results showing that small spherical nanoparticles produce highly asymmetric coating arrangements, when coated with simple polymer chains. These coatings are not symmetric even when extremely uniform grafting arrangements and full coverages are employed. I will also discuss the geometric properties which dictate the coating shape. When particles are placed in an anisotropic environment, such as the liquid/vapor interface, the asymmetric coatings are amplified and oriented by the surface. Particle shape and its responsive behavior is seen to strongly influence interactions. Implications and examples of controlled self-assembly will be presented.

Session X45 DPOLY: Focus Session: Nanocomposite Physics I-Dispersions and Physical Properties A310

2:30PM X45.00001 Dynamical Aspects of Percolation Networks of Carbon Nanotubes in Polymer Composites , GYEMIN KWON, BONG JUNE SUNG, Department of Chemistry, Sogang University, Korea — Carbon nanotubes (CNTs) form a percolating network easily in polymer nanocomposites due to their high aspect ratios, thus improving both electrical and mechanical properties of composites. However, poor dispersion of CNTs has been a stumbling block to their application in industry. Therefore, extensive studies on the structure and thermodynamics of CNTs have been carried out to enhance the dispersion of CNTs in composites and find optimal conditions for better electrical and mechanical properties. But little attention has been paid to the dynamic aspects of percolation networks of CNTs, which should be also a critical factor to determine physical properties of composites. In this study, we investigate the 1st order survival rate, the assortative coefficients, and the bond connectivity time correlation function of percolation networks by using molecular dynamics simulations. We find that the CNT network dynamics becomes significantly slow and the CNT networks become dynamically stable as the concentration of CNTs increases beyond the percolation threshold concentration. We also investigate the effect of intermolecular interaction between CNTs and polymers on the dynamic behaviors of CNT networks.

2:42PM X45.00002 Langevin Approach to Optimizing Thermal Conductivity in Composite Materials , ABDELLAH AIT MOUSSA, K.G.S.H. GUNAWARDANA, KIERAN MULLEN, Homer L. Dodge Dept. of Physics and Astronomy, University of Oklahoma — The quest for high thermal conductivity materials has lead to nano-composites incorporating materials with excellent thermal conductivity in a matrix of poorer thermal conductivity. To minimize the interface thermal resistance the stiff, incorporated materials can be chemically functionalized with various side chains. We report here an efficient theoretical method to evaluate different choices for functionalization. We use this method to examine how effective different alkane chains improve the heat flux through a graphene nano-sheet.

2:54PM X45.00003 Use of embedded metal nanoparticles as photothermal heaters in polymer nanocomposites , SOMSUBHRA MAITY, JASON BOCHINSKI, LAURA CLARKE, NC State University — Embedded metallic nanoparticles within polymer nanofibers can internally heat and thus thermally-modify (soften, melt, or bond) polymer composites when irradiated with visible light via excitation and non-radiative relaxation of the nanoparticle surface plasmon resonance. Because the heating originates at the nanoparticle surface and propagates outward, a strong spatial temperature gradient exists. We discuss a non-contact, temperature-sensitive fluorescence technique to determine local temperature within the composite, which utilizes changes in the emission spectrum of perylene.....,[1] in addition to determining temperature from changes in polymer morphology. The efficacy of plasmonic heating in different morphologies (nanofibers/films) as well as its effect on material mechanical properties when heated between T_g and T_m is discussed. The spatial specificity of the photothermal heating as determined by the nanoparticle location represents a unique nanoprocessing tool.

3:06PM X45.00004 Resistive switching in bulk polymer nanocomposites containing silver nanowires , KAREN WINEY, University of Pennsylvania, SADIE WHITE, PATRICK VORA, JAY KIKKAWA, ROSE MUTISO, University of Pennsylvania — Traditionally, bulk nanocomposites of electrically conducting particles and insulating polymers have been categorized as either insulating or conducting when the nanoparticle concentration is below or above the percolation threshold, respectively. We present the first examples of reversible resistive switching in bulk, glassy polymer nanocomposites. At compositions close to the electrical percolation threshold, silver nanowire-polystyrene nanocomposites demonstrate reversible resistive switching upon increase voltage at room temperature. Nanocomposites with compositions outside of this range exhibit either irreversible switching, or no switching at all. We propose that resistive switching in these materials is the result of the field-induced formation of silver filaments that bridge adjacent nanowire clusters, extending the percolation network and decreasing the sample's bulk resistivity. We also describe the temperature-dependent characterization of resistive switching in these nanocomposites between 10 and 300K. These findings break from the usual dichotomy of insulating or conducting properties in polymer nanocomposites and could inspire new devices that capitalize on this responsive behavior in these versatile materials.

3:18PM X45.00005 The Development of Structure in Nanoscale Colloidal Silica – Polymer Nanocomposites , JEFF METH, J. DAVID LONDONO, CHANGZAI CHI, BARBARA WOOD, PATRICIA COTTS, Nanocomposite Technologies, Central R&D, DuPont Co., SANGAH GAM, KAREN WINEY, RUSSELL COMPOSTO, Dept. of Materials Science & Engineering, Univ. of Pennsylvania — Controlling the state of dispersion or agglomeration in polymeric nanocomposites has a profound impact on their properties. Many nanocomposites are manufactured by a solution process. In such processes, colloidal silica dispersed in a formulation possesses a certain interparticle structure, and this structure changes as the coating formulation dries. In this work, we have measured the structure of colloidal silica – PMMA formulations as a function of solvent content using small angle X-ray scattering (SAXS). We found that the formulations dried in two stages: concentration and neutralization. In the concentrating stage, the charged colloid structure prevails, and the formulation simply concentrated down. In the neutralization stage, the colloid gradually lost its charge. Controlling the matrix viscosity enables one to control the final state of dispersion. These findings explain how and why it is possible to create good nanodispersions in some material systems. These general findings are applicable to a wide range of material systems.

3:30PM X45.00006 Dispersion Behavior of Au Nanorods in Polymer Thin Films Mediated by Brush-Matrix Interactions , MICHAEL J.A. HORE, RUSSELL J. COMPOSTO, Department of Materials Science and Engineering, University of Pennsylvania — Moderate volume fractions (∼5 v%) of poly(ethylene glycol) or polystyrene-functionalized Au nanorods are incorporated into poly(ethylene oxide), poly(methyl methacrylate), or polystyrene thin films (thickness ∼30 nm). Their dispersion is characterized via TEM, AFM, and x-ray reflectivity. When the chemical species of the brush is identical to that of the matrix, nanorod dispersion is dominated primarily by entropy and controlled by the ratio of the chain lengths of the brush and matrix. When there is a favorable enthalpic interaction between the brush and matrix, the dispersion is independent of the molecular weights of the brush and matrix. These experimental data are compared to Monte Carlo simulations.

3:42PM X45.00007 Particle networks through aggregation in polymer nanocomposites , MEISHA SHOFNER, Georgia Institute of Technology, JASMEET KAUR, JI HOON LEE — Structure-property research in polymer nanocomposites has often focused on producing systems that are homogeneously dispersed in order to capitalize on the large amount of specific surface area available from nanoparticles. However, inhomogeneous dispersion is often obtained and in some cases has been deliberately sought to enhance functional properties through the formation of particle networks. In this research, we are seeking to understand how particle aggregation impacts network formation in polymer nanocomposites as a function of native particle shape. Specifically, we are characterizing nanocomposites comprised of calcium phosphate particles with different shapes and a polyhydroxybutyrate matrix. Experimental results concerning the effect of particle aggregation and shape on polymer crystalline structure, thermal transitions and mechanical properties are presented to correlate particle aggregation to network formation and understand structure-property relationships in these materials.

3:54PM X45.00008 A silica nanoparticle based ionic material[1] , NIKHIL FERNANDES, ZUBAIR AZAD, EMMANUEL GIANNELIS, Cornell University — We report an ionic fluid consisting of silica nanoparticles as the anion, and amine-terminated polyethylene glycol as the cation. Unlike previous work that has required chemical functionalization of the silica surface, the charge on the nanoparticle anion is carried by the intrinsic surface hydroxyls, simplifying the synthesis, and thus making this a simple test system to probe the physics of these nanoscale ionic materials. Charge and steric factors result in excellent dispersion of the nanoparticles in the polymer matrix. The resulting material is a soft glass that has thermal and rheological properties that depend on the silica:polymer ratio. In particular, at a critical silica:polymer ratio, the ionic material shows a significant depression of the normalized heat of melting and the melting temperature compared to samples with higher or lower silica content (showing eutectic-like behaviour), and to controls without the ionic interaction between the polymer and the particle.

4:06PM X45.00009 Structure-Properties Relationship in Segmented Polyurethane/Silica Nanoparticle Composites , MATTHEW HOOD, Drexel University, JAMES SANDS, JOHN LA SCALA, FREDERICK BEYER, Army Research Laboratory, CHRISTOPHER LI, Drexel University — Segmented polyurethanes (SPUs) phase separate into hard and soft domains due to differences in segment composition, resulting in extraordinary mechanical properties. We have synthesized a set of SPU/nanoparticle composites possessing 25, 35 or 45wt.% hard segment content and loaded with less than 5wt.% silica nanoparticles (SiNPs). SiNPs were added either during SPU synthesis or blended after. Drastic effects on morphology and mechanical properties were observed. Blended composites, due to their destabilizing of the hard domain, showed decreased mechanical robustness. When particles are added, at very low SiNP concentrations, during SPU synthesis the SiNPs are covalently attached to the SPU matrix and hard domains are intact which enhanced elongation to break and tensile strength considerably. With increasing SiNP concentration this effect was reversed and hard domain crystallization was hindered. Thermal, mechanical and diffraction experiments were used to correlate the relationship between interfacial chemistry of the SiNP and SPU matrix and the mechanical properties of the composites.

4:18PM X45.00010 Polyurethane Nanocomposites Reinforced with Core-shell Magnetic Particles for Microwave Absorption Applications , ZHANHU GUO, Lamar University, JIAHUA ZHU, RAHUL PATIL, NEEL HALDOLAARACHCHIGE, DAVID YOUNG, SUYING WEI — Iron-silica core-shell particles with controlled shell thickness are fabricated using a sol-gel method. Polyurethane nanocomposites are fabricated with a surface initialized polymerization (SIP) method. The thermal stability of iron-silica NPs and its corresponding PNCs is significantly enhanced due to the barrier effect of silica shell. The anti-corrosive property of the core-shell particle is dramatically improved which is able to keep stable in 1M acid solutions. Salt fog exposure tests on PNCs reveal a better anti-corrosive performance with the incorporation of core-shell particles. By embedding different NPs, unique physical properties such as enlarged coercivity and dielectric constant (real permittivity) are observed. After coating a silica layer on iron NPs, the PNCs show lower real permittivity as compared to the PNCs filled with pure NPs. However, it is interesting to observe that only slight difference in real permeability is observed in both samples at the same loading. The permittivity and permeability of the PNCs are investigated with frequency ranging from 2-18 GHz. Results indicate that the PNCs reinforced with core-shell NPs exhibit a reflection loss in a wider frequency ranges. The maximum reflection loss is around -20 dB.

4:30PM X45.00011 Studies of Microwave Absorption Properties of Carbon Nanotubes-Epoxy Composites , Z. YE, Z. LI, Southern University and A&M College, J.A. ROBERTS, University of North Texas, G.L. ZHAO, Southern University and A&M College — Less weight, excellent mechanical properties, and high efficiency in absorbing electromagnetic (EM) wave make carbon nanotubes (CNTs) composites attractive for microwave technology applications. Six groups of multi-walled carbon nanotube (MWCNT)-epoxy composite samples with various outside diameter (OD) distributions were fabricated. The weight percentages of MWCNTs in the polymer composites were controlled in the range from 1 to 10%. A microwave resonant cavity technique was utilized to measure the microwave absorption properties of all the sixty samples near a central frequency of 9.968 GHz. The results show that the maxima of EM wave absorptions for the six groups of samples were all around 7% MWCNTs weight percentage. In general, the MWCNTs with smaller diameters have higher microwave absorption at 9.968 GHz. However, the sample group M5 (OD<8nm) shows unusual results, a lower microwave absorption than other samples. SEM was used to study the morphologies of the MWCNT samples. Based on the SEM analysis and microwave absorption measurements, it was found that the efficiency of the microwave absorption of MWCNT-Epoxy composites is also affected by the morphologies/structures of MWCNTs in individual bundles. *The work is funded in part by AFOSR, NSF, and Louisiana Board of Regents.

4:42PM X45.00012 Ecobionanocomposites: a new class of green materials , JOHN DORGAN, Colorado School of Mines — This abstract not available.

Friday, March 25, 2011 8:00AM - 11:00AM –

Session Y1 DCMP: New Insights Into the Mott Transition Ballroom A1

8:00AM Y1.00001 Renewed Understanding on Doped Mott Insulators[1] , MASATOSHI IMADA, Dept. Applied Physics, Univ. Tokyo and JST CREST — Mott transitions and nearby underdoped metals in two dimensions remain a major challenge in condensed matter physics, because of large spatial and quantum fluctuations, with its relevance to cuprate superconductors. Recent theoretical and computational developments have renewed its understanding with a unified picture for the unconventional metals. We overview historical backgrounds followed by a recent coherent picture obtained by path-integral renormalization group, many-variable variational Monte Carlo methods, and cluster-type dynamical mean-field theory [1]. Coexisting zeros and poles of the single-particle Green's function hold a key for Mott physics. Non-Fermi-liquid caused by topological transitions of Fermi surface including Lifshitz transitions naturally emerges. The energy-momentum dependent spectra reproduce the arc/pocket and pseudogap formation. We propose that the pseudogap in the cuprates is d-wave-like only below the Fermi level while it retains s-wave-like full gap above the Fermi energy even in the nodal point. In addition, the spectral asymmetry, back-bending and waterfall dispersions as well as the low-energy kink emerge within the same framework in agreement with the underdoped cuprates, excluding the scenarios by preformed pairs and d-density-waves, but supporting the proximity to the Mott insulator. We also propose that an extension of the exciton concept to doped Mott insulators by using cofermions accounts for the above unconventionality and superconductivity [2].

8:36AM Y1.00002 Quantum criticality in the Hubbard model[1] , MARK JARRELL, Louisiana State University — In large scale dynamical cluster quantum Monte Carlo simulations of the two-dimensional (2D) Hubbard model with only nearest neighbor hopping, we find a quantum critical point (QCP) at finite doping separating a Fermi liquid region at low filling from a non-Fermi liquid pseudogap region near half-filling. Marginal Fermi liquid behavior is seen in the thermodynamics and single-particle properties for a wide range of doping and temperatures above the QCP. The QCP is due to the second-order terminus of a line of first order phase separation transitions that is driven to zero temperature as the next near-neighbor hopping t' vanishes. The superconducting dome surrounds the QCP. The proximity the QCP and the dome is due to an algebraic divergence, replacing the BCS log divergence, of the bare pairing polarization. This behavior is captured with a simple variation of the quantum critical BCS formalism.

9:12AM Y1.00003 Cluster Dynamical Mean Field Methods and the Momentum-selective Mott transition[1] , EMANUEL GULL, Columbia University — Innovations in methodology and computational power have enabled cluster dynamical mean field calculations of the Hubbard model with interaction strengths and band structures representative of high temperature copper oxide superconductors, for clusters large enough that the thermodyamic limit behavior may be determined. We present the methods and show how extrapolations to the thermodynamic limit work in practice. We show that the Hubbard model with next-nearest neighbor hopping at intermediate interaction strength captures much of the exotic behavior characteristic of the high temperature superconductors. An important feature of the results is a pseudogap for hole doping but not for electron doping. The pseudogap regime is characterized by a gap for momenta near Brillouin zone face and gapless behavior near the zone diagonal. for dopings outside of the pseudogap regime we find scattering rates which vary around the fermi surface in a way consistent with recent transport measurements. Using the maximum entropy method we calculate spectra, self-energies, and response functions for Raman spectroscopy and optical conductivities, finding results also in good agreement with experiment.

9:48AM Y1.00004 Finite doping signatures of the Mott transition in the two-dimensional Hubbard model , GIOVANNI SORDI, Departement de physique and RQMP, Universite de Sherbrooke, Sherbrooke, Quebec, Canada J1K 2R1 — The evolution from the conventional metal at high doping to the Mott insulator at zero doping remains a central problem in physics of copper-oxide superconductors. Here we solve the cellular dynamical mean-field equations [1,2] for the two-dimensional Hubbard model on a plaquette with continuous-time quantum Monte Carlo [3,4]. The normal-state phase diagram as a function of temperature T, interaction strength U, and filling n reveals that, upon increasing n towards the Mott insulator, there is a surface of first-order transition between two metals at nonzero doping. That surface ends at a finite temperature critical line originating at the half-filled Mott critical point [5,6]. There is a maximum in scattering rate associated with this transition. These findings suggest a new scenario for the normal-state phase diagram of the high temperature superconductors. The criticality surmised in these systems can originate not from a T=0 quantum critical point, nor from the proximity of a long-range ordered phase, but from a very low temperature transition between two types of normal state metals at finite doping. The influence of Mott physics extends well beyond half-filling.

10:24AM Y1.00005 Computational Studies of Realistic Multiband Models of the Copper Oxides , CEDRIC WEBER, Rutgers University — High temperature superconductivity was achieved by introducing holes in a parent compound consisting of copper oxide layers separated by spacer layers. It is possible to dope some of the parent compounds with electrons, and their physical properties are bearing some similarities but also significant differences from the hole doped counterparts. Here, we use a modern first principles method, to study the electron doped cuprates and elucidate the deep physical reasons why their behavior is so different than the hole doped materials. We find that electron doped compounds are Slater insulators, e.g. a material where the insulating behavior is the result of the presence of magnetic long range order. This is in sharp contrast with the hole doped materials, where the parent compound is a Mott charge transfer insulator, namely a material which is insulating due to the strong electronic correlations but not due to the magnetic order. In particular, we point out that both hole and electron doped compounds are located close to the charge-transfer insulator to metal transition, and we discuss the consequences for optical and specific heat measurements done for the normal state, and additional consequences for the magnetic and superconducting orders of electron and hole doped copper oxides.

Session Y2 DCMP: Topological Insulators: Transport and Interactions Ballroom A2

8:00AM Y2.00001 Quantum oscillations and Hall anomaly of surface electrons on Topological Insulators[1] , N. PHUAN ONG, Princeton University — The investigation of Topological Insulators (TI) by transport experiments is a challenge, because the surface currents cannot be well-resolved when the bulk conductance is dominant, as in most crystals. I will review the progress starting from Ca-doped Bi_2Se_3, and proceeding to Bi_2Te_3 and to Bi_2SeTe_2. Using Ca dopants in Bi_2Se_3, we succeeded in lowering the Fermi energy E_F into the bulk gap. However, in non-metallic crystals, the substantial dopant-induced disorder precluded observation of Shubnikov-de Haas (SdH) oscillations. Fortunately, E_F in undoped Bi_2Te_3 can be tuned into the gap by heat treatment. The non-metallic samples display a bulk resistivity ρ = 4-12 mΩcm at 4 K. In these crystals, weak SdH oscillations are observed below 10 K. We confirmed that these oscillations arise from a 2D Fermi Surface by tilting the magnetic field $\mathbf{H}$. From the behavior of the SdH amplitude versus temperature T and H, we infer a surface Fermi velocity v_F = 3.7-4.2 $\times 10^5$ m/s, and a high surface mobility μ = 10,000 cm^2/Vs. The high mobility of the surface electrons is confirmed by the appearance of an unusual weak-field anomaly in the Hall conductance G_{xy}. I will discuss recent progress in further lowering the bulk conductance in the new TI Bi_2Se_3, in which a Se layer is sandwiched between two Te layers in each quintuplet unit cell. In these crystals, ρ at 4 K is a factor of 1000 larger (6 Ωcm). The interesting pattern of SdH oscillations in this new system will be reported.

8:36AM Y2.00002 Dirac Fermions in HgTe Quantum Wells , LAURENS W. MOLENKAMP, Physics Institute (EP3), Wuerzburg University — Replace this text with your abstract. Narrow gap HgTe quantum wells exhibit a band structure with linear dispersion at low energies and thus are very suitable to study the physics of the Dirac Hamiltonian in a solid state system. In comparison with graphene, they boast higher mobilities and, moreover, by changing the well width one can tune the effective Dirac massfrom positive, through zero, to negative. Negative Dirac mass HgTe quantum wells are 2-dimensional topological insulators and, as a result, exhibit the quantum spin Hall effect. In this novel quantum state of matter, a pair of spin polarized helical edge channels develops when the bulk of the material is insulating, leading to a quantized conductance. I will present transport data provide very direct evidence for the existence of this third quantum Hall effect: when the bulk of the material is insulating, we observe a quantized electrical conductance. Apart from the conductance quantization, there are some further aspects of the quantum spin Hall state that warrant experimental investigation. Using non-local transport measurements, we can show that the charge transport occurs through edge channels - similar to the situation in the quantum Hall effect. However, due to the helical character of the quantum spin Hall edge channels, inhomogeneities in the potential profile of the experimental devices have a much stronger effect on the transport properties. Moreover, the quantum spin Hall edge channels are spin polarized. We can prove this fact in split gate devices that are partially in the insulting and partly in the metallic regime, making use of the occurrence of the metallic spin Hall effect to convert the magnetic spin signal into an electrical one. Finally, I will address another aspect of Dirac Fermion physics: HgTe quantum wells at a critical thickness of 6.3 nm are zero gap systems and exhibit transport physics that is very similar to that observed over the past few years in graphene. However, zero gap HgTe wells have a higher mobility than graphene, and also have only a single Dirac valley. This makes them especially suitable to study quantum interference effects under a Dirac Hamiltonian.

9:12AM Y2.00003 Band Topology, Electron Correlations and 3D Dirac Metal in Pyrochlore Iridates , ASHVIN VISHWANATH, UC Berkeley — We study consequences of strong spin orbit interaction in a class of correlated systems. We discuss the possibility of novel phases such as a π axion insulator, protected by inversion, rather than time reversal symmetry and a gapless topological phase, the three dimensional Dirac semimetal. The latter phase has unusual surface states that take the form of 'Fermi Arcs', that cannot be realized in any two dimensional band structure. The pyrochlore iridates, (such as $Y_2Ir_2O_7$) according to LDA+U calculations and existing experimental data, are argued to be promising materials for realizing these states. This work was done in collaboration with Xiangang Wan (Nanjing U.), Sergey Savrasov (UC Davis) and Ari Turner (UC Berkeley).

9:48AM Y2.00004 General Theory of interacting Topological insulators , SHOUCHENG ZHANG, Stanford University — In this talk, I shall first briefly review the theory of topological insulators and the experimental status. I will then discuss the general theory of an interacting topological insulator, whose topological order parameter is expressed in terms of the full interacting Green function. This topological order parameter is also experimentally measurable in terms of the quantized magneto-electric effect. I shall discuss various applications of this theory to realistic materials which could realize the topological Mott insulator state.

10:24AM Y2.00005 Classification of Topological Insulators and Superconductors: the "Ten-Fold Way"[1] , ANDREAS LUDWIG, Dept. of Physics, University of California, Santa Barbara — We review the exhaustive ten-fold classification scheme of topological insulators and superconductors. It is found that the conventional (i.e.: "Z_2", or 'spin-orbit') topological insulator, experimentally observed in 2D ('Quantum Spin Hall') and in 3D materials, is one of a total of five possible classes of topological insulators or superconductors which exist in every dimension of space. Different topological sectors within a given class can be labeled, depending on the case, by an integer winding number, or by a "binary" Z_2 quantity. The topological nature of the bulk manifests itself through the appearance of "topologically protected" surface states. These surface states completely evade the phenomenon of Anderson localization due to disorder. Examples of the additional topological phases in 3D include topological superconductors (i) with spin-singlet pairing, and (ii) with spin-orbit interactions, as well as ^{3}He B. – The classification of topological insulators (superconductors) in d dimensions is reduced to the problem of classifying Anderson localization at the (d-1)-dimensional sample boundary which, in turn, is solved. The resulting five symmetry classes of topological insulators (superconductors) found to exist in every dimension of space correspond to a certain subset of five of the ten generic symmetry classes of Hamiltonians introduced 16 years ago by Altland and Zirnbauer in the context of disordered systems (generalizing the three well-known "Wigner-Dyson" symmetry classes). For a significant part of the phases of topological insulators (superconductors) of the classification a characterization can be given in terms of the responses of the system. For these, the responses are described by a field theory possessing a [gauge, gravitational (thermal), or mixed] anomaly. This implies that these phases are well defined also in the presence of inter-fermion interactions.

Session Y3 DCMP: Recent Developments in Solid 4He Ballroom A3

8:00AM Y3.00001 Dynamics, Defects and Deformation in Solid Helium[1]

, JOHN BEAMISH, University of Alberta — The shear modulus of solid ^{4}He shows remarkable softening above 100 mK, the same temperature range in which the apparent supersolid disappears in torsional oscillator experiments. We have measured helium's shear modulus and dissipation at frequencies from 0.5 to 8500 Hz. The onset temperature for softening/stiffening is broad, frequency dependent, and is accompanied by a dissipation peak - features typical of a dynamical crossover in a disordered system rather than a true phase transition. This behavior can be qualitatively explained if dislocations are mobile at high temperatures but are pinned by ^{3}He impurities below 100 mK. To better understand the role of dislocations, we have plastically deformed crystals by rapid thermal quenching and used pressure gradient measurements to study subsequent annealing. In our most recent experiments we have sheared solid helium mechanically and looked at the effect of large deformations on the helium's elastic properties.

8:36AM Y3.00002 New evidence of supersolidity in rotating solid helium[1]

, EUNSEONG KIM, Department of Physics, KAIST — The irrotationality of superfluid causes it to decouple form the container, leading to a reduction in the rotational inertia. This is more technically known as non-classical rotational inertia (NCRI). Although it is intuitively most natural to associate superflow only with the liquid phase, a decrease in the resonant period of a torsional oscillator (TO) was detected in solid helium below about 200 mK and interpreted as the appearance of NCRI. However, the resonant period may be also reduced for reasons other than supersolidity, such as the temperature dependence of the elastic modulus of solid helium. Unusual increase in the shear modulus with striking resemblance to those of NCRI supports the non-superfluid explanations. We superimposed dc rotation onto oscillatory measurements to distinguish between the supersolidity and classical elastic modulus change effects. We performed such simultaneous measurements of the TO and the shear modulus, and observed substantial change in the resonant period with rotational speed where the modulus remained unchanged. This contrasting behavior suggests that the decrease in the TO period is a result of supersolidity. This work is performed by collaboration with H. Choi, D. Takahashi, and K. Kono.

9:12AM Y3.00003 Quantum plasticity and supersolidity[1]

, SEBASTIEN BALIBAR, ENS & CNRS - Paris (France) — We have discovered that, in the total absence of impurities, helium 4 crystals are anomalously soft [1]. In our opinion, this is a consequence of the quantum properties of their dislocation lines which are able to move macroscopic distances (typically a fraction of a millimeter) at high speed (several meters per second) as a response to very small applied stresses (one microbar). Moreover, this quantum plasticity appears to be closely related to another astonishing property of quantum crystals, namely their "supersolidity," that is the possible superflow of a fraction of the crystal mass through the rest which remains elastic, actually more rigid than in the normal state [2]. Very tiny traces of helium 3 impurities are sufficient to pin the dislocations below about 100 mK and destroy the quantum plasticity. By studying rotational and elastic properties of crystals with various qualities and variable helium 3 content, we are now checking that supersolidity is a consequence of matter flowing along dislocation lines but only if these dislocations are pinned by impurities.

9:48AM Y3.00004 Mass Flow in Solid ^{4}He as Observed by Fountain Effect Measurements[1]

, ROBERT HALLOCK, University of Massachusetts Amherst, Amherst, MA 01003 — We have created an experimental cell in which solid helium is sandwiched between two Vycor rods which are each in turn in contact with reservoirs of superfluid ^{4}He [1]. Application of a temperature difference between the two reservoirs creates a thermo-mechanical effect, which causes a flux of atoms from one reservoir to the other through the solid helium, which is off the melting curve. The flux is measured to increase with falling temperature below about 650 mK, fall precipitously near 80 mK and then rise again at lower temperatures [2]. Results of these experiments as well as the behavior of solid growth will be presented and discussed in the context of recent theoretical work.

10:24AM Y3.00005 Superclimb of Dislocations in Solid ^{4}He[1]

, ANATOLY KUKLOV, CSI, CUNY — Edge dislocation with superfluid core can perform *superclimb* – non-conservative motion (climb) assisted by superflow along its core. Such dislocation, with Burgers vector along the C-axis, has been found in *ab initio* simulations of *hcp* solid ^{4}He [1]. Uniform network of superclimbing dislocations can induce *isochoric compressibility* $\chi = dN/d\mu$ which is finite (in contrast to ideal solid where it vanishes) and, practically, independent of the network density. Here N is total number of atoms and μ is chemical potential [1]. Such giant response has been observed by Ray and Hallock during superfluid flow events through solid He4 [2]. Study [3] of superclimbing dislocation within the model of Granato-Lücke string, subjected to Peierls potential and to vanishing bias by μ, has found that χ exhibits wide peak in the intermediate range of temperatures (T) - above some T_p determined by Peierls energy and below $T_s \sim 0.5$K above which superfluidity of the core essentially vanishes. Non-Luttinger type behavior characterized by $\chi \sim L^b$ scaling as some power $1 < b \leq 2$ of dislocation length L is observed in the wide peak region. Biasing superclimbing dislocation by finite μ (due to a contact with liquid ^{4}He through vycor electrodes [2],[4]) can induce core roughening caused by thermally assisted tunneling of jog-antijog pairs through the barrier produced by combination of Peierls potential and the bias [5]. The threshold for this effect scales as $\mu_c \sim 1/L^a$ with some power $a \approx 1.7$. The roughening is found to be hysteretic below some temperature $T_{\rm hyst}$. At $T_{\rm hyst} < T < T_R$, with T_R determining temperature of thermal roughening, χ exhibits strong and narrow resonant peak leading to a dip in the core superfluid sound velocity. This mechanism is proposed as an explanation for a strong and narrow dip observed in critical superflow rate [4]. It is found that the dip characteristics are sensitive to the bias by μ and, therefore, this can be used as a test for the proposed mechanism. It is also predicted that the dip depth at given T should be periodic in μ with the period $\sim \mu_c$.

Friday, March 25, 2011 8:00AM - 11:00AM –
Session Y4 DPOLY: Polymer Colloids: Structure, Function and Dynamics Ballroom A4

8:00AM Y4.00001 Colloidal photonic crystals: Beyond optics, beyond spheres , KOEN CLAYS, University of Leuven, Belgium — Monodisperse and symmetrically shaped colloidal particles tend to form ordered aggregates. When the particle size is in the hundreds of nanometres, such highly ordered structures exhibit fascinating optical properties, hence their name and fame as colloidal "photonic crystals" or as "photonic bandgap material", because they exhibit a forbidden energy band for photons, very much like semiconductor crystals are characterized by a bandgap for electrons. Photonic bandgap engineering is possible by a proper choice of the size and nature of the "photonic atom", and by a proper combination of different kinds of particles. The fame of monodisperse colloidal spheres as photonic atoms is largely based on the self-assembling capabilities into inherently three-dimensional photonic crystals. Colloidal photonic crystals can hence be used as an easy photonic crystal platform to demonstrate proof-of-principle for effects such as reduced local density of states for photons on their emission probability. We have induced spectral narrowing for emission from dye molecules and enhanced energy transfer between light-absorbing molecules in colloidal photonic crystals. By inserting superparamagnetic particles in the tens of nanometres range, it is possible to additionally impart magnetic properties to the photonic crystal. Tuning and enhancing Faraday rotation was possible by careful nanoscale bandgap engineering at two different nanoscales. One disadvantage of colloidal spheres for photonic crystals is the incomplete bandgap that is typical for the highly symmetrical crystal structures that are commensurable with dense packing of spheres. A number of approaches allow deviating from this paradigm towards a complete bandgap in the visible. Etching of material allows a less dense crystal, while non-spherical colloidal particles provide alternate crystal structures. Orientational ordering of such anisotropic particles in an anisotropic photonic crystal requires an additional handle on the particles, the colloidal assembly providing the positional order. Magnetism again provides this handle. Post-formation processing of crystals of positionally ordered spheres into orientationally anisotropic crystals represents another approach.

8:36AM Y4.00002 Near Wall Dynamics in Colloidal Suspensions Studied by Evansescent Wave Dynamic Light Scattering[1] , PETER R. LANG, Research Centre Juelich, Juelich, Germany — The dynamics of dispersed colloidal particles is slowed down, and becomes anisotropic in the ultimate vicinity of a flat wall due to the wall drag effect. Although theoretically predicted in the early 20th century, experimental verification of this effect for Brownian particles became possible only in the late 80s. Since then a variety of experimental investigations on near wall Brownian dynamics by evanescent wave dynamic light scattering (EWDLS) has been published. In this contribution the method of EWDLS will be briefly introduced, experiments at low and high colloid concentration for hard-sphere suspensions, and the theoretical prediction for measured initial slopes of correlation functions will be discussed. On increasing the particle concentration the influence of the wall drag effect is found to diminishes gradually, until it becomes negligible at volume fractions above $\phi > 0.35$. The effect that a wall exerts on the orientational dynamics was investigated for different kinds of colloids. Experiments, simulations and a virial expansion theory show that rotational dynamics is slowed down as well. However, the effect is prominent in EWDLS only if the particles' short axis is of the order of the evanescent wave penetration depth.

[1]The author acknowledges financial support from the EU through FP7, project Nanodirect (Grant 395 No. NMP4-SL-2008-213948).

9:12AM Y4.00003 Assembly of Dimer-Based Photonic Crystals , CHEKESHA M. LIDDELL WATSON, Department of Materials Science and Engineering, Cornell University — Recent advances in colloid synthesis to prepare monodisperse shape anisotropic particles provide the opportunity to address challenges related to structural diversity in ordered colloidal solids. In particular, computational simulations and mechanical models suggest that upon system densification nonspherical dimer colloids undergo disorder-order and order-order phase transitions to unconventional solid structures including, base-centered monoclinic crystals, degenerate aperiodic crystals, plastic crystal or rotator, etc. based on free energy minimization. The particle systems have notable analogy to molecular systems, where the shape of molecules and their packing density has been shown to critically influence structural phase behavior and lead to a rich variety of structures, both natural and synthetic. The materials engineering challenges have been in attaining sufficiently monodisperse (size uniformity) colloidal building blocks, as well as the lack of understanding and control of self-assembly processes for non-spherical colloids. This talk highlights our investigations of how particle shape programs the self-organization of colloidal structures. Methods including evaporation mediated assembly and confinement provide a platform to understand the formation of complex colloidal structures from non-spherical building blocks (silica-coated iron oxide, polystyrene, hollow silica shell). Optical property simulations for unconventional 2D and 3D structures with nonspherical particle bases will also be discussed.

9:48AM Y4.00004 Directed self-assembly of small colloidal clusters[1] , VINOTHAN MANOHARAN, Harvard University — We study the formation and structure of equilibrium colloidal clusters at small particle number ($N \sim 10$) using optical microscopy. Our experimental system consists of isolated groups of colloidal microspheres with short-ranged attractions. With non-specific depletion interactions, we observe that the number of configurations increases sharply with N. The most favorable states are those with the lowest symmetry. With specific DNA-mediated attractions, the number of states is reduced. Experiments and theoretical calculations suggest that it is possible to direct the assembly of specific structures through multiple competing DNA-mediated interactions.

10:24AM Y4.00005 Convective microsphere monolayer deposition , JAMES GILCHRIST, Lehigh University — There is perhaps no simpler way of modifying surface chemistry and morphology than surface deposition of particles. Micron-sized microspheres were deposited into thin films via rapid convective deposition, similar to the 'coffee ring effect' using a similar method to that studied by Prevo and Velev, Langmuir, 2003. By varying deposition rate and blade angle, the optimal operating ranges in which 2D close-packed arrays of microspheres existed were obtained. Self-assembly of colloidal particles through a balance of electrostatic and capillary forces during solvent evaporation was revealed. These interactions were explored through a model comparing the residence time of a particle in the thin film and the characteristic time of capillary-driven crystallization to describe the morphology and microstructure of deposited particles. Co-deposition of binary suspensions of micron and nanoscale particles was tailored to generate higher-quality surface coatings and a simple theory describes the immergence of instabilities that result in formation of stripes. Optical and biomedical applications that utilize the described nanoscale control over surface morphology will also be discussed.

Friday, March 25, 2011 8:00AM - 11:00AM –
Session Y5 DCOMP DCP: Opening the Gap: Chemical Functionalization and Substitution in Graphene Ballroom C1

8:00AM Y5.00001 Magnetic Moment and Electronic Correlations in Chemically Functionalized Graphene

, JORGE SOFO, Penn State — Magnetic moments in extended systems are the result of local electronic correlations. In the case of graphene functionalized with chemisorbed atoms such as hydrogen, fluorine, or oxygen, the Anderson Model picture, where correlations in a localized state are responsible for the formation of a magnetic moment, has to be modified to properly describe the magnetic moment formation and their interactions. We use a tight-binding model with local correlations to analyze the results obtained with Density Functional Theory calculations for these systems. The model allows the treatment of local correlations beyond the mean field level and the investigations of a possible Kondo effect. We find that the Coulomb repulsion at the carbon atoms near the impurity play a crucial role in the magnetic moment formation. External doping with a gate voltage can control the nature of the binding and the formation of the magnetic moment. This effect could be observed in transport experiments as the scattering of the graphene electrons at the Fermi energy strongly depends on the structure of the defect.

8:36AM Y5.00002 A theoretical study of chemical functionalisation of graphene: graphane and graphXene

, OLLE ERIKSSON, Uppsala University — Chemical functionalisation of graphene is reported from a first principles, theoretical study [1]. The electronic structure, including band gap, of H adsorbed on graphene (i.e. graphane) is discussed in this presentation [2]. In addition, adsorption of Group VII elements on graphane (named graphXene) is also reported [3]. Similarities and differences in the chemical binding and electronic structure of graphane and graphXene are analyzed. The adsorption on graphene is found to, depending on adatoms, result in sp2 or sp3 binding, where in general the sp3 bonded systems show a bandgap. The theoretical calculations make use of both GGA functionals as well as the GW approximation. In addition to large graphene layers, theoretical analysis of functionalised graphene nano-ribbons will also be presented [4]. References:

9:12AM Y5.00003 Gap control via graphene solid-state reactions

, BORIS I. YAKOBSON, Rice University — While a gapless dispersion law of Dirac fermions in graphene does warrant admiration, to serve as useful semiconductor graphene needs a gap. Relatively inert, it can nevertheless be induced to react. A generic outcome of a reaction, C + A -> $C_{1-x}A_x$ is a transition of some C-atoms from their sp^2- into sp^3-state, corresponding to a situation of the insulating, ultimate (mono- or few-layer) diamond slab [1]. Computations support a concept that the product of such reactions (A = H, F, O, Cl, etc.) forms a well-defined phase [2], permitting a patterning of 2D-geometries with useful properties: interconnects-nanoroads [3], quantum isles-dots [4], etc. Comparison of hydrogenation (A = H) into graphAne with fluorination (A = F) into 2D-teflon, shows the former as hindered by nucleation barrier and reversible (H-storage), in contrast to barrier-less reaction into a stable CF in the latter. *** In collaboration with F. Ding, E. Penev, M.A. Ribas, and A.K. Singh. ***

9:48AM Y5.00004 Spin-polarized semiconductor induced by magnetic impurities in graphene[1]

, MARIA DAGHOFER, IFW Dresden — Magnetic impurities adsorbed on graphene sheets are coupled antiferromangetically via the itinerant electrons in the graphene. We study this interaction and its impact on the electrons' spectral density by use of unbiased Monte-Carlo simulations. The antiferromagnetic order breaks the symmetry between the sublattices, and a gap for the itinerant electrons opens. Our simulations show that the itinerant states below and above the gap are not dispersionless states trapped by the impurities, but are instead mobile states with a large dispersion. We compare various scenarios for the impurity distribution and find that random doping produces a standard semiconductor. If, on the other hand, all or most of the impurities are localized in the same sublattice, the spin degeneracy is lifted and the conduction band becomes spin-polarized. We also discuss the properties of edge states at edges or magnetic domain boundaries.

10:24AM Y5.00005 Graphene monofluoride: a wide bandgap material derived from graphene

, JUN ZHU, Penn State University — Fluorination provides an effective way of controlling the properties of carbon materials. In this talk, I will describe our experimental and theoretical work on the synthesis, structural, electrical and optical properties of fully fluorinated graphene and graphite, i. e., graphene monofluoride CF and graphite monofluoride $(CF)_n$. $(CF)_n$ is synthesized by reacting HOPG graphite with F_2 gas at high temperature. Transmission electron microscopy and electron diffraction measurements show crystalline few-layer CF with a lattice constant 4% larger than that of graphene, in good agreement with first principle calculations. We observe the E_g and A_{1g} Raman modes of graphene monofluoride using UV Raman spectroscopy. Photoluminescence measurements of $(CF)_n$ using variable excitation wavelength (244-514 nm) and temperature (5-295 K) show several emission modes in the visible spectrum, which likely originate from mid-gap defect states. The absence of the band edge emission suggests a large band gap of greater than 5 eV. Partially fluorinated graphene fluoride exhibits non-linear, strongly insulating transport with variable-range hopping temperature dependence, consistent with the presence of localized states due to missing fluorine atoms. Highly conductive graphene can be recovered by annealing CF in Ar/H_2 at high temperature, resulting in a conductance improvement of five orders of magnitude. As a transparent and atomically thin insulator, graphene monofluoride may find its use in graphene electronics and photonics. In collaboration with: Bei Wang, Shih-Ho Cheng, Justin Sparks, Humberto Gutierrez, Ke Zou, Ning Shen, Youjian Tang, Qingzhen Hao, Awnish Gupta, Peter Eklund, Vincent Crespi, Jorge Sofo and Fujio Okino (Shinshu University, Japan). Session Y6 GMAG: Ultrafast Magnetization Dynamics: Where Are We Today? Ballroom C2

8:00AM Y6.00001 The x-ray few of femtosecond spin-orbit excitations in ferromagnets

, HERMANN DURR, SLAC — Polarized soft x-rays have been used over the past 20 years to obtain fascinating new insights into nanoscale magnetism. The separation of spin and orbital magnetic moments, for instance, enabled detailed insights into the interplay of exchange and spin-orbit interactions at the atomic level. The now available polarized soft x-ray pulses with only 100 fs duration allow us to observe the magnetic interactions at work in real time. The ultimate goal of such studies is to understand how spins may be manipulated by ultrashort magnetic field, spin polarized current or light pulses. In this talk I will focus on fs laser induced spin-orbit dynamics in 3d transition metals. Using fs x-ray pulses from the BESSY II femtoslicing facility I will show how fs excitation of the electronic system modifies the spin-orbit interaction enabling ultrafast angular momentum transfer between spin, orbital and lattice degrees of freedom.

8:36AM Y6.00002 Possibility of Nanoscale Imaging of Ultrafast Magnetization Dynamics[1]

, ANDREAS SCHERZ, SIMES, SLAC Nat. Acc. Lab., California — Understanding the microscopic mechanisms driving the magnetization dynamics on the fs time scale is of essential importance for manipulating and controlling the macroscopic state in magnetic storage devices. The demagnetization in ferromagnetic films by an ultrashort laser excitation on a time scale of a few hundred fs raised controversies about the effective path to dissipate angular momentum to the lattice, see e.g. [1]. Even more intriguing is the demonstration of all-optical magnetization reversal in ferrimagnetic compounds using circularly polarized, fs laser pulses [2]. Until only recently, the field of "Femto-magnetism" has naturally been driven by all-optical pump-probe techniques. Femtosecond time-resolved X-ray magnetic circular dichroism spectroscopy has been utilized to unambiguously determine the ultrafast quenching of spin and orbital moments after ultrashort laser excitation [3]. While all-optical pump-probe techniques allow ultrafast excitations (pump) and the study of their evolution (probe) on the macroscopic scale by use of the magneto-optical Kerr or Faraday effect, little is known about the microscopic processes on nano- and sub-nanometer length scales because of the lack of real or momentum space resolution of optical techniques. By combining resonant coherent resonant magnetic scattering with the unique high peak-brightness, short pulse structure, and fully transverse coherence of the new x-ray free-electron lasers, the dynamics of magnetic fluctuations and magnetization relaxation processes can be studied on the nanometer scale with sub-picosecond time resolution. We demonstrate the possibility of nondestructive single shot imaging of the magnetization in Co/Pd multilayers at LCLS.

9:12AM Y6.00003 Imaging Magnetization Dynamics on the Nanoscale Using X-ray Microscopy

, GUIDO MEIER, University of Hamburg — We aim at time- and spatially resolved imaging of excitations in ferromagnetic materials such as spin waves, the motion of domain walls and the gyration of magnetic vortices and antivortices. Special emphasize is given to the interaction of electrical currents with magnetic inhomogeneities like domains walls and vortices. The spin-polarized current can give rise to a spin torque on spatially inhomogeneous magnetization configurations. With magnetic transmission X-ray microscopy we observe a current-driven oscillation of an individual domain wall on its genuine time scale. In the framework of an analytical model insight into the domain-wall motion and its characteristic damping time is gained by examination of different phase spaces [1]. Current-induced depinning of a domain wall from a pinning site depends on the temporal shape of the current pulse. Apart from resonant excitation of the wall this effect arises from an additional force on the wall due to a fast changing current. Efficient depinning is achieved for rise times smaller than the damping time of the domain wall [2]. Time-resolved X-ray microscopy is used to image the influence of alternating high-density currents on the magnetization dynamics of vortices and antivortices. They behave as two-dimensional oscillators with a gyrotropic eigenmode which can be resonantly excited by spin currents and magnetic fields [3]. It is shown that the two excitation types couple in an opposing sense of rotation in case of resonant antivortex excitation with circular-rotational currents [4]. We report on the experimental observation of purely spin-torque induced antivortex-core reversal. Financial support by the DFG via SFB 668 and via GK 1286 as well as by the City of Hamburg via the Landesexzellenzcluster Nano-Spintronics is gratefully acknowledged. The ALS is supported by the Director, Office of Science, Office of Basic Energy Sciences, of the US Department of Energy.

9:48AM Y6.00004 Ultrafast magnetization dynamics in lanthanide ferromagnets: From bulk to surfaces[1]

, UWE BOVENSIEPEN, University of Duisburg-Essen, Faculty of Physics, Germany — The intense research on femtosecond laser-induced magnetization dynamics resulted in rich ultrafast phenomena [1]. A microscopic description of the underlying elementary processes, however, remains a challenge. Most efforts focus on the $3d$ transition metal ferromagnets and related compounds. This talk discusses recent work on the lanthanide ferromagnets Gd and Tb. Their magnetic moment is dominated by $4f$ electrons which are localized at the ion core. Their spin-lattice coupling is determined by the angular momentum of the $4f$ electrons. Using femtosecond x-ray magnetic circular dichroism at the femtosecond slicing facility at the BESSY II storage ring in Berlin, Germany, we measure the ultrafast change in the magnetic moment, which occurs on two specific timescales [2]. The faster one is 0.75 ps. It is driven by hot electrons and is identical for both lanthanides. The slower one is different for Gd (40 ps) and Tb (8 ps) due to the stronger spin-lattice coupling in Tb. The talk also discusses time-resolved non-linear optical studies on Gd(0001) and Tb(0001) surfaces [3]. We find a coherent surface phonon which is strongly coupled with the ultrafast magnetic response and pronounced differences compared to the bulk dynamics which are attributed to spin-polarized transport effects.

10:24AM Y6.00005 Ultrafast magnetization dynamics in a system with tunable angular momentum , ANDREI KIRILYUK, Radboud University Nijmegen — Many peculiarities of the magnetization dynamics are related to the fact that a certain amount of angular momentum is associated with magnetic moment. Here the dynamics of angular momentum is studied in ferrimagnetic rare-earth – transition metal alloys, e.g. GdFeCo, where both magnetization and angular momenta are temperature dependent. Depending on their composition, such ferrimagnets can exhibit a magnetization compensation temperature TM where the magnetizations of the sublattices cancel each other and similarly, an angular momentum compensation temperature TA where the net angular momentum vanishes. At the latter point, the frequency of the homogeneous spin precession diverges. As a consequence, ultrafast heating of a ferrimagnet across its compensation points may result in a subpicosecond magnetization reversal [1]. Moreover, we have experimentally demonstrated that the magnetization can be manipulated and even reversed by a single 40 femtosecond circularly polarized laser pulse, without any applied magnetic field [2,3]. This optically induced ultrafast magnetization reversal is the combined result of laser heating of the magnetic system and circularly polarized light acting as a magnetic field with amplitudes of up to several Teslas. The direction of this opto-magnetic switching is determined only by the helicity, i.e. angular momentum, of light. This novel reversal pathway (see [4]) is shown to crucially depend on the net angular momentum reflecting the balance of the two opposite sublattices.

Session Y8 FGSA FIP: Experiences and Issues for Young Physicists in the International Arena: Impact on the Future of Physics followed by Panel Discussion Ballroom C4

8:00AM Y8.00001 Impact of Visa Issues on an International Physics Graduate Student in the U.S. , AZADEH KEIVANI, Louisiana State University — More than 35 percent of the physics graduate students in the US are temporary visa holders. Many of these students work in large international collaborations and must travel abroad for research and international conferences, sometimes more than once a year. In many cases, students have to reapply for their visas in order to return to the U.S., a process that can be time-consuming and costly. Furthermore, many international students cannot leave the U.S. even in the case of an emergency because a slow visa process may mean deferring for a semester or losing financial support. Thus visa issues affect not only the scholastic life of students but also their personal lives. Finding ways to resolve these issues could positively affect the quality of graduate research by eliminating these extra hurdles to the progress of international physics graduate students.

8:20AM Y8.00002 Overcoming the Cultural Barrier: An International Physicist's Experience , J. PEDRO OCHOA, Berkeley lab — Doing experimental physics in the midst of an international community, a necessity in certain fields due to the breadth and the complexity of the projects involved, is a task that presents many advantages but also challenges. I will be reviewing some of these from the point of view of an international physicist working in China. I will also be sharing my personal experiences in overcoming the cultural barriers and in transitioning from a country that is traditionally underrepresented in science.

8:40AM Y8.00003 Life In a large scientific collaboration , RISHIRAJ PRAVAHAN — I will be talking about life in a large scientific collaboration. The dynamics of dealing with many groups, collaborating with people from various linguistic and cultural origins can be a daunting experience. However, it is exactly this diversity of culture and learning that can make it an invigorating journey. You need to find your place in terms of professional contribution as well as personal liaisons to be productive and innovative in a large work culture. Scientific problems today are not solved by one person hunched over an old notebook. It is solved by sharing computer codes, experimental infrastructure and your questions over coffee with your colleagues. An affinity to take in and impart healthy criticism is a must for productive throughput of work. I will discuss all these aspects as well as issues that may arise from adjusting to a new country, customs, food, transportation or health-care system. The purpose of the talk is to familiarize you with what I have learned through my past five years of stay at CERN and working in the ATLAS collaboration.

9:00AM Y8.00004 Perspectives from an International Female Physicist in Academia , TULIKA BOSE, Boston University — I will bring my perspective as an international physicist in academia to the discussion of issues facing international physicists. I will also talk about issues facing women physicists worldwide.

9:20AM Y8.00005 Panel Discussion: Issues Facing International Physicists and the Future of Physics , AMY FLATTEN[1], American Physical Society — The panel will discuss the challenges and key issues faced by today's young physicists, especially when participating in international collaborations.

Friday, March 25, 2011 8:00AM - 11:00AM –

Session Y9 DFD: Motility, Locomotion and Cellular Fluid Mechanics D220

8:00AM Y9.00001 ABSTRACT WITHDRAWN –

8:12AM Y9.00002 Coordinated Swimming: Hydrodynamic interactions between multi-flagellated bacteria , NOBUHIKO WATARI, RONALD LARSON, University of Michigan — Multi-flagellated bacteria, such as Escherichia coli, often have flagella attached at random locations to the cell body, which drive swimming behavior. To study the effect of hydrodynamic interactions on the swimming behavior, we develop a bead-spring model which represents both the body and the flagella using up to 240 Stokeslets, or hydrodynamic drag centers. These beads are bonded by 1) a spring potential, 2) a bending potential, and 3) a torsional potential to adjacent beads. This modeled bacterium swims by rotating the flagella with constant torques. We find that the number and arrangement of the flagella along the bodies of the swimmers affects how two such swimmers approach each other, when swimming either in a line, or side by side, and affects whether or not flagellar rotations are synchronized or not. We show how the flow field generated by each swimmer can be represented using a low order multipole expansion, which can capture the qualitative features of their interactions. With this simple low order expansion, simulations of hundreds or thousands of such swimmers can be carried out, allowing the effects of numbers and locations of flagella on swimming pattern formation to be captured.

8:24AM Y9.00003 Remote Powering and Steering of Self-Propelling Microdevices by Modulated Electric Field , RACHITA SHARMA, ORLIN VELEV, North Carolina State University — We have demonstrated a new class of self-propelling particles based on semiconductor diodes powered by an external uniform alternating electric field [1]. The millimeter-sized diodes floating in water rectify the applied voltage. The resulting particle-localized electroosmotic flux propels them in the direction of the cathode or the anode depending on their surface charge. These particles suggest solutions to problems facing self-propelling microdevices, and have potential for a range of additional functions. The next step in this direction is the steering of these devices. We will present a novel technique that allows on-demand steering of these self-propelling diodes. We control remotely their direction of motion by modifying the duty cycle of the applied AC field. The diodes change their direction of motion when a DC component (wave asymmetry) is introduced into the AC signal. The DC component leads to redistribution of the counterions near the diode surface. The electric field resulting from this counterion redistribution exerts a torque on the dipole across the diode, causing its rotation. Thus, the reversal of the direction of the electroosmotic flux caused by field asymmetry leads to reversal of the direction of diode motion. This new principle of steering of self-propelling diodes can find applications in MEMs and micro-robotics. [1] S. T. Chang, V. N. Paunov, D. N. Petsev, O. D. Velev, Nat Mater, 6, 235-240 (2007).

8:36AM Y9.00004 Motility of rotating flagella in viscoelastic fluids , BIN LIU, THOMAS POWERS, KENNETH BREUER, Brown University — Bacteria achieve motility by eluding the constraints of kinematic reversibility, for instance, by rotating a helical flagellum. We study experimentally the motility of the flagellum with a scaled-up model system, a motorized helical coil that rotates along its axial direction. The rotating helix is tethered on a linear stage that advances at a predetermined speed along the axial direction. A free-swimming speed is obtained when the net force on the helix is zero. In the Newtonian case, the free-swimming speed of the helix is always proportional to its rotation rate. We show how such motility is affected by the presence of the viscoelasticity of the fluid, a ubiquitous environment for living bacteria.

8:48AM Y9.00005 Electrical Control of Microtubule Translocation on Graphene , EUNJI KIM, Department of Biophysics and Chemical Biology, Seoul National University, Seoul 151-747, Korea, DONG SHIN CHOI, Department of Nano Science and Engineering, Seoul National University, Seoul, 151-747 Korea, KYUNG-EUN BYUN, Department of Physics and Astronomy, Seoul National University, Seoul, 151-747, Korea, HEEJUN YANG, JINSEONG HEO, HYUN-JONG CHUNG, SUNAE SEO, Semiconductor Devices Lab, Samsung Advanced Institute of Tech., Giheung-Gu, Yongin-Si, Gyeonggi-Do 449-712, Korea, SEUNGHUN HONG, Department of Biophysics and Chemical Biology, Seoul National University, Seoul 151-747, Korea — Motor protein systems such as a kinesin-microtubule complex play an important role in intracellular cargo transport by directly converting a chemical energy into a mechanical work. For exploiting their high energy efficiency, there have been considerable efforts to integrate them with various nanostructures to build nanoscale biodevices such as an advanced nano-transportation system. Herein, we demonstrated a successful motility assay of microtubules on a kinesin-functionalized graphene electrode which has a good transparency and conductivity. By applying a voltage bias onto the graphene electrode, we could spatially control the translocation of the microtubules. Our result clearly shows that graphene can be used not only as a good substrate for a motor-protein motility assay but also as a key component for a nano-mechanical system based on biomotors.

9:00AM Y9.00006 Swimming speed of an oscillating sheet in Newtonian and viscoelastic fluids , MOUMITA DASGUPTA, MICHAEL BERHANU, ARSHAD KUDROLLI, Clark University, HENRY FU, University of Nevada, Reno, KENNETH BREUER, THOMAS POWERS, Brown University — We discuss a mechanical experimental model of a flexible sheet swimming with a prescribed wave pattern - a Taylor swimmer - through a fluid. Our study is motivated by a need for a fundamental understanding of microorganism locomotion through non-Newtonian fluids. In order to simplify the problem, we suspend a tall flexible cylindrical sheet concentric within a cylindrical tank filled with the fluid. Torque free boundary conditions are imposed by supporting the flexible sheet and the tank with friction-free ball-bearings. A traveling wave is imposed on the sheet with a pair of rollers in the azimuthal direction. We first demonstrate a linear response in the swimming velocity of the sheet with respect to its phase velocity in a viscous Newtonian fluid. Further, we show that the analytical system is essentially two dimensional by varying the height of fluid in the tank. We then discuss measurements of swimming speed in Polyox-water mixtures as a function of wave speed. We demonstrate that the swimming speed in this viscoelastic fluid decrease relative to the Newtonian case as wave speed is increased. We will further discuss the dependence of swimming speed on Deborah number and other characteristics of the fluid.

9:12AM Y9.00007 Highly-Controllable Near-Surface Swimming of Magnetic Nanorods , BENJAMIN EVANS, Elon University, LAMAR MAIR, UNC - Chapel Hill — Directed manipulation of nanomaterials has significant implications in the field of nanorobotics, nanobiotechnology, microfluidics, and directed micro- and nano-object assembly. With this in mind, we present a simple, efficient method for the fabrication and controlled manipulation of rod-shaped micro-scaled swimmers in a low-Reynolds environment. We demonstrate fine spatial control of the swimmers' motion and we approach, capture, and manipulate a polystyrene microbead as proof of principle. The swimmers consist of 200-nm-diameter gold nanowires which are grown by electrodeposition in an AAO template. The template is removed via dissolution in NaOH, and a layer of nickel (50 nm) is subsequently evaporated onto the surface of the wires. These wires settle near the floor of an enclosed water-filled cell and are observed via optical microscopy. Rotation is induced via an external magnetic field provided by a permanent magnet. The field is rotated in a plane nearly parallel to the floor; a small tilt out-of-plane results in symmetry-breaking, with the end of the rod nearest the floor experiencing an enhanced drag coefficient due to the presence of the boundary. The imbalance in drag forces between the two ends of the rotating rod results in a net translation. We use resistive force theory to develop an analytical model which describes the motion of these swimmers and correlate this model with experimental results.

9:24AM Y9.00008 Textured boundaries and their effects on ciliary locomotion , SAIKAT JANA, Department of Engineering Science and Mechanics, Virginia Tech, SUNG YANG, Department of Nanosystems and Engineering, GIST, South Korea, SUNGHWAN JUNG, Department of Engineering Science and Mechanics, Virginia Tech — Many microorganisms in nature propel themselves by creating coordinated motion of the cilia and often interact with each other through hydrodynamic interactions. We study the behavior of these organisms near boundaries of different topography and rationalize the hydrodynamic effects involved. Various geometries like wavy, rough or solid walls are simulated using micro fabrication and their effects on the locomotory traits are observed. Finally a comprehensive discussion on the effect of different boundaries on the swimming characteristics of the organism is presented.

9:36AM Y9.00009 Motion of Elastic Microcapsules on Compliant Surfaces with Adhesive Ligands , EGOR MARESOV, GERMAN KOLMAKOV, ANNA BALAZS, University of Pittsburgh — By integrating mesoscale models for hydrodynamics, micromechanics and adhesion, we examine the fluid driven motion of elastic microcapsules on compliant surfaces. The capsules, modeled as three-dimensional fluid-filled elastic shells, represent polymeric microcapsules or biological cells. Our combined integrated Lattice Boltzmann model/Lattice spring model (LBM/LSM) approach allows for a dynamic interaction between the elastic capsule's wall and surrounding fluid. To capture the interaction between the shell and the surface, we adopt the Bell model, used previously to describe the interaction of biological cell like leukocytes rolling on surfaces under the influence of an imposed shear. The surface of the microcapsule contains receptors with an affinity to adhesive ligands of the substrate. We examine how the parameters of adhesion and rigidity of the capsules and the substrate affect movement of the capsules. The findings provide guidelines for creating smart surfaces that could regulate the microcapsules' motion.

9:48AM Y9.00010 Modelling the dynamics of colloidal nanorods in a spatially varying electric field , GREGORY RICHARDS, Dept. of Mathematical Sciences and Liquid Crystal Institute - KSU, XIAOYU ZHENG, Dept. of Mathematical Science - KSU, PETER PALFFY-MUHORAY, Liquid Crystal Institute - KSU — The behavior of anisotropic nanoparticles is of great current interest in the design of optical metamaterials. We have carried out numerical simulations to model the dynamical behavior of metallic nanorods, dispersed in an isotropic solvent, under the influence of a radially varying electric field. Diffusive and convective transport is considered both in orientation and position space. The Smoluchowski equation governing the spatial and orientational probability density function (PDF) was derived. Discretization was carried out using a finite-volume method on a mesh generated via Voronoi tesselation and regularization on the unit sphere. The time evolution of the PDF was obtained using a combination of operator splitting and a stable biconjugate gradient method. We present the results of our numerical experiments. We report interesting and anomalous behavior, where, due to the coupling of orientation and translational mobility, the applied field depopulates certain orientational states, similar to 'orientational hole burning' in nonlinear optics.

10:00AM Y9.00011 Designing self-propelling micro-swimmer that navigates in microfluidic channels , BEN BINGHAM, HASSAN MASOUD, ALEXANDER ALEXEEV, Georgia Institute of Technology — Using a fully-coupled computational approach that integrates the lattice Boltzmann model for the hydrodynamics and the lattice spring model for the micromechanics of deformable solids, we design a synthetic micro-swimmer that not only self-propels but also successfully navigates in a low Reynolds number environment of a microfluidic channel. The swimmer body consists of a responsive polymer gel that undergoes periodical swelling and shrinking. Two thin elastic flappers are attached to the opposite sides of the swimmer body. The flappers wiggle driven by swimmer body oscillations and, in this fashion, propel the micro-swimmer through its highly viscous fluid environment. Third, light sensitive flapper is attached in the front of the swimmer and serves to steer its trajectory in microchannel. When exposed to light, the steering flap bends towards the light source. We show that this swimmer can either move straight or turn in the required direction following light signals. Thus, guided by light, the micro-swimmer can successfully navigate towards the target in a microfluidic channel.

10:12AM Y9.00012 Azobenzene Crystal Shooting and Shape Behavior in the Context of Time Dependent Ginzburg-Landau Equations[1] , THOMAS SUTTER, Polymer Engineering, University of Akron, GRANG RILEY, Physics Department, Miami University, DMITRY GOLOVATY, Theoretical and Applied Mathematics, University of Akron, THEIN KYU, Polymer Engineering, University of Akron — Blends of azobenzene chromophore and diacrylate monomer show novel nucleation instability. Once a crystal nucleates near a larger growing crystal, it shoots away from the growing front. This shooting phenomenon is explained in the context of "Marangoni propulsion," an imbalance of surface energies at the leading and trailing crystal edges. A concentration gradient is established during the course of diffusion-controlled crystal growth; as the crystal front pulls azobenzene molecules in and rejects acrylate solvent molecules. Thus, crystal growth dynamics influence the concentration gradient build up at the advancing front, as well as the crystal's shape. The time dependent Ginzburg-Landau model C equation was used to simulate crystal growth using a free energy expression which combines Flory-Huggins theory of liquid-liquid demixing and the phase field free energy of crystallization. We have also established a theoretical phase diagram by self-consistently solving the free energy expression. Crystal shape and shooting character will be explained in the context of the phase diagram.

[1]We thank the donors of the American Chemical Society Petroleum Research Fund (PRF#48735-ND7).

10:24AM Y9.00013 Flagellar generated flow mediates attachment of *Giardia lamblia*[1] , JEFFREY URBACH, HAIBEI LUO, THEODORE PICOU, RYAN MCALLISTER, HEIDI ELMENDORF, Georgetown University — *Giardia lamblia* is a protozoan parasite responsible for widespread diarrheal disease in humans and animals worldwide. Attachment to the host intestinal mucosa and resistance to peristalsis is necessary for establishing infection, but the physical basis for this attachment is poorly understood. We report results from TIRF and confocal fluorescence microscopy that demonstrate that the regular beating of the posterior flagella generate a flow through the ventral disk, a suction-cup shaped structure that is against the substrate during attachment. Finite element simulations are used to compare the negative pressure generated by the flow to the measured attachment force and the expected performance of the flagellar pump.

[1]NIH grant 1R21AI062934-0

10:36AM Y9.00014 Probing the directional structure and intracellular microrheology of vascular endothelial cells , MANUEL GOMEZ-GONZALEZ, KATHRYN OSTERDAY, JULIE LI, GERARD NORWICH, JUAN LASHERAS, SHU CHIEN, JUAN CARLOS DEL ALAMO, University of California, San Diego — The magnitude of the rheological properties of cytoplasm is important because it sets the level of intracellular deformation in response to stress. The directionality is equally important because it allows the cell to modulate the stress-strain relation differently along different directions. We aim to elucidate the relation between the structural organization of the cytoplasm and the directionality of its rheological properties by 1) measuring the local orientation of fluorescently labeled intracellular filaments and 2) determining the local directions of the maximum and minimum intracellular viscosity. For this purpose, we improved current microrheology measurements by studying the drag force experienced by a microsphere in an anisotropic viscoelastic network permeated by a liquid. In the limit of strong frictional coupling between network and liquid, the flow around the sphere is modeled with a generalized Stokes equation using several viscosity parameters. We solve this equation analytically to provide new closed-form microrheology formulae relating the resistance measured experimentally to the anisotropic properties of the network. Tracking the random motion of endogenous particles in 2D and using these novel microrheology formulae we measured directional intracellular viscosities.

10:48AM Y9.00015 Non-equilibrium fluctuations of cell membranes: The effect of cytoskeletal motor activity on membrane dynamics , ROIE SHLOMOVITZ, ALEX LEVINE, UCLA, Department of Chemistry & Biochemistry — The mechanics and non-equilibrium (i.e. molecular motor-driven) fluctuation spectrum of living cells remains an open problem. In this talk, we explore the question: What can one infer about the action of endogenous motors in the cytoskeleton by observing the height fluctuations of cell membrane? To address this, we treat the cytoskeleton as a uniform elastic half-space bounded by a membrane with a finite bending modulus and driven out of equilibrium by molecular motors (i.e. myosin). These motors produce transient and stochastic contractile stresses in the elastic bulk. We first calculate the induced undulations of the membrane-bound surface due to the action of a single molecular motor. Then, making assumptions about the spectrum of motor force fluctuations, we calculate the expected non-thermal contribution to the cellular membrane fluctuations due to the action of an ensemble of such motors. We discuss extensions of this simple model to include, e.g. the effect spatially inhomogeneous coupling between the cytoskeleton and the membrane. We also mention ongoing experimental tests of these ideas.

Friday, March 25, 2011 8:00AM - 11:00AM –

Session Y10 DCMP: Electronic Structure of Surfaces and Interfaces D221

8:00AM Y10.00001 Interface structure and magnetic anisotropy of Fe/Pd(001) and Pd/Fe/Pd(001) monatomic films , TETSURO UENO, MASAHIRO SAWADA, KAZUHITO FURUMOTO, TETSURO TAGASHIRA, AKIO KIMURA, HIROFUMI NAMATAME, MASAKI TANIGUCHI, Hiroshima University — Fe and Pd are known to form $L1_0$-ordered alloy, which exhibits easy magnetization axis perpendicular to the atomic stacking plane. In order to reveal the origin of the uniaxial magnetic anisotropy in the point of view of atomic structure, we performed the experiments on bare and Pd-covered Fe monatomic films on Pd(001) surface. Interface structure analysis was done by means of intensity-voltage analysis of low-energy electron diffraction (LEED I-V), and the magnetic anisotropy was investigated by X-ray magnetic circular dichroism (XMCD). Sample fabrication and XMCD experiments were performed at HiSOR-BL14 of Hiroshima Synchrotron Radiation Center, Hiroshima University. It is revealed that the intermixing between Fe films and Pd substrate occurs at room temperature growth, and Pd-overlayer compresses the interlayer distance around Fe layer. Fe thickness dependent XMCD revealed that the spin reorientation transition from perpendicular to in-plane direction occurs in bare Fe/Pd(001) with Fe thickness increase. On the contrary, in-plane magnetic anisotropy is stable in Pd/Fe/Pd(001). We attributed the perpendicular magnetic anisotropy in Fe/Pd(001) to the $L1_0$-like interface structure which realized in this system.

8:12AM Y10.00002 Enhancement of Kondo effect through Rashba spin-orbit interactions[1] , NANCY SANDLER, MEHDI ZAREA, SERGIO ULLOA, Ohio University — The role of Rashba spin-orbit (RSO) interactions on the Kondo regime has been a topic of debate since resistivity measurements on Pt doped Cu:Mn compounds were interpreted as evidence for suppression of the Kondo effect by SO scattering. Subsequent theoretical and experimental activity has yielded conflicting results. Thus, the question: what is the role of SO interactions in the Kondo regime? remains open. To provide a definite answer we obtain an exact solution of an Anderson magnetic impurity model in a two-dimensional metallic host with RSO interactions. We show that the Hamiltonian reduces to an effective two-band Anderson model coupled to a S=1/2 impurity. An appropriate Schrieffer-Wolff transformation produces an effective 2-channel Kondo model plus a Dzyaloshiinski-Moriya (DM) interaction term. The exact solution reveals that the impurity couples to the bath with ferro- and antiferromagnetic couplings. DM interactions, that vanish at half-filling and at the Hubbard U-infinity limits, introduce an exponential increase in the value of the Kondo temperature.

8:24AM Y10.00003 Correlation induced charge ordering metal-insulator transition in a two-dimensional triangular lattice , R. CORTES, Univ. Complutense de Madrid, A. TEJEDA, Institut Jean Lamour, J. LOBO-CHECA, CIN2, C. DIDIOT, B. KIERREN, D. MALTERRE, Institut Jean Lamour, J. MERINO, F. FLORES, E.G. MICHEL, Univ. Autonoma de Madrid, A. MASCARAQUE, Univ. Complutense de Madrid — Mott insulators are one of the clearest examples on how electronic correlations limit the band theory. Semiconducting surfaces offer an ideal playground to study correlation effects in two dimensions. We report here a combined experimental and theoretical analysis on correlation effects in an atomically ordered reconstruction of 1/3 ML of Sn on Ge(111). This interface exhibits a Mott metal insulator transition below 30 K [1,2]. We find a novel phase between the known metallic and insulating phases, settled by electronic correlations and characterized as a charge ordering insulator (COI) that competes with the lower temperature Mott phase. We describe here the electronic mechanism behind the stabilization of the COI-phase, the role of atomic vibrations in the process, and interpret these findings on the basis of DMFT theoretical calculations. These results explain recent controversies [3] on the interpretation of the nature of the low temperature phase. [1] A. Tejeda et al. Phys. Rev. Lett. 100 (026103) 2008 [2] R. Cortes et al. Phys. Rev. Lett. 96 (126103) 2006 [3] H. Morikawa et al. Phys. Rev. B 78 (245307), 2008; S. Colonna et al., Phys. Rev. Lett. 101 (186102) 2008

8:36AM Y10.00004 Passage from Spin-Polarized Surface States to Unpolarized Quantum Well States in Topologically Nontrivial Sb Films , GUANG BIAN, University of Illinois at Urbana-Champaign, THOMAS MILLER, University of Illinois, TAI-CHANG CHIANG, University of Illinois at Urbana-Champaign, CNL TEAM — Topological insulators, which possess robust gapless surface states as a result of strong spin-orbit coupling, have attracted much interest because of their unusual surface spin structures. When such materials are reduced to ultrathin films, the spin-split surface states must connect, by analytic continuation, to quantum well states, which are spin-unpolarized in centrosymmetric systems. We report herein a combined experimental and theoretical study of this passage from polarized to unpolarized states in Sb films. Bulk Sb is semimetallic with a negative band gap; nevertheless, it shares the same topological order as $Bi_{1-x}Sb_x$ ($0.07< x< 0.2$), the first material identified as a three-dimensional topological insulator. Angle-resolved photoemission (ARPES) from Sb films, aided by first-principles calculations, shows smooth dispersion relations associated with this passage; the spin polarizations of the two states fade away, while the energy splitting is maintained through the emergence of different charge density patterns of the resulting quantum well states.

8:48AM Y10.00005 Electron-grain boundary scattering and the resistivity of nanometric metallic structures , R.C. MUNOZ, M. FLORES, G. KREMER, R. HENRIQUEZ, J.G. LISONI, L. MORAGA, S. OYARZUN, M.A. SUAREZ, Dept. of Physics, University of Chile — The resistivity of metallic structures depends on electron-grain boundary and electron-surface scattering. By tuning the grain size, we have been able to separate the contribution to the resistivity originating in electron-grain boundary scattering, from that arising in electron-surface scattering. The resistivity of gold films approximately 54 nm thick deposited onto mica substrates under high vacuum, was measured between 4 and 300 K. It exhibits a cross over, in samples where the average grain diameter $d > 38$ nm and the resistivity is determined by electron-surface plus electron-phonon scattering, to a regime where it is determined by electron-grain boundary plus electron phonon scattering , in samples where $d < 38$nm. l(300)=38 nm is the electron mean free path in the bulk at 300 K. The resistivity can described by Drude's model. It can be described as well by Mayadas's theory using the grain boundary reflectivity R *as the only adjustable parameter.* Funded by FONDECYT 1085026. **References.** R. Henriquez et al., Phys. Rev. **B82** (2010) 113409.

9:00AM Y10.00006 Atomic and Electronic Structures of the Cu2O/TiO2 Heterostructure Interface , SHUZHI WANG, BALASUBRAMANIAM KAVAIPATTI, JOEL AGER, Lawrence Berkeley National Laboratory, RAMAMOORTHY RAMESH, University of California, Berkeley, LIN-WANG WANG, Lawrence Berkeley National Laboratory, LAWRENCE BERKELEY NATIONAL LABORATORY COLLABORATION, UNIVERSITY OF CALIFORNIA, BERKELEY COLLABORATION — Earth-abundant metal oxides have great potentials in replacing Si in semiconductor solar cells and meeting the terawatt scale global energy demand. The structural and electronic properties of the heterojunction interface in oxide-based thin film solar cells, which is of great importance to the energy conversion efficiency, however, is not well understood yet. In this talk, we will present our experimental and theoretical work on the atomic and electronic structures of the interface of Cu_2O and anatase TiO_2. Despite the large lattice mismatch of 13%, Cu_2O can be grown epitaxially on TiO_2(001) in the cube-on-cube orientation by pulsed laser deposition. The interface is found to form a regular coincidence lattice of 8 Cu_2O and 9 TiO_2 unit cells in each in-plane direction. The relaxed structure of this coincidence lattice is simulated using density functional theory calculations. The local density of states along the interface is found to shift as much as 0.4 eV, depending on the local alignment of the two lattices. As a result, the valence band and conduction band edge wave functions are well separated.

9:12AM Y10.00007 Response of the Shockley surface state on Cu(111) to an external electrical field: A density-functional theory study[1] , KRISTIAN BERLAND, PER HYLDGAARD, Chalmers U. of Tech., T.L. EINSTEIN, U. of Maryland — We study the response of the Cu(111) Shockley surface state to an external electrical field E by combining a density-functional theory calculation for a finite slab geometry with an analysis of the Kohn-Sham wavefunctions to obtain a well-converged characterization. We find that the surface state displays isotropic dispersion, quadratic until the Fermi wave vector but with a significant quartic contribution beyond. We find that the shift in band minimum and effective mass depend linearly on E. Most change in electrostatic potential profile, and charge transfer occurs outside the outermost copper atoms, and most of the screening is due to bulk electrons. Our analysis is facilitated by a method used to decouple the Kohn-Sham states due to the finite slab geometry, using a rotation in Hilbert space. We discuss applications to tuning the Fermi wavelength and so the many patterns attributed to metallic surface states.

9:24AM Y10.00008 Measuring Transport Properties of Thin Films Under Isotropic and Anisotropic Strain Using Piezoelectric Substrates , S. WOLGAST, C. KURDAK, Department of Physics, University of Michigan, Ann Arbor, Michigan 48109, A. GAITAS, W. ZHU, PicoCal, Inc., 333 Parkland Plaza, Ann Arbor, Michigan 48103 — Thin film systems have been of great technological interest in the last few decades due to their unique properties. It is crucially important to understand transport properties of such films under strain for some applications such as in strain gauges. Piezoelectric materials have been used in the past to study the isotropic strain-dependent properties of magnetotransport devices. We have extended this technique using one of the shearing modes of a Lead Magnesium Niobate-Lead Titanate (PMN-PT) crystal poled in the <011> direction to study anisotropic strain in thin films. A double Hall Bar pattern oriented along the eigenaxes of the piezoelectric shearing mode permits the characterization of the film in both directions simultaneously. A uniform field in the piezoelectric substrate may be achieved for patterned devices by growing a metal surface surrounding the entire pattern. We will discuss how the changes in the carrier density and electron mobility associated with strain can be characterized in thin metal films deposited directly on the PMN-PT substrate.

9:36AM Y10.00009 Symmetry-induced confinement in reconstructed Au(100) , S. BENGIO, Universidad Autónoma de Madrid, Madrid, Spain, V. NAVARRO, M.A. GONZALEZ-BARRIO, R. CORTES, Universidad Complutense, Madrid, Spain, I. VOBORNIK, TASC National Laboratory, Trieste, Italy, E.G. MICHEL, Universidad Autónoma de Madrid, Madrid, Spain, A. MASCARAQUE, Universidad Complutense, Madrid, Spain — The clean reconstructed Au(100) surface was investigated by angle-resolved photoemission spectroscopy, Low Energy Electron Diffraction and Scanning Tunneling Microscopy. The reconstruction can be described as a floating, corrugated hexagonal layer on top of the bulk-terminated substrate, as in the case of Ir(100) and Pt(100) surfaces. We determine a superperiodicity of (5x26). The substrate Shockley surface state survives the reconstruction and becomes an interfacial surface state. Compelling evidence supports that the overlayer behaves as a quasi-1D system. The presence of quasi-1D states and Shockley surface states are both a consequence of a certain degree of vertical electronic confinement induced by the different symmetry of the hexagonal overlayer and the square bulk-terminated Au(100). The existence of quasi-1D states reveals a significant lateral confinement perpendicular to the atomic chains of the reconstructed Au layer.

9:48AM Y10.00010 Surface states localization induced by single adatoms at metal surfaces , SIMONA ACHILLI, Dept. Material Science, University of Milan Bicocca, MARIO ITALO TRIONI, CNR – National Research Council of Italy, ISTM — The perturbation introduced at metal surfaces by the adsorption of a single adatom affects the surface states. Due to their two dimensional character, localized bound states could result at energy lower then the pristine surface states. The extent of such a localization depends on a variety of aspects such as the attractive strength of the adatom induced potential, the adsorption distance, the nature of the surface state. We investigate this effect through a density functional theory approach that accounts for the semi-infinite character of the substrate and which reproduces the experimental surface states and the surface projected energy gap. The results obtained for different kind of adatoms (both magnetic and paramagnetic) on metal surfaces are discussed, focusing on the localization of the Shockley state and of the image states for different adsorption configurations. The spin splitting of the localized bound state will be also analyzed for magnetic adatoms.

10:00AM Y10.00011 Structure, Morphology and SRF Characteristics of Superconducting Niobium Thin Films on Ceramic Substrates , DOUGLAS BERINGER, Department of Physics, The College of William and Mary, WILLIAM ROACH, CESAR CLAVERO, Department of Applied Science, The College of William and Mary, ROSA ALEJANDRA LUKASZEW, Professor of Physics and Applied Science, The College of William and Mary, CHARLES REECE, Director of Institute for SRF Science and Technology, Jefferson Lab, INSTITUTE FOR SRF SCIENCE AND TECHNOLOGY, JEFFERSON LAB COLLABORATION — The need to improve superconducting thin film coatings for radio frequency (SRF) cavities used in linear accelerators has inspired recent niobium thin film research. To better understand the SRF properties in thin film niobium, correlated studies of structure, surface morphology and SRF performance are examined. Recent work on epitaxial growth of niobium on insulating ceramic substrates — a-plane sapphire and MgO (001) — anticipates Superconducting / Insulating / Superconducting (SIS) multilayer structures, which have been proposed as a means to achieve higher field gradients in SRF cavities, overcoming the intrinsic SRF limitations of bulk niobium. A fundamental study correlating structure, morphology and SRF superconducting properties of niobium thin films is an imperative first step towards realizing next generation SRF materials.

10:12AM Y10.00012 The Electronic Structure and Properties of Different Surface Terminations of Li2B4O6 Single Crystal , IHOR KETSMAN, University of Nebraska -Lincoln, YAROSLAV LOSOVYJ, Louisiana State University, VOLODYMYR ADAMIV, YAROSLAV BURAK, Institute of Physical Optics, Lviv, Ukraine, DAVID WOOTEN, JAMES PETROSKY, JOHN MCCLORY, Air Force Institute of Technology, Wright Patterson Air Force Base, OH, USA, PETER DOWBEN, University of Nebraska -Lincoln — The electronic structure of the(100) and (110) surfaces of Li2B4O6 single crystal was investigated by combined angle- resolved photoemission and inverse photoemission spectroscopies. The obtained results are in a qualitative agreement with the available model bulk band structure calculations.Together with some common features, they reveal clear differences between the two surfaces. For both of them the observed dispersion of the conduction band is much greater than that of valence band and both surfaces are of n-type, though the feature is more pronounced for (100) surface, which, on the whole, is more polar. However, the (110) surface demonstrates much more sofisticated properties exhibiting, in particular, the true surface states and complicated temperature and time dependent photovoltaic charging behaviour. For this surface, in the temperature range of(80-280)K, the off-axis pyroelectric effect was observed with strongly temperature dependent currents in the <110> direction and much smaller pyroelectric coefficient than that measured in the <001> direction.

10:24AM Y10.00013 Correlated electron effects in low energy alkaline earth ion scattering , XIAOXIAO HE, JORY YARMOFF, Department of Physics & Astronomy, University of California, Riverside — The spin correlations of many electrons can lead to emergent phenomena that cannot be extrapolated from the behavior of independent electrons. The role of such multi-electron processes in charge exchange during atom-surface collisions remains a challenging and unsolved problem. Two prior independent theoretical investigations predicted that when a projectile has a single unpaired electron or hole, this localized spin impurity would induce a Kondo resonance at the Fermi energy leading to a mixed-valent state in the metal conduction band. The occupancy of this sharp state would be a strong function of the surface temperature, which would cause an anomalous temperature dependence of the neutralization probability in a scattering experiment. We demonstrate such dependence for low energy Sr^+ scattered from clean polycrystalline gold. This unusual temperature dependence is amplified when the metal work function is reduced by embedding Sr atoms into the material.

8:12AM Y13.00002 Homogeneous linear shear of a two dimensional granular system , JOSHUA A. DIJKSMAN, JIE REN, ROBERT P. BEHRINGER, Duke University — Using a novel shear device, we experimentally study the response of dry granular materials to quasi-static shear. Our apparatus is capable of creating linear strain profiles over the entire width of the two dimensional shear cell. By eliminating the usual tendency of granular shear to localize in non-uniform shear bands, we can study the poorly understood nature of granular flows in great detail. We employ photo elastic particles, fluorescent labelling and high resolution imaging to obtain information about particle positions, rotation and inter particle forces. We discuss our results in the context of the jamming scenario and also look at various measures capable of elucidating the physics of dense granular flows.

8:24AM Y13.00003 Constitutive relations for granular fluid of smooth inelastic hard spheres, to Burnett order , VINAY GUPTA, MEHEBOOB ALAM, JNCASR, Bangalore, India — In the framework of kinetic theory for dilute granular gases, we have generalized the work of Sela & Goldhirsch (1998) by including body force (gravity) term in the Boltzmann equation. In order to derive the constitutive relations for flows of smooth inelastic hard spheres in three dimensions, the Boltzmann equation is perturbatively solved by performing generalized Chapman-Enskog (double expansion) in two small parameters, the Knudsen number and the degree of inelasticity. We have derived the constitutive relations till Burnett order (up to second order in small parameters). In this talk I would like to present the methodology for obtaining the constitutive relations.

Ref: Sela, N. & Goldhirsch, I. 1998 Hydrodynamic equations for rapid flows of smooth inelastic spheres, to Burnett order. *J. Fluid Mech.* **361**, 41–74.

8:36AM Y13.00004 Random to ordered granular sphere packings through cyclic shear , ANDREEA PANAITESCU, ANKI REDDY, ARSHAD KUDROLLI, Clark University — We investigate the structure of a dense granular packing submitted to quasi-static cyclic shear deformations using a fluorescent liquid refractive index matching method. This technique allows us to obtain the three dimensional position of 1mm glass spheres in the bulk during each cycle. The granular packing is observed to evolve towards crystallization over hundreds of thousands of shear cycles and the packing fraction is correspondingly observed to increase from loose packing fraction, 0.59, to above random close packing, 0.634. The appearance and the propagation of the crystalline order was studied using the orientational order metric, Q_6. In the early stages of nucleation the particles belonging to the nucleating crystallites are predominantly in hexagonal close packed configuration. When the packing volume fraction approaches a value close to random close packing, a rapid increase of the global Q_6 and the number of particles with local face centered cubic order is observed. Following the evolution of the crystallites, we find the critical nuclei size to be between 10-50 particles, surprisingly consistent with transitions observed with thermal elastic frictionless spheres. A detailed description of the crystalline clusters and their development will be presented.

8:48AM Y13.00005 Shearbanding Instability and Patterns in Granular Shear Flows , PRIYANKA SHUKLA, MEHEBOOB ALAM, J.N.Centre for Advanced Scientific Research, Bangalore — When a (dense) granular material is sheared in shear-cell experiments, shearing remains confined to a narrow localized zone ("shearband") near the moving boundary. Such shear-banding has also been realized in the molecular dynamics simulations of granular plane Couette flow for a range of densities (even without gravity) in the rapid flow regime. In this talk I will present the shear-banding instability of granular shear flow via an order parameter equation.

9:00AM Y13.00006 Shearing granular media: from elasticity to compaction , JEAN-FRANCOIS METAYER, MPI for Dynamics and Self-Organization, Bunsenstr. 10, 37073 Göttingen, ELIE WANDERSMAN, MARTIN VAN HECKE, University of Leiden, MATTHIAS SCHRÖTER, MPI for Dynamics and Self-Organization, Bunsenstr. 10, 37073 Göttingen — A granular system is able to behave like a solid (a sand pile for example) or like a liquid depending on the deformation imposed on the material. Using rheometry measurements we investigate the response of a granular bed to an imposed deformation or an imposed stress as a function of its packing fraction. We observed different regimes: elastic and plastic behaviors, flow regime and finally compaction. The dependence of these regimes on the packing fraction and on the pressure allows us to delineate the phase diagram of granular media.

9:12AM Y13.00007 Microscopic rearrangements and macroscopic stress fluctuations in dense emulsion flow , DANDAN CHEN, KENNETH W. DESMOND, ERIC R. WEEKS, Emory University — One characteristic of dense granular materials is they can resist small stresses but start to flow under large stresses. During granular flow, the stress exerted on the boundaries of the flow can have large fluctuations. These fluctuations are thought to originate from internal rearrangements and from changes of force chains; however, the connection between these internal microscopic changes and the macroscopic influences seen at the boundaries is not yet clear. We experimentally study the shear flow of oil-in-water emulsion droplets in a Hele-Shaw cell with a hopper shape. Due to the thinness of the Hele-Shaw cell, the droplets are deformed into quasi-2D pancakes, somewhat analogous to soft photoelastic disks. As droplets approach the hopper exit, they shear past one another and droplets are forced to rearrange. We focus on a typical plastic rearrangement called T1 event, where local four particles have neighbor exchanges. Simultaneously, we use the deformation of the droplets to determine the interdroplet forces, which also change as the sample is sheared. These forces fluctuate over large regions as expected. Our analysis of this emulsion system shows a direct and local relationship between microscopic T1 rearrangements and macroscopic stress ?uctuations.

9:24AM Y13.00008 Flow and Sedimentation of particulate suspensions in Fractures[1] , TAK SHING LO, JOEL KOPLIK, Levich Institute and Department of Physics, City College of CUNY — Suspended particles are commonly found in reservoir fluids. They alter the rheology of the flowing liquids and may obstruct transport by narrowing flow channels due to gravitational sedimentation. An understanding of the dynamics of particle transport and deposition is, therefore, important to many geological, enviromental and industrial processes. Realistic geological fractures usually have irregular surfaces with self-affine structures, and the surface roughness plays a crucial role in the flow and sedimentation processes. Recently, we have used the lattice Boltzmann method to study the combined effects of sedimentation and transport of particles suspended in a Newtonian fluid in a pressure-driven flow in self-affine channels, which is especially relevant to clogging phenomena where sediments may block fluid flows in narrow constrictions of the channels. The lattice Boltzmann method is flexible and particularly suitable for handling irregular geometry. Our work covers a broad range in Reynolds and buoyancy numbers, and in particle concentrations. In this talk, we focus on the transitions between the "jammed" and the "flow" states in fractures, and on the effects of nonuniform particle size distributions.

9:36AM Y13.00009 Dilation of Granular Packings of Spheres and Non-Spherical Particles under Shear , ABIGAIL POLIN, BEZ LADERMAN, CHRISTOPHER PEEL, JOHN R. ROYER, PAUL M. CHAIKIN, New York University — A parallelepiped shear cell is used to experimentally measure the dilation of particles prepared at different initial volume fractions from relatively loose assemblies to densely packed ones. The samples consist of spherical marbles, plastic ellipsoids and tetrahedral dice at the centimeter scale and specially prepared particles at the millimeter scale. Under quasi-static shear, loosely packed samples compact while densely packed particles dilate, as in previous studies. For small shear amplitudes, both the dilation and compaction of the tetrahedral packings is significantly larger than that of spheres.

9:48AM Y13.00010 Dynamic crystallization in granular flow[1] , ALINE HUBARD, MARK D. SHATTUCK, The City College of New York — We explore dynamic crystallization in simulations of two dimensional (2D) inelastic frictional hard disks as a model for granular materials. Previous simulations and experiments show formation of hexagonal structures in quasi-2D systems under vibration, rotation, and shearing. In experiments of a uniform but non-equilibrium steady-state (UNESS) under constant pressure the gas-crystal transition shows all of the classic signs of a first-order sublimation phase transition including discontinuous change in density, rate dependent hysteresis, and an equation of state consistent with sublimation. We use molecular dynamics to simulate steady shear under a variety of boundary conditions to determine a dynamic equation of state in the in the density range of the crystallization transition. We compare the dynamic equation of state with that found in non-flowing UNESS experiments, simulations, and theory.

10:00AM Y13.00011 The path to fracture: dynamics of broken-link networks in granular flows , MARK HERRERA, University of Maryland, SHANE MCCARTHY, STEVEN SLOTTERBACK, MICHELLE GIRVAN, WOLFGANG LOSERT, University of Maryland — Capturing the dynamics of granular flows on intermediate length scale can often be difficult. We propose the broken-links network as a new tool to study fracture at the intermediate scale. Using experimental data on the 3D tracks of all particles in a region, we calculate the dynamically evolving broken-links network and observe a second-order, percolation-like phase transition in the formation of the giant component as links are broken. We implement a velocity gradient model of link breakages and find that the model demonstrates a faster growth of the giant component than the data. Surprisingly, the broken-links network formed in the model is also more highly clustered than our empirical observations.

10:12AM Y13.00012 Hockey night in phase space , KIRI NICHOL, Leiden University, KAREN DANIELS, North Carolina State University — In order to explore the possibility of developing a statistical mechanics for dissipative ensembles, we have performed an experiment in which we track the translational and rotational velocities of pucks on an air hockey table. The pucks are driven by bumpers at the boundaries and are bidisperse to prevent crystallization. At packing fractions of 60% we find that the system distributes rotational and translation energy according to the equipartition theorem. However, as the packing fraction increases, the ratio of rotational energy to translational energy also increases to a value larger than predicted by equipartition. The translational and angular velocity distributions are approximately exponential and the distributions of the translational velocity are the same for both large and small particles. In contrast, the distribution of the angular velocities is broader for the small particles than for the large.

10:24AM Y13.00013 Rotational statistics in dense granular flows of smooth cylindrical particles , JEFFREY OLAFSEN, JACOB JANTZI, Department of Physics, Baylor University — We report the results of an experiment to investigate the dissipation in the rotational degree of freedom for smooth cylindrical particles in a dense, driven granular flow. The flow is studied in a rotating drum of radius R = 30 cm for particles of radius r = 0.635 cm while the cell is rotated at speeds between 0.25 and 0.75 Hz. The 2D geometry of the experimental design allows for the measurement of two translational degrees of freedom as well as the rotation of the disks within the driven flow. The rotational velocity statistics demonstrate non-Gaussian behavior as well as a significant amount of energy being dissipated within the flow via the tangential friction between the particles. The results of this experiment are significant in that many driven granular experiments use smooth cylindrical or spherical particles to investigate granular dynamics, but the contribution from the rotational degrees of freedom are often unmeasured. A novel imaging technique is used to extract both the translational and rotational velocity statistics to a high degree of precision in the entire cell during the experiment.

10:36AM Y13.00014 ABSTRACT WITHDRAWN –

10:48AM Y13.00015 Size Segregation of Granular Materials , ANURAG TRIPATHI, D.V. KHAKHAR, Indian Institute of Technology Bombay — Segregation of granular materials due to size difference while flowing/energized is a very well known but poorly understood phenomena. Despite of some good understanding of the mechanism of size segregation, predictive models for size segregation are not available. Size segregation of binary granular mixtures flowing over inclined plane is studied by means of DEM simulations. Buoyant force acting on trace particles of a bigger size is obtained by varying the density of the trace particles rising/sinking in the granular flow. We show that moderately big trace particles of same density as that of the light particles tend to rise because of higher buoyancy forces than the weight of the trace particles. For very big trace particles of same density, however, the buoyant force becomes smaller than the weight of the particles causing the particles to settle down. Drag force on the trace particle is found to be given by Stokes' law. Friction drag is found to almost $10 - 12\%$ of the weight of the trace particles. Incorporating the Stokes' law and balancing the segregation and diffusion flux of big particles, we are able to predict the number fraction of the big particles in terms of viscosity and diffusivity for moderately dilute binary mixture of different size particles. The proposed theory is tested against DEM simulation results and very good agreement has been found with the simulation results.

Session Y14 GSNP: Focus Session: Statistical Mechanics of Complex Networks II D227

8:00AM Y14.00001 Universal features of dynamic small-world networks , THOMAS STONE, Husson University, SUSAN MCKAY, University of Maine — In a dynamic small-world contact network, an individual has fixed short range links within its local neighborhood and time-varying stochastic long range links outside of that neighborhood. The probability of a long range link occurring (p, in analogy with the standard small-world rewiring parameter) is a measure of the mobility of the population. In this study we investigate the epidemic to non-epidemic phase transition that occurs in a susceptible-infected-recovered (SIR) disease spreading model located on this type of dynamic network. We first derive the finite-valued critical mobility p_c and find excellent agreement with numerical simulations. Close to p_c the outbreak size scales as $(p\text{-}p_c)^\beta$ since it is a continuous transition; we find that β is near 2, but varies as a function of the infectivity and recovery rates. At the critical point our study shows that the distribution of outbreak sizes scales as $\sim N^{-\alpha}$ with $\alpha = 1.5 \pm 0.03$. We compare these critical exponents to those found in related small-world and dynamic small-world networks and comment on potential universality.

8:12AM Y14.00002 Robustness and dynamics of networks of coupled modules , JAMES BAGROW, YONG-YEOL AHN, Northeastern University, SUNE LEHMANN, Technical University of Denmark — Many systems, from power grids and the internet, to the brain and society, can be modeled using networks of coupled overlapping modules. The elements of these networks perform individual and collective tasks such as generating and consuming electrical load or transmitting data. We study the robustness of these systems using percolation theory: a random fraction of the elements fail which may cause the network to lose global connectivity. We show that the modules themselves can become isolated or uncoupled (non-overlapping) well before the network falls apart. This has important structural and dynamical consequences for these networks and may explain how missing information hides pervasive overlap between communities in real networks.

8:24AM Y14.00003 Explosive Percolation in the Human Protein Homology Network , HERNAN ROZENFELD, APS, LAZAROS GALLOS, HERNAN MAKSE, CCNY — We study the explosive character of the percolation transition in a real-world network. We show that the emergence of a spanning cluster in the Human Protein Homology Network (H-PHN) exhibits similar features to an Achlioptas-type process and is markedly different from regular random percolation. The underlying mechanism of this transition can be described by slow-growing clusters that remain isolated until the later stages of the process, when the addition of a small number of links leads to the rapid interconnection of these modules into a giant cluster. Our results indicate that the evolutionary-based process that shapes the topology of the H-PHN through duplication-divergence events may occur in sudden steps.

8:36AM Y14.00004 ABSTRACT WITHDRAWN –

9:12AM Y14.00005 Power Spectrum of the Finite Kuramoto Model , DAVID MERTENS, RICHARD WEAVER, University of Illinois at Urbana-Champaign — We study the synchronization of oscillators in the finite Kuramoto model, a simple model for coupled phase oscillators that exhibits a phase transition. The usual self-consistent approach used in studying the Kuramoto model gives a prediction for the distribution of modified frequencies that includes a Dirac delta at the synchronized frequency and a depletion of nearby frequencies. For finite systems, the prediction adequately describes the distribution of frequencies averaged over very long durations, but the accompanying power spectrum of the order parameter looks very different. The sharp peak at the synchronization frequency has a finite width and oscillators that are otherwise entrained manage to occasionally escape. The resulting harmonics of these escaped oscillators leads to a power spectrum with an exponential drop-off from the peak, rather than the originally predicted depletion.

9:24AM Y14.00006 Recruitment dynamics in adaptive social networks , MAXIM SHKARAYEV, LEAH SHAW, College of William and Mary, IRA SCHWARTZ, Naval Research Lab — We model recruitment in social networks in the presence of birth and death processes. The recruitment is characterized by nodes changing their status to that of the recruiting class as a result of contact with recruiting nodes. The recruiting nodes may adapt their connections in order to improve recruitment capabilities, thus changing the network structure. We develop a mean-field theory describing the system dynamics. Using mean-field theory we characterize the dependence of the growth threshold of the recruiting class on the adaptation parameter. Furthermore, we investigate the effect of adaptation on the recruitment dynamics, as well as on network topology. The theoretical predictions are confirmed by the direct simulations of the full system.

9:36AM Y14.00007 The spread of opinion on co-evolving networks[1] , PRAMESH SINGH, S. SREENIVASAN, G. KORNISS, B. K. SZYMANSKI, RPI — We discuss a model of opinion formation in co-evolving networks. In realistic scenarios, the network constantly changes structure favoring connections between similar individuals (homophily). Here we allow the opinions to co-evolve with the reorganization of links in the network. This dynamical nature of the network impedes the spreading of opinions. We study how this resistance to the spread can be overcome and consensus can be achieved by randomly distributing a few committed agents (-nodes that are not influenceable in their opinions). In this model adjacent nodes influence each other if they are similar on at least Q attributes, where Q is the influence threshold. Nodes will rewire their existing links if they are not similar enough. We demonstrate through simulations that in the absence of committed agents, time to reach consensus in opinions diverges exponentially with system size N. However, as committed agents are added, beyond a small value of committed fraction, the consensus time becomes a slowly varying function of N. (Ref- F. Vazquez et al. - Phys. Rev. E76, 046120 -2007)

9:48AM Y14.00008 Network resilience to real-world disasters: Eyjafjallajökull and 9/11 , OLIVIA WOOLLEY, Northwestern University, CHRISTIAN THIEMANN, DANIEL GRADY, DIRK BROCKMANN, Northwestern University — We investigate the resilience of the the world-wide air transportation network (WAN) to the 9/11 terrorist attacks and the recent eruption of the volcano Eyjafjallajökull. Although both disasters caused wide-spread disruption, the number of airports that were closed and the volume of interrupted traffic were well below the percolation threshold predicted by the classical theory. In order to quantify and visualize network deformation before breakdown, we introduce a framework based on the increase in shortest-path distance and homogenization of shortest-path structure. These real-world disasters are a new type of disruption because the removal of all vertices (airports) is geographically compact. Our framework incorporates the dual perspective of individual airports and geopolitical regions to capture how the impact interacts with the sub-network structure.We find that real-world events have an impact signature which is qualitatively different from that of random or high-centrality attacks. Furthermore, we find that the network is more resilient to the 9/11 disaster, although it removed more airports and traffic than the volcanic ash-cloud. This is due to the network roles of Europe and North America. We discuss how regional roles influence resilience to a region's removal.

10:00AM Y14.00009 Stochastic Moment Equations - Case Closed , BARUCH BARZEL, Northeastern university, OFER BIHAM, The Hebrew University — Reaction networks frequently appear in many natural systems, such as chemistry, biology and ecology. The modelling of these networks is commonly based on rate equations models, incorporating the law of mass action kinetics. However, when the system is microscopic, it becomes governed by fluctuations, the law of mass action kinetics no longer applies, and the rate equations fail. To obtain an accurate description of microscopic reaction networks, one must refer to stochastic methods based on the master equation. The problem is that the number of equations rises exponentially with the number of species, rendering the treatment of the master equation infeasible. Moment equations are known to be more efficient, however the equations are not closed, and become prohibitively complicated when moments of high order are included. In this talk we present the binomial moment equations. The binomial moments are linear combinations of the ordinary moments related to the population size of the reactive species. They capture the essential combinatorics of the reaction processes reflecting their stoichiometric structure. This leads to a simple and transparent form of the equations, allows a highly efficient and surprisingly simple truncation scheme and enables the inclusion of moments up to any desired order. The result is a set of equations that enables an equation-based stochastic analysis of reaction networks under a very broad range of conditions.

10:12AM Y14.00010 Using a Projector to Control BZ Drops: Attractor Selection by Pattern Entrainment , NATHAN TOMPKINS, HECTOR GONZALEZ OCHOA, IRVING EPSTEIN, SETH FRADEN, Brandeis University — An emulsion consisting of drops in the 100μm diameter range containing the Belousov-Zhabotinsky (BZ) oscillatory chemicals can interact via diffusive inhibition and can be thought of as coupled phase oscillators. For weak coupling, a 2-D hexagonal lattice of these drops naturally develop regions of attractor states of sequential oscillations with phase differences of plus/minus $2\pi/3$ much like the 2D anti-ferromagnetic Heisenberg spin model. An untrained system of these oscillators will develop unstable regions of both attractors that grow and compete. We use photo-initiated inhibition to optically entrain the system with a projected $+2\pi/3$ pattern in an attempt to force the system into the $+2\pi/3$ attractor state. However, both the left and right handed variants of the $2\pi/3$ attractor are present in the entrained system. Defining an order parameter $e^{i3\phi}$ allows for a quantitation of the purity of the $2\pi/3$ attractor state in the final system.

10:24AM Y14.00011 Complexity facilitates perturbation of a coherent dynamical process , MALGORZATA TURALSKA, University of North Texas, ELVIS GENESTON, La Sierra University, PAOLO GRIGOLINI, University of North Texas — We discuss the influence of perturbation on networks of globally coupled three state stochastic oscillators. When coupled, the system shows intermittent behavior characterized by a waiting time distribution which reveals both inverse power-law and coherent dynamical properties. Specifically, we compare the results of perturbation realized with a periodic signal to those obtained using perturbation provided by a matching system. We find that the SNR (signal-to-noise ratio) does not depend on the frequency of the perturbing signal. We also observe that the second approach results in higher values of SNR. We discuss how those findings cannot be explained by either classical or statistical resonance theory. With the help of the fluctuation-dissipation theorem [1] we determine the role of the scaling dynamics in the system under investigation.

10:36AM Y14.00012 Coupled Oscillations in a 1D Emulsion of Belousov-Zhabotinsky Droplets[1] , SETH FRADEN, JORGE DELGADO, NING LI, MARCIN LEDA, HECTOR GONZALEZ-OCHOA, IRVING EPSTEIN, Brandeis University — We experimentally and computationally study the dynamics of interacting oscillating Belousov-Zhabotinsky (BZ) droplets of $\sim$120 μm diameter separated by perfluorinated oil and arranged in a one-dimensional array (1D). The coupling between BZ droplets is dominated by inhibition and is strongest at low concentrations of malonic acid (MA) and small droplet separations. A microfluidic chip is used for mixing the BZ reactants, forming monodisperse droplets by flow-focusing and directing them into a hydrophobized 100 μm diameter capillary. For samples composed of many drops and in the absence of well defined initial conditions, the anti-phase attractor, in which adjacent droplets oscillate 180° out of phase, is observed for strong coupling. When the coupling strength is reduced the initial transients in the phase difference between neighboring droplets persist until the BZ reactants are exhausted. In order to make quantitative comparison with theory, we use photosensitive Ru(bipy)$_3^{2+}$-catalyzed BZ droplets and set both boundary and initial conditions of arrays of small numbers of oscillating BZ droplets with a programmable illumination source. In these small collections of droplets, transient patterns decay rapidly and we observe several more complex attractors, including ones in which some adjacent droplets are in-phase.

10:48AM Y14.00013 Quarantine generated phase transition in epidemic spreading , MARK DICKSION, Boston University, CECILIA LAGORIO, F. VAZQUEZ, L. BRAUNSTEIN, P.A. MACRI, M.V. MIGUELES, S. HAVLIN, H.E. STANLEY — We study the critical effect of quarantine on the propagation of epidemics on an adaptive network of social contacts. For this purpose, we analyze the susceptible-infected-recovered (SIR) model in the presence of quarantine, where susceptible individuals protect themselves by disconnecting their links to infected neighbors with probability w, and reconnecting them to other susceptible individuals chosen at random. Starting from a single infected individual, we show by an analytical approach and simulations that there is a phase transition at a critical rewiring (quarantine) threshold w_c separating a phase ($w < w_c$) where the disease reaches a large fraction of the population, from a phase ($w >= w_c$) where the disease does not spread out. We find that in our model the topology of the network strongly affects the size of the propagation, and that w_c increases with the mean degree and heterogeneity of the network. We also find that w_c is reduced if we perform a preferential rewiring, in which the rewiring probability is proportional to the degree of infected nodes.

Session Y15 GMAG DMP FIAP: Focus Session: Spins in Semiconductors - Spin Currents IV

D171

8:00AM Y15.00001 Electrically-generated electron spin polarization for non-reciprocal integrated photonic devices , CHRISTOPHER TROWBRIDGE, BENJAMIN NORMAN, VANESSA SIH, University of Michigan — Electron spin polarization based photonic devices offer promising advantages over current technologies. Spin orbit coupling allows for an all-electrical means of control over light in semiconductor waveguides. Electrically generated spin polarization results in a circular dichroism near the absorption edge which results in non-reciprocal Faraday rotation. We investigate the requirements for manipulating light in semiconductor waveguides using electrically-generated spin polarization. Ultimately, device performance will be limited by the magnitude of achievable Faraday rotation, birefringence, and absorption. We show that one can limit birefringence by appropriate waveguide design and that substantial Faraday rotation is accessible sufficiently far below the band edge for material absorption to be minimal.

8:12AM Y15.00002 Spin Control of Drifting Electrons using Local Nuclear Polarization in Ferromagnet-Semiconductor Heterostructures[1]

, M.E. NOWAKOWSKI, G.D. FUCHS, S. MACK, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106, N. SAMARTH, Department of Physics and Materials Research Institute, The Pennsylvania State University, University Park, PA 16802 — We demonstrate a spatially-confined magnetic field gate to modulate the Larmor frequency of an optically-injected spin ensemble drifting down a GaAs channel [1]. The gate is activated either optically or electrically and polarizes GaAs nuclear spins at the interface between a lithographically-defined MnAs island and the channel via the ferromagnetic proximity polarization effect. We measure the rotation angle of the spin ensemble as it emerges from the polarized region using time-resolved Kerr rotation. The ensemble's spin rotation angle can be tuned by up to 5π radians as the spins travel over 30 μm by controlling the nuclear field strength and adjusting the drift velocity.

8:24AM Y15.00003 Large and Small Signal Analyses of Spin Modulation in Lasers

, CHRISTIAN GOTHGEN, JEONGSU LEE, RAFAL OSZWALDOWSKI, IGOR ZUTIC, SUNY at Buffalo — We have developed a set of rate equations for semiconductor spin-lasers that contain spin-polarized carriers (electrons and holes) in the active region due to spin-polarized (electrical or optical) injection. Previous studies consider the steady-state regime [1-5], showing advantages of the spin-lasers over its conventional counterparts such as threshold reduction and enhanced emission intensity [6]. We suggest a further improvement of spin lasers under dynamical operation. We use both large and small signal analyses to show that the spin-polarized injection can lead to an enhanced bandwidth and desirable switching properties of spin-lasers. Supported by ONR, AFOSR, NSF-ECCS CAREER.

8:36AM Y15.00004 Mapping between Quantum-Dot and Quantum-Well Spin-Lasers

, JEONGSU LEE, RAFAL OSZWALDOWSKI, CHRISTIAN GOTHGEN, IGOR ZUTIC, SUNY at Buffalo — It has been demonstrated that performance of semiconductor lasers with a quantum-well (QW) active region can be improved by injecting spin-polarized carriers [1-3]. Their rate-equation models have been developed [4-5], however, description of a quantum-dot (QD) spin-laser, demonstrated recently [6], is more complicated [7]. Here, we present a method which allows to employ the simple QW rate equations to study the QD spin-lasers. With this method, one can easily extract QW-like parameters such as differential gain, gain compression factor and time constants. This effort is worthwhile, because the QW spin-laser rate equations have exact analytical solutions, unlike their QD counterparts [7]. Supported by US ONR, AFOSR, DOE-BES, and NSF-ECCS CARRER. [1] J. Rudolph et al., Appl. Phys. Lett. 82, 4516 (2003). [2] M. Holub et al., Phys. Rev. Lett. 98, 146603 (2007). [3] S. Hovel et al., Appl. Phys. Lett. 92, 041118 (2008). [4] C. Gothgen, R. 8:48AM Y15.00005 High frequency dynamics and output polarization of a spin laser

, PALLAB BHATTACHARYA, University of Michigan, Ann Arbor, DIPANKAR SAHA, Indian Institute of Technology Bombay, DEBASHISH BASU, University of Michigan, Ann Arbor — The dynamic characteristics of a spin laser have been studied theoretically and experimentally. Calculations with the coupled carrier and photon rate equations show that the small signal modulation bandwidth of the preferred polarization mode is enhanced due to spin injection. The large signal modulation characteristics show temporally separated relaxation oscillations corresponding to the two polarization modes. More importantly, it is shown that an output polarization of 100% can be obtained, with appropriate biasing conditions, irrespective of the degree of spin injection. This is experimentally verified in a quantum dot spin-vertical cavity surface emitting laser (spin VCSEL), where an output polarization of $\sim$ 60% is measured with a 5-6% carrier spin polarization in the active region.

9:00AM Y15.00006 Consequences of spin transport in heterogeneous environments

, VIDYA BHALLAMUDI, Department of Electrical and Computer Engineering, The Ohio State University, ANDREW BERGER, Department of Physics, The Ohio State University, DOMINIC LABANOWSKI, Department of Electrical and Computer Engineering, The Ohio State University, DAVID STROUD, P. CHRIS HAMMEL, Department of Physics, The Ohio State University — Understanding behavior of spins in spatially varying environments such as magnetic fields, spin lifetime and gyromagnetic ratio is very important for real spintronic devices [1]. We present here numerical solutions of the spin diffusion equation in such situations. We show that local magnetic fields can be useful as an imaging tool for spin properties such as spin lifetime. It can also complicate the interpretation of experimental results in the case of spin injection from a ferromagnet into a semiconducting channel through a rough interface [1,2].

9:12AM Y15.00007 Robust Level Coincidences in the Subband Structure of Quasi 2D Systems[1]

, R. WINKLER, Northern Illinois University and Argonne National Lab , L.Y. WANG, Y.H. LIN, C.S. CHU, National Chiao Tung University, Hsinchu, Taiwan — Recently, level crossings in the energy bands of crystals have been identified as a key signature for topological phase transitions. In general, three independent parameters must be tuned appropriately to bring two quantum levels into degeneracy. Using realistic models we show that for Bloch electrons in a crystal the parameter space controlling the occurrence of level coincidences has a much richer structure than anticipated previously. In particular, we identify cases where level coincidences depend on only two independent parameters thus making the level coincidences robust, i.e., they cannot be removed by a small perturbation of the Hamiltonian compatible with the crystal symmetry. We consider HgTe/CdTe quantum wells as a specific example. (See arXiv:1011.xxxx)

9:24AM Y15.00008 Anomalous spin-resolved point-contact transmission of holes due to cubic Rashba spin-orbit coupling

, STEFANO CHESI, University of Basel, GABRIELE GIULIANI, LEONID ROKHINSON, Purdue University, LOREN PFERIFFER, KEN WEST, Princeton University — We present experimental and theoretical evidence for the crossing at finite wave vector of the two lowest one-dimensional spin-split subbands in quantum point contacts fabricated from two-dimensional hole gases with strong spin-orbit interaction. We derive the existence of such crossing point from a two-dimensional spin-orbit interaction with a cubic momentum dependence, appropriate for asymmetric quantum wells. This phenomenon provides an explanation for the anomalous sign of the spin polarization filtered by the point contact, as observed in magnetic focusing experiments. Anticrossing in the one-dimensional spin subbands is introduced by a magnetic field parallel to the channel or an asymmetric potential transverse to it. Controlling the magnitude of the spin-splitting affords a novel mechanism for inverting the sign of the spin polarization.

9:36AM Y15.00009 Energy Spectra and Spin Properties of Electrons in Spin-Orbit Superlattice Quantum Wires[1] , VANITA SRINIVASA, JEREMY LEVY, University of Pittsburgh — We calculate the energy spectra of electrons in quantum wires with spatially uniform and modulated spin-orbit coupling. The effects of Rashba spin-orbit coupling arising from asymmetric confinement in perpendicular and lateral directions with respect to the plane containing the wire are considered. We investigate the resulting interplay of strong lateral confinement, a periodic one-dimensional superlattice potential, and spin-orbit coupling in two orthogonal directions. The implications for the spin-dependent properties of electrons confined within these quantum wires are discussed. A potential realization of such systems within narrow nanowires at the interface of $LaAlO_3/SrTiO_3$ heterostructures is also described.

9:48AM Y15.00010 Unexpected Anisotropy of Electron g-factor in GaAs/AlGaAs(110) Quantum Well , YANG JI, SKLSM, Institute of Semiconductors, CAS — Semiconductor spin qubit is a promising candidate for solid state quantum computation. A lot of effort has been devoted to study spin dynamics in semiconductors ever since a revival of research interest in this field in the late 1990s. Spin lifetime longer than 1ns at room temperature has been discovered in GaAs/AlGaAs(110) quantum wells (QW) as a result of the absence of a predominant spin scattering mechansim (DP mechanism), which also leads to a strong anisotropy of electron spin decoherence in such QWs, with the spin lifetime of spins along the growth direction 10 times bigger than that of spins perpendicular to the growth direction. However, not much is known about the (an)isotropy of spin-related processes in the (110) QW plane, despite that it may offer useful information about spin relaxation. Utilizing a time-resolved Kerr rotation (TRKR) system with a rotatable in-plane magnetic field, we studied the spin processes in GaAs/AlGaAs (110) QWs and found an unexpected anisotropy of electron g-factor in such QWs. The g-factor as measured with the magnetic field along the [1-10] axis is some 10% larger than that along the [001] axis. Such a strong anisotropy is not only unexpected for QWs, but also much bigger than that found in InGaAs/GaAs quantum dots. An explanation for these results is still in demand but it may give some hints to improve our understanding of spin dephasing mechanisms in semiconductors.

10:00AM Y15.00011 High Resolution Magneto-Optic Measurements in GaAs using a Sagnac Interferometer , ALEXANDER FRIED, Stanford — The Sagnac Interferometer is a tool which measures the Polar Kerr effect–a direct indicator of magnetism. Using 820 nm light from a superluminescent diode, we probe GaAs structures and measure the Kerr angle with sub-microradian resolution. By utilizing diffraction limited optics and a piezoelectric scanner, we also achieve high spatial resolution. Our measurements are performed at cryogenic temperatures and offer a way to measure the Spin Hall Effect in the DC regime along with other forms of magnetic order.

10:12AM Y15.00012 Temperature-dependent spin- and phase coherence measured via h/e and h/2e quantum oscillations in resistance of mesoscopic ring arrays in an InAs 2DES , R.B. LILLIANFELD, R.L. KALLAHER, J.J. HEREMANS, Virginia Tech, W. VAN ROY, G. BORGHS, IMEC- Belgium — We investigate electron spin- and phase coherence in an array of quasi-ballistic InAs quantum well mesoscopic rings through observation of Aharonov-Bohm h/e oscillations (AB) and Altshuler-Aronov-Spivak h/2e oscillations (AAS). The temperature dependence of the AAS oscillations is characterized through a single effective coherence length, $L_{\rm eff}$, following the formalism of Douçot and Rammal, from which the phase coherence length, L_ϕ and the spin coherence length as limited by spin-orbit interaction, $L_{\rm SO}$, are extracted. AB oscillations are also present, and can be separated from AAS by Fourier transformation. We contrast the AAS method of extracting the coherence lengths with analysis of the AB oscillation amplitudes. Previous studies have examined L_ϕ from AB signals in single ballistic rings, or by using AAS amplitudes in large networks, or have observed AB and AAS in single rings with spin-orbit interaction. Here the presence of both AB and AAS in an array with spin-orbit interaction allows for study of both L_ϕ and $L_{\rm SO}$, and enables direct juxtaposition of different quantum coherence phenomena as means for measuring coherence lengths (DOE DE-FG02-08ER46532).

10:24AM Y15.00013 Weak Antilocalization and Spin-Orbit Coupling in InAlN/AlN/GaN Heterostructures , H. CHENG, C. KURDAK, Department of Physics, University of Michigan, Ann Arbor, MI, 48109, J.H. LEACH, M. WU, H. MORKOC, Department of Electrical and Computer Engineering, Virginia Commonwealth University, Richmond VA, 23284 — Spin-orbit coupling is investigated by magnetotransport and weak antilocalization (WAL) measurements in $In_xAl_{1-x}N$/AlN/GaN heterostructures in the carrier density ranges extending from 1.22×10^{13} cm^{-2} to 1.41×10^{13} cm^{-2} and from 1.99×10^{13} cm^{-2} to 2.15×10^{13} cm^{-2}. By combining the data from AlGaN/AlN/GaN samples, we find that the spin-orbit field is not a constant at high carrier densities and the electron spin-splitting energies show a deviation from linear behavior with Fermi wavefactor. However, the spin-splitting energies extracted from WAL oscillations, even in this high carrier density regime, were found to be much smaller than the previous reports based on Shubnikov-de Haas (SdH) measurements. We will discuss how the nonuniformities in the carrier density can lead to beating features in SdH oscillations, which can then be misinterpreted as large spin-splitting energies. This finding may resolve the long-standing discrepancy between the WAL and SdH results.

10:36AM Y15.00014 Spin Coulomb Drag in the Hubbard Chain[1] , PEDRO SCHLOTTMANN, Florida State University — The spin Coulomb drag is the decay of the spin current in a metal as a consequence of the Coulomb interaction between up- and down-spin carriers and is a distinctive feature of spin- polarized transport. The current of majority spins can induce a current of minority spin carriers via the transresistivity. This friction reduces the current but does not change the spin- polarization.[2] We calculate the critical exponents of the resistivity for up- and down-spin electrons and the transresistivity for the spin-polarized Hubbard chain with nonmagnetic impurities within the Kubo formalism using (1) bosonization techniques[3] and (2) the Bethe ansatz solution and conformal invariance.[4] The charge-spin separation in 1D is strictly valid only in the absence of spin-polarization. Due to the Luttinger liquid properties the temperature dependence of the transport correlation functions follow power laws of T with non-universal exponents. A large spin polarization is more favorable for a sustained spin current than a small magnetization.

10:48AM Y15.00015 Spin Texture in a Cold Exciton Gas , ALEXANDER HIGH, AARON HAMMACK, JASON LEONARD, SEN YANG, LEONID BUTOV, UC San Diego, TOMAS OSTATNICKY, Charles University, Prague, ALEXEI KAVOKIN, University of Southhampton, ARTHUR GOSSARD, UC Santa Barbara — We report on the observation of a spin texture in a cold exciton gas in a GaAs/AlGaAs coupled quantum well structure. The spin texture is observed around the rings in the exciton emission pattern. The observed phenomena include: a ring of linear polarization, a vortex of linear polarization with polarization perpendicular to the radial direction, an anisotropy in the exciton flux, a skew of the exciton fluxes in orthogonal circular polarizations and a corresponding four-leaf pattern of circular polarization, and a periodic spin texture. These phenomena emerge when the exciton gas is cooled below a few Kelvin.

Friday, March 25, 2011 8:00AM - 11:00AM –

Session Y16 GMAG DMP: Focus Session: Spins in Carbon-Based Materials – Magnetoresistance, Magneto-Electric Effect D173

8:00AM Y16.00001 Quantum Linear Magnetoresistance and Extraordinary Magnetoresistance in Graphene , ADAM FRIEDMAN, US Naval Research Laboratory — Graphene, a single atomic layer of hexagonally arranged carbon atoms, presents the optimal platform to study rarely-observed magnetoresistance (MR) effects because of its temperature-independent mobility and linear band structure with zero band gap. Linear magnetoresistance (LMR), which is characterized as a large, non-saturating linear MR, is one such unusual effect. Normally, the resistance of a conductor in an applied magnetic field increases quadratically with field and then saturates at a relatively low value. Models that explain LMR behavior have been proposed that include both quantum and classical origins, but most systems studied thus far can be explained by a purely classical model. However, we find that quantum LMR is observed in multilayer epitaxial graphene grown on SiC at temperatures as high as 300 K and with a magnitude greater than 200% at 12 Tesla (T). In addition, a phenomenon closely related to classical LMR called extraordinary magnetoresistance (EMR) and characterized by even larger MR, can be realized in metal-shunted graphene devices. Here, due to the different magnetic-field-dependent resistances of the metallic shunt, graphene, and shunt-graphene interface, current flows easily through the shunt in zero and low magnetic field, while in high magnetic field, more current flows around the shunt and is redistributed in the graphene. Devices made from chemical vapor deposition (CVD) graphene grown on copper and transferred to a SiO_2/Si substrate with Ti/Au shunts display gate-tunable longitudinal MR of $\sim$600% at 12 T and also show promise for use as Hall sensors. Graphene magnetoresistance devices have many possible applications including magnetic field sensors and magnetic read-heads. In contrast with the many proposed electronic uses for graphene, which necessitate the creation of a band-gap, graphene magnetoresistance devices that exploit LMR or EMR provide a use for as-grown or deposited graphene.

8:36AM Y16.00002 Frequency dependence of organic magnetoresistance[1] , FUJIAN WANG, JAMES RYBICKI, RAN LIN, KENT HUTCHINSON, JIA HOU, MARKUS WOHLGENANNT, University of Iowa — Organic magnetoresistive (OMAR) devices show a large enough magnetoresistive response (typically 10%) for potential applications as magnetic field sensors. However, applications often require sensing high frequency magnetic fields, and the examination of the frequency-dependent magnetoresistive response is therefore required. Analysis of time constants that limit the frequency response may also shed light on the mechanism behind the OMAR effect, because different OMAR mechanisms occur at different time scales In our experiments, the AC magnetic field is supplied by a coil with a ferrite core which is driven by a function generator The AC magnet shows a frequency response that is almost flat up to 1MHz. We found that the OMAR frequency limit is about 10 kHz for a typical organic semiconductor device and at least 100 kHz for devices made from a doped polymer film. We also performed capacitance and conductance vs. frequency measurements to understand the origin of the observed limit frequencies.

8:48AM Y16.00003 Room Temperature Ferromagnetic Polymer and the Correlated Anomalous Magnetoresistance Phenomenon[1] , JINSONG HUANG, University of Nebraska Lincoln, BIN YANG, JEFFREY SHIELD — Organic magnetoresistance (OMAR) has been observed in organic semiconductor devices where resistance can change in a relatively small external magnetic field at room temperature. Since a weak magnetic field is involved, the hyperfine interaction (HFI) is employed to explain OMAR in the reported literatures. None of these issues consider the magnetic properties of the organic semiconductors themselves. However, the we recently discovered that polymer semiconductors, such as poly(3-hexylthiophene) P3HT, can have room temperature (RT) ferromagnetic properties in their crystalline phase and when mixed with phenyl-C61-butyric acid methyl ester (PCBM). Here, we will report the possible correlation between the ferromagnetic property of the P3HT:PCBM and anomalous OMAR phenomenon including the anisotropic and hysteretic OMAR behavior. The magnetic property of the polymer including the anisotropic and photo induced change of magnetism will be also discussed to explore the possible mechanism of the room temperature ferromagnetism.

9:00AM Y16.00004 Magnetic fringe field control of electronic transport in an organic film[1] , MARKUS WOHLGENANNT, FUJIAN WANG, University of Iowa, FERRAN MACIA, ANDREW KENT, New York University, MICHAEL FLATTE, University of Iowa — Random nuclear hyperfine fields in organic materials dramatically affect electronic transport properties such as the electrical (photo)conductivity and electroluminescence. The influence of these nuclear hyperfine fields can be overwhelmed by a uniform external applied magnetic field. As a result, in applied magnetic fields of about 10mT the kinetics of exciton formation, bipolaron formation, and carrier hopping are all modified, leading to changes in room-temperature electrical transport properties in excess of 10 % in many materials. Here we demonstrate a new method of controlling the electronic transport in an organic film, using the spatially-varying magnetic fringe fields of an unsaturated ferromagnetic electrode. The effect of these magnetic fringe fields is hysteretic, anisotropic, and depends sensitively on the distance of the organic material from the ferromagnetic electrode; all these effects appear in the magnetic-field dependences of electronic transport in these films. Such structures, which do not rely on spin injection or spin-valve behavior, may provide a simple approach to integrating magnetic metals and organics for hybrid spintronic devices.

9:12AM Y16.00005 Spin-Boson Theory of Organic Magnetoresistance , CHANG-QIN WU, Department of Physics, Fudan University, Shanghai 200433 — The discovery of room-temperature, low-field magnetoresistance (MR) in organic light-emitting devices was one of major achievements of spintronics in the last decade. Compared to its inorganic counterpart, a sizable organic MR (OMR) is relatively easy to be obtained, showing extensive potential in magnetically controlled applications. Yet, after years of intense research, a comprehensive understanding of this magnetic field effect out of these nonmagnetic materials is still lacking. In this work, we present a spin-boson theory for magnetotransport in organic semiconducting materials, on the basis of a coupling between charge carriers' spin and a local bosonic environment, which is shown to be an irreducible ingredient in understanding of the anomalous OMR. Among those compose this environment triplet excitons play a basic role. The incoherent hopping rate between molecules is calculated to give out the basic behavior of OMR. The underlying mechanism is revealed from the calculation of entanglement, represented by the von Neumann entropy, between the carrier's spin and bosons. We also obtain the dependence of OMR on both of the bias voltage and the spin-boson coupling. The results obtained from the theory are in good agreement with experiments.

9:24AM Y16.00006 Electronic and transport properties of Cobalt-based valence tautomeric molecules and polymers , YIFENG CHEN, Department of Physics, North Carolina State University, ARRIGO CALZOLARI, Istituto Nanoscienze CNR-NANO-S3, MARCO BUONGIORNO NARDELLI, Department of Physics, North Carolina State University — The advancement of molecular spintronics requires further understandings of the fundamental electronic structures and transport properties of prototypical spintronics molecules and polymers. Here we present a density functional based theoretical study of the electronic structures of Cobalt-based valence tautomeric molecules Co^{III}(SQ)(Cat)L $Co^{II}(SQ)_2$L and their polymers, where SQ refers to the semiquinone ligand, and Cat the catecholate ligand, while L is a redox innocent backbone ligand. The conversion from low-spin Co^{III} ground state to high-spin Co^{II} excited state is realized by imposing an on-site potential U on the Co atom and elongating the Co-N bond. Transport properties are subsequently calculated by extracting electronic Wannier functions from these systems and computing the charge transport in the ballistic regime using a Non-Equilibrium Green's Function (NEGF) approach. Our transport results show distinct charge transport properties between low-spin ground state and high-spin excited state, hence suggesting potential spintronics devices from these molecules and polymers such as spin valves.

9:36AM Y16.00007 Spin polarized transport properties of impurity induced Carbon nanostructures , SERKAN CALISKAN[1], Fatih University, MEHMET CANTURK, Atilim University — We study spin polarized transport on structures consisting of Carbon wires including impurities. We perform first principle calculations on these structures using the nonequilibrium Green Function formalism combined with the density functional theory. The different impurity induced Carbon nanostructures are found to depend strongly on the geometrical disorder. Through the conductance, transmission spectra, density of states and current-voltage characteristics the numerical results of spin polarized calculations are discussed.

9:48AM Y16.00008 Spin transport in organic semiconductor single crystals , H.-JAE JANG, Semiconductor Electornics Div. NIST & Dept. of Physics, Wake Forest Univ., OLEG KIRILLOV, KURT PERNSTICH, Semiconductor Electornics Div. NIST , WILLIAM RIPPARD, Electromagnetics Div. NIST, KATELYN P. GOETZ, OANA D. JURCHESCU, Dept. of Physics, Wake Forest Univ., DAVID GUNDLACH, MARIONA COLL BAU, BRAD R. CONRAD, CHRISTINA HACKER, CURT A. RICHTER, Semiconductor Electornics Div. NIST — Organic semiconductors have been attracting much attention as potential spin transport media due to their weak spin-orbit and hyperfine interactions that promise long spin lifetimes. However, to date most studies have focused on amorphous, or polycrystalline thin-film based organic semiconductors. In addition, short transport distances equal to or less than a couple of hundred nanometers have been measured despite the prediction of long spin transport distance. We have investigated spin injection and transport in high purity single-crystal organic semiconductors, especially rubrene(5,6,11,12-tetraphenylnaphthacene). We will present and discuss our experimental results obtained in both vertical and lateral transport geometries. Great care is needed to understand and avoid possible spurious effects in these studies.

10:00AM Y16.00009 Correlation of electric polarization and magnetic ordering in cobalt chloride thiourea , EUNDEOK MUN, National High Magnetic Field Laboratory (NHMFL), Los Alamos National Lab (LANL), Los Alamos, NM, JASON WILCOX, JAMIE MANSON, Department of Chemistry and Biochemistry Eastern Washington University Cheney, WA 99004 USA, BRIAN SCOTT, MPA-MC, Los Alamos National Lab (LANL), Los Alamos, NM, PAUL TOBASH, ERIC BAUER, VIVIEN ZAPF, MPA-CMMS, Los Alamos National Lab (LANL), Los Alamos, NM — The coupling between electricity and magnetism in magneto-electric multiferroics has been intensively investigated in a wide range of transition metal oxides. Recently the material classes have been extended to organo-metallic insulators (sometimes known as metal-organic frameworks or molecular magnets) such as $NiCl_2$-4[$SC(NH_2)_2$], which provides a new arena for designing magneto-electric multiferroics. We have grown single crystals of cobalt chloride thiourea, $CoCl_2$-n[$SC(NH_2)_2$], which forms two different crystal structures with n = 2 and 4. The compound $CoCl_2$-2[$SC(NH_2)_2$] has a triclinic crystal structure with strong magnetic anisotropy and $\sim$ 3 μ_B/Co ion, indicating **S** = 3/2 Co spins, and the compound $CoCl_2$-4[$SC(NH_2)_2$] has a tetragonal structure with almost no magnetic anisotropy and 1 μ_B/Co ion, indicating **S** = 1/2 Co spins. We will present details of the magnetic field-induced electric polarizations and magnetic properties of these compounds.

10:12AM Y16.00010 Magneto-electric multiferroic behavior in a metal-organic framework , VIVIEN S. ZAPF, National High Magnetic Field Lab, Los Alamos National Lab, Los Alamos, NM, PINAKI SENGUPTA, Nanyang Technological University, Singapore, CRISTIAN BATISTA, Theoretical Division, Los Alamos National Lab, FARZANA NASREEN, NHMFL, LANL and New Mexico State University, FREDERIK WOLFF-FABRIS, NHMFL, LANL, now at Dresden Hochfeld Labor, ARMANDO PADUAN-FILHO, Universidade de Sao Paulo — We will discuss strong magneto-electric coupling in the metal-organic compound $NiCl_2$-4$SC(NH_2)_2$(also known as a metal-organic framework or molecular magnet). Magneto-electric multiferroic behavior is traditionally investigated in transition-metal oxides, however we are expanding the field to metal-organics, which are designable materials with soft lattices and electrically polar organic elements. In this material we observe a magnetic field-induced change in the electric polarization of 50 $\mu C/m^2$ driven by ordering of the Ni S = 1 spins. We can model it in terms of a combination of exchange striction and crystal electric fields, and Quantum Monte Carlo simulations of these effects provide an excellent fit to the data. We find that the induced electric polarization is a sum of $<S_z^2>$ and the nearest neighbor correlation function $<S_i$ dot $S_j>$ The presence of electrically polar thiourea molecules [$SC(NH_2)_2$] amplifies the effect of small magnetically induced crystal distortions on the electric polarization.

10:24AM Y16.00011 Manipulating singlet-triplet equilibrium in organic biradical materials , O. GUNAYDIN-SEN, J. FOSSO-TANDE, P. CHEN, J.L. WHITE, J.L. MUSFELDT, University of Tennessee, R.J. HARRISON, University of Tennessee and Oak Ridge National Laboratory, T.L. ALLEN, P.M. LAHTI, University of Massachusetts, J. CHERIAN, T. TOKUMOTO, S. MCGILL, National High Magnetic Field Laboratory — We investigated the tunability of the singlet-triplet equilibrium population in 1,4-phenylenedinitrene via magneto-optical spectroscopy. Both temperature- and magnetic field-induced spectral changes in this organic biradical are sensitive to magnetic energy scales, specifically the spin gap, demonstrating the important interplay between charge, and magnetism in this system. These measurements also establish the value of local-probe photophysical techniques for extraction of magnetic properties data in systems where a traditional Curie law analysis has intrinsic limitations. *This work is supported by the National Science Foundation.

10:36AM Y16.00012 Reversible mechanism for spin crossover in transition-metal cyanides , MUKUL KABIR, KRYSTYN J. VAN VLIET, Department of Materials Science and Engineering, Massachusetts Institute of Technology, Cambridge, MA 02139, USA — Spin transitions generally occur in compounds of octahedrally coordinated $3d$ transition metal ions. These transitions can be induced by external perturbations such as light, heat, pressure, magnetic field, and chemical substitution. Transition metal cyanides are one such material, which exhibit *reversible* spin transition while perturbed with light at T <10 K. Here we report the first-principles (DFT+U) study of anhydrated $KCoFe(CN)_6$. We find that the complete spin transition from the low spin ground sate ($S = 0$) to a high spin ($S = 2$) state takes place due to intra-atomic and inter-atomic charge transfers in two steps. In the first step a d-electron is transferred from Fe to Co through cyanide ligand, which is followed by the d-electron rearrangement in the Co. This spin transition is strongly correlated with the internal lattice, and we find as large as 10% extension of the Co−N bond via a Jahn-Teller active (tetragonally distorted) lattice in the intermediate spin ($S = 1$) state. The calculated energy required for this transition is in agreement with experiments. We further predict that this spin transition in such materials can be induced, and further tuned, by external pressure to enable realization of such reversible transitions at ambient temperatures.

10:48AM Y16.00013 Psuedo-entanglement between nuclear spins in photoexcited functionalized fullerenes , VASILEIA FILIDOU, STEPHANIE SIMMONS, University of Oxford, HARRY L. ANDERSON, University of Oxford, G. ANDREW D. BRIGGS, ARZHANG ARDAVAN, University of Oxford, STEVEN KARLEN, University of Chicago, FELICIANO GIUSTINO, JOHN J.L. MORTON, University of Oxford — Optically excited triplet electron spins can be used to polarise, manipulate, couple and measure nuclear spins. Here we present photoexcited pulsed magnetic resonance experiments for the characterization of functionalized fullerene structures with homo and hetero nuclear spins. We use density functional theory in order to predict the hyperfine interaction between the photoexcited triplet and various nuclear spins in the structure, and then use magnetic resonance (ENDOR) to investigate these values experimentally. In addition to the hyperfine coupling strength, we measure the relevant relaxation rates and initial hyperpolarisation of the triplet in order to understand the possible degree of entanglement of nuclear spins through the optically excited mediator spin. We measure an increased nuclear-nuclear coupling in the presence of the triplet which permits fast nuclear controlled-NOT gates.These operations, in conjunction with the transfer of electron polarisation to the nucleus, allow the demonstration of nuclear-nuclear pseudo-entanglement, measured using quantum state tomography.

Friday, March 25, 2011 8:00AM - 11:00AM –

Session Y18 GMAG DMP: Focus Session: Low D/Frustrated Magnetism - More Frustrated Magnets D172

8:00AM Y18.00001 Field-induced thermal transport in BEC antiferromagnets[1] , SASHA CHERNYSHEV, UC Irvine, CRISTIAN BATISTA, LANL — Recent experiments in BEC quantum magnets exhibit a dramatic evolution of the thermal conductivity of these materials in magnetic field. By considering various relaxation mechanisms of bosonic excitations in the vicinity of the BEC quantum-critical point at finite temperature we provide a detailed explanation of several unusual features of the data. We identify the leading impurity-scattering interaction and demonstrate that its renormalization due to quantum fluctuations of the paramagnetic state compensates the related mass renormalization effect. This explains the enigmatic absence of the asymmetry between the two critical points in the low-T thermal conductivity data, while such an asymmetry is prominent in many other physical quantities. The observed characteristic "migration" of the peak in thermal conductivity away from the transition points as a function of temperature is explained as due to a competition between an increase in the number of heat carriers and an enhancement of their mutual scattering. An important role of the three-boson scattering processes within the ordered phase of these systems is also discussed. Other qualitative and quantitative features of the experiment are clarified and the future directions are sketched.

8:12AM Y18.00002 Investigation of the magnetic susceptibility of the disordered BEC system $NiCl_{0.85}Br_{0.15}$-4SC$(NH_2)_2$ at ultralow-temperatures , LIANG YIN, CHAO HUAN, JIAN-SHENG XIA, NEIL SULLIVAN, University of Florida, VIVIEN ZAPF, LANL, ARMANDO PADUAN-FILHO, Universidade de Sao Paulo, RONG YU, Rice University, TOMMASO ROSCILDE, ENS Lyon — We report measurements of the magnetic susceptibility of a disordered BEC system of magnons for single crystals of $NiCl_{0.85}Br_{0.15}$-4SC$(NH_2)_2$ (with 15% Cl atoms replaced by Br). $NiCl_{0.85}Br_{0.15}$-4SC$(NH_2)_2$ is a potential candidate for a Bose glass (BG) phase of the spins adjacent to a region of Bose-Einstein condensation (BEC). The BG to BEC phase is the bosonic analog of a metal-insulator transition for fermions. The measurements were carried out for temperatures down to 1mK and for applied magnetic fields up to 14.5T. The results show that the critical fields H_c do not obey the conventional 3D universality class for a BEC, $H_c(T) - H_c(0) \sim T^{\alpha}$, where $\alpha = 1.5$ [1]. The values of α changes from $\alpha = 0.52$ for T $>$ 300 mK to $\alpha = 0.91$ for T $<$ 250 mK and then again at 70$\sim$90mK to $\alpha = 0.48$ for T$<$ 70 mK, indicating a crossover to possible BG behavior.

8:24AM Y18.00003 Bose-Einstein Condensation in Han Purple - a NMR Study[1] , RAIVO STERN, NICPB, Tallinn, Estonia, STEFFEN KRÄMER, MLADEN HORVATIC, CLAUDE BERTHIER, LNCMI, Grenoble, France, IVO HEINMAA, ENNO JOON, NICPB, Tallinn, Estonia, TSUYOSHI KIMURA, Osaka University, Japan — NMR study of the two quasi-2D coupled spin-1/2 dimer compound, $BaCuSi_2O_6$ (Han Purple) [1], is presented. $T_{\rm BEC}$ varies as $(H - H_{c1})^{2/d}$, where d is the dimensionality of the system, and H_{c1} the critical field which closes the gap. $BaCuSi_2O_6$ was claimed to exhibit an reduction of d from 3D to 2D at low T [2]. However, due to a structural transformation at 90 K, different intradimer exchange couplings and different gaps ($\Delta_{\rm B}/\Delta_{\rm A}$=1.16) exist in every second plane along the c axis [3]. In our first NMR experiments [3], we have shown that the population of bosons in the B planes $n_{\rm B}$ was much smaller than $n_{\rm A}$, but finite in the field range $\Delta_{\rm A}/g\mu_{\rm B} < H < \Delta_{\rm B}/g\mu_{\rm B}$ where $n_{\rm B} = 0$ is expected in a naive model of uncoupled planes. Recently, a new model has been presented [4] which takes into account both frustration and quantum fluctuations. This leads to a non-zero population $n_{\rm B}$ of *uncondensed* bosons in the B plane, increasing quadratically with $(H - H_{c1})$, as compared to the linear dependence of $n_{\rm A}$. We compare our new NMR results to these predictions. [1] M. Jaime *et al.*, PRL **93**,087203 (2004). [2] S. E. Sebastian *et al.*, Nature **441**, 617 (2006). [3] S. 8:36AM Y18.00004 Magnetic neutron scattering of a Prussian blue analogue photomagnet[1] , D.M. PAJEROWSKI, Dept. Phys. and NHMFL, Univ. Florida and NCNR-NIST, E.S. KNOWLES, Y.M. CALM, M.W. MEISEL, Dept. Phys. and NHMFL, Univ. Florida, M.J. ANDRUS, J.E. GARDNER, D.R. TALHAM, Dept. Chem., Univ. Florida, V.O. GARLEA, S.E. NAGLER, NSSD-ORNL — Since the discovery of photoinduced magnetism in cobalt hexacyanoferrate (CoFe) Prussian blue analogues (PBAs) in 1996,[1] there have been many, multifarious studies that elucidated the nature of the photoeffect. However, the magnetization in CoFe has proven difficult to model quantitatively using macroscopic data due to the presence of multiple magnetic species, magnetic bistability, superexchange, and unquenched orbital angular momentum. To investigate the ordered magnetization directly, we have studied dueterated powders of CoFe using unpolarized and polarized neutron diffraction, and observed magnetic neutron scattering for the first time in this compound. A model for the magnetic structure based upon neutron diffraction, elemental analysis, infrared spectroscopy, and macroscopic magnetization will be presented.

8:48AM Y18.00005 Photoinduced Magnetism in Nanoscale Heterostructures of Prussian Blue Analogues*

E.S. KNOWLES, D.M. PAJEROWSKI, M.W. MEISEL, Dept. Phys. and NHMFL, Univ. Florida, M.F. DUMONT, A. GUIET, D.R. TALHAM, Dept. Chem., Univ. Florida, A. GOMEZ, S.W. KYCIA, Dept. Phys., Univ. Guelph — Nanometer-scale cubic heterostructures of two Prussian blue analogues, ferromagnetic $K_jNi_k[Cr(CN)_6]_l{\cdot}nH_2O$ (**A**) with $T_c \sim 70$ K and photo-active ferrimagnetic $Rb_aCo_b[Fe(CN)_6]_c{\cdot}mH_2O$ (**B**) with $T_c \sim 20$ K, have been studied.[1] These samples exhibit a persistent photoinduced decrease in magnetization at temperatures up to $T_c \sim 70$ K of the **A** constituent, resembling results from analogous **ABA** heterostructured films.[2] This net decrease suggests that the photoinduced structural transition in the **B** layer generates a strain-induced decrease in the magnetization of the **A** layer, similar to a pressure-induced decrease previously observed in the pure **A** material.[3] Core-shell and core-shell-shell configurations **AB**, **BA**, **ABA**, and **BAB** have been characterized by TEM, FTIR, XRD, and SQUID magnetometry.

*Supported, in part, by NSF DMR-0701400 (MWM) and DMR-1005581 (DRT), NSERC, CFI, the NHMFL, and the State of Florida.

9:00AM Y18.00006 Structural and Magnetic Interplay in Molecule-based Magnets with Photocontrollable Properties[1]

Y.M. CALM, E.S. KNOWLES, D.M. PAJEROWSKI, A.M. ZIEGLER, M.W. MEISEL, Dept. Phys. NHMFL, Univ. Florida, H. PHAN, M. SHATRUK, Dept. Chem., Florida State Univ., M.J. ANDRUS, M.F. DUMONT, D.R. TALHAM, Dept. Chem., Univ. Florida — Understanding the cooperative effects, such as electron-lattice interactions, in molecule-based magnetic coordination complexes possessing photoinduced phase transitions is an important step to being able to rationally tune the variables governing the process.[2] Specifically, variable temperature FTIR spectroscopy and magnetometry have been used to explore the temperature and photocontrollable spin transitions in Co-Fe Prussian blue analogues, $A_jCo_k[Fe(CN)_6]_\ell \cdot nH_2O$, where A is an alkali ion, and in new Fe spin-crossover complexes. By studying nanoparticles[3] and heterostructures,[4] the data provide insight into the roles played by restricted lattice geometries and strain-pressure effects.

9:12AM Y18.00007 Interplay between charge fluctuations and magnetic order in a stacked triangular-Kagome lattice : Applications to FeCrAs

JEFFREY RAU, HAE YOUNG KEE, University of Toronto — The recently studied antiferromagnet FeCrAs [Wu et al, EPL, 85 17009 (2009)] exhibits a surprising combination of experimental signatures, with Fermi liquid like specific heat but resistivity showing strong non-Fermi liquid character. From the material properties we motivate a minimal model for the low energy degrees of freedom, and study its properties using slave-rotor mean field theory. Using this approach we find a variety of exotic phases and propose that the features of FeCrAs can be qualitatively explained by a spin liquid proximate to a metal-insulator transition.

9:24AM Y18.00008 Giant Anomalous Hall Effect in (Ba,Sr)$T_{2+x}Ru_{4-x}O_{11}$ (T=Fe,Co,Mn) Ferrites[1]

LANCE DELONG, LARYSA SHLYK, University of Kentucky — Hexagonal R-type ferrites (Ba,Sr)$T_{2+x}Ru_{4-x}O_{11}$ are promising spintronic materials that exhibit collinear ferrimagnetic order at unusually high critical temperatures $T_C \leq 490$ K for Fe-bearing compositions, and an in-plane, "all-in/all-out" order at T_C's $<<$ 300 K due to frustrated antiferromagnetic interactions within the Kagome basal plane in metallic Co or Mn compositions. A strong, nonmonotonic field dependence of the anomalous Hall effect is observed in metallic ferrites, which is generated by non-zero scalar spin chirality and the Berry phase acquired by carriers moving in the "topologically nontrivial" spin background of the Kagome plane. The FM semiconductor $BaFe_{3.4}Ru_{2.6}O_{11}$ (T_C = 440 K) exhibits a giant Hall resistivity = 77 $\mu\Omega$-cm at 300 K, with a low-temperature sign change and monotonic field dependence that are consistent with a strong Berry phase curvature (gauge field) acquired by carriers in momentum space.

9:36AM Y18.00009 Coexistence of ferromagnetic and antiferromagnetic orders in Ba-doped cobalt perovskites studied by neutron scattering[1]

HUIBO CAO, Oak Ridge National Laboratory, FANGWEI WANG, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, CAS, VASILE GARLEA, Oak Ridge National Laboratory, ARSEN GUKASOV, Centre de Saclay, DSM/IRAMIS/Laboratoire Léon Brillouin, CEA, ZHAOHUA CHENG, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, CAS — Cobalt-containing oxide compounds have attracted a great deal of interest in recent years due to the variety of magnetic and electrical properties. We performed single crystal neutron diffraction on 6T2 at the LLB in France and the HB3A four-circle diffractometor at the HFIR of ORNL. The Ba-doped cobalt perovskite ($La_{0.8}Ba_{0.2}CoO_3$) crystal was measured in the temperature range of 2-250 K. At temperature $T < 200$ K, a set of ferromagnetic peaks ($k_1 = 0$) onsets and then antiferromagnetic peaks with k_2* = (1/2 0 1/2) and (0 0 3/2) join in at $T < 100$ K. Both ferromagnetic and antiferromagnetic peaks saturate at $T \approx 40$ K. By refining the peaks collected for k_1 and k_2 sets, magnetic structures were determined.

9:48AM Y18.00010 Density matrix renormalization group study of optical conductivity in the one-dimensional Mott insulator Sr_2CuO_3

SHIGETOSHI SOTA, TAKAMI TOHYAMA, Yukawa Institute for Theoretical Physics, Kyoto University — We examine the optical conductivity of Sr_2CuO_3 by using zero and finite temperature dynamical density matrix renormalization group (DMRG) methods. Employing a Hubbard- Holstein model containing Holstein-type coupling of electron to the Einstein phonons, we reproduce both the Mott-gap excitation and phonon-assisted spin excitation observed experimentally [1,2] by using the dynamical DMRG method combined with a regulated polynomial expansion [3]. We find a parameter set describing Sr_2CuO_3. Furthermore, by using a low- temperature dynamical DMRG method which is recently developed by present authors [4], we examine the temperature effect of the Mott-gap excitation to clarify the effect of optical phonons on spectral shape at finite temperatures. We find that the presence of phonons induces the enhancement of the width of an excitonic peak in the optical conductivity. [1] M. Ono, K. Miura, A. Maeda, H. Matsuzaki, H. Kishida, Y. Taguchi, Y. Tokura, M. Yamashita, and H. Okamoto, Phys. Rev. B **70**, 085101 (2004). [2] H. Suzuura, H. Yasuhara, A. Furusaki, N. Nagaosa, Y. Tokura: Phys. Rev. Lett. **76**, 2579 (1996). [3] S. Sota and M. Itoh, J. Phys. Soc. Jpn. **76**, 054004 (2007). [4] S. Sota and T. Tohyama, Phys. Rev. B **78**, 113101 (2008).

10:00AM Y18.00011 A Compton scattering study of the magnetic structure of $NbFe_2$, THOMAS HAYNES, University of Bristol, UK, MATTHEW BUTCHERS, JONATHAN DUFFY, University of Warwick, UK, STEPHEN DUGDALE, University of Bristol, JONATHAN TAYLOR, SEAN GIBLIN, ISIS Facility, RAL, UK, JUDE LAVEROCK, Boston University, CLAUDIA UTFELD, University of Bristol, ROSS STEWART, ISIS Facility, RAL, UK — $NbFe_2$ displays a diverse phase diagram over a narrow compositional range, possibly due to close proximity to a Quantum Critical Point. The ground state of $NbFe_2$ has been the subject of a number of recent theoretical investigations [1,2], but for near-stoichiometric compositions its exact nature remains ambiguous. We have probed the low temperature magnetic structure by performing Magnetic Compton Scattering (MCS) measurements on polycrystalline $Nb_{1+y}Fe_{2-y}$ samples with $y = -0.02, 0.00$ and 0.03. MCS is able to measure how the magnetic electrons within a sample are distributed in momentum space, and can be a useful tool for resolving site-specific contributions to the spin moment. The interpretation of these measurements was aided by electronic structure calculations, which favour a ferrimagnetic ground state. The results are presented with reference to the possible presence of spin fluctuations.

10:12AM Y18.00012 Impurity-entanglement in dimerized spin chains , ANDREAS DESCHNER, ERIK SORENSEN, McMaster University — To quantify the entanglement caused by an impurity in an $S = \frac{1}{2}$ dimerized $J_1 - J_2$ quantum spin chain, several different entanglement-measures have been utilized. We present the results of variational calculations of the impurity entanglement entropy as well as the negativity for a chain with an impurity attached at one end. We compare the results for both of these measures.

10:24AM Y18.00013 On the low-temperature behavior of a geometrically frustrated Heisenberg antiferromagnet[1] , STEFAN SCHNABEL, D.P. LANDAU, U. of Georgia — The thermodynamic behavior of the Heisenberg antiferromagnet on the kagome lattice and the effects of its geometrical frustration are widely understood [1]. At low temperatures planar spin configurations due to multiple zero-modes (so-called Weathervane loops) are favored entropically. These modes occur when spin clusters are bounded by spins pointing in a similar direction, so that the cluster spins revolve freely around this direction. However, it remains unclear if with decreasing temperature the number of these modes continues to increase and if this eventually leads to a highly ordered $\sqrt{3}\times\sqrt{3}$ state. In order to investigate this system we applied the simulated tempering method, combined with the Heatbath algorithm for single spins and a Metropolis loop-flip Monte Carlo move. We examined the thermodynamic properties for temperatures $\frac{k_B T}{J} \geq 10^{-6}$; and found that once the planar state is attained, the out-of-plane excitations are reduced with decreasing temperature but no further order is established. Hence, the prevailing spin structure represents a temperature independent entropy maximum where any entropy gain produced by additional zero modes is neutralized by an entropy loss in the Weathervane loop structure.

10:36AM Y18.00014 Topological phases and quenches in spin-ladder systems , SMITHA VISHVESHWARA, WADE DEGOTTARDI, Univ. of Illinois at Urbana-Champaign, DIPTIMAN SEN, Indian Institute of Science — We show that a ladder version of Kitaev's honeycomb model can be directly mapped to a one-dimensional p-wave superconducting system. The ladder system is characterized by Z_2 vortices at every unit cell; the presence of vortices is encoded in the sign of the local chemical potential in the p-wave system. Compared to recently studied phases in topological superconductors, we show that certain vortex patterns in this ladder system can result in new topological phases and can alter the universality classes for associated phase transitions. We discuss the effect of performing time-dependent quenches in these new phases.

10:48AM Y18.00015 Multi-spin exchange model for a quantum spin liquid on the honeycomb lattice , YI-FEI WANG, Zhejiang Normal Univ. and California State Univ. Northridge, DONNA SHENG, California State Univ. Northridge, CHANG-DE GONG, Zhejiang Normal Univ. — Recently, a possible quantum spin liquid (QSL) state has been found through quantum Monte Carlo studies of Hubbard model on the honeycomb lattice. The obtained QSL does not show long range correlation of any known type, which has a finite spin gap and a short range dimer-dimer correlation pattern resembling the short range resonant-valence-bond (RVB) state. Given the intensive current interest in such an exotic QSL, it is natural and timely to ask a question: what is the effective spin model to capture the essential low-energy physics near this QSL region? We report here a comparative numerical study based on finite-size exact diagonalizations (ED) of the Hubbard model, and a multi-spin exchange model with two-, four- and six-spin exchange terms. The latter model is derived from the strong coupling expansion of the former one. Through extensive ED calculations of low-energy spectra and ground-state correlation functions of both models, we try to establish connections between them, especially near the QSL region. Furthermore, the phase diagram of the multi-spin exchange model is explored in details.

Session Y20 DMP FIAP GERA: Focus Session: Thermoelectric Materials: Chalcogenides and 1D/2D Systems D168

8:00AM Y20.00001 Resonant Energy Levels and the Thermoelectric Figure of Merit[1] , JOSEPH P. HEREMANS, Ohio State University, Dept of Mechanical Engineering, and Dept. of Physics — Distortions of the electronic density of states are a potent mechanism to increase the thermopower and ZT of thermoelectric semiconductors. Band-structure engineering approaches will be reviewed that can be used to do this, namely quantum size effects, hybridization effects in strongly correlated electron systems, and resonant impurity levels. The properties of known resonant impurities for PbTe, SnTe, Bi_2Te_3 and GaSb will also be reviewed. They can increase the thermoelectric power through 2 mechanisms, (1) the increase in density of states, and (2) resonant scattering. The first increases the thermopower in a nearly temperature-independent way; the second results in an electron energy filtering effect that increases the thermopower, but only at cryogenic temperatures where the electron-phonon interactions are weaker. An analysis of the thermomagnetic tensor components makes it possible to dissociate the two contributions experimentally.

8:36AM Y20.00002 The Effect of Sintering on the Thermoelectric Properties of Chemically Synthesized Nano-Bulk $Bi_{2-x}Sb_xTe_3$, J.S. DYCK, S. DORROH, Physics Dept., John Carroll University, B.D. MAO, J.W. WANG, C. BURDA, Chemistry Dept., Case Western Reserve University — Considerable research effort has gone into improving the performance of traditional thermoelectric (TE) materials such as $Bi_{2-x}Sb_xTe_3$ through a variety of nanostructuring approaches. Bottom-up, chemical approaches have the potential of producing very small nanoparticles ($<$ 50 nm) with narrow size distributions and controlled shape. For this study, nanocrystalline powder of $Bi_{2-x}Sb_xTe_3$ with x = 0 – 1.5 has been synthesized using a ligand- assisted chemical method, and consolidated into bulk pellets with cold pressing followed by sintering. These materials have the interesting property that a wide range of carrier concentrations are accessible through different Bi/Sb ratios, with low values of x being n-type and higher values becoming p-type. In this work, we present the thermoelectric transport measurements from 6 – 300 K as a function of sintering temperature, and a beneficial effect is found. The samples are also characterized by Hall effect, XRD, and compositional analysis. We will present results on the structure-property relations, and discuss strategies for optimization of this class of TE materials for high performance.

8:48AM Y20.00003 Coherent Phase Stability of IV-VI Rocksalt Semiconductor Alloys[1] , JEFFREY DOAK, CHRIS WOLVERTON, Northwestern University — The creation of nanoscale precipitates via phase separation provides a mechanism for decreasing the lattice thermal conductivity of some bulk thermoelectric materials. The IV-VI semiconductor alloy systems may phase separate by either a spinodal decomposition or nucleation and growth mechanism. To better understand these phase transformations, we use first-principles density functional theory (DFT) calculations to investigate the coherent and incoherent phase stability of a series of IV-VI rocksalt semiconductor alloys (IV=Pb, Sn, Ge and VI = S, Se, Te). We use mixing enthalpies derived from calculations of special quasirandom structures (SQS), along with coherency strain energies to model the thermodynamic driving forces for incoherent and coherent phase separation. By fitting these inputs to a sub-regular mixing enthalpy model and including an ideal mixing entropy term, we calculate incoherent and coherent phase diagrams. We show the incorporation of coherency strain energies cause large depressions of the coherent spinodals for each system. The depressions are large enough that at realistic processing temperatures, the dominant precipitation mechanism of phase separation is nucleation and growth.

9:00AM Y20.00004 Electronic structure of PbTe doped with K and Na[1] , MAL-SOON LEE, S. D. MAHANTI, Michigan State University — PbTe is a well-known thermoelectric which shows excellent thermoelectric performance (for both p- and n-type) in the temperature range between ambient and 600°C. Thermopower (S) of PbTe can be enhanced with proper doping. Hermann *et al.* have found the figure of merit ZT=1.5 at 773 K with 2 % Tl doping in PbTe. They ascribe this to the enhancement of the density of states (DOS) caused by Tl-induced resonance level in the valence band. This is in agreement with the *ab initio* studies of Ahmad *et al.*, who also found an enhanced DOS associated with K defects in PbTe. Recently Androulakis *et al.* have looked for resonant states in the valence band associated with Na/K impurities in PbTe. Although they observe an increase in power factor at high temperature, they do not find any evidence of resonant states. We have reexamined this issue by carrying out detailed band structure calculations in the presence of K and Na defects in PbTe using 64-atom supercells. The question of the existence of resonant states and the origin of the enhanced DOS near the valence band maximum will be discussed.

9:12AM Y20.00005 Ho Doped Bi_xSb_y Nanopolycrystalline Alloys[1] , K.C. LUKAS, G. JOSHI, DEZHI WANG, Z.F. REN, C.P. OPEIL — Department of Physics, Boston College, Chestnut Hill, Massachusetts, 02467. Bismuth-Antimony alloys have been shown to have high ZT values below room temperature, especially for single crystals. For polycrystalline samples, impurity doping and magnetic field have proven to be powerful tools in the search for understanding and improving thermoelectric performance. Nanopolycrystalline Bi_xSb_y doped with 1 and 3% Ho were prepared by ball milling and dc hot pressing technique. Electrical resistivity, Seebeck coefficient, thermal conductivity, carrier concentration, mobility, and magnetization are measured in a temperature range of 5-350 K and in magnetic fields up to 9 Tesla. The effects of Ho doping on the thermoelectric properties of Bi_xSb_y in magnetic field will be discussed.

9:24AM Y20.00006 Thermoelectric properties of Quintuple Layer Bi_2Te_3[1] , ROGER LAKE, FERDOWS ZAHID, University of California Riverside — Motivated by recent experimental results,[2] we derive the thermoelectric parameters of a Bi_2Te_3 film of one quintuple layer thickness. Our results show approximately ten times increase in the figure of merit (ZT) for the thin film (ZT = 7.2) compared to that for the bulk (ZT = 0.68). The large enhancement in ZT results from the change in the distribution of the valence band density of modes brought about by the quantum confinement in the thin film. Our theoretical model uses ab initio electronic structure calculations as implemented in the VASP software package combined with a Landauer approach for calculating the linear-response transport coefficients. We employ two fitting parameters: a rigid shift of the conduction and valence bands to match the known bulk bandgap (i.e. a 'scissors operator'), and an energy independent electron mean free path for the phonon scattering inside the device. With these two fitting parameters, our results show excellent agreement with the known experimental values for bulk Bi_2Te_3.

[2]D. Teweldebrhan, V. Goyal and A. A. Balandin, Nano Lett. 10, 1209 (2010); D. Teweldebrhan, V. Goyal, M. Rahman, and A. A. Balandin, Appl. Phys. Lett. 96, 053107 (2010); Y. Zhang et al., Nat. Phys. 6, 584 (2010).

9:36AM Y20.00007 Phase diagram of thermoelectric Bi2S3-Bi2Se3-Bi2Te3 system , WEISHU LIU, QINYONG ZHANG, QIAN ZHANG, Boston College, BO YU, GANG CHEN, ZHIFENG REN, Boston College, BOSTON COLLEGE TEAM, MIT TEAM — It is well known that the highest ZT value, at an optimized carrier concentration, is mainly determined by a material parameter $\beta = \mu(m^*/m0)3/2/\kappa lat$, where $\mu(m^*/m0)3/2$ and κlat are the weighted carrier mobility and lattice thermal conductivity, respectively. In order to explore some new compositions in Bi2S3-Bi2Se3-Bi2Te3 system, we propose a compositional thermoelectric phase diagram (TPD), including weighted carrier mobility, lattice thermal conductivity, and material parameter, for the 1% copper doped Bi2S3-Bi2Se3-Bi2Te3 solid solution fabricated by MA-HP method. Here, the $\mu(m^*/m0)3/2$ and κlat values could be deduced from the measured electrical resistivity, Seebeck coefficient, and thermal conductivity. The alloying effect on the thermoelectric phase diagram will be discussed from varying atomic size, chemical bond, lattice structure, etc.

9:48AM Y20.00008 Exploration of effects of various impurities in Bismuth and its extension to Bismuth-Antimony alloys[1] , HYUNGYU JIN, KATHERINE WHITEHOUSE, Department of Mechanical Engineering, The Ohio State University, JOSEPH HEREMANS, Department of Mechanical Engineering and Department of Physics, The Ohio State University — While Te and Se are known donors and Pb and Sn known acceptors in elemental bismuth, little is known about other possible dopants. The effect of various impurities on thermoelectric properties of elemental bismuth is investigated here. Impurities investigated encompass the transition metals, group III and IV elements, and the chalcogens. The thermoelectric power, electrical resistivity and Hall coefficients of Bi samples doped with these impurities are measured from room temperature to 2K. Indium is found to be an acceptor, which is surprising because it is mostly trivalent. A calculation of the band structure subsequently performed at the AGH University of Science and Technology in Cracow reveals that In gives an excess density of states in the valence band. This finding in elemental Bi is extended to the case of bismuth-antimony alloys which have superior thermoelectric efficiency at cryogenic temperatures.

10:00AM Y20.00009 Thermoelectric properties of Sn1-xEuxTe , YIBIN GAO, JOSEPH HEREMANS, the Ohio State University — SnTe has potential in thermoelectric application for intermediate temperature [1]. However, the figure of merit ZT of SnTe is limited because that it always has a high hole concentration owing to Sn vacancies. As a result, the Seebeck coefficient of SnTe is low and it is very difficult to get SnTe to the optimized doping level required to get a good figure of merit. SnTe also has heavy valence band close to the light valence band edge. We know from theoretical calculations that degenerate bands are preferable than bands separated by an energy difference for thermoelectric application. EuTe has a much higher band gap than SnTe. Recent results [2] show that in Sn1-xEuxTe films prepared by hot-wall epitaxy, the direct L-point bandgap first closes with x, and then opens. In this presentation, we report on the synthesis of bulk Sn1-xEuxTe samples, and report on their Seebeck coefficient, Hall coefficient, resistivity and thermal conductivity. A simplified model is proposed to explain the experimental data. The results confirm the results of the previous study, and point towards the possibility of finding a high-ZT formulation in these compounds. The work is supported by ZTPlus.

10:12AM Y20.00010 Incipient Ferroelectricity in Thermoelectric Lead Telluride[1] , EMIL BOZIN, Brookhaven National Laboratory, CHRISTOS MALLIAKAS, Northwestern U, PETROS SOUVATZIS, THOMAS PROFFEN, Los Alamos National Laboratory, NICOLA SPALDIN, ETH Zurich, MERCOURI KANATZIDIS, Northwestern U, SIMON BILLINGE, Brookhaven National Laboratory, Columbia U — PbTe, is the parent compound of currently the most important thermoelectric (TE) materials in applications just above room temperature [1]. It has an anomalously low thermal conductivity resulting in a rather high TE figure of merit. Our neutron total scattering and atomic pair distribution function analysis shows the existence of a novel paraelectric state at and above room temperature. However, on cooling the structural dipoles do not order, but disappear resulting in an undistorted rock-salt ground-state. We suggest that new thermoelectrics should be sought among materials that, like PbTe [2], are close to a ferroelectric instability.

10:24AM Y20.00011 Enhancement of thermoelectric figure-of-merit in a wide temperature range in $In_4Se_{3-x}Cl_y$ bulk crystals , JONG-SOO RHYEE, Kyung Hee University, KYUNGHAN AHN, KYU HYOUNG LEE, Samsung Advanced Institute of Technology, JI HOON SHIM, Pohang University of Science and Technology, JAE HOON KIM, Yonsei University, KYUNG HEE UNIVERSITY TEAM, SAMSUNG ADVANCED INSTITUTE OF TECHNOLOGY COLLABORATION, POHANG UNIVERSITY OF SCIENCE AND TECHNOLOGY COLLABORATION, YONSEI UNIVERSITY COLLABORATION — Recently, we proposed that the charge density wave is a new pathway for high thermoelectric performance in bulk crystalline materials [1,2]. Through the quasi one-dimensional lattice distortion (Peierls distortion) in In_4Se_{3-x} bulk single crystals, we have achieved a high thermoelectric figure-of-merit ZT of 1.48 at 705 K. From the Boltzman transport calculation, it was confirmed that the reported ZT could be further increased if we could increase the chemical potential of the In_4Se_{3-x} crystals. Here we report the significant increase of ZT over a wide temperature range from 50 °C to 425 °C by chlorine doping in the In_4Se_{3-x}, which comes from the improvement of crystal quality and increase of chemical potential, resulting in the power factor enhancement and the thermal conductivity reduction.

10:36AM Y20.00012 Thermoelectricity in the ultra-thin limit[1] , JAYAKANTH RAVICHANDRAN, PIM ROSSEN, VINCENT WU, University of California, Berkeley, ARUN MAJUMDAR, Department of Energy, R. RAMESH, University of California, Berkeley — Hicks and Dresselhaus [1] predicted an enhanced thermoelectric power factor due to quantum confinement. In the past, superlattices have been employed to demonstrate this effect but the results have remained controversial. Sustained efforts on surface termination and treatment of single crystalline oxide substrates has enabled growth of high quality thin films using techniques like pulsed laser deposition and molecular beam epitaxy. In this work, we explore the nature of thermoelectric response for ultra thin layers ($\sim$ 1 – 100 nm) of model thermoelectric oxides such as doped $SrTiO_3$ and $Bi_2Sr_2Co_2O_y$grown by pulsed laser deposition. Thermopower, resistivity and Hall measurements were carried out as a function of thickness to understand the role of quantum confinement and other extraneous effects like surface depletion etc. on the thermoelectric response. References: [1] L.D. Hicks and M. S. Dresselhaus, Phys. Rev. B, 47, 12727 (1993).

10:48AM Y20.00013 Zero-dimensional nanostructured material with metallic bismuth nanoparticles: a new route for thermoelectrics , ROLAND BENOIT, MONA TREGUER, CNRS, MARIE-LOUISE SABOUNGI — The thermoelectric figure of merit ZT has so far not exceeded the value ZT=3 need to compete with mechanical energy conversion systems. However, theoretical work has shown that it is possible to reach values of ZT higher than this. One of the most promising routes is nanostructured materials, which offer the opportunity to tailor physical properties such as electrical and heat transport, due to the effects of electron filtering and phonon confinement. Dresselhaus *et al. (ref.?)* were among the first to show that 2D and 1D structures are capable of reaching ZT values higher than 2. The thermoelectric materials of current interest are in the form of nanotubes, nanodots and, more generally, superlattices composed of a matrix and nanoparticles. In our work we synthesize a periodic network of bismuth nanoparticles in a matrix of mesoporous SiO_2. We find that in this form bismuth transforms from a rhombohedral to a cubic structure, with improved filtering of electrons and phonons.

Session Y21 GIMS: High Magnetic Field Measurements, Novel sensors, and Neutron Diffraction

8:00AM Y21.00001 Stand alone experimental setup for measurements of magnetoresistance tensor by dc reversal technique[1] , ALEXEY SUSLOV, NHMFL-FSU, Tallahassee, Florida 32310, USA — Several years ago Keithley Instruments, Inc. created a combination of a Current Source and a Nanovoltmeter (Model 6221 and Model 2182A, respectively) for low level transport measurements. That nanovoltmeter/ current source combination was designed for measurements of *one* voltage only. Proposed are the setups assembled from several nanovoltmeter/current source pairs which allow to measure simultaneous *several* voltages associated with the same current. The setups utilize specific wiring and a unique triggering sequence. Several milliseconds delays incorporated into triggering sequence secure stable triggering and proper data flow. The delays might be assured by selection of specific time parameters in the current sources and nanovoltmeters. The setups allow utilizing the built-in functions of the devices. Tested setups consisted of up to four pairs, allowing measurements of up to four voltages.[2] Application of the setups to simultaneous measurements of magnetoresistance tensor components will significantly simplify the experiment, increase precision, and decrease consumption of resources.

[1]NHMFL is supported by NSF DMR-0084173, the State of Florida, and the DOE.

8:12AM Y21.00002 High Magnetic Field Characterization of Cu-Sn Alloys for Distortion-free MRI Probes[1] , M.K.A. PEPRAH, E.S. KNOWLES, M.W. MEISEL, Dept. Physics and NHMFL, Univ. Florida, G.W. ASTARY, T.H. MARECI, Dept. Biochem. and Molecular Biology, Univ. Florida, C.R. FISHER, R.L. STEWART, M.V. MANUEL, Dept. Mat. Sci. and Engineering, Univ. Florida — For a wide-range of reasons, magnetic resonance imaging (MRI) of brain activity is now exploiting miniturized electrodes and cannulas. However, common construction materials such as stainless steel cause significant distortion of the MRI signals.[2] With the goal of developing brain-susceptibility-matched electrodes and cannula for distortion-free MRI in fields up to 11 T, we have investigated the magnetic properties of a spectrum of Cu-Sn alloys. The results of various characterization studies, including SQUID magnetometry up to 7 T and MRI studies up to 11 T, will be reported and related to the stoichiometric composition of the Cu-Sn solutions. Extensions to device development and other metal alloy combinations will be discussed.

8:24AM Y21.00003 Addressing signal recovery challenges in pulsed field environment[1] , FEDOR BALAKIREV, YOSHIMITSU KOHAMA, MOAZ ALTARAWNEH, ROSS MCDONALD, MARCELO JAIME, ALBERT MIGLIORI, CHARLES MIELKE, LANL — We review approaches to recovering weak electric signals in the challenging environment of pulsed magnetic fields implemented at the National High Magnetic Field Laboratory Pulsed Field Facility (NHMFL-PFF). Recent technique developments including AC-specific heat measurements at sub-kelvin temperatures, nanosecond-scale resistivity measurements, as well as customized instrumentation and computer-assisted signal detection using Field Programmable Gate Arrays will be discussed.

[1]Work at NHMFL-LANL is performed under the auspices of the National Science Foundation, Department of Energy and State of Florida.

8:36AM Y21.00004 The National High magnetic Field Laboratory Pulsed Field Facility. An overview of high field magnet operations and scientific techniques[1] , JON BETTS, NHMFL-PFF Los Alamos National Laboratory — The National High magnetic Field Laboratory – Pulsed Field Facility (NHMFL-PFF) is the home to the pulsed field user facility which routinely delivers 85T pulses for user science using a 1.4GW motor generator. The facility also houses a 60T shaped waveform magnet, 65T short pulse and 50T mid pulse capacitor driven magnets. Many techniques are available to users including, Transport, magnetization, calorimeter and cantilever techniques. I will describe the facilities and the measurement techniques available to users.

[1]There work at the NHMFL-PFF was carried out under the auspices of the NSF, DOE and State of Florida.

8:48AM Y21.00005 Extreme Material Physical Properties and Measurements above 100 tesla[1] , CHARLES MIELKE, NHMFL-PFF (LANL) — The National High Magnetic Field Laboratory (NHMFL) Pulsed Field Facility (PFF) at Los Alamos National Laboratory (LANL) offers extreme environments of ultra high magnetic fields above 100 tesla by use of the Single Turn method as well as fields approaching 100 tesla with more complex methods. The challenge of metrology in the extreme magnetic field generating devices is complicated by the millions of amperes of current and tens of thousands of volts that are required to deliver the pulsed power needed for field generation. Methods of detecting physical properties of materials are essential parts of the science that seeks to understand and eventually control the fundamental functionality of materials in extreme environments. De-coupling the signal of the sample from the electro-magnetic interference associated with the magnet system is required to make these state-of-the-art magnetic fields useful to scientists studying materials in high magnetic fields. The cutting edge methods that are being used as well as methods in development will be presented with recent results in Graphene and High-Tc superconductors along with the methods and challenges.

[1]National Science Foundation DMR-Award 0654118

9:00AM Y21.00006 Sub 100 nm ballistic sensors for ultra high spatial resolution magnetic field detection , A.M. GILBERTSON, L.F. COHEN, Imperial College, M. FEARN, T. ASHLEY, QinetiQ, S.A. SOLIN, University of Washington in St. Louis, A. KORMÁNYOS, C.J. LAMBERT, Lancaster University — There is an ongoing drive to develop non-invasive magnetic field sensors with ultra high spatial resolution (UHSR) of 100 nm or less for numerous applications.[1,2] Conventional field sensors e.g. based on the Hall effect, rely on diffusive transport, where high mobility III-V semiconductors offer the best field sensitivity ($T/Hz^{0.5}$).[2] For UHSR, the critical dimensions of the device must be reduced below the mean free path where transport is ballistic, and the detection properties are not preserved, e.g. the Hall response can be suppressed and/or nonlinear. We report sub 100 nm sensors utilizing the negative bend resistance of InSb/InAlSb ballistic structures at elevated temperatures.[3] These devices exhibit an enhanced responsivity that is tunable by geometric design and extremely attractive for the detection of ultra small magnetic fields. Our smallest device studied to date has an active sensor area of 35 x 35 nm^2, and a sensitivity of 0.87 $\mu T/Hz^{0.5}$ at 100 K. The performance and detection properties are reviewed with respect to state-of-the-art technologies.
[1]P. Manandhar, Nanotechnol. 20, 355501 (2009). [2]A. Sandhu, Microelectron. Eng. 73, 524 (2004). [3]A. M. Gilbertson, et al., Submitted to Appl. Phys. Letts. (2010).

9:12AM Y21.00007 dc SQUIDs as displacement detectors for embedded micromechanical resonators , SAMIR ETAKI, Delft University of Technology, MENNO POOT, yale, KOJI ONOMITSU, HIROSHI YAMAGUCHI, NTT basic research laboratories, HERRE VAN DER ZANT, Delft University of Technology — Superconducting quantum interference devices (SQUIDs) can detect tiny amounts of magnetic flux and are also used to study macroscopic quantum effects. We employ a dc SQUID as a linear detector of the displacement of an embedded micromechanical resonator with femtometer sensitivity. We have also measured the backaction of the dc SQUID on the resonator, where the resonance frequency and damping of the resonator can be tuned with bias current and applied magnetic flux. The backaction can tune the resonator from strongly damped to self-sustained oscillation and may be used to cool the resonator.

9:24AM Y21.00008 A Novel Ambient Operating Force and Acceleration Detector , MING YIN, Benedict College, SC 29204, HUAIZHOU ZHANG, MICHAEL WESCOTT, YEUNCHEOL JEONG, JAMES GAMBREL, TIMIR DATTA, Univ of South Carolina, SC 29208 — An investigation to develop a novel accelerometer capable of operating under ambient conditions without any cryogenics is in progress in our laboratory. In this device the proof mass comprises of magnetic or diamagnetic materials. This mass is freely suspended in stable equilibrium under gravity by the combined actions of magnetic attraction and repulsion forces. Stability is achieved along all three Cartesian axes even at zero frequency. For highly dynamical onboard platforms, realtime nulling by active control at high-frequency is desirable. A description of prototypes and measurements will be discussed. Sensitivity in the $\sim$ 0.1ngal regime to both kinematic and gravitational accelerations and $\sim$ pN force resolution is observed. Our initial results including (i) detection of tidal changes in the gravitational background, (ii) seismic tremors, (iii) Fourier analysis of time displacement data and (iv) design considerations for enhanced sensitivity and improved performance will be presented. Several scientific and technological implications will be suggested.

9:36AM Y21.00009 Driving electronics for a z-positioner in a new SPM design.[1] , LEUJEN CHEN, SEONG HEON KIM, ALEX DE LOZANNE, Department of Physics, University of Texas at Austin — We use a modified Pan-type walker as the z coarse approach mechanism in our new SPM design. We developed new electronics for driving and exercising the walker with the main circuit consisting of six 12V relays. Connecting the relays in series produces a timing cascade due to the mechanical delay in each relay. The traditional slow linear ramp has been replaced with the charge and discharge behavior of the RC circuits, where C is the capacitance of the piezolelectric plates. Initial tests with a 6Hz frequency input showed 10 nm step size and a 3 millimeter range. A single 555 timer serves as our frequency generating source. A highly stabilized square wave can be generated in its monostable mode, with the output frequency determined by two external resistors and a capacitor. We also replace the high voltage supply with a voltage quadrupler circuit that is compact and inexpensive, with 64V and 128V DC output in the final configuration.

[1]Supported by NSF DMR-0923231

9:48AM Y21.00010 A unique 30 Tesla single-solenoid pulsed magnet instrument for x-ray studies[1] , ZAHIRUL ISLAM, Advanced Photon Source, Argonne National Laboratory, DANA CAPATINA, JACOB RUFF, RITESH DAS, APS, ANL, HIROYUKI NOJIRI, Institute for Materials Research, Tohoku University, YASUO NARUMI, IMR, TU — We present a dual-cryostat pulsed-magnet instrument at the Advanced Photon Source (APS) with unique capabilities. The dual-cryostat independently cools the solenoid (Tohoku design) using liquid nitrogen and the sample using a closed-cycle refrigerator, respectively. Liquid nitrogen (LN) cooling allows a repetition rate of seven minutes for peak fields of 30 Tesla. The system is unique in that the LN cryostat incorporates a double-funnel vacuum tube passing through the solenoid's bore preserving the entire angular range allowed by the magnet. This scheme is advantageous in that it allows the applied magnetic field to be parallel to the scattering plane complementing typical split-pair magnets with fields normal to the scattering plane. Performance of the coils along with preliminary x-ray diffraction and spectroscopic studies will be presented.

[1]Use of the APS is supported by the U. S. DOE, Office of Science, under Contract No. DE-AC02-06CH11357. The work was supported in part by ICC-IMR, Tohoku University.

10:00AM Y21.00011 Applications of superconducting trapped field magnets for x-ray scattering experiments[1] , R.K. DAS, Z. ISLAM, J.P.C. RUFF, J.C. LANG, Argonne National Lab, R.P. SAWH, R. WEINSTEIN, University of Houston — Two long standing problems in x-ray and neutron scattering studies in applied magnetic fields are, 1) limited optical access and 2) practical impossibility to apply magnetic field parallel to x-ray (neutron) momentum transfer. In order to overcome these obstacles we have developed an application of Type-II superconducting magnets. In this approach, a small and thin plate-like single crystal sample is mounted on the surface of a melt-textured superconductor (SC). The SC is magnetized by cooling it from temperature above its superconducting critical temperature (T_c) in an applied magnetic field. Below T_c, magnetic flux gets trapped inside the SC disk after the removal of the external magnetic field. The SC disk acts as a permanent magnet with applied field normal to the flat surface of the disk providing unrestricted optical access to the entire hemisphere allowing a magnetic field parallel to the x-ray momentum transfer.

10:12AM Y21.00012 ABSTRACT WITHDRAWN –

10:24AM Y21.00013 Efficient conversion of ^{3}He(n,tp) and ^{10}B(n,α^7Li) reaction energies into far-ultraviolet radiation by noble gas excimers , PATRICK P. HUGHES, MICHAEL A. COPLAN, University of Maryland, ALAN K. THOMPSON, ROBERT E. VEST, National Institute of Standards and Technology, CHARLES W. CLARK, Joint Quantum Institute, National Institute of Standards and Technology and University of Maryland — Previous work[1,2]showed that the ^{3}He(n,tp) reaction in a cell of ^{3}He at atmospheric pressure generated tens of far-ultraviolet (FUV) photons per reacted neutron. Here we report amplification of that signal by factors of 1000 when noble gases are added to the cell. Calibrated filter-detector measurements show that this large signal is due to noble-gas excimer emissions, and that the nuclear reaction energy is converted to FUV radiation with efficiencies of up to 30%. Our results have been placed on an absolute scale through calibrations at the NIST SURF III Synchrotron and Center for Neutron Research.[3] We have also seen large neutron-induced FUV signals when the ^{3}He gas in our system is replaced with a ^{10}B film target; an experiment on substituting ^{3}He with BF_3 is underway. Our results suggest possibilities for high-efficiency, non-^{3}He neutron detectors as an alternative to existing proportional counters. [1]A. K. Thompson, *et al., J. Res. Natl. Inst. Stand. Technol.* **113**, 69 (2008) [2]M. A. Coplan, A. K. Thompson and C. W. Clark, U.S. Patent No. 7,791,045 (2010) [3]P.P. Hughes, *et al.,* arXiv:1009.4707 (*Appl. Phys. Lett.* in press, 2010)

10:36AM Y21.00014 First Results from the Triple-axis Spectrometer at OPAL , SERGEY DANILKIN, MOHANA YETHIRAJ, THOMAS SAERBECK, FRANK KLOSE, Australian Nuclear Science and Technology Organization — The thermal triple-axis spectrometer TAIPAN is the first instrument for inelastic scattering at Australian research reactor OPAL. TAIPAN started operation in February 2009 and is in full user service since November 2010. The instrument can operate with variable incident or final energies and has a secondary spectrometer with a single detector. Presently the PG (002) double-focusing monochromator and analyzer are in use. The incident energy range on the TAIPAN is from $\sim$ 5 meV up to $\sim$ 100 meV with neutron flux at sample position of $\sim 10^8 \mathrm{n/cm^2/s}$ [1]. First experiments were performed with superionic conductor $Cu_{2-x}Se$ [2]. The measurements reveal a presence of soft mode in addition to the flat optic-like phonon branch. The DFT calculations show that unstable soft mode is related to ordering of Cu atoms followed by $\alpha - \beta$ phase transition at a lower temperature. The evolution of the magnetic structure with temperature in magnetically modulated $FePt_3$ thin film was investigated in the diffraction mode of TAIPAN. The results show that the film fabricated by modulation of the chemical order parameter consists of a magnetic FM/AFM superlattice in single-crystalline $FePt_3$ [3]. [1] S.A. Danilkin et al., Neutron News, 20 (2009) 37; [2] S.A. Danilkin et al., J. Phys. Soc. Jpn. 79 (2010) Suppl. A, 25; [3] T. Saerbeck et al., Phys. Rev. B 82 (2010) 134409.

Friday, March 25, 2011 8:00AM - 11:00AM –
Session Y22 DCMP: Ferroelectric and Structural Phase Transitions D163

8:00AM Y22.00001 Magnetic and magnetoelectric excitations in multiferroic $BiFeO_3$, DIYAR TALBAYEV, Yale University, STUART A. TRUGMAN, ANTOINETTE J. TAYLOR, Los Alamos National Laboratory, SEONGSU LEE, SANG-WOOK CHEONG, Rutgers University — Ferroelectric antiferromagnet $BiFeO_3$ combines ferroelectricity with an antiferromagnetic order at room temperature. A control of its magnetic state by voltage has been demostrated both in bulk and in thin film $BiFeO_3$. The distortion of the cubic perovskite lattice leads to two effects through the Dzyaloshinski-Moriya magnetic interaction: the ferroelectric distortion results in the observed incommensurate spiral spin structure, and the rotation of oxygen octahedra with alternating sense on neighboring Fe ions results in a local canting of spins. We present a terahertz spectroscopic study of magnetic excitations in $BiFeO_3$. We interpret the observed spectrum of long-wavelength magnetic resonance modes in terms of the normal modes of the material's spiral antiferromagnetic structure. We find that the modulated Dzyaloshinski-Moriya interaction and the local spin canting lead to a splitting of the out-of-plane resonance modes. We also assign one of the observed absorption lines to an electromagnon excitation that results from the magnetoelectric coupling between the ferroelectric polarization and the spiral magnetic structure of $BiFeO_3$.

8:12AM Y22.00002 Size-dependent infrared phonon modes and ferroelectric phase transition in $BiFeO_3$ nanoparticles[1] , PENG CHEN, XIAOSHAN XU, CHRISTOPHER KOENIGSMANN, ALEXANDER C. SANTULLI, STANISLAUS S. WONG, JANICE L. MUSFELDT, University of Tennessee — One emergent property of ferroelectric nanoparticles is the sized-induced structural distortion to a high-symmetry paraelectric phase at small particle sizes. Finite length scale effects can thus be advantageously employed to elucidate ferroelectric transition mechanisms. In this work, we combine infrared spectroscopy with group theory and lattice dynamics calculations to reveal the displacive nature of the ferroelectric transition in $BiFeO_3$, a room temperature multiferroic. Systematic intensity and frequency trends in selected vibrational modes show that the paraelectric phase is $Pm\bar{3}m$ and the lowest frequency A_1 feature is the soft mode that drives the first order transition. Finite length scale effects are also evident in the electronic structure with a red shifted band gap in nanoscale $BiFeO_3$ compared with that of the rhombohedral film, a result that can impact the development of ferroelectric photovoltaics and oxide- based electronics. Taken together, these findings demonstrate the foundational importance of size effects for enhancing the rich functionality and broad utility of transition metal oxides.

8:24AM Y22.00003 Remarkably robust ferroelectric state in multiferroic $Mn_{1-x}Zn_xWO_4$, B. LORENZ, R.P. CHAUDHURY, Y.Q. WANG, Y.Y. SUN, C.W. CHU[1], Dept. of Physics and TCSUH, Univ. of Houston, Houston, TX 77204-5002, F. YE, H.A. MOOK, Neutron Scattering Science Division, ORNL, Oak Ridge, TN 37831, J.A. FERNANDEZ-BACA, Dept. of Physics and Astronomy, Univ. of Tennessee, Knoxville, TN 37996 — Zinc doping in $Mn_{1-x}Zn_xWO_4$ is equivalent to the removal of Mn spins and a dilution of the magnetic system. The multiferroic (ferroelectric) phase of $MnWO_4$ is stabilized through Zn substitution and the low-temperature commensurate phase (up-up-down-down phase) is completely suppressed at a Zn concentration of more than 5%. The magnetic and ferroelectric phases as well as the multiferroic properties are studied through magnetic, heat capacity, polarization, and neutron scattering experiments. The multiferroic phase is remarkably stable and it still exists for Zn substitution levels up to and above 50%. At low doping (2%) the incommensurate helical and the commensurate low-T phases coexist. External magnetic fields do lift the phase degeneracy and stabilize either one of the two ground states, depending on the direction of the field.

8:36AM Y22.00004 Ferroelectricity in $CaTiO_3$ Single Crystal Surfaces and Thin Films and Probed by Nonlinear Optics and Raman Spectroscopy , EFTIHIA VLAHOS, TOM LUMMEN, RYAN HAISLMAIER, SAVA DENEV, CHARLES BROOKS, The Pennsylvania State University, MICHAEL BIEGALSKI, Oak Ridge National Lab, DARRELL SCHLOM, Cornell University, CARL-JOHAN EKLUND, KARIN RABE, Rutgers University, CRAIG FENNIE, Cornell University, VENKATRAMAN GOPALAN, The Pennsylvania State University — Bulk $CaTiO_3$ has a centrosymmetric point group and is *not* polar or ferroelectric. However, we present surprising results that show highly regular polar domains in single crystals of $CaTiO_3$. Confocal Second Harmonic Generation (SHG) and Raman imaging studies were carried out on perovskite $CaTiO_3$ crystal surfaces. They reveal large, crystallographic polar domains at room temperature, with in-plane polarization components delineated by twin walls. SHG analysis indicates that the highest symmetry of the polar surface is m(space group Pc) with polarization in the m plane. In addition, we present results of the polar domain structure imaged before and after the application of an external electric field. Finally, we present the SHG studies of $CaTiO_3$ thin films grown using reactive Molecular Beam Epitaxy (MBE); these films are predicted by theory to be ferroelectric and are shown experimentally, both with SHG and in-plane dielectric measurements, to be ferroelectric for temperatures less than $\sim$150 K with group symmetry *mm*2.

8:48AM Y22.00005 Phase transitions in relaxors as seen by neutron scattering , SEVERIAN GVASALIYA, Laboratorium für Festkörperphysik, ETH Hönggerberg, Zürich, Switzerland, ROGER COWLEY, Clarendon Laboratory, Physics Department, Oxford University, UK, SERGEY LUSHNIKOV, Ioffe Physico-Technical Institute, St Petersburg, Russia, BERTRAND ROESSLI, Laboratory for Neutron Scattering, Paul Scherrer Institut, Villigen PSI, Switzerland, GELU-MARIUS ROTARU, Empa, Laboratory for Protection and Physiology, St Gallen, Switzerland — Relaxors have a broad temperature and frequency-dependent peak in the dielectric permittivity that is not necessarily linked to a structural phase transition. A model relaxor is $PbMg_{1/3}Nb_{2/3}O_3$ (PMN) doped with $PbTiO_3$ (PT). We report neutron studies of the low-energy spectra of (1-x)PMN-xPT crystals. Apart from phonons which do not show a soft mode, there are two components of the diffuse scattering: one is quasi-elastic (QE) and the other static. The energy width of the QE scattering decreases as the peak of the susceptibility is approached. The static component behaves like an order parameter. In the crystals that become ferroelectric it is maximal at the ferroelectric phase transition, but in PMN it steadily increases on cooling. We discuss previously reported and new results in terms of a random-field model of the cubic crystal.

9:00AM Y22.00006 ABSTRACT WITHDRAWN –

9:12AM Y22.00007 Elastic collapse and avalanche criticality near a Mott transition[1] , J.L. SMITH, D.J. SAFARIK, J.C. LASHLEY, Los Alamos, E.K.H. SALJE, Cambridge, C.P. OPEIL, Boston College, P.S. RISEBOROUGH, Temple University — We study some dynamic aspects of a Mott transition in a rare-earth alloy $Ce_{0.90}Th_{0.10}$ by resonant-ultrasound spectroscopy (RUS), electrical-transport, and thermal-expansion measurements. In the temperature range spanning the first-order transition, we observe a stiffening of the elastic response that is associated with a continuous front propagation ($e.g.$ solitons). A defining characteristic of a mixed phase regime, slow scanning rates (0.01 K/min) show these solitons to be superimposed with jerks and avalanches in all three data sets: RUS, resistivity, and thermal expansion data. Analysis of the avalanche data give power law distributions with critical exponents $P(E) = E^n$ for energy, in the case of thermal expansion data and length, in the case of electrical transport data.

[1]Work performed under the auspices of the U.S. Dept. of Energy.

9:24AM Y22.00008 Calculated temperature dependence of elastic constants and phonon dispersion of hcp and bcc beryllium[1] , STEVEN HAHN, Ames Laboratory and Iowa State University, SERGIU ARAPAN, Uppsala University, BRUCE HARMON, Ames Laboratory and Iowa State University, OLLE ERIKSSON, Uppsala University — Conventional first principle methods for calculating lattice dynamics are unable to calculate high temperature thermophysical properties of materials containing modes that are entropically stabilized. In this presentation we use a relatively new approach called self-consistent *ab initio* lattice dynamics (SCAILD) to study the hcp to bcc transition (1530 K) in beryllium. The SCAILD method goes beyond the harmonic approximation to include phonon-phonon interactions and produces a temperature-dependent phonon dispersion. In the high temperature bcc structure, phonon-phonon interactions dynamically stabilize the N-point phonon. Fits to the calculated phonon dispersion were used to determine the temperature dependence of the elastic constants in the hcp and bcc phases.

9:36AM Y22.00009 Influence of the Magnetic State on the Chemical Order-Disorder Transition Temperature in Fe-Ni Permalloy , MARCUS EKHOLM, Linköping University, Sweden, HELENA ZAPOLSKY, Université de Rouen, France, ANDREI RUBAN, Royal Institute of Technology, Sweden, IRYNA VERNYHORA, DENIS LEDUE, Université de Rouen, France, IGOR ABRIKOSOV, Linköping University, Sweden, LINKÖPING UNIVERSITY, SWEDEN TEAM, UNIVERSITÉ DE ROUEN, FRANCE TEAM, ROYAL INSTITUTE OF TECHNOLOGY, SWEDEN TEAM — In magnetic alloys, the effect of finite temperature magnetic excitations on phase stability below the Curie temperature is poorly investigated, although many systems undergo phase transitions in this temperature range. In this study [1], we consider random Ni-rich Fe-Ni alloys, which undergo chemical order-disorder transition approximately 100 K below their Curie temperature, to demonstrate from *ab-initio* calculations that deviations of the global magnetic state from ideal ferromagnetic order due to temperature induced magnetization reduction have a crucial effect on the chemical transition temperature. We propose a scheme where the magnetic state is described by partially disordered local magnetic moments, which in combination with Heisenberg Monte-Carlo simulations of the magnetization allows us to reproduce the transition temperature in good agreement with experimental data. [1] Ekholm et al., Phys. Rev. Lett. 105:167208 (2010)

9:48AM Y22.00010 Structural and magnetic properties of Ni_2MnGa from first-principles , VAMSHI KATUKURI, BURAK HIMMETOGLU, MATTEO COCOCCIONI, CEMS University of Minnesota — Ni_2MnGa is the prototype magnetic shape-memory alloy. In this work we use ab-initio calculations to characterize structural and magnetic transitions and to identify possible strategies to tune them towards the same critical point. To this aim both the austenite and the martensite phases of the Ni_2MnGa alloy are studied with particular attention to the electronic factors controlling their stability and the onset of the structural transition. Our results indicate that, in spite of its metallic character, electronic correlations play an important role in determining the behavior of this compound and, in particular, the entity (and sign) of the deformation accompanying the transition from the austenite phase to the martensite one. The vibrational properties of the austenite phase are also studied and structural instabilities (soft modes) are investigated as possible signatures of intermediate "modulated" structures.

10:00AM Y22.00011 ABSTRACT WITHDRAWN –

10:12AM Y22.00012 Origin of "aging" in shape-memory alloys , XIANGDONG DING, Los Alamos National Laboratory, JUNKAI DENG, Xi'an Jiaotong University,China, TURAB LOOKMAN, AVADH SAXENA, Los Alamos National Laboratory, XIAOBING REN, National Institute for materials science, Japan — For more than half a century it has been widely observed that a majority of shape-memory alloys exhibit a gradual change in physical properties with time in the martensitic phase, and this is referred to as "aging." However, its microscopic mechanism has remained controversial due to lack of experiments that can probe atomic level processes. We clarify the atomic mechanism for how shape memory alloys "age" in time using a combination of molecular dynamics and Monte-Carlo simulations. Through analysis of the atomic configurations during aging, we find that the observed phenomenon is associated with a gradual change in the short range order of point defects so that the defect short range order tends to adopt the same "symmetry" as the crystal symmetry of the host martensite lattice. The results provide atomic-level evidence for the symmetry-conforming short-range order model, and may provide new insight into how to control aging to design aging-free shape memory alloys. Reference: 1). J. Deng, X. Ding, T. Lookman, et al, Physical Review B , **81**, 220101(R), 2010 2). J. Deng, X. Ding, T. Lookman, et al, Physical Review B, **82**,184101, 2010 3). J. Deng, X. Ding, T. Lookman, et al, Applied Physics Letters, **97**,171902, 2010

10:24AM Y22.00013 Microstructure from ferroelastic transitions using strain pseudospin clock models in two and three dimensions , TURAB LOOKMAN, Los Alamos National Laboratory, ROMAIN VASSEUR, Ecole Normale Superieur, Paris, SUBODH SHENOY, School of Physics, University of Hyderabad — We show how microstructure can arise in first-order ferroelastic structural transitions, in two and three spatial dimensions, through a local mean-field approximation of their pseudospin Hamiltonians, that include anisotropic elastic interactions. Such transitions have symmetry-selected physical strains as their order parameters, with Landau free energies that have a single zero-strain "austenite" minimum at high temperatures, and spontaneous-strain "martensite" minima of structural variants at low temperatures. The total free energy also has gradient terms, and power-law anisotropic effective interactions, induced by "no-dislocation" St Venant compatibility constraints. In a reduced description, the strains at Landau minima induce temperature dependent, clocklike Hamiltonians, with strain- pseudospin vectors S pointing to discrete values including zero. We study elastic texturing in five such first-order structural transitions through a local mean-field approximation of their pseudospin Hamiltonians, that include the power-law interactions. The local mean-field solutions in 2D and 3D yield or oriented domain- wall patterns as from continuous-variable strain dynamics, showing the discrete- variable models capture the essential ferroelastic texturings.

10:36AM Y22.00014 Symmetry breaking in amorphous solids undergoing martensitic phase transformation - a relation to Landau's theory , MICHAEL FISCHLSCHWEIGER, Materials Center Leoben Forschung, EDUARD OBERAIGNER, University of Leoben, Institute of Mechanics — Martensitic phase transformation can be classified as displacive solid -solid phase transformations, where the symmetry of the high temperature phase (austenite) breaks when phase transformation occurs. The martensitic phase (low temperature phase) and its variants are products of symmetry breaking in solids. Based on a quasiparticle statistical mechanics approach the canonical free energy of a representative solid volume element consisting of several quasiparticles (representative mole number) can be derived. The symmetry breaking order parameter of the system is the total strain which is an ensemble mean value in the statistical mechanics concept. In the current theory the order parameter is a macroscopic strain in a sense that the representative volume element stands for the macroscopic level, whereas the lattice parameter changes are considered in the hamiltonian definition of each quasiparticle. Computational results of the developed theory correspond to experimentally observed phenomena in materials undergoing martensitic phase transformation. The present study is focusing the region nearby the phase transformation and shows how the developed theory for describing symmetry breaking and order parameter changes correspond to Landau's phenomenological theory of phase transitions.

10:48AM Y22.00015 Probing driven first order structural transitions with resistivity noise , U. CHANDNI, ARINDAM GHOSH, Indian Institute of Science — We study the avalanche-mediated driven first order structural transition in nickel titanium shape memory alloys with time-dependent fluctuations in electrical resistivity. Higher order statistics of the fluctuations, or noise, has been used as a kinetic detector of the underlying two stage athermal phase transition. We have found that the non-gaussian component of the higher order statistics carries significant information about the transition parameters and is coupled to the microscopic origin of the phase transition. The results can be explained with a model based on three competing time scales dependent on avalanche relaxation, thermal fluctuations and drive rate. The transition temperature was found to decrease with increasing drive rate indicative of the increased possibility of the system being driven towards the athermal limit. Moreover, the magnitude of the non-gaussian component is found to have signatures of the extent of correlations in the system and hence a viable tool to detect any overlap of avalanches in space or time. The study establishes noise as a sensitive tool to probe the kinetics of driven structural transitions which can be exploited in a variety of other systems. References: U. Chandni et. al, Phys. Rev. Lett. 102, 025701 (2009) U. Chandni and A. Ghosh, Phys. Rev B. **81**, 134105 (2010)

Friday, March 25, 2011 8:00AM - 10:36AM –
Session Y23 DCMP: Superconductivity: Proximity Effects D165

8:00AM Y23.00001 Supercurrent-Induced Magnetization Dynamics , JACOB LINDER, Department of Physics, NTNU, TAKEHITO YOKOYAMA, Department of Physics, Tokyo Institute of Technology — We investigate supercurrent-induced magnetization dynamics in a Josephson junction with two misaligned ferromagnetic layers, and demonstrate a variety of effects by solving numerically the Landau-Lifshitz-Gilbert equation. In particular, we demonstrate the possibility to obtain supercurrent-induced magnetization switching for an experimentally feasible set of parameters, and clarify the favorable condition for the realization of magnetization reversal. These results constitute a superconducting analogue to conventional current-induced magnetization dynamics and indicate how spin-triplet supercurrents may be utilized for practical purposes in spintronics.

8:12AM Y23.00002 Superfluid Densities in Superconducting/Ferromagnetic (Nb/NiV/Nb) Heterostructures , MICHAEL HINTON, BRIAN PETERS, ADAM HAUSER, Ohio State University, JULIA MEYER, OSU & INAC/SPSMS, CEA, FENGYUAN YANG, THOMAS LEMBERGER, Ohio State University — Superfluid density measurements allow us to probe the superconducting structure of thin films below T_c with remarkable detail. They yield information not only of the inherent robustness of the superconducting state, but also about the homogeneity of the sample and possible "hidden" transitions at temperatures lower than the initial T_c. For this reason multiple transitions in superconducting heterostructures are revealed to us. We use superfluid density measurements on $Nb/Ni_{0.95}V_{0.05}/Nb$ trilayers to study the interplay between two superconducting films separated by the destructive proximity effects of a ferromagnet. We show there are trilayers with strong coupling, which produces a single transition, that become decoupled to the point of separation into two transitions as the ferromagnetic layer thickness increases. We discuss the difficulties in observing the second transition in σ_1, while obvious in λ^{-2}.

8:24AM Y23.00003 Magnetic-state-controlled proximity effect across high-T_C superconductor/ferromagnetic interfaces.[1] , C. VISANI, C. DERANLOT, R. BERNARD, K. BOUZEHOUANE, J. BRIATICO, J.E. VILLEGAS, Unité Mixte de Physique CNRS/Thales, 1 avenue A. Fresnel, 91767 Palaiseau, France — We have investigated the electronic density of states of a ferromagnet (F: a Co/Pt superlattice) in contact with a c-axis YBCO film. This was done by measuring the current-perpendicular-to-plane differential conductance across vertical junctions of area down to 6 μm^2, which were fabricated using optical lithography and ion etching. We have found salient features of the leakage of the superconducting order parameter into the F layer, such as a zero-bias conductance peak which can be modulated by the magnetic state of the ferromagnet. We discuss the possibility of triplet superconducting correlations induced in the F layer as the origin of this behavior.

8:36AM Y23.00004 Long-Range Superconducting Proximity Effect in Template-Fabricated Single-Crystal Nanowires[1] , WENHAO WU, Texas A&M University, HAIDONG LIU, Intel Corporation, ZHIYUAN WEI, ISABEL SCHULTZ, Texas A&M UNiversity — We study a superconducting proximity effect observed in single-crystal nanowires of Zn, Sn, and Pb of length up to 60 μm. These nanowires are electrochemically deposited into the pores of anodic aluminum oxide membranes and polycarbonate membranes. Using an *in situ* self-contacting method, single nanowires are electrically contacted on both ends to a pair of macroscopic film electrodes of Au, Sn, or Pb pre-fabricated on both surfaces of the membranes. Superconductivity in the nanowires is strongly suppressed when Au electrodes are used. When electrodes having higher superconducting transition temperatures are used, the nanowires become superconducting at the transition temperatures of the electrodes. Microscopy analyses of the structure and the chemical composition of the nanowires will be presented. Measurements of sample resistance and $I-V$ characteristics at various temperatures and magnetic fields will also be presented. Furthermore, the effects of the length, the diameter, and the residual resistance ratio of the nanowires on the proximity induced superconductivity will be analyzed and discussed.

[1]Supported by NSF DMR-0551813 and DMR-0606529.

8:48AM Y23.00005 Radiative Interband Transition of Cooper Pairs in a Semiconductor , I. SUEMUNE, Y. ASANO, H. SASAKURA, C. HERMANNSTAEDTER, J.-H. HUH, Hokkaido Univ, K. TANAKA, Hamamatsu Photonics, T. AKAZAKI, NTT BRL, R. INOUE, H. TAKAYANAGI, Tokyo Univ of Science, H. KUMANO, Hokkaido Univ — Interactions of photons and superconductors have been a hot topic for superconducting (SC) qubit operations. The relevant photon energies were limited below the superconducting gap of superconductors, that is, microwave frequencies. The possibility of electron Cooper-pair interactions with photons with much higher energies was discussed theoretically [1]. In this talk we will demonstrate that Cooper pairs penetrated into a semiconductor from an adjacent superconductor by the proximity effect play a major role in interband radiative recombinations in the semiconductor experimentally. SC Nb electrodes were formed on an InGaAs/InP light emitting diode (LED) and electroluminescence (EL) around 1.55um was observed from a slit formed on the surface Nb electrode. EL was drastically enhanced below the Nb SC critical temperature (T_c) of ∼8K [2]. The reduction of radiative recombination lifetime consistent with the observed EL enhancement was observed below T_c[3]. These results are well explained with the theory [1]. We will discuss the possibility of generating entangled photon pairs based on this new scheme. [1] Y. Asano et al., PRL 103 (2009) 187001. [2] Y. Hayashi et al., Appl. Phys. Express 1 (2008) 011701. [3] I. Suemune et al., APEX 3 (2010) 054001.

9:00AM Y23.00006 Robustness of Majorana modes and minigaps in a spin-orbit-coupled semiconductor-superconductor heterostructure , LI MAO, CHUANWEI ZHANG, Department of Physics and Astronomy, Washington State University — We study the robustness of Majorana zero energy modes and minigaps of quasiparticle excitations in a vortex by numerically solving Bogoliubov-deGennes equations in a heterostructure composed of an *s* -wave superconductor, a spin-orbit-coupled semiconductor thin film, and a magnetic insulator. This heterostructure was proposed recently as a platform for observing non-Abelian statistics and performing topological quantum computation. The dependence of the Majorana zero energy states and the minigaps on various physics parameters (Zeeman field, chemical potential, spin-orbit coupling strength) is characterized. We find the minigaps depend strongly on the spin-orbit coupling strength. In certain parameter region, the minigaps are linearly proportional to the *s*-wave superconducting pairing gap Δ_s, which is very different from the Δ_s^2 dependence in a regular *s*- or *p*-wave superconductor. We characterize the zero energy chiral edge state at the boundary and calculate the STM signal in the vortex core that shows a pronounced zero energy peak. We show that the Majorana zero energy states are robust in the presence of various types of impurities. We find the existence of impurity potential may increase the minigaps and thus benefit topological quantum computation.

9:12AM Y23.00007 Topological superconductivity and Majorana fermions in half-metal / superconductor heterostructure[1] , SUK BUM CHUNG, HAI-JUN ZHANG, XIAO-LIANG QI, SHOUCHENG ZHANG, Stanford University — A half-metal is by definition spin-polarized at its Fermi level and therefore was conventionally thought to have little proximity effect to an s-wave superconductor. Here we show that if there is spin-orbit coupling at the interface between a single-band half-metal and an s-wave superconductor, $p_x + ip_y$ superconductivity would be induced on the half-metal. This can give us topological superconductor with a single chiral Majorana edge state. We show that two atomic layers of CrO_2 or CrTe gives us the single-band half-metal and is thus a candidate material for realizing this physics.

[1]This work is supported by DOE under contract DE-AC02-76SF00515, the Sloan Foundation, and NSF under grant number DMR-0904264

9:24AM Y23.00008 Superconducting proximity effects of Pb nano-islands[1] , JUNGDAE KIM, GREGORY FIETE, HYOUNGDO NAM, ALLAN MACDONALD, CHIH-KANG SHIH, Department of Physics, The University of Texas at Austin, Austin, Texas 78712 — Superconductivity in systems with spatial dimensions smaller than the coherence length has been the subject of intense interest for decades. We systematically address how superconducting nano-islands interact each other via a detailed scanning tunneling microscopy/spectroscopy (STM/STS). By measuring the spatial mapping of the local superconducting gap, an intriguing lateral proximity effect is observed in an island containing regions of different thicknesses and different superconducting strength which shows a gradual but evident change of local superconductivity at the thickness boundary. This must be due to a lateral proximity effect caused by the tunneling of Cooper pairs with different binding energies across the boundary. We were also able to experimentally determine a proximity length. When an island is smaller than the proximity length, it is found that superconductivity within the island is rather uniform, indicating the rigidity of the order parameter on the scale of proximity length.

[1]NSF grant DMR-0906025, CMMI-0928664, Welch Foundation F-1672, and Texas Advanced Research Program 003658-0037-2007

9:36AM Y23.00009 S -N-S junction formed by graphene with lead (Pb) contacts , IVAN BORZENETS, Duke University, ULAS COSKUN, University of Illinois , GLEB FINKELSTEIN, Duke University — We fabricate lead (Pb) contacts to graphene that allow us to observe supercurrent in the Pb-graphene-Pb structure up to temperatures of ∼3K. The measured critical current is much smaller than a naive expectation based on calculations for a superconductor-insulator-superconductor (S-I-S) junction. Hysteresis is seen in the switching current despite the fact that the junction is made to be overdamped. The behavior of the Pb-graphene-Pb structure is qualitatively explained by considering it as an S-N-S junction.

9:48AM Y23.00010 Switching and retrapping behavior in graphene proximity-effect superconducting junctions , MATTHEW BRENNER, ULAS COSKUN, ALEXEY BEZRYADIN, University of Illinois Physics — Since the pioneering work by R. Holm and W.Meissner [Z. Physik. 86, 787 (1933)], who observed zero resistance in SNS pressed contacts, many manifestations of the superconducting proximity effect have been reported. Recently it was shown that when closely spaced superconducting leads are placed on graphene, the proximity effect is induced and a supercurrent can flow between the electrodes. Here we fabricate graphene proximity-effect junctions (GPJ) and compare them to Josephson junctions (JJ). As the bias current is increased to near the critical current, a thermal escape from the washboard potential can occur driving the junction into the runaway voltage state. The standard deviation of the switching current is measured as a function of temperature and compared to the thermal and quantum escape models for JJs. We find that the temperature dependence of the standard deviation of switching currents of graphene proximity junctions is qualitatively different from the well-studied behavior of the insulator-based JJs. Possible reasons will be discussed.

10:00AM Y23.00011 Interface Engineering of Thin Film Superconductor Heterostructures[1] , CHENDONG ZHANG, Department of Physics, UT Austin; Institute of Physics, CAS, JISUN KIM, JUNGDAE KIM, HYOUNGDO NAM, Department of Physics, UT Austin, HONGJUN GAO, Institute of Physics, CAS, CHIH-KANG SHIH, Department of Physics, UT Austin — Thin film superconductivity is a subject with great scientific and technological importance. The previous works demonstrated that the superconductivity exits in extreme two-dimensional lead film with a thickness of only two atomic layers. Most strikingly, the Tc is only slightly suppressed from the bulk value. However, when the film is pseudomorphically strained, the Tc is suppressed further, implying the importance of the interface. In this work we explore thin film superconductivity in a new direction by engineering superconductor/normal metal heterostructures with atomically flat interface. Using in-situ scanning tunneling microscopy/spectroscopy, we explore the superconductivity of the Pb/Ag heterostructure by independently tuning the thicknesses of the atomically flat Ag films and superconducting Pb films respectively. The intriguing role of the Ag thin films on the superconductivity of Pb thin films will be reported.

10:12AM Y23.00012 Tunneling Measurements of the Exchange Field in Superconducting Al-EuS Bilayers[1] , PHILIP ADAMS, YIMIN XIONG, SHANE STADLER, Louisiana State U., GIANLUIGI CATELANI, Yale University — We present tunneling density of states measurements of the proximity-induced exchange field in superconducting Al-EuS bilayers. By depositing thin Al films onto an insulating EuS layer we demonstrate that one can induce an exchange field of several tesla in the superconducting Al. Contrary to expectations, this exchange field is a strong function of the applied field below 2 T. This applied-field dependence is not associated with the alignment of domains in the EuS, but instead appears to be an intrinsic effect. In addition, we show that the exchange field decreases significantly with increasing temperature below 1 K.

10:24AM Y23.00013 Exploring the Parameter Space of the Anti-Proximity Effect[1] , MEENAKSHI SINGH, JIAN WANG, MINGLIANG TIAN, Physics Department, Penn State University, THOMAS MALLOUK, Chemistry Department, Penn State University, MOSES CHAN, Physics Department, Penn State University — The anti-proximity effect, in which the superconductivity of a nanowire is weakened by the superconductivity of measuring bulk electrodes, has been reported in Zn nanowires (Tian et. al., PRL 95, 076802 (2005), Chen et. al., PRL 103, 127002 (2009)). The mechanism of this effect is not completely understood. We have studied the anti-proximity effect in Al nanowires in a variety of configurations. The effect is found to manifest only when the critical temperature (T_c) of the nanowire is greater than the T_c of its bulk form. The range of the effect is found to be $\sim 1\mu$m. The effect is seen in single nanowires in the absence of a magnetic field establishing that the effect depends on the nature of the measuring electrodes and is not caused by an external magnetic field. The anti-proximity effect has also been seen with the bulk superconductor not connected to the measurement circuitry.

Session Y24 DCOMP: Density Functional Theory II D167

8:00AM Y24.00001 Exact Exchange calculations for periodic systems: a real space approach , AMIR NATAN, NOA MAROM, ADI MAKMAL, LEEOR KRONIK, Weizmann Institute of Science, Israel, STEPHAN KUEMMEL, Bayreuth University, Germany — We present a real-space method for exact-exchange Kohn-Sham calculations of periodic systems. The method is based on self-consistent solutions of the optimized effective potential (OEP) equation on a three-dimensional non-orthogonal grid, using norm conserving pseudopotentials. These solutions can be either exact, using the S-iteration approach, or approximate, using the Krieger, Li, and Iafrate (KLI) approach. We demonstrate, using a variety of systems, the importance of singularity corrections and use of appropriate pseudopotentials.

8:12AM Y24.00002 Dissociation of diatomic molecules and the exact-exchange Kohn-Sham potential: the case of LiF , ADI MAKMAL, Department of Materials and Interfaces, Weizmann Institute of Science, Rehovoth 76100, Israel, STEPHAN KUEMMEL, Physikalisches Institut, Universitat Bayreuth, D-95440 Bayreuth, Germany, LEEOR KRONIK, Department of Materials and Interfaces, Weizmann Institute of Science, Rehovoth 76100, Israel — The incorrect fractional-charge dissociation of stretched diatomic molecules, predicted by semi-local exchange-correlation functionals, is revisited. This difficulty can be overcome with asymptotically correct non-local potential operators, but should also be absent in exact Kohn-Sham theory, where the potential is local. Here, we show, for the illustrative case of the LiF dimer, that the exact-exchange local Kohn-Sham potential, constructed within the Krieger, Li, and Iafrate (KLI) approximation, can lead to binding energy and charge dissociation curves that are qualitatively correct. This correct behavior is traced back to a characteristic "step" structure in the local exchange potential and its relation to the Kohn-Sham eigenvalues is analyzed.

8:24AM Y24.00003 A Projector Augmented Wave Treatment of Fock Exchange in Hartree-Fock and Optimized Effective Potential Calculations[1] , XIAO XU, N.A.W. HOLZWARTH, Wake Forest University — The use of orbital-dependent exchange-correlation functionals within electronic structure calculations has recently received renewed attention as a means of improving accuracy. In particular, the Fock exchange functional exactly cancels the electron self-interaction error which can be particularly significant in transition metals and other materials with localized orbitals. Since the Projector Augmented Wave (PAW) formalism[2] accurately evaluates the interaction integrals including all multiple moments, it is a natural choice for representing the Fock exchange functional within an efficient pseudopotential-like scheme. We have adapted the PAW formalism for use both in Hartree-Fock (HF) theory and in the KLI approximation to Optimized Effective Potential theory.[3] We show that the effects of core electrons are significant and can be accurately treated within a frozen core orbital approximation.[4] PAW-HF and PAW-KLI basis, projector, and pseudopotential functions are presented for several elements throughout the periodic table.

8:36AM Y24.00004 Localized resolution of identity for efficient Hartree-Fock exchange, based on numeric atom-centered orbitals , JUERGEN WIEFERINK, VOLKER BLUM, XINGUO REN, PATRICK RINKE, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin — Methods based on an exact exchange operator (EX) are increasingly popular, but are still restricted to analytical basis functions (e. g. Gaussians) for medium system sizes. We here introduce a localized resolution-of-identity approach for the two-electron Coulomb operator, based on expanding single-particle basis function products separately into auxiliary atom-centered basis sets that are restricted to two centers. Our approach produces accurate results for all-electron EX, can be applied both to analytical and numeric basis functions, requires only $\mathcal{O}(N^2)$ intermediate storage and retains a path towards $\mathcal{O}(N)$ EX for large systems. We demonstrate a total-energy accuracy of < 1 meV/atom for systems including Alanine chains and the S22 benchmark molecule set [1], using the numeric atom-centered orbital based all-electron electronic structure code FHI-aims [2].

8:48AM Y24.00005 Analytic Treatment of the Pair Density in Kohn-Sham Density Functional Theory[1] , MARKUS DAENE, Oak Ridge National Laboratory, ANTONIOS GONIS, Lawrence Livermore National Laboratory, DON M. NICHOLSON, G. MALCOLM STOCKS, Oak Ridge National Laboratory — We have developed a new treatment of the LDA functional in Kohn-Sham density functional theory which is expressed in terms of the pair density of a non-interacting system of particles, thus avoiding from the outset self-interaction effects. The pair density is expressed explicitly in terms of the density using a orthonormal and complete basis expressed as a functional of the density. This allows its functional differentiation with respect to the density by analytic means. The method is illustrated with numerical results for the potential in the case of one and three dimensional systems and is compared to the potentials obtained from the Hartree term.

9:00AM Y24.00006 Wave Function Functionals for the Density , MARLINA SLAMET, Sacred Heart University, XIAOYIN PAN, Ningbo University, VIRAHT SAHNI, Brooklyn College, CUNY — In recent work we have developed[1] a constrained-search variational method for the construction of wave functions that are functionals of a function $\chi : \Psi = \Psi[\chi]$. These wave function functionals are *simultaneously* normalized, reproduce the *exact* expectation of either single- or two-particle operators, and lead to rigorous upper bounds to the energy. In this paper we extend this method to the construction of wave function functionals $\Psi[\chi]$ that are simultaneously normalized, reproduce the density *exactly*, and lead to rigorous upper bounds to the energy. We apply the method to the ground state of the He atom to obtain wave function functionals that reproduce the density of an accurate correlated wave function. The wave function functionals as expected give rise to the exact expectation of non-differential single particle operators, and lead to accurate two-particle expectations and highly accurate energies.

9:12AM Y24.00007 Koopmans' condition for density-functional theory , ISMAILA DABO, CERMICS, University Paris-Est, ANDREA FERRETTI[1], NICOLAS POILVERT, Department of Materials Science and Engineering, Massachusetts Institute of Technology, YANLI LI, Department of Physics, Xiamen University, NICOLA MARZARI[2], Department of Materials Science and Engineering, Massachusetts Institute of Technology, MATTEO COCOCCIONI, Department of Chemical Engineering and Materials Science, University of Minnesota — In approximate Kohn-Sham density-functional theory, self-interaction manifests itself as the dependence of the energy of an orbital on its fractional occupation. Here, we first examine self-interaction in terms of the discrepancy between total and partial electron removal energies, and then highlight the importance of imposing the generalized Koopmans' condition to resolve this discrepancy. In the process, we derive a correction to approximate functionals that, in the frozen-orbital approximation, eliminates the unphysical occupation dependence of orbital energies up to the third order in the single-particle densities. This non-Koopmans correction brings physical meaning to single-particle energies; when applied to common local or semilocal density functionals it provides results that are in excellent agreement with experimental data while providing an explicit total energy functional that preserves or improves on the description of established structural properties.

9:24AM Y24.00008 Density Functional Theory for Open Systems[1] , ANTONIOS GONIS, Lawrence Livermore National Laboratory, DON NICHOLSON, MALCOLM STOCKS, XIAOGUANG ZHANG, Oak Ridge National Laboratory — We provide a formal proof of the convexity relation, $2E[N] \leq E[N-1] + E[N+1]$, characterizing the total energy of interacting N-electron systems under the action of a given external potential, hitherto assumed to be true only on experimental grounds. This is used to prove the inequality, $I(N) - A(N) \geq 0$, where $I(N)$ and $A(N)$ are, respectively, the ionization potential and electron affinity of a N-electron system.

9:36AM Y24.00009 Volume effects in band gap predictions for solids , ANUBHAV JAIN, Massachusetts Institute of Technology, MARIA K. CHAN, Argonne National Laboratory, RICKARD ARMIENTO, GERBRAND CEDER, Massachusetts Institute of Technology — The *ab initio* prediction of band gaps for solids is important for fundamental and practical reasons. Many approaches exist to remedy the "band gap problem" in Density Functional Theory (DFT) in which band gaps are severely underestimated. We recently proposed the Δ-sol method [1], an adaptation of the ΔSCF method towards solids, in which the fundamental gap is evaluated using total energies from DFT. Using Δ-sol, we obtained band gaps for over 100 crystalline semiconductors at accuracies similar to those of hybrid functionals such as HSE, but at significantly smaller computational costs. However, the accuracy of band gap predictions from first principles remains dependent on accurate determination of lattice parameters and cell volumes. In this talk, we discuss the effects of the accuracy in lattice parameters on predicted band gaps. We present results on the accuracy of cell volumes determined using several exchange-correlation functionals: LDA, PBE, HSE and AM05, and compare the dependence of Kohn-Sham gaps and band gaps predicted using Δ-sol on cell volumes. Finally we discuss optimal approaches for predicting band gaps for compounds with unknown lattice parameters.

9:48AM Y24.00010 Fundamental gaps in finite systems from the eigenvalues of generalized kohn-sham method , TAMAR STEIN, HELEN EISENBERG, Fritz Haber Center for Molecular Dynamics, Institute of Chemistry, Hebrew University, Jerusalem, LEEOR KRONIK, Department of Materials and Interfaces, Weizmann Institute of Science, Rehovoth, ROI BAER, Fritz Haber Center for Molecular Dynamics, Institute of Chemistry, Hebrew University, Jerusalem — We present a broadly-applicable, physically-motivated first-principles approach to determining the fundamental gap of finite systems. The approach is based on using a range-separated hybrid functional within the generalized Kohn-Sham approach to density functional theory. Its key element is the choice of a range-separation parameter such that Koopmans' theorem for both neutral and anion is obeyed as closely as possible. We demonstrated the validity, accuracy, and advantages of this approach on first, second and third row atoms, the oligoacene family of molecules, and a set of hydrogen-passivated silicon nanocrystals. This extends the quantitative usage of density functional theory to an area long believed to be outside its reach.

10:00AM Y24.00011 Self-optimizing Kohn-Sham hybrid functional , ISAAC TAMBLYN, Molecular Foundry, LBNL, ROI BAER, Hebrew University, Jerusalem, LEEOR KRONIK, Weizmann Institute of Science, Israel, JEFFREY NEATON, Molecular Foundry, LBNL — Recent work using range-separated hybrid functionals has confirmed the importance of including long-range exchange in treatments of phenomena such as charge transfer reactions. Using a self-optimizing [1,2] form of the BNL [3] functional, we present results for structural, electronic, and thermochemical properties of a large set of molecules (including the G2 and G3 test sets). The success of this approach, as well as its ability to describe reaction barriers, will be discussed.

10:12AM Y24.00012 TDDFT and qualitative properties of excited states: three illustrative applications using DMol^3 , BERNARD DELLEY, Paul Scherrer Institut, CMT — Three applications of DMol^3 TDDFT [1] are presented to show possible new frontiers in each case. First, excitations involving multiplet structure for the example of the Ti^{4+} ion are discussed, showing that atomic multiplet splitting is fully exhibited within TDDFT. This approach to multiplets exhibits notable similarities and also notable differences with a first principles based Condon-Shortley-Cowan multiplet theory. Second, UV-VIS spectra of benzene and derivative molecules are discussed by comparing experimental log plots of molar extinction with a TDDFT results completed by the Gaussian envelope model for the vibrational progression. The envelope model provides a natural scale for comparing TDDFT excitations with measured absorption spectra. In the third example, excited states of $(Fe(CN)_5NO)^{-2}$ are studied along the reaction coordinate connecting the long lived metastable states that can be produced by optical excitation.

10:24AM Y24.00013 Exact Time-Dependent Kohn-Sham Potential for an Interacting Few-Body System , RUDOLPH J. MAGYAR, Sandia National Laboratories — Time-dependent density functional theory enables practical simulations of the dynamic many-electron systems, but one of the biggest obstacles to reliable application is the quality of the approximate potential. It is often difficult to determine whether ever-more sophisticated approximations properly include new physics, as there exist few benchmark exact potentials. Towards this ends, we have developed and tested a scheme to extract the exact (non-adiabatic) time-dependent Kohn-Sham potential for few body systems. We will present some examples on 1D model systems. The approach is general and can be used to back engineer high-level quantum mechanical simulations to gain insight into TDDFT on a broad scale. Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a wholly owned subsidiary of the Lockheed Martin company, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

10:36AM Y24.00014 TDDFT approach to study nonlinear excitonic effects in Four-Wave Mixing processes[1] , VOLODYMYR TURKOWSKI, Physics Department and NSTC, University of Central Florida, Orlando, FL 32816, MICHAEL N. LEUENBERGER, Physics Department and NSTC, University of Central Florida, Orlando FL 32816 — We develop a time-dependent density-functional theory (TDDFT) formalism to study nonlinear effects in the processes in Four-Wave Mixing experiments. Namely, we generalize our recently proposed approach to calculate excitonic and biexcitonic eigen-energies within TDDFT on the dynamical case, which includes nonlinear effects, the like exciton-exciton interaction. In particular, we derive the TDDFT version of the nonlinear time-dependent equation for excitonic polarization with terms which correspond to exciton-exciton correlations through the memory functions. We have obtained the formula which relates the memory functions with the TDDFT exchange- correlation (XC) kernel. To test the formalism, we calculate the 2D Fourier spectra of a GaAs multi-quantum well system and compare them with experimenatal results in the case of several XC kernels. In addition, we compare the results with the ones obtained within a many-body method for non-linear effects in semiconductors. It is shown that the results obtained within the TDDFT approach may reproduce semi-quantively the 2D Fourier spectra, including the nonlinear effects, in the case of several phenomenological potentials.

10:48AM Y24.00015 Long-range corrected time-dependent density functional theory with spin-orbit couplings , AYAKO NAKATA, TAKAO TSUNEDA, KIMIHIKO HIRAO, RIKEN, JST-CREST — Relativistic time-dependent density functional theory (TDDFT) is a powerful tool to include both of relativistic and correlation effects with low computational cost. However, TDDFT with conventional exchange functionals have severe problems in e.g. the reproducibility of charge transfer (CT) and Rydberg excitation energies and oscillator strengths. These problems are due to the lack of long-range exchange interactions in conventional exchange functionals. We have proposed long-range corrected (LC) DFT and have overcome these problems. Especially, LC-TDDFT succeeds in describing CT excitations with remarkable accuracy. CT excitations often play a major role in spin-forbidden transitions, because the spin-orbit couplings are significant for excitations inducing the changes in electron distributions. In this study, LC-DFT has been applied to a spin-orbit TDDFT to describe spin-forbidden transitions appropriately by TDDFT. Our results have demonstrated that LC-DFT accurately reproduces the splitting of ionization energies of heavy atoms and spin-forbidden excitation energies for which electrons are moved to widely-distributed orbitals.

Friday, March 25, 2011 8:00AM - 11:00AM –
Session Y25 DCMP: Superconductivity: Mainly HTSC Theory D166

8:00AM Y25.00001 The underdoped cuprates as fractionalized Fermi liquids , EUN GOOK MOON, SUBIR SACHDEV, Harvard University — We model the underdoped cuprates using fermions moving in a background with local antiferromagnetic order. The antiferromagnetic order fluctuates in orientation, but not in magnitude, so that there is no long-range antiferromagnetism, but a 'topological' order survives. The normal state is described as a fractionalized Fermi liquid (FL*), with electron-like quasiparticles coupled to the fractionalized excitations of the fluctuating antiferromagnet. The FL* and its mother state, algebraic charge liquid, reveal interesting features in the underdoped cuprates such as shift of the Fermi pocket center from the magnetic Brillouin zone boundary . Also, with transition to superconductivity, the normal states can explain puzzling experiment data such as a nodal-anti-nodal 'dichotomy' identifying characteristics of the two gaps. Implication of our model and extensions are discussed.

8:12AM Y25.00002 Collective Modes in the Loop Ordered Phase of Cuprates , YAN HE, UC Riverside — We show that the two branches of collective modes discovered recently in under-doped Cuprates with huge spectral weight are a necessary consequence of the loop-current state. Such a state has been shown in earlier experiments to be consistent with the symmetry of the order parameter competing with superconductivity in four families of Cuprates. We also predict a third branch of excitations and suggest techniques to discover it. Using parameters to fit the observed modes, we show that the direction of the effective moments in the ground state lies in a cone at an angle to the c-axis as observed in experiments.

8:24AM Y25.00003 Unconventional superconductivity in honeycomb lattice , YANG QI, Tsinghua University, KAI SUN, University of Maryland, ZHENGCHENG GU, Kavli Institute for Theoretical Physics, LIANG FU, Harvard University — Motivated by results of DMRG and tensor network simulations on doped t-J model on honeycomb lattice, we study superconductivity of singlet and triplet pairing in this model. We show that a coexistence of singlet and triplet pairing superconductivity is induced by antiferromagnetic order near half-filling. The superconducting state we obtain is a topological superconductor.

8:36AM Y25.00004 Superconductivity as a Condensate of Collective Cooper Pairs , CARLOS RAMIREZ, CHUMIN WANG, Instituto de Investigaciones en Materiales, Universidad Nacional Autonoma de Mexico — Along the last century, the fascinating phenomenon of superconductivity has recurrently been considered as a Bose-Einstein condensation (BEC) of Cooper pairs. However, creation and annihilation operators of the Cooper pairs do not satisfy the bosonic commutation relations [1] and then, the superconductivity theories based on the BEC have a weakness in their foundation. In this work, for the dilute limit we prove the bosonic nature of collective Cooper pairs (CCP), defined as linear combinations of Cooper pairs [2]. This bosonic nature is given rise from their diffuse character on the Cooper pairs, which allows the accumulation of many collective pairs at a single quantum state. Moreover, the superconducting ground state proposed by Bardeen, Cooper and Schrieffer (BCS) can be written in terms of these CCP, leading to a possible BEC theory of superconductivity. Finally, the energy spectra of CCP are calculated for a mixture of bosons and fermions, which permit to determine the condensation critical temperature as well as other thermodynamic properties of the CCP condensate.

8:48AM Y25.00005 Self-consistent Eliashberg theory, T_c, and the gap function in electron-doped cuprates , DHANANJAY DHOKARH, ANDREY CHUBUKOV, University of Wisconsin, Madison — We consider normal state properties, the pairing instability temperature, and the structure of the pairing gap in electron-doped cuprates. We assume that the pairing is mediated by collective spin excitations, with antiferromagnetism emerging with the appearance of hot spots. We use a low-energy spin-fermion model and Eliashberg theory up to two-loop order. We justify ignoring vertex corrections by extending the model to $N >> 1$ fermionic flavors, with $1/N$ playing the role of a small Eliashberg parameter. We argue, however, that it is still necessary to solve coupled integral equations for the frequency dependent fermionic and bosonic self-energies, both in the normal and superconducting state. Using the solution of the coupled equations, we find an onset of $d-$wave pairing at $T_c \sim 30$ K. To obtain the momentum and frequency dependent d-wave superconducting gap, $\Delta(\vec{k}_F, \omega_n)$, we derive and solve the non-linear gap equation. We find that $\Delta(\vec{k}_F, \omega_n)$ is a non-monotonic function of momentum along the Fermi surface, with its node along the zone diagonal and its maximum some distance away from it. We obtain $2\Delta_{\max}(T \to 0)/T_c \sim 4$. We argue that the value of T_c, the non-monotonicity of the gap, and $2\Delta_{\max}/T_c$ ratio are all in good agreement with the experimental data on electron-doped cuprates.

9:00AM Y25.00006 Spin-space entangled orbitals in a Hartree-Fock scheme predicting the AF and insulator properties of La2CuO4 , ALEJANDRO CABO MONTES DE OCA, Departamento de Fisica Teorica, Instituto de Cibernetica, Matematica y Fisica, La Habana, Cuba, ALEJANDRO CABO-BIZET, Centro de Estudios Aplicados al Desarrollo Nuclear, La Habana, Cuba — Its is argued that spin-orbit entangled single particle states in a Hartree-Fock scheme can describe the insulator and antiferromagnetic nature of La2CuO4, as independent particle properties. Therefore, a currently considered as a Mott insulator material, is represented as a Slater one. This curious outcome is not strange if we consider that, strictly speaking, correlation quantities should be defined by the differences between the exact result and the "best" Hartree-Fock one. The discussion opens a road for understanding the connections between the successful phenomenological Mott picture and the First Principle (Slater) schemes of calculations. The results also furnish a simple framework for further studying the normal state properties of HTc superconductors. In particular, the microscopic structure of the antiferromagnetic order and the isolator size of the gap in La2CuO4 are both explained as coherent effects coming from the entangled "spin-orbit" structure of the single particle Hartree-Fock states. The possibility of the stability of the isolator gap when temperature rises up to the experimental Neel value is argued to be allowed by the same entanglement effect.

9:12AM Y25.00007 Anomalous Isotope Effect in Low and High Tc Superconductors: the contribution of the electronic structure , G.L. ZHAO, Southern University and A&M College — Some of the low and high Tc superconductors exhibit an anomalous isotope effect, where the exponent (α) for the isotope effect is much smaller than $1/2$. We present first-principles calculations of the electronic structures of the selected superconductors, including Zirconium (Zr) and $YBa_2Cu_3O_7$(YBCO). The characteristically narrow electron bands around the Fermi levels (E_f) in these materials suggest that the rapid variations of the densities of states around E_f, within the range of phonon energy, can have a noticeable effect on the total coupling matrix elements. Such effect may explain the anomalous isotope effect on Tc in these superconductors. The work is funded in part by NSF and the Air Force Office of Scientific Research.

9:24AM Y25.00008 Electronic Specific Heat and Dissipative Viscosity of Hole-Doped Cuprates , PARTHA GOSWAMI, D.B. College, University of Delhi — We investigate a d-density wave (DDW) mean field model Hamiltonian in the momentum space suitable for the hole-doped cuprates, such as YBCO, in the pseudo-gap phase to obtain the Fermi surface(FS)topologies, including the elastic scattering by disorder potential ($|v_0|$). For the chemical potential $\mu = -$ 0.27 eV (at 10% doping level), and $|v_0| \geq |t|$ (where $|t| = 0.25$ eV is the first neighbor hopping), at zero/non-zero magnetic field (B) the FS on the first Brillouin zone is found to correspond to electron pockets around anti-nodal regions and barely visible patches around nodal regions. We next relate our findings regarding FS to the entropy per particle(S), the electronic specific heat C_{el} and the dissipative viscosity (η). The magneto-quantum oscillations in C_{el} are shown to take place in the moderate disorder regime ($|v_0| \sim$0.2 eV) only for B $\sim$ 40 T. For the density of viscosity $\eta(\mathbf{k})$ on the first Brillouin zone, we find that whereas the negative contribution arises from the electron pockets in the anti-nodal region, the positive contributions are from the hole-pockets in the nodal region. The KSS bound ($\eta/S \geq h/4\pi k_B$)is easily satisfied for the moderately strong disorder potential. The viscosity is found to be proportional to the magnetic field up to B $\sim$ 50 T.

9:36AM Y25.00009 The stripe-like collective excitation in cuprates: A variational Monte-Carlo study , CHUNG-PIN CHOU, TING-KUO LEE, Institute of Physics, Academia Sinica — In this study we report variational Monte-Carlo calculations of collective excitations for the extended $t-J$ model. We found a particular collective excitation involving modulation of charge, spin and pair field have a fairly small stiffness constant. These very easily excitable excitations are the same as the stripe-like states observed in our previous results for the $t-J$ model. This anomalous low rigidity from these low-lying collective excitations may provide a better understanding of the ubiquitous nature of the stripe states in cuprates.

9:48AM Y25.00010 Pairing theory of striped superconductivity[1] , SIEGFRIED GRASER, ARNO KAMPF, THILO KOPP, FLORIAN LODER, University of Augsburg — Starting from a pairing Hamiltonian with an attractive interaction for electrons on nearest-neighbor sites on a square lattice we present a Hartree-Fock scheme which allows for spin and charge density order simultaneously with d-wave superconductivity. Specifically for filling 7/8 the stable groundstate solution is a striped superconductor with a stripe wavelength of eight lattice constants and π-shifted order parameters for d-wave pairing and antiferromagnetism. The superconducting state contains Cooper pairs with finite center of mass momenta $\mathbf{q}$ and $-\mathbf{q}$ corresponding to half the wavelength for the stripe pattern of the charge density. Despite the d-wave symmetry of the local pairing amplitude the striped superconductor is fully gapped. We characterize the striped superconducting state in real-space and in momentum space and discuss its possible relevance to $La_{1.875}Ba_{0.125}CuO_4$.

10:00AM Y25.00011 Pair Density Wave correlations in the Kondo-Heisenberg Model[1] , EDUARDO FRADKIN, Department of Physics, University of Illinois, EREZ BERG, Department of Physics, Harvard University, STEVEN KIVELSON, Department of Physics, Stanford University — We show, using density matrix renormalization group calculations complemented by field theoretic arguments, that the spin gapped phase of the one dimensional Kondo-Heisenberg model exhibits quasi-long range superconducting correlations *only* at a non-zero momentum. The local correlations in this phase resemble those of the pair density wave state which was recently proposed to describe the phenomenology of the striped ordered high temperature superconductor $La_{2-x}Ba_xCuO_4$, in which the spin, charge, and superconducting orders are strongly intertwined.

[1]Supported in part by the NSF, under grants DMR- 0758462, DMR-0531196, and DMR-0757145, and by the DOE under Contracts DE-FG02-07ER46453 and DE-FG02-06ER46287

10:12AM Y25.00012 Uniform and pair-Density-Wave SC states in asymmetric ladders[1] , AKBAR JAEFARI, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — We consider the problem of the superconducting state in ladder fermionic systems and focus on two possible types of condensates: a uniform ("d-wave") state and a pair-density wave state (PDW). The uniform SC state is known to occur generically in symmetric hole-doped ladders. Recently it was shown that the PDW state occurs in the Kondo-Heisenberg chain on a broad range of parameters. The Kondo-Heisenberg chain is an extreme version of an asymmetric two-leg ladder. These facts suggest that there must be a quantum phase transition between these two states as a function of the relative doping of the two legs of a ladder. We investigate the nature of this quantum phase transition in the weak coupling limit, by taking advantage of bosonization methods available for 1D systems, and investigate the mechanism of this phase transition. We speculate on the relevance of these results to 2D systems. References: S. R. White, R. M. Noack and D. J. Scalapino: Phys. Rev. Lett 73 (1994) A.E. Sikkema, I. Affleck, and S.R. White, Phys. Rev. 10:24AM Y25.00013 Unconventional superconductivity nearby antiferromagnetism in quasi-1D conductors:the role of electron-phonon interaction , CLAUDE BOURBONNAIS, Departement de physique, Universite de Sherbrooke, Sherbrooke, QC, Canada, J1K-2R1 and Canadian Institute for Advanced Research, Toronto, Canada, HASSAN BAKRIM, Departement de physique, Universite de Sherbrooke, Sherbrooke, QC, Canada, J1K-2R1 — The stabilization of unconventional superconductivity (SCd) close to a spin-density-wave state (SDW) under pressure in organic conductors like the Bechgaard salts points out the primary importance of the repulsive Coulomb term in the origin of these phases. However, the electron-(acoustic) phonon interaction is known to be finite in practice, as borne out for example by diffuse X-ray scattering experiments. The question then arises about the role of this coupling, if any, in the mechanism of interaction between SDW and SCd orders in such materials. In this work, we address this issue using the renormalization group method. This is done in the framework of the quasi-1D electron gas model with repulsive direct Coulomb terms and weak retarded electron-phonon interaction, which are treated on equal footing. The impact of electron-phonon interaction on the SDW and SCd instability lines of the phase diagram and on the strength of spin correlations in the normal phase are analyzed at arbitrary phonon frequency, and discussed in connection with experiments in organic superconductors like the Bechgaard salts.

10:36AM Y25.00014 Resonant alteration of supercurrent in guiding structures with complex de Gennes distance and its magnetic-field-induced restoration , OLEG OLENDSKI, King Abdullah Institute for Nanotechnology — Properties of the superconducting 2D disk and 3D wire are calculated within the framework of linearized Ginzburg-Landau theory with the complex de Gennes distance Λ in the boundary condition. As a result, the self-adjointness of the Hamiltonian is lost, its eigenvalues E become complex too and the discrete bound states of the disk turn into the quasibound states with their lifetime defined by the eigeneneries imaginary parts E_i. Accordingly, the longitudinal supercurrent undergoes alteration with its attenuation/amplification being E_i-dependent too. It is shown that E_i as a function of the de Gennes imaginary part Λ_i exhibits a pronounced sharp extremum with its magnitude being the largest for the zero real part Λ_r of the de Gennes distance. Increasing magnitude of Λ_r quenches the $E_i - \Lambda_i$ resonance and at large Λ_r the eigenenergies E approach the asymptotic real values independent of the de Gennes length imaginary component. The extremum is also wiped out by the applied longitudinal uniform magnetic field. The finite lifetime of the disk quasibound states stems from the Λ_i-induced currents flowing through the superconductor boundary. The effect can be observed in the superconductors by applying to them the external electric field.

10:48AM Y25.00015 A real space study of the effect of disorder on superconductivity , SHREEMOYEE GANGULY, Department of Materials Science, S.N.Bose National Centre for Basic Sciences, JD-III Salt Lake City, Kolkata 700098, India, A.VENKATASUBRAMANIAN TEAM, KARTICK TARAFDER TEAM, INDRA DASGUPTA TEAM, ABHIJIT MOOKERJEE TEAM — Our method of studying the effect of disorder on superconductivity is based on the augmented space formalism that goes beyond mean-field approximations for configuration averaging and effectively deals with the influence of configuration fluctuations of the neighbourood of an atom. In the regime of validity of Anderson's theorem our results for s- and d-wave dirty superconductors has excellent agreement with existing results. The formalism is extended and tested for random negative **U** Hubbard model. Having verified the reliability of our method we use it to study environment dependent, inhomogeneous randomness in disordered superconducting systems. Our model can be easily extended to study multi-band systems which takes us a step closer to studying real materials.

Friday, March 25, 2011 8:00AM - 10:48AM –

Session Y26 DMP DCOMP: Focus Session: Iron Based Superconductors – Orbital Order D162/164

8:00AM Y26.00001 Effect of doping on the crystalline structure and superconductivity properties in $Ca_{1-x}Na_xFe_2As_2$ single crystals[1] , LEONARDO CIVALE, NESTOR HABERKORN, BORIS MAIOROV, MARCELO JAIME, Los Alamos National Laboratory, Los Alamos, NM, USA, G. CHEN, W. YU, Renmin University of China, Beijing, China — We have studied the crystalline structure and the superconducting properties of $Ca_{1-x}Na_xFe_2As_2$ single crystals for various levels of the chemical doping (x). We performed a comparative analysis of the angular dependent $H_{c2}(\Theta)$ (where Θ is the angle between the magnetic field and the c axis) for x$\sim$0.5 and x $\sim$ 0.75, corresponding to $T_c \sim$ 19 K and 33 K, respectively. We found that in both cases $H_{c2}(\Theta)$ near T_c exhibits a single band character with the same anisotropy $\gamma \sim 1.8$. In the crystal with $T_c \sim 33$ K we detected the presence of a narrow vortex-liquid phase, in agreement with the expectation from estimates based on the Lindemann criterion and the Ginzburg number. We also found large and anisotropic flux creep rates, with temperature dependences that indicate glassy relaxation. We analyzed those results in terms of single vortex and collective pinning regimes associated with random and correlated disorder.

8:12AM Y26.00002 First-principles study of orbital-selective magnetism in FeAs-based superconductors , HYUNGJU OH, DONGHAN SHIN, HYOUNG JOON CHOI, Department of Physics and IPAP, Yonsei University — $LaFeAsO_{1-x}F_x$ and related compounds show unconventional superconductivity (SC) in the vicinity of the antiferromagnetism (AFM). These compounds are featured with multiple Fermi surfaces with strong orbital characters. We perform first-principles calculations of the electronic and magnetic properties in LnFeAsO (Ln=La, Ce, Pr, Nd, Sm, and Gd) as a function of Fe magnetic moment to study material-dependent interplay between orbitals and magnetic moments. With this approach, we show orbital-selective magnetic phases in small-Fe-moment regime: d_{xy} magnetic phase, which is itinerantly driven by orbital selection of Fermi-surface nesting, and d_{yz} magnetic phase, which is driven by local interactions. The Fe magnetic moments in the two phases show different coupling strengths to Fermi-surface electrons orbital-selectively, suggesting different roles in SC and in AFM, and making orbital characters of the Fe magnetic moment resolvable by measuring the electronic structures. This work was supported by the NRF of Korea (Grant No. 2009-0081204). Computational resources have been provided by KISTI Supercomputing Center (Project No. KSC-2008-S02-0004)

8:24AM Y26.00003 Orbital characters of the iron-pnictides[1] , DONGLAI FENG, Fudan University — The orbital degree of freedom plays an important role in the physics of iron-based high-temperature superconductors and their parent compounds. For example, possible orbital ordering has been associated with the spin density wave, and we recently found that the superconducting gap sizes are different at the same Fermi momentum for two bands with different spatial symmetries. We studied the orbital characters of the electronic structure in optimally electron-doped $BaFe_{1.85}Co_{0.15}As_2$ by exploiting the polarization-sensitivity of the orbitals in angle resolved photoemission spectroscopy. The orbital characters of the low energy electronic structure and Fermi surface in three dimensional momentum space are determined. Our results indicate that the previous orbital assignments of band structure calculations are just partially correct. Particularly, the contributions of the d_{xy} and d_{x2-y2} orbitals were not right. Our results lay the foundation for constructing realistic microscopic models of iron-based superconductors. Furthermore, we studied the transport properties and electronic structure of magnetically detwinned NaFeAs, and $AEFe_2As_2$. We identify the roles of various orbitals in the spin density wave formation.

8:36AM Y26.00004 Dichotomy between Large Local and Small Ordered Magnetic Moments in Iron-Based Superconductors , PHILIPP HANSMANN, Vienna University of Technology, RYOTARO ARITA, Department of Applied Physics, University of Tokyo, ALESSANDRO TOSCHI, SHIRO SAKAI, GIORGIO SANGIOVANNI, KARSTEN HELD, Institut for Solid State Physics, Vienna University of Technology — We study a four-band model for iron-based superconductors within the local density approximation combined with dynamical mean-field theory (LDA+DMFT). This successfully reproduces the results of models which take As p degrees of freedom explicitly into account and has several physical advantages over the standard five d-band model. Our findings reveal that the new superconductors are more strongly correlated than their single-particle properties suggest. Two-particle correlation functions unveil the dichotomy between local and ordered magnetic moments in these systems, calling for further experiments to better resolve the short time scale spin dynamics.

8:48AM Y26.00005 High-energy x-ray diffraction studies of $AEFe_2As_2$ compounds[1] , D.K. PRATT, A. KREYSSIG, M.G. KIM, S. RAN, A. THALER, S.L. BUD'KO, R.J. MCQUEENEY, P.C. CANFIELD, A.I. GOLDMAN, Ames Laboratory, USDOE and Iowa State University — The relationship between structure, magnetism and superconductivity has become a major theme in studies of the iron arsenide family of superconductors. We have used high-energy x-ray diffraction, together with two-dimensional area detectors, to image large regions of reciprocal space in order to gain further insight into the structural transitions in the $AEFe_2As_2$ (AE = Ca, Sr, Ba) compounds. Here we present results of our study of the impact of annealing and temperature on the structure of these materials.

[1]We thank D. Robinson for his excellent support of the measurements. This work was supported by the Office of Basic Energy Sciences, U.S. Department of Energy.

9:00AM Y26.00006 High Resolution X-ray Scattering Studies of Structural Phase Transitions in $BaFe_{2-x}Cr_xAs_2$, B.D. GAULIN, J.P. CLANCY, J.J. WAGMAN, McMaster University, A.S. SEFAT, Oak Ridge National Laboratory — While the effects of electron-doping on the parent compounds of the 122 family of Fe-based superconductors have been extremely well-studied in recent years, far less is known about the influence of hole-doping in compounds such as $BaFe_{2-x}Cr_xAs_2$. In contrast to the electron-doped 122 systems, the hole-doped compounds do not become superconducting. Furthermore, while the hole-doped compounds exhibit similar structural and magnetic phase transitions, they appear to be much less sensitive to dopant concentration. We have performed high resolution x-ray scattering and magnetic susceptibility measurements on single crystal samples of $BaFe_{2-x}Cr_xAs_2$ for Cr concentrations ranging from $0 \leq x \leq 0.67$. These measurements allow us to determine the magnetic and structural phase transitions for this series and map out the low temperature phase diagram as a function of doping. In particular, we have carried out detailed measurements of the tetragonal (I4/mmm) to orthorhombic (Fmmm) structural phase transition which reveal how the orthorhombicity of the system evolves with increasing Cr concentration and how this correlates with the values of T_s and T_m.

9:12AM Y26.00007 Orbital Order and Spontaneous Orthorombicity in Iron Pnictides[1] , RAJIV SINGH, University of California, Davis — Phase diagram of the Iron Pnictide families of superconductors show a tetragonal to orthorhombic transition, sometimes coincident with the antiferromagnetic phase transition and sometimes at temperatures clearly above the antiferromagnetic phase transition. Inelastic neutron scattering spectra show exchange constants with strong spatial anisotropy. Recent photoemission measurements in mechanically detwinned samples show clear evidence of unequal orbital occupation and strikingly different spectra for dxz and dyz iron orbitals. Scanning Tunneling Microscopy and transport measurements have also shown substantial orthorhombicity in these materials. We discuss a simple microscopic picture for coupled spin and orbital degrees of freedom as the root cause for such an anisotropy and discuss the extent to which this picture can be distinguished from spin-frustration induced Ising nematic fluctuations as being the dominant driver for this phenomena.

9:48AM Y26.00008 Commensurate antiferromagnetic ordering in $Ba(Fe_{1-x}Co_x)_2As_2$ determined by x-ray resonant magnetic scattering at the Fe K edge[1] , M.G. KIM, A. KREYSSIG, Y.B. LEE, Ames Laboratory and Dep. of Physics and Astronomy, Iowa State University, Ames, J.W. KIM, Advanced Photon Source, Argonne National Laboratory, D.K. PRATT, A. THALER, S.L. BUD'KO, P.C. CANFIELD, B.N. HARMON, R.J. MCQUEENEY, A.I. GOLDMAN, Ames Laboratory and Dep. of Physics and Astronomy, Iowa State University, Ames — We describe x-ray resonant magnetic diffraction measurements at the Fe K edge of both the parent $BaFe_2As_2$ and superconducting $Ba(Fe_{0.953}Co_{0.047})_2As_2$ compounds. From these high-resolution measurements we conclude that the magnetic structure is commensurate for both compositions. The energy spectrum of the resonant scattering is in reasonable agreement with theoretical calculation using the full-potential linear augmented plane-wave method with a local density functional. The calculation suggests that the resonant scattering at the Fe K edge in the σ-to-π scattering channel arises from dipole allowed transitions from the core $1s$ states to the unoccupied $4p$ states that are spin polarized due to hybridization with the $3d$ states close to the Fermi energy.

10:00AM Y26.00009 Antiferromagnetic ordering in the absence of a structural distortion in $Ba(Fe_{1-x}Mn_x)_2As_2$[1] , A.I. GOLDMAN, M.G. KIM, A. KREYSSIG, A. THALER, D.K. PRATT, W. TIAN, J.L. ZARESTKY, Ames Laboratory, USDOE and Iowa State University, M.A. GREEN, NIST Center for Neutron Research, S.L. BUD'KO, P.C. CANFIELD, R.J. MCQUEENEY, Ames Laboratory, USDOE and Iowa State University — Neutron and x-ray diffraction studies of $Ba(Fe_{1-x}Mn_x)_2As_2$ for low doping concentrations ($x \leq 0.176$) reveal that at a critical concentration, $0.102 < x < 0.118$, the tetragonal-to-orthorhombic transition abruptly disappears whereas magnetic ordering with a propagation vector of ($1/2$ $1/2$ 1) persists. Among all of the iron arsenides this observation is unique to Mn doping, and unexpected because all models for stripe-like antiferromagnetic order anticipate an attendant orthorhombic distortion due to magnetoelastic effects. We discuss these observations and their consequences in terms of previous studies of $Ba(Fe_{1-x}TM_x)_2As_2$ compounds (TM = transition metal), and models for magnetic ordering in the iron arsenide compounds.

10:12AM Y26.00010 An empirical method to account for spin-fluctuation suppression of magnetism in Fe pnictides , PETER BLAHA, TU Wien, IGOR MAZIN, MICHELLE JOHANNES, Naval Research Laboratory — Parent materials of Fe-based superconductors, such as $BaFe_2As_2$, are itinerant antiferromagnets, and as such should be better described by LDA calculations than are strongly-correlated cuprates. To an extent, this is true, but LDA, being a mean-field approximation, underestimates the suppression of the long-range magnetism due to spin fluctuations. These can be accounted for within Moria's self-consistent renormalization theory, which, however, includes unknown parameters such as the mean amplitude of the spin-fluctuations. We propose to include Moria's renormalization empirically, through a scaling of the LDA exchange-correlation magnetic field by a uniform constant factor, tuned so as to reproduce the observed phase diagram. This is a much more physical method to produce electronic bands with a proper exchange splitting, than adding an artificial "negative-U" term within an LDA+U formalism, a technique used now. We will report the results of such renormalized calculations for $BaFe_2As_2$ and, for comparison, for a prototypical itinerant magnet, $ZrZn_2$.

10:24AM Y26.00011 In-plane resistivity anisotropy in underdoped $Ba(Fe_{1-x}Ni_x)_2As_2$ and $Ba(Fe_{1-x}Cu_x)_2As_2$[1] , HSUEH-HUI KUO, JIUN-HAW CHU, JAMES ANALYTIS, LEO YU, KRISTIAAN DE GREVE, PETER MCMAHON, YOSHIHISA YAMAMOTO, IAN FISHER, Stanford University — Underdoped Fe arsenide superconductors suffer a structural transition that is either coincident with, or precedes the onset of long range antiferromagnetic order. Crystals tend to form a dense array of twins upon cooling through the structural transition, but uniaxial pressure can be used to almost completely detwin samples, enabling measurement of the associated in-plane electronic anisotropy. Initial experiments on detwinned samples of $Ba(Fe_{1-x}Co_x)_2As_2$ revealed a large in-plane resistivity anisotropy which varied non-monotonically with cobalt concentration. Here we present data extending the initial study to include detwinned samples of $Ba(Fe_{1-x}Ni_x)_2As_2$ and $Ba(Fe_{1-x}Cu_x)_2As_2$. The composition-dependence of the resistivity anisotropy ρ_b/ρ_a reveals a striking correlation with that of the Hall coefficient for all three substitution series.

10:36AM Y26.00012 Quasiparticle interference of C_2-symmetric surface states in LaOFeAs parent compound , XIAODONG ZHOU, CUN YE, PENG CAI, Department of Physics, Tsinghua University, Haidian, Beijing 100084, P.R. China, XIANGFENG WANG, XIANHUI CHEN, National Laboratory for Physical Science at Microscale and Dept of Physics, University of Science and Technology of China, Hefei, 230026, P.R. China, YAYU WANG, Department of Physics, Tsinghua University, Haidian, Beijing 100084, P.R. China — We present scanning tunneling microscopy studies on the LaOFeAs parent compound of iron pnictide superconductors [1]. High resolution spectroscopic imaging reveals strong standing wave patterns induced by quasiparticle interference of two-dimensional surface states. Fourier analysis shows that the distribution of scattering wavevectors exhibits pronounced two-fold (C_2) symmetry, strongly reminiscent of the nematic electronic state found in $CaFe_{1.94}Co_{0.06}As_2$ [2]. The implications of these results to the electronic structure of the pnictide parent states will be discussed.

Session Y27 GQI: Focus Session: Semiconductor Qubits- In Search of Majorana C155

8:00AM Y27.00001 Non-Abelian statistics and topological quantum information processing in 1D wire networks , JASON ALICEA, YUVAL OREG, GIL REFAEL, FELIX VON OPPEN, MATTHEW P.A. FISHER — Topological quantum computation provides an elegant way around decoherence, as one encodes quantum information in a non-local fashion that the environment finds difficult to corrupt. Here we establish that one of the key operations—braiding of non-Abelian anyons—can be implemented in one-dimensional semiconductor wire networks. Previous work [Lutchyn et al., arXiv:1002.4033 and Oreg et al., arXiv:1003.1145] provided a recipe for driving semiconducting wires into a topological phase supporting long-sought particles known as Majorana fermions that can store topologically protected quantum information. Majorana fermions in this setting can be transported, created, and fused by applying locally tunable gates to the wire. More importantly, we show that networks of such wires allow braiding of Majorana fermions and that they exhibit non-Abelian statistics like vortices in a p+ip superconductor. We propose experimental setups that enable the Majorana fusion rules to be probed, along with networks that allow for efficient exchange of arbitrary numbers of Majorana fermions. This work paves a new path forward in topological quantum computation that benefits from physical transparency and experimental realism.

8:12AM Y27.00002 Majorana fermions in nanowires without gating superconductors[1] , CHIEN-HUNG LIN, HOI YIN HUI, JAY SAU, SANKAR DAS SARMA, Condensed Matter Theory Center and Joint Quantum Institute, Department of Physics, University of Maryland, College Park, Maryland 20742-4111, USA — Majorana fermions have been proposed to be realizable at the end of the semiconductor nanowire on top of an s-wave superconductor [1,2]. These proposals require gating the nanowire directly in contact with a superconductor which may be difficult in experiments. We analyze [1,2] in configurations where the wire is only gated away from the superconductor. We show that some signatures of the Majorana mode remain but the Majorana mode is not localized and hence not suitable for quantum computation. Therefore we propose an 1D periodic heterostructure which can support localized Majorana modes at the end of the wire without gating on the superconductor.

8:24AM Y27.00003 Effects of Interactions on a Topological Phase Exhibiting Majorana Fermions in Quantum Wires , MILES STOUDENMIRE, JASON ALICEA, UC Irvine — The ability to create and manipulate Majorana fermions in condensed matter systems is not only of fundamental interest for understanding topological phases but also provides a realistic route toward quantum computation. Recently, a series of devices have been proposed that could realize exotic Majorana physics in relatively conventional settings; among the most promising is a superconducting wire system with strong spin-orbit coupling. Because superconducitivity is induced in this system by proximity effect, the system remains superconducting even with net repulsive interactions. The effects of such interactions on this system have until now remained unexplored. Using the Density Matrix Renormalization Group method, we explore the fate of the topological phase in the presence of interactions. Obtaining a matrix product state representation of the degenerate ground states is especially helpful as it allows us to determine detailed properties of the Majorana edge states. Furthermore, we find that interactions significantly expand the topological region of the phase diagram, a result which strengthens proposals to realize Majorana fermions in such wire systems experimentally.

8:36AM Y27.00004 The exchange statistics of Majorana fermions in quasi-one-dimensional networks , DAVID J. CLARKE, University of California, Riverside, JAY D. SAU, University of Maryland, College Park, SUMANTA TEWARI, Clemson University — Under appropriate external conditions a semiconductor with strong spin-orbit coupling in proximity to an s-wave superconductor can be in a topological superconducting (TS) phase. In the topological phase, various defects of the order parameter trap zero energy excitations called Majorana bound states. In a wire geometry the relevant defects are the two ends of the topological region, and each traps a localized zero energy excitation. A network of such wires allows the pairwise exchange of the Majorana bound states. Alicea et al. have shown that these bound states obey non- Abelian exchange statistics, and have proposed [1] such a system as a platform for topological quantum computation (TQC). Here we show that the particular realization of non- Abelian statistics produced in a Majorana wire network is highly dependent on the local properties of individual wire junctions. For a simply connected network, the possible realizations can be characterized by the chirality of individual junctions. We demonstrate how this chirality may be calculated for a particular junction. There is in general no requirement for junction chiralities to remain consistent across a wire network. Careful control of the junction chirality is required for TQC applications of Majorana wire networks. [1] J. Alicea et al., arXiv:1006.4395.

8:48AM Y27.00005 Interferometry and topological quantum computation using Majorana Fermions at semiconductor/superconductor interfaces[1] , JAY SAU, CMTC, Dept of Physics, University of Maryland, College Park, SUMANTA TEWARI, Dept of Physics, Clemson Unversity, South Carolina, SANKAR DAS SARMA, CMTC, Dept of Physics, University of Maryland, College Park — Majorana Fermions are hitherto unobserved exotic Fermionic excitations, which are their own anti-particles. Recently, a lot of excitement has been generated by proposals to realize Majorana fermions in topological superconductors in a rather general class of topological superconductors, some of which may be as simple as the interface 1D or 2D InAs and Al in the appropriate parameter regime might have exotic topological properties and Majorana Fermions [1]. In my talk, I will discuss recent proposals for performing interferometry in 2D and 1D versions of such systems [2] together with ideas for performing Quantum Computation [3] using such robust Majorana fermion based qubits.

9:00AM Y27.00006 Topological Phases in Dissipative Quantum Transport , MARK RUDNER, Harvard, MICHAEL LEVIN, Maryland, LEONID LEVITOV, MIT — Recently, a new type of topological quantization was discovered in dissipative quantum transport on a one dimensional bipartite lattice with decay [1]. The transition between distinct topological phases is accompanied by a discontinuous change in the expected displacement covered by a particle before it decays. Here we show that this behavior extends to a much wider family of models, and provide a prescription for computing the topological invariant which distinguishes all of the phases which arise in the general case. When the underlying hopping problem without decay possesses time reversal symmetry, we show that the expected displacement, averaged with respect to all initial states, is quantized. The topological nature of this phenomenon, which is unique to systems with decay, places it on a similar footing as other robust topological phenomena such as the quantization of the Hall conductance [2], or of the adiabatically-pumped charge in periodically-driven 1D systems [3]. Correspondingly, here we find that quantization is robust against a range of perturbations and certain types of decoherence. Similarities and differences with the phases of one-dimensional topological insulators will be discussed. [1] M. S. Rudner and L. S. Levitov, Phys. Rev. Lett. 102, 065703 (2009). [2] D. J. Thouless, M. Kohmoto, M. P. Nightingale, and M. den Nijs, Phys. Rev. Lett. 49, 405 (1982). [3] D. J. Thouless, Phys. Rev. B 27, 6083 (1983).

9:12AM Y27.00007 Counting Majorana zero modes in superconductors , LUIZ SANTOS, Harvard University, YUSUKE NISHIDA, MIT, CLAUDIO CHAMON, Boston University, CHRISTOPHER MUDRY, PSI, Switzerland — We present a counting formula for computing the number of (Majorana) zero modes bound to topological point defects. The counting formula is evaluated in a gradient expansion for systems with charge-conjugation symmetry. We will consider examples that include Dirac fermions and the chiral p-wave superconductor in two-dimensional space. In all cases, we explicitly relate the counting of zero modes to Chern numbers.

9:24AM Y27.00008 Non-Abelian order in s-wave superconductors: Phases and quantum transitions[1] , SUMANTA TEWARI, Physics & Astronomy, Clemson University, Clemson, SC, TUDOR STANESCU, Department of Physics, West Virginia University, Morgantown, WV, JAY SAU, Condensed Matter Theory Center, Dept. of Physics, University of Maryland, College Park, MD, PARAG GHOSH, Dept. of Physics and Astronomy, George Mason University, Fairfax, VA, SANKAR DAS SARMA, Condensed Matter Theory Center, Dept. of Physics, University of Maryland, College Park, MD — Non-Abelian topological superconductivity has been predicted to occur in s-wave superconductors with a sizable spin-orbit (SO) coupling. As is now well known, such a system can be used for topological quantum computation. When an external Zeeman splitting crosses a critical value, the system passes from a regular, non-topological, superconducting phase to a topological one. On the other hand, in the absence of SO coupling this critical value corresponds to the Zeeman splitting above which the system loses its s-wave superconductivity. We are thus led to the paradoxical conclusion that the topological superconducting phase appears in a parameter regime at which the system actually is non- superconducting in the absence of SO coupling. In this work we resolve this paradox.

9:36AM Y27.00009 Induced Chiral f-wave Superconducting Pairing and Majorana Fermions in a Hole-doped Semiconductor[1] , CHUANWEI ZHANG, LI MAO, Department of Physics and Astronomy, Washington State University, Pullman, Washington, 99164 USA, JUNREN SHI, International Center for Quantum Materials, Peking University, Beijing 100871, China, QIAN NIU, Department of Physics, The University of Texas, Austin, Texas 78712 USA — We show that a chiral f + if-wave superconducting pairing may be induced in the lowest heavy hole band of a hole-doped semiconductor thin film through proximity contact with an s-wave superconductor. The chirality of the pairing originates from the 3π Berry phase accumulated for a heavy hole moving along a close path on the Fermi surface. There exist three chiral gapless Majorana edge states, in consistence with the chiral f + if-wave pairing. We show the existence of zero energy Majorana fermions in vortices in the semiconductor-superconductor heterostructure by solving the Bogoliubov-de-Gennes equations numerically as well as analytically in the strong confinement limit. The proposed semiconductor/superconductor heterostructure can be used as a platform for observing non-Abelian statistics and performing TQC.

9:48AM Y27.00010 Anyonic entanglement renormalization , ROBERT KOENIG, ERSEN BILGIN, Institute for Quantum Information, Caltech — We introduce a family of variational ansatz states for chains of anyons which optimally exploits the structure of the anyonic Hilbert space. This ansatz is the natural analog of the multi-scale entanglement renormalization ansatz for spin chains. In particular, it has the same interpretation as a coarse-graining procedure and is expected to accurately describe critical systems with algebraically decaying correlations. We numerically investigate the validity of this ansatz using the anyonic golden chain and its relatives as a testbed. This demonstrates the power of entanglement renormalization in a setting with non-abelian exchange statistics, extending previous work on qudits, bosons and fermions in two dimensions.

10:00AM Y27.00011 Protected phase gates for superconducting qubits , PETER BROOKS, JOHN PRESKILL, California Institute of Technology — Quantum systems with inherent error-correcting properties offer a powerful tool for building quantum computers to be insensitive to the effects of errors. Kitaev [arXiv:cond-mat/0609441] has proposed an intrinsically fault-tolerant qubit design based on superconducting systems. The phase gate $\Lambda(i)$ in this system is performed by coupling the qubit to a quantum LC oscillator for a period of time. The evolution of the oscillator can be understood as being protected by a family of continuous variable quantum codes at every point in its evolution, providing natural robustness against random variations in the duration and strength of the coupling. We present the results of numerical simulations of this system which investigate the fidelity of the phase gate operation as a function of the duration mistiming. We discuss the robustness of the gate under the effect of anharmonic perturbations to the oscillator and oscillator coupling, and adiabaticity requirements for this scheme to properly function.

10:12AM Y27.00012 Resilience of Topological Codes to Depolarization , RUBEN S. ANDRIST, Department of Physics, ETH Zurich, HECTOR BOMBIN, Perimeter Institute for Theoretical Physics, MIGUEL ANGEL MARTIN-DELGADO, Departamento de Fisica, Universidad Complutense, HELMUT G. KATZGRABER, Department of Physics, Texas A&M University & ETH Zurich — Standard error correction is based on redundant storage of quantum information. However, in topological quantum error correction decoherence effects are prevented by encoding logical qubits in nonlocal degrees of freedom, while actively correcting for errors that occur locally in the system. Previous studies have shown that the two hallmark topological codes—the toric code and color codes—are stable against bit-flip/phase-flip and measurement errors. In this work we study the effects of the depolarizing channel to both the toric code and topological color codes. By mapping the quantum problem onto a disordered statistical-mechanical 8-vertex model we compute the error tolerance of these systems using large-scale Monte Carlo simulations. Our results show that the error threshold increases significantly for both the toric code and color codes.

10:24AM Y27.00013 Local equivalence of topological order: Kitaev's code and color codes , GUILLAUME DUCLOS-CIANCI, Universite de Sherbrooke, HECTOR BOMBIN, Perimeter Institute for Theoretical Physics, DAVID POULIN, Universite de Sherbrooke — We demonstrate that distinct topological codes can be mapped onto each other by local transformations. The existence of such a local mapping can be interpreted as saying that these codes belong to the same topological phase. When used as quantum error correcting codes, the local mapping also enables us to use any decoding algorithm suitable for one of these codes to decode other codes in the same topological phase. We illustrate this idea with the topological color code and the topological subsystem color code that are found to be locally equivalent to two copies of Kitaev's toric code. We are therefore able to decode these two codes that had no previously known efficient decoding algorithm, and find error thresholds comparable to previously estimated optimal values. These local mappings could have additional use for fault-tolerant quantum computation. In particular, one could in principle take advantage of the features (transversal gates, topological gates, etc.) of all the codes that are locally equivalent by switching between them during the computation in a fault-tolerant fashion.

10:36AM Y27.00014 Exactly solvable 3D quantum model with finite temperature topological order , ISAAC KIM, Institute of Quantum Information — We present a family of exactly solvable spin-$\frac{1}{2}$ quantum hamiltonians on a 3D lattice. The degenerate ground state of the system is characterized by a quantum error correcting code whose number of encoded qubits are equal to the second Betti number of the manifold. These models 1) have solely local interactions 2) admit a strong-weak duality relation with an Ising model on a dual lattice 3) have topological order in the ground state, some of which survive at finite temperature. The associated quantum error correcting codes are all non-CSS stabilizer codes.

10:48AM Y27.00015 Universal Behavior of Entanglement in 2D Quantum Critical Dimer Models , BENJAMIN HSU, EDUARDO FRADKIN, UIUC — We examine the scaling behavior of the entanglement entropy for the 2D quantum dimer model (QDM) at criticality and derive the universal finite sub-leading correction γ_{QCP}. We compute the value of γ_{QCP} without approximation working directly with the wave function of a generalized 2D QDM at the Rokhsar-Kivelson QCP in the continuum limit. Using the replica approach, we construct the conformal boundary state corresponding to the cyclic identification of n-copies along the boundary of the observed region. We find that the universal finite term is $\gamma_{QCP} = \ln R - 1/2$ where R is the compactification radius of the bose field theory quantum Lifshitz model, the effective field theory of the 2D QDM at quantum criticality. We also demonstrated that the entanglement spectrum of the critical wave function on a large but finite region is described by the characters of the underlying conformal field theory. It is shown that this is formally related to the problems of quantum Brownian motion on n-dimensional lattices or equivalently a system of strings interacting with a brane containing a background electromagnetic field and can be written as an expectation value of a vertex operator.

Friday, March 25, 2011 8:00AM - 11:00AM –

Session Y29 GQI: Focus Session: Superconducting Qubits - Coherence and Materials II C148

8:00AM Y29.00001 Investigating decoherence in the transmon qubit using a 3D resonator[1] , HANHEE PAIK, D.I. SCHUSTER[2], L. BISHOP[3], A.P. SEARS, G. KIRCHMAIR, L. FRUNZIO, M.H. DEVORET, R.J. SCHOELKOPF, Yale University — We studied the coherence times of transmon qubits using three-dimensional resonators. The three-dimensional (3D) superconducting resonant cavity is machined with aluminum alloy, whose quality factor is higher than 5 million at 10 mK inside a magnetic shield. The transmons are fabricated on sapphire substrates whose internal Q was not lower than 2 million when evaluated in the 3D resonator. We measured the relaxation and dephasing times of the qubits and were able to draw a lower bound on these numbers.

8:12AM Y29.00002 Decoherence in Improved Transmon Qubits , ADAM SEARS, HANHEE PAIK, DAVID SCHUSTER, LEV BISHOP, GERHARD KIRCHMAIR, LUIGI FRUNZIO, MICHEL DEVORET, ROB SCHOELKOPF, Yale University — The transmon is a simple superconducting qubit which has less dependence on the usual sources of 1/f noise, and has coherence which is mostly limited by a source of anomalous dissipation. The quality factors of transmon qubits on sapphire are observed to be $\sim$ 50,000, similar to that of transmission line resonators made with the same geometry. It is likely that both these devices may be limited by surface dielectric losses. We will report on the design and characterization of transmon qubits which are fabricated with reduced dielectric losses to possibly increase coherence times.

8:24AM Y29.00003 Measurements of quasiparticle tunneling rate in a superconducting transmon qubit , LUYAN SUN, Departments of Physics and Applied Physics, Yale University, LEONARDO DICARLO, MATTHEW REED, LEV BISHOP, TERRI YU, GIANLUIGI CATELANI, LEONID GLAZMAN, LUIGI FRUNZIO, MICHEL DEVORET, ROBERT SCHOELKOPF, Departments of Physics and Applied Physics, Yale University — A practical quantum computer requires qubits with long coherence times in order to perform many quantum gates. For a superconducting qubit, non-equilibrium quasiparticle tunneling is one possible source of decoherence. Spectroscopy measurements of a superconducting transmon qubit can be used to set a bound on the quasiparticle tunneling rate. When operated in the low E_J/E_C regime, the transmon qubit transition frequency switches between two well-resolved branches due to quasiparticle tunneling. A selective π pulse applied to one of these two branches can excite the qubit only if the qubit is at that frequency. Thus by repeatedly applying π pulses to interrogate the qubit state, the quasiparticle dynamics can be studied. We will present our results on the quasiparticle tunneling rate in a transmon qubit.

8:36AM Y29.00004 Dynamical decoupling and noise spectroscopy with a superconducting flux qubit , JONAS BYLANDER, SIMON GUSTAVSSON, FEI YAN, Massachusetts Institute of Technology, FUMIKI YOSHIHARA, KHALIL HARRABI, Institute of Physical and Chemical Research RIKEN, DAVID CORY, MIT and University of Waterloo, YASUNOBU NAKAMURA, JAW-SHEN TSAI, RIKEN and NEC Corporation, WILLIAM D. OLIVER, MIT Lincoln Laboratory — We demonstrate dynamical decoupling in a superconducting flux qubit with a long energy-relaxation time, $T_1 = 12\,\mu$s. Low-frequency noise acts to dephase the qubit, reducing its transverse coherence time T_2. At the noise-optimal bias point we observe a free-induction decay time $T_2^* = 2.5\,\mu$s and T_1-limited spin-echo decay, $T_{2E} = 2\,T_1$. Biased away from this point, the increased sensitivity to flux noise leads to increased echo and free-induction decay rates. We moderate the dephasing effects of this noise by applying dynamical-decoupling sequences with up to 200 π-pulses. Using the CPMG sequence, we achieve a more than 50-fold enhanced decay time over T_2^*, and Gaussian pure-dephasing times $T_\varphi > 100\,\mu$s. We use the filtering property of this pulse sequence to facilitate spectroscopy of the environmental noise and reconstruct its $1/f$ power spectral density, which we independently confirm by a Rabi-spectroscopy approach. We characterize the noise sources coupling to the energy-bias and tunnel-coupling terms of the Hamiltonian.

8:48AM Y29.00005 Multi-mode circuit quantum electrodynamics , JEROME BOURASSA, Universite de Sherbrooke, JAY M. GAMBETTA, IQC and University of Waterloo, ALEXANDRE BLAIS, Universite de Sherbrooke — In circuit QED experiments with low anharmonicity superconducting qubits, like the transmon, it has been shown how the many-level structure of the qubits can give rise to non-trivial effects. Examples are the straddling regime [1] and high-power qubit readout induced by qubit nonlinearities [2]. In the same spirit, there are also clear experimental evidences to the effect that higher resonator modes play an important role in setting the size of the qubit-qubit flip-flop interaction mediated by virtual resonator photons [3] and the qubit decay rate due to the Purcell effect [4]. In this talk we explore how these higher modes can be taken into account in a theoretical description of the system, and how they affect the flip-flop and Purcell decay rates.

9:00AM Y29.00006 Dissipation in the ultra-strong coupling regime , FELIX BEAUDOIN, Universite de Sherbrooke, JAY GAMBETTA, Institute for Quantum Computing, University of Waterloo, ALEXANDRE BLAIS, Universite de Sherbrooke — It has recently been shown that the ultra-strong coupling regime, in which the rotating-wave approximation breaks down, can be obtained using a flux qubit coupled to a transmission line [1]. This regime has been observed experimentally in [2, 3]. We will show the usual quantum optics master equation fails in this context and give a more accurate one. We will also explain how non-trivial properties of the ground state could be experimentally studied.

9:12AM Y29.00007 Strong frequency dependence of coupling of a Cooper- pair box qubit to Quantum Noise , B. SURI, Dept.of Phys., Univ.of MD., Z. KIM, Dept.of Phys., Univ. of MD., V. ZARETSKEY, S. NOVIKOV, Dept. of Phys., Univ. of MD., K.D. OSBORN, A. MIZEL, Lab. for Physical Sciences, B.S. PALMER, Lab.for Physical Sciences, F.C. WELLSTOOD, Dept. of Phys., Univ. of MD., JQI, CNAM — Our system consists of an Al/AlO_x/Al Cooper-pair box (CPB) charge qubit coupled to a lumped element resonator, which in turn is coupled to a transmission line. From the measured Rabi frequency, for a given microwave frequency f and amplitude in the transmission line, we can extract the coupling of qubit to the transmission line. We observe an order of magnitude variation in this coupling over the range of $f = 4$ to 8GHz which is in agreement with the variation of our measured lifetimes. Assuming that our qubit is coupled directly to a 50Ω impedance with the measured coupling, we find that for $f = 6$ to 7 GHz the lifetime of 30μs measured at the charge sweet spot can be well explained by quantum noise. At $f = 4$GHz, we observe an order of magnitude weaker coupling and a T_1 of 200μs .

9:24AM Y29.00008 Dephasing Measurements of a Cooper-pair box , VITALEY ZARETSKEY, Dept. of Physics, Univ. of Maryland, S. NOVIKOV, B. SURI, Z. KIM, Dept. Of Physics, Univ. Of Maryland, F. C. WELLSTOOD, JQI, CNAM, Dept. of Physics, Univ. of Maryland, B. S. PALMER, Lab. For Physical Sciences — We present data on the dephasing properties of our Al/AlO_X/Al Cooper-pair box (CPB) qubit. The CPB had a charging energy E_C/h = 6.25 GHz and a maximum E_J/h = 19 GHz which was decreased by an external magnetic field to an effective E_J/h of 6.1 GHz. The qubit was capacitively coupled to a lumped element microwave resonator ($f_0 = 5.446$ GHz, $Q_L = 1.8 \times 10^4$) which was in turn coupled to a transmission line. To manipulate the qubit, a microwave pulse at 6.1 GHz was sent to the transmission line. The state of the qubit was then measured by sending a second microwave pulse at f_0 and measuring the amplitude and phase of the transmitted power. We observed Rabi oscillations with Rabi frequencies from 1.94 to 5.32 MHz decay with time constants in the range T' = 0.6 to 1.6 μs. We measured an inhomogeneous dephasing time (T_2*) of 322 ns by performing a Ramsey fringe experiment. Assuming $1/f$ charge noise is the dominant dephasing mechanism we extracted a $1/f$ charge noise amplitude of $1.6\times10^{-3}e/\sqrt{Hz}$ at 1 Hz.

9:36AM Y29.00009 Improved T2 in Josephson Phase Qubits , DANIEL SANK, RAMI BARENDS, RADOSLAW BIALCZAK, YU CHEN, JULIAN KELLY, MICHAEL LENANDER, ERIK LUCERO, MATTEO MARIANTONI, MATTHEW NEELEY, AARON O'CONNELL, PETER O'MALLEY, AMIT VAINSENCHER, HOAHUA WANG, MARTIN WEIDES, JAMES WENNER, THEODORE WHITE, YI YIN, JIAN ZHAO, ANDREW CLELAND, JOHN MARTINIS, UCSB — Phase qubit gate fidelities are limited by individual device dephasing times (T2). Reduction of dephasing is therefore an important immediate goal for phase qubit experiments. A simple way to reduce dephasing is to increase the device loop inductance in order to lower the noise currents driven by magnetic flux noise; T2 should scale linearly with loop inductance. Surface spin models for flux noise also predict that wider loop traces should reduce the noise. We present data on T2 for phase qubits with varied loop inductance and trace width. We present data from experiments in which we find that doubling the loop inductance increases T2 by 25%.

9:48AM Y29.00010 Evidence for coherent quantum phase slips from dephasing of fluxonium qubit[1] , ARCHANA KAMAL, NICHOLAS MASLUK, Yale University, VLADIMIR MANUCHARYAN, Harvard University, JENS KOCH, Northwestern University, LEONID GLAZMAN, MICHEL DEVORET, Yale University — Phase slips are events in which the phase across a superconducting wire changes by 2π. The thermally activated phase slips at high temperatures are well understood but the coherent phase slips caused by quantum fluctuations well below the critical temperature have, so far, eluded observation. We report new decoherence data for the fluxonium qubit [1] that provide evidence for coherent quantum phase slips across the qubit inductance, implemented with a long array of Josephson tunnel junctions. Coherent quantum phase slips result in broadening of the qubit transition frequency due to Aharonov-Casher interference of multiple phase slip paths (or flux tunneling through different junctions) encircling random offset charges on array islands [2].

10:00AM Y29.00011 Relaxation mechanisms of the fluxonium qubit[1] , NICHOLAS MASLUK, ARCHANA KAMAL, Yale University, VLADIMIR MANUCHARYAN, Yale University, Harvard University, JENS KOCH, Northwestern University, LEONID GLAZMAN, MICHEL DEVORET, Yale University — Fluxonium is a highly anharmonic artificial atom, which utilizes an inductance formed by an array of large Josephson junctions to shunt the junction of a Cooper-pair box. The first excited state transition frequency is widely tunable with flux, yet can be read out over the entire five octave range due to interactions of the 2nd excited state with the readout cavity, enabling a dispersive readout. We present T1 times of several fluxonium samples over the full range of flux dependent transition energies. By mapping out the qubit lifetimes we are able to distinguish between the contributions due to the Purcell effect and quantify dissipation internal to the qubit. With this understanding, we can design a qubit with minimized contribution from internal losses, which should push lifetimes further into the tens of microseconds. [1] V. E. Manucharyan et al., Science 326, 113 (2009).

10:12AM Y29.00012 1/f noise and susceptibility-magnetization correlation in disordered ferromagnets[1] , KOSTYANTYN KECHEDZHI, Rutgers, The State University of New Jersey — We consider a strongly disordered ferromagnet modeled by Ising spins placed at random in 2D with ferromagnetic interactions decaying exponentially with inter-site distance. Ferromagnetic phase in this model arises due to formation of infinite percolation cluster of strongly interacting spins. Fractal nature of the percolation cluster manifests itself in the dynamics of the system in the vicinity of the percolation transition. Simulating the dynamics with single spin flip Monte Carlo algorithm we observe 1/f power spectra of magnetization noise in a wide temperature range near the transition. Subjected to external AC magnetic field the system shows significant cross-correlation between susceptibility and magnetization in the ferromagnetic phase. This results suggest a possible explanation of the inductance-flux cross-correlation recently observed in SQUIDs [1].

10:24AM Y29.00013 Are "pinholes" the cause of excess current in superconducting tunnel junctions? A study of Andreev current in highly resistive junctions[1] , MARKKU STENBERG, TINE GREIBE, CHRISTOPHER WILSON, THILO BAUCH, VITALY SHUMEIKO, PER DELSING, Chalmers University of Technology — In highly resistive superconductor—insulator—superconductor (SIS) and superconductor—insulator—normal-metal (SIN) junctions, "excess" subgap current is usually observed. We have studied subgap conductance in Al/AlO_x/Al and Al/AlO_x/Cu tunnel junctions. In the former, we observed a huge (two orders of magnitude) decrease in subgap conductance upon the transition from the SIS to the SIN regime. In the latter, we observed several signatures of coherent diffusive two-particle transport. We use the quasiclassical Keldysh-Green function theory to quantify the contributions of the single- and two-particle processes on subgap conductance. Our observations indicate insignificance of highly transparent microscopic defects ("pinholes") in the tunneling barrier, and we therefore argue that the common "pinhole" scenario is not the explanation for the observed excess subgap current in SIS tunnel junctions.

[1]This research was partly funded by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA), through the Army Research Office.

10:36AM Y29.00014 Critical current noise and junction resonators in Josephson junction from interacting trap states , MOHAMMAD H. ANSARI, Institute for Quantum Computing, IQC and University of Waterloo, FRANK K. WILHELM-MAUCH, Institute for Quantum Computing, IQC and University of Waterloo — We analyze the impact of trap states in the oxide layer of superconducting tunnel junctions on the fluctuation of the Josephson current. These are known to inhibit the coherent operation of superconducting qubits. These have a twofold effect: Occupying trap states blocks out parts of the critical current of the Josephson junction. Electrons can also cross the junction via hopping across a trap. We are extending previous studies of noninteracting traps to the case where the traps have on-site electron repulsion. We use second order perturbation theory which allows to obtain analytical results but limited to small and intermediate repulsion. Remarkably, it still reproduces the main features of the model as identified from the Numerical Renormalization group. We present analytical formulations for the subgap bound state energies, the singlet-doublet phase boundary, and the spectral weights, which are in agreement with recent Numerical Renormalization Group analysis. We show that interactions can reverse the supercurrent across the trap. We finally work out the resonance noise spectrum in the presence of on-site repulsive electrons and suggest a criteria for the fabrication of parameters that may help to suppress low frequency noise from superconducting quantum computation devices.

10:48AM Y29.00015 Energy relaxation mechanisms in capacitively shunted flux qubits , ANTONIO CORCOLES, JIM ROZEN, MARY BETH ROTHWELL, GEORGE KEEFE, DAVID DI VINCENZO, MARK KETCHEN, JERRY CHOW, CHAD RIGETTI, JACK ROHRS, MARK BORSTELMANN, MATTHIAS STEFFEN, IBM, IBM QUANTUM COMPUTING GROUP TEAM — Energy losses in superconducting qubits remain a major object of study in the road towards scalable, highly coherent qubit devices. The current understanding of the loss mechanisms in these devices is far from being complete and it is sometimes difficult to experimentally separate the different contributions to decoherence. Here we compare a traditional three Josephson-junction flux qubit to the recently implemented capacitively shunted flux qubit [1], whose energy decay is thought to be limited by dielectric losses arising from native oxides in the shunting capacitor. Keeping all parameters identical except for the shunting capacitance, we obtain energy relaxation times that are comparable for both types of qubit. This suggests that the energy relaxation time is not limited by junction losses in capacitively shunted flux qubits. We discuss some other possible loss mechanisms present in these devices.

8:00AM Y30.00001 Apparent Power-Law Behavior of Conductance in Disordered Quasi-One-Dimensional Systems[1] , ALEKSANDR RODIN, MICHAEL FOGLER, UCSD — Observation of power-law dependence of conductance on temperature and voltage has been reported for a wide variety of low-dimensional systems(nano-wires, nano-tubes, and conducting polymers). This behavior has been attributed to the Luttinger liquid effects expected in a pure one-dimensional wire. However, the systems studied were neither one-dimensional nor defect-free. Using numerical simulations we show that the power-law behavior can arise from variable-range hopping in an ensemble of non-interacting disordered wires connected in parallel. This power-law behavior holds in restricted ranges of voltage and temperature, typical of experimental situations. Physically, it comes from rare, but highly conducting hopping paths that appear by chance in some members of the ensemble. The power-law exponents and their dependence on system parameters are consistent with the great majority of available empirical data.

8:12AM Y30.00002 Equilibration of a One-Dimensional Wigner Crystal , K.A. MATVEEV, Argonne National Laboratory, A.V. ANDREEV, University of Washington, M. PUSTILNIK, Georgia Institute of Technology — Equilibration of a one-dimensional system of interacting electrons requires processes that change the numbers of left- and right-moving particles. At low temperatures such processes are strongly suppressed, resulting in slow relaxation towards equilibrium. We study this phenomenon in the case of spinless electrons with strong long-range repulsion, when the electrons form a one-dimensional Wigner crystal. We find the relaxation rate by accounting for the umklapp scattering of phonons in the crystal. For the integrable model of particles with inverse-square repulsion, the relaxation rate vanishes. We apply our results to calculation of the correction to the conductance of a long quantum wire due to the equilibration processes.

8:24AM Y30.00003 STM images of carbon-nanotube quantum dots: Seeing a Wigner molecule of correlated electrons , ANDREA SECCHI, MASSIMO RONTANI, CNR-NANO S3 and University of Modena, Italy — The paradigm of few-electron complexes in quantum dots (QDs) relies on the idea that the lowest quantized levels are filled according to Pauli's exclusion principle. If Coulomb repulsion is sufficiently strong to overcome the kinetic energy cost of localization, a different scenario is predicted: a "Wigner" molecule (WM) forms, made of electrons frozen in space according to a geometrical pattern. Despite considerable experimental effort, evidence of the WM in semiconductor QDs has been elusive so far. Here we demonstrate theoretically that WMs occur in gate-defined QDs embedded in typical semiconducting carbon nanotubes (CNTs). The unambiguous signatures of the WM state must be searched in the scanning tunneling microscopy (STM) images of the electrons. Through exact diagonalisation (ED) calculations, we unveil the inherent features of the electron molecular states. We show that, like nuclei in a usual molecule, electrons have localized wave functions and hence negligible exchange interactions. ED results for single and double QDs provide a simple interpretation for transport experiments in ultraclean CNTs.

8:36AM Y30.00004 All-Semiconducting nanotube networks Thin Film Transistors: An insight towards High Performance Printed Nanoelectronics , DHEERAJ JAIN, NIMA ROUHI, KATAYOUN ZAND, PETER BURKE, University of California, Irvine — In this work, we present our progress towards devices fabrication using all semiconducting nanotubes as the starting material. A critical issue is the ink formulation and dependence of electronic properties on the nanotube density after deposition. These are some of the first spin-on, all semiconducting nanotube devices ever made and initial results are quite promising for printed RF electronics. Semiconducting single-walled nanotube (99%) ink was used to deposit nanotube network on APTES modified Si/SiO_2 substrate. Following the nanotube deposition, source and drain electrodes (Pd/Au) were deposited using standard photolithography and E-beam evaporation. The Si wafer was used for back gating and SiO_2 as the gate dielectric. The impact of density of nanotube was studied for 3 random densities. We also studied the effect of gate length on mobility, and on/off ratio, for devices with different gate lengths ($10\sim100$ μm). DC characterization of devices shows a high mobility, up to 40 cm^2/V-s, and good on/off ratio up to the order of 10^4 in some cases. Since we are using 99% semiconducting ink, a high on/off ratio is expected, which is true in our devices. The on/off ratio of more than 1000 and mobilities up to $\sim$40 cm^2/V-s were observed in almost all devices.

8:48AM Y30.00005 Spin-valley blockade and electron valley resonance in carbon-based quantum dots , GUIDO BURKARD, ANDRAS PALYI[1], University of Konstanz, Germany — The spin blockade effect in the electric conduction through two semiconductor quantum dots connected in series has allowed the monitoring of spin-breaking effects, notably single-spin rotations induced via external fields in electron spin resonance (ESR) and spin decoherence due to the hyperfine coupling to the nuclear spin environment. Electrons in double quantum dots in carbon nanotubes and graphene comprise a valley isospin in addition to their spin. We show that this can lead to a spin-valley blockade which is sensitive to both spin and valley breaking effects. The hyperfine interaction due to residual ^{13}C nuclear spins turns out to be both spin- and valley-breaking, while non-magnetic atomic impurities can lead to pure valley-breaking. We study the magnetic-field dependent leakage current in the spin-valley blockade, also taking into account the spin-orbit interaction in carbon nanotubes. In analogy to ESR, we propose a resonance effect for the valley isospin (electron valley resonance) driven by an oscillatory electric field in a graphene or carbon nanotube quantum dot. 9:00AM Y30.00006 Single tube electric transport properties of synthesized Titania nanotubes , MOHAMED ABDELMOULA, LATIKA MENON, Northeastern University — Titania nanotube arrays fabricated by means of electrochemical anodization is currently the main interest of several research groups due to its promising applications. The high aspect ratio, durability, cheap and scalable fabrication technique make it highly attractive material for efficient solar cell. In this regard extensive research work is being carried out to investigate its properties. In our previous work we were able to find a mechanism for separating a single titania nanotube from the titania nanotube arrays and to measure its electric transport properties using e-beam lithography technique, In this work we investigated the effect of thermal annealing on the transport properties, we studied the effect of different annealing temperatures, heating and cooling rates, and in different gases. As a result, we were able to find the optimal annealing conditions to enhance the transport properties in blank titania nanotube. Under these optimal conditions, we were able to study the effect of coating TNTs with N719 dye and gold nanoparticles on the transport properties. As a result of our work we were able to optimize the treatments for more efficient solar cell fabrication.

9:12AM Y30.00007 Computer Simulated Cold Welding of Gold Nanowires[1] , EDISON DA SILVA, ZENNER PEREIRA, Institute of Physics "Gleb Wataghin," UNICAMP, 13083-970, Campinas - SP, Brazil — Recently cold welding was achieved in gold and silver nanowires (NWs) with diameters in the range of 4 to 10 nm [1]. Since metallic contacts are of great importance in electronic devices, the ability of welding them without temperature change is quite remarkable and of interest. In the present work we use computer simulations to produce cold welding in gold NWs at room temperature. We used molecular dynamics with many body effective potentials based on the embedded-atom method EAM using the LAMMPS code to simulate first the braking of gold NWs, the two produced NWs are then cold welded and similarly as the experiments, the newly welded NWs showed fcc structures as the pristine samples. The structural analysis is done with two independent methods [2] and strain stress curves of the breaking and welding are present. Our computer simulation compare very well with the experiments.

9:24AM Y30.00008 Nanowire FET as a measurement tool: A method for distiguishing molecular configurations using Debye Screening effect[1] , ALEKSANDAR VACIC, JASON CRISCIONE, NITIN RAJAN, TAREK FAHMY, MARK REED, Yale University — Silicon nanowires/nanoribbons configured as field effect transistors (FETs) with receptor modified surface can be utilized for sensing of charged biomolecular species due to surface potential modulation upon receptor-ligand binding. However, charged ionic species of the sensing buffers interfere with a sensing process by lowering the effective charge of the bound molecules sensed by an FET. In this work, we exploit the Debye screening effect on the device signal by modulating the ionic strength of the sensing buffer i.e. the Debye length, to distinguish between the different configurations of the receptor-ligand complex. We compare our experimental data with a theoretical model and are able to extract characteristic length parameters of the receptor-ligand system. We will discuss the use of the suggested method for the sensing of conformational changes of biomolecules. References Sorensen M. H., Mortensen N. A., Brandbyge M., Appl. Phys. 9:36AM Y30.00009 Silicene Nano-Ribbons: Strong Resistance Towards Oxidation due to sp^2 Hybridization of the Si Valence Orbitals , GUY LE LAY, CINaM-CNRS, PAOLA DE PADOVA, CLAUDIO QUARESIMA, CNR-ISM, BRUNO OLIVIERI, CNR-ISAC, PAOLO PERFETTI, CNR-ISM — We have synthesized for the first time silicene, that is, a new silicon allotrope analogous to graphene recently theoretically predicted [1], in the form of a massively parallel array of quantized zigzag nano-ribbons with a common "magic" width of 1.6 nm. They display characteristic linear band dispersions similar to the Dirac cones of graphene, in correspondence with their hexagonal arrangement seen in STM imaging [2]. Here we show, through the angle-dependence of REEL spectra taken at the Si $L_{2,3}$ edge, the typical signatures of 2p $\rightarrow$ π^* and 2p $\rightarrow$ σ^* transitions associated with sp^2 hybridization of the Si valence orbitals. We further show through high-resolution synchrotron radiation Si 2p core-level spectroscopy measurements that the afore mentioned silicene grating is very resistant toward oxidation. Typically, the oxygen uptake starts at about 10^4 higher doses than on the clean Si(111)7x7 surface. Indeed, this striking behavior is directly related to the sp^2 bonding, an additional confirmation of the silicene (i.e., graphene-like) nature of the nano-ribbons.

9:48AM Y30.00010 Low- Temperature Magneto-conductance In Carbon Nano-tubes , YUICHI OCHIAI, ATSURO SEINO, MICHIO KIDA, NOBUYUKI AOKI, Chiba University, TAKESHI NAKANISHI, AIST, JONATHAN BIRD, SUNY Buffalo, G-COE COLLABORATION, CHIBA UNIV VBL COLLABORATION — Angular dependent magneto-resistance (MR) has been studied in Multi- walled carbon nano-tubes (MWNTs). In case of thin MWNTs, the flux cancelation has been observed in the low temperature MR. Based on the theoretical studies on the scattering behaviors in the carbon nano-tube (CNT) and flux cancelation in one dimensional transport in CNT, we can analyze an intrinsic carrier scattering based on our MR result of the angular dependence between the angle of thin MWNT axis in parallel and perpendicular directions to the magnetic fields. Also, we can discuss on the positive MR appeared in the perpendicular field direction into the thin MWNT axis.

8:00AM Y31.00001 Synthesis, Homogenization and Molecular Structure of Chalcogenide glasses[1]

, SIDDHESH BHOSLE, KAPILA GUNASEKERA, PUNIT BOOLCHAND, University of Cincinnati, PING CHEN, Boise State University — Over the years, bulk glasses have been synthesized by reacting starting materials in evacuated (10^{-5} Torr to 10^{-7}Torr) quartz tubings for various periods at suitable elevated temperatures. The lack of a non-invasive structural probe to track spatial heterogeneity of samples during synthesis has been an impediment to tune synthesis conditions, and obtain a homogeneous product. We have developed a Raman profiling technique to understand the homogenization kinetics of Ge_xSe_{100-x} melts, and find dry samples (2 gram size) take 7 days of reaction at 950°C to homogenize on a scale of 50 microns, while wet ones homogenize quicker (∼3 days), but possess physical properties measurably different from their dry counterparts. Rotating sample tubes during synthesis assists in homogenization of samples incrementally but not dramatically. A score of compositions were homogenized across the 10% < x < 33.3% range, and calorimetric, Raman scattering, and molar volume data accumulated. These data provide clear evidence for three distinct regimes of behavior as a function of Ge content, which are identified with the three elastic phases discussed earlier.[2]

8:12AM Y31.00002 Elastic phases in $Ge_xSb_xSe_{100-2x}$ ternary glasses[1]

, K. GUNASEKERA, P. BOOLCHAND, University of Cincinnati, M. MICOULAUT, University of Paris VI — The rigidity and stress phase transitions in titled ternary glasses are examined in Raman scattering, modulated DSC and molar volume measurements, and found to occur at $x_c(1) = 14.9\%$ (rigidity) and $x_c(2) = 17.5\%$ (stress). Raman scattering provides evidence of the structural motifs populated in these networks. Using Size Increasing Cluster Agglomeration, Rigidity theory and the decoded structural motifs, we have calculated the rigidity and stress transitions in the first step of agglomeration to occur at $x_c(1)^t = 15.2\%$ and $x_c(2)^t = 17.5\%$ respectively, in reasonable accord with experiments. Theory predicts and experiments confirm that these transitions will coalesce if edge-sharing Ge- tetrahedral motifs were absent in the structure, a circumstance that prevails in the Ge-deficient $Ge_7Sb_xSe_{93-x}$ ternary, where a narrow IP is reported.[2] These results underscore the central role played by topology in determining the elastic phases of network glasses.

8:24AM Y31.00003 Short Range Order Signature in Crystalline and Amorphous GeSbTe Xanes Spectra[1]

, JEAN-YVES RATY, CÉLINE OTJACQUES, RENGIN PEKOZ, University of Liège, CHRISTOPHE BICHARA, CNRS- University Aix-Marseille, VINCE LORDI, Lawrence Livermore National Laboratory — A new implementation of XANES spectra calculations within DFT and PAW potentials is used to compute the XANES spectra of various amorphous and crystalline GeSbTe structures. A clear correlation between the local order, either tetrahedral or distorted octahedral, and the shape of the XANES signal is observed. These calculations provide a new interpretation of past XANES measurements, relating essentially the phase change mechanism to a moderate modification of the local environment of the Ge atoms.

8:36AM Y31.00004 ABSTRACT WITHDRAWN –

8:48AM Y31.00005 Photocrystallization in a-Se films with and without As-Se buffer layers

, B.A. WEINSTEIN, R.E. TALLMAN, G.P. LINDBERG, Dep. of Physics, Univ. at Buffalo, Buffalo, NY, USA, J.A. ROWLANDS, A. REZNIK, Thunder Bay Regional Resch. Inst., Ontario, Canada, M. KUBOTA, K. TANIOKA, NHK Research Labs, Tokyo, Japan — Photo-induced crystallization is studied for temperatures of 250 - 435 K in amorphous Se (a-Se) HARP* imaging targets using Raman spectroscopy to detect the appearance and growth-rate of trigonal Se in these thin-film structures. We observe striking differences between HARP films in which a thin buffer layer of As-Se alloy is, or is not, deposited prior to growth of the principal a-Se photoconductive layer. Films containing an As-Se buffer appear to be much more stable; no photocrystallization is found within the temperature range studied, even after 3.5 hours of laser exposure (0.17W/mm^2 at 647nm). Whereas for films with no As-Se buffer, photocrystallization readily occurs in two temperature regimes below and above the a-Se glass transition (Tg ∼310K), and there is a regime in the neighborhood of Tg where photocrystallization is absent. We discuss these results in terms of a polymerization model under the competing effects of shear-strain at the substrate and As-cross-linking in the buffer layer, which, respectively, tend to promote and inhibit crystallization in the thick Se over-layer. **High-gain Avalanche Rushing Photodetector*.

9:00AM Y31.00006 Diffraction studies of short- and intermediate-range order of phosphorus-selenium glasses

, DAVID PRICE, ALEKSEI BYTCHKOV, MARIANA MILOSHOVA, EUGENE BYCHKOV, SHINJI KOHARA, LOUIS HENNET — We present state-of-the-art neutron and X-ray diffraction data that provide a definitive picture of the short- and intermediate-range structure of P-Se glasses spanning both glass regions. Specific goals were (1) to obtain detailed information about the development with increasing of intermediate-range order on the length scale around 10 Å, based on the behavior of the first sharp diffraction peak; and (2) to obtain a reliable statistical picture of the short-range order, using the information about types and concentrations of local structural units provided by recent NMR measurements to interpret the trends observed as the P concentration is varied. Particular attention is given to the fine structure of the first peak in the pair distribution function and to a feature in the structure factor at 7.5 Å^{-1}, highlighted by Sergi et al. as a signature of molecular units.

9:12AM Y31.00007 Structure investigation of ultra-small CdSe nanoparticles using the atomic PDF

, AHMAD S. MASADEH, Dept of Phys, University of Jordan, Amman 11942, Jordan, SIMON J.L. BILLINGE, EMIL S. BOZIN, Dept of Applied Phys and Applied Math., Columbia University, NY, 10027, and Condensed Matr. Dept., BNL., Upton, NY, 11973 USA, JAMES R. MCBRIDE, SANDRA J. ROSENTHAL, Dept of Chem, Vanderbilt University, Nashville, TN 37235, USA — The size-dependent structure of CdSe nanoparticles, with diameter ranging from 1.5 to 3.6 nm, has been studied using the atomic pair distribution function (PDF) method. The samples are prepared by the methods of Peng *et al* [1], with modifications. The structure of the smallest stable size, (∼1.5 nm), have been found to posses locally distorted wurtzite structure, with no clear evidence of a heavily disordered surface region [2]. The PDF data of the smallest particle show an extra structural peak appears around r = 3.5 A indicates there is structure modification happened in this sample. This peak start appearing the nanoparticles PDF data gradually as nanoparticle size decreases. The structural parameters are reported quantitatively. We measure a size-dependent strain on the Cd-Se bond which reaches 1.0% at the smallest particle size [3]. The size of the well-ordered core extracted directly from the data agrees with the size determined from other methods.

9:24AM Y31.00008 Evidence of an Intermediate Phase in bulk alloy oxide glass sysem[1] , S. CHAKRABORTY, P. BOOLCHAND, University of Cincinnati — Reversibility windows have been observed in modified oxides (alkali-silicates and -germanates) and identified with Intermediate Phases(IPs).[2] Here we find preliminary evidence of an IP in a ternary oxide glass, $(B_2O3)_5(TeO_2)_{95-x}(V2O5)_x$, which is composed of network formers. Bulk glasses are synthesized across the 18% $<$ x $<$ 35% composition range, and examined in Raman scattering, modulated DSC and molar volume experiments. Glass transition temperatures T_g(x) steadily decrease with V_2O_5 content x, and reveal the enthalpy of relaxation at T_g to show a global minimum in the 24% $<$ x $<$ 27% range, the reversibility window (IP). Molar volumes reveal a minimum in this window. Raman scattering reveals a Boson mode, and at least six other vibrational bands in the 100 cm^{-1} $< \nu <$ 1700 cm^{-1} range. Compositional trends in vibrational mode strengths and frequency are established. These results will be presented in relation to glass structure evolution with vanadia content and the underlying elastic phases.

9:36AM Y31.00009 Glasses, Stress, Attenuation and Thermal Conductivity[1] , JIANSHENG WU, CLARE YU, University of California, Irvine — A wide variety of amorphous materials exhibit similar behavior in their thermal properties. Examples include universal features in the specific heat,thermal conductivity, and ultrasonic attenuation. Recent experiments from the Parpia group at Cornell find that high stress silicon nitride thin film resonators exhibit a remarkably high Q factor, exceeding that of amorphous SiO_2 by 2 to 3 orders of magnitude over a broad range of temperatures, and even exceeding that of single crystal silicon at room temperature. We present a model of why the stress reduces the attenuation. The basic assumption is that high stress increases the potential barriers of the excitations of defects that produce the loss, thus reducing the effective density of lossy fluctuators. We predict that high stress could lead to high thermal conductivity and low dielectric loss, making high stress SiN an excellent candidate as a substrate for integrated circuits.

9:48AM Y31.00010 Highly stable glasses as a general phenomenon: Physical vapor depositions of four different trisnaphthylbenzene isomers , KEVIN DAWSON, University of Wisconsin-Madison, LEI ZHU, LAURA KOPFF, ROBERT J. MCMAHON, LIAN YU, M.D. EDIGER — Glasses of each of the trisnaphthylbenzene (TNB) isomers, a low molecular weight glass forming family of four isomers, were created by physical vapor deposition. These glasses were analyzed using differential scanning calorimetry and wide angle x-ray scattering, and then compared to glasses prepared by quenching each melt. All four isomers produced stable glasses (increased onset temperature, large enthalpy overshoot, and excess x-ray scattering) when vapor-deposited at 0.85 T_g and at low deposition rates. This result is surprising as one of the TNB isomers readily crystallizes when cooled as a liquid. When coupled with previous experiments, these results show that stable glasses are not just produced by a small set of good glass forming molecules but seem to be a general phenomenon. Thus physical vapor deposition can be used as a general route to create unusual glasses for future scientific exploration and technological uses.

10:00AM Y31.00011 In-situ characterization of vapor-deposited glasses of toluene by differential AC chip nanocalorimetry , MATHIAS AHRENBERG, University of Rostock, KATIE WHITAKER, University of Wisconsin-Madison, HEIKO HUTH, University of Rostock, MARK D. EDIGER, University of Wisconsin-Madison, CHRISTOPH SCHICK, University of Rostock, UNIVERSITY OF ROSTOCK TEAM, UNIVERSITY OF WISCONSIN-MADISON TEAM — We use ac nanocalorimetry to investigate extraordinarily stable glasses of toluene prepared by vapor deposition. For that purpose we've built a vapor deposition chamber that allows in-situ characterization of vapor-deposited organic glasses down to liquid nitrogen temperature. With highly sensitive nanocalorimeters in a differential setup, we are able to measure ng-samples over a frequency range from 0.1 Hz up to 8 kHz. The device was used to investigate the transformation of as-deposited stable toluene glasses into ordinary glasses. For films about 100 nm thick, the transformation was studied as a function of time at constant temperature above the common glass transition and as function of temperature at constant heating rate. The stability of the thin films was investigated as a function of substrate temperature and deposition rate.

10:12AM Y31.00012 Thermal Evolution of Defects and Hydrogenated Surfaces in nc-Si:H[1] , KRISTIN KIRILUK, DON WILLIAMSON, Colorado School of Mines, DAVID BOBELA, National Renewable Energy Lab, ARUN MADAN, FENG ZHU, MV Systems, Inc., P. CRAIG TAYLOR, Colorado School of Mines — Photovoltaics research has created a push for new materials and nanotechnology is a primary focus. The most familiar of the nanomaterials is hydrogenated nanocrystalline silicon (nc-Si:H). nc-Si:H has less light-induced degradation than a-Si:H and is cheaper to make than crystalline silicon. X-ray diffraction (XRD), small angle X-ray scattering (SAXS), and electron spin resonance (ESR) experiments explored the crystallite size, orientation and defect density on nc-Si:H samples with varying crystalline volume fraction (CVF). Samples with CVF $\sim$ 50% show preferential [220] crystallite orientation, whose microstructure changes with thermal annealing. Modeling of SAXS data for as-grown material shows that the crystallite surfaces are 20% to 40% hydrogenated. After high temperature annealing, hydrogen leaves these surfaces and the ESR signal increases by about 10 times. We discuss these results and then speculate on the relationship between hydrogen, defects, and microstructure.

Friday, March 25, 2011 8:00AM - 10:00AM –
Session Y33 DCMP: Cold Fusion C143/149

8:00AM Y33.00001 Justifying Condensed Matter Nuclear Phenomena Using Hot Fusion Data , XING ZHONG LI, Tsinghua University, Beijing 10084, China — The selective resonant tunneling model [1] has been successful in describing 6 major fusion cross-section data (d+T, d+D, d+He3, t+T, t+He3, p+D). The new formula needs only 3 parameters; however, it gives much better results than what were given by the 5-parameter formula in NRL Plasma Formulary. It provides an opportunity to find the resonance energy level which is necessary to explain the Condensed Matter Nuclear Phenomena in metal-hydrides. The proton-lithium fusion data, the astrophysical S-factor data, the K-electron capture data of beryllium, and the anomalous ratio of the isotope abundance of lithium in palladium-hydride (7Li/6Li) will be presented as an example for this justification. Thus, selective resonant tunneling model explains not only the 3 puzzles in Condensed Matter Nuclear Science (i.e. tunneling the Coulomb barrier, excess heat without commensurate neutron radiation, and the missing gamma radiation), but also 7 sets of hot fusion data. It predicts that there must be neutrino radiation accompanied with Condensed Matter Nuclear Phenomena in metal-hydrides.

8:12AM Y33.00002 -dimensional Symmetry Catalysts for A-Z Gas Loading Fusion , TALBOT CHUBB, Greenwich Corp., Arlington, VA 22207 — An epitaxial mating of a metal layer to a chemically stable ionic crystal minimizes system energy for cold fusion based on Bloch function symmetry and using gas loading and nm-Pd at a favored interface.[1] To achieve epitaxy second and third metal layers need to have imperfections. One thinks of the stable ionic crystal as a template and the nano-Pd solid as a malleable lattice. The interior volume of the nano-Pd solid has a face-centered cubic structure. ZrO2 was the template ionic crystal used in A-Z gas loading studies at elevated T in (2005). A template crystal using the sapphire crystal equivalent of a double-layer graphene crystal is suggested. Impurity Rh and Ru are suggested as impurity atoms in the nano-metal (as in gem-quality Zircon) and a amall amount of interstitial H in addition to dominant D as involved in diffusion. Ref. [1] "Interface Modeling of Cold Fusion," Talbot A. Chubb, Proc. ICCF14, Book 2, pp 534-539 (2008).

8:24AM Y33.00003 Comparison of Calorimetry: MIT and Fleischmann-Pons Systems , MELVIN H. MILES, University of La Verne, La Verne, CA 91750, PETER HAGELSTEIN, Masschusetts Institute of Technology — The history of cold fusion shows that the MIT heat conduction calorimetry in 1990 reported a sensitivity of 40 mW while the Fleischmann-Pons Dewar calorimetry achieved a sensitivity of 0.1 mW. Additional information about the MIT calorimetry allows a more detailed analysis. The major finding is that the MIT calorimetric cell was so well insulated with glass wool (2.5 cm in thickness) that the major heat transport pathway was out of the cell top rather than from the cell into the constant temperature water bath. It can be shown for the MIT calorimeter that 58% of the heat transport was through the cell top and 42% was from the cell into the water bath. Analysis of the Fleischmann-Pons Dewar cell shows that under conditions similar to the MIT experiments, almost all of the heat flow would be from the Dewar calorimetric cell to the constant temperature water bath. Furthermore, the sensitivity of the Fleischmann- Pons temperature measurements was 0.001 K versus 0.1 K for the MIT calorimetric cell. Evaluations of the calorimetric equations and data analysis methods leads to the conclusion that the Fleischmann-Pons calorimetry was far superior to that of MIT.

8:36AM Y33.00004 Can LENR Energy Gains Exceed 1000? , DAVID J. NAGEL, The George Washington University — Energy gain is defined as the energy realized from reactions divided by the energy required to produce those reactions. Low Energy Nuclear Reactions (LENR) have already been measured to significantly exceed the energy gain of 10 projected from ITER,possibly 15 years from now. Electrochemical experiments using the Pd-D system have shown energy gains exceeding 10. Gas phase experiments with the Ni-H system were reported to yield energy gains of over 100. Neither of these reports has been adequately verified or reproduced. However, the question in the title still deserves consideration. If, as thought by many, it is possible to trigger nuclear reactions that yield MeV energies with chemical energies of the order of eV, then the most optimistic expectation is that LENR gains could approach one million. Hence, the very tentative answer to the question above is yes. However, if LENR could be initiated with some energy cost, and then continue to "burn," very high energy gains might be realized. Consider a match and a pile of dry logs. The phenomenon termed "heat after death" will be examined to see if it might be the initial evidence for nuclear "burning."

8:48AM Y33.00005 Lattice Assisted Nuclear Reactions From Nanostructured Metamaterials Electrically Driven at Their Optimal Operating Point , MITCHELL R. SWARTZ, JET Energy, PO Box 81135, Wellesley Hills, MA 02481 — In lattice assisted nuclear reactions, hydrogen-loaded alloys enable near room temperature deuterium fusion and other nuclear reactions (1). The structural metamaterial shape of some D-loaded Pd nanostructures and deuterium flux (2) through them, driven by an applied electric field, appear to play decisive roles. The spiral Phusor®-type cathode with open helical cylindrical geometry in a high electrical resistance solution is a LANR metamaterial design creating intrapalladial deuteron flow. Optimal operating point technology allows improved and more reproducible operation (3). LANR power gain can be considerable. In situ imaging has revealed that the excess power gain is linked to non-thermal near-IR emission when the LANR devices are operated at their OOP. LANR devices have shown power gains more than 200%, and short term power gains to $\sim$8000%. 1. Swartz, M, J. Sci. Exploration, 23, 4, 419-436 (2009). 2. Swartz, M, Fusion Technology, 22, 2, 296-300 (1992); 26, 4T, 74-77 (1994); 32, 126-130 (1997). 3. Swartz. M, Fusion Technology, 31, 63-74 (1997).

9:00AM Y33.00006 The Use of SSNTD's in the Pd-D Co-deposition Experiment , FRANCIS TANZELLA, Materials Research Laboratory, SRI International, Menlo Park, CA, 94025, USA. , MICHAEL M.C.H. MCKUBRE, SRI International, Menlo Park, CA, 94025, USA. — An early derivative experiment of the original Fleischman-Pons electrochemical experiment [1-3] was that of Szpak et al [4-5]. Szpak et al. chose to electro- deposit bulk metal palladium on a conductive metal substrate from a deuterium oxide (D2O) solution of a Pd salt, as opposed to electrolytically loading a bulk Pd cathode in a D2O solution. Recent work, by Boss et al [6] has concentrated on using solid state nuclear track detectors (SSNTD, specifically CR-39) to search for evidence of nuclear particles. In most of these experiments the CR-39 was immersed in the electrolyte, which makes the interpretation of the tracks potentially ambiguous because of the possibility of chemical damage. However, different interpretations of results presented have concluded that the data argue for the generation of alpha particles, protons, and/or neutrons. We have chosen to reproduce one version of these recent experiments using CR-39 immersed and separated from the electrolyte with a 6 μm thick piece of Mylar® film. A 60 μm thick piece of polyethylene, used as a protective cover during handling, was occasionally allowed to remain on the film to facilitate thermalization of possible product neutrons. 1. Fleischmann, M., S. Pons, and M. Hawkins, "Electrochemically induced nuclear fusion of deuterium". J. Electroanal. Chem., 1989. 261, 301

9:12AM Y33.00007 LENR BEC Clusters on and below Wires through Cavitation and Related Techniques , ROGER STRINGHAM, Firstgate Energies, PO Box 1230 Kilauea, HI 96754, Phone: 808 828 2859, JULIE STRINGHAM, Firstgate Energies, PO Box 1230 Kilauea, HI 96754 — During the last two years I have been working on BEC cluster densities deposited just under the surface of wires, using cavitation, and other techniques. If I get the concentration high enough before the clusters dissipate, in addition to cold fusion related excess heat (and other effects, including helium-4 formation) I anticipate that it may be possible to initiate transient forms of superconductivity at room temperature.

9:24AM Y33.00008 Use of Helium Production to Screen Glow Discharges for Low Energy Nuclear Reactions (LENR) , THOMAS O. PASSELL, TOP Consulting, P.O. Box 336, Palo Alto, CA 94302-0336 — My working hypothesis of the conditions required to observe low energy nuclear reactions (LENR) follows: 1) High fluxes of deuterium atoms through interfaces of grains of metals that readily accommodate movement of hydrogen atoms interstitially is the driving variable that produces the widely observed episodes of excess heat above the total of all input energy. 2) This deuterium atom flux has been most often achieved at high electrochemical current densities on highly deuterium-loaded palladium cathodes but is clearly possible in other experimental arrangements in which the metal is interfacing gaseous deuterium, as in an electrical glow discharge. 3) Since the excess heat episodes must be producing the product(s) of some nuclear fusion reaction(s) screening of options may be easier with measurement of those "ashes" than the observance of the excess heat. 4) All but a few of the exothermic fusion reactions known among the first 5 elements produce He-4. Hence helium-4 appearance in an experiment may be the most efficient indicator of some fusion reaction without commitment on which reaction is occurring. This set of hypotheses led me to produce a series of sealed tubes of wire electrodes of metals known to absorb hydrogen and operate them for $>$100 days at the $<$1 watt power level using deuterium gas pressures of $\sim$100 torr powered by 40 Khz AC power supplies. Observation of helium will be by measurement of helium optical emission lines through the glass envelope surrounding the discharge. The results of the first 18 months of this effort will be described.

9:36AM Y33.00009 Conventional Physics can Explain Excess Heat in the Fleischmann-Pons Cold Fusion Effect , SCOTT CHUBB, Infinite Energy Magazine — In 1989, when Fleischmann and Pons (FP) claimed they had created room temperature, nuclear fusion in a solid, a firestorm of controversy erupted. Beginning in 1991, the Office of Naval Research began a decade-long study of the FP excess heat effect. This effort documented the fact that the excess heat that FP observed is the result of a form of nuclear fusion that can occur in solids at reduced temperature, dynamically, through a deuteron (d)+d?helium-4 reaction, without high-energy particles or ? rays. This fact has been confirmed at SRI and at a number of other laboratories (most notably in the laboratory of Y. Arata, located at Osaka University, Japan). A key reason this fact has not been accepted is the lack of a cogent argument, based on fundamental physical ideas, justifying it. In the paper, this question is re-examined, based on a generalization of conventional energy band theory that applies to finite, periodic solids, in which d's are allowed to occupy wave-like, ion band states, similar to the kinds of states that electrons occupy in ordinary metals. Prior to being experimentally observed, the Ion Band State Theory of cold fusion predicted a potential d+d?helium-4 reaction, without high energy particles, would explain the excess heat, the helium-4 would be found in an unexpected place (outside heat- producing electrodes), and high-loading, x?1, in PdDx, would be required.

9:48AM Y33.00010 Electrochemical and Electron Probe Microanalysis Measurements on Nanostructured Palladium , JAN MARWAN, BAM Federal Institute for Research and Testing, Division VI.4 Surface technologies,12200 Berlin, Germany, VANESSA RACKWITZ, Forschung & Entwicklung, Rudower Chaussee 29, D-12489 Berlin, Germany — The hydrogen region of nanostructured Pd in the cyclic voltammetry in 1 M H2SO4 was more resolved than that of plain Pd because of the thin walls of the nanostructure and the high surface area. We could distinguish the hydrogen adsorption and absorption processes. The permeation of hydrogen into the Pd metal lattice occurs with fast kinetics when the Pd surface is blocked by either crystal violet or Pt. We believe that the hydrogen absorption process takes place without passing through the adsorbed state so that hydrogen diffuses directly into the Pd bulk. This process speeds up when the formation of adsorbed hydrogen is suppressed by the coverage of poisons. These results were compared to those obtained in a heavy water solution to which the Pd electrode was exposed. Adsorption characteristics of deuterium on the Pd metal surface are slightly different to those obtained for hydrogen in previous studies. Diffusion of deuterium into the Pd metal lattice works with fast kinetics under appropriate surface modification. We are also interested in studying the Pd structure before and after long term electrolysis in light and heavy water using electron probe micronanalysis (EPMA) with a energy dispersive spectrometer (EDS)

Friday, March 25, 2011 8:00AM - 11:00AM –
Session Y35 DCMP: Topological Insulators: Applications C140

8:00AM Y35.00001 Physical Vapor Deposition Growth of Topological Insulator Nanostructures[1] , LOREN ALEGRIA, ANASUA CHATTERJEE, ZHONG ZHANG, MICHAEL PRETKO, JAMES TING, SHIVANG PATEL, JASON PETTA, Princeton University — Nanostructures consisting of strong topological insulators are of interest for the fabrication of devices in which surface state transport is dominant. We report Bi_2Se_3 nanoribbon and nanoplatelet growth using a multi-zone furnace.[2] Nanoribbons are grown by the vapor-liquid-solid method, using Au nanoparticles or Au thin films ($\sim$5 nm) as catalysts, while nanoplatelets are grown on bare silicon. We systematically vary the growth parameters, including the temperatures of the powdered Bi_2Se_3 precursor and growth substrate, the growth pressure and duration, the rate of the Argon carrier gas flow, size of the gold catalyst, and the quantity of Bi_2Se_3 source material. Typical nanoribbon growth occurs at 450°C and 350 Torr, with the precursor held at 530°C in an Argon carrier gas flow rate rate of 140 sccm. Typical platelet growth occurs at lower pressures and temperatures. High resolution transmission electron microscopy, diffraction, and energy dispersive x-ray analysis are used to characterize the synthesized structures.

8:12AM Y35.00002 Topological insulators for high performance terahertz to infrared applications , XIAO ZHANG, Stanford University, JING WANG, Tsinghua University, SHOU-CHENG ZHANG, Stanford University — Topological insulators in the Bi2Se3 family have an energy gap in the bulk and a gapless surface state consisting of a single Dirac cone. Low frequency optical absorption due to the surface state is universally determined by the fine structure constant. When the thickness of these three dimensional topological insulators is reduced, they become quasi-two dimensional insulators with enhanced absorbance. The two dimensional insulators can be topologically trivial or non-trivial depending on the thickness, and we predict that the optical absorption is larger for topological non-trivial case compared with the trivial case. Since the three dimensional topological insulator surface state is intrinsically gapless, we propose its potential application in wide bandwidth, high performance photo-detection covering a broad spectrum ranging from terahertz to infrared. The performance of photodetection can be dramatically enhanced when the thickness is reduced to several quintuple layers, with a widely tunable band gap depending on the thickness.

8:24AM Y35.00003 Two Dimensional Transport Induced Linear Magneto-resistance in Topological Insulator Bi_2Se_3 Nanoribbons[1] , DONG LIANG, HAO TANG, RICHARD QIU, XUAN GAO, Dept of Physics, Case Western Reserve University, Cleveland, OH 44106 — Bulk Bi_2Se_3 has been proposed and confirmed as a type of three-dimensional (3D) topological insulators (TI's) with a single Dirac cone for the surface state. Although the existence of topological surface state in Bi_2Se_3 has been established by surface sensitive techniques (ARPES, STM), the transport properties of two dimensional (2D) surface state in 3D TI's has been plagued by the dominating conductivity from bulk carriers. Here, we report the study of a novel linear magneto-resistance (MR) under perpendicular magnetic fields in Bi_2Se_3 nanoribbons, and show that this linear MR is purely due to 2D transport by angular dependence experiments. The 2D magneto-transport induced linear MR in Bi_2Se_3 nanoribbons is in agreement with the recently discovered linear MR from topological surface state in bulk Bi_2Te_3, and the MR of other gapless semiconductors and graphene. We further show that the linear MR of Bi_2Se_3 nanoribbons persists up to room temperature, underscoring the potential of exploiting TI's for room temperature magneto-electronic applications.

[1]The authors thank ACS PRF grant #48800-DNI10 for partial funding support.

8:36AM Y35.00004 Quantum impurity spin in Majorana edge modes , RYUICHI SHINDOU[1], Department of Physics, Tokyo Institute of Technology, AKIRA FURUSAKI, Condensed Matter Theory Laboratory, RIKEN, Japan, NAOTO NAGAOSA, Department of Applied Physics, University of Tokyo and CERG and CMRG, RIKEN, Japan — We show that Majorana edge modes of two-dimensional spin-triplet topological superconductors (superfluids) have Ising-like spin density whose direction is determined by the d-vector characterizing the spin-triplet pairing symmetry in the bulk. Thus, when a quantum impurity spin is introduced at the edge of the spin-triplet topological superconductors (superfluids), the exchange coupling between this impurity spin and the Majorana modes becomes Ising-type. Observing this, we argue that, under the external magnetic fields, this quantum impurity spin exhibits anisotropic dissipative quantum dynamics due to the 'background' massless Majorana edge modes. We also discuss how the magnetic response of this impurity spin can serve as a local probe for spin-triplet superconducting order parameter in the bulk.

[1]This work was done when the first author was affiliated to Condensed Matter Theory Laboratory in RIKEN.

8:48AM Y35.00005 Surface state transport in Bi2Se3 nanodevices , HADAR STEINBERG, VALLA FATEMI, PABLO JARILLO-HERRERO, MIT — We report on electronic transport measurements on thin (<100 nm) Bi2Se3 devices and show that the density of the surface states can be modulated via the electric field effect by using a top-gate with a high-k dielectric insulator. The conductance dependence on geometry, gate voltage, and temperature all indicate that transport is governed by parallel surface and bulk contributions.

9:00AM Y35.00006 Thermoelectric transport of edge/surface states of topological insulators , SHUICHI MURAKAMI, Department of Physics, Tokyo Institute of Technology and PRESTO-JST, RYUJI TAKAHASHI, Department of Physics, Tokyo Institute of Technology — In my talk we theoretically study thermoelectric properties of topological insulators (TI) [1], where novel properties of edge/surface states are expected to appear. As compared to the number of bulk states, the edge/surface states are very few; we therefore consider a narrow ribbon for 2D and a thin slab for 3D TI to make the edge/surface-state transport larger. By considering edge/surface and bulk transport together, we calculate the charge and heat conductivity, and Seebeck coefficient. We find that in 2D TI the bulk and edge transport compete each other in the thermoelectric transport. By lowering temperature, the thermoelectric figure of merit ZT has a minimum, corresponding to the bulk-to-edge crossover, and then increases again at low temperature where the edge state dominates. The crossover is estimated to be at around 5K-10K for 10nm-width ribbon. We also discuss surface state transport for 3D TI as well.

[1] R. Takahashi and S. Murakami, Phys. Rev. B81, 161302 (R) (2010).

9:12AM Y35.00007 Mobility and thermopower of surface and bulklike charges in Bi and Sb nanowires[1] , T.E. HUBER, Howard University, Washington, DC 20059, A. ADEYEYE, Howard University, Washington DC 20059, A. NIKOLAEVA, L. KONOPKO, Academy of Sciences of Moldova and International Laboratory of High Magnetic Fields and Low Temperature Physics, R.C. JOHNSON, M.J. GRAF, Boston College, Chestnut Hill, MA 02467 — Topological insulators (TI) surface charges are predicted to have high mobilities and other properties. Bi and Sb, that are classified as TI trivial and true, respectively, are interesting candidates but are not very good bulk insulators. However, in very thin nanowires, quantum confinement opens a gap for the bulk states that is not expected to change the material's TI character. We studied the electronic transport of 18-nm to and 200-nm diameter nanowires in arrays, fabricated by Bi injection in porous alumina, via coupled measurements of resistance and thermopower (4-300 K). Surface carriers and holes Landau level spectra were analyzed to extract densities. The nanowires low temperature thermopower (T<100 K) is -1 T microvolt/(K^2) consistent in sign and magnitude with surface electrons. Coexistence of bulklike holes with surface electrons, consistent with the carrier's hybridization that is expected in Bi, is observed. Results for Sb will be presented also.

[1]Support by Army Research Office, Materials and National Science Foundation (PREM) is acknowledged.

9:24AM Y35.00008 Raman spectroscopy of exfoliated Bi2Se3 , LUKE SANDILANDS, FRANK ZHAO, CHRISTIANNE BEEKMAN, JOHN BASHUCKY, University of Toronto, DANIEL KWOK, Rutgers University, NARA LEE, SANG-WOOK CHEONG, Rutgers University, KENNETH BURCH, University of Toronto — The study of topological insulators is often frustrated by the presence of a residual bulk conductivity arising from defects which makes isolating the surface contribution to a given measurement difficult. Nanoscale topological insulators are therefore an appealing alternative to bulk crystals, as a small volume should emphasize surface contributions and allow the suppression of the residual bulk carriers by gating. To this end we have produced, via mechanical exfoliation, nanocrystals as thin as a 2 nm of the topological insulator Bi2Se3 on Mica substrates. Exfoliated crystals of a variety of thicknesses have been characterized by optical, Raman, and atomic force microscopies. We observe an emergent mode at 158 cm-1 which is attributed to the breaking of inversion symmetry at the Bi2Se3 surfaces. The utility of this emergent mode for determining nanocrystal thickness is discussed.

9:36AM Y35.00009 Mechanical Exfoliation and Electron Transport of Topological Insulator Nanoribbons , SEUNG SAE HONG, WORASOM KUNDHIKANJANA, Department of Applied Physics, Stanford University, JUDY CHA, Department of Materials Science and Engineering, Stanford University, KEJI LAI, Department of Applied Physics, Stanford University, DESHENG KONG, Department of Materials Science and Engineering, Stanford University, ZHI-XUN SHEN, Department of Applied Physics, Stanford University, YI CUI, Department of Materials Science and Engineering, Stanford University — Bismuth selenide (Bi_2Se_3), a stoichiometric material of a single Dirac-cone band structure, is one of the most promising candidates to realize the topologically non-trivial surface state protected by time reversal symmetry. Especially, many exotic physical phenomena are predicted to emerge in low dimensional nanostructures of Bi_2Se_3, such as the crossover between 3D to 2D topological insulator. Due to the weak Van der Waals interaction between adjacent quintuple layers (QLs), Bi_2Se_3 can be exfoliated down to a few QLs. We will present the mechanical exfoliation of topological insulator nanoribbons by an atomic force microscope (AFM) tip, which enables ultra-thin topological insulator down to a single QL. Electron transport measurement on low dimensional topological insulator will be also discussed, as well as the conductivity mapping experiment using a microwave scanning probe technique.

9:48AM Y35.00010 Topological surface states along antiwires , ALEXANDER PUNNOOSE, WEI LIU, City College of New York — Surface states along amorphous columnar defects in three-dimensional topological insulators are considered. The response of these states to a magnetic field and their contribution to thermoelectric transport will be discussed.

10:00AM Y35.00011 Bias dependence of h/e and h/2e Aharonov-Bohm oscillations in topological insulators[1] , PRAMEY UPADHYAYA, FAXIAN XIU, YABIN FAN, IGOR OVCHINNIKOV, KANG WANG, University of California Los Angeles, UNIVERSITY OF CALIFORNIA LOS ANGELES TEAM — Recently Aharonov-Bohm (AB) oscillations were observed in Bi_2Se_3 nanoribbons by Peng *et al.* [1] as a direct evidence for the existence of surface states in topological insulator. However, the resistance showed only h/e oscillations with a minimum in resistance at zero flux while the ballistic and diffusive theory predicts either h/e oscillations with a maximum in resistance at zero flux or h/2e oscillations with a minimum in resistance at zero flux respectively [2]. A possible explanation of the results of Peng *et al.* was given in the theory of disordered topological insulators proposed by Bardarson *et al* .[2] and Zhang *et al.* [3] where they attributed the results of Peng *et al.* to presence of weak disorder. Furthermore authors of [2] and [3] studied dependence of h/e and h/2e oscillations on disorder strength and doping using their proposed theory. In this work we look at the effect of doping by studying bias dependence of AB oscillations using a gated device and observe both h/e and h/2e oscillations whose relative strength depends on the applied bias and compare the proposed theory of ref. [2] and [3] with the experimental results. [1] H. Peng, *et al.* Nature Mater. 9, 225 (2010).[2] J. Bardarson, *et al*, Phys. Rev. Lett. 105, 156803 (2010).[3] Y. Zhang and A. Vishwanathan, Phys. Rev. Lett. 105, 206601 (2010).

10:12AM Y35.00012 Spin polarization and transport of surface states in the topological insulators Bi_2Se_3 and Bi_2Te_3 from first principles[1] , OLEG YAZYEV, JOEL MOORE, STEVEN LOUIE, UC Berkeley and LBNL — We investigate the band dispersion and the spin texture of topologically protected surface states in the reference bulk topological insulators Bi_2Se_3 and Bi_2Te_3 by using a first-principles approach. Exceptionally strong spin-orbit interaction in these materials entangles the electronic states across broad energy ranges thus reducing the spin-polarization of the topologically protected surface states to ∼50% in both cases. This reduction is absent in simple phenomenological models but of important implications to essentially any application of bulk topological insulators in spintronics and likely to some other phenomena. We further propose a way of controlling the magnitude of spin polarization associated with a charge current in thin films of topological insulators by means of an external electric field. The proposed dual-gate device configuration provides new possibilities for electrical control of spin.

[1]Support by NSF Grant Nos. DMR07-05941, DMR08-04413, US DOE Cont. No. DE-AC02-05CH1123 and Swiss NSF Fellowship PBELP2-123086. Computer resources provided by NICS.

10:24AM Y35.00013 Manipulating surface states in topological insulator nanostructures , FAXIAN XIU, LIANG HE, KANG L. WANG, University of California Los Angeles — Topological insulators show unique properties resulting from massless, Dirac-like surface states that are protected by time-reversal symmetry. Theory predicts that the surface states exhibit quantum spin Hall effect that allows for spins to transport without scattering. However, to date, the direct manipulation of these states with external means remains a significant challenge owing to the predominance of bulk carriers. Here we show the first experimental evidence of surface-state modulation through the observation of voltage-controlled quantum oscillations in Bi2Te3 nanostructures. The surface conduction can be dramatically enhanced with external gate bias. Up to 51 percent of the total conductance is attributed to the surface states. The ability to manipulate the surface states mark an important milestone in the development of TI materials and may further open up exciting and novel applications in nanoelectronics and spintronics.

10:36AM Y35.00014 Aharonov-Bohm oscillations in disordered topological insulator nanowires , JENS H. BARDARSON, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, California 94720, USA, P.W. BROUWER, Dahlem Center for Complex Quantum Systems and Institut fur Theoretische Physik, Freie Universitat Berlin, Arnimallee 14, 14195 Berlin, Germany, J.E. MOORE, Department of Physics, University of California, Berkeley, Berkeley, California 94720, USA — A direct signature of electron transport at the metallic surface of a topological insulator is the Aharonov-Bohm oscillation observed in a recent study of Bi_2Se_3 nanowires [Peng *et al.*, Nature Mater. 2010] where conductance was found to oscillate as a function of magnetic flux ϕ through the wire, with a period of h/e and $maximum$ conductance at zero flux. This seemingly agrees neither with diffusive theory (period of $h/2e$) nor with ballistic theory, which in the simplest form predicts a period of h/e but a $minimum$ at zero flux due to a nontrivial Berry phase. We show how the magneto-conductance depends on doping and disorder strength, provide a possible explanation for the experiments, and discuss further experiments that could verify the theory.

10:48AM Y35.00015 Terahertz conductivity of Bi_2Se_3 topological insulator thin films[1] , ROLANDO VALDÉS AGUILAR, L.S. BILBRO, Department of Physics & Astronomy, Johns Hopkins University, Baltimore, MD 21218, N. BANSAL, Y-S. KIM, S. OH, Department of Physics & Astronomy, Rutgers University, Piscataway, NJ 08854, C. CHANG, Y. ZHANG, K. HE, X. MA, Institute of Physics, The Chinese Academy of Sciences, Beijing, 100190, P.R. China, X. ZHU, Q-K. XUE, Department of Physics, Tsinghua University, Beijing, 100084, P. R. China, N.P. ARMITAGE, Department of Physics & Astronomy, Johns Hopkins University, Baltimore, MD 21218 — We report a study of high quality MBE grown Bi_2Se_3 topological insulator thin films. We have measured the ac conductivity in the terahertz region using time domain terahertz spectroscopy. By measuring films with different thickness we can set limits on the value of the bulk and surface conductivites. We will also report on measurements of the Faraday rotation using polarized light at these frequencies.

Friday, March 25, 2011 8:00AM - 10:36AM –

Session Y36 DCMP: Graphene: Optical Properties II C142

8:00AM Y36.00001 Raman spectroscopy of graphite in high magnetic fields , YOUNGHEE KIM, National High Magnetic Field Laboratory, ANTONIO LOMBARDO, Engineering Department, Cambridge University, NIKOLAI G. KALUGIN, Department of Materials and Metallurgical Engineering, New Mexico Tech, JUNICHIRO KONO, Department of Electrical & Computer Engineering, Rice University, ANDREA C. FERRARI, Engineering Department, Cambridge University, DMITRY SMIRNOV, National High Magnetic Field Laboratory — Recently, much attention has been paid to electron-phonon coupling in graphene. In particular, significant re-normalization and broadening of long-wavelength optical phonons are predicted to occur through resonant interaction with Landau-quantized Dirac fermions. We report here on a high-field magneto-Raman spectroscopy study of highly-oriented pyrolytic graphite (HOPG) and natural graphite at temperatures down to 5 K and in magnetic fields up to 45 T. The E_{2g} graphite phonon line exhibits anticrossing-like behavior at approximately 30 T, which we attribute to the magneto-phonon resonance (MPR) of graphite's massless holes at the H-point. Additionally, we observed features related to inter-Landau-level transitions at the K-point of graphite. We also observed weak graphene-like signatures of MPR, indicating the existence of graphene flakes on the graphite surface.

8:12AM Y36.00002 Raman measurements of graphene in magnetic fields , SEBASTIAN REMI, ANNA SWAN, BENNETT B. GOLDBERG, Boston University — Electron phonon interactions in graphene are effectively measured using Raman spectroscopy. For example the G-Band of graphene grown on SiC shows characteristic anticrossings when tuning an external magnetic field exactly at the resonances between the G-Band phonon and the electronic Landau Levels. We measure the micro Raman spectra of mechanically exfoliated graphene lithographically prepared as field effect devices. Unlike prior high magnetic field studies, this provides charge tunability and allows simultaneous Raman and transport measurements under variable B-field. Our initial results show a Landau Level dependent splitting of the G-band for magnetic fields B $>$ 10T. We present our latest results of studies of the Raman G and 2D Band and single and bilayer graphene at T=4.2K and fields to 12T.

8:24AM Y36.00003 Raman Maps of Carbon Nanoscrolls and their Bundles , GUANGJUN CHENG, IRENE CALIZO, XUELEI LIANG, BRENT SPERLING, JAMES MASLAR, CURT A. RICHTER, ANGELA R. HIGHT WALKER, National Institute of Standards and Technology (NIST), Gaithersburg, MD 20899 — Recent theoretical simulations and experimental data have shown that carbon nanoscrolls, formed by rolling a single layer of graphene, exhibit different electronic and optical properties from carbon nanotubes or the planar graphene sheet. They hold promise in a variety of applications areas such as energy storage and nanomechanics. Here, we present our investigation on the formation of carbon nanoscrolls and their bundles from large-area graphene originally grown on copper foil by chemical vapor deposition. When graphene is transferred from a copper foil onto a silicon wafer using wet chemistry, both filled and unfilled carbon nanoscrolls are produced upon the rupture of graphene. These nanoscrolls can further form bundles. The results from Raman mapping, optical microscopy, scanning electron microscopy, and atomic force microscopy measurements will be presented and the formation mechanism will be discussed.

8:36AM Y36.00004 Controlling Inelastic Light Scattering Quantum Pathways in Graphene , JASON HORNG, CHI-FAN CHEN, CHEOL-HWAN PARK, BRYAN W. BOUDOURIS, BAISONG GENG, CAGLAR GIRIT, ALEX ZETTL, MICHAEL CROMMIE, RACHEL SEGALMAN, STEVEN LOUIE, FENG WANG, UC Berkeley — Graphene exhibits unique tunable optical properties. Researchers have observed infrared absorptions in graphene interband transitions as well as intraband transitions can be modified substantially through electrostatic gating. At the same time, inelastic Raman scattering from few layer graphene is readily observable and widely used to characterize graphene quality, and to probe graphene electron-phonon interactions. In strongly gated graphene, Raman scattering from graphene can also be varied from electrical doping through direct change of electronic transitions. In this talk, I will describe how the Raman intensity of G-mode and 2D-mode Raman varies with the Fermi energy in doped graphene.

8:48AM Y36.00005 Ab initio calculation of double-resonant Raman spectra for bilayer graphene , PAOLA GAVA, LSI - Ecole Polytechnique, MATTEO CALANDRA, MICHELE LAZZERI, FRANCESCO MAURI, IMPMC - Universite Paris 6 — The discovery that the application of an external electric field induces a band gap opening in bilayer graphene attracted a lot of interest on this system, due to important applications in nanoelectronics [1]. Raman spectroscopy is one of the most important experimental techniques for the characterisation of carbon based materials, providing informations on carriers concentration [2], disorder [3], number of layers on multi-layers graphene systems [4], and phonon properties. Most of the theoretical studies on multi-layers graphene are performed using a Tight Binding (TB) model, and full calculation of Raman matrix elements to obtain frequencies, intensities and linewidths of Raman bands has not been performed up to now. The developpement of a fully ab initio theoretical tool to compute Raman spectra is therefore higly desirable and particularly relevant for systems where a simple TB parametrization of the electronic structure and of the electron-phonon interaction is not available. In this talk I will discuss a recently developped methodology to compute fully ab initio double-resonant Raman spectra and I will present results for bilayer graphene.

[1] Ohta et al, Science **313**, 951 (2006), [2] Malard et al, PRL **101**, 257410 (2008), [3] Lucchese et al, Carbon **48**, 1592 (2010), [4] Ferrari et al, PRL **97**, 187401 (2006)

9:00AM Y36.00006 Observation of out-of-plane vibrations in few-layer graphene using combination and overtone Raman modes , SUK HYUN KIM, CHUN HUNG LUI, LEANDRO MALARD, GABRIEL LANTZ, FRANÇOIS LAVERGE, Columbia University, RIICHIRO SAITO, Tohoku University, TONY HEINZ, Columbia University, HEINZ TEAM, SAITO TEAM — We have studied three distinct higher-order Raman features, appearing at $\sim$ 1660, 1730 and 1760 cm^{-1}, in graphene samples of 1-6 layers thickness and both Bernal and rhombohedral stacking. By detailed analysis of the measured dispersions of these lines using double-resonance theory, we have identified the features, respectively, as the LO+ZA, LO+ZO' combination modes and the 2ZO overtone mode. Here LO, ZA, and ZO, and ZO' denote, respectively, the in-plane longitudinal optical mode, the out-of-plane acoustic, optical and layer-breathing modes. All three of these Raman features are absent in single-layer graphene, which lacks the layer-breathing vibration and exhibits particularly high symmetry. The line shape of LOZO' mode shows a dramatic dependence on the stacking order of the layers and can serve as a means of identifying stacking order in few-layer graphene. In addition, the LOZO' mode allows us to access the properties of the low-energy layer-breathing (ZO') mode in few-layer graphene samples.

9:12AM Y36.00007 Infrared Kerr and Faraday Measurements in Gated, Multi-Layer SiC Graphene , C.T. ELLIS, A.V. STIER, A. STABILE, M.-H. KIM, G. SAMBANDAMURTHY, B.D. MCCOMBE, J. CERNE, Dept of Physics, University at Buffalo, SUNY, B.J. SCHULTZ, S. BANERJEE, Dept of Chemistry, University at Buffalo, SUNY, J.G. TISCHLER, Naval Research Laboratory — Magneto-optical Kerr and Faraday measurements are used to probe the Landau level structure of SiC graphene in the mid- and far-infrared regimes (100-1000 meV and 3-10 meV, respectively). Transmittance/reflectance spectroscopy probes the longitudinal conductivity (σ_{xx}), which is related to the sum of chiral response. In contrast, polarization sensitive techniques provide new insights into the electronic structure by probing the Hall conductivity (σ_{xy}), which reflects the difference in the chiral response. Samples, which are studied in applied fields (B) up to 7T and temperatures ranging from 10-300K, show robust features arising from two distinct sets of Landau level transitions. One set displays transition energies that are $\sqrt{B}$ dependent as expected of monolayer graphene. Interestingly, below a critical photon energy ($\sim$100 meV) these features become symmetric with B. The other set is consistent with expectations of bilayer graphene and graphite, showing a linear B dependence and the expected odd symmetry in B. Further investigation of Landau level behavior is accomplished by tuning the Fermi energy in samples with a gate. Work supported by NSF-DMR1006078.

9:24AM Y36.00008 Landau level-phonon resonances in graphene and their spectroscopic signatures in magneto-optical measurements , LIANG Z. TAN, Department of Physics, University of California at Berkeley, and Materials Sciences Division, Lawrence Berkeley National Lab, CHEOL-HWAN PARK, Department of Materials, University of Oxford, GERARD MARTINEZ, LNCMI, CNRS, Grenoble, France, STEVEN G. LOUIE, Department of Physics, University of California at Berkeley, and Materials Sciences Division, Lawrence Berkeley National Lab — The excited states and the optical spectra of a two-dimensional electronic system under a magnetic field are strongly influenced by the electron-phonon interaction when the energy spacing of the Landau levels is resonant with the frequency of an optical phonon. We have performed a theoretical study of these excited states in graphene, and have calculated the optical absorption spectra for a range of magnetic fields. Electron-electron interactions are found to redistribute the spectral weight of the coupled modes and have important consequences for the absorption spectra. Our results are in good agreement with recent magneto-optical transmission experiments on epitaxial graphene on SiC. This work was supported by NSF Grant No. DMR10-1006184 and U.S. DOE Contract No. DE- AC02-05CH11231.

9:36AM Y36.00009 Probing plasmons in graphene , LONG JU, BAISONG GENG, JASON HORNG, CAGLAR GIRIT, Dept of Physics, University of California at Berkeley, MICHAEL MARTIN, ZHAO HAO, HANS BECHTEL, Advanced Light Source Division, Lawrence Berkeley National Laboratory, XIAOGAN LIANG, Molecular Foundry, Lawrence Berkeley National Laboratory, ALEX ZETTL, FENG WANG, Dept of Physics, University of California at Berkeley — Plasmon behaviour in graphene is important for the understanding of many body interaction of 2D Dirac fermions. It also provides physical background for potential graphene applications in optoelectronics and ultrahigh speed THz electronics. In this talk, we will describe our study of plasmon behaviour in graphene using far-infrared spectroscopy and compare our experimental results to theoretical predictions.

9:48AM Y36.00010 Plasmon-Enhanced Photocurrent in a Graphene Nanoconstriction , SU-FEI SHI, Cornell University, XIAODONG XU, University of Washington, P.L. MCEUEN, D.C. RALPH, Cornell University — A plasmonic nanostructure can act like an optical antenna, concentrating light into a deep sub-wavelength volume and enabling manipulation of light-electron interactions at the nanometer scale. Achieving efficient coupling from such antennas to functional electrical devices has been challenging, because the region of field enhancement is so small. We report the use of a use a self- aligned fabrication process to couple a gold break junction acting as a plasmonic antenna with a sub-10-nm graphene constriction. The nonlinear electrical characteristics of the graphene device allow it to serve as a photodetector. We observe a photocurrent that is peaked at the plasmon frequency and strongly modulated by the polarization direction of the incident light. The enhancement of the local optical-frequency electric field induced by the plasmon is a factor of 1.5-10.

10:00AM Y36.00011 Thermal broadening effects on unstable plasmons in extrinsic graphene with injected carriers[1] , BEN YU-KUANG HU, The University of Akron, ANTTI-PEKKA JAUHO, Danmarks Tekniske Universitet and Aalto University — We study theoretically the charge density collective oscillations (plasmons) of an extrinsic (*i.e.*, doped) graphene system into which charge carriers (either electrons or holes) are injected. When the injected carriers are sharply peaked so that the distribution function of the injected carriers can be well approximated by $f_{\text{inject}}(\mathbf{p}) = n\delta(\mathbf{p} - \mathbf{p}_0)$, some of the plasmons in the system become unstable, in the sense that the amplitudes of these plasmons grow exponentially in time (at least initially, in the linear-response regime). This effect is analogous to the two-stream instability that is seen in classical plasma systems. As with the classical plasma system, thermal broadening of the injected carriers tends to suppress the instability. We report a theoretical study of the effect of the thermal broadening of the injected carriers on the plasmon instability in graphene, and we delineate the parameters where the thermal effects completely suppress the instability.

10:12AM Y36.00012 Electromagnetic wave propagation through a graphene-based photonic crystal , OLEG BERMAN, VLADIMIR S. BOYKO, ROMAN YA. KEZERASHVILI, New York City College of Thechnology, City University of New York — A novel type of photonic crystal formed by embedding a periodic array of constituent stacks of alternating graphene and dielectric discs into a background dielectric medium is proposed [1]. The frequency band structure of a 2D photonic crystal with the square lattice of the metamaterial stacks of the alternating graphene and dielectric discs is obtained. The electromagnetic wave transmittance of such photonic crystal is calculated. The graphene-based photonic crystals have the following advantages that distinguish them from the other types of photonic crystals. They can be used as the frequency filters and waveguides for the far infrared region of spectrum at the wide range of the temperatures including the room temperatures. The photonic band structure of the graphene-based photonic crystals can be controlled by changing the thickness of the dielectric layers between the graphene discs and by the doping. The sizes of the graphene-based photonic crystals can be much larger than the sizes of metallic photonic crystals due to the small dissipation of the electromagnetic wave. The advantages of the graphene-based photonic crystal are discussed.

10:24AM Y36.00013 Effects of Layer Stacking on the Combination Raman Modes in Graphene , RAHUL RAO, Air force research laboratory, RAMAKRISHNA PODILA, Clemson University, RYUICHI TSUCHIKAWA, JYOTI KATOCH, DEREK TISHLER, University of Central Florida, APPARAO RAO, Clemson University, MASA ISHIGAMI, University of Central Florida — We have observed new combination modes in the range from 1650 – 2300 cm^{-1} in single-(SLG), bi-, few-layer and incommensurate bilayer graphene (IBLG) on silicon dioxide substrates. The M band at $\sim$1750 cm^{-1} is suppressed for both SLG and IBLG. A peak at $\sim$1860 cm^{-1} (iTALO$^-$) is observed due to a combination of the iTA and LO phonons. The intensity of this peak decreases with increasing number of layers and this peak is absent in bulk graphite. Two previously unidentified modes at $\sim$1880 cm^{-1} (iTALO$^+$) and $\sim$2220 cm^{-1} (iTOTA) in SLG are tentatively assigned as combination modes around the K point of the graphene Brillouin zone. The peak frequencies of the iTALO$^+$ (iTOTA) modes are observed to increase (decrease) linearly with increasing graphene layers.

Session Y38 DCP DBP: Focus Session: Non-Equilibrium Insights into Single Molecules and Cell Function II A130/131

8:00AM Y38.00001 Can Simple Biophysical Principles Yield Complicated Biological Functions? , JAN LIPHARDT, Physics Dept., UC Berkeley — About once a year, a new regulatory paradigm is discovered in cell biology. As of last count, eukaryotic cells have more than 40 distinct ways of regulating protein concentration and function. Regulatory possibilities include site-specific phosphorylation, epigenetics, alternative splicing, mRNA (re)localization, and modulation of nucleo-cytoplasmic transport. This raises a simple question. Do all the remarkable things cells do, require an intricately choreographed supporting cast of hundreds of molecular machines and associated signaling networks? Alternatively, are there a few simple biophysical principles that can generate apparently very complicated cellular behaviors and functions? I'll discuss two problems, spatial organization of the bacterial chemotaxis system and nucleo-cytoplasmic transport, where the latter might be true. In both cases, the ability to precisely quantify biological organization and function, at the single-molecule level, helped to find signatures of basic biological organizing principles.

8:36AM Y38.00002 Single-Molecule Analysis of Protein Large-Amplitude Conformational Transitions , HAW YANG, Princeton Uninversity — Proteins have evolved to harness thermal fluctuations, rather than frustrated by them, to carry out chemical transformations and mechanical work. What are, then, the operation and design principles of protein machines? To frame the problem in a tractable way, several basic questions have been formulated to guide the experimental design: (a) How many conformational states can a protein sample on the functionally important timescale? (b) What are the inter-conversion rates between states? (c) How do ligand binding or interactions with other proteins modulate the motions? (d) What are the structural basis of flexibility and its underlying molecular mechanics? Guided by this framework, we have studied protein tyrosine phosphatase B, PtpB, from M. tuberculosis (a virulence factor of tuberculosis and a potential drug target) and adenylate kinase, AK, from E. coli (a ubiquitous energy-balancing enzyme in cells). These domain movements have been followed in real time on their respective catalytic timescales using high-resolution single-molecule Förster resonance energy transfer (FRET) spectroscopy. It is shown quantitatively that both PtpB and AK are capable of dynamically sampling two distinct states that correlate well with those observed by x-ray crystallography. Integrating these microscopic dynamics into macroscopic kinetics allows us to place the experimentally measured free-energy landscape in the context of enzymatic turnovers.

9:12AM Y38.00003 Unfolding proteins with mechanical forces: From toy models to atomistic simulations[1] , DMITRII MAKAROV, University of Texas at Austin — The remarkable combination of strength and toughness, displayed by certain biological materials (e.g. spider silk) and often unmatched by artificial materials, is believed to originate from the mechanical response of individual load-bearing protein domains. Single-molecule pulling experiments carried out during the last decade showed that those proteins, when loaded, respond in a non-equilibrium fashion and can dissipate large amounts of energy though the breaking of sacrificial bonds. In my talk, I will discuss what structural properties correlate with mechanical strength and toughness at the single-molecule level, how thermodynamic stability is related to the mechanical stability, and why both atomistic simulations and simple models seem to fail to reconcile the mechanical responses of the same proteins measured under varied loading regimes. I will further discuss whether it is easier to unfold a protein mechanically by pulling at its ends or by threading it through a narrow pore. The latter process is believed to commonly occur in living organisms as an intermediate step in protein degradation.

9:48AM Y38.00004 Non-equilibrium microrheology of living cells , MING-TZO WEI, Bioengineering, Lehigh University, Bethlehem, PA, USA 18015, H. DANIEL OU-YANG, Physics and Bioengineering, Lehigh University, Bethlehem, PA, USA 18015 — Intracellular stresses generated by molecular motors can actively modify cytoskeletal network and change intracellular mechanical properties. We study the out-of-equilibrium microrheology in living cells using endogenous organelle particles as probes. This paper reports measurements of the intracellular mechanical properties using passive, particle-tracking and active, optical tweezers-based microrheology approaches. Using arguments based on the fluctuation-dissipation theorem, we compared the results from both approaches to distinguish thermal and non-thermal mechanical fluctuations in living cells.

10:00AM Y38.00005 Dissecting the heterogeneity of gene expressions in mouse embryonic stem cells[1] , LING-NAN ZOU, MATT THOMSON, S. JOHN LIU, FAS Center for Systems Biology, Harvard University, SHARAD RAMANATHAN, Department of Molecular and Cellular Biology, FAS Center for Systems Biology, Harvard University — A population of genetically identical cells, of the same nominal cell type, and cultured in the same petri dish, will nevertheless often exhibit varying patterns of gene expression. Taking mouse embryonic stem (ES) cells as a model system, we use immunofluorescence and flow cytometry to examine in detail the distribution of expression levels for various transcription factors key to the maintenance of the ES cell identity. We find the population-level distribution of many proteins, once rescaled by the average expression level, have very similar shapes. This suggest the largest component of observed heterogeneity comes from a single source. More subtly, we find the expression many of genes appears to modulate with the cell cycle. This may suggest that the program for maintaining ES cell identity is tightly coupled to the cell cycle machinery.

10:12AM Y38.00006 Synchronization of Cell Cycle Oscillator by Multi-pulse Chemical Perturbations , YIHAN LIN, YING LI, AARON DINNER, NORBERT SCHERER, University of Chicago — Oscillators underlie biological rhythms in various organisms and provide a timekeeping mechanism. Cell cycle oscillator, for example, controls the progression of cell cycle stage and drives cyclic reproduction in both prokaryotes and eukaryotes. The understanding of the underlying nonlinear regulatory network allows experimental design of external perturbations to interact and control cell cycle oscillation. We have previously demonstrated in experiment and in simulation that the cell cycle coherence of a model bacterium can be progressively tuned by the level of a histidine kinase. Here, we present our recent effort to synchronize the division of a population of bacterium cells by external pulsatile chemical perturbations. We were able to synchronize the cell population by phase-locking approach: the external oscillator (i.e. periodic perturbation) entrains the internal cell cycle oscillator which is in analogous to the phase-locking of circadian clock to external light/dark oscillator. We explored the ranges of frequencies for two external oscillators of different amplitudes where phase-locking occurred. To our surprise, non-periodic chemical perturbations could also cause synchronization of a cell population, suggesting a Markovian cell cycle oscillation dynamics.

10:24AM Y38.00007 Analysis of Cell Cycle Phase Response Captures the Synchronization Phenomena and Reveals a Novel Cell Cycle Network Topology , YING LI, YIHAN LIN, NORBERT SCHERER, AARON DINNER, University of Chicago — Cell cycle progression requires a succession of temporally-regulated sub-processes, including chromosome replication and cell division, which are each controlled by their own regulatory modules. The modular design of cell cycle regulatory network allows robust environmental responses and evolutionary adaptations. It is emerging that some of the cell cycle modules involve their own autonomous periodic dynamics. As a consequence, the realization of robust coordination among these modules becomes challenging since each module could potentially run out of sync. We believe that an insight into this puzzle resides in the coupling between the contributing regulatory modules. Here, we measured the phase response curve (PRC) of the cell cycle oscillator by driving the expression of a master regulator of the cell cycle in a pulsatile manner and measuring the single cell phase response. We constructed a return map that quantitatively explains the synchronization phenomena that were caused by periodic chemical perturbation. To capture the measured phase response, we derived a minimalist coupled oscillator model that generalizes the basic topology of the cell cycle network. This diode-like coupling suggests that the cell is engineered to ensure complete coordination of constituent events with the cell cycle.

10:36AM Y38.00008 Swimming Response of Individual Paramecia to Variable Forces[1] , ILYONG JUNG, MICHAEL WAGMAN, JAMES M. VALLES, JR., Brown University — Experiments demonstrate that swimming paramecia exhibit a negative force-kinetic response. In particular, upward swimming paramecia exert a stronger propulsive force as they fight their tendency to sediment. This response is remarkable because it suggests that paramecia can sense forces as small as their apparent weight, which is less than 100 pN. We are investigating the origins of this response by applying variable magnetic forces to individual swimming paramecia and measuring how their swimming trajectories change. We conduct the experiments at the National High Magnetic Field Laboratory where it is possible to achieve forces sufficient to stall the swimmers. We will present our latest data on how paramecia adjust the geometry of their helical trajectories under varying forces.

Session Y39 DCP: Focus Session: Imaging and Interfaces in Energy Science A124/127

8:00AM Y39.00001 Imaging Interfacial Structure and Reactivity with X-ray Reflectivity and Microscopy[1] , PAUL FENTER, Argonne National laboratory — A fundamental understanding of interfacial reactions is best achieved with ability to observe the systems of interest directly, ideally with molecular-scale resolution and/or sensitivities. X-ray-based approaches offer broad opportunities for probing complex interfaces in environments (e.g., liquids) that are normally inaccessible. I will describe two complimentary approaches for imaging interfaces. The first, X-ray reflection interface microscopy (XRIM), uses the weak interface-reflected X-ray beam to image laterally heterogeneous interfacial structures and processes using a full-field imaging approach. This approach incorporates all of the sensitivities of X-ray reflectivity (XR, including sensitivity to interfacial topography, structure and composition) as potential contrast mechanisms. Recent applications of XRIM will be described, including the abilities to observe: elementary surface topography (i.e., 6.5 Å-high steps) with ∼100 nm spatial resolution; interfacial reactivity; and liquid-solid interfaces, in-situ. A second, complementary, approach images the vertical distributions of element-specific sub-structures at an interface through the use of resonant dispersion at X-ray energies close to element's absorption edge (resonant anomalous X-ray reflectivity, RAXR). Recent applications of RAXR will be described including the ability to image element-specific distributions (i.e., ions near a charged liquid-solid interface) and its sensitivity for probing oxidation state specific structures at interfaces. The use of these techniques to observe charge transport at interfaces with respect to energy-related processes will be discussed.

[1]This work supported by the Geoscience Research Program of the US Department of Energy, Office of Basic Energy Sciences. This work is done in collaboration with M. J. Bedzyk, J. Catalano, S. S. Lee, C. Park, N. C. Sturchio, Z. Zhang, and P. Zschack.

8:36AM Y39.00002 Small-Pore Molecular Sieves SAPO-34 with Chabazite Structure: Theoretical Study of Silicon Incorporation and Interrelated Catalytic Activity , HONG WANG, JAMES LEWIS, West Virginia University, ZHONGMIN LIU, Dalian Institute of Chemical Physics — The catalytic conversion of methonal to olefin (MTO) has attracted attention both in industrial and academic fields. Strong evidence shows that small-pore molecular sieves with certain amount silicon incorporated (SAPO) present promising high catalytic activity in MTO conversion. Using DFT, we study the structural and electronic properties of chabazite SAPO-34. Although there are extensively experimental results show that silicon incorporation does not change the overall structure as the original AlPO structure, local structural changes are still created by silicon substitution, which probably accounted for the high catalytic activity. It is noted that the catalytic activity of SAPO-34 presents increasing trend along with the silicon incorporation amount increasing and maintain a flat peak even with more silicon incorporated. Hence, there is an optimal silicon incorporation amount which possibly yields the highest catalytic MTO conversion.

8:48AM Y39.00003 Nanosecond Scanning Tunneling Microscopy: resolving spin dynamics at the atomic scale , SEBASTIAN LOTH, IBM Research - Almaden — With the advent of nanoelectronics, functional electronic elements advance towards atomic dimensions and analysis techniques need to keep pace. Scanning tunneling microscopes (STM) have evolved into standard tools to measure the static electronic properties of nanostructures, molecules and atoms. Here we show how the STM can be used to access the equally important dynamical properties on time scales ranging from pico- to nanoseconds. We combine inelastic electron tunneling spectroscopy (IETS) with an all-electronic pump-probe measurement scheme and record the dynamical evolution of magnetic atoms on surfaces in the time domain [1]. We focus on the dynamics of electron spin relaxation in transition metal atoms placed onto a copper nitride decoupling layer on Cu(100). On this surface Fe atoms experience large magneto-crystalline anisotropy [2] that enables long spin lifetimes. At the same time the quantum mechanical nature of the discrete spin states allows for an additional path of spin relaxation: quantum tunneling of magnetization. We probe the dynamic behavior associated with this process and find that placing a Cu atom close to a Fe atom boosts the uniaxial anisotropy energy and creates a long-lived spin state with relaxation times in excess of 200 ns. The ability to probe individual nanostructures with atomic spatial and nanosecond temporal resolution opens a new avenue to explore spin dynamics and other dynamical phenomena on the intrinsic length scale of the underlying interactions.

9:24AM Y39.00004 Tracking Oxygen Vacancies in Thin Film SOFC Cathodes[1] , DONOVAN LEONARD, AMIT KUMAR, STEPHEN JESSE, SERGEI KALININ, Oak Ridge National Laboratory, YANG SHAO-HORN, ETHAN CRUMLIN, EVA MUTORO, Massachusetts Institute of Technology, MICHAEL BIEGALSKI, HANS CHRISTEN, STEPHEN PENNYCOOK, ALBINA BORISEVICH, Oak Ridge National Laboratory — Oxygen vacancies have been proposed to control the rate of the oxygen reduction reaction and ionic transport in complex oxides used as solid oxide fuel cell (SOFC) cathodes [1,2]. In this study oxygen vacancies were tracked, both dynamically and statically, with the combined use of scanned probe microscopy (SPM) and scanning transmission electron microscopy (STEM). Epitaxial films of $La_{0.8}Sr_{0.2}CoO_3$ (LSC_{113})and LSC_{113}/$LaSrCoO_4$(LSC_{214}) on a GDC/YSZ substrate were studied, where the latter showed increased electrocatalytic activity at moderate temperature. At atomic resolution, high angle annular dark field STEM micrographs revealed vacancy ordering in LSC_{113} as evidenced by lattice parameter modulation and EELS studies. The evolution of oxygen vacancy concentration and ordering with applied bias and the effects of bias cycling on the SOFC cathode performance will be discussed.

[1]Research is sponsored by the of Materials Sciences and Engineering Division, U.S. DOE.

9:36AM Y39.00005 First principles study of GaN(10$\underline{1}$0)/Water interface[1] , JUE WANG, MARIA VICTORIA FERNANDEZ-SERRA, XIAO SHEN, Stony Brook University — GaN/ZnO alloy semiconductors have been shown to be promising materials to serve as photo-anode in photocatalytical fuel cells. In recent study by Shen et al[2], the non polar GaN(10$\underline{1}$0) surface has been studied with atomistic modeling and a sequence of intermediate steps for the water oxidation process at the interface are proposed. Here we present a first principles molecular dynamics study of the GaN(10$\underline{1}$0)/Water interface. We found dissociation events happen within 1ps and we show a detailed analysis of the changes in structure and dynamics of water molecules interacting with a dissociating wet surface. The complex hydrogen bond network near the surface is also analyzed in detail, including a throughout study of the proton diffusion processes. We perform a detailed analysis of the dynamics of the hole localization. The link between water surface dissociation and quantum efficiency will be discussed.

9:48AM Y39.00006 Ions at interfaces and their spectroscopic consequences , PHILLIP GEISSLER, U.C. Berkeley — The affinity of relatively small ions for air-water interfaces challenges our basic understanding of the basic driving forces for solvation. Here I will show that this adsorption is a general phenomenon for ions in polar solvents. Its physical origin lies in a precarious and unexpected balance of strong nonlinear contributions. The statistics of solvent electric fields suggests a key role for interfacial fluctuations. I will also present an intuitive perspective on surface-specific vibrational spectroscopy, and discuss observable signatures for ion adsorption at aqueous interfaces.

10:24AM Y39.00007 First-Principles Studies of Functionalized Si(111) in Air and in Water[1] , YAN LI, Brookhaven National Laboratory, GIULIA GALLI, University of California, Davis — We have investigated structural, electronic and vibrational properties of hydrogen and methyl-terminated Si(111) surfaces both in air and in contact with water, by combining density functional theory and many-body perturbation theory within the GW approximations. The computed surface dipole moments for both H-Si(111) and CH3-Si(111) surfaces were found to be consistent with measured electron affinities (EAs), and can be explain by simple electronegative trends. While GW self-energy corrections greatly improve the absolute values of EAs, the EA difference of the two surfaces remains overestimated by about 0.3 eV. The variations in CH3 frequencies, e.g. the umbrella mode and CH stretching mode, for the surface in air and water are also well reproduced by our calculations. The influence exerted by the adsorption of water molecules on the hydrophobic H-Si(111) and CH3-(111) surfaces, in particular, on the EAs and the surface vibrational frequencies will be discussed and compared with recent experiments.

10:36AM Y39.00008 Interaction between surfaces with ionizable sites , STEPHEN BARR, ATHANASSIOS PANAGIOTOPOULOS, Chemical and Biological Engineering, Princeton University — A key factor controlling the interaction between surfaces in aqueous solutions is the surface charge density. Surfaces typically become charged though a titration process where surface groups can become ionized based on their dissociation constant and the pH of the solution. In this work we use a Monte Carlo method to treat this process explicity in a system with two planar surfaces in a salt solution. We find that the surface charge density changes as the surfaces come close to contact due to interactions between the ionizable groups on each surface. In addition, we observe an attraction between the surfaces above a threshold surface charge, in good agreement with previous theoretical predictions based on uniformly charged surfaces. However, close to contact we find the force is significantly different than the uniformly charged case. We also explore the role of salt concentration and the density of the ionizable sites.

Friday, March 25, 2011 8:00AM - 10:36AM –

Session Y40 DPOLY: Focus Session: Nanocomposite Physics II-Polymer Dynamics A122/123

8:00AM Y40.00001 Particles Bridge the Gap – Relevance of Polymer Graft Architecture on the Properties of Particle Brush Assemblies[1] , MICHAEL BOCKSTALLER, Carnegie Mellon University — Current interest in the assembly of ligand-coated nanoparticles into 2D and 3D array structures is driven by the opportunities for novel material technologies that derive from the interactions within nanoparticle superlattice structures. A common challenge in the solution-based assembly of particle superlattice structures is the propensity of hard-sphere type particle assemblies to crack formation and brittle fracture during solvent evaporation. Recent progress in controlled radical polymerization offers novel opportunities for polymer-stabilized particle systems (particle brushes) as building blocks of particle superlattice structures. This contribution will discuss synthetic strategies to realize particle brush systems with well defined polymer graft-architecture in the dense or semi-dilute brush regime and discuss the effect of polymer grafting on the structure formation and cohesive interactions in particle brush assemblies. In particular, it will be demonstrated chain entanglements between surface-grafted chains give rise to fracture through polymer-like crazing thus dramatically increasing the toughness and flexibility of the particle assembly. The modulus and toughness of polymer nanocomposites synthesized by self-assembly of particle brush systems will be shown to exceed those of "conventional" particle-filled polymer composites – a result that will be interpreted as a consequence of the particular conformational constraints of surface grafted chains.

8:36AM Y40.00002 How do Macromolecules Diffuse Through Pathways imposed by Nanoparticles? , RUSSELL COMPOSTO, KAREN WINEY, University of Pennsylvania, NIGEL CLARKE, Durham University, SANGAH GAM, University of Pennsylvania, JEFF METH, DuPont Co. — Macromolecular motion slows down in crowded biological and engineered systems. Polymer nanocomposites (PNC) containing nanotubes and nanospheres are ideal systems for probing the underlying mechanisms of diffusion in a crowded system. Here, we review the current experimental studies of tracer diffusion in PNC. For silica nanospheres (12nm and 28nm), the normalized diffusion coefficients fall on a master curve when plotted against the interparticle separation divided by the probe size. The entropic barrier model accounts for the reduced diffusion by the loss of chain entropy due to the constrictive bottlenecks between nanoparticles. A new flux-based model depicts confined chains as diffusing along narrow pathways arranged by the NPs. This model captures experimental results while accounting for the distribution of particle separations inherent to real PNC.

8:48AM Y40.00003 Macromolecular Diffusion in Polymer Nanocomposites , SANGAH GAM, University of Pennsylvania, JEFF METH, STEVE ZANE, DuPont Co., KAREN WINEY, University of Pennsylvania, NIGEL CLARKE, Durham University, RUSSELL COMPOSTO, University of Pennsylvania — Macromolecular diffusion in crowded systems is important in biological and engineered systems. We have studied macromolecular diffusion through a model polymer nanocomposite (PNC) containing phenyl grafted silica nanoparticles (NPs), randomly distributed in a polystyrene matrix. Over a wide range of NP loading and tracer molecular weight (M), the scaling of the diffusion coefficient with M is in excellent agreement with the entropic barrier model (EBM) previously used to describe diffusion of DNA through confined media (e.g., gels and nanopores). To investigate the effect of NP size, diffusion was measured in PNC's with silica NPs having diameters of 28 and 12 nm. The normalized diffusion coefficients (D/D_0) plotted against the interparticle separation relative to probe size (i.e., $ID/2R_g$) collapse on a master curve. Diffusion in a poly(methyl methacrylate):silica NP system was also investigated to understand how attractive interactions (i.e., enthalpy) perturb motion relative to the polystyrene and phenyl-silica NP system which is athermal. Finally, a flux-based model is proposed and compared with experimental results.

9:00AM Y40.00004 Role of Particle – Polymer Interactions on the Dynamics of Polymer Nanocomposites , GUGLIELMO CAPUANO, University of Naples, RAMAKRISHNA PONNAPATI, University of Houston, DOMENICO ACIERNO, University of Naples, RAMANAN KRISHNAMOORTI, University of Houston — Understanding the physics of polymers in the presence of nanoparticle fillers is of crucial importance, since it can lead to the formulation of truly engineered, functional nanocomposites with unique features and broad commercial utilization. The thermomechanical behavior of polymer nanocomposites qualitatively resembles those of polymer films confined to the nanoscale. It has been recently hypothesized that the suppression of physical aging in PMMA/silica nanocomposites is primarily due to hindered mobility of polymer molecules resulting from hydrogen bonding with hydroxyl units on the silica. Further, when solid nanoparticles are dispersed in polymer melts adsorption of polymer chains on the surface of nanoparticles alters the mobility of the chains far into the bulk, and several non-continuum effects are observed. We therefore investigate the effects of polymer-particle interactions on the relaxation dynamics and viscoelastic properties of a model nanocomposite based on a mixture of silica nanoparticles and poly(methyl acrylate). Narrow molecular weight distribution PMA was synthesized using ATRP and mixed with nanoparticles at different concentrations. Alterations in the viscoelastic behavior are attributed to filler structuring and interactions with the host polymer.

9:12AM Y40.00005 The relationship between the T_g depression and the speeding up of physical aging in polystyrene/gold nanocomposites , VIRGINIE M. BOUCHER, DIPC, DANIELE CANGIALOSI, ANGEL ALEGRIA, JUAN COLMENERO, CSIC — The effect of gold nanoparticles on the segmental dynamics, glass transition (T_g) and physical aging of polystyrene (PS) was studied in PS/Gold nanocomposites samples containing 5 and 15 wt.% of 60 nm spherical gold nanoparticles, surface-treated with thiolated-PS. While the segmental dynamics of PS, as assessed by broadband dielectric spectroscopy (BDS), was found to be unchanged in presence of gold nanoparticles, the calorimetric T_g of PS was shown to decrease with increasing the amount of nanoparticles in the samples. Furthermore, the physical aging of PS, monitored by measuring the enthalpy relaxation below T_g by means of DSC, was shown to speed up with increasing the nanoparticles weight fraction, i.e. the amount of PS/Gold interface in the hybrid material. Thus, the main conclusion of our work is that PS molecular mobility and out-of-equilibrium dynamics are decoupled in these nanocomposites. The significant effect of the amount of PS/Gold interface on both the physical aging rate of PS and the calorimetric T_g depression are quantitatively accounted for by a model based on the diffusion of free volume holes towards polymer interfaces, with a diffusion coefficient depending only on the molecular mobility.

9:24AM Y40.00006 Nanoparticle-directed self-assembly of amphiphilic block-copolymers[1] , SOJUNG PARK, University of Pennsylvania — The self-assembly of nanoparticles and amphiphilic polymers provides a powerful tool for the fabrication of functional composite materials for a range of applications spanning from nanofabrication to medicine. Here, we present how the incorporation of nanoparticles affects the self-assembly behavior of amphiphilic block-copolymers and how to control the morphology of nanoparticle-encapsulating polymer assemblies. Based on the approach, we have prepared various types of well-defined nanoparticle-encapsulating polymeric nanostructures, including polymersomes packed with magnetic nanoparticles and unique cavity-like quantum dot assembles. We found that the incorporation of nanoparticles drastically affects the self-assembly structure of block-copolymers by modifying the relative volume ratio between the hydrophobic block and the hydrophilic block. In addition, the nanoparticle-polymer and nanoparticle-solvent interactions impact the arrangement and the hybridization of nanoparticles in polymer matrix. These findings should form the basis for the design rules of the self-assembly of nanoparticles and polymer amphiphiles, which will allow one to create new hybrid structures with predesigned morphology and properties. Furthermore, we demonstrated that the morphology of nanoparticle-encapsulating polymer assemblies significantly affects their properties such as magnetic relaxation properties, underscoring the importance of the overall self-assembly structure and the nanoparticle arrangement in polymer matrixes.

10:00AM Y40.00007 Isothermal Crystallization of Poly(ethylene oxide) / Single Walled Carbon Nanotube Nanocomposites , ARNALDO LORENZO, TIRTHA CHATTERJEE, RAMANAN KRISHNAMOORTI, University of Houston — The isothermal crystallization behavior of poly(ethylene oxide)/single walled carbon nanotubes (PEO/SWNT) nanocomposites were studied with a focus on the *overall crystallization kinetics* and the *morphological* evolution of PEO using differential scanning calorimetry and in-situ small angle x-ray scattering measurements, respectively. The overall crystallization process of the PEO was strongly affected by lithium dodecyl sulfate (LDS) stabilized carbon nanotubes. Further, analysis of the overall crystallization kinetics showed that the PEO chains were topologically constrained by the presence of LDS with an increased energy barrier associated with nucleation and crystal growth, and the nanotubes further act as a barrier to chain transport or enhance the LDS action on the PEO chains. The energy penalty and diffusional barrier to chain transport in the nanocomposites disrupt the PEO crystal helical conformation. This destabilization leads to formation of thinner crystal lamellae and suggests that the crystallization kinetics is primarily controlled by the growth process. This study is particularly interesting considering the suppression of the PEO crystallinity in presence of small amounts of Lithium ion based surfactant and carbon nanotubes.

10:12AM Y40.00008 MD Simulations of DNA-Programmable Nanoparticle Self-Assembly[1] , CHRISTOPHER KNOROWSKI, ALEX TRAVESSET, Department of Physics and Astronomy and Ames Laboratory, Iowa State University, Ames, IA — Self-assembly through linker mediated hybridization is a powerful technique to control self-assembly at the nanoscale. Recent experiments with complementary ssDNA attached to Au nanoparticles have shown crystallization into BCC and FCC crystals. We give a brief overview of a coarse grained model and present molecular dynamics simulations of the model. We discuss its static and dynamical properties.

10:24AM Y40.00009 Hierarchical Superstructures from the Self-assembly of Giant Surfactants in Condensed State[1] , WEN-BIN ZHANG, XINFEI YU, XUEHUI DONG, YIWEN LI, KAN YUE, JINLIN HE, STEPHEN CHENG, Department of Polymer Science, College of Polymer Science and Polymer Engineering, The University of Akron — Giant surfactants are a class of tadpole-shaped hybrid nanomaterials with a functional nanoparticle as the head group and a polymer chain as the tail, such as perfluorochain-functionalized polyhedral oligomeric silsesquioxane end-capped poly(ε-caprolactone) (FPOSS-PCL). The self-assembly of FPOSS-PCL with different composition in bulk were studied using DSC, SAXS, WAXD, and TEM. The compact arranagement of the perfluorochains on the POSS nanoparticles clearly distinguishes them from the polymer chain, leading to the formation of nanophase-separated supramolecular structures such as spheres, cylinders, and bilayered lamellaes. This physical picture is rather unusual and quite reminescent to that observed in the aggregates of small-molecule surfactants. The striking similarity indicates the importance in tuning the interactions to control the hierarchical structure formation in hybrid nanomaterials.

Session Y41 DPOLY: Elastomers and Gels A115/117

8:00AM Y41.00001 Swelling Kinetics of a Microgel Shell , JOSHUA WAHRMUND, University of North Texas, JIN-WOONG KIM, LIANG-YIN CHU, Harvard University, CHANJIE WANG, Haynes and Boone, LLP, YONG LI, Kimberly-Clark Corporation, ALBERTO FERNANDEZ-NIEVES, Harvard University, DAVID A. WEITZ, Harveard University, ARKADII KROKHIN, ZHIBING HU, University of North Texas — Tanaka's approach to swelling kinetics of a solid gel sphere is extended to a spherical microgel shell. The boundary condition at the inner surface is obtained from the minimization of shear elastic energy. Temporal evolution of a shell is represented in a form of expansion over eigenfunctions of the corresponding diffusion equation. The swelling of Tanaka's solid spherical gel is recovered as a special case of our general solution if the inner radius approaches zero. To test our theoretical model, we prepared monodisperse poly-N-isopropylacrylamide (PNIPAM) hydrogel shells using a microfluidic device. The temporal dependence of the inner and outer radii of the shell was measured and the data was fitted to our theoretical model. As a result, we obtained the collective diffusion constants for shrinking and for swelling processes. The obtained values for microgel shells are in excellent agreement with the previous results obtained for sub-millimeter PNIPAM solid spheres in the same temperature interval. Our model shows that the characteristic swelling time of a gel shell should be proportional to the square of its outer radius—just as with Tanaka's model.

8:12AM Y41.00002 Indentation of polydimethylsiloxane submerged in organic solvents , YUHANG HU, Harvard University, XIN CHEN, GEORGE WHITESIDES, JOOST VLASSAK, ZHIGANG SUO — This study uses a method based on indentation to characterize a polydimethylsiloxane (PDMS) elastomer submerged in an organic solvent (decane, heptane, pentane, or cyclohexane). An indenter is pressed into a disk of a swollen elastomer to a fixed depth, and the force on the indenter is recorded as a function of time. By examining how the relaxation time scales with the radius of contact, one can differentiate the poroelastic behavior from the viscoelastic behavior. By matching the relaxation curve measured experimentally to that derived from the theory of poroelasticity, one can identify elastic constants and permeability. The measured elastic constants are interpreted within the Flory-Huggins theory. The measured permeabilities indicate that the solvents migrate in PDMS by diffusion, rather than by convection. This work confirms that indentation is a reliable and convenient method to characterize swollen elastomers.

8:24AM Y41.00003 Synthesis and mechanical properties of resilin-like hydrogels , JUN CUI, MELISSA LACKEY, University of Massachusetts Amherst, GREGORY TEW, University of Massachussets Amherst, ALFRED CROSBY, University of Massachusetts Amherst — Resilience measures a material's efficiency for mechanical energy storage. Many materials exhibit high resilience at low strains, but relatively few can maintain this performance at high strain levels. One of the most notable examples of a resilient material is resilin, a protein used strategically when Nature requires elasticity with minimal loss over large deformations. Similar to resilin in many aspects, we present a novel hydrogel network with well-defined architecture by introducing hydrophobic polydimethylsiloxane (PDMS) into hydrophilic polyethylene glycol (PEG)-based network. As a function of the PDMS to PEG ratio, we demonstrate that maximum water content can range from 97% to 80% and Young's modulus from 5kPa to 75kPa. Across this full range of network compositions and water content, the resiliency is nearly 100% for uniaxial strains exceeding 80%. This unique balance of properties is associated with two network attributes: uniformity in network connectivity and negligible secondary structures.

8:36AM Y41.00004 Pre-Stressed Double Network Elastomers And Hydrogels , NAVEEN SINGH, ALAN LESSER, Polymer Science and Engineering Dept., University of Massachusetts at Amherst — A new approach to prepare and characterize pre-stressed double network elastomers and hydrogel systems is investigated. In one example, a styrene-butadiene-styrene (SBS) tri-block copolymer system containing physical cross-links is used to achieve a pre-stressed double network by additional chemical crosslinking in a strained state using ultra-violet (UV) light. Unusual physical and mechanical properties that result from the interactions between each network are presented. These double network elastomers show a transition between competitive and collaborative behavior in their mechanical properties, as well as lower permanent set in both low and high strain regimes along with lower hysteresis. These networks exhibit lower modulus, along with lower coefficient of thermal expansion, still showing lower swelling ratios, which results from a competition of the networks. In another example, a new two-step curing schedule is utilized for Polyacrylamide based hydrogels, where a strain is induced in the middle of curing reaction. The final mechanical properties of these double network hydrogels are studied and compared to both first network and the single network formed without any step strain.

8:48AM Y41.00005 Topological effects on viscoelasticity of polyacrylamide hydrogels , JAN KALFUS, ALAN LESSER — Viscoelastic behavior of long linear chains in a concentrated solution is governed by the topology of the molecules and interchain excluded volume interaction. As a consequence, chain diffusive motion is significantly retarded and such an assembly of chains exhibits highly pronounced entropy elastic behavior. In this contribution, two types of additional chain confinements imposed on a concentrated solution of linear polyacrylamide (L-PAA) will be discussed. The confinement was realized either by adding silica nano-filler into the concentrated solution of L-PAA or by cross-linking of acrylamide in the concentrated solution of L-PAA. While in the first case the trapped entanglement interaction is caused by interaction of chains with large nano-filler surface, in the second case the L-PAA chains are trapped among the cross-links of the PAA network. Viscoelastic response of both types of composite systems exhibited generic characteristics. In both cases, the trapped entanglement interaction significantly changed the relaxation spectrum of the matrix polymer solution and considerably enhanced the linear elastic modulus.

9:00AM Y41.00006 Memory Effects in Strained Polymer Networks Caused By Multiple Stages of Crosslinking , JOANNE BUDZIEN, Frostburg State University — Polymer networks crosslinked in multiple strain states usually are analyzed with the independent network model. For networks that undergo scission in addition to crosslinking, however, the networks have been shown not to be completely independent. Even with complete removal of all crosslinks from a given network reacted in a particular strain state, the system still responds as though a portion of the original network remains. This talk will present simulation results of a coarse-grained model that has multiple networks with crosslinking and scission occurring in stages.

9:12AM Y41.00007 Viscoelastic Properties and Ionic Conductivity of Block Copolymer-Based Ion Gel Electrolytes[1] , SIPEI ZHANG, KEUN HYUNG LEE, C. DANIEL FRISBIE, TIMOTHY P. LODGE, University of Minnesota — The viscoelastic properties and ionic conductivity of block copolymer-based ion gels were investigated with polymer concentrations of 10 – 50 wt% over a temperature range of 25 – 200 °C. Ion gels were prepared through the self-assembly of poly(styrene-*b*-ethylene oxide-*b*-styrene) (SOS) and poly(styrene-*b*-methyl methacrylate-*b*-styrene) (SMS) triblock copolymers in a room-temperature ionic liquid, 1-ethyl-3-methylimidazolium bis(trifluoromethylsufonyl)imide ([EMI][TFSI]). The S end-blocks associate into micelles, whereas the O and M midblocks are well-solvated by this ionic liquid. Under oscillatory mechanical shear, two relaxation modes have been observed in the SMS ion gels. The faster mode corresponds to the relaxation of the M midblocks in the ionic liquid, while the slow mode reflects motion of the S end blocks within their micellar cores. Comparison of the solid gels and the liquid homopolymer solutions showed that the reduction of ionic conductivity of the gels with respect to that of the solutions is relatively small, and depends primarily on the volume fraction of S micelles.

9:24AM Y41.00008 Fracture Behavior of High-Toughness, Ionically Cross-linked Triblock Copolymer Hydrogels , KEVIN HENDERSON, KATHRYN OTIM, KENNETH SHULL, Northwestern University — Mechanisms for enhancing energy dissipation and hence toughness are important for the generation of robust synthetic soft materials for biomedical applications. Ionic cross-linking in particular has been explored in triblock copolymer hydrogels and affords a remarkable change in mechanical performance comparable to non-cross-linked analogs. Here we employ a physically associated base triblock copolymer network composed of hydrophobic poly(methyl methacrylate) endblocks and a hydrophilic poly(methacrylic acid) midblock capable of complexing with divalent cations. Increases in stiffness and strength have previously been reported, with the extent dependent upon the identity, concentration, and pH of a cross-linking cation solution. We delineate the measured toughness in such systems using tensile tear tests and relate the mechanical performance to a damage zone model reminiscent of loading behavior observed in double network hydrogels.

9:36AM Y41.00009 Origin of the Toughness and the Elastomeric Properties of Gels from Block Copolymers with Semicrystalline Syndiotactic Polypropylene Blocks , FANNY DEPLACE, ZHIGANG WANG, GLENN H. FREDRICKSON, EDWARD J. KRAMER, MC-CAM and the Departments of Materials and Chemical Engineering, UC Santa Barbara, JEFFREY M. ROSE, GEOFFREY W. COATES, Department of Chemistry and Chemical Biology, Baker Laboratory, Cornell University, FUMIHIKO SHIMIZU, Mitsubishi Chemical Group, Science and Technology Research Center, Inc., Yokohama, LIXIA RONG, BENJAMIN S. HSIAO, SUNY Stony Brook, Department of Chemistry, Stony Brook — The exceptional toughness and elastomeric properties of gels from block copolymers with semicrystalline syndiotactic polypropylene blocks have been reported. From results obtained from small angle and wide angle X-ray scattering experiments simultaneously performed with step cycle tensile stretching, the toughness can be attributed to the formation, orientation and elongation of crystalline fibrils along the tensile direction. The evolution of the crystalline structure during deformation is confirmed by FTIR measurements and the crystalline morphology is characterized by polarized microscopy imaging. Both polypropylene crystals and the rubbery phase play a role in the elasticity of the gels. Due to the viscoelasticity of the rubbery phase, an increase in the elastic recovery is observed when the gels are allowed to relax at zero load before starting the next cycle.

9:48AM Y41.00010 Chemomechanical Characterization of Autonomic Polyacrylamide Gels , MATTHEW SMITH, Nanostructured and Biological Materials Branch, AFRL, WPAFB, OH, KEVIN HEITFELD, Renegade Materials Corporation, RYAN KRAMB, MAXIM TCHOUL, DANIEL GALLAGHER, RICHARD VAIA, Nanostructured and Biological Materials Branch, AFRL, WPAFB, OH — Autonomic behavior is a distinctive attribute of complex biological systems. Like biological tissue, self-oscillating hydrogels driven by the Belousov-Zhabotinsky (BZ) reaction can convert chemical signals into a mechanical response. Under appropriate conditions BZ gels exhibit sustained mechanical swell-deswell oscillations; and arrays of these gels have the potential to form networks of coupled oscillators. One of the key challenges to developing criteria for device design and assessing practical performance limits of these materials is the need for detailed knowledge of the chemomechanical characteristics of the BZ gels at various states of autonomic behavior. Recently we developed an easily synthesized BZ gel system based on polyacrylamide. Here in, the swell-deswell amplitude, mechanical forces produced during uniform oscillations, and the chemical response to external loads are discussed in context with current poly(N-isopropylacrylamide)-based systems. These studies establish the parameter space leading to robust chemomechanical oscillations and provide an experimental foundation to refine currently available theoretical models to guide the design of autonomic materials and devices.

10:00AM Y41.00011 Block copolymer photonic crystal gels for mechanochromic sensing , EDWIN CHAN, NIST, JOSEPH WALISH, EDWIN THOMAS, MIT, CHRISTOPHER STAFFORD, NIST — Block copolymer based photonic crystal gels (BCPG) have been previously demonstrated for chemical sensing by taking advantage of dynamic changes in structural color upon interactions with their environment. With their high degree of tunability in structural color and mechanical properties, these materials can function as mechanochromic sensors with the potential application for measuring local mechanical deformation such as cell adhesion and mechanics. In this work, we demonstrate the application of a BCPG for local mechanical sensing by investigating the changes in structural color in response to mechanical deformation. The BCPG consists of a hydrophobic block (polystyrene) – hydrophilic polyelectrolyte (poly(2-vinyl pyridine)) block copolymer that self-assembles into a one- dimensional periodic lamellar structure and functions as a one dimensional Bragg reflector. Contact adhesion testing is used to measure and relate the changes in structural color of the BCPG films as a function of mechanical deformation. We explore the effects of solvent conditions and applied mechanical deformation in determining the relationships between structural color changes and mechanical strain.

10:12AM Y41.00012 Theoretically Informed Coarse-Grained Simulations of Polymer Nanogels , PRATEEK JHA, JOS ZWANIKKEN, Northwestern University, FRANCOIS DETCHEVERRY, JUAN DE PABLO, University of Wisconsin - Madison, MONICA OLVERA DE LA CRUZ, Northwestern University — Nanoscale finite-sized polymer networks (nanogels) are smart responsive materials that undergo large reversible volume changes with moderate changes in environmental conditions such as temperature, pH, light, and electric field. We develop a coarse-grained model of nanogels in terms of experimentally measurable physical quantities, and perform a theoretically informed Monte Carlo simulation that combines ideas from both the particle and continuum approaches of polymer physics. The elastic interactions are treated through beads connected by harmonic springs ("particles"), and the van der Waals and electrostatic interactions are treated by weighted densities ("fields"). Our simulations predict high degrees of swelling and a discontinuous volume phase transition in ionic nanogels, in contrast to moderate swelling and a continuous volume phase transition for the non-ionic case. We analyze the effects of mesh-size, polymer charge fraction, ionic strength, and solvent quality, on the swelling behavior of nanogels. A comparison is made with the results of a simplified continuum model, where the electrostatic interactions are treated using the Poisson-Boltzmann approximation.

Friday, March 25, 2011 8:00AM - 11:00AM –

Session Y42 DPOLY: Focus Session: Dynamics of Polymers–Phenomena due to Confinement–Theory, Wrinkling, and Glass Transitions A302/303

8:00AM Y42.00001 Twinkling Fractal Analysis of Confinement Effects on the Glass Transition of Thin Films , RICHARD WOOL, JOSEPH STANZIONE III, Chemical Engineering, Univ Delaware — The Twinkling Fractal Theory (TFT) of the Glass Transition has recently been verified experimentally [J.F. Stanzione, et al., "Observing the twinkling fractal nature of the glass transition", J. Non-Cryst. Solids (2010), doi:10.1016/j.jnoncrysol.2010.06.041] Here we apply the TFT to understand nanoconfinement effects on T_g for amorphous thin films of thickness h with free and adhered surfaces. The TFT states that T_g occurs when the dynamic clusters percolate rigidity at the rate of testing γ. The lifetime τ of these fractal clusters of size R behaves as $\tau \sim R^{\delta}$ exp $\Delta E/kT$, where $\delta = D_f/d_f$ in which D_f is the fractal dimension and $d_f = 4/3$ is the fracton dimension for the vibrational density of states $g(\omega) \sim \omega^{df}$. The activation energy $\Delta E = \beta[T^{*2}\text{-}T_g^2]$ in which $\beta \approx 0.3$ cal/mol $^oK^2$ and $T^* \approx 1.2T_g$. In confined spaces, only clusters of size R<h can exist and these have a very fast relaxation time compared to the bulk. Thus, for free surfaces, T_g must be dropped at that test rate to percolate rigidity and we obtain the familiar expression $T_g(h)/T_{g\infty} \approx [1\text{-}(B/h)^{\delta}]$ where $\delta \approx 1.8$ when $D_f \approx 2.5$ and B is a known constant. For thin films adhered to solid substrates, T_g increases in accord with the adhesion energyΔA as $\Delta E \rightarrow \Delta E + \Delta A$ and the adhered cluster lifetime increases. As the rate of testing γ increases, the confinement effects diminish as T_g increases in accord with $T_g(\gamma) = T_{go} + (k/2\beta) \ln \gamma/\gamma_o$.

8:12AM Y42.00002 Mechanical properties of thin polymer films close to the glass transition: a mesoscale model , DIDIER R. LONG, ALAIN DEQUIDT, PAUL SOTTA, CNRS/Rhodia — Polymer dynamics slows down in the vicinity of a solid substrate (when interactions are sufficiently strong), as can be evidenced experimentally by measuring the glass transition temperature Tg in thin films. We extend here the Long and Lequeux model which quantitatively accounts for this effect. We describe the mechanical properties of the polymers on the scale of dynamical heterogeneities (of a few nanometers). We propose a constitutive relation regarding the local relaxation time, the local stress, and the deformation history. The mechanical equations coupled to these constitutive relations are solved, allowing to reach a scale of a few tens of nanometers and macroscopic time scales. In particular, we measure the elastic modulus G' as a function of temperature, for various films thicknesses. This measurement allows for measuring the glass transition temperature of the film as a function of thickness. The results show that the glass transition temperature is shifted as compared to the bulk (corresponding to large film thickness), depending on the strength of the polymer/substrates interaction, with values which are consistent with experimental results.

8:24AM Y42.00003 A Simple Approach to Free Volume Transport in Molten/Glassy Material[1] , JANE LIPSON, Dartmouth College, SCOTT MILNER, Penn State University, NICHOLAS TITO, Dartmouth College — A key component of microscopic models for the glass transition, in polymer thin films and more generally, is the local dynamics of free volume, which governs what portions of a near-glassy liquid are mobile at a given instant in time. For example, our recent Delayed Glassification (DG) model implements a proposal of de Gennes that segment-sized kinks of free volume may travel from a free surface into a film along polymeric loops or bridges, helping to plasticize material within some accessible distance from the surface. Recently, we have constructed a simple model for 'the mobility of mobility', i.e., how local mobility is itself transported through a dense liquid slightly above Tg. Our simple model results in growing cooperativity lengths and intermittency timescales as Tg is approached from above. If time permits, we shall also describe how the model may be adapted to describe the approach to glassy behavior in supported and freestanding films.

[1]Support from NSF-DMR is gratefully acknowledged.

8:36AM Y42.00004 Deviations in mechanical properties of ultrathin polymer films via surface wrinkling , CHRISTOPHER M. STAFFORD, Polymers Division, National Institute of Standards and Technology — In ultrathin polymer films (h $<$ 100 nm), the measurement of stress relaxation and Young's modulus is a difficult problem due to the delicate nature of such thin films and the lack of appropriate measurement tools for this length scale. Recent work has shown that the Young's modulus of ultrathin glassy polymer films can be measured by a wrinkling-based metrology. Interestingly, the modulus of such thin films was observed to deviate considerably from their bulk counterparts. Building off these observations, we have shown that the rate of structural relaxation and the temperature dependence of the film modulus can also be obtained by following the 'relaxation' of strain-induced wrinkling patterns back to their flat equilibrium state. By measuring the decay or relaxation of surface undulations in compressed thin films, we demonstrate that the structural relaxation of the polymer film is highly thickness-dependent and obeys Arrhenius temperature dependence with an activation energy that decreases progressively with decreasing film thickness. This gives rise to an overall broadening of glass transition and to a relatively weak temperature dependence of structural relaxation.

9:12AM Y42.00005 Calorimetry of Thin Films – From Single Layer Glass Transitions to Interlayer Diffusion in Double Layers , CHRISTOPH SCHICK, Institute of Physics, University of Rostock, Germany, DONGSHAN ZHOU, State Key Laboratory of Coordination Chemistry, Nanjing University, China, HEIKO HUTH, MATHIAS AHRENBERG, Institute of Physics, University of Rostock — Nanocalorimetry allows studying the glass transition in nanometer thin films. One of the striking results of fast scanning (FSC) as well as alternating current (AC) calorimetry is the commonly observed constant Tg in thin films down to a few nm. Blends of polystyrene and poly(phenylene oxide) (PS/PPO) confined in thin films (down to 6 nm) were investigated by AC nanocalorimetry. For this blend, we see even for the thinnest films (6 nm, corresponding to about half of PPO's radius of gyration Rg) only one unchanged glass transition. The good miscibility between PS and PPO remains even in ultrathin films. Finally, we show that our chip calorimeter is sensitive enough to study the inter-layer diffusion in ultrathin films. The PS chains in a 150 nm PS/PPO double layer that is prepared by spin coating PPO and PS thin films in tandem gradually diffuse into the PPO layer when heated above the Tg of PS, forming a PSxPPO100-x blend. However, on top of the PSxPPO100-x blend, there exists a stable pure PS like layer (ca. 30nm in our case) that does not diffuse into the blend beneath even staying at its liquid state over 10 hours.

9:24AM Y42.00006 T_g depression and segmental dynamics of polystyrene thin films , DANIELE CANGIALOSI, CSIC-CFM, VIRGINIE M. BOUCHER, DIPC, ANGEL ALEGRIA, CSIC-CFM and UPV/EHU, JUAN COLMENERO, CSIC-CFM and DIPC — The glass transition temperature (T_g) of polymer thin films has been a subject of intense debate in the last two decades. (Pseudo)thermodynamic determinations, such as calorimetry and ellipsometry, generally suggest a significant depression of T_g, whereas the dynamic T_g, measured by techniques such broadband dielectric spectroscopy and AC-calorimetry directly probing the molecular mobility, is found to be unchanged. The present study provides a resolution to this controversy on polystyrene by showing that the experimental relaxation time obtained from (pseudo)thermodynamic techniques, and the intrinsic molecular relaxation time can be rescaled on a master curve, only accounting for the thickness of the film. Furthermore the thickness and cooling rate dependence of the (pseudo)thermodynamic T_g is quantitatively captured by the free volume holes diffusion model. In this framework, the T_g depression emerges from the ability of thinner films to maintain equilibrium, due to the shortest distance free volume holes have to diffuse to the polymer interface.

9:36AM Y42.00007 Evidence for Two Simultaneous Mechanisms Causing Tg Reductions in High Molecular-Weight Free-Standing Films Observed as Dual Glass Transitions More Than 30 K Apart in a Single Film , JUSTIN PYE, CONNIE ROTH, Emory University — Glass transition temperature (Tg) changes seen in nanoconfined polymer films have been well documented over the past 15+ years. Supported films exhibit a molecular-weight (MW) independent Tg reduction that manifests itself as a gradient in dynamics emanating from the free surface. Low MW free-standing films show qualitatively the same Tg reduction as supported films, but with the presence of two free surfaces resulting in a Tg reduction that is twice as large for a given film thickness. In contrast, high MW free-standing films exhibit a qualitatively different behavior with a linear reduction in Tg that is MW dependent, potentially described by de Gennes' sliding mode theory. These observations suggest that there may exist two separate mechanisms which can propagate enhanced mobility from the free surface into the film. With ellipsometry measurements over an extended temperature range, we have observed two reduced Tgs more than 30 K apart in individual high MW free-standing polystyrene films suggesting that both mechanisms act simultaneously within a film. These results may explain recent studies on high MW free-standing films using different experimental techniques that contradict the original literature.

9:48AM Y42.00008 Demonstration of Glass Transition Temperature Depression in Thin Supported Polystyrene Films Using Internal Standard , MIKHAIL EFREMOV, PAUL NEALEY, Department of Chemical and Biological Engineering, University of Wisconsin - Madison, Madison, WI 53706 — Clear evidence for glass transition temperature (Tg) depression in $\sim$ 5 nm thick atactic polystyrene (Mw = 212 kg/mol) films supported on silicon substrates is demonstrated by ellipsometry in vacuum [1]. Transition in polystyrene droplets formed by dewetting is used as an internal reference. Both temperature-modulated [2] and linear temperature scanning techniques are utilized; measurements are performed at $10^{-6} - 10^{-8}$ torr residual gas pressure. The method is sensitive enough to observe glass transition in $1 - 2$ nm thick supported polystyrene films. Our recent study shows appreciable reduction of Tg in less than $10 - 20$ nm thick samples; Tg versus thickness function is found to follow a step-like curve originally reported by [3]. The curve is characterized by moderate (about 17 K) constant Tg depression for thickness less than $7 - 8$ nm. References: [1]. M. Y. Efremov, S. S. Soofi, A. V. Kiyanova, C. J. Munoz, P. Burgardt, F. Cerrina, and P. F. Nealey, Rev. Sci. Instrum., 79, 043903 (2008). [2]. M. Y. Efremov, A. V. Kiyanova, and P. F. Nealey, Macromolecules, 41, 5978 (2008). [3] T. Miyazaki, K. 10:00AM Y42.00009 Effect of Packing Density on the Measurement of Glass Transition Temperatures in Thin Film , GI XUE, Nanjing University, DEPARTMENT OF POLYMER SCIENCE, NANJING UNIVERSITY TEAM — In the measurement of *Tg* of polymers, a break or jump in some properties is seen at the transition temperature. For bulk polymer, the measurement of *Tg* by different methods has similar result. However, the results reported for thin films have shown quite disagreement among different experimental methods. We used NMR and fluorescence spectroscopy to detect interchain distance and found that the thin film and the freeze-dried polymers show reduced packing densities. And we also found no thickness dependence of *Tg* in thin film and no changes of *Tg* in the freeze-dried polymer measured by calorimetric method or by dynamic mechanical thermal analysis. However the *Tg* in the same samples measured by thermo-mechanical analysis or by positron annihilation lifetime spectroscopy is significantly lower than that in bulk polymers. We argue that the reduction in packing density is a major factor which causes the disagreement among *Tg* measured by different methods for thin films. During the processes of some measurements, an unjamming transition is proposed to take place, which reduces *Tg*.

10:12AM Y42.00010 The Effect of Molecular Weight on the Glass Transition Temperature of Polymer Thin Films , QIANG GU, DONGSHAN ZHOU, GI XUE, Department of Polymer Science and Engineering, The School of Chemistry and Chemical Engineering, Nanjing University, Nanjing 210093, GI XUE TEAM — The thickness dependence of glass transition temperature (Tg) of polymer thin films has attracted considerable attention in both technological and scientific fields. With decreasing polymer film thickness d, the Tg(d) can decrease, increase or remain constant lying on the details of measurement techniques and sample preparation, etc. Using the recently developed differential alternating current chip calorimeter, we directly measured the calorimetric Tg of polystyrene thin films with various molecular weights. We found that when the molecular weight of polystyrene is below the critical chain entanglement, its Tg in a thin film with a thickness of 15 nm can reduce by 20 degrees (compared to bulk sample). However, the Tg of polystyrene film above the entanglement molecular weight remains constant as the film thickness changes. We argue that the molecular weight plays an important role in the thickness dependence of glass transition temperature of polymer thin films.

10:24AM Y42.00011 Glassy dynamics within surface-bound molecular monolayers , L.I. CLARKE, Dept. of Physics, NC State University, Raleigh, NC 27695, M.P. ROMAN, D.R. STEVENS, M.C. SCOTT, J.R. BOCHINSKI — Dynamics within a monolayer collection of surface-bound substituted-alkyl chains are studied with narrow-band dielectric spectroscopy. A transition from independent (intra-molecular) motion in low density systems to complex, glassy (inter-molecular) motion as the density is increased is observed. At high density, both the glassy mode [1,2] and the sub-Tg relaxation [3] have direct analogy to equivalent relaxations in polyethylene. Thus this experimental approach enables observation of the formation of a fragile glass as an explicit function of density; in addition by altering the molecular characteristics and surface arrangement, resultant changes in the nature of the glass transition (its glass transition temperature Tg and fragility m) can be determined. The effects of packing efficiency, chain length, and molecule-molecule interactions, as tuned by altering dipoles within the chain, will be discussed.

10:36AM Y42.00012 Interchain Coupling in Thin Polymer Film Studied by Fluorescence Non-radiative Energy Transfer , JIE XU, GI XUE, Nanjing University, NANJING UNIVERSITY TEAM — According to many views, the glass transition temperature (Tg) changes with decreasing polymer film thickness. There is an ongoing debate on the origin of the changes. As an important parameter, however, the interchain distance of thin film was still a challenge. We used Non-radiative energy transfer (NET) method to characterize polymer interchain proximity and association in polymer thin film, by attaching carbazolyl probe (donor) or anthryl probe (accepter) to the side groups of polymethyl methacrylate (PMMA) chain, respectively. We measured the NET results of PMMA films on silicon and found that the NET results decreased with decreasing film thickness. The NET results represented the interchain distance or density. With decreasing film thickness h, the density of the films decreased, which caused an increment of the polymer chain mobility. That might help us to understand the physical nature Tg changes.

10:48AM Y42.00013 Impact of annealing and adsorption on the distribution of segmental mobility and tracer diffusivity of ultrathin films of polystyrene[1] , SIMONE NAPOLITANO, CINZIA ROTELLA, MICHAEL WUBBENHORST, Katholieke Universiteit Leuven — We show experimental evidence that the changes ultrathin films undergo during annealing are strongly correlated to the amount of chains irreversibly adsorbed at the interface. A careful analysis of the time evolution of the dielectric function during annealing steps above Tg revealed three different regimes: at times much shorter than the adsorption time, the thickness of the adsorbed layer is constant and the interface mimics the effect of a free surface (packing frustration); upon increase of surface coverage, the films undergo a series of metastable states characterized by the largest changes in the deviations from bulk behavior; finally, when the thicknesses of the irreversibly adsorbed layer doubles its starting value, the system approach a new equilibrium whose properties are fixed by the new interfacial configurations. Our picture is further confirmed by the effect of annealing on the distribution of glass transition temperatures [1], dielectric relaxation strength and tracer diffusivity at different distances from the adsorbing interface.

Session Y43 DPOLY: Molecules, Solutions, Networks, & Gels A306/307

8:00AM Y43.00001 Distinct Tensile Response of Model Semi-flexible Elastomer Networks[1] , BERNARDO M. AGUILERA-MERCADO, CLAUDE COHEN, FERNANDO A. ESCOBEDO, School of Chemical & Biomolecular Engineering, Cornell University — Through coarse-grained molecular modeling, we study how the elastic response strongly depends upon nanostructural heterogeneities in model networks made of semi-flexible chains exhibiting both regular and realistic connectivity. Idealized regular polymer networks have been shown to display a peculiar elastic response similar to that of super-tough natural materials (e.g., organic adhesives inside abalone shells). We investigate the impact of chain stiffness, and the effect of including tri-block copolymer chains, on the network's topology and elastic response. We find in some systems a dual tensile response: a liquid-like behavior at small deformations, and a distinct saw-tooth shaped stress-strain curve at moderate to large deformations. Additionally, stiffer regular networks exhibit a marked hysteresis over loading-unloading cycles that can be deleted by heating-cooling cycles or by performing deformations along different axes. Furthermore, small variations of chain stiffness may entirely change the nature of the network's tensile response from an entropic to an enthalpic elastic regime, and micro-phase separation of different blocks within elastomer networks may significantly enhance their mechanical strength.

8:12AM Y43.00002 Elastically tuned defect mode in cholesteric elastomers , JUAN ADRIAN REYES, LAURA OLIVIA PALOMARES, Instituto de Fisica Universidad Nacional Autonoma de Mexico — We consider an axially elongated cholesteric elastomer having a twist defect. We show that its localized mode can be mechanically tuned, and the scaling of the inverse relative line width can be largely enhanced when the values of the deformation and shape anisotropy are near the pseudo isotropic curve. This choice causes a tremendous variation in the behavior of the photon dwell time in the defect mode, which then grows linearly versus the sample thickness. The shift of the defect wavelength, the reflection band width, and the angle between the electric and magnetic fields are also calculated.

8:24AM Y43.00003 Glassy structure and thermal fluctuations of amorphous nematogenic solids , FANGFU YE, BING LU, University of Illinois, XIANGJUN XING, Shanghai Jiao Tong University, PAUL GOLDBART, University of Illinois — Amorphous nematogenic solids (ANS) are media comprising rod-like nematogens that have been randomly linked to form macroscopic, elastically deformable networks. Classes of ANS include chemical nematogen gels (i.e., networks of small molecules) and liquid crystalline elastomers (built from crosslinked nematogen-containing macromolecules), as well as biophysical networks, such as those composed of actin filaments. One common feature of these systems is that the linking process introduces into them a new type of random field, consisting of a conventional static part along with a new, thermal-fluctuation-induced, dynamic part. We develop a phenomenological model of ANS which shows how this composite random field, together with the coupling between the orientational and positional fluctuation that nematogens exhibit, leads to the occurrence of decaying but also oscillatory correlations of the thermal fluctuation, and also shows how these correlations influence the glassy structure of ANS.

8:36AM Y43.00004 Thermal and Mechanical Properties of Sequential and Simultaneous Thiol-Ene-Isocyanate Networks , OLIVIA MCNAIR, DAVIS BRENT, DANIEL SAVIN, School of Polymers and High Performance Materials, University of Southern Mississippi — Ternary networks containing having stoichiometrically balanced thiol /(ene+isocyanate) ranging from 0 to 20 molsynthesized via sequential or simultaneous thiol/ene and thiol/isocyanate click reactions. The effects of cross-link density were studied using three thiols, GDMP (difunctional), 3T (trifunctional) and 4T (tetrafunctional) respectively. TEA catalyzes the isocyanate-thiol coupling and chain extension, while the photoinitiator DMPA initiates a radical thiol-ene crosslinking process. Real-time FTIR was used to study kinetics of both light and dark reactions utilizing thiol, ene and isocyanate peaks which appear independently. It was found that difunctional thiols and isocyanates reacted initially, forming chain extended prepolymers end-capped with thiol functionalities. Upon UV irradiation, thiol functionalized prepolymers reacted with TTT, a trifunctional ene, forming networks containing incorporated thiourethane linkages. Initial DSC results indicated higher Tgs for higher cross-linked networks; however, isocyanate content has significant effects on each system. Films were also be thermally characterized via DMA and mechanical properties measured using MTS.

8:48AM Y43.00005 Computational and Experimental Investigation of Morphology of Polymer Gels , YELENA SLIOZBERG, KENNETH STRAWHECKER, JAN ANDZELM, JOSEPH LENHART, U. S. Army Research Laboratory — Thermo-reversible polymer gels based on block copolymers represent a remarkable class of materials for a wide range of applications. An efficient approach to control and modify the properties of these gels is to use multicomponent mixtures of self-assembling block copolymers differing in architecture, length and chemical nature. As a result of microphase separation, "mixed" or "pure" micelles, containing block copolymers of the same or different types, are developed. Here, we present a dissipative particle dynamics (DPD) study of the morphology of a binary mixture of AB/ABA block copolymers differing in length of the insoluble blocks in B-selective solvent. We have observed numerous morphologies of AB/ABA blends, which are characterized by formation of pure and mixed micelles of various compositions, structures and sizes. We have discovered that changing the copolymer ratio and processing conditions impacts morphology of these blends. Finally, we have established factors that affect an intermicellar distance and a bridge fraction which ultimately determines the mechanical properties of the gels. Results of our computations were compared with our experimental findings based on atomic force microscopy and the other experimental and theoretical studies and demonstrated a good agreement.

9:00AM Y43.00006 Theory of volume phase transitions of polyelectrolyte gels , JING HUA, MITHUN MITRA, MURUGAPPAN MUTHUKUMAR, University of Massachusetts, Amherst — We will present theoretical results for the effect of charge regularization accompanying volume phase transitions of polyelectrolyte gels. Our theoretical formulation of the cascade effect that couples the effective degree of ionization and the polymer density leads to significant deviations from the classical Flory-type theories.

9:12AM Y43.00007 Plasticity and slow relaxation phenomena in reinforced rubbers , PAUL SOTTA, STEPHANE DUPRES, DIDIER LONG, CNRS — Elastomers reinforced with nanometric solid particles or aggregates exhibit remarkable properties: temperature dependent reinforcement of the modulus in the linear regime, non linear effects, irreversibility and hysteretic effects. Important progress has been achieved recently in modeling these properties, based on glassy layers around filler particles. In some cases, reinforcement as a function of temperature and filler volume fraction was explained quantitatively. We shall focus here on the plasticity and related slow relaxation phenomena which occur in these systems. We show that the amplitude of plasticity is correlated to the reinforcement amplitude, and that plasticity relaxes with a very broad distribution of relaxation times (similar to an ageing phenomenon), in the same way as the stress relaxes at high strain amplitude. These experimental observations of long time evolution are well described by the mesoscale model for reinforced rubbers that we have proposed.

9:24AM Y43.00008 Migration of chemical additives in a rubber under UV irradiation , LUDOVIC DEVANT, CNRS, ROLAND BENOIT, MARIE-LOUISE SABOUNGI, EMMANUEL GOMEZ, BENOIT LE ROSSIGNOL — The evolution of the chemical composition of a rubber, in particular that of its surface, is governed by several factors including temperature, oxidation and migration of additives. Oxidation mechanisms alone do not account for all the phenomena observed, for example the appearance of deposits on the surface. We have studied the effects of temperature and photo-oxidation on the migration of chemical additives on a rubber surface. The morphological and chemical evolution were followed by AFM and XPS, respectively. 3D reconstruction with time-of-flight secondary-ion mass spectrometry (TOF-SIMS) combined with the AFM and XPS results enabled us to establish a relation between the oxidizing degradation of the rubber and the surface migration of the additives. This finding is supported by a kinetic study of the surface evolution.

9:36AM Y43.00009 Probing the sliding interactions between bundled actin filaments , ANDY WARD, ZVONIMIR DOGIC, Brandeis University — Assemblies of filamentous biopolymers are hierarchical materials in which the properties of the overall assemblage are determined by structure and interactions between constituent particles at all hierarchical levels. For example, the overall bending rigidity of a two bundled filaments greatly depends on the bending rigidity of, and the adhesion strength between individual filaments. However, another property of importance is the ability for the filaments to slide freely against one another. Everyday experience indicates that it is much easier to bend a stack of papers in which individual sheets freely slide past each other than the same stack of papers in which all the sheets are irreversibly glued together. Similarly, in filamentous structures the ability for local re-arrangement is of the utmost importance in determining the properties of the structures observed. In order to study this phenomenon we create bundles of biopolymers by inducing attractive interactions between actin filaments via the depletion mechanism. We find that bundles of actin filaments to do not slide freely across one another. In order to characterize these sliding interactions, we perform active experiments using laser tweezers to pull one filament across the other at constant velocity.

9:48AM Y43.00010 Apparent Yield Stress and Interfacial Viscoelasticity of Globular Protein Solutions , VIVEK SHARMA, ADITYA JAISHANKAR, Hatsopoulos Microfluids Lab, Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, MA 02139, YING-CHIH WANG, Rheosense Inc, San Ramon, CA 94583, GARETH H. MCKINLEY, Hatsopoulos Microfluids Lab, Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, MA 02139 — Globular proteins influence the dynamics, phase behavior and transport of biomolecules and drugs in the mammalian body. In conventional rheological studies conducted on torsional rheometers, protein solutions are commonly reported to have a solid-like response at concentrations as low as 0.03% by weight. In this study, we probe the bulk and interfacial viscoelasticity of bovine serum albumin (BSA) solutions as a canonical example of a globular protein system. Using a stress-controlled rotational rheometer, augmented by microfluidic rheometry and interfacial rheometry, we demonstrate that the origin of the yield-like response reported in bulk viscometric flows lies in the formation of a film of adsorbed protein, formed spontaneously at the solution/gas interface. We directly measure the concentration-dependent interfacial viscoelasticity of the adsorbed protein and we describe a coherent means of extracting the interfacial contribution from bulk viscosity measurements. Finally, we demonstrate how the presence of surfactants changes both the interfacial and bulk rheology of pharmaceutical formulations based on protein solutions.

10:00AM Y43.00011 The enhanced bubble formation in short dsDNA loops , O-CHUL LEE, WOKYUNG SUNG[1], Pohang university of science and technology (POSTECH) — Recent experiments have shown the dsDNAs readily bend and loop over the nanometer scale much shorter than its persistence length (50 nm). Motivated by this, we study possibility of enhanced bubble formation in short dsDNA loops by evaluating free energy of bubble formation analytically, and also by simulating the breathing DNA model. We analyze the bubble size distribution and the average bubble size as a function of the loop length, which are compared with those of the linear DNA of the same length. 1) T. E. 10:12AM Y43.00012 Universality in the timescales of internal loop formation in unfolded proteins and single-stranded oligonucleotides[1] , RYAN CHENG, UT Austin, TAKANORI UZAWA, Hokkaido University, Japan, KEVIN PLAXCO, UC Santa Barbara, DMITRII MAKAROV, UT Austin — Understanding the rate at which various parts of a molecular chain come together to facilitate the folding of a biopolymer (e.g., a protein) into its functional form remains an elusive goal. Here we use experiments, simulations, and theory to study the kinetics of internal loop closure in disordered biopolymers such as single-stranded DNA and unfolded proteins. We present theoretical arguments and computer simulation data to show that the relationship between the timescale of internal loop formation and the positions of the monomers enclosing the loop can be recast in a form of a universal master dependence. Our measurements of the loop closure times in single-stranded oligonucleotides, as well the internal loop closure kinetics in unfolded proteins reported by others, are all well described by this theoretically predicted dependence. Experimental deviations from the master dependence can then be used as a sensitive probe of dynamical and structural order in unfolded proteins and other biopolymers.

10:24AM Y43.00013 Topological interactions between ring polymers , DIETER HEERMANN, University of Heidelberg — The detailed topological and entropic forces between loops still remain elusive. We have quantitatively determined the potential of mean force between the centers of mass of two ring polymers, i.e. loops. We find that the transition from a linear to a ring polymer induces a strong increase in the entropic repulsion between these two polymers. On top, topological interactions such as the non-catenation constraint further reduce the number of accessible conformations of close-by ring polymers by about 50 percent, resulting in an additional effective repulsion.

10:36AM Y43.00014 Modulation of DNA condensation by cation valence , PREETHI CHANDRAN, Section on Tissue Biophysics and Biomimetics, NICHD; NIBIB; National Institutes of Health, Bethesda, MD 20892, EMILIOS DIMITRIADIS, Laboratory of Bioengineering and Physical Science, NIBIB, National Institutes of Health, Bethesda 20892, CANDIDA SILVA, PETER BASSER, FERENC HORKAY, Section on Tissue Biophysics and Biomimetics, NICHD, National Institutes of Health, Bethesda, MD 20892 — Aggrecan is a negatively charged bottlebrush-shaped proteoglycan in the extracellular matrix, with unique polyelectrolyte properties. Aggrecan-hyaluronic acid aggregates are responsible for the compressive resilience of articular cartilage. Unlike linear polyelectrolytes such as DNA, aggrecan is insensitive to the presence of multivalent counterions (e.g., calcium ions) and self-assembles into micro-gels in near-physiological salt solutions. These features are preserved by aggrecan adsorbed on mica surfaces. To probe both the nature of aggrecan assemblies in solution and their surface interactions, we image the aggrecan assemblies adsorbed on mica surface using Atomic Force Microscopy The effect of counterion valence on the hydration-dehydration properties of the aggrecan assemblies will be discussed.

10:48AM Y43.00015 Combining DNA Nanotechnology and Fluorescence Polarization Microscopy to Determine the Orientation of DNA-bound Fluorophores , HUNTER BANKS, CHRISTOPH SCHNEIDER, DEBORAH FYGENSON, UC Santa Barbara — We describe a technique to measure the axis of the transition dipole moment of a fluorophore bound to dsDNA and compare results with existing techniques. We use DNA nanotubes to present the dsDNA in a known orientation and query a variety of intercalating (e.g., YO-YO, TO-TO), groove-binding (e.g. DAPI) or covalently linked (e.g., Fluorescein, Cy3, Cy5) dyes. A de Sénarmont prism in front of the camera generates simultaneous images of fluorescence polarized perpendicular and parallel to the DNA nanotube axis, allowing for ratio measurements that are insensitive to bleaching. We suggest the use of technique to detect helical supertwist, and possibly other nanoscale structural features, of DNA nanostructures.

Session Y44 DMP DPOLY: Focus Session: Organic Electronics and Photonics – Exciton and charge separation physics A309

8:00AM Y44.00001 Charge transport studies in organic semiconductors using carrier extraction by linearly increasing voltage (CELIV) technique , ALMANTAS PIVRIKAS, Johannes Kepler University Linz — Organic optoelectronic devices, such as solar cells, light emitting diodes and transistors, share a common feature: their performance critically depends on the efficiency with which charge carriers (electrons and/or holes) move in the material. Understanding and improving the charge transport is the main goal when improving the device performance or designing novel organic compounds through chemical engineering. Due to low carrier mobility in disordered films, as well as due to its time, electric field and carrier density dependence, standard measurement technique like Hall effect and Time-of-Flight are either inapplicable or limited in applicability. Charge Carrier Extraction by Linearly Increasing Voltage (CELIV) technique has become a world standard used by many scientific groups to measure charge transport and recombination in inorganic and organic semiconductors. The method can be used to study the charge carrier mobility dependence on time, carrier concentration, electric field, temperature, film thickness and morphology directly in the operational devices. However, the latest research have shown that CELIV current transients and extraction maximum used for mobility evaluation is strongly dependent on experimental conditions such as carrier density, light absorption profile and electric field. Procedure, allowing estimating the correction factor in mobility relation will be presented. In contrast to inorganic crystalline semiconductors, the long-range disorder in the films of organic devices makes the charge transport properties strongly dependent on the degree of disorder and nanomorphology of the films. Carrier density, electric field and temperature dependent mobility in disordered organic semiconductors is shown to obey Arrhenius-type, Poole-Frenkel-type, Meyer-Neldel rule, and Gill's law. Stochastic transport theories are used to describe charge carrier hopping within localized Density-Of-States as opposed to delocalized band-transport in the crystals.

8:36AM Y44.00002 Direct determination of energy level alignment of organic-organic bulk heterojunction: cases of the P3HT:PCBM and P3HT:FLN-i blend , ZELEI GUAN, ANTOINE KAHN, Department of Electrical Engineering, Princeton University, JONG BOK KIM, HE WANG, YUEH-LIN LOO, Department of Chemical Engineering, Princeton University — Using photoemission spectroscopy (UPS&IPES) combined near edge X-ray absorption fine structure method, we have determined the surface compositions and electronic alignments of the blend films comprising poly(3-hexylthiophene) (P3HT) and [6,6]-phenyl-C61-butyric acid methyl ester. Given the fact that the surface of the blend film is a nearly pure P3HT wetting layer, we use a lift-off method to access the originally buried surface, which is rich in both P3HT and PCBM and thus representative of the BHJ. We show that the donor/acceptor LUMO-HOMO gap is 1.46 eV, implying a 0.5-0.6 eV interface dipole barrier between the two materials. As far as we know, this is the first report of the direct determination of electronic structure of the blend. The combined measurement and lift-off method are standard and can be applied to other organic blend films, like P3HT and FLN-i.

8:48AM Y44.00003 Direct Determination of Energy Level Alignment and Charge Transport at Metal/Alq_3 Interfaces via Ballistic-Electron-Emission Spectroscopy (BEES) , J.S. JIANG, J.E. PEARSON, S.D. BADER, Argonne National Laboratory — In organic electronic devices, the difference between the electrode work function and the organic lowest unoccupied molecular orbital (LUMO) or highest occupied molecular orbital (HOMO) is a crucial parameter in determining the nature of charge transport. However, experimental determination of LUMO is challenging.[1] For the archetypal electroluminescent organic semiconductor tris-(8-hydroxyquinoline) aluminum (Alq_3), various techniques gave significantly different HOMO-LUMO gap values.[2] Using BEES, we directly determined the energy barrier for electron injection at clean interfaces of Alq_3 with Al and Fe to be 2.1 eV and 2.2 eV, respectively. We quantitatively modeled the sub-barrier BEES spectra with an accumulated space charge layer, and found that the transport of non-ballistic electrons is consistent with random hopping over the injection barrier. Supported by U.S. DOE Office of Science Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

9:00AM Y44.00004 ABSTRACT WITHDRAWN –

9:12AM Y44.00005 Band alignment optimization of bulk rrP3HT/C_{60} heterojunction , ARNAUD MAILLARD, ALAIN ROCHEFORT, Ecole Polytechnique de Montreal, Engineering Physics Department — Organic solar cells could overcome the cost limitation of traditional solar cells by using large-scale fabrication techniques associated with polymers. However, a better understanding of the bulk heterojunctions (BHJs) electronic properties used in these devices is required to reach an efficiency of 10%. DFT and GW computations were used to study BHJs formed by the inclusion of C_{60} in a regioregular poly(3- hexylthiophene) polymer (rrP3HT) crystal. An increasing packing density in the BHJ extent the energy separation between the C_{60}-LUMO and the rrP3HT-HOMO, which is proportional to the open circuit voltage of the device (Voc). This trend is consistent with the induced dipole moment variation observed at a pentacene- C_{60} junction upon reduction of the intermolecular distance [1]. In contrast, an increasing size of rrP3HT crystal domain leads to decrease both Voc and rrP3HT bandgap, in a similar fashion than upon the formation of rrP3HT crystallite along the annealing of BHJs [2].

9:24AM Y44.00006 Strong interface p-doping and band bending in C_{60}[1] , IRFAN IRFAN, HUANJUN DING, YONGLI GAO, MINLU ZHANG, CHING TANG, University of Rochester, DEPARTMENT OF PHYSICS AND ASTRONOMY COLLABORATION, DEPARTMENT OF CHEMICAL ENGINEERING COLLABORATION — C_{60} is a strongly n-type material with its lowest unoccupied molecular orbital very close to the Fermi level, and p-doping C_{60} has been a challenging issue. We measured the electronic energy level evolution of C_{60} on molybdenum oxide (MoO_x)/ conducting indium tin oxide (ITO) interfaces with ultra-violet photoemission spectroscopy (UPS), inverse photoemission spectroscopy (IPES) and atomic force microscopy (AFM). We found that MoO_x strongly p-dopedC_{60}at the interface, resulting in an inversion layer in C_{60}. The energy levels of C_{60}relax gradually as the thickness of C_{60} increases, and the band bending region is observed to be greater than 400 Å in C_{60}. The root mean square (RMS) roughness measured with AFM of 581 Å thick C_{60} film was 68 Å, slightly increased from that of the ITO substrate of 55 Å. We have also investigated the effect of exposing the MoO_x air, and found that it eliminated the doping effect.

[1]NSF DMR- 1006098

9:36AM Y44.00007 Understanding the role of interfaces in small molecule organic photovoltaics , TIM JONES, University of Warwick — This abstract not available.

10:12AM Y44.00008 Photophysics of Poly(3-dodecylthinylenevinylene) with Controlled Regioregularity , EVAN LAFALCE, University of South Florida, Dept. of Physics, XIAOMEI JIANG, University of South Florida, Dept. of Physics — Poly(thienylene vinylene) (PTV) is a conductive polymer with potential applications for use in photovoltaics owing to its low-band gap, good hole-mobility and low oxidation potential. It is generally considered a non-luminescent material and reports suggest its emissive properties are highly dependent upon the excitation, conjugation length, alkyl side group and regio-regularity, complicating the interpretation of the non-radiative decay routes for photo-generated excitations. Better understanding of this behavior could explain the low efficiencies so far observed in PTV based solar cells and lead to improved performance. We have studied photoluminescence of Poly(3-dodedyl -2,5-thienylene vinylene) as a function of regio-regularity in thin films and solutions. By varying the excitation, temperature, and also by controlling the morphology through the use of different solvents, concentrations, and film preparation techniques, we hope to deduce the physical mechanisms competing with radiative recombination. Complimentary characterization of films through XRD and electro-absorption yield detailed information about the semi-crystalline structure and electronic levels, respectively.

10:24AM Y44.00009 Magneto-Optical Studies of Internal Photovoltaic Processes in Organic Solar Cells , HUIDONG ZANG, ZHIHUA XU, BIN HU, University of Tennessee — It has been found that exciton dissociation inevitably forms electron-hole pairs, namely charge-transfer (CT) complexes, at donor-acceptor interfaces due to Coulomb attraction in organic solar cells. In particular, the dissociation of CT complexes is a critical process that is accountable for the generation of photocurrent. However, it is a challenging issue to study the CT complexes formed at donor-acceptor interfaces. Here, we use magneto-optical measurements: magnetic field effects of photocurrent (MFE_{PC}) and light-assisted dielectric response (LADR) as effective experimental tools to experimentally examine the formation of CT complexes and the related photovoltaic processes. Our studies reveal that internal electrical drifting and local Coulomb interaction can largely change the binding energy and dissociation probability of CT complexes through intrinsic electrical polarization in donor-acceptor interpenetrating network. This experimental finding indicates that intrinsic electrical polarization plays an important role in controlling charge dissociation, transport, and collection in organic solar cells.

10:36AM Y44.00010 Photoluminescence Influenced by Chain Conformation in Thin Conjugated Polymer Films by Spin Coating and Dewetting , P.W. LEE, W.C. LI, Y. CHIEN, Department of Materials Science and Engineering, National Tsing Hua University, G. REITER, nstitute of Physics, Albert-Ludwigs-Universität, Freiburg, Germany, A.C.-M. YANG, Department of Materials Science and Engineering, National Tsing Hua University — Motivated by recent observations of photoluminescence (PL) enhancement by molecular constraints, the chain conformation effect was explored. It was found that PL efficiency decreased with film thickness under a constant spin speed but increased under a constant solution concentration indicating that prolonged solvent evaporation, and hence more open entangled coils, improved PL efficiencies. Strong substrate dependence was observed in the ultrathin regime, revealing the role of substrate-polymer interactions during the condensation process. Upon annealing, the thin film dewetted and resulted multi-fold PL enhancement. As revealed by micro-PL spectroscopy, the PL efficiency was about 10 times greater in the residual layer (∼3 nm) than that in the droplets and demonstrated independence of substrate quenching effect, unveiling important optoelectronic features of the molecular constrained states.

8:00AM Y45.00001 ABSTRACT WITHDRAWN –

8:12AM Y45.00002 Dissipative Effects on Quantum Sticking[1] , YANTING ZHANG, DENNIS CLOUGHERTY, University of Vermont — Using variational mean-field theory, many-body dissipative effects on the threshold law for quantum sticking and reflection of neutral particles are examined. For the case of an ohmic bosonic bath, we study the effects of the infrared divergence on the probability of sticking and obtain an analytic expression for the rate of sticking as an asymptotic expansion in the incident energy E. The low-energy threshold law for quantum sticking is found to be robust with respect to many-body effects and remains a universal scaling law to leading order in E. Non-universal many-body effects alter the coefficient of the rate law and the exponent of a subdominant term.

[1]We gratefully acknowledge support from NSF under DMR-0814377.

8:24AM Y45.00003 Breaking Quantum Mirrors with Thermal Fluctuations[1] , IAN GOYETTE, DENNIS CLOUGHERTY, University of Vermont — We study ultracold atoms interacting with a surface at finite temperature. For the case where the surface is out of thermal equilibrium with the environment, the asymptotic form of the Casimir-Polder potential decays as an inverse square law and can be either attractive or repulsive, depending on the temperature difference. We analyze the effect of this interaction on the threshold law for quantum sticking, the probability that an atom will stick to the surface $s(E)$ as the incident energy tends to zero. We predict a new threshold law for neutral atoms interacting with a surface out of thermal equilibrium with its environment: $s(E) \sim E^{\gamma}$ as $E \to 0$ where γ $(0 \leq \gamma \leq 1/2)$ depends on the strength of the non-equilibrium Casimir-Polder interaction which can be tuned with temperature.

[1]We gratefully acknowledge support by NSF under DMR-0814377.

8:36AM Y45.00004 ABSTRACT WITHDRAWN –

8:48AM Y45.00005 Temperature dependence of the depolarization rates of $Ne^*(2p_i$ [J=1]) atoms induced by He atom collisions , VAIBHAV KHADILKAR, Dept.of Physics, Lamar University, CHRISTIAN BAHRIM, Dept. of Computer Science, UT Dallas — Our theoretical depolarization rates for the disalignment, disorientation, and alignment relaxation of $Ne^*(2p_i$ [J=1]) atoms at temperatures between 10 K and 3000 K are compared with various experiments. We perform quantum close-coupling many-channel calculations using a new model potential for the interaction between $Ne^*(2p_i$ [J=1]) and He atoms [1]. We analyze isotropic collisions in a gaseous mixture at thermal equilibrium, and find excellent agreement between our calculations and the experimental data above 77 K [1, 2]. We explain the temperature dependence of the depolarization rates using the anisotropy of the collisional channels [2]. For T < 77 K, our disalignment rates for the $Ne^*(2p_2$ [J=1]) and $Ne^*(2p_{10}$ [J=1]) atoms are larger than the experimental data. The experiment predicts a linear variation of the intra-multiplet cross sections to zero-energy. Our calculations indicate that for the $2p_2$ and $2p_{10}$ states, at low collision energies, the nuclear rotation at large atomic separation has a stronger influence in the molecular Hamiltonian than the electrostatic interaction. This situation does not occur for the $2p_5$ and $2p_7$ states, where the agreement between theory and experiment is found even at 20K [1]. 9:00AM Y45.00006 Dipole Transitions for the hydrogen molecule using Fully Nonadiabatic Wavefunctions , STEVEN ALEXANDER, Southwestern University, R.L. COLDWELL, University of Florida — Using variational Monte Carlo and simple, explicitly-correlated fully-nonadiabatic wavefunctions we have computed highly accurate trial wavefunctions for the lowest rovibrational state of several states of the hydrogen molecule. With these wavefunctions we have calculated the transition moments for all possible dipole transitions and we compare our results with those from more traditional calculations.

9:12AM Y45.00007 Formation of the negative molecular ion MH- by radiative association of a neutral molecule M with H- , VIATCHESLAV KOKOOULINE, University of Central Florida, MEHDI AYOUZ, University of Marquette, MAURICE RAOULT, OLIVIER DULIEU, Lab. Aime Cotton, University of Paris XI — We consider the formation of negative molecular ions MH^- through the reaction of radiative association: $M+H^- \to MH^- + ?\omega$, where M is a diatomic or triatomic neutral molecule. We present a theoretical approach to calculate the cross-section and the rate constant for the reaction and apply the theory to study formation of molecular ions from H^- and neutral molecules abundant in the interstellar medium (ISM): We consider H_2, CO, and H_2O as possible candidates to form negative ions. Such ions have never been observed in the ISM. Their eventual observation would serve as a proof of presence of H^- in the ISM too. The H^- ion cannot be detected directly by the photoabsorption spectroscopy. Supported by Triangle de la Physique contract QCCM and the National Science Foundation grant PHY-0855622

9:24AM Y45.00008 Terahertz Time-Domain Spectroscopy of Ices of N_2, CO_2, and Ar[1] , BAGVANTH R. SANGALA, PERRY A. GERAKINES, DAVID J. HILTON, Department of Physics, The University of Alabama at Birmingham, AL 35294-1170, USA — We used Terahertz Time-Domain Spectroscopy (THz- TDS) to study thin ice films of N_2, CO_2, and Ar from 0.1 -1.6THz. We observed an absorption line for N_2 ice films at 1.46THz in the temperature range of 10-28K. Ar ice films have absorption lines at 0.47THz and 0.97THz in the temperature range of 10-30K. We observed no absorption line for CO_2 ice films in the temperature range of 10-40K from 0.1-1.6THz. These results will be helpful in analyzing the data terms from observations of THz radiation from astronomical sources impinging upon interstellar materials.

9:36AM Y45.00009 Collision-Induced Infrared Absorption by Collisional Complexes in dense Hydrogen-Helium gas mixtures at Thousands of Kelvin[1] , MARTIN ABEL, LOTHAR FROMMHOLD, The University of Texas at Austin, XIAOPING LI, KATHARINE L.C. HUNT, Michigan State University — The interaction-induced absorption by collisional pairs of H_2 molecules is an important opacity source in the atmospheres of the outer planets and cool stars. The emission spectra of cool white dwarf stars differ significantly in the infrared from the expected blackbody spectra of their cores, which is largely due to absorption by collisional H_2–H_2, H_2–He, and H_2–H complexes in the stellar atmospheres. Using quantum-chemical methods we compute the atmospheric absorption from hundreds to thousands of kelvin [1]. Laboratory measurements of interaction-induced absorption spectra by H_2 pairs exist only at room temperature and below. We show that our results reproduce these measurements closely [1], so that our computational data permit reliable modeling of stellar atmosphere opacities even for the higher temperatures [1].

9:48AM Y45.00010 Size dependent ionization dynamics of argon clusters in intense x-ray pulses , SEBASTIAN SCHORB, M. SWIGGERS, R. COFFEE, M. MESSERSCHMIDT, S. MOELLER, G. WILLIAMS, J. BOZEK, SLAC National Accelerator Laboratory / LCLS, T. OSIPOV, Western Michigan University, S. WADA, Hiroshima University, D. RUPP, T. MOELLER, Technische Universitaet Berlin, C. BOSTEDT, SLAC National Accelerator Laboratory / LCLS — Free Electron Lasers open the door for novel experiments in many science areas ranging from ultrafast chemical dynamics to single shot imaging of molecules. For the success of virtually all experiments with free electron lasers a detailed understanding of the light - matter interaction in the x-ray regime is pivotal. The Linac Coherent Light Source (LCLS) free electron laser in Stanford allows for the first time to study innershell ionization dynamics of intense x-ray pulses on a femtosecond time scale. We performed experiments on the ionization dynamics of Argon clusters at different pulse length using the slotted spoiler foil in the second LCLS bunch compressor [1]. The Auger rate of argon clusters is predicted to be size dependent and lower than in atoms due to delocalization of the valence electrons [2]. We observe a dependence of the ionization dynamics on pulse length and cluster size. The results are discussed and also compared to recent atomic and molecular data from LCLS.

10:00AM Y45.00011 *Ab initio* **calculations of atomic coherence excited by optical pulses: CEP effects and generation of X-ray radiation** , SUMAN DHAYAL, YURI ROSTOVTSEV, univ of North Texas — Recent progress in ultrashort, e.g. attosecond, laser technology allows to obtain ultra-strong fields which can be of the same order of magnitude as the electric field created by an atomic nucleus. Interaction of such strong and broadband field with atomic systems even under the action of a far-off resonance strong pulse of laser radiation should be revisited. As we have shown, such pulses can excite remarkable coherence on high frequency transitions. We have found and analyzed analitical solutions for various pulse shapes. We have developed new mechanisms of efficient atomic coherent excitation by using two-frequency laser pulses and via tunneling through electric fields. We have done *ab initio* calculations using TDDFT for several atoms and simple molecules interacting with strong optical fields. We compare efficiency generation with the efficiency of high harmonic generation approach, and discuss the CEP effects and possible applications of the results obtained to cooperative generation of XUV radiation. The efficiency of XUV generation is calculated for particular candidates for XUV radiation such as H (100 nm) and He (50 nm) atoms and H-like ions (Li^{2+} (30 nm), as well as Ar^{8+} and Xe^{8+} (30-50 nm).

10:12AM Y45.00012 XAS measurements at LCLS: Investigating Electronic Damage at an X-Ray FEL , CATHERINE GRAVES, DAVID BERNSTEIN, Stanford University, SLAC, JOSHUA TURNER, WILLIAM SCHLOTTER, HERMANN DÜRR, ANDREAS SCHERZ, JOACHIM STÖHR, SLAC — As X-ray FEL sources such as the LCLS ramp up scientific studies, the damage caused by the intense x-ray pulses has become a central question. X-ray FEL investigations of solid-state materials must consider the change in the electronic system during the x-ray pulse, in contrast to proposed biomolecular imaging experiments which must suppress atomic motion.[1] The potential electronic damage to the system is also amplified in many materials investigations which probe absorption edges. Therefore, a key need of all studies involving materials research with X-ray FELs is to mitigate or overcome the electronic damage when probing the system. We report the first x-ray absorption spectroscopy (XAS) results from LCLS, which show significant line shape changes dependent on the fluence and x-ray pulse length. We employ a technique previously developed at FLASH which also allows us to visualize the beam dispersion.[2] Our spectroscopy results from LCLS demonstrate a safe fluence and pulse length regime at which material investigations can be conducted without perturbing the ground state of the system during the probing x-ray pulse.

10:24AM Y45.00013 Berry phase-like effect near DOS singularity in continuum models coupled with discrete states , SAVANNAH GARMON, DVIRA SEGAL, University of Toronto, INGRID ROTTER, Max Planck Institute for the Physics of Complex Systems — Threshold effects in a continuum model (cut-off frequency in a waveguide or the band edge in tight-binding chains) may significantly modify the single-particle discrete eigenvalue spectrum resulting from coupled discrete states. Focusing on tight-binding chains as an example we reveal a Berry phase-like effect as the system parameters are adiabatically varied about certain exceptional points (non-analytic points in the eigenvalue spectrum) that are related to the threshold (van Hove) singularity in the density of states. We show that this effect is related to the form of the eigenvalue expansion in the vicinity of the band edge. In particular, for a semi-infinite model with a side-coupled impurity the eigenvalues in this vicinity may be expanded in powers of the coupling g, rather than the more usual g^2. In another example, in the case of an infinite tight-binding chain with a side-coupled impurity (or a two-level atom traveling in an infinite waveguide) the DOS singularity results in a $g^{4/3}$ amplification of the decay width of the resonant state [1, 2].

DUCHESNE, R. MORANDOTTI, M. VOLATIER-RAVAT, V. AIMEZ, DEPT. OF PHYSICS, UNIVERSITY OF ARKANSAS, FAYETTEVILLE, AR, USA TEAM, COLLEGE OF OPTICS & PHOTONICS-CREOL, UNIVERSITY OF CENTRAL FLORIDA, ORLANDO, FL, USA COLLABORATION, INRS-EMT, VARENNES, QUEBEC J3X 1S2, CANADA COLLABORATION, CENTRE DE RECHERCHE EN NANOFABRICATION ET EN NANOCARACTERISATION, UNIVERSITE DE SHERBROOKE, SHERBRO COLLABORATION — In 1998 Bender and Boettcher discovered that the spectrum of a system with PT-symmetric Hamiltonian can still be entirely real. This subject attracts more and more attention during the last few years. One of the intriguing characteristics of PT-symmetric systems is the possibility of a *phase transition* beyond which the spectrum ceases to be entirely real. This symmetry breaking occurs suddenly once the imaginary component of the potential exceeds a certain critical level. Here we report the observation of a phase transition in a passive PT-symmetric optical structure once the loss exceeds a certain critical value. This counterintuitive loss-enhanced transmission is purely an outcome of a spontaneous PT symmetry breaking.

11:15AM Z1.00001 Control of single-spin decoherence by dynamical decoupling and spin bath manipulation , RONALD HANSON, Kavli Institute of Nanoscience Delft, Delft University of Technology, The Netherlands — Controlling the interaction of a single quantum system with its environment is a fundamental challenge in quantum science and technology. We dramatically suppress the coupling of a single spin in diamond with the surrounding spin bath by using high-fidelity double-axis dynamical decoupling [1]. The coherence is preserved for arbitrary quantum states, as verified by quantum process tomography. The resulting coherence time enhancement is found to follow a general scaling with the number of decoupling pulses. No limit is observed for the decoupling action up to 136 pulses, for which the coherence time is enhanced more than 25 times compared to spin echo. Furthermore, we have exploited multi-pulse sequences to enhance the sensitivity of single-spin magnetometry and to measure properties of the decoupling sequences themselves [2]. In this talk, I will present an overview of this work combined with our latest results on coherent manipulation of the spin bath environment.

[1] Universal dynamical decoupling of a single solid-state spin from a spin bath, G. de Lange, Z.H. Wang, D. Ristè, V.V. Dobrovitski, and R. Hanson, Science 330, 60 (2010).

11:51AM Z1.00002 Control of electron spin decoherence in nuclear spin baths[1] , REN-BAO LIU, The Chinese University of Hong Kong — Nuclear spin baths are a main mechanism of decoherence of spin qubits in solid-state systems, such as quantum dots and nitrogen-vacancy (NV) centers of diamond. The decoherence results from entanglement between the electron and nuclear spins, established by quantum evolution of the bath conditioned on the electron spin state. When the electron spin is flipped, the conditional bath evolution is manipulated. Such manipulation of bath through control of the electron spin not only leads to preservation of the center spin coherence but also demonstrates quantum nature of the bath. In an NV center system, the electron spin effectively interacts with hundreds of ^{13}C nuclear spins. Under repeated flip control (dynamical decoupling), the electron spin coherence can be preserved for a long time ($>$1 ms). Therefore some characteristic oscillations, due to coupling to a bonded ^{13}C nuclear spin pair (a dimer), are imprinted on the electron spin coherence profile, which are very sensitive to the position and orientation of the dimer. With such finger-print oscillations, a dimer can be uniquely identified. Thus, we propose magnetometry with single-nucleus sensitivity and atomic resolution, using NV center spin coherence to identify single molecules. Through the center spin coherence, we could also explore the many-body physics in an interacting spin bath. The information of elementary excitations and many-body correlations can be extracted from the center spin coherence under many-pulse dynamical decoupling control. Another application of the preserved spin coherence is identifying quantumness of a spin bath through the back-action of the electron spin to the bath. We show that the multiple transition of an NV center in a nuclear spin bath can have longer coherence time than the single transition does, when the classical noises due to inhomogeneous broadening is removed by spin echo. This counter-intuitive result unambiguously demonstrates the quantumness of the nuclear spin bath.

12:27PM Z1.00003 Single spin qubits in self-assembled quantum dots , RICHARD WARBURTON, Department of Physics, University of Basel, Switzerland — The search for a highly coherent electronic spin in the solid state has led most spectacularly to the NV colour centre in diamond. Have self-assembled quantum dots, InGaAs in GaAs, been left behind? The advantages of self-assembled quantum dots are considerable - there is a strong optical transition, advanced heterostructure technology and post-growth processing techniques - but so far the spin coherence has been at best modest. This talk will present some possible ways to out fox the decoherence processes in a semiconductor with the goal of creating a highly coherent spin.

1:03PM Z1.00004 Preserving electron spin coherence in solids by optimal dynamical decoupling , JIANGFENG DU, University of Science and Technology of China — To exploit the quantum coherence of electron spins in solids in future technologies such as quantum computing, it is first vital to overcome the problem of spin decoherence due to their coupling to the noisy environment. Dynamical decoupling, which uses stroboscopic spin flips to give an average coupling to the environment that is effectively zero, is a particularly promising strategy for combating decoherence because it can be naturally integrated with other desired functionalities, such as quantum gates. Errors are inevitably introduced in each spin flip, so it is desirable to minimize the number of control pulses used to realize dynamical decoupling having a given level of precision. Such optimal dynamical decoupling sequences have recently been explored. The experimental realization of optimal dynamical decoupling in solid-state systems, however, remains elusive. Here we use pulsed electron paramagnetic resonance to demonstrate experimentally optimal dynamical decoupling for preserving electron spin coherence in irradiated malonic acid crystals at temperatures from 50K to room temperature [1]. Using a seven-pulse optimal dynamical decoupling sequence, we prolonged the spin coherence time to about 30 ms; it would otherwise be about 0.04 ms without control or 6.2 ms under one-pulse control. By comparing experiments with microscopic theories, we have identified the relevant electron spin decoherence mechanisms in the solid. Recently, we demonstrate experimentally that dynamical decoupling can preserve bipartite pseudo-entanglement in phosphorous donors in a silicon system [2]. In particular, the lifetime of pseudo entangled states is extended from 0.4 us in the absence of decoherence control to 30 us in the presence of a two-flip dynamical decoupling sequence.

Session Z2 DCMP: Pseudogap in High Tc Cuprates Ballroom A2

11:15AM Z2.00001 Loop-Current Order in Several Families of Cuprates , PHILIPPE BOURGES, LLB-CEA Saclay — In high temperature copper oxides superconductors, a novel long range 3D magnetic order associated with the pseudogap phase has been identified in two different cuprate families - $YBa_2Cu_3CuO_{6+x}$ (YBCO),[1] $HgBa_2CuO_4$ (Hg1201)[2] - over a wide region of temperature and doping. That magnetic order, evidended using polarized neutron diffraction, respects the translation symmetry of the lattice and can be described as a Q=0 antiferromagnetism with active role of in-plane oxygens atoms. Such a magnetic order can be associated with orbital moments in the circulating currents phase proposed by C. Varma. Similar magnetic ordering is observed in the archetypal cuprate $La_{2-x}Sr_xCuO_4$ (LSCO) system below 120 K for x=0.085.[3] In contrast to the previous reports, the magnetic ordering in LSCO is **only** short range with an in-plane correlation length of $\sim$ 10 Å and is bidimensional (2D). Such a less pronounced order suggests an interaction with other electronic instabilities. In particular, LSCO also exhibits a strong tendency towards stripes ordering at the expense of the superconducting state. Additional polarized neutron diffraction measurements have been performed in YBCO.[4] At lower doping (8.5 %), the magnetic order is observed at lower temperature ($\sim$ 150 K) than the generally assumed value for the pseudogap. It tends to vanish for dopings where the nematic electronic liquid crystal phase sets up. Recently, two others cuprates families have been studied: $Bi_2Ca_2SrCu_2O_{8+\delta}$ (Bi2212) and electron doped $Nd_{2-x}Ce_xCuO_4$ (NCCO). In both families, a magnetic order related to the pseudogap phase has been also observed. The recent results will be discussed during the talk.

11:51AM Z2.00002 Novel magnetic excitations in a model cuprate high-T_c superconductor[1] , YUAN LI, Max Planck Institute for Solid State Research, Germany — Magnetic fluctuations might be essential to the mechanism of high-temperature superconductivity in the cuprates. For a long time, such fluctuations have been theoretically regarded as arising from the antiferromagnetic correlations within the copper-oxygen layers, and experimental studies of magnetic excitation spectrum have mainly been carried out near the corresponding wave vector (1/2, 1/2). Following neutron diffraction experiments which demonstrated the universal existence of a "$q = 0$ antiferromagnetic order" in the pseudogap phase of three different cuprates [1-3], our recent inelastic neutron scattering experiments on the model compound $HgBa_2CuO_{4+\delta}$ (Hg1201) revealed the existence of unusual magnetic excitations that weakly disperse throughout the entire Brillouin zone [4,5]. Like the $q = 0$ antiferromagnetic order, the new excitations are observed in the pseudogap phase and therefore appear to be associated with the order. The excitations possess very large spectral weights at well-defined characteristic energies that are comparable to the resonance energy [6] and to those of electron-boson-coupling features observed in a wide range of cuprates, highlighting their possible influence on the electronic structure. These findings demonstrate that the pseudogap state is a distinct phase of matter rather than a mere crossover. They furthermore cast doubt on the presumed predominant importance of the wave vector (1/2, 1/2) in the magnetic excitation spectrum, and have the profound implication that a single-band description of the cuprates is insufficient.

12:27PM Z2.00003 Collective Modes in Cuprates and their coupling to Fermions , CHANDRA VARMA, University of California, Riverside, CA. — The quantum-critical fluctuations of the loop current order observed universally in underdoped Cuprates have been derived and shown to be local in space and power law in time. The coupling of these fluctuations to fermions are shown to promote d-wave pairing as well as to give the Marginal Fermi liquid single particle spectra in the normal state [1]. Three collective fluctuations modes in the loop order modes are derived [2]. They are massive weakly dispersive magnetic modes. Two of these branches have been discovered. Experiments are suggested to discover the third branch.

1:03PM Z2.00004 Disentangling Cooper-pair formation above T_c from the pseudogap state in the cuprates , TAKESHI KONDO, Ames Laboratory, Iowa State University — The discovery of the pseudogap in the cuprates created significant excitement amongst physicists as it was believed to be a signature of pairing, in some cases well above room temperature. This was supported by a number of experiments detecting phase-fluctuating superconductivity above T_c. However, several recent experiments reported that the pseudogap and superconducting state are characterized by different energy scales, and likely compete with each other, leaving open the question of whether the pseudogap is caused by pair formation. To address this issue, we investigate the spectral weights, which are easier to quantify and in many cases interpret than the spectral feature, which is traditionally used. A key such measure is the density of states at the Fermi energy $D(E_F)$. In conventional, clean superconductors this weight is zero below T_c, but can be finite if there are strong impurity scattering effects. In such cases $D(E_F)$ reflects the pair breaking states. A separate scenario is a generic "density wave state" in the absence of pairing, which leads to a decrease of the $D(E_F)$ due to the opening of the density wave gap. In addition there is also the possibility of the coexistence of superconductivity and the density wave state - inhomogeneous superconductors such as the cuprates, where superconducting and non-superconducting patches coexist in the sample. One can then expect that the temperature dependence of $D(E_F)$ can be used to distinguish between these scenarios and disentangle the electronic ground states of the cuprates. Since the spectral gap in the cuprates displays significant momentum dependence, in our study we use the intensity of the spectral function at E_F, $I(E_F, k)$, which when integrated over all momenta equals $D(E_F)$. This allows us to isolate the behavior at a specific k-point and avoid smearing due to averaging. In this talk, we report the discovery of a spectroscopic signature of pair formation and demonstrate that in a region commonly referred to as the "pseudogap", two distinct states coexist: one that persists to an intermediate temperature T_{pair} and a second that extends up to T^*. The first state is characterized by doping independent scaling behavior and is due to pairing above T_c, but significantly below T^*. The second state is the "proper" pseudogap - characterized by the loss of low energy spectral weight, anomalies in transport properties and the absence of pair formation. T_{pair} has a universal value around 120-150K even for materials with very different T_c and it likely sets limit on the highest attainable T_c in the cuprates.

1:39PM Z2.00005 Phenomenology of electronic nematic and smectic states in STM studies of high T_c cuprates[1] , EUN-AH KIM, Cornell University — Electronic liquid crystals are phases in which electronic structure of a material breaks the spatial symmetries of its crystal lattice: electronic nematic only breaks the point group symmetry, while smectic (stripe) additionally breaks the translational symmetry. Here I define two independent order parameter fields for nematic and smectic that can be constructed from STM data. Using these order parameters we find long range intra-unit cell nematicity in the pseudogap states [1]. In contrast, we observe many topological defects that disorder the smectic fields. However, these defects reveal a remarkable coupling between smectic tendency and fluctuations in the nematic order. From these observations, we propose a Ginzburg-Landau free energy describing the quantum nematic/smectic coupling and demonstrate how it can explain the coexistence of these states and correctly predict their interplay [2]. In principle, this understanding may enable us to disentangle the complexities of the system specific cuprate phase diagrams.

Session Z9 DFD: Complex Fluids, Polymers, Gels D220

11:15AM Z9.00001 An anisotropic continuum model for flow, aggregation and microstructure evolution in magnetorheological fluids , MURAT OCALAN, GARETH MCKINLEY, Massachusetts Institute of Technology — The complexities associated with the transport of magnetorheological (MR) fluids under non-uniform magnetic and flow fields pose unresolved problems for generating accurate computational models. The evolutions of the electromagnetic and rheological properties of MR fluids are strong functions of the suspension microstructure; however, the geometrical features that lead to the field non-uniformities are often of a much larger length scale. To address these commonly occurring flow problems, we develop an anisotropic continuum model for MR fluids in which the electromagnetic stress is incorporated into the constitutive model for the viscoplastic stress generated in the bulk fluid by considering the generation and distortion of suspension microstructure under flow. The new model is incorporated into both a single-phase and a two-phase continuum description of the suspension. The aggregation dynamics and the evolution of MR fluid microstructure are observed in unique ferromagnetic microfluidic channels that replicate flow conditions of practical interest. The predictions of the newly developed models are verified with the experimental observations of microstructure evolution and macroscopic measurements of fluid rheology.

11:27AM Z9.00002 Electrorheological response of dense strontium titanyl oxalate suspensions , CARLOS ORELLANA, JINBO HE, HEINRICH JAEGER, James Franck Institute and Department of Physics, The University of Chicago, Chicago, IL 60637, USA — Strontium Titanyl Oxalate (STO) particles were synthesized using a new method of precipitating the STO out of a water solution by adding alcohol. When dispersed in silicon oil, dense STO suspensions exhibit a high static yield stress in the presence of an electric field (200kPa at 5kV/mm), high shear stress at high shear rates and low current densities. We also find that the yield stress increases roughly linearly with applied field. This behavior is a key characteristic of a polar molecule dominated electrorheological effect. We also observed stress stiffening with time under low shear, stress oscillations, and stress reduction with strain. These effects can be accounted for by the interaction of permanent dipoles with the particles, the creation of shear bands of a few particles in width and the lack of self-diffusion in the samples.

11:39AM Z9.00003 Molecular Simulations of Particle Nanorheology , MIR KARIM, RAJESH KHARE — Over the past few years, experimental and theoretical developments in the field of microrheology have enabled determination of the local mechanical properties of complex materials. In this presentation, we will extend this approach to determine the local viscoelastic properties of polymeric materials using molecular dynamics (MD) simulations. Molecular simulations provide the unique ability to explicitly account for the intermolecular interactions in the system. Thus an approach based on molecular simulations allows for the determination of the viscoelastic properties at the nanoscale. The specific system that is studied in this work consists of a polymeric melt in which the polymers are modeled as bead-spring chains. We will present a comparison of the results obtained from the passive and the active nanorheology approaches. A discussion of the parameter (e.g. amplitude and frequency) ranges that allow usage of these techniques will also be presented.

11:51AM Z9.00004 Microscopic Approach for the Friction on a Spherical Particle in Dense Liquids: Hydrodynamics and Beyond , UMI YAMAMOTO, KENNETH SCHWEIZER, University of Illinois, Urbana-Champaign — We propose a new microscopic, non-mode-coupling, statistical dynamical approach to deriving the Stokes-Einstein (SE) friction coefficient of a large spherical particle dissolved in a dense fluid. The real space method is based on including as a slow variable the force exerted on a particle by the surrounding fluid. By exploiting the appropriate separation of time and length scales, and the Kirkwood superposition approximation for multi-point correlations, the SE result is obtained including the slip and stick limits plus the crossover function. This advance provides the foundation for developing a unified theory of friction for nanoparticles that includes both hydrodynamics and the non-hydrodynamic contribution associated with material-specific particle-fluid and particle-particle forces. Applications to nanoparticles in unentangled and entangled polymer solutions and melts, under various interfacial polymer-particle structure conditions, will be reported. Questions of particular interest include how the non-hydrodynamic friction contribution scales with particle radius, the role of length-scale-dependent viscosity in polymer liquids, and the conditions required for crossover to the hydrodynamics-dominated regime.

12:03PM Z9.00005 Rheology of bacterial flagella suspensions , SEVIM YARDIMCI, THOMAS GIBAUD, DANIEL CHEN, EDWARD BARRY, ZVONIMIR DOGIC, Physics Department, Brandeis University — The mechanical behavior of a suspension of rigid and semiflexible filaments has been studied in great detail. In comparison the effect of the filament geometry has been relatively unexplored. We present experimental results on the rheological behavior of suspensions of curly and straight flagella with an identical average contour length. We find that both suspensions are trapped in a glassy state and exhibit a solid-like behavior. We observe that the scaling of viscoelastic moduli is highly dependent on filament geometry. Taken together, this highlights the role of filament geometry in suspension mechanics.

12:15PM Z9.00006 Brownian Dynamics simulations of dilute graphene solutions under flow , YUEYI XU, MICAH GREEN, Department of Chemical Engineering, Texas Tech University — Many graphene-based materials (such as thin conductive films and nanocomposites) are processed in the liquid phase and require the conformation and alignment of graphene in solution to be precisely controlled. However, prior studies of conformation dynamics of sheetlike macromolecules such as graphene have been limited to equilibrium behavior, and there have been no studies of the dynamics of sheetlike macromolecules on flow processing timescales. Here we develop Brownian Dynamics (BD) algorithms in order to quantify the effects of flow processing on graphene conformation. The method is conceptually similar to those used for linear polymers; we coarse-grain the sheet using a bead-rod lattice of arbitrary 2-D connectivity and develop a novel theoretical framework for bending and metric forces. Using this technique, we simulate the conformation dynamics of dilute sheetlike macromolecule solutions in shear flow and compute the corresponding solution properties as a function of flow strength, sheet size, and solvent quality.

12:27PM Z9.00007 Orientation Dependent Gelation of Platelet Suspensions , YA-WEN CHANG, ANDRES MEJIA, ZHENGDONG CHENG[1], Artie McFerrin Department of Chemical Engineering, Texas A&M University, College Station, TX 77832 — Gelling behavior of colloidal suspensions of disk-shaped particles has long been used as an ideal system for studying the formation of arrested state of matter. High aspect ratio synthetic α-Zirconium phosphate (α–ZrP) monolayer platelets have recently received our attention as a new type of liquid crystal building blocks. We report the phase diagram of charged α-Zirconium phosphate platelet suspensions across the isotropic (I) –nematic (N) region versus salt concentrations. Typical electrostatic screening induced flocculation and gelation of platelet suspensions were observed. The morphological and rheological characteristics of liquid crystalline and colloidal gel phases were studied with polarized optical imaging and rotational/oscillatory rheometer. At high ionic strengths (>10mM), a re-entrance of fluidic liquid crystal phase occurs when particle volume fractions are above the arrested gel phase. We contribute this behavior to the competition between the driving forces for isotropic/nematic and sol/gel transitions of attractive colloidal platelets. Strong particle alignment hinders gelation, which usually demonstrates the "house of card" configuration in platelet suspensions; Isotropic suspensions flocculate and gel easily, as we confirmed experimentally.

12:39PM Z9.00008 Dynamic separation of macromolecules under temperature gradient[1] , YUSUKE MAEDA, The Rockefeller University, Center for Studies in Physics and Biology, AXEL BUGUIN, Institut Curie, Centre de recherche, CNRS/UMR, ALBERT LIBCHABER, The Rockefeller University — Thermophoresis is a motion of suspensions in a fluid that are subjected to a temperature gradient. Although its effect is widely studied in case of single solute in water, little is known about how the mixture of different solutes is affected. We heated water with an infrared laser by $\Delta T_{\max}$=5C and ∇T=0.25C/um to induce thermophoresis of polyethylene glycol (PEG) and DNA. PEG is depleted from the hot region and results in a stationary gradient of its high volume fraction ϕ. Under this high concentration of PEG, DNA of small concentration is submitted to thermophoresis and osmotic pressure difference. The DNA shows regime of depletion, ring-like localization and accumulation as the volume fraction of PEG increases. As the osmotic force depends on the size of trapped solutes, DNA of different size accumulates at different regions. Depending whether the DNA size is below or above 5kbp a different scaling of position versus DNA size is observed. Thermal separation is a general phenomenon. It applies also to RNA and microbeads.

12:51PM Z9.00009 Non-affine deformations in flexible and semi-flexible polymer gels[1] , ANINDITA BASU, Physics and Astronomy, University of Pennsylvania, QI WEN, Institute for Medicine and Engineering, University of Pennsylvania, XIAOMING MAO, TOM LUBENSKY, Physics and Astronomy, University of Pennsylvania, PAUL JANMEY, Institute for Medicine and Engineering; Physics and Astronomy, University of Pennsylvania, ARJUN YODH, Physics and Astronomy, University of Pennsylvania — We test the validity of affine deformation assumption in flexible and semi-flexible polymer networks by embedding different-sized fluorescent tracer beads within model polymer networks and quantifying their displacements under shear. A conventional rheometer is used with a confocal microscope for this purpose. Non-affinity is quantified as a function of applied strain, polymer chain density, cross-link concentration, network morphology, reaction kinetics and size of probe particles used. Non-affinity measurements in flexible polymer gels are in qualitative agreement with current theories in rubber elasticity. For semi-flexible bio-polymer gels, measurements indicate that non-affine deformations are small for networks of thinner, relatively flexible filaments and get smaller as strain increases into non-linear elastic regime. These small measures are consistent with the entropic model for non-linear elasticity of semi-flexible gels. However, as filament stiffness and mesh size increase, the deformations become more non-affine, as predicted by the enthalpic bending and stretching models of non-linear elasticity.

[1]MRSEC DMR-0520020, DMR-0505048, and DMR- 0079909

1:03PM Z9.00010 Drying of polymer films: study of demixing phenomena , JULIE FICHOT, RODOLPHE HEYD, CNRS, MARIE-LOUISE SABOUNGI, CHRISTOPHE JOSSEREND, EMILIE COMBARD, JEAN FRANCOIS TRANCHANT — Understanding the mechanisms that control the stability of polymeric films is important in beauty care. We have prepared films starting from a water-soluble organic polymer, a preservative and water. We study the drying of these films as a function of several physicochemical parameters that control their interfaces such as temperature, humidity and the nature of the support. The viscoelastic properties of the solutions before spreading out are analyzed with a rheometer in order to adjust the temperature. The topography of the films is observed by optical microscopy and the evolution of the drying is determined with a precision gravimetric balance. The behavior of the films on a nanometric scale is followed by AFM. During the drying process, droplets appear on the surface of the film, made up of water surrounded by a shell of preservative. As the films dries, the water evaporates from the droplets and the preservative spreads on the surface of the film, leading to the formation of craters on the surface of the dried film. The dimensions and numbers of the craters depend strongly on the type and concentration of the preservative employed.

1:15PM Z9.00011 Multiple Particle Collision Dynamics Simulations of the Effect of Catenation on the Structural and Dynamic Properties of Ring Polymers in Solution , GOVIND HEGDE, RAJESH KHARE, Department of Chemical Engineering, Texas Tech University — Multiple particle collision dynamics (MPCD) is a particle based mesoscale simulation technique that coarse-grains the solvent while preserving the hydrodynamics, thus enabling simulations over longer length and time scales as compared to molecular dynamics (MD) simulations. In this work, MPCD is used to study the effect of topology on the structural and dynamic behavior of complex fluids. The systems of interest in this work are the dilute solutions of ring and catenated ring polymers. MPCD simulation results are compared with those obtained from MD simulations in which the hydrodynamic interactions are governed by the explicit intermolecular interactions. Different chain topologies are considered such as catenated as well as multi-catenated rings. Results will be presented for the effect of chain length on the radius of gyration and chain diffusion coefficient for the various topologies studied. Our results will also be compared with previous theoretical and experimental work reported in literature.

1:27PM Z9.00012 Strongly anisotropic polymer networks , STEPHAN ULRICH, University of Goettingen, ANNETTE ZIPPELIUS, University of Goettingen, Max Planck Institute for Dynamics and Self-Organization, PANAYOTIS BENETATOS, Cavendish Laboratory, University of Cambridge — We investigate a network of worm-like chains, which are strongly oriented along a preferred direction due to an external field, boundary conditions, or a nematic environment. We discuss the effects of random permanent cross-links, whose density may follow an arbitrary distribution along the alignment direction. We show that the tilt modulus is unaffected by cross-links. As the cross-link density is increased beyond the gel point, the network develops a stiffness to in-plane shear deformations. Results for the shear elasticity and fluctuations of the polymer chains are presented. The case of cross-linking the chains on one end only is highlighted, it constitutes a simple model for polymer brushes. Moreover force-extension curves are presented for a toy model that consists of two cross-linked chains.

1:39PM Z9.00013 Structure and Dynamics of Water Absorbed in Polyamide , MARCO LAURATI, PAUL SOTTA, DIDIER LONG, LUDOVIC ODONI, VERONIQUE BOSSENEC, THIERRY BADEL, Laboratoire Polymeres et Materiaux Avances, UMR5268, CNRS/Rhodia Recherches et Technologies, 85 Rue des freres Perret, 69192 Saint-Fons Cedex, ARANTXA ARBE, ANGEL ALEGRIA, JUAN COLMENERO, Centro de Fisica de Materiales (CSIC-UPV/EHU), Paseo Manuel de Lardizabal 5, 20018 Donostia/San Sebastian, Spain — We present results of elastic and inelastic neutron scattering, dielectric spectroscopy and MD simulations concerning the structural organization and the dynamics of water absorbed in an amorphous polyamide material. We find that, different from predictions of available models of water absorption in polyamide, only a small fraction of water binds to the amide groups while most of it organizes into aggregates. Such structural model is supported by results on the microscopic dynamics of water, which can be described as diffusive motions with a relaxation time following a VFT dependence on temperature, similarly to bulk water. Measured average diffusion coefficients of water absorbed in Polyamide are approximately two orders of magnitude smaller than in bulk water, revealing the confinement effect of the polymer matrix.

1:51PM Z9.00014 Order parameter defining liquid-liquid transition in water[1] , J. RAUL GRIGERA, OSVALDO CHARA, ANDRES MCCARTHY, IFLYSIB (UNLP-CONICET), c.c. 565, La Plata, Argentina — Water presents both open tetrahedral and compact hexagonal structures. Although several order parameters have been proposed to quantify this, all of them are only applicable to data produced by simulation. We present an order parameter (P_r) that is calculated from the radial distribution function $g(r)$, also available from experiment. We hereby extract the tetrahedral and hexagonal components from the $g(r)$, each one reconstructed as the sum of a Freundlich distribution for the first peak, two subsequent Gaussian distributions, and a sigmoidal to account for the rest. The order parameter can be calculated from the relative contribution of tetrahedral over hexagonal contribution. We obtained the P_r for SPC/E water model from molecular dynamics simulations of water at different pressures and temperatures. At 300K, the pressure in which both, tetrahedral and hexagonal contributions become equal (P_r= 0), a structural crossover is found in the vicinity of 2kbar, close to the pressure at which the ''anomalous'' behavior manifests. Having computed P_r for this wide range of pressure and temperature we then calculate the HDL spinodal, the coexistence line, the second critical point, and the Widom line.

2:03PM Z9.00015 Particle and fluid diffusivity of non-colloidal suspensions , EMMANOUELA FILIPPIDI, ALEXANDRE FRANCESCHINI, CHUI-LAI CHEUNG, JACOB TUTMAHER, SEAN PARADISO, TARUN JAIN, DAVID PINE, Center for Soft Matter Research, New York University — Suspensions of non-colloidal spheres at moderate volume fractions (0.2-0.4) under slow periodic strain undergo a phase transition from an absorbing to an active fluctating state. Particle trajectories change from reversible below the critical strain to irreversible above. We measure the fluid diffusivity of the fluorescently labelled fluid and compare it with the particle diffusivity in order to obtain a measure of the coupling between the two. Of particular interest is how the fluid diffusivity changes near the onset of irreversibility of the particle trajectories.

Session Z10 DCMP: Novel Instrumentation and Techniques in Surface Science D221

11:15AM Z10.00001 Development of a device-oriented UHV scanning probe microscope based on quartz sensors[1] , JACOB TOSADO, WILLIAM G. CULLEN, MICHAEL S. FUHRER, University of Maryland — Scanning tunneling microscopy (STM) provides atomic-scale spatial resolution and performs local electronic spectroscopy of conducting materials. The recent emergence of graphene has highlighted the ability to tune carrier density by applying a gate voltage. However, preparation of samples as field-effect-transistors necessitates a dielectric substrate below the device, which is problematic for STM. Driven by the need to carry out high resolution imaging in ultrahigh vacuum, we are now developing an instrument which combines STM with atomic force microscopy (AFM) using a quartz sensor. This combination allows AFM approach and navigation, with uncompromised STM performance due to the very high stiffness of the quartz sensor. Primary features of the microscope design include in-situ exchange of probes and samples, with flexibility in probe and sample geometries and multiple contacts to both probe and sample. The microscope is housed in a UHV chamber with complete surface preparation and analysis capability. This talk will cover unique design features as well as testing of the microscope concept.

11:27AM Z10.00002 Low-temperature STM/STS study on superconducting FeSe films[1] , XUCUN MA, CANLI SONG, YILIN WANG, PENG CHENG, LILI WANG, KE HE, XI CHEN, QIKUN XUE, INSTITUTE OF PHYSICS, CHINESE ACADEMY OF SCIENCES TEAM, DEPARTMENT OF PHYSICS, TSINGHUA UNIVERSITY TEAM — By using molecular beam epitaxy (MBE) technique, we have prepared single crystalline and atomically flat FeSe thin films on graphene-terminated SiC substrate. Low temperature scanning tunneling microscopy/spectroscopy (STM/STS) measurements reveal that the local superconducting gap in the quasiparticle density of states remains robust down to two triple layers ($\sim$1.1 nm), and that the FeSe films show a novel thickness-dependent superconductivity transition behavior. We show that the superconductivity of the FeSe films can be manipulated by concise control of their surface structures. *dI/dV* mapping of the vortex lattice confirms that FeSe is a typical type II superconductor. Understanding these properties may help us to unravel the mechanism of the recently discovered Fe-based superconductors and even the long-term studied cuprates.

[1]The work was financially supported from NSF and MOST of China.

11:39AM Z10.00003 In situ coherent x-ray scattering and STM studies of hexagonally reconstructed Au(001) in Electrolytes[1] , MICHAEL S. PIERCE, Materials Science Division, Argonne National Laboratory, VLADIMIR KOMANICKY, Faculty of Science, Safarik University, ANDI BARBOUR, DANIEL HENNESSY, Materials Science Division, Argonne National Laboratory, JUNDAR SU, ALEC SANDY, Advanced Photon Source, Argonne National Laboratory, HOYDOO YOU, Materials Science Division, Argonne National Laboratory — We have studied the dynamics of Au(001) and Au(111) surfaces in situ in 0.1 M HClO4 electrolyte solution using coherent x-ray scattering experiments and STM microscopy. Our coherent x-ray scattering experiments measure a correlation time for the surface as a function of applied potentials. Coherent x-ray scattering differs from the ordinary x-ray diffraction in sensitivity to the structural and temporal details. The correlation times were obtained from measurements conducted while the surface is in equilibrium and the ordinary surface scattering intensity is constant. The correlation time changes from high 10^3 seconds to low 10^2 seconds. The correlation times of reconstructed surfaces at low potential are at least an order of magnitude smaller than those measured at the reconstructed surfaces in vacuum. The correlation times also change dramatically in response to the applied potential. These experiments also represent the first successful application of coherent x-ray scattering to the study of electrochemical interfaces in situ.

11:51AM Z10.00004 Local transport measurements at mesoscopic length scales on epitaxial graphene using scanning tunneling potentiometry , WEIGANG WANG, KO MUNAKATA, MICHAEL ROZLER[1], FRANCOISE KIDWINGIRA[2], MALCOLM BEASLEY, Stanford University — By contrast to quantum transport measurements across nanostructures (single molecular, carbon nanotube, or lithographically manufactured), local transport measurements on macroscopic samples at mesoscopic length scales are relatively uncharted territory. Scanning tunneling potentiometry (STP) is the natural tool to perform such measurements. Due to its characteristic materials parameters, thin epitaxial graphene on silicon carbide is an attractive model system for search of quantum mechanical effects in local transport. We report results of STP measurements on epitaxial graphene at room temperature. In addition to the expected residual resistivity dipoles, we have observed features in the measured potential that are counter intuitive to classical diffusive considerations. Based on these results, we conclude that a more complete theoretical description of STP measurement is necessary. Work supported by AFOSR.

12:03PM Z10.00005 Possible microscopic origin of large broadening parameter in point Andreev reflection spectroscopy[1] , JIAN WEI[2], GOUTAM SHEET[3], VENKAT CHANDRASEKHAR, Northwestern University — We report on the low frequency noise in ballistic point-contacts between a silver tip and a niobium foil. The ballistic nature is confirmed by point-contact Andreev reflection (PCAR) spectroscopy. As has been found by others, a broadening parameter Γ needs to be introduced to fit the PCAR spectra. For contacts with higher resistance, a larger Γ is required to fit the PCAR spectra, and we find that random two level fluctuations dominate the noise spectra. This finding suggests that two level fluctuations contribute to the broadening of the gap features.

12:15PM Z10.00006 Scanning SQUID measurements of the superconducting state of δ-doped $SrTiO_3$ heterostructures , JULIE A. BERT, Stanford University, MINU KIM, CHRIS BELL, HAROLD Y. HWANG, University of Tokyo, KATHRYN A. MOLER, Stanford University — The discovery of interface superconductivity in complex oxide heterostructures has generated significant excitement. We used scanning SQUID microscopy to investigate the magnetic properties of one such heterostructure, δ-doped structures in $SrTiO_3$ thin films. We have observed a diamagnetic response and imaged vortices providing further evidence of a two-dimensional superconducting state. Finally we measured the magnetic susceptibility from which we observe spatial inhomogeneities in the superconducting response and can estimate the temperature dependence of the magnetic penetration depth.

12:27PM Z10.00007 Probing Transient Structures during interfacial charge transfer mimicking solar cells and heterogeneous catalysis[1] , LIN CHEN, Argonne National Lab./Northwestern U., XIAOYI ZHANG, Argonne National Lab., GRIGORY SMOLENTSEV, Southern Federal University, JIANCHANG GUO[2], KLAUS ATTENKOFER, ANDREW B. STICKRATH, DI-JIA LIU, Argonne National Lab, NOSHEEN GOTHARD, Northwestern University — Photoinduced charge transfer at interfaces is a key process in photocatalysis and dye sensitized solar cells (DSSCs). Using X-ray transient absorption (XTA) spectroscopy, we extracted metal center surrounding transient structural information in a DSSC mimic, namely the RuN3 dye on the TiO_2 nanoparticle surfaces. Structural evolution of the adsorbed dye sensitizer and the rearrangement of the nanocrystal surface associated with the electron density shift during and after the interfacial charge injection were investigated. The other interfacial charge transfer system is a suspension of Pt nanoparticles on TiO_2 where the photoexcitation induces redox reactions and generate hydrogen fuel. The preliminary XTA results demonstrate the feasibility of the method in probing heterogeneous catalytic systems.

12:39PM Z10.00008 Composition of CuAu alloy and changes upon corrosion studied by Hard X-ray Photoelectron Spectroscopy , PARASMANI RAJPUT, BLANKA DETLEFS, ESRF, Grenoble, France, AJAY GUPTA, UGC-DAE Consortium for scientific research, Indore 452017, India, DIETER KOLB, University Ulm, Germany, JORG ZEGENHAGEN, ESRF, Grenoble, France — Metals and their alloys are highly susceptible to corrosion in wet environment. Dealloying is a particular type of corrosion, attacking practically all metals in industrial use: When an alloy is coming into contact with an electrolyte, the less noble metal may go into solution, typically causing crack formation and subsequent material failure upon stress. We used bulk sensitive Hard X-ray photoelectron spectroscopy (HAXPES) with an excitation energy of 6 keV as a new powerful tool to investigate the chemical composition of alloys and changes upon dealloying, studying Cu_xAu (with x = 4.1) alloy films of 9 to 50 nm thickness. Morphology, structure and composition were further characterized by atomic force microscopy, X-ray reflectivity and quantitative X-ray fluorescence. The HAXPES analysis revealed that chemical shifts of metal core-levels, i.e. Au4f and Cu3s, can be used as a benchmark for the alloy composition. HAXPES as a function of electron emission angle allowed depth sensitive determination of the chemical composition before and after dealloying in sulphuric acid.

12:51PM Z10.00009 X-Ray Characterization of Electrodeposited Alloy Thin Films[1] , NICHOLAS WOZNIAK, DANIEL MCNEEL, ALYSSA FREY[2], JENNIFER HAMPTON, Hope College — Particle-Induced X-ray Emission (PIXE) was used to measure the composition of electrodeposited NiFe and NiFeCu thin films. The thin films were deposited on gold-plated silicon wafers, and PIXE spectra were analyzed to obtain the Ni, Fe, Cu, and Au content in each sample. By comparing the Ni, Fe, and Cu content in a sample to the Au content in the same sample, the relative amounts of deposited material between samples could be measured. The effect of the deposition solution, deposition parameters and duration of deposition was explored. The results were compared to those measured with Energy Dispersive Spectroscopy. The results show that PIXE can measure the total deposited metal in a sample over at least four orders of magnitude with similar fractional uncertainties. The technique is also sensitive enough to observe the variations in alloy composition due to sample non-uniformity or variations in deposition parameters.

1:03PM Z10.00010 Thermal conductance of interfaces with molecular layers - low temperature transient absorption study on gold nanorods supported on self assembled monolayers , WEI WANG, JINGYU HUANG, CATHERINE MURPHY, DAVID CAHILL, UNIVERSITY OF ILLINOIS AT URBANA CHAMPAIGN, DEPARTMENT OF MATERIALS SCIENCE AND ENGINEERING TEAM, DEPARTMENT OF CHEMISTRY COLLABORATION — While heat transfer via phonons across solid-solid boundary has been a core field in condense matter physics for many years, vibrational energy transport across molecular layers has been less well elucidated. We heat rectangular-shaped gold nanocrystals (nanorods) with Ti-sapphire femtosecond pulsed laser at their longitudinal surface plasmon absorption wavelength to watch how their temperature evolves in picoseconds transient. We observed single exponential decay behavior, which suggests that the heat dissipation is only governed by a single interfacial conductance value. The "RC" time constant was 300ps, corresponding to a conductance value of 95MW/m^{2}K. This interfacial conductance value is also a function of ambient temperature since at temperatures as low as 80K, which are below the Debye temperature of organic layers, several phonon modes were quenched, which shut down the dominating channels that conduct heat at room temperature.

1:15PM Z10.00011 Contact voltage-induced softening transition of gold-on-gold contacts at cryogenic temperatures , DIANA BERMAN, MATTHEW WALKER, JACQUELINE KRIM — A series of experiments were performed in vacuum environments to investigate the impact of contact voltage on the surface softening transition for gold-on-gold contacts at cryogenic temperatures [1]. The purpose of this work was twofold: (1) To examine whether asperity heating models already validated for high temperature contacts were also applicable at cryogenic temperatures, and (2) to explore the implications and validity of prior suggestions that contact temperatures between 338 and 373 K are high enough to dissociate adsorbed film and/or push them aside, but low enough to prevent asperities from becoming soft and adherent. Measurements on two distinct RF MEMS switch types were performed in the temperature range 79 - 293K and for contact voltages ranging from 0.01 to 0.13 V. Contact resistance values at all temperatures were observed to be lower for higher contact voltages associated with increased heating and softening effects. In-situ removal of adsorbed species by oxygen plasma cleaning resulted in switch adhesive failure. Switches that had not been cleaned meanwhile exhibited distinct reductions in resistance at contact temperatures close to 338 K, consistent with suggestions that films begin to desorb, disassociate, and/or be pushed aside at that temperature. Funding agencies: AFOSR, DARPA, and NSF DMR. [1] D. Berman, M. Walker, J. Krim, J. Appl. Phys., 108, 044307 (2010).

1:27PM Z10.00012 Reduction of a polar oxide surface in a strong DC-field[1] , WOLFRAM STEURER, SVETLOZAR SURNEV, Institute of Physics, University of Graz, Universitaetsplatz 5, Graz, A-8010, Austria, GIOVANNI BARCARO, ALESSANDRO FORTUNELLI, IPCF/CNR, via G. Moruzzi 1, Pisa, I-56124, Italy, FALKO P. NETZER, Institute of Physics, University of Graz, Universitaetsplatz 5, Graz, A-8010, Austria — Polar oxide surfaces are of fundamental scientific interest because of their inherent instability in bulk samples on electrostatic grounds. Here we report first experimental evidence of field-induced reduction of a polar oxide surface by applying homogeneous external DC-fields. Ultrathin Ni-oxide nanostructures immersed into an Ag(100) substrate have been grown by reactive evaporation and have subsequently been exposed to electric fields in the range of 0.5-1.6 V/nm. We achieve such high fields in a setup resembling a plate capacitor where the Ag(100) substrate (with the deposited NiO film) acts as the cathode with a counter electrode placed 800nm apart. For fields exceeding the threshold of 0.9 V/nm, oxygen atoms are torn away from the surface, thus, efficiently reducing the initially highly-ordered Ni-oxide film. The remaining Ni atoms on the surface are highly mobile and cluster together. No oxide reduction occurs if the field polarity is inverted.

[1]This work is supported by the ERC Advanced Grant "SEPON."

1:39PM Z10.00013 Interference between Surface and Bulk Scattering in Nanoscale Conductors , SWARBHANU CHATTERJEE, ALEXANDER MEYEROVICH, University of Rhode Island — We analyze the quasiclassical and quantum interference between the bulk and boundary scattering channels in thin high quality films. The effective transport time is calculated beyond the Matthiessen's approximation as an expansion in inverse bulk mean free path. The interference corrections to resistivity exhibit a crossover between two regimes that are characterized by distinct dependences on temperature and/or impurity concentration. In our quasiclassical approximation the results reduce to a transparent analytical expression. We discuss differences between quantum and quasiclassical approaches and experimental implications of our results.

1:51PM Z10.00014 Quantitative Transmission Electron Microscopy of Nanoparticles and Thin-Film Formation in Electroless Metallization of Polymeric Surfaces[1] , ANIRUDDHA DUTTA, HELGE HEINRICH, STEPHEN KUEBLER, CHRIS GRABILL, University of Central Florida, ANIKET BHATTACHARYA — Gold nanoparticles(Au-NPs) act as nucleation sites for electroless deposition of silver on functionalized SU8 polymeric surfaces. Here we report the nanoscale morphology of Au and Ag nanoparticles as studied by Transmission Electron Microscopy (TEM). Scanning TEM with a high-angle annular dark-field detector is used to obtain atomic number contrast. From the intensity-calibrated plan-view scanning TEM images we determine the mean thickness and the volume distribution of the Au-NPs on the surface of the functionalized polymer. We also report the height and the radius distribution of the gold nanoparticles obtained from STEM images taking into consideration the experimental errors. The cross sectional TEM images yield the density and the average distance of the Au and Ag nanoparticles on the surface of the polymer.

Session Z13 GSNP DFD: Granular Materials II D225/226

11:15AM Z13.00001 Perfect fluid flow from the impact of a dense granular jet , WENDY W. ZHANG, JAKE ELLOWITZ, NICHOLAS GUTTENBERG, University of Chicago, HERVE TURLIER, Institut Curie, SIDNEY R. NAGEL, University of Chicago — Axisymmetric collision of a cylindrical water jet with a circular target generates a thin conical sheet, also known as a water bell [Cheng et al. Phys. Rev. Lett. 99, 2007]. Intriguingly, recent experiments on granular jet impact in the regime of dense inertial flow reveal similar behavior: the angles by which the collimated sheets of particles are ejected from the target agree closely with the angles measured in the water-bell experiments [Clanet, C. J. Fluid Mech. 430, 2001] . This quantitative correspondence suggests that the collective granular motion during impact can be modeled as an incompressible, continuum fluid. Since viscous effects are weak in water-jet impact and the granular jet is comprised of non-cohesive particles (hence possessing zero surface tension), the simplest scenario is that the continuum motion corresponds to the flow of a perfect fluid. We show an exact solution of 2D perfect fluid impact agrees quantitatively with 2D discrete-particle simulation results. Therefore, the emergence of a highly collimated outgoing sheet does not necessarily signal the creation of a thermodynamic liquid phase. Such a coherent outcome results generically when the motion is nearly incompressible and dominated by inertia.

11:27AM Z13.00002 Jet-Induced Granular 2-D Crater Formation with Horizontal Symmetry Breaking[1] , ABE CLARK, ROBERT BEHRINGER, Duke Physics — We investigate the formation of a crater in a 2-D bed of granular material by a jet of impinging gas, motivated by the problem of a retrograde rocket landing on a planetary surface. As the strength and height of the jet are varied, the crater is characterized in terms of depth and shape as it evolves, as well as by the horizontal position of the bottom of the crater. The crater tends to grow logarithmically in time, a result which is common in related experiments. We also observe an unexpected horizontal symmetry breaking at certain well-defined conditions. We present data on the evolution of these asymmetric states and attempt to give insights into the mechanism behind the symmetry-breaking bifurcation. This horizontal symmetry breaking is highly suggestive of a pitchfork bifurcation, and we give evidence to classify it as forward or backward in different regimes of operation. As we will demonstrate, the formation of an asymmetric crater could be of considerable practical concern for lunar or planetary landers, particularly in the case of a backward pitchfork bifurcation, which is characterized by hysteresis and very rapid transitions.

11:39AM Z13.00003 Simulations of granular jet impact deadzone formation , NICHOLAS GUTTENBERG, JAKE ELLOWITZ, WENDY ZHANG, University of Chicago, HERVE TURLIER, Univ. Pierre & Marie Curie, SIDNEY NAGEL, University of Chicago — Motivated by granular experiments showing the emergence of continuum-like dynamics when a dense jet hits a target, we simulate the impact of 2D and 3D granular jets of frictional, cohesion-less grains upon a fixed target. This is a inertial, dense jet regime where the motion is essentially incompressible. Impact deflects the material in the jet into a hollow conical sheet. The cone angles measured in simulation are consistent with previous experimental studies of the 3D granular jet impact. In addition, experiments have revealed the formation of a "dead zone," a region where the grain motion is negligibly small. The simulation shows that this dead zone can only form when a no-slip boundary condition is enforced at the target. The presence or absence of the dead zone leads to a change in cone angle consistent with the experimentally observed differences in cone angle between the 3D granular flow and the corresponding water bell flow.

11:51AM Z13.00004 Endless penetration in impact cratering[1] , J. CARLOS RUIZ-SUAREZ, Cinvestav-IPN, Unidad Monterrey, FELIPE PACHECO-VAZQUEZ, Cinvestav-IPN, Unidad Merida, J. MANUEL SOLANO-ALTAMIRANO, Cinvestav-IPN, Unidad Monterrey, GABRIEL CABALLERO-ROBLEDO, Cimav-Unidad Monterrey — The phenomena of impact cratering have been in the minds of physicists at least for two decades; the reason being the interest for elucidating the intriguing rheological response produced by granular systems when they are penetrated. With the great amount of work done in this regard, one could think that the problem is reasonably well understood. However, we study here a fascinating phenomenon never observed before in granular penetration experiments: depending on the mass of a projectile colliding onto a granular bed, it either stops at a given depth like normally expected, or keeps sinking with a terminal velocity as if the medium were a newtonian fluid. Understanding this intriguing behaviour could help us to know the subtleties of intrusion phenomena in granular media.

12:03PM Z13.00005 Avalanches of Singing Sand in the Laboratory , SIMON DAGOIS-BOHY, Kamerlingh Onnes Laboratorium, Universiteit Leiden, SYLVAIN COURRECH DU PONT, STÉPHANE DOUADY, Laboratoire M.S.C., Univ. Paris Diderot — The song of dunes is a natural phenomenon that has arisen travellers' curiosity for a long time, from Marco Polo to R.A. Bagnold. Scientific observations in the XXth century have shown that the sound is emitted during a shear flow of these particular grains, the free surface of the flow having coherent vibrations like a loud speaker. The sound emission is also submitted to a threshold effect with many parameters like humidity, flow speed, surface of the grains. The sound has been reproduced in laboratory avalanche experiments close to the natural phenomenon on field, but set in a channel with a hard bottom and a few centimeters of sand flowing, which contradicts explanations of the sound that involve a sand dune under the avalanche flow. Flow rates measurements also show the presence of a plug region in the flow above the sheared band, with the same characteristic length as the coherence zones of the sound. Finally we show experimentally that the Froude number, once modified to take into account the height of this plug band, is the parameter that sets the amplitude of the sound, and produces a threshold that depends on the grain type.

12:15PM Z13.00006 Shear strength of vibrated granular/granular-fluid mixtures , BRIAN UTTER, RALPH HERMAN, BEN FOLTZ, James Madison University — The behavior of dense granular materials can be characterized by the continuous forming and breaking of a strong force network resisting flow. This jamming/unjamming behavior is typical of a variety of systems and is influenced by factors such as grain packing fraction, applied shear stress, and the random kinetic energy of the particles. We present experiments on shear strength of granular and granular-water mixtures under the influence of external vibrations, one parameter that leads to unjamming. We use low vibration (< 1g) and slow shear and measure avalanching statistics in a rotating drum and the torque required to move a stirrer through a sand/water mixture. We find that external vibration (i) increases granular strength at small vibrations in the dry system, (ii) removes history dependence (memory), and (iii) decreases shear strength at all accessible saturation levels in the sand-fluid system. Additionally, shear strength is found to be smallest for both dry and completely saturated mixtures. Additional ongoing experiments probe beyond a dimensionless acceleration of 1 and explore jamming and surface chemistry effects in the avalanching flow of granular/fluid mixtures.

12:27PM Z13.00007 Collisions between solitary waves in granular alignments[1] , SURAJIT SEN, SUNY Buffalo, DIANKANG SUN, New Nexico Resonance — Solitary waves arise naturally when an unloaded alignment of elastic spheres, that is held between fixed end walls, is perturbed at one end. Unlike most known classes of solitary waves, those in granular materials are special and tend to break down and reform during any collision. Here we present what happens when two solitary waves of unequal magnitude suffer head-on and overtaking types of collisions. We will show that these collisions provide ways for solitary waves to not only become smaller but also become larger (within bounds) and that they are the underlying reason behind the emergence of the quasi-equilibrium phase.

12:39PM Z13.00008 Oil in Water Emulsion Flow in a 2D Hopper[1] , XIA HONG, DANDAN CHEN, KENNETH DESMOND, ERIC WEEKS, Physics Dept., Emory University — Granular flows are still somewhat poorly understood. One such case is the flow of 2D disks through a hopper. In a prior experiment by To (K. To, et al. PRL 86(1) 2001), they found that as 2D disks flow through a hopper they may jam due to arch formations at the hopper exit, and that the jamming probability can be increased by enhancing the static friction between the disks. In our study we remove the effects of static friction by using quasi-2D oil in water emulsion droplets flowing through a hopper to understand the role of friction in jamming. The droplets feel a viscous friction, but no static friction. Similar to the granular experiment, our oil droplets flow due to gravity. We have observed the transition between jammed and unjammed flows in our setup, and we are currently investigating its nature as the hopper size changes. In our experiments, jamming seems to occur only for very small hopper openings, and arches are always unstable.

12:51PM Z13.00009 Water Retention of Mixed Hydrogel Particles and Sandy Soil , YULI WEI, DOUGLAS DURIAN, University of Pennsylvania — We study the water-holding capacity of mixed hydrogel particles and a model sandy soil. To probe static behavior, we develop a custom pressure plate method that measures the expelled water per unit pressure increment per unit cross-sectional area; results are analyzed in terms of the water-accessible pore areas in the granular packing. To probe dynamic behavior, we build a raindrop impingement set-up that measures the retained water inside a dry granular packing during steady rain at a fixed rate. The percentage saturation of the granular packing is deduced. In both studies, we first determine the influence of the packing height and then of the gel concentration and size. Results from pressure plate method show that the swollen hydrogel particles partially clog the pores in the sandy soil, so that less water could be expelled for a given pressure increment. The total water-accessible area determined from the expelled water curve decreases exponentially as the gel concentration increases. Large hydrogel particles are less efficient in clogging the pores when no extra confinement is applied on the packing. Results from the raindrop impingement measurements also show that the water-holding capacity of sandy soil is improved by addition of hydrogel particles.

1:03PM Z13.00010 Granular "electrophoresis": in situ measurement of charge and size of freely-falling grains , SCOTT WAITUKAITIS, The University of Chicago, GUSTAVO CASTILLO, Universidad de Chile, SEBASTIAN GONZALEZ, University of Twente, HEINRICH JAEGER, The University of Chicago — We present measurements of tribocharged, chemically identical grains falling from a hopper. Tribocharging is the transfer of electrical charge between contacting surfaces. Granular interactions are governed by contacts, and not-surprisingly tribocharging can have important effects on bulk granular behavior. What is surprising is that this occurs even in grains of the same material. Typically same chemistry tribocharging (SCT) correlates with the particle size distribution: larger particles charge positively and smaller particles negatively. However, the detailed mechanism of SCT remains elusive. We have developed an experimental technique to make *in situ* measurements of the particle size and charge on small ($\sim$100-500 μm) grains. With high speed videography of freely-falling grains we resolve particle sizes down to a few microns, charges as small as a few thousand electrons, and forces as small as a few picoNewtons. Our results confirm the qualitative charge segregation observed in previous SCT experiments and provide quantitative measurement for theoretical comparison.

1:15PM Z13.00011 Strain-stiffening in random packings of granular chains , HEINRICH JAEGER, ALICE NASTO, DYLAN MURPHY, ERIC BROWN, University of Chicago — We report on triaxial compression experiments performed to characterize the mechanical response of random packings of granular particles. For a wide variety of particle shapes, the packings yield when the shear stress exceeds a value on the order of the confining pressure. In contrast, granular chains consisting of flexibly connected beads exhibit strain stiffening (i.e., the effective modulus increases with strain), sustain stresses far beyond the confining pressure, and do not yield until the chains break. The critical chain length required for significant strain-stiffening to occur corresponds to the minimum circumference of closed loops the chains are able to form during the formation of the packings. This strain-stiffening behavior is similar to that found in polymer materials, and chain packings therefore may serve as a model system to quantify the contribution of pure entanglement effects to the strength of polymer materials in the absence of Brownian motion.

1:27PM Z13.00012 Anisotropic diffusion of vibrated semi-flexible granular rods , VIKRANT YADAV, ARSHAD KUDROLLI, Clark University — We discuss the diffusive dynamics of semi-flexible granular rods as a function of their concentration in a vertically vibrated container. These rods are composed of short beaded chains and are tracked with a camera, and their trajectories used to analyze the rotational and translational displacement as a function of area fraction ϕ. We observe that the diffusion in the parallel and perpendicular direction in the body frame of reference deviate from those calculated for thermally excited elastic polymer rods. In particular we find that the diffusion perpendicular to the major axis in dilute regime is observed to be greater than that in the parallel direction due to rotation about the major axis of the rod. The motion is observed to become sub-linear above $\phi = 0.48$ and 0.54 in the perpendicular and parallel directions, respectively, both lower than for spherical particles. Rotational diffusion is also investigated and found to deviate systematically from exponential decays with increase in ϕ.

1:39PM Z13.00013 Vibrofluidized melting of geometrically cohesive granular media , NICK GRAVISH, GEOFFREY RUSSELL, Georgia Tech, SCOTT V. FRANKLIN, Rochester Institute of Technology, DAVID HU, DANIEL I. GOLDMAN, Georgia Tech — Dry granular media composed of particles of special shapes (e.g. long rods or c-shaped particles) can display cohesive effects through particle geometry alone. We study the solid to gas transition in piles of c-shaped particles under vertical vibration as we vary acceleration and frequency. A cylindrical solid of particles is formed with wall angles near 90° and is placed on a solid surface. For fixed frequency as acceleration increases, the pile undergoes two transitions. The first is from the solid-like state to a liquid-like state in which the wall angles relax but the mobile particles remain spatially localized. The second is from the liquid-like state to the gaseous state in which particles become separated (not entangled). Using video and accelerometer measurements, we record the temporal evolution of the spatial density and pile-plate collisional impulse. A critical energy scale, set by the particle geometry and gravitational potential energy, governs the liquid-gas transition.

1:51PM Z13.00014 Switchable capillary bridges in sphere packings , CHRISTOPH GÖGELEIN, MARTIN BRINKMANN, MATTHIAS SCHRÖTER, STEPHAN HERMINGHAUS, Max-Planck-Institute for Dynamics and Self-Organization — If one adds a small amount of water to a heap of sand, it becomes paste-like since the grains get interconnected by capillary bridges. Due to this effect, we can easily sculpture wet sand (e.g., building a sand castle), whereas a heap of dry grains ripples away and cannot sustain any shape. In the present work, we use a non-Brownian suspension of glass spheres immersed in a binary liquid mixture. The suspending water-lutidine mixture exhibits a well studied lower critical point slightly above ambient temperature. Hence, the mixture starts to phase separate upon heating. Since the water-rich phase wets the hydrophilic glass spheres, capillary bridges are formed between adjacent particles. If the system is cooled below the demixing temperature, the bridges disappear within a few seconds by intermolecular diffusion. Thus, this systems offers the opportunity to switch the capillary bridges on and off by altering the temperature. In this presentation, we will show the temperature-induced formation of capillary bridges using confocal and bright light microscopy [1]. Furthermore, we will discuss the effect of capillary bridges on random sphere packings using a fluidized bed setup.

2:03PM Z13.00015 Stable Solitary Waves in Granular Alignments[1] , YOICHI TAKATO, SURAJIT SEN, SUNY Buffalo — We study the propagation of an impulse in a loaded chain of elastic spheres where the spheres are held between fixed walls. We show that for a certain critical loading, propagating impulses develop into solitary waves and these solitary waves are not measurably affected by wall collisions, the latter being typically the case with granular solitary waves. The properties of these special solitary waves and of possible connections between this problem and the Fermi-Pasta-Ulam problem will be addressed.

11:15AM Z14.00001 Frequency of Relevant Nodes with Different Function Classes in Critical Boolean Networks[1] , SHABNAM HOSSEIN, MATTHEW REICHL, KEVIN E. BASSLER, University of Houston — Boolean networks have two phases of dynamical behavior, fixed and chaotic, depending on the update functions of the nodes. Boolean functions can be categorized by their symmetry properties, which are related to their canalization properties. Canalization is a type of network robustness, which was first introduced to explain the stability of phenotype expression of biological systems. For networks with 3 inputs per node, the 256 possible Boolean functions can be divided into 14 classes that correspond to the group orbits of rotation plus parity. For critical networks at the boundary of the fixed and chaotic phases, we analytically derive the frequency of the different types of Boolean functions among the relevant nodes that control the dynamics. By setting up a set of differential equations that determines the relevant nodes through a pruning process, we can find the average number of nodes in each of the classes. Then, considering the effects of fluctuations, the probability distribution of the number of relevant nodes is accurately derived. We find that in critical networks the frequency of relevant nodes is inversely correlated with canalization.

11:27AM Z14.00002 Two-Component Diffusion[1] , ANNA STEPHENSON, JAYANTA RUDRA, Oklahoma School of Science and Mathematics — When two diffusing components propagate through the same material, the space that is occupied by one component may not be occupied by the other. This interaction, which is purely geometrical and non-chemical in nature, plays an important role in the dynamics of two-component flow. It redefines the diffusing space for each of them and each component sees its surrounding space being constrained by the other. We use a novel approach to describe the diffusion of two components through a discrete lattice of a narrow channel. Specially, we look at the influence of a fast component on a slow one and vice versa. We express the time evolution of the joint probability distribution of two diffusing components in terms of a modified Master equation such that both of these may not occupy the same lattice site at the same time. From this restricted time evolution of the joint probability distribution we then calculate relative flow rate of the component and infer whether such a channel could be used as a molecular sieve to separate a slow component from a fast one.

11:39AM Z14.00003 Backbones and borders from shortest-path trees , DANIEL GRADY, CHRISTIAN THIEMANN, DIRK BROCKMANN, Northwestern University — One of the most important tasks in complex network research is to distinguish between vertices and edges that are topologically essential and those that are not. To this end, a variety of vertex and edge centrality measures have been introduced, ranging from measuring local properties (degree, strength) to quantities that depend on the global structure of the graph (betweenness). Here we introduce a novel technique based on the family of shortest-path trees, which is applicable to strongly heterogeneous networks. This approach can identify significant edges in the network, distinct from conventional edge betweenness, and these edges make up a network backbone relevant to dynamical processes that evolve on such networks. We will show that important network structures can be extracted by investigating the similarity and differences of shortest-path trees and show that tree dissimilarity in combination with hierarchical clustering can identify communities in heterogeneous networks more successfully than ordinary reciprocal-weight distance measures. We demonstrate the success of this technique on complex multi-scale mobility networks.

11:51AM Z14.00004 Interactive Network Exploration using Shortest-Path-Tree Tomography , CHRISTIAN THIEMANN, DIRK BROCKMANN, Northwestern University — The shortest-path tree of a node contains information on the whole network as observed from a specific node, thus combining local and global information in a two- dimensionally embeddable sub-network. We developed new visualization software that reduces a complex network to its nodes' shortest-path trees and allows for interactive exploration of this network in a structured way. In this talk I will present various example networks and also briefly talk about off-spring projects that have been sparked by looking at networks in this way, including a simplified view on disease spreading on networks.

12:03PM Z14.00005 Searching for the extreme values of the mutual information between two interacting subsystems , ILYA GRIGORENKO, VINCENT CRESPI, Penn State University — We have considered two interacting subsystems represented by classical spins with a long-range interaction immersed in a thermal reservoir. We searched for maxima and minima of the mutual information between the subsystems by tuning the interaction parameters within only one subsystem: the parameters of the second subsystem - which can be thought of as an environment for the first one - and the interaction parameters between the first subsystem and the environment remain unchanged. We have identified the conditions leading to maximisation and minimisation of the mutual information between the subsystems, and their relation to a degeneracy of the energy spectrum that is spontaneously engineered by the optimisation procedure. We interpret the spatially inhomogeneous structure of the optimised subsystem in terms of information heterogeneity.

12:15PM Z14.00006 Synchronization Dynamics of Coupled Anharmonic Plasma Oscillators , JOHN LAOYE, Department of Physics, Olabisi Onabanjo University, PMB 2002, Ago-Iwoye, Nigeria, UCHECHUKWU VINCENT, Department of Physics, Lancaster University, Lancaster LA1 4YB, United Kingdom, TAIWO ROY-LAYINDE, Department of Physics, University of Ibadan, Ibadan Nigeria — The synchronization of two identical mutually driven coupled plasma oscillators modeled by anharmonic oscillators was investigated. Each plasma oscillator was described by a nonlinear differential equation of the form: $\ddot{x} + \epsilon(1 + x^2)\dot{x} + x + \kappa x^2 + \delta x^3 = F \cdot \cos(\omega t)$. The model employed the spring-type coupling. Numerical simulations, including Poincaré sections, time series analysis, and bifurcation diagram were performed using the fourth-order Runge-Kutta scheme. The numerical value of the threshold coupling K_{th} was determined to be approximately 0.15.

12:27PM Z14.00007 Visual analytics for discovering node groups in complex networks[1] , TAKASHI NISHIKAWA, Clarkson University — Given the abundance of relational data from a variety of sources, it is becoming increasingly more important to be able to discover hidden structures in the topology of real-world complex networks. In this talk, I will extend the usual definition of groups as densely connected sets of nodes and show that many real networks have groups distinguished by a diverse combinations of node properties, but not by the density of links alone. To overcome the virtually unlimited ways to potentially distinguish groups, we have developed an **exploratory** analysis tool that exploit human visual ability. In this visual analytical approach, the user input from **visual interaction** is integrated into the analysis to discover unknown group structures, rather than simply detecting a known type of structure. I will also address the problem of determining an appropriate number of groups, when it is not known *a priori*. I will demonstrate that our method can effectively find and characterize a variety of group structures in model and real-world networks, including community and k-partite structures defined by link density, as well as groups distinguished by combinations of other node properties.

[1]Funded by FODAVA NSF-DMS-0808860

1:03PM Z14.00008 A Network Approach to Rare Disease Modeling , SUSAN GHIASSIAN, SABRINA RABELLO, AMITABH SHARMA, CCNR Northeastern University, OLAF WIEST, University of Notre Dame, ALBERT-LASZLO BARABASI, CCNR Northeastern University — Network approaches have been widely used to better understand different areas of natural and social sciences. Network Science had a particularly great impact on the study of biological systems. In this project, using biological networks, candidate drugs as a potential treatment of rare diseases were identified. Developing new drugs for more than 2000 rare diseases (as defined by ORPHANET) is too expensive and beyond expectation. Disease proteins do not function in isolation but in cooperation with other interacting proteins. Research on FDA approved drugs have shown that most of the drugs do not target the disease protein but a protein which is 2 or 3 steps away from the disease protein in the Protein-Protein Interaction (PPI) network. We identified the already known drug targets in the disease gene's PPI subnetwork (up to the 3rd neighborhood) and among them those in the same sub cellular compartment and higher coexpression coefficient with the disease gene are expected to be stronger candidates. Out of 2177 rare diseases, 1092 were found not to have any drug target. Using the above method, we have found the strongest candidates among the rest in order to further experimental validations.

1:15PM Z14.00009 Flavor network and the principles of food pairing , YONG-YEOL AHN, Northeastern University, SEBASTIAN AHNERT, Cambridge University, JAMES BAGROW, ALBERT-LASZLO BARABASI, Northeastern University — We construct and investigate a flavor network capturing the chemical similarity between the culinary ingredients. We found that Western cuisines have a statistically significant tendency to use ingredient pairs that share many flavor compounds, in line with the food pairing hypothesis used by some chefs and molecular gastronmists. By contrast, East Asian cuisine tend to avoid compound sharing ingredients. We identify key ingredients in each cuisine that help us to explore the differences and similarities between regional cuisines.

1:27PM Z14.00010 Relationship between structural and functional networks in complex systems with delay , TONI PEREZ, Lehigh University, VICTOR EGUILUZ, IFISC, JAVIER BORGE-HOLTHOEFER, ALEX ARENAS, Universitat Rovira i Virgili — Functional networks of complex systems are usually obtained from the analysis of the temporal activity of their components, and are often used to infer their unknown underlying connectivity. Here we investigate on this challenge from a fundamental physical perspective, analyzing the functional network resulting from the simplest dynamical system with delay presenting a synchronous dynamics on a given topology. We have found the conditions for the emergence of locked dynamical states and the equations relating topology and function in a system of diffusively delay-coupled elements in complex networks. We solve exactly the resulting equations in motifs (directed structures of three nodes), and in directed networks. The mean-field solution for directed uncorrelated networks shows that the clusterization of the activity is dominated by the in-degree of the nodes, and that the locking frequency decreases with increasing average degree. We find that the exponent of a power law degree distribution of the structural topology, γ, is related to the exponent of the associated functional network as $\alpha = (2 - \gamma)^{-1}$, for $\gamma < 2$.

1:39PM Z14.00011 Why hubs may not be the most efficient spreaders , LAZAROS GALLOS, City College of New York, MAKSIM KITSAK, CAIDA, University of California-San Diego, SHLOMO HAVLIN, Bar-Ilan University, FREDRIK LILJEROS, Stockholm University, LEV MUCHNIK, New York University, H.E. STANLEY, Boston University, HERNAN MAKSE, City College of New York — The origin of a spreading process in a complex network can drastically influence the extent of the area that spreading can reach. In principle, the network hubs should be the most efficient spreaders. Here, we find that, in contrast to common belief, there are plausible circumstances where the best spreaders do not correspond to the best connected nodes or to the most central nodes (high betweenness centrality). Using the SIR model we find that: *(i)* The most efficient spreaders are those located within the core of the network as identified by the k-shell decomposition analysis. *(ii)* When multiple spreaders are considered simultaneously, the distance between them becomes the crucial parameter that determines the extent of the spreading. Similarly, we find that, in the SIS model, infections persist in the high k-shells of the network. Our analysis provides a plausible route for an optimal design of efficient dissemination strategies.

1:51PM Z14.00012 Finite size scaling theory for discontinuous percolation transitions , B. KAHNG, Y.S. CHO, Seoul National University, S.W. KIM, J.D. NOH, University of Seoul, D. KIM, KIAS — Finite-size scaling (FSS) theory has been useful for characterizing phase transitions. When the phase transition is continuous, the critical behavior of a system in the thermodynamic limit can be extracted from the size-dependent behaviors of thermodynamic quantities. However, FSS approach for discontinuous transitions arising in disordered systems has not been studied yet. Here, we develop a FSS theory for the discontinuous PT in the modified Erdös-Rényi model under the Achlioptas process. A scaling function is derived based on the observed fact that the derivative of the curve of the order parameter at the critical point t_c diverges with system size in a power-law manner, which is different from that for continuous percolation transitions. Numerical simulation data for different system sizes are well collapsed onto a scaling function.

2:03PM Z14.00013 Monte Carlo Simulations of Metastable Decay in the Ising Model on the Hyperbolic Plane[1] , HOWARD L. RICHARDS, Physics, Marshall University, MALLORY A. PRICE, Math, Marshall University, JULIE E. LANG, Physics, Morehead State University — Consider a regular network of Ising spins with short-ranged, ferromagnetic interactions and a weak, negative magnetic field. The system evolves under single-spin-flip Metropolis dynamics from an initial state of all spins "up" ($s_i = +1, \forall i$). For Euclidean networks in less than 6 dimensions, decay from the "metastable" state occurs in a finite time (measured in Monte Carlo steps per spin) through the nucleation and growth of one or more finite critical droplets. For networks on the hyperbolic plane, however, we show that the size of a critical droplet diverges at a nonzero magnetic field – the spinodal field. We then use Monte Carlo simulations on the $\{5, 4\}$ grid to demonstrate the divergence of the lifetime of the metastable state at nonzero spinodal fields.

Friday, March 25, 2011 11:15AM - 1:27PM –
Session Z22 DCMP: Properties of Semiconducting Nanosystems D163

11:15AM Z22.00001 ABSTRACT WITHDRAWN –

11:27AM Z22.00002 Conductivity of Thin Film Structures Fabricated by E-Beam Lithography from Gold Nanoparticle Resists[1] , STEFAN DICKERT, MYOUNG-HWAN PARK, COLIN JERMAIN, VINCENT M. ROTELLO, MARK T. TUOMINEN, University of Massachusetts Amherst — Drop- and spin-coated solutions of ligand coated nanoparticles act as a novel "direct write" e-beam resist, which can be prepared with metallic, magnetic and semiconducting nanoparticles (Y.Ofir. et. al, Adv. Mater. 20, 2561-2566 (2008)). We prepared thin films from gold nanoparticles in which we varied the ligand length, ligand type and the film thickness. Small angle X-Ray scattering experiments as well as SEM imaging of the samples were performed to determine structural properties of the nanoparticle films at various stages of the fabrication process, after drop coating, ebeam exposure and annealing. We further performed resistance measurements in the 2-350K temperature range and report different conductivity mechanisms based on the ligand type and film thickness, ranging from insulating to Mott hopping conduction to metallic. We observed different results for Thioalkylated trimethyl ammonium (TMA) and thioalkyl tetra (ethylene glycol)ated trimethyl ammonium (TTMA) ligands.

11:39AM Z22.00003 Terahertz Ionization of Highly Charged InGaAs Quantum Posts , CHRISTOPHER MORRIS, DOMINIK STEHR, TUAN-ANH TRUONG, HYOCHUL KIM, PIERRE PETROFF, MARK SHERWIN, University of California Santa Barbara, CRAIG PRYOR, University of Iowa — Quantum posts (QPs) are quantum dot based nanostructures grown by MBE. They form short $In_{.4}Ga_{.6}As$ cylinders embedded in an $In_{.1}Ga_{.9}As$ quantum well (QW). Terahertz absorption measurements are performed on 30 nm high QPs with ∼6 electrons per post and a charge density of $\sim 2.4 \times 10^{11}/cm^2$ in the surrounding well. Comparison of spectra from QP and reference QW samples shows an absorption feature due to the QPs absent in the QW sample. Temperature dependent measurements show this absorption is due to electrons in the QPs. 8 band k.p calculations of post and well energies are performed as a function of the number of electrons in the posts, and the absorption is determined to be due to an "ionizing" transition from the posts to the well. The highest filled QP state absorbs a terahertz photon, transitioning to a weakly bound unfilled post state ∼20 meV higher. From there, the electron quickly scatters into the two dimensional electron gas in the quantum well matrix. Coulomb repulsion from QP electrons locally depopulates the quantum well states, leaving open states for the QP electrons. QPs represent a promising structure for investigation of Coulomb blockade physics and ionizing transitions in artificial atom systems.

11:51AM Z22.00004 The dipole moments of ZnO nanorods , SEFA DAG, SHUZHI WANG, LIN-WANG WANG, Lawrence Berkeley National Laboratory — A self-consistent linear scaling three dimensional fragment (LS3DF) method is used to study the dielectric properties of large ZnO nanorods. Our ab initio calculations show that the ZnO nanorod with unpassivated (10-10) side surface has a large dipole moment which is caused by both surface and interior bulk dipoles. An systematic analysis is carried out, and we found that the biggest contribution to the total dipole moment is from the (10-10) surface. Dielectric screening model is used to illustrate how the dipole moment changes with nanostructure size and geometry. We also show the effect of the dipole moment on the interior electronic structure of the nanorod.

12:03PM Z22.00005 Natural interface states in coherent and isovalent III-V heterostructures[1] , VOICU POPESCU[2], National Renewable Energy Laboratory, Golden, CO, ALEX ZUNGER, National Renewable Energy Laboratory — Interface states occur in semiconductor heterojunctions whenever a significant perturbation is present, caused by interface defects, lattice mismatch, discontinuities in the effective mass or sharp variations in the potential across the interface. We discuss the natural interface states appearing in perfectly coherent and isovalent III-V heterojunctions when a Γ-well and an X-anti-well coexist in the conduction band. We use empirical pseudopotential calculation to illustrate this type of states for a few III-V heterostructures. For InP/GaP the interface localised states lie energetically in the band-gap and possess, because of their mixed $\Gamma - X$ character, a strong optical signature. This allows us to provide a different interpretation of the photoemission data existent in the literature for InP/GaP quantum wells and dots. We further discuss the presence of the interface localised states in other III-V heterojunctions, investigating the conditions under which they might be experimentally observed.

12:15PM Z22.00006 Electronic Phase Diagram of Single-Element Silicon "Strain" Superlattices[1] , ZHENG LIU, University of Utah, WENHUI DUAN, JIAN WU, Tsinghua University, MAX LAGALLY, University of Wisconsin-Madison, FENG LIU, University of Utah — The evidence that the band gap of Si changes significantly with strain suggests that by alternating regions of strained and unstrained Si one creates a single-element electronic heterojunction superlattice (SL), with the carrier confinement defined by strain rather than by the chemical differences in conventional compositional SLs. Using first-principles calculations, we map out the electronic phase diagram of a one- dimensional pure-silicon SL. It exhibits a high level of phase tunability, e.g., tuning from type I to type II. Our theory rationalizes a recent observation of a strain SL in a Si nanowire and provides general guidance for the fabrication of single-element strain SLs.

[1]This work is supported by DOE-BES (Grants No. DEFG02-03E46027 and No. 46028). We thank DOE-NERSC for providing the computing resources. M.G. L. acknowledges facilities support from UW NSF/MRSEC.

12:27PM Z22.00007 Quantum Boundary Effect in Nanomaterials: Undo the Quantum Size Effect by Surface Passivation of Silicon Nanofilms , YIYANG SUN, XIN LIU, SHENGBAI ZHANG, Rensselaer Polytechnic Institute — It is well known that when the size of a semiconductor is reduced, its band gap will increase due to the increased kinetic energy of the electrons and holes. However, first-principles calculations reveal that there should also be a quantum boundary effect (QBE), which can drastically change the band gap to the extent that the quantum size effect (QSE) is completely erased. It is found that, for Si(001) nanofilms, surface passivations could show such a strong QBE. While the films are passivated by hydrogen, they show a clear QSE with significant increase in band gap. When some of the hydrogen atoms are replaced by =NH ligands, however, the band gap recovers to that of bulk silicon even for film size as small as two nanometers. The concept of zero confinement state for semiconductors will be introduced. It elucidates why it is possible to remove the seemingly universal QSE. The finding here could be highly desirable for certain applications of nanostructured semiconductors where gap increasing due to QSE is detrimental.

12:39PM Z22.00008 Excitation energy dependence of the exciton inner ring , YULIYA KUZNETSOVA, JASON LEONARD, LEONID BUTOV, University of California at San Diego, JOE WILKES, ALEX IVANOV, Cardiff University, ARTHUR GOSSARD, University of California at Santa Barbara — We report on the excitation energy dependence of the inner ring in the emission pattern of indirect excitons. The contrast of the inner ring is found to increase with excitation energy until it reaches the direct exciton plus LO phonon energy and saturate at higher excitation energies. The data show that excitation by low-energy laser light tuned to the direct exciton resonance can effectively suppress the laser-induced heating of the exciton gas. The observed dependence is explained in terms of exciton transport and cooling.

12:51PM Z22.00009 Dynamic coherent exciton condensates in a semiconductor planar microcavity[1] , CHIH-WEI LAI, KYAW ZIN LATT, Michigan State University, YI-SHAN LI, SHENG-DI LIN, National Chiao Tung University — We observed a coherent exciton state with a long decay time $\sim$1000 ps in a semiconductor planar microcavity structure. The lifetime of cavity polariton condensates previously reported has been limited to $\sim$10 ps. The sample consists of InGaAs quantum wells positioned near anti-nodes of the photon field in a GaAs λ-cavity sandwiched by GaAs/AlAs-based Bragg mirrors. Under a pulsed excitation above the stop-band of the Bragg mirrors (excess energy $>$150 meV), spatially coherent exciton emissions were observed to last for $\sim$1 ns. Conventional dynamic exciton-polariton condensates with a $\sim$10 ps lifetime were observed under a near-resonant (excess energy $\sim$ 6 meV) ps pulsed excitation. Dynamics of spatial coherence, energy relaxation, and spin polarization were characterized by time-resolved spectroscopies, including double-slit and polarimetry experiments. The fluctuation of excitonic emissions was characterized by a photon-correlation measurement. The existence of such a long-lived coherent exciton state is attributed to formation of dark excitons under an excitation with significant excessive energy.

1:03PM Z22.00010 Amplitude oscillations in a non-equilibrium polariton condensate , RICHARD BRIERLEY, PETER LITTLEWOOD, University of Cambridge, PAUL EASTHAM, Trinity College Dublin — Like cold atomic gases, semiconductor nanostructures provide new opportunities for exploring non-equilibrium quantum dynamics. In semiconductor microcavities the strong coupling between trapped photons and excitons produces new quasiparticles, polaritons, which can undergo Bose-Einstein condensation. Quantum quenches can be realised by rapidly creating cold exciton populations with a laser [Eastham and Phillips, PRB 79 165303 (2009)]. The mean field theory of non-equilibrium polariton condensates predicts oscillations in the condensate amplitude due to the excitation of a Higgs mode. These oscillations are the analogs of those predicted in quenched cold atomic gases and may occur in the polariton system after performing a quench or by direct excitation of the amplitude mode. We have studied the stability of these oscillations beyond mean field theory. We show that homogeneous amplitude oscillations are unstable to decay into lower energy phase modes at finite wavevectors, suggesting the onset of chaotic behaviour. The resulting hierarchy of decay processes can be understood by analogy to optical parametric oscillators in microcavities. Polariton systems thus provide an interesting opportunity to study the dynamics of Higgs-like modes in a solid state system.

1:15PM Z22.00011 Coherence dynamics of a long-lived excitonic condensate in an optical microcavity[1] , KYAW ZIN LATT, Michigan State University, YI-SHAN LI, SHENG-DI LIN, National Chiao Tung University, CHIH-WEI LAI, Michigan State University — We report dynamics of long-range spatial coherence of an excitonic condensate with a $\sim$1000 ps life-time in a planar Fabry-Perot microcavity. The sample consists of three sets of three InGaAs(8nm)/GaAs (14nm) quantum wells positioned near anti-nodes of the photon field in a GaAs λ-cavity sandwiched by two GaAs/AlAs-based Bragg mirrors. Conventional dynamic exciton-polariton condensates with a $\sim$10 ps lifetime were observed under a near-resonant (excess energy $\sim$ 6 meV) ps pulsed excitation at a 50 degree incident angle. Under an excitation above the stop-band of the Bragg mirrors (excess energy $\sim$170 meV), an excitonic state with 100-μeV luminescence linewidth was observed to last for $\sim$1 ns. Coherence dynamics were characterized by time-resolved double-slit experiment in a confocal geometry with a ps streak camera system as a function of excitation intensity (fluence) and temperature. The visibility of interference fringes reached above 0.3 within 40 ps and remained above 0.1 up to $\sim$1ns for a double-slit-distance of 12 μm.

Friday, March 25, 2011 11:15AM - 1:27PM –
Session Z23 DCMP: Superconductivity: Thermodynamics, etc. D165

11:15AM Z23.00001 Evolution of ground state and upper critical field in $R_{1-x}Gd_xNi_2B_2C$ (R = Lu, Y): Coexistence of superconductivity and spin-glass state[1] , S.L. BUD'KO, V.G. KOGAN, H. HODOVANETS, S. RAN, S.A. MOSER, M.J. LAMPE, P.C. CANFIELD, Ames Laboratory and Dept. of Physics and Astronomy, Iowa State University — We report effects of local magnetic moment, Gd^{3+}, doping ($x \leq 0.3$) on superconducting and magnetic properties of the closely related $Lu_{1-x}Gd_xNi_2B_2C$ and $Y_{1-x}Gd_xNi_2B_2C$ series. The superconducting transition temperature decreases and the heat capacity jump associated with it drops rapidly with Gd-doping; qualitative changes with doping are also observed in the temperature-dependent upper critical field behavior, and a region of coexistence of superconductivity and spin-glass state is delineated on the $x - T$ phase diagram. The evolution of superconducting properties can be understood within the Abrikosov-Gor'kov theory of magnetic impurities in superconductors taking into account the paramagnetic effect on upper critical field and the details of the $x - T$ phase diagrams.

[1]Supported by the US DOE - BES under Contract No. DE-AC02-07CH11358.

11:27AM Z23.00002 Micro-Calorimeter for Heat Capacity Studies of Sub-Microgram Superconducting Crystals[1] , CARLOS CHAPARRO, U. WELP, L. FANG, W.K. KWOK, Argonne National Laboratory, Argonne, IL 60439, USA, M. ESKILDSEN, Department of Physics, University of Notre Dame, Notre Dame, IN 46556, USA — A steady-state ac-temperature micro-calorimeter for heat capacity measurement of sub-microgram superconducting samples is presented. It utilizes thermocouple thermometers nano-patterned onto 150 nm thick Si_3N_4 membranes. Theoretical models, mathematical relations describing the operation of the calorimeter and calibration procedures are discussed. The system achieves a resolution of 10^{-4}; and allows for measurements from 5 K to room temperature. The calorimeter can be continuously rotated in a split-coil magnet generating up to 8 T. To demonstrate the performance of our device we present measurements of the specific heat of single crystals of $SmFeAsO_{0.85}F_{0.15}$ (120 μm wide and 10 μm thick, crystal w1) and of $BaFe_2(As_{1-x}P_x)_2$ (150 μm wide and 30 μm thick).

[1]This work was supported by DOE-BES under Contact No. DE-AC02-06CH11357.

11:39AM Z23.00003 Search for quantum critical behavior in the specific heat of HTS cuprates[1] , JEFFERY TALLON, MacDiarmid Institute, Industrial Research Ltd, FELIX BARBER, Industrial Research Ltd, JOHN COOPER, JOHN LORAM, Cavendish Lab., Cambridge University — Much evidence has been accumulated suggesting the presence of a quantum critical point in the lightly overdoped regime for high-T_c superconductors, around p=0.19 holes per Cu. It is however not decisive. In the neighborhood of a quantum critical point the normal-state electronic specific heat should contain a $T\ln(T)$ term. While this would be concealed by the onset of superconductivity it is in principle recoverable using the entropy balance that exists in a second-order phase transition. This paper reviews the data for $Y_{0.8}Ca_{0.2}Ba_2Cu_3O_{7-d}$ and $Bi_2Sr_2CaCu_2O_{8+d}$ and places limits on the magnitude and doping evolution of a $T\ln(T)$ term in the specific heat across the phase diagram.

[1]Work supported by the Marsden Fund of New Zealand.

11:51AM Z23.00004 Thermodynamic effects in superconducting hybrid devices , LAETITIA PASCAL, SUKUMAR RAJAURIA, HUNG NGUYEN, BERNARD PANNETIER, Neel Institute, CNRS, Grenoble, France, FRANK HEKKING, LPMMC, Grenoble, France, HERVE COURTOIS, Neel Institute, CNRS, Grenoble, France — Investigating thermal transport in hybrid superconducting nanostructures can yield a better understanding of such devices and give access to new and useful phenomena. Sub-gap biased superconducting-insulator-normal metal (SIN) junctions exhibit electron cooling, which is useful for achieving electronic temperatures below the cryostat bath temperature. We have designed an experiment to allow independent monitoring of the electron and phonon populations temperatures. An electronic cooler was studied under out-of-equilibrium conditions, in both cooling and heating regimes. The results are interpreted using a thermal model, which takes into account the electron, phonon and photon heat transfer. The Kapitza and electron-phonon couplings, along with a generalized circuit theory approach for the photon heat transfer, will be discussed.

12:03PM Z23.00005 Caloric determination of the anisotropic phase diagram of $BaFe_2(As_{1-x}P_x)_2$ crystals[1] , WAI-KWONG KWOK, ULRICH WELP, CARLOS CHAPARRO, LEI FANG, ALEXEI KOSHELEV, Argonne National Laboratory — We report specific heat measurements on a series of $BaFe_2(As_{1-x}P_x)_2$ single crystals with phosphorous contents ranging from optimal doping (x$\sim$0.3, T_c = 29.5 K) to highly overdoped (x$\sim$0.6, T_c = 11K). We find a sharp superconducting transition at T_c for all doping levels, a suppression of the ΔC-step at $T_c$with increasing doping and enhanced magnetic field dependence at higher doping. The phase diagrams determined from specific heat data show a decrease of dH_{c2}/dT with increasing doping and a nearly constant superconducting anisotropy of $\Gamma \sim$2.5. Our results will be compared with the proposed "universal" scaling of $\Delta C_p/T_c$ and dH_{c2}/dT due to quantum criticality and non Fermi liquid behavior [1] and due to strong pair-breaking and non-magnetic interband scattering [2], respectively.

12:15PM Z23.00006 Growth of thin superconducting films and heterostructures by atomic layer deposition , JEFFREY KLUG, THOMAS PROSLIER, NICHOLAS BECKER, JEFFREY ELAM, JAMES NOREM, Argonne National Laboratory, JOHN ZASADZINSKI, Illinois Institute of Technology, MICHAEL PELLIN, Argonne National Laboratory — We report the use of atomic layer deposition (ALD) to synthesize thin superconducting films and superconductor-insulator (S-I) heterostructures. ALD uses sequential self-saturating surface chemical reactions to produce uniform coatings with atomic scale control on substrates with arbitrary shape. The ALD process therefore offers the possibility of conformally coating complex shapes with precise, layered structures with tightly constrained morphology and chemical properties. Among other applications, such coatings may enable the production of superconducting radio frequency (SRF) structures with significantly better performance and yield than those obtained from bulk niobium. Furthermore, the atomic-scale thickness control afforded by ALD enables the study of superconductivity and associated phenomena in homogeneous layers in the ultra-thin film limit. In this respect, we will present results of ALD-grown $Nb_{1-x}Ti_xN$-based films and S-I heterostructures. Our program looks both at the metallurgy and superconducting properties of these coatings, and also their performance in working SRF structures.

12:27PM Z23.00007 Laser Processing on the Surface of Niobium Superconducting Radio-Frequency Accelerator Cavities , SENTHILRAJA SINGARAVELU, Old Dominion University, MICHAEL KLOPF, GEOFFREY KRAFFT, Jefferson Laboratory, MICHAEL KELLEY, College of William and Mary — Superconducting Radio frequency (SRF) niobium cavities are at the heart of an increasing number of particle accelerators. Their performance is dominated by a several nm thick layer at the interior surface. Maximizing its smoothness is found to be critical and aggressive chemical treatments are employed to this end. We describe laser-induced surface melting as an alternative "greener" approach. Modeling guided selection of parameters for irradiation with a Q-switched Nd:YAG laser. The resulting topography was examined by SEM, AFM and Stylus Profilometry.

12:39PM Z23.00008 Charge order phase diagrams of hole-doped cuprates , ROBERT MARKIEWICZ, Northeastern University, JOSE LORENZANA, U Rome, La Sapienza, GOETZ SEIBOLD, U. Cottbus, ARUN BANSIL, Northeastern University — "Stripe"-like phases in the cuprates can be dominated by either spin or charge fluctuations. We calculate the phase diagram of charge-order phases stabilized by a lattice distortion using Gutzwiller approximation (GA) + RPA, and compare it to the magnetic phase diagrams [1]. The stripe periodicity is determined by Fermi surface [double] nesting, and hence is very similar for charge or magnetic stripes. A detailed analysis of the susceptibility reveals that the leading charge instability in Bi2201 and Bi2212 is an electronically driven phonon soft mode associated with a "Pomeranchuk wave." This instability has the pseudogap doping dependence and shares many properties with the phase seen in scanning tunneling microscopy (STM) Work supported in part by the USDOE and by a Marie Curie Grant.

12:51PM Z23.00009 Using Disorder to Detect Locally Ordered Electron Nematics via Hysteresis , ERICA CARLSON, Purdue University, KARIN DAHMEN, University of Illinois at Urbana Champaign — The interplay between charge, orbital, and lattice degrees of freedom in correlated electron systems has resulted in many proposals for new electronic phases of matter. An electron nematic breaks the point group symmetry of the host crystal, often from C_6 or C_4 rotational symmetry to C_2. Electron nematics have been reported in several condensed matter systems including cuprate and iron arsenic based high temperature superconductors, and they have been proposed to exist in many other materials. However, the combination of reduced dimensionality and material disorder typically limits the spatial range over which electron nematic order persists, rendering its experimental detection extremely difficult. Despite the tantalizing possible connection between the phase and high temperature superconductivity, there is surprisingly little guidance in the literature about how to detect the remaining disordered electron nematic. We propose a general method for detecting disordered electron nematics in bulk condensed matter systems using nonequilibrium methods.

1:03PM Z23.00010 Superconducting-to-Normal State Switching Experiments using Graphene-based Josephson Junctions , JOSEPH LAMBERT, STEVEN CARABELLO, ROBERTO RAMOS, Department of Physics, Drexel University — We report results of ongoing superconductor-to-normal state switching experiments using graphene-based Josephson junctions. These devices consist of a single-layer graphene flake contacted by two superconducting parallel leads separated by a few hundred nanometers. Through the proximity effect, the superconducting state is induced in the graphene region below the leads and the Josephson supercurrent is mediated through the normal graphene region by multiple Andreev reflections. The Josephson effect has been firmly demonstrated in these devices, where supercurrents in the hysteretic current-voltage characteristic, Shapiro steps, the Fraunhofer-like diffraction pattern in the critical current versus external magnetic field, and the current-phase relationship have been observed. We report on work in progress, in measuring I-V characteristics, thermal activation and microwave resonant activation in graphene-based junctions, at various temperatures below 1 Kelvin. We modulate the density of charge carriers using a back-gate voltage, which tunes the critical current. This provides another knob for studying these state switching properties.

1:15PM Z23.00011 Noise spectroscopy: a sensitive probe to explore hot electron effect in highly correlated systems[1] , SUDESHNA SAMANTA, ARUP K. RAYCHAUDHURI, S N Bose National Centre for Basic Sciences, Block-JD, Sector-3, Salt Lake, Kolkata, India — Non-linear electrical conductance in ferromagnetic insulating (FMI) state of manganites can give rise to reversible colossal electro-resistance and current induced resistance change due to heating of the electrons in the system. In FMI state (<120K), the temperature of the lattices or phonon (T_{ph}) and electrons (T_e) in the sample can decouple by high input power density giving rise to heating of the electronic bath. We investigated whether white noise like Nyquist noise can be used to measure T_e (which is expected to be larger than T_{ph}) when the two baths get decoupled. The use of the Nyquist noise to measure T_e assumes that the electron bath forms a proper temperature bath in equilibrium. A dc stressing current was used to heat the electron bath while a small ac signal was used to measure the noise. With enhanced power input to the electron system, the white noise enhances and there is a large deviation from the simple estimate of Nyquist relation ($4k_BT_eR_{sample}$) indicating that the electron system is not in thermal equilibrium and is a non-ergodic system where Fluctuation Dissipation Theorem has broken down.

Session Z25 DCMP: Novel Superconductors II D166

11:15AM Z25.00001 Momentum-dependent multiple gaps of MgB_2 probed by electron tunneling spectroscopy on MgB_2/native oxide/Pb junctions[1] , KE CHEN, Temple University, WENQING DAI, QI LI, The Pennsylvania State University, X.X. XI, Temple University — Distinct multi-band superconductivity is a unique feature that distinguishes MgB_2 from all other phonon-mediated Bardeen-Cooper-Schrieffer (BCS) superconductors. According to a first-principles calculation employing an anisotropic Eliashberg formalism [Choi *et al.* Nature 418, 758 (2002)], there is a distribution of superconducting energy gap values on the Fermi surface of MgB_2 (two σ bands and two π bands). However, only two distinct gaps have been observed experimentally, leading to the suggestion that consideration of the fully anisotropic electron-phonon interaction may not be necessary for real MgB_2 samples. Here, we present an electron tunneling spectroscopy study on MgB_2/native oxide/Pb junctions that clearly shows the distribution of energy gaps. By deconvoluting the tunneling spectrum based on the density of state of Pb, we derive the momentum-dependent energy gaps of MgB_2, which are in good agreement with the anisotropic Eliashberg calculation. The result affirms the importance of the anisotropic electron-phonon interaction in MgB_2 as well as its important impact on device applications.

[1]The work is partially funded by ONR and by DOE.

11:27AM Z25.00002 Non-Cuprate Superconductor with Cubic Structure and T_c = 85 K , J.M. ESTRADA, E. CHAVIRA, I. ROSALES, O. NOVELO, E. FREGOSO, Instituto de Investigaciones en Materiales, Universidad Nacional Autonoma de Mexico, D.F., Mexico, E.E. MARINERO, M. NISHIOKA, Hitachi GST San Jose Research Center, 3404 Yerba Buena Rd, San Jose, CA 95135, USA, V. GARCIA-VAZQUEZ, Instituto de Fisica, Benemerita Universidad Autonoma de Puebla, Puebla, Mexico, M. SUCHOMEL, Argonne National Laboratory, 9700 Cass Ave., Argonne, IL 60439-4856, USA — We have synthesized a new superconductor material, namely: **Ba(Yb**$_{0.38}$ **In**$_{0.10}$**Sn**$_{0.42}$ **Pb**$_{0.10}$**)O**$_{2.66}$, by solid-state reaction in air and ambient pressure. The new compound is determined to have a T_c of 85 K, which is new record for a non-cuprate structure. Employing synchrotron XRD and Rietveld refinement, 5 structural phases are identified in the reaction products. The phases identified are: $BaTb_{0.5}Sb_{0.5}$ O_3 (41.3%), Yb_2BaCuO_5 (26.1%), CuO (22.6%), $Yb_2Cu_2O_5$ (4.4%) and $Ba_{1.99}Y_{1.01}$ Cu_3O_8 (5.6%). The microstructure exhibits cubic morphology (SEM) and EDX analysis is utilized to determine the stoichiometry of the new superconducting material, **Ba(Yb**$_{0.38}$ **In**$_{0.10}$**Sn**$_{0.42}$ **Pb**$_{0.10}$**)O**$_{2.66}$, which is isostructural to the cubic $BaTb_{0.5}Sb_{0.5}$ O_3 phase. Magnetic and Resistance measurements vs T indicate a superconducting transition at T_c at 85 K.

11:39AM Z25.00003 Suppression of time reversal symmetry breaking superconcutivity in $Pr(Os,Ru)_4Sb_{12}$ and $(Pr,La)Os_4Sb_{12}$[1] , LEI SHU, UCSD, W. HIGEMOTO, JAEA, Japan, Y. AOKI, TMU, Japan, A.D. HILLIER, ISIS, UK, K. OHISHI, K. ISHIDA, KU, Japan, R. KADONO, A. KODA, KEK, Japan, O.O. BERNAL, CSU, D.E. MACLAUGHLIN, UCR, Y. TUNASHIMA, Y. YONEZAWA, S. SANADA, D. KIKUCHI, H. SATO, TMU, Japan, H. SUGAWARA, UT, Japan, T.U. ITO, JAEA, Japan, M.B. MAPLE, UCSD — Zero-field muon spin relaxation (μSR) experiments have been carried out in the $Pr(Os_{1-x}Ru_x)_4Sb_{12}$ and $Pr_{1-y}La_yOs_4Sb_{12}$ alloy systems to investigate broken time-reversal symmetry (TRS) in the superconducting state, signaled by the onset of a spontaneous static local magnetic field B_s. In both alloy series B_s initially decreases linearly with solute concentration. Ru doping is considerably more efficient than La doping ,with a $\sim$50% faster initial decrease. The data suggest that broken TRS is suppressed for Ru concentration larger than 0.6, but persists for essentially all La concentrations. Our data support the theory of TRS-breaking superconductivity via crystal-field excitonic Cooper pairing of Koga, Matsumoto, and Shiba.

11:51AM Z25.00004 Signatures of half-quantum vortices in magnetoresistance of perforated samples[1] , VICTOR VAKARYUK, VALERII VINOKUR, Argonne National Laboratory — Recent cantilever magnetometry measurements of annular micron-size samples of Sr_2RuO_4 [1] have revealed evidence for the existence of half-quantum vortices (HQVs) in this material. Here we suggest to look for HQVs at temperatures close to T_c in magnetoresistance of "punctured" (perforated) Sr_2RuO_4 samples which consist of an array of regularly spaced micron-size holes in an otherwise uniform superconducting matrix. Due to the dissipative nature of resistive measurements signatures of HQVs might be seen even if their thermodynamic stability is not expected. We analyze the dependence of magnetoresistance on the thermodynamic stability of HQVs and point out features which may help to identify them.

12:03PM Z25.00005 Nonintegral flux penetration in superconductors with broken time-reversal symmetry via bent domain walls , DAVID FERGUSON, PAUL GOLDBART, University of Illinois at Urbana-Champaign — Sr_2RuO_4 is a candidate material for realizing a superconducting state that spontaneously breaks time-reversal symmetry [1]. In such a state, the spatial pattern of the superconductivity may be broken up into regions of differing chirality, separated by domain walls. Here, we show that, near to bends in such domain walls, nonintegral (and even nonquantized) multiples of the superconducting magnetic flux quantum would penetrate the system [2]. We discuss the implications of this "bend flux" effect for various experimental probes that are sensitive to time-reversal symmetry breaking. For the example of scanned-probe magnetic imaging, the observation of localized-nonquantized flux penetrating a z-axis surface of the sample, could be interpreted in terms of the presence of bent walls between domains of opposing chirality, and hence would be suggestive of time-reversal symmetry-breaking superconductivity. Alternatively, if observations should reveal localized but only *quantized* flux, this would suggest either (i) the absence of domain walls or (ii) their presence, but as a parallel array of straight walls.

12:15PM Z25.00006 Scenarios for half-integer fluxoid behavior of annular rings of Sr_2RuO_4 , RAFFI BUDAKIAN, DAVID FERGUSON, PAUL M. GOLDBART, JOONHO JANG, University of Illinois at Urbana-Champaign, VICTOR VAKARYUK, Argonne National Laboratory — Recently, cantilever torque magnetometry experiments on annular rings of superconducting Sr_2RuO_4 have revealed half- height steps in the magnetization [1]. These features are suggestive of the existence, in these annular samples, of half- quantum fluxoid states (i.e., the coreless analogs of half- quantum vortices). We consider the existence and energetic stability (for various forms of triplet superconductivity) of half-quantum fluxoid states in annular samples. We also consider alternative scenarios that could give rise to magnetization steps. One particular scenario requires the presence, in the bulk of the sample, of thermodynamically stable "wall vortices" By analyzing the equilibrium state of the superconductor, as a function of the applied magnetic field, we conclude that any wall-vortex scenario consistent with the observations of Ref. [1] would require a (to date, unexplained) fine tuning of various material parameters.

[1] J. Jang, D. Ferguson, V. Vakaryuk, R. Budakian, S. Chung, P.Goldbart, and Y. Maeno, (2010 unpublished)

12:27PM Z25.00007 The Atomic-Scale Onset of Charge Density Waves in $NbSe_2$, CHOCKALINGAM S P, L. ZHAO, C. ARGUELLO, E. ROSENTHAL, C. GUTIERREZ, J. KANG, A. PASUPATHY, Columbia University, S. JIA, R. CAVA, Princeton University — Many modern complex materials exhibit spatially ordered electronic states such as charge and spin density waves, and scanning tunneling microscopy (STM) has recently been used successfully to visualize some of these phases. Unfortunately such phases often occur simultaneously in a single sample making the interpretation of experimental data difficult. In order to gain insight into the nature of spatial order in a simple material, we study the transition-metal dichalcogenide $NbSe_2$, which displays a 2D charge density wave (CDW) phase at low temperature. How does this CDW phase manifest itself in real space at the atomic scale? In order to answer this question, we have performed variable-temperature STM experiments on $NbSe_2$single crystals at various temperatures around T_c (33.5 K). We discover that static, short-range CDW order exists around crystal defects and impurities at temperatures up to $3T_c$. We will describe the temperature evolution as well as the energy dependence of the short-range CDW using spectroscopic mapping. Our experiments provide a high-resolution measurement of the changes in electronic structure caused by the formation of CDW in the dichalcogenides.

12:39PM Z25.00008 Multiband Superconductivity in $2H$-$NbSe_2$ Probed by Cryomagnetic STM Spectroscopy[1] , IGOR FRIDMAN, J.Y.T. WEI, University of Toronto and Canadian Institute for Advanced Research, C. KLOC, Nanyang Technological University, Singapore, V. LUKIC, Department of Bioengineering, University of Pennsylvania, RONGWEI HU[2], C. PETROVIC, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory — Using a novel magnetic field geometry, we study multiband pairing in single crystals of superconducting $2H$-$NbSe_2$ under finite superfluid momentum. Spectroscopy and conductance imaging were performed with a scanning tunneling microscope (STM) at 300 mK and in a field of up to 9 T, applied in the ab-plane. We observed multiple spectral features that evolve systematically with field, and a two-sloped zero-bias conductance that dips anomalously at 0.7 T. Our analysis yields distinct evidence for multiple gaps coming from the various Fermi-surface sheets, and has possible implications on the origin of the coexisting charge density wave order.

12:51PM Z25.00009 Spin density in UCoGe , JONATHAN TAYLOR, STFC RAL UK, JONATHAN DUFFY, MATTHEW BUTCHERS, Warwick university UK, CHRIS STOCK, NIST, E. BAUER, Los Alomos — Below T = 0.8K, superconductivity and ferromagnetism (T_C = 3K) coexist in UCoGe. The total magnetic moment is 0.03 μ_B at low temperatures. UCoGe is considered to be a weak itinerant ferromagnet. Recent theoretical studies Predict UCoGe indicate that UCoGe is ferromagnetic, but that the small total magnetic moment arises from the near cancellation of large U $5f$ spin and orbital moments. Theory also predicts there to be a Co spin moment. However, the total moment is predicted to be considerably larger than observed experimentally. Using magnetic Compton scattering experiments together with KKR electronic structure calculations we have measured the spin density of the ferromagnetic superconductor UCoGe and determined that at 1.3K the U$5f$ and Co$3d$ spin moments are antiparallel, in agreement with theory, but disagreeing with polarized neutron diffraction results. The measured total spin moment is determined to be -0.35$\mu_B FU^{-1}$, and the orbital moment hence determined to be 0.5$\mu_B FU^{-1}$. These moments are reduced with respect to the LDA calculations. The small ratio of U orbital to spin moments indicates that the 5f moment is itinerant.

1:03PM Z25.00010 Interplay of charge density modulations and superconductivity[1] , JASON W. SADOWSKI, K. TANAKA, Dept. of Physics & Engineering Physics, University of Saskatchewan — Although charge density waves (CDW) in transition metal dichalcogenides (TMDs) have been studied for over three decades, there is yet no consensus on the mechanism for CDW in two-dimensional TMDs. Moreover, the layered 2H-type TMDs which exhibit coexistence of CDW order and superconductivity (SC) present an intriguing opportunity for studying the interplay of SC and charge density modulations. In particular, 2H-$NbSe_2$ is most suitable for such investigation as its transition temperatures for CDW and SC are well separated, and as it is easy to cleave is ideal for surface-sensitive measurements. The relation between CDW and SC in this material is still under debate, with one experiment indicating an enhancement of SC by CDW [1] and another implying a competition of the two kinds of orders [2]. Motivated by these experiments, we study the effects of Fermi surface structure on CDW and its interplay with SC in terms of the Bogoliubov-de Gennes formalism.

1:15PM Z25.00011 First-principles study of the noncentrosymmetric superconductors Li_2Pt_3B and Li_2Pd_3B , TATSUYA SHISHIDOU, ADSM, Hiroshima Univ, TAMIO OGUCHI, ISIR, Osaka Univ — Effect of spin-orbit coupling (SOC) associated with lack of space-inversion symmetry has been a central issue in condensed-matter physics. Li_2Pt_3B and Li_2Pd_3B are superconducting below 2.7 K and 7 K, respectively, and have the same crystal structure (cubic $P4_332$, No. 212), which is noncentrosymmetric and is characterized by highly distorted corner-sharing BPt(Pd)$_6$ octahedra. Despite the same valency and structure, they show quite different superconducting behavior. NMR measurements [1] indicate that Li_2Pt_3B would be a spin-triplet superconductor with line nodes in the gap function while Li_2Pd_3B is a conventional spin-singlet s-wave superconductor. SOC would be a key to understand this difference. To clarify the electronic band structure and Fermi surface of these compounds, we performed density-functional (GGA PBE) calculations with FLAPW method. Relativistic effects were fully taken into account. The band structures calculated are in good accordance with previous work[2] and the spin splitting due to SOC is quite significant in Li_2Pt_3B. This work was supported by a MEXT KAKENHI on Innovative Areas "Topological Quantum Phenomen". [1] M. Nishiyama, Y. Inada, and G.-q. Zheng, PRL **98**, 047002 (2007); PRB **71**, 220505(R) (2005). 1:27PM Z25.00012 The electron-boson spectral density function of underdoped $Bi_2Sr_2CaCu_2O_{8+\delta}$ and $YBa_2Cu_3O_{6.50}$, JUNGSEEK HWANG, Pusan National University — We investigate the electron-boson spectral density function, $I^2\chi(\omega,T)$, of CuO_2 plane in underdoped $Bi_2Sr_2CaCu_2O_{8+\delta}$ (Bi-2212) and underdoped $YBa_2Cu_3O_{6.50}$ (Y-123) systems using the Eliashberg formalism. We apply a new (in-plane) pseudogap model to extract the electron- boson spectral function. For extracting the spectral function we assume that the spectral density function consists of two components: a sharp mode and the broad Millis-Monien-Pines (MMP) mode. We observe that both the resulting spectral density function and the intensity of the pseudogap show strong temperature dependences: the sharp mode takes most spectral weight of the function and the peak position of the sharp mode shifts to lower frequency and the depth of pseudogap, $1-\tilde{N}(0,T)$, is getting deeper as temperature decreases. We estimate fictitious (maximum) superconducting transition temperatures, $T_c(T)$, from the extracted spectral functions at various measured temperatures using a generalized McMillan formula. The estimated (maximum) T_c also shows a strong temperature dependence; it is higher than the actual T_c at all measured temperatures and decreases with temperature lowering. Since as lowering temperature the pseudogap is getting stronger and the maximum T_c is getting lower we propose that the pseudogap may suppress the superconductivity in cuprates.

1:39PM Z25.00013 Modulation of Spin-Orbit interaction and superconductivity in two-dimensional electron gas at the Mott-Insulator - Band-Insulator interface: LaTiO3 - SrTiO3 , JOHAN BISCARAS, N. BERGEAL, LPEM, A. KUSHWAHA, ITT Kanpur, T. WOLF, LPEM, A. RASTOGI, ITT Kanpur, RAMESH CHANDRA BUDHANI, Low Dimensional Systems Laboratory, Department of Physics, Indian Institute of Technology Kanpur, Kanpur 208016, India, JEROME LESUEUR, LPEM-UMR8213/CNRS - ESPCI ParisTech, 10 rue Vauquelin - 75005 Paris — It has been shown recently that a two-dimensional electron gas could form at the interface of two insulators such as $LaAlO_3$ and $SrTiO_3$ [1], or $LaTiO_3$ (a Mott insulator) and $SrTiO_3$ [2]. We present low temperature transport and magneto-transport measurements on $LaTiO_3/SrTiO_3$ hetero-structures, whose properties can be modulated by field effect using a metallic gate on the back of the substrate. The corresponding phase diagram has been investigated, and superconductivity evidenced for the first time in this system which involves a Mott insulator [3]. We will discuss the role of the confinement potential and the $SrTiO_3$ band structure on the phase diagram, and show the specific role of the spin-orbit coupling measured by localization corrections to the magnetoconductivity. Finally, the superconducting to insulator transition will be analyzed. [1] N. Reyren et al, Science 317, 1196 (2007) [2] A. Ohtomo et al, Nature 419, 378 (2002) [3] J. Biscaras et al, Nature Commun, DOI: 10.1038/ncomms1084 (2010)

1:51PM Z25.00014 Upper Critial Field Calculations in p-Wave Tripet Ferromagnetic Superconductors , CHRISTOPHER LÖRSCHER, RICHARD KLEMM, University of Central Florida — We report $H_{c2}(T)$ calculations for novel triplet ferromagnetic superconductors using a uniaxially anisotropic pairing interaction, obtained by means of the linearized Gor'kov gap equation. In addition to the intrinsic anisotropy of the p-wave states, we also include effective mass anisotropies in our calculations. We investigate the $H_{c2}(T)$ phase diagrams for several combinations of anisotropy, leading to novel $H_{c2}(T)$ properties, including upward curvature. We discuss the relevance of our results to experiments on UCoGe.

2:03PM Z25.00015 Identifying d-vectors in spin-orbit coupled multi-orbital superconductors , CHRISTOPH PUETTER, HAE-YOUNG KEE, University of Toronto — In multi-orbital systems, Hund's interaction has been recognized to play a significant role in spin-triplet pairing. On the other hand, spin-orbit coupling has been treated as a perturbation, which is not a good approximation in 4d or 5d transition metal compounds. We have treated both effects on an equal footing in t2g orbital systems and studied their combined effect on spin-triplet superconductivity. We also discuss the implications of our results for spin-triplet candidate materials.

Session Z26 DMP DCOMP: Focus Session: Iron Based Superconductors – Electronic Anisotropy D162/164

11:15AM Z26.00001 In-plane electronic anisotropy of underdoped iron arsenide superconductors , IAN FISHER, Department of Applied Physics, Stanford University — Common to the high Tc cuprates, superconductivity in the Fe arsenides and related compounds is associated with suppression of an antiferromagnetic ground state. On the underdoped side of the phase diagram, in addition to the antiferromagnetic transition, the materials also suffer a phase transition that breaks the 4-fold rotational symmetry of the high-temperature crystal structure, this occurring at either the same or higher temperature than the Neel transition. Emerging evidence based on measurements of detwinned single crystals reveals a dramatic in-plane electronic anisotropy associated with this nematic transition.[1]

[1]In collaboration with: J.-H. Chu, H.-H Kuo, J. Analytis, M. Yi, D. H. Lu, Z. X. Shen, A. P. Sorini, A. F. Kemper, S.-K. Mo, T. P. Devereaux, R. G. Moore, M. Hashimoto, W. S. Lee, Z. Hussain, K. De Greve, P. L. McMahon, Y. Yamamoto (Stanford); Z. Islam (APS,ANL); A. Dusza, A. Lucarelli, F. Pfuner & L. Degiorgi (ETHZ).

11:51AM Z26.00002 Superconducting properties and the interplay between magnetism and superconductivity in 1111 Fe arsenides as revealed by torque magnetometry , GANG LI, GAEL GRISONNANCHE, BENJAMIN CONNER, National High Magnetic Field Lab, NIKOLAI ZHIGADLO, SERGIY KATRYCH, ZBIGNIEW BUKOWSKI, JANUSZ KARPINSKI, Laboratory for Solid State Physics, ETH Zürich, CH-8093 Zürich, Switzerland, LUIS BALICAS, National High Magnetic Field Lab — We performed a study of the angular dependence of the magnetic torque in $LaFeAsO_{0.9}F_{0.1}$ single crystals. We developed a method to separate the magnetic and the superconducting components inherent to the FeAs layers and which are superimposed onto the reversible torque signal $\tau_{\rm rev}(\theta, H, T)$. We show that by exploring the amplitude of the superconducting component in $\tau_{\rm rev}(\theta)$ as a function of H, it is possible to extract the thermodynamic value of the superconducting upper critical field H_{c2}. This so obtained value can be used to extract the field and the temperature dependencies of respectively, the superconducting anisotropy and the superfluid density through the Kogan formalism. We observe a strong temperature and field dependence of the superconducting anisotropy as expectable within a multi-band superconducting scenario. The resulting T-dependence of the superfluid-density resembles the behavior previously reported for LaFePO and which was ascribed to nodal superconductivity.

12:03PM Z26.00003 Properties of de-twinned iron-arsenide $SrFe_2As_2$, ERICK BLOMBERG, M.A. TANATAR, A. KREYSSIG, N. NI, A. THALER, R.W. HU, P.C. CANFIELD, S.L. BUD'KO, A.I. GOLDMAN, R. PROZOROV, Department of Physics & Astronomy and The Ames Laboratory, Iowa State University, Ames, IA 50011, USA — The iron-pnictides, AFe_2As_2 (A = alkali earth metal), undergo a tetragonal to orthorhombic structural transition below T_s, which is in the range between 130 K to 210 K depending on the compound. To release elastic deformation the orthorhombic phase is spontaneously divided into four degenerate, equally populated, structural domains. This makes any measurements of in-plane anisotropy extremely difficult. Unlike high$-T_c$ Y-Ba-Cu-O which is orthorhombic already at room temperature, detwinning of pnictides is more difficult, because of lower T_s. We developed a technique of mechanical de-twinning of these materials that allows transport, x-ray and direct optical measurements [1]. Here we report polarized light microscopy, synchrotron X-ray analysis and AC transport measurements on $SrFe_2As_2$, which represents a clean case of first-order magnetic/structural transition.

12:15PM Z26.00004 Magnetic Field Effect on the In-plane Electrical Resistivity of $FeTe_{1-x}Se_x$ Single Crystals , YIMIN XIONG, AMAR KARKI, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803-4001, BRIAN SALES, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, RONGYING JIN, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803-4001 — The in-plane electrical resistivity (ρ_{ab}) of $FeTe_{1-x}Se_x$ single crystals is measured as a function of temperature (T), magnetic field (H), and the angle (θ) between H and electric current (I). The results reveal that ρ_{ab} strongly depends on both H and θ, indicating the participation of spin scattering in the electrical transport. The underlying physics will be discussed.

12:27PM Z26.00005 Anisotropy of normal and superconducting states of FeSeTe , M.A. TANATAR, Ames Laboratory, Ames, IA, E.C. BLOMBERG, Department of Physics and Astronomy, Iowa State University and Ames Laboratory, Ames, IA, J.-PH. REID, Departement de Physique, Universite deSherbrooke, Sherbrooke, Quebec, Canada, J. HU, J. QUIAN, Z.Q. MAO, Department of Physics and Engeenering Physics, Tulane UNiversity, New Orleans, Louisiana, USA, LOUIS TAILLEFER, Departement de Physique, Universite deSherbrooke, Sherbrooke, Quebec, Canada, R. PROZOROV, Department of Physics and Astronomy, Iowa State University and Ames Laboratory, Ames, IA 50011, USA — We report anisotropic electrical and thermal transport measurements in non-superconducting parent FeTe and superconduicting optimally doped FeTeSe. Intrinsic in- plane anisotropy of the electrical resistivity was measured in mechanically detwinned crystals of the parent compound [1]. In-plane and inter-plane heat transport was used to probe the symmetry of the superconducting gap in the material close to optimal doping (Tc=15 K). The results are compared to those of superconducting FeSe [2] and doping evolution of thermal conductivity in BaFe2As2 doped with cobalt [3,4]. [1] M.A. Tanatar, *et al.* Phys. Rev. B **81**, 184508 (2010). [2] J. K. Dong, *et al.* Phys. Rev. B **80**, 024518 (2009). [3] M. A. Tanatar, *et al.* Phys. Rev.Lett. **104**, 067002 (2010). [4] J.-Ph. Reid, *et al.* Phys. Rev. B **82**, 064501 (2010).

12:39PM Z26.00006 Pulsed-field contactless mapping of the anisotropic upper critical field in LiFeAs superconducting crystals , K. CHO, H. KIM, M.A. TANATAR, R. PROZOROV, Ames Laboratory, USA, Y.J. SONG, Y.S. KWON, Sungkyunkwan University, Rep. of Korea, W.A. CONIGLIO, C.C. AGOSTA, Clark University, USA, A. GUREVICH, National High Magnetic Field Laboratory, USA — Angle - resolved measurements of the upper critical field were performed using a tunnel diode resonator in the stoichiometric iron arsenide superconductor LiFeAs (T_c=18 K) in pulsed magnetic fields up to 50 T at temperatures down to 0.6 K. Complete $H_{c2}^{\|c}(T)$ and $H_{c2}^{\perp c}(T)$ curves with $T \to 0$ extrapolated values of $H_{c2}^{\|c}(0) = 17 \pm 1$ T and $H_{c2}^{\perp c}(T) = 26 \pm 1$ T were obtained. The anisotropy, $\gamma_{H_{c2}} \equiv H_{c2}^{\perp c}/H_{c2}^{\|c} \approx 2$, close to T_c has revealed the essentially three-dimensional electronic structure of the material. Both temperature - dependent $H_{c2}(T)$ can be well fit within a single set of band structure, magnetism and scattering parameters. In a configuration with $H \parallel c$, $H_{c2}^{\|c}(T)$ is limited by orbital effects with modest scattering. In the perpendicular orientation, $H_{c2}^{\perp c}(T)$ shows a notable low-temperature saturation and a strong departure from the orbital Werthamer-Helfand-Hohenberg model. Instead, fitting results suggest paramagnetic Pauli limiting and the development of a spatially - modulated superconducting state.

12:51PM Z26.00007 Symmetry breaking orbital anisotropy observed in detwinned $Ba(Fe_{1-x}Co_x)_2As_2$ above the spin density wave transition , MING YI, Stanford University, D.H. LU, J.-H. CHU, J.G. ANALYTIS, A.P. SORINI, A.F. KEMPER, S.-K. MO, R.G. MOORE, M. HASHIMOTO, W.-S. LEE, Z. HUSSAIN, T.P. DEVEREAUX, I.R. FISHER, Z.-X. SHEN — Nematicity has recently been observed in the competing phases in proximity to the superconducting phase in the cuprates. Similarly, the iron pnictides exhibit symmetry breaking competing phases in the form of a tetragonal to orthorhombic structural transition and a collinear spin density wave (SDW) transition in the underdoped regime. Evidence for strong in-plane anisotropy in the SDW state has been reported by neutron scattering, scanning tunneling microscopy, and transport measurements, but the nature of this nematic behavior is still elusive. Here we present the results of an ARPES study of detwinned single crystals of underdoped $Ba(Fe_{1-x}Co_x)_2As_2$, resolving single domain electronic structure in the orthorhombic SDW state which exhibits strong in-plane anisotropy consistent with other probes. The anisotropy is evident in a large splitting of the dxz and dyz bands, which is seen to develop almost fully above the onset of the long range magnetic order.

1:03PM Z26.00008 Nematic spin fluid in the tetragonal phase of $BaFe_2As_2$, LELAND HARRIGER, University of Tennessee, HUIQIAN LUO, MENGSHU LIU, TOBY PERRING, CHRIS FROST, JIANGPING HU, MIKE NORMAN, PENGCHENG DAI — We use inelastic neutron scattering to demonstrate the presence of a large spin anisotropy above T_N in the unstressed tetragonal phase of $BaFe_2As_2$. In the low-temperature orthorhombic phase, we find highly anisotropic spin waves with a large damping along the AF a-axis direction. On warming the system to the paramagnetic tetragonal phase, the low-energy spin waves evolve into quasi-elastic excitations, while the anisotropic spin excitations near the zone boundary persist. These results strongly suggest that the spin nematicity we find in the tetragonal phase of $BaFe_2As_2$ is the source of the electronic and orbital anisotropy observed above T_N by other probes, and has profound consequences for the physics of these materials.

1:15PM Z26.00009 Reconstructed electronic structure from orbital ordering and antiferromagnetism in the iron pnictides , WEICHENG LV, PHILIP PHILLIPS, Department of Physics, University of Illinois — Recent experimental developments have unambiguously demonstrated the in-plane electronic and magnetic anisotropy of the iron-based superconductors. It has been argued that this nematic state can arise from orbital ordering physics. Including an energy splitting term that breaks the degeneracy of the Fe d_{xz} and d_{yz} orbitals, we solve the multi-orbital Hubbard model within a mean-field approximation. Despite sensitivity of the resulting state to the input parameters, we find that a weak orbital order that places the d_{yz} orbital slightly higher in energy than the d_{xz} orbital, along with the interactions U and J being of intermediate strength, is compatible with current experimental results. In this regime, the stripe antiferromagnetism is further stabilized and the existence of the Dirac cones is preserved. Furthermore, this anisotropic electronic state leads to the observed resistivity anisotropy and STM interference patterns. Finally the relation between orbital order and superconductivity is discussed.

1:27PM Z26.00010 Magnetic Torque Evidence for Broken Rotational Symmetry in the Tetragonal Phase of $BaFe_2(As_{1-x}P_x)_2$ Single Crystals , SHIGERU KASAHARA, HONGJIE SHI, RYUJI OKAZAKI, KENICHIRO HASHIMOTO, MINORU YAMASHITA, TAKASADA SHIBAUCHI, TAKAHITO TERASHIMA, YUJI MATSUDA, Kyoto University — The emergence of broken four-fold symmetry is found in the tetragonal phase of $BaFe_2(As_{1-x}P_x)_2$ single crystals [1] by in-plane anisotropy measurements of magnetic susceptibility. Magnetic torque detects a spontaneous growth of two-fold oscillations under in-plane field rotations, whose amplitude is linked to an order parameter of an electronic "nematic" phase. Our findings reveal that the spontaneous rotational symmetry breaking sets in far above the tetragonal to orthorhombic structural transition, which might be also linked to the unconventional superconductivity of this system [2,3].

1:39PM Z26.00011 Interplay of orbital ordering and magnetism in the parent compounds of the iron pnictides , ANDRIY NEVIDOMSKYY, Physics and Astronomy, Rice University — The neutron scattering experiments on the parent compounds of the 122 family of the iron pnictide superconductors show a pronounced orhthorhombic anisotropy in the spin wave spectra [1], also observed in resistivity measurements on detwinned crystals [2,3]. Orbital ordering of the d_{xz} and d_{yz} orbitals may be a possible explanation for this behaviour [4]. In this work, we establish the effect of orbital ordering on the magnetism and study their interplay through a combination of the first-principles band theory calculations and phenomenological analysis in the framework of the Landau theory. This enables us to establish the coupling between the orbital and magnetic degrees of freedom in these materials. Consequences for the symmetry of the superconducting order parameter are discussed.

1:51PM Z26.00012 Orbital-ordering and In-plane Anisotropy in Low-moment Ground-state of Parent Compounds of Iron-based Superconductors[1] , MASAHIKO MACHIDA, HIROKI NAKAMURA, Japan Atomic Energy Agency — Since the discovery of the iron-based superconductor, a large discrepancy between experimental observations and first-principles calculations in the magnetic moment of the antiferromagnetic state of the parent compounds has been intensively debated. The observed moment values are about 3 to 5 times smaller than those of the calculation although there is a variety of the difference depending on the materials. Very recently, an interesting calculation data fully reproducing the observed low moment has been suggested by F. Cricchio et al., (Phys. Rev. B 81 (2010) 140403) who performed first-principles calculations using a LDA+U scheme. In this study, we suggest that the new state is a possible candidate to well explain the other data, e.g., strong anisotropy in spatial patterns measured by STM and magnetic excitations found by neutron scattering. Furthermore, we compare the result with other theoretical works reproducing similar low moment in terms of orbital ordering.

2:03PM Z26.00013 Conductivity Anisotropy in the Antiferromagnetic State of Iron Pnictides , BELEN VALENZUELA, ELENA BASCONES, MARIA J. CALDERON, Inst. Ciencia de Materiales de Madrid-CSIC — Recent experiments on iron pnictides have uncovered a large in- plane resistivity anisotropy with a surprising result: the system conducts better in the antiferromagnetic x direction than in the ferromagnetic y direction [1]. We address this problem by calculating the ratio of the Drude weight along the x and y directions, D_x/D_y, for the mean-field $\mathbf{Q} = (\pi, \mathbf{0})$ magnetic phase diagram of a five-band model for the undoped pnictides [2,3]. We find [4] that D_x/D_y ranges between $0.2 < D_x/D_y < 1.7$ for different interaction parameters. Large values of the orbital ordering favor an anisotropy opposite to the one found experimentally. On the other hand, D_x/D_y is strongly dependent on the topology and morphology of the reconstructed Fermi surface. Our results point against orbital ordering as the origin of the observed conductivity anisotropy, which may be ascribed to the anisotropy of the Fermi velocity. [1] J.-H. Chu et al., Phys. Rev. Session Z27 GQI: Focus Session: Semiconductor Qubits - Theory and Experiment C155

11:15AM Z27.00001 Quantum dot charge stability diagram from a generalized Hubbard model[1]

, XIN WANG, SHUO YANG, SANKAR DAS SARMA, Condensed Matter Theory Center, Department of Physics, University of Maryland — We develop a theory for the charge stability diagram in solid state quantum dot spin qubits using a general form of the Hubbard model. We argue that the extended Hubbard model (with both on-site and inter-site Coulomb repulsion) is the minimal model to describe the system. The appropriate parameters of the Hubbard model can be read off by comparing our theoretically derived results with the experimental charge stability plots. We make predictions on how the charge stability diagram depends on various parameters of the Hubbard model, especially the spin-exchange and hopping energies.

[1]This work is supported by IARPA, LPS-CMTC, and CNAM.

11:27AM Z27.00002 Microscopic theory for the charge stability diagram of coupled quantum dot systems[1]

, SHUO YANG, XIN WANG, SANKAR DAS SARMA, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, MD 20742 — We present a quantitative microscopic theory for the charge stability diagram of coupled quantum dot systems. Using the configuration interaction method we obtain a generalized Hubbard model, from which the charge stability diagram is calculated and compared with experiments. We establish an exact connection between experimental measurements and the microscopic theory, and predict some experimentally observable quantum effects. We also map the classical capacitance model to the extended Hubbard model, and argue that the effect of spin-exchange and various hopping terms cannot be expressed in the capacitance model.

[1]This work is supported by LPS-CMTC, IARPA, and CNAM.

11:39AM Z27.00003 Formation and electrical characterization of directed self-assembled Ge/Si quantum dot[1]

, DONGYUE YANG, U. Pittsburgh, CHRIS PETZ, U. Virginia, JEREMY LEVY, U. Pittsburgh, JERROLD FLORO, U. Virginia — Directed self-assembly of sub-10 nm Ge islands is a candidate for producing laterally coupled quantum dot molecules with geometrically-defined spin exchange couplings. The islands are created by the nucleation of Ge islands on nanoscale SiC templates defined by direct-write electron-beam lithography.[2] Ge islands are coupled through ohmic contacts to the Si capping layer, and geometries can be defined that are suitable for either vertical or lateral transport.We describe low-temperature magneto-transport measurements on individual and small arrays of Ge islands grown on semi-insulating silicon substrates.

11:51AM Z27.00004 The Kondo Effect in a Double Quantum Dot

, SAMI AMASHA, ILEANA RAU, ANDREW KELLER, Stanford University, JORDAN KATINE, Hitachi Global Storage Technologies, HADAS SHTRIKMAN, Weizmann Institute, DAVID GOLDHABER-GORDON, Stanford University — A quantum dot consists of a confined droplet of electrons connected to electron reservoirs by tunnel barriers. When the dot has an odd number of electrons it has a net spin. The electrons in the reservoir can screen this spin via the Kondo effect, which corresponds to a many-body, highly correlated electron state. We study a lateral GaAs/AlGaAs double quantum dot, where one or both of the dots can be in the Kondo regime. The dots are also coupled to each other, and this inter-dot interaction can compete with the Kondo effect. We report transport measurements in this system at low electron temperatures and for a variety of inter-dot couplings.

12:03PM Z27.00005 Exhibition of tunnel coupling of negatively charged dangling bonds on Si Surface Using Scanning Tunneling Microscope

, M. BASEER HAIDER, Dept of Physics, King Fahad University of Petroleum & Minerals, Saudi Arabia, L. LIVADARU, Dept of Physics, University of Alberta, Canada, J. PITTERS, National Institute for Nanotechnology, National Research Council of Canada, Canada, R. WOLKOW, Dept of Physics, University of Alberta, Canada — We have performed Scanning tunneling microscopy study of hydrogen terminated Si (100). We will show that single Si atoms in a solid state environment can be served as quantum dots. These negatively charged quantum dots can be tunnel coupled to the nearby Si quantum dots. We will demonstrate that this tunnel coupling can be controlled by adjusting the separation between the two Si atomic quantum dots. Moreover electron occupation in the tunnel coupled Si quantum dots can be controlled. We have used this tunnel coupling effect of Si atomic quantum dots to fabricate Quantum Cellular Automata Cells. Quantum Cellular Automata are used to transmit binary information through electrostatic interaction between adjacent cells without the transfer of charge from one cell to the next. Devices based on Quantum Cellular Automata will consume much less power compared to the conventional transistor based devices. Moreover, since there is no transfer of charge so power dissipation during its operation is minimal compared to conventional semiconductor devices. This Si based Quantum Cellular Automat Cell works at room temperature.

12:15PM Z27.00006 The RKKY Interaction and the Nature of the Ground State of Double Dots in Parallel

, MANAS KULKARNI, Stony Brook University and Brookhaven National Laboratory, ROBERT KONIK, Brookhaven National Laboratory — We argue through a combination of slave boson mean field theory and the Bethe ansatz that the ground state of closely spaced double quantum dots in parallel are Fermi liquids. We do so by studying the dots conductance, impurity entropy, and spin correlation. In particularly we find that the zero temperature conductance is characterized by the Friedel sum rule, a hallmark of Fermi liquid physics, and the impurity entropy vanishes in the limit of zero temperature, indicating the ground state is a singlet. This conclusion is in contradistinction to a number of numerical renormalization group studies. We suggest a possible reason for the discrepancy. Our findings are also consistent with a 1/N diagrammatic approach to the same setup.

12:27PM Z27.00007 Frequency-dependent Fano factor of multilevel systems with inelastic decay processes[1]

, FARZAD QASSEMI, Institute for Quantum Computing and Department of Physics and Astronomy, University of Waterloo, Ontario, Canada, BILL COISH, Department of Physics and Astronomy, McGill University, Montreal, Canada, JOAKIM BERGLI, Department of Physics, University of Oslo, Norway, FRANK K. WILHELM, Institute for Quantum Computing and Department of Physics and Astronomy, University of Waterloo, Ontario, Canada — We study the frequency-dependent noise of electrons passing through a multilevel quantum dot or molecule accounting for "dark" states through which current is prohibited and inelastic transitions between the levels. Our theory results in simple closed-form expressions directly relating the frequency-dependent noise to inelastic decay rates in the limit where the rates are widely separated. To demonstrate the method, we apply it to evaluate the shot noise for electrons passing through single and double quantum dots in the presence of multiple spin decay mechanisms.

12:39PM Z27.00008 Electron Localization in the Inhomogeneous Electron Gas: Quantum Point Contacts , ABHIJIT C. MEHTA, Duke University, CYRUS J. UMRIGAR, Cornell University, A. DEVRIM GUCLU, National Research Council of Canada, HAROLD U. BARANGER, Duke University — We use Quantum Monte Carlo (QMC) techniques to investigate the behavior of electrons in an inhomogeneous quasi-one-dimensional wire as a model of quantum point contact geometries. Previous QMC work by Guclu et al. demonstrated that electrons can be strongly localized in quantum point contacts, and this result was reproduced by Welander et al. using LSDA calculations. We model a quantum point contact as a constriction in a quantum ring, and we use variational and diffusion Monte Carlo to investigate the effects of different point contact lengths and geometries on the electronic properties of the QPC. A key issue is how robust the previous results are to the length of the constriction, the depth and steepness of the confining potential, and to increasing the density of the electrons in the high-density lead region.

12:51PM Z27.00009 Electron pair tunneling resonance in a double-dot interferometry , JINHONG PARK, H.-S. SIM, KAIST — It is difficult to experimentally detect an electron pair tunneling resonance in a quantum dot with repulsive Coulomb interactions, since it is usually masked by lower-order single-electron tunneling processes. We propose to use an Aharonov-Bohm interferometry consisting of two quantum dots for the detection. We find that in the second harmonics of the interference current, pair tunneling processes give a leading non-monotonous contribution around the bias voltages at which pair tunneling resonances appear. The second-harmonics differential conductance shows the signal of a pair tunneling resonance as well as the destructive interference of two pair tunneling resonances.

1:03PM Z27.00010 Giant current fluctuations in an overheated single-electron transistor , MATTI LAAKSO, TERO HEIKKILÄ, Low Temperature Laboratory, Aalto University, YULI NAZAROV, Kavli Institute of Nanoscience, Delft University of Technology — Interplay of cotunneling and single-electron tunneling in a thermally isolated single-electron transistor leads to peculiar overheating effects. In particular, there is an interesting crossover interval where the competition between cotunneling and single-electron tunneling changes to the dominance of the latter. In this interval, the current exhibits anomalous sensitivity to the effective electron temperature of the transistor island and its fluctuations. We present a new theoretical method for the study of the temperature fluctuations and induced fluctuations of other quantities, e.g., current, based on the Fokker–Planck equation. We apply this method to the study of the current and temperature fluctuations in an overheated SET around the crossover interval.

1:15PM Z27.00011 Electron exchange between quantum dot and ring by jumping in magnetic field , IGOR FILIKHIN, SERGEI MATINYAN, JAMES NIMMO, BRANISLAV VLAHOVIC, North Carolina Central University — Semiconductor heterostructures as quantum dots (QD) or quantum rings (QR) demonstrate discreet atom-like energy level configuration. In the presented work we show that in the weak coupled Double Concentric Quantum Ring (DCQR) electron position jumping can exist due to the energy level crossing. We study DCQR composed of GaAs in an $Al_{0.70}Ga_{0.30}As$ substrate under influence of magnetic field. In our model the DCQR is considered in three dimensional space within single sub-band effective mass approach [1]. Magnetic field is applied in z direction, perpendicular to the DCQR plane. The electron position in DCQR is defined by effective radius which is radius of most probable localization of a single electron. We study electron structure of QD located at the center of QR. The electron position jumping between QD and QR is considered. Discussed will be possibility of experimental implementations of the jumping effect for composite object of QD and QR.

1:27PM Z27.00012 Quantum phase transition of light as a control of the entanglement between interacting quantum dots , ANGELA BARRAGAN, Instituto de Fisica, Universidad de Antioquia, Medellin, Colombia; Instituto de Ciencias Nucleares, Universidad Nacional Autonoma de Mexico, Mexico, CARLOS VERA-CIRO, Instituto de Fisica, Universidad de Antioquia, Medellin, Colombia; Kapteyn Institute, University of Groningen, Groningen, The Netherlands, IAN MONDRAGON-SHEM, Instituto de Fisica, Universidad de Antioquia, Medellin, Colombia; Department of Physics, Cornell University, Ithaca, NY, USA — We study coupled quantum dots arranged in a photonic crystal, interacting with light which undergoes a quantum phase transition. At the mean-field level for the infinite lattice, we compute the concurrence of the quantum dots as a measure of their entanglement. We find that this quantity smoothly changes in the vicinity of the phase transition, and in a step-like fashion in the Mott-insulator phase. This behavior can be externally monitored through the second-order correlation function for the light in each lattice site. For the finite case, we discuss boundary induced effects using a mean-field ansatz, as well as the impact of having finite temperatures on the entanglement of the quantum dots.

1:39PM Z27.00013 First-principles study of the energy and spin structure of excited states of NV^-center in diamond and its corresponding Hubbard model parameters , SANGKOOK CHOI, MANISH JAIN, STEVEN G. LOUIE, University of California, Berkeley and Lawrence Berkeley National Laboratory — A negatively charged nitrogen-vacancy pair defect (NV) in diamond is one of the promising candidates to embody a qubit for quantum computation in solid states. It is an individually addressable quantum system that may be initialized, manipulated, and measured with high fidelity at room temperature due to a long coherence time of the spin in the ground states and long-life time of the excited states. The knowledge of the electronic and spin structures of the NV center in the ground as well as excited state is crucial in understanding them. Here, we evaluate the energies and spin structures of its excited states employing the first-principles GW-BSE methods. We further obtain the Hubbard model parameters for this defect system by comparing the excited-state energies from our ab-initio GW-BSE calculation with those from the model Hamiltonian. This work was supported by NSF Grant No. DMR10-1006184, the U.S. DOE under Contract No. DE-AC02-05CH11231. Computational resources have been provided by DOE at LBNL's NERSC facility.

Session Z29 GQI: Focus Session: Superconducting Qubits - Coherence and Materials III C148

11:15AM Z29.00001 Improving the Quality Factor of Microwave Compact Resonators , K. GEERLINGS, S. SHANKAR, E. EDWARDS, L. FRUNZIO, R.J. SCHOELKOPF, M.H. DEVORET, Applied Physics Dept., Yale University — Superconducting microwave resonators are now widely used for coupling to superconducting qubit systems. Compact resonators [1] consisting of an interdigitated capacitance and a meander inductance take up much less space than a typical coplanar waveguide resonator. Since the design of compact resonators and qubits share common features, qubit decoherence mechanisms can be studied through the measurement of resonator loss. We measured of order 100 resonators and have achieved internal quality factors in excess of 300,000. Results indicate loss appears to be due to spurious two level systems. Loss increases when the participation of surfaces in the energy density is increased. Thus a large separation of electrodes is preferred, in agreement with the findings of other groups. Work in progress involves the combination of these resonators with transmon qubits. Work supported by IARPA, ARO and the NSF.

11:27AM Z29.00002 Radiative Losses in Superconducting Coplanar Resonators , JAMES WENNER, R. BARENDS, R.C. BIALCZAK, Y. CHEN, J. KELLY, M. LENANDER, E. LUCERO, M. MARIANTONI, M. NEELEY, A.D. O'CONNELL, P. O'MALLEY, D. SANK, A. VAINSENCHER, H. WANG, M. WEIDES, T. WHITE, Y. YIN, J. ZHAO, A.N. CLELAND, JOHN M. MARTINIS, UC Santa Barbara — Radiation is a potential loss mechanism in superconducting qubits. Radiation loss was studied in superconducting coplanar resonators, which are important both in coupling superconducting qubits and because they provide a simple system to quantitatively measure the resulting effects. We fabricated 8 GHz resonators and measured the resulting reduction of the high-power Q. We found it was necessary to design the resonators carefully to reduce stray coupling between the resonators so that losses would be dominated by radiation. The radiation loss is measured to be 30 times greater than predicted by a simple theoretical model, but was predicted accurately by simulation data. We attribute this to the effects of the device mount and the finite substrate height on the radiation pattern. We conclude that radiation is an unlikely decoherence mechanism for the present generation of qubits and resonators.

11:39AM Z29.00003 Minimal resonator loss for circuit quantum electrodynamics , RAMI BARENDS, UC Santa Barbara, N. VERCRUYSSEN, A. ENDO, P.J. DE VISSER, T. ZIJLSTRA, T.M. KLAPWIJK, Delft University of Technology, P. DIENER, S.J.C. YATES, J.J.A. BASELMANS, SRON Netherlands Institute for Space Research, H. WANG, M. HOFHEINZ, J. WENNER, M. ANSMANN, R.C. BIALCZAK, M. LENANDER, E. LUCERO, M. NEELEY, A.D. O'CONNELL, D. SANK, M. WEIDES, A.N. CLELAND, J.M. MARTINIS, UC Santa Barbara — In Josephson quantum information processing superconducting coplanar waveguides are used as memory elements and coupling buses. Quality factors of these resonators reach up to a million at high excitation powers, but decrease down to below $100x10^3$ at the single photon level in the presently used materials, such as Al and Nb. We report quality factors of up to $500x10^3$ by using NbTiN or Re and removing the dielectric from regions with high electric fields. Using a model-analysis and by a comparison with Ta, the crucial sources of intensity-dependent loss are dielectrics on the surface of the metal and substrate. Our approach shows that using non-oxidizing superconductors such as Re and NbTiN and removing dielectrics is a straightforward route to high quality factors in the single photon regime.

11:51AM Z29.00004 Low-loss superconducting microwave resonators with NbN films[1] , C. SONG, B. XIAO, M. WARE, B.L.T. PLOURDE, Syracuse University — The native oxide that forms on the surface of most superconducting thin films contains a distribution of two-level system (TLS) defects that results in a significant microwave loss channel at low temperatures and powers. One of the key limitations in the quality factor of microwave devices in this regime for superconducting quantum information processing schemes is due to this surface loss mechanism. Thus, nitride superconducting materials are promising candidates due to their lack of a significant surface oxide. We have fabricated coplanar waveguide microwave resonators from reactively sputtered NbN films on sapphire and Si substrates. We characterize the resonators with measurements of the center frequency and quality factor as a function of temperature and power. In the low-temperature and low-power limit, we have observed quality factors for NbN resonators in excess of 200,000.

12:03PM Z29.00005 Low Loss Superconducting Titanium Nitride Coplanar Waveguide Resonators , MICHAEL VISSERS, DAVID WISBEY, JIANSONG GAO, JEFFREY KLINE, MARTIN WEIDES, DAVID PAPPAS, NIST-Boulder — The introduction of new, low loss superconducting materials will be necessary for the improvement of superconducting qubits. To fulfill this aim, thin films of titanium nitride (TiN) were sputter-deposited onto intrinsic Si and c-plane sapphire wafers with and without SiN buffer layers. The films were then fabricated into RF coplanar waveguide resonators, and internal quality factor measurements were taken at millikelvin temperatures in both the high and low power limits, i.e. many and single photon regimes, respectively. At high power, internal quality factors (Qi's) higher than 10^7 were measured for multiple TiN films with a predominantly (200) orientation. Films that showed significant (111) texture invariably had much lower Qi's in this regime, on the order of 10^5. Our studies show that the (200) TiN is favored for growth at high temperature on either bare Si or substrates with SiN buffer layers. However, growth on bare sapphire or Si (100) at low temperature resulted in primarily a (111) orientation. Ellipsometry and Auger measurements indicate that the (200) TiN growth on the bare Si substrates is correlated with the formation of a thin, $\sim$2nm, layer of SiN during the pre-deposition procedure. We found that TiN grown on these surfaces also showed significant increases of Qi in the low power limit, while thicker SiN buffer layers resulted in reduced Qi's.

12:15PM Z29.00006 Dielectric loss measurements using an embedded transmission line resonator[1] , BAHMAN SARABI, M.J.A. STOUTIMORE, MOE KHALIL, SERGIY GLADCHENKO, University of Maryland and Laboratory for Physical Sciences, ALEXANDER KOZEN, GARY RUBLOFF, F.C. WELLSTOOD, J.C. LOBB, University of Maryland, K.D. OSBORN, Laboratory for Physical Sciences — Lossy dielectrics are a major source of decoherence in superconducting qubits. Superconducting linear resonators have proven to be ideally suited for measuring loss in different dielectrics due to their versatility and relative simplicity in design, fabrication, and measurement. We will present data from samples where the low-loss coplanar resonators are fabricated on top of AlOx dielectric films grown using atomic layer deposition (ALD). Although the low-power loss can be extracted from this geometry, embedding the dielectric under study between metal films has advantages that we will discuss. In addition, ALD films can be grown conformally and without pinholes to small thicknesses in comparison to conventional PECVD films. This allows us to make lumped-element resonators with a relatively small footprint, which can easily be embedded within the transmission line.

[1]This research was supported by the Intelligence Advanced Research Projects Activity through the U.S. Army Research Office award No. W911NF-09-1-0351.

12:27PM Z29.00007 Design and Fabrication of High Q Titanium Nitride Resonators , DAVID WISBEY, JIANSONG GAO, MICHAEL VISSERS, JEFFREY KLINE, MARTIN WEIDES, DAVID PAPPAS, National Institute of Standards and Technology — Titanium nitride (TiN) is a new material that shows promise in quantum information circuits as a low loss material for resonators, and as a multiplexed kinetic inductance photon detector. We have measured lumped element LC resonators and coplanar waveguides resonators. For the lumped element resonator we report internal quality factor (Qi) of over 300,000 at low power, in the single photon regime, and 4 million at high power, and for a half wave coplanar waveguide we report low power Qi of 800,000 and high power Qi of 5 million. We found that overetch in single layer devices can shift the resonance frequency and affect the internal quality factor Qi, and that as the trench depth grew, both the resonance frequency and internal quality factor increased. When designing resonators it is important to know quantities such as the kinetic inductance, superconducting transition temperature (Tc), penetration depth, and amount of overetch so the resonator can be accurately simulated.

Session Z33 DCMP: Quantum Fluids and Solids II C143/149

11:15AM Z33.00001 Dissipation of compound torsional oscillator loaded with solid ^{4}He containing ^{3}He impurity level from 0.3 to 25 ppm[1] , PATRYK GUMANN[2], MICHAEL KEIDERLING, DAVID RUFFNER, Rutgers University, HARRY KOJIMA — High sensitivity of supersolid phenomenon in solid ^{4}He to low levels of ^{3}He impurity(x_3) is a puzzle not yet understood. We have analyzed the data taken using our compound torsional oscillator on the variation of dissipation as x_3 was varied between 0.3 and 25 ppm. The compound oscillator allows studies of the dissipation at two oscillator mode frequencies(0.5 and 1.2 kHz). Arrhenius plots of temperatures, where peaks in dissipation occur, vs. frequency allow extracting the activation energy and the characteristic time. The data are consistent with distributions of activation energy whose widths increase with x_3 but the mean value of $\sim$ 430 mK independent of x_3. The characteristic time varies approximately as $\propto x_3^{2/3}$. Temperature dependence of the dissipation is consistent with Debye model but frequency dependence is not. We give an interpretation of the characteristic time in terms of diffusion of ^{3}He along dislocation lines.

[2]Present address: Institute for Quantum Computing, University of Waterloo, Waterloo, Canada

11:27AM Z33.00002 The rotation anomaly of high quality ^{4}He single crystals , XAVIER ROJAS, ARIEL HAZIOT, Ecole Normale supérieur, Paris, JOSHUA T. WEST, MOSES H.W. CHAN, The Pennsylvania State University, HUMPREY MARIS, Brown University, SÉBASTIEN BALIBAR, Ecole Normale supérieur, Paris — We have built a transparent torsional oscillator in order to monitor the growth of ^{4}He crystals near 20 mK. It allows us to measure the rotational inertia of high quality oriented single crystals and compare it with low quality crystals or polycrystals grown at constant volume. It is also possible to vary the ^{3}He concentration from 0 to 0.3 ppm (natural purity). Since the change in TO period associated with the change in shear modulus of the He sample could be calculated, we could see if supersolidity is really due to superflow along dislocation lines.

11:39AM Z33.00003 Shear Modulus of Solid Helium Confined in Aerogel[1] , ARIF RABBANI, JOHN BEAMISH, University of Alberta — Torsional oscillator experiments on ^{4}He show supersolid behavior which appears to be associated with disorder. However, confining helium in the pores of an aerogel does not enhance the supersolid decoupling, even though x-ray measurements confirm that the crystals are highly disordered. Solid helium's shear modulus also shows anomalous behavior below 150 mK, stiffening as mobile dislocations are pinned by ^{3}He impurities at low temperatures. A highly porous material such as aerogel should also provide effective pinning sites for dislocations. We have made shear modulus measurements on solid ^{4}He grown in a 95% porosity aerogel. We see large modulus decreases as the samples are warmed but these occur at much higher temperatures and over a broader range than in bulk ^{4}He. The frequency dependence of the modulus and dissipation are consistent with a thermally activated process. The activation energies are roughly 10 to 15 K and may be associated with vacancy motion.

[1]This work was supported by NSERC.

11:51AM Z33.00004 Possible glass anomalies in the shear modulus and dielectric function of solid helium , JUNG-JUNG SU, MATTHIAS J. GRAF, ALEXANDER V. BALATSKY, Los Alamos National Laboratory — The shear modulus of solid ^{4}He exhibits an anomalous change at low temperature that is qualitatively similar to a frequency change in torsional oscillator experiments. We propose that in solid ^{4}He the stiffening of the shear modulus with decreasing temperature can be described with a generalized susceptibility including a glassy backaction by assuming a distribution of temperature-dependent relaxation times $\tau(T)$. The glass susceptibility captures the freezing out of glassy degrees of freedom below a characteristic crossover temperature T_X, when the dynamic response of the solid satisfies $\omega\tau(T_X) \sim 1$, thus leading to a viscous response. We predict that the maximum change of the amplitude of the shear modulus and the height of the dissipation peak are independent of the applied frequency ω. Recent measurements of the dielectric function $\epsilon(\omega)$ by the UFL group show a similar amplitude increase. We propose that changes in $\epsilon(\omega)$ are due to the glassy dynamics of low-lying excitations and are related to the shear modulus through acousto-optical coupling. We predict a dissipation peak in the imaginary part of the dielectric function, where the change in the real part is largest.

12:03PM Z33.00005 Stress induced roughening of superclimbing dislocation in solid ^{4}He[1] , DARYA ALEINIKAVA, ANATOLY KUKLOV, CSI, CUNY — We investigate numerically superclimb [1] of dislocation in solid ^{4}He biased by externally imposed chemical potential μ. The effective action takes into account quantum phase slips in the core superfluid as well as the core displacement in Peierls potential within the Granato-Lücke string model. The bias produces stress on the core and this can result in dislocation roughening. Such roughening is characterized by hysteretic behavior at temperatures (T) below some threshold $T_{\rm hyst}$. At $T > T_{\rm hyst}$ strong resonant peaks develop in the dislocation differential response. These peaks exhibit periodic behavior vs μ, with the period determined by Peierls potential and dislocation length. We explain these effects by thermally assisted tunneling of jog-antijog pairs across the barrier created by Peierls potential and the bias. Since superclimbing is controlled by core superflow, speed of sound along the superfluid core exhibits dip-like features at the peak positions. We propose that this effect is seen in the mass transport experiment [2].

12:15PM Z33.00006 Andreev-Lifshitz Theory Applied to Normal Solids under Pressure[1] , MATTHEW SEARS, WAYNE SASLOW, Texas A&M University — On letting the superfluid density go to zero, the Andreev-Lifshitz hydrodynamic theory of supersolids becomes applicable to an ordinary solid.[2] Under applied pressure P_a, needed to produce solid He^3 and He^4 or to be of geophysical relevance, the system has both an elastic stress λ_{ik} and an internal pressure P, with $P\delta_{ik} = P_a\delta_{ik} + \lambda_{ik}$ in equilibrium. P may be thought of as being due to a vacancy fluid. For P_a small compared to the bulk modulus, Maxwell relations give $P \sim P_a^2$. The dynamical equations lead to three sets of propagating elastic modes (longitudinal and transverse sound) and two diffusive modes (one largely of entropy density and one largely of vacancy density – or, more generally, defect density), all of which we study for non-zero P_a.[3] The vacancy diffusion mode has diffusion constant $D_L \sim P_a^2$, and is diffusive because its associated internal pressure fluctuation P' nearly cancels its lattice stress fluctuation λ'_{ik}. This mode permits the system to respond differently to transducers with different surface treatments. We specifically have in mind solid ^{4}He, which requires $P_a \sim 25$ bars to solidify; however, the results should apply to any solid under pressure.

12:27PM Z33.00007 Quantum phases of grain boundaries in solid ^{4}He[1] , DEBAJIT GOSWAMI, KINJAL DASBISWAS, ALAN DORSEY, Department of Physics, University of Florida — First-principles Monte Carlo simulations show that the core of a dislocation in solid ^{4}He is superfluid and has Luttinger-liquid like properties [Phys. Rev. Lett. **99**, 035301 (2008), Phys. Rev. Lett. **103**, 175301 (2009)]. Low angle grain boundaries in crystals can be thought of as a linear array of dislocations, suggesting that a grain boundary in solid ^{4}He can be modeled as an array of coupled Luttinger liquids. By exploiting this analogy, in this work we study the quantum phases of the grain boundary, as well as analogies with dipolar condensates in one dimensional optical lattices.

[1]This work is supported by the NSF

12:39PM Z33.00008 Supersolid ^{4}He monolayer , MASSIMO BONINSEGNI, University of Alberta — The conditions for the existence of a low temperature supersolid ^{4}He monolayer are investigated by Monte Carlo simulations. The crystalline film considered here is one that not registered with the underlying substrate crystal structure. Its superfluid response is underlain by large zero-point motion of atoms in the direction perpendicular to the substrate. It is proposed that the physics described here might be observable in a helium film adsorbed on a Ni substrate.

12:51PM Z33.00009 U(1) $\times$ U(1) Kosterlitz-Thouless transition of the Larkin-Ovchinnikov phase in an anisotropic two-dimensional system , CHUNGWEI LIN, XIAOPENG LI, W. VINCENT LIU, University of Pittsburgh — We study Kosterlitz-Thouless (KT) transitions of the Larkin-Ovchinnikov (LO) phase for a two-dimensional system composed of coupled one-dimensional tubes. The main character of LO phase is a stripe structure (periodic in only one direction) in the order parameter. The low energy excitations involve the deformation of the stripe configuration and the fluctuation of the phase which can be described by two anisotropic XY model. We compute from a microscopic model the coefficients of XY model from which the KT transition temperatures are determined. We found the $T^{KT} \propto t_\perp$ for small intertube tunneling $t_\perp$. As $t_\perp$ increases the system undergoes a first-order transition to normal phase at zero temperature. Our method can be used to determine the Goldstone excitations of any stripe order involving charge or spin degrees of freedom.

1:03PM Z33.00010 Small-angle Neutron Scattering Measurements of Liquid Helium Mixtures Confined in MCM-41[1] , HELMUT KAISER, Low Energy Neutron Source (LENS), Indiana University, TIMOTHY PRISK, PAUL SOKOL, IAN STEWARD, Indiana University Department of Physics, CLAUDIA PANTALEI, Ecole Normale Superieure — Small-angle neutron scattering (SANS) was used to study the isotopic distribution of liquid helium mixtures confined in MCM- 41, a silica glass with a 2D hexagonal net of monodisperse cylindrical pores, as a function of filling and He^3 concentration. The ordered pore array of MCM-41 gives rise to Bragg reflections with intensities determined by both how the liquid fills the pores and how the isotopes are distributed within the pores. The modulation in peak intensity can be modeled by writing down a form factors for cylindrical objects with varying scattering length density. Comparison will be made with small-angle X-ray (SAXS) scattering measurements performed with synchrotron light on liquid helium mixtures confined in aerogel.

[1]This work was supported by award 70NANB5H1163 from NIST, U.S. DOC. This Research at Oak Ridge National Laboratory's High Flux Isotope was sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, U. S. Department of Energy.

1:15PM Z33.00011 Deep Inelastic Neutron Scattering Study of Nanoconfined Liquid Helium Mixtures[1] , PAUL SOKOL, TIMOTHY PRISK, NARAYAN DAS, Indiana University Department of Physics — The single-particle momentum distribution $n(p)$ plays a central role in the contemporary understanding of quantum many- body systems, especially the helium liquids. The superfluid behavior of liquid He^4 below the famous lambda-point temperature is associated with the Bose condensation of a macroscopic fraction of the He^4 atoms to the zero momentum state. This manifests itself in $n(p)$ as a δ-function singularity at $p = 0$. Similarly, the Fermi liquid character of He^3 is associated with a sharp discontinuity in the Fermi surface at the Fermi momentum p_F. Using the Wide Angular Chopper Spectrometer at the Spallation Neutron Source, we recently carried out a deep inelastic neutrons scattering study of dilute He^3 + He^4 solutions confined in mesoporous MCM-41 in order to investigate the effects of confinement on the non-classical momentum distribution of an isotopic helium solution. The Bose condensate fraction, Fermi surface, average isotopic kinetic energies, and related work in the literature will be discussed.

1:27PM Z33.00012 A Luttinger liquid core inside helium-4 filled nanopores , ADRIAN DEL MAESTRO, Johns Hopkins University — We study the effects of confining helium-4 at low temperatures inside long narrow pores with nanometer radii using worm algorithm path integral quantum Monte Carlo. The results show that even in the phase with a finite superfluid response, the interaction between helium atoms and the surface of the pore induces radial density oscillations which decay as the center of the pore is approached. For some special radii, an "inner tube" of helium atoms exists, and a careful scaling analysis confirms that it behaves like a one dimensional Luttinger liquid at low energies.

1:39PM Z33.00013 ^{4}He Adsorption on a Single Graphene Sheet: Path-integral Monte Carlo Study , YONGKYUNG KWON, School of Physics, Konkuk University, DAVID CEPERLEY, Dept. of Physics, U. of Illinois at Urbana-Champaign — We have performed path-integral Monte Carlo calculations to study ^{4}He adsorption on a single graphene sheet, where the ^{4}He-substrate interaction is described by the sum of the helium-carbon pair potentials. Among those proposed to account for helium scattering data on the graphite surface, we employ three different types of the inter-atomic pair potentials; a spherical 6-12 potential, an anisotropic 6-12 potential, and an anisotropic Yukawa-6 potential. Regardless of the choice of the pair potential, a first ^{4}He monolayer is found to show the $C_{1/3}$ commensurate structure at a surface density of 0.0636 Å^{-2} and to go through the domain wall phases for densities above the commensurate one before crystallizing into an incommensurate triangular solid. Below the commensurate density, however, the low-temperature phase of this helium adlayer varies depending on the choice of the ^{4}He-substrate interaction. The calculation based on the spherical pair potentials suggests a superfluid liquid phase at lower densities while incorporation of anisotropy into the helium-carbon pair potential results in a low-density state of a solid with clustered vacancies. Finally we observe van der Waals correlation between the upper monolayer and the one below the graphene sheet. The effects of this interlayer correlation on a possible formation of stable vacancies will be discussed.

1:51PM Z33.00014 Commensurate-Incommensurate Transition in ^{4}He Monolayer Adsorbed on a C_{60} Molecule , HYEONDEOK SHIN, YONGKYUNG KWON, School of Physics, Konkuk University — Path-integral Monte Carlo calculations have been performed to study adsorption of ^{4}He on a single C_{60} fullerene molecule. In order to account for helium corrugations on the molecular surface, the sum of all interatomic pair potentials between a carbon atom and a ^{4}He atom is used for the ^{4}He-C_{60} interaction. The radial density distributions reveal a layer-by-layer growth of ^{4}He with the first adlayer being located at a distance of $\sim$ 6.2 $\mathring{A}$ from the center of a C_{60} molecule. This first layer is found to exhibit various quantum states as the number of adsorbed ^{4}He atoms N varies. For N=32 the helium layer shows a commensurate solid structure with twenty helium atoms being localized on the tops of the hexagon centers of the C_{60} surface and the other twelve atoms above the pentagon centers. As more ^{4}He atoms are added, a commensurate-incommensurate transition is observed. After going through various domain wall states the first layer is crystallized into an incommensurate solid for $N \sim 52$. We find that solid states observed for N=32,44, and 48 do not show any superfluid response even below 0.2 K while domain-wall fluids formed with 45 to 47 ^{4}He atoms show significant superfluid fractions below 0.6 K. Finally different quantum states oberseved in the first ^{4}He layer around a C_{60} are compared with phase diagrams determined for the helium monolayer on a graphite surface.

Session Z35 DCMP: Insulators and Dielectrics II C140

11:15AM Z35.00001 Opacification of dielectrics oxides investigated by infrared emittance spectroscopy , MYRIAM ECKES, DOMINGOS DE SOUSA MENESES, MOHAMMED MALKI, PATRICK ECHEGUT, CEMHTI-CNRS, Universite d Orleans, Orleans, France — With increasing temperature, some compounds that are transparent in the near infrared range at room temperature become progressively opaque towards the liquid phase. Such a behavior deeply impacts their thermal radiative properties which knowledge is of main importance in crystal growth processes for example. To understand this phenomena, infrared emittance spectra were acquired from room temperature up to the liquid state on crystalline $LaAlO_3$ and $LiAlO_2$. The samples are heated with a CO_2 laser that allows a direct measurement of emittance up to their melting point and in a wide spectral range, i.e. between 50 and 10000 cm^{-1}. In the transparency region, we observed an increase of emittance up to 1000 K for $LaAlO_3$ (more than 1000 K before the solid to liquid transition) and no significant increase of emittance for $LiAlO_2$ before the solid to liquid phase transition. The experimental data have been fitted with a dielectric function model including a Debye relaxation term. The absorption mechanism at the origin of the opacification is thermally activated and has a relaxation time compatible with a motion due to electrons. Electrical conductivity measurements of these compounds were also made up to 800K.

11:27AM Z35.00002 Non-equilibrium ballistic phonon transport in microstructures , JARED HERTZBERG, OBAFEMI OTELAJA, RICHARD ROBINSON[1], Cornell University — We demonstrate a method to locally excite and detect phonon modes in silicon microstructures. Decay of quasiparticles injected into an adjacent superconducting film excites phonons in a non-thermal spectral distribution [1]. Phonons of frequency of order 100 GHz are detected by the excitations they cause in a second superconducting film, after ballistically traversing microstructures of 10 to 50 micron dimension. Measurements are made at temperatures of 0.3 to 1.2 K. Such a device advances the goal of building a nanoscale phonon spectrometer to study acoustic confinement and surface scattering effects. This work is supported by KAUST (KUS-C1-018-02), NSF (DMR 0520404), and DOE (DE-SC0001086).

11:39AM Z35.00003 Dielectric measurements above 100 GHz using a high-Q open hemispherical resonator , REZWANUR RAHMAN, JOHN SCALES, Department of Physics, Colorado School of Mines — High-Q cavities can be used to study materials (or perturbations to materials) whose effects are too small to be seen by other methods. We have developed a millimeter wave cavity operating above 100 GHz in order to measure the dielectric properties of thin films and ultra low loss materials. The cavity is a open hemispherical resonator. Millimeter waves are introduced and measured via 2 closely spaced sub-wavelength holes in the center of a 15cm spherical, copper mirror. Cavity perturbation techniques are applied to extract the complex permittivity of a sample. This is a paraxial system and axissymmetric modes are of primary interest but nonaxisymmetric modes area also generated and need to be dealt with. Applications to thin films and other materials will be shown. This was was partially supported by US Department of Energy under grant DE-FG02-09ER16018

11:51AM Z35.00004 ABSTRACT WITHDRAWN –

12:03PM Z35.00005 Comparison between Resonant Inelastic X-Ray Scattering and the Dynamical Structure Factor , CHUNJING JIA, CHENG-CHIEN CHEN, BRIAN MORITZ, ADAM SORINI, THOMAS DEVEREAUX, Stanford/SLAC — Momentum dependent resonant inelastic X-ray scattering (RIXS) is an effective probe of many-body excitations. Theoretical and experimental work has shown that under certain circumstances RIXS can be viewed as an approximate probe of the dynamical structure factor $S(q,\omega)$. We perform cluster diagonalization combined with the bi-conjugate gradient stabilized method to model the RIXS spectra and $S(q,\omega)$ for the single-band and multi-orbital Hubbard models. While these two cross sections share some similar features, there are significant quantitative differences, which highlight the qualitative distinction between these two probes.

12:15PM Z35.00006 Observations of ferroelastic switching by Raman spectroscopy in 18-percent ceria-stabilized zirconia , AMY BOLON, Texas A&M University, JUAN MUNOZ SALDANA, Cinvestav-Quetetaro, MOLLY GENTLEMAN, Texas A&M University — Ferroelastic switching has been shown to be responsible for significant increases in the toughness of tetragonal zirconia ceramics. Observations of switching and measurements of coercive stress have generally been limited to TEM studies on large single crystals. In this study we show that it is possible to observe ferroelastic switching in 18 mole-percent ceria stabilized zirconia using polarized confocal Raman spectroscopy. Observations were made on bulk polycrystalline samples indented with a standard Vicker's indent and exhibited reorientation of crystal domains along the crack as well as near the crack tip. Coercive stress measurements were made by loading the samples uniaxially while making measurements of domain orientation.

12:27PM Z35.00007 Impact of Bond Coordination and Percolation on Mechanical Properties of a-SiC:H Thin Films

, SEAN KING, JEFF BIELEFELD, Intel Corporation, BRIAN DALY, Vassar College — Plasma Enhanced Chemically Vapor Deposited a-SiC:H thin films are compelling materials for both semiconductor nano-electronic and MEMS/NEMS technologies due to the extreme chemical inertness of this material and the ability to tune a variety of material properties across an extreme range of values. As one example of the latter, we demonstrate that using PECVD the Young's modulus of a-SiC:H thin films can be varied from $<$ 10 GPa to $>$ 200 GPa and the Hardness can be varied over an equally impressive range of $<$ 0.5 to $>$ 30 GPa. Utilizing Fourier Infrared-Transform Spectroscopy, we show that this remarkable range in materials properties is achieved primarily via the incorporation of terminal hydrogen groups which lowers the overall connectivity of the Si-C network bonding. We find that once the average network coordination number for Si and C falls below 2.6, the Si-C network becomes under constrained and there is a loss of rigidity percolating through the system. There results are compared and found to be in agreement with constraint theory for amorphous materials.

12:39PM Z35.00008 First Principles Investigation of Structure and Electronic Properties of $a-$ Si_3N_4

, RAVI PRAMOD VEDULA, NATHAN L. ANDERSON, ALEJANDRO STRACHAN, Purdue University — We use a combination of molecular dynamics with empirical inter-atomic potentials and density functional theory (DFT) calculations to generate an ensemble of statistically independent, well relaxed a-Si_3N_4 structures. Variations in the annealing conditions used to generate the structures lead to zero-stress structures spanning a wide range of densities (2.6g/cm^3 to 3.1g/cm^3) but exhibiting very similar cohesive energies. The bulk modulus was found to be varying between 110-180 GPa depending on the density. The predicted density variation agrees well with the range in experimentally observed density, resulting from different fabrication conditions. The radial distribution functions and angle distributions for different densities are in good agreement with diffraction experiments; further validating our models. The slow annealing procedure used to generate the structures leads to well equilibrated structures with relatively small density of coordination defects and several defect free structures. We also compute the formation energy and charge transition levels for the defects found.

12:51PM Z35.00009 Thermal transport and surface sensitivity in suspended amorphous silicon nitride thin films[1]

, R. SULTAN, A.D. AVERY, D. BASSETT, B.L. ZINK, University of Denver, Physics and Astronomy — Thermal transport in disordered materials continues to provide surprising new results, which often have direct consequences for applications ranging from quantum computation to cutting-edge cosmology. For example, some of the most sensitive detectors of radiation currently in use are thermal detectors that use highly sensitive micromachined thermometers to register the temperature rise caused by absorption of incident light or particles. To achieve this sensitivity, the thermometer is commonly thermally isolated using free-standing amorphous silicon-nitride membranes. As a result, the heat flow through this material is often a critical design parameter. In this talk we present recent measurements of thermal conductivity of a large number of suspended silicon-nitride structures. The results show not only deviation from previously reported measurements, but also very clear but somewhat puzzling dependence on the surface preparation of the structures. Such surface-sensitivity is expected at very low temperatures, but is seen in our experiments even near 300 Kelvin, where one normally expects heat flow to be dominated by carriers with very short mean-free-paths. We discuss possible interpretation of our results and compare to other recent surprises in the thermal properties of disordered materials.

1:03PM Z35.00010 Accessing short and intermediate range orders of silicate glasses by infrared spectroscopy

, DOMINGOS DE SOUSA MENESES, Université d'Orléans, Polytech'Orléans, Avenue du Parc Floral, BP 6749, 45067 Orléans Cedex 2, France, CRISTIANE N. SANTOS, MYRIAM ECKES, CNRS, UPR3079 CEMHTI, 1D Avenue de la Recherche Scientifique, 45071 Orléans Cedex 2, France 2, YANN VAILLS, Université d'Orléans, Polytech'Orléans, Avenue du Parc Floral, BP 6749, 45067 Orléans Cedex 2, France, PATRICK ECHEGUT, CNRS, UPR3079 CEMHTI, 1D Avenue de la Recherche Scientifique, 45071 Orléans Cedex 2, France 2 — The characterization of short and intermediate range orders in glasses is a very active field since this knowledge is of main importance for understanding how order impacts their properties. The chemical simplicity of binary silicate glasses makes them model systems that are suitable to show how their dielectric functions include such kind of information. We show that it is possible to extract from infrared reflectivity measurements no solely quantitative information on short range order, i.e. populations of Q^n tetrahedral units (n : number of bridging oxygens) but also intermediate range information like the presence and evolution of 3D network silicate clusters and silicate sheet clusters. Examples will be given for alkaline silicates glasses and discussed in the light of predictions obtained from structural glass models and literature results.

1:15PM Z35.00011 In situ high-temperature infrared emissivity spectroscopy of silicate glasses and glass-ceramics[1]

, CRISTIANE N. SANTOS, DOMINGOS DE SOUSA MENESES, VALERIE MONTOUILLOUT, PATRICK ECHEGUT, CEMHTI - CNRS, Universite d Orleans, Orleans, France — Glasses and glass-ceramics are materials of widespread application in industry, building, photonics, microelectronics and medicine. Glass-ceramics are obtained by controlled glass crystallization, and many efforts have been done in the last years to better understand the structural changes occurring in this process. Here we show that in situ infrared emissivity spectroscopy is also a suitable technique for this purpose and a wide spectral and temperature range could be accessed (25-16000 cm^{-1} and 400-1700 K, respectively). We use a home-made instrument composed of two spectrometers, and a CO_2 laser for locally heat the glass samples up to the melt. A dielectric function model was applied to fit the experimental data and compute the materials optical properties. We show that using new decomposition procedure quantitative information on the distribution of the Q^n tetrahedral units (n being the number of bridging oxygen) can be obtained. The results at room temperature are in good agreement with recent molecular dynamics simulations. The major changes occur during quartz crystallization, with a remarkable increase of Q^4 units.

1:27PM Z35.00012 CrN electronic structure and vibrational modes: an optical analysis[1]

, XUNYUAN ZHANG, DANIEL GALL, Department of Materials Science and Engineering, Rensselaer Polytechnic Institute, 110 8th ST, Troy, NY 12180 — The electronic structure of the paramagnetic insulating phase of CrN is investigated using optical spectra from epitaxial CrN(001) layers. The imaginary part of the dielectric function indicates direct interband transitions at $\hbar\omega$ = 0.64, 1.5 and 2.9 eV, and suggests a depletion in the density of states at the Fermi level. This is attributed to local magnetic moments that cause splitting of the t_{2g} bands and the formation of an indirect band gap of 0.19$\pm$0.46 eV, as estimated by comparing the optical transition energies with reported direct gap energies from calculations with different magnetic ordering and Coulomb interaction terms. The dielectric function shows a strong resonance at $\hbar\omega_0$ = 48.7$\pm$0.2 meV, and values of dielectric constants ε_{dc} = 53$\pm$5 and ε_∞ = 22$\pm$2, respectively, providing values for transverse and longitudinal optical phonon frequencies at the zone center of 11.7 and 18.2 THz, respectively. The vibrational frequencies are confirmed by Raman spectroscopy peaks at 800, 1170, and 1330 cm^{-1} which are attributed to 2TO(X), 2LO(X), and 2LO(L) modes.

1:39PM Z35.00013 Surface states control and thermoelectric properties of CrN films , ANTIA S. BOTANA, ALBERTO PIÑEIRO, University Santiago de Compostela, VICTOR PARDO, University of California Davis, DANIEL BALDOMIR, University Santiago de Compostela — The manipulation of the electronic structure of a material by quantum confinement has attracted much attention recently, e.g. the appearance of conducting surface states or the novel phenomena at the interface between oxides being the most notorious. CrN is a degenerate semiconductor with large thermoelectric power in the bulk[1]. We have performed electronic structure calculations in thin CrN films and studied the evolution of the electronic structure and conduction properties (calculated using Boltzmann formalism) with thickness, focussing on the evolution of the Seebeck coefficient and electrical conductivity. We have utilized a density functional theory (LDA+U) formalism for our calculations with the U value (4 eV) that reproduces the experimental gap for the material as a bulk. When nanostructured, (almost conducting) surface states arise due to the dangling bonds at the surface that reduce the symmetry of the octahedral crystal field around Cr. When the film is relaxed, a gap opens and the material remains semiconducting. In addition, we have analyzed the role of these surface states in a possible improvement of the CrN thermoelectric properties by studying the figure of merit dependence with thickness.

1:51PM Z35.00014 Temperature Dependence of Internal Deformation Field in Zeolites[1] , WONSUK CHA, SANGHOON SONG, NAK CHEON JEONG, TUNG PHAM, Sogang University, Korea, ROSS HARDER, Advanced Photon Source, ANL, GANG XIONG, University College London, UK, KYUNG BYUNG YOON, Sogang University, Korea, IAN K. ROBINSON, University College London, UK, HYUNJUNG KIM, Sogang University, Korea — We studied temperature dependent internal deformation field distributions in zeolite microcrystals using coherent x-ray diffraction. We measured the coherent x-ray diffraction patterns around (200) and (020) Bragg peaks of the crystals. The three-dimensional real space images were obtained by phasing and inverting the oversampled diffraction patterns using the phase retrieval algorithm combined with error reduction and hybrid input-output method. The internal deformation fields show unusual temperature dependent behaviors which might be originated from the synthesis and calcination process.

[1]This work was supported by National Research Foundation of Korea (Nos. 2010-0000112 and R15-2008-006-01001-0), Seoul Research and Business Development Program (10816), and Sogang University Research Grant (2010).

2:03PM Z35.00015 Tension in the Initial Growth Stages of Sputter Deposited WSi_2 on Si in Multilayers[1] , ALBERT MACRANDER, Argonne, KIMBERLEY MACARTHUR, Argonne/NIU, BING SHI, Argonne, RAY CONLEY, ANL/BNL — We concentrate on the initial stages of growth of sputtered amorphous multilayers with equal WSi_2 and Si layer thicknesses of 5.5 nm, and we report observations of tension in the first 1.1 nm of WSi_2 grown on Si layers. Measurements of wafer curvature were made *in-situ* in the sputtering chamber. Stresses in the conjugate interface of Si on WSi_2 were observed to be significantly smaller. A clear asymmetry in the stress of these conjugate interfaces rules out an explanation based solely on lattice misfit. We find a value of 1.3×10^{10} dynes/cm^2 for the biaxial film stress at the WSi_2 on Si interface grown at 2.3 mTorr of Ar pressure, a value comparable to values calculated for hybridization of Si(111) facets by various adatoms [1]. Our observations thereby support a model for chemically induced changes in packing density during sputtering of the interfaces. As an example of a particular application, WSi_2/Si multilayers consisting of many hundreds periods have been used to make lenses for nanofocusing of hard x-rays [2-3].

Session Z39 DCP: Surfaces, Interfaces and Colloids A124/127

11:15AM Z39.00001 Two-dimensional soft solids: a rheological study[1] , GABRIEL ESPINOSA, Department of Physics, Simon Fraser University, Burnaby, BC, DUYANG ZANG, Laboratory of Materials Science in Space, Northwestern Polytechnical University, Xi-an, China, DOMINIQUE LANGEVIN, Laboratoire de Physique des Solides, Université Paris Sud, Orsay, France, BERNARD BINKS, Department of Chemistry, University of Hull, Hull, UK — Many soft solids, such as concentrated suspensions, emulsions, foams, behave in a similar way under an applied shear: they exhibit a Maxwell-type relaxation with a characteristic relaxation time that varies inversely with the applied shear rate. When the storage and loss moduli are measured at different frequencies and constant shear rate, the curves obtained can be rescaled [1]. We will show here that the behavior in two dimensions can be strikingly similar. We will present data on monolayers of nanoparticles and on mixed layers made with DNA and surfactant. The physical origin of the relaxation time will be discussed. The nonlinear behavior will be also discussed. Depending on the compaction degree, the layers can behave as brittle or plastic solids. This has been confirmed by images of the layers after a shear deformation made using Brewster angle microscopy.

11:27AM Z39.00002 ABSTRACT WITHDRAWN –

11:39AM Z39.00003 Direct measurement of short range colloidal interactions using digital holographic microscopy[1] , REBECCA W. PERRY, Harvard University, Sch. of Engineering and Applied Sciences, JEROME FUNG, DAVID M. KAZ, GUANGNAN MENG, Harvard University, Dept. of Physics, VINOTHAN N. MANOHARAN, Harvard University, Dept. of Physics and Sch. of Engineering and Applied Sciences — Using digital holographic microscopy, we record the 3D positions of micron-sized polystyrene particles as they approach and retreat from each other. Analysis of the holograms using an exact solution for the scattering from pairs of spheres allows us to separate vibrational, translational, and rotational motion. The vibrational mode supplies the information needed to characterize the inter-particle interactions down to separation distances on the order of 10 nm. In particular, we study an aqueous system of one micron diameter sulfate-coated polystyrene beads suspended in a solution of 95 nm hydrogel particles. The attractive depletion interaction we measure deviates from the Asakura-Oosawa model, likely because of electrostatic interactions at these short distances.

[1]We acknowledge support from NSF through grant no. CBET-0747625 and the NSF graduate research fellowship program.

11:51AM Z39.00004 Fabrication of Monolayer of Polymer/Colloids Hybrid at a Water-Air Interface , CHI-CHIH HO, TING-HUI CHEN, PO-YUAN CHEN, KENG-HUI LIN, WEN-TAU JUAN, WEI-LI LEE, Institute of Physics, Academia Sinica, INSTITUTE OF PHYSICS, ACADEMIA SINICA TEAM — Polymer-assisted assembly of polystyrene (PS) colloids with diameter ranging from 100 nm to 1 μm at water-air interface is demonstrated. Initially, PS colloids were slowly spread onto water surface and crystallized into triangular lattice with finite separation between colloids due to the coulomb repulsive force. By adding merely 1-3 ppm water-soluble polyethylene oxide (PEO) in water, the colloids gradually moved closer. Eventually, the separation between colloids was equal to or less than 60 nm determined from its diffraction pattern by a laser beam. In addition, the Brownian motion of colloids was suppressed by the PEO adsorption effect which was demonstrated from the analysis of colloids trajectory recorded by ultra high speed camera. We showed that the resulting monolayer of colloids /PEO hybrid can be deposited on various substrates, including a plastics sheet, curved surface and even across 10 μm-diameter hole. Our method may further extend the scope of nanosphere lithography technique for large area nanostructure fabrication.

12:03PM Z39.00005 Heterogeneous crystallization of hard-sphere colloids near a wall[1] , KYRIL SANDOMIRSKI, Heinrich-Heine-Universitaet Duesseldorf, IPkM, Universitaetstraße 1, D-40225 Duesseldorf, Germany, ELSHAD ALLAHYAROV[2], Physics Department, CWRU, Cleveland OH, USA, HARTMUT LÖWEN, Heinrich-Heine Universitaet Duesseldorf, Institut fuer Theoretische Physik II, Universitaetstraße 1, D-40225 Duesseldorf, Germany, STEFAN EGELHAAF, Heinrich-Heine-Universitaet Duesseldorf, IPkM, Universitaetstraße 1, D-40225 Duesseldorf, Germany — Confocal microscopy experiments and equilibrium Brownian Dynamics computer simulations were combined to investigate heterogeneous crystallization near a hard wall in a suspension of hard-sphere colloids. Particles near the wall initially rearrange, before an extended regime of steady-state crystal growth is observed. Finally, a depletion zone develops which slows down the progressing crystal-fluid interface. In good agreement between experiment and simulation, the steady-state growth velocity shows a maximum in its dependence on the bulk volume fraction. Beyond this, these techniques allow us to obtain local microscopic information on the level of individual particles, namely the temporal evolution of the density profiles in the fluid and crystal phase as well as the width of the interface.

12:15PM Z39.00006 ^{19}F NMR Study of Molecular Aggregation of Lithium Perfluorooctylsulfonate in Water at Temperatures from 30 to 250 $^\circ$C , DOBRIN BOSSEV, Indiana University, MUTSUO MATSUMOTO, MASARU NAKAHARA, Kyoto University — ^{19}F NMR chemical shifts have been measured to determine the critical micelle concentration (cmc) and aggregation number (m) of lithium perfluorooctylsulfonate (LiFOS) in water at temperatures ranging from 30 to 250 $^\circ$C under the saturation pressure. The cmc slightly increases in the temperature range from 30 to 100 $^\circ$C, whereas above 125 $^\circ$C the increase is much steeper; cmc is 6.5, 13.2, and 161 mmol kg^{-1} at 30, 100, and 250 $^\circ$C, respectively. The aggregation number, estimated on the basis of a mass action model exhibits a rapid decrease in the temperature range of 30 - 125 $^\circ$C and becomes almost constant at higher temperatures; m is 36, 6.8, and 2.4 at 30, 100, and 250 $^\circ$C, respectively. Thermodynamic parameters indicate similar values for the free energy at all temperatures, and constant values for the enthalpy and entropy of aggregation at high temperatures.

12:27PM Z39.00007 Dielectric dispersion of clustered living cells via the boundary integral equation method , SAI KIT YUNG, KIN LOK CHAN, KIN WAH YU, The Chinese University of Hong Kong — We have developed a boundary integral equation (BIE) method for computing the dielectric response of clusters of biological particles like living cells. In the BIE, we formulate a surface integral equation for the scalar potential for an arbitrary number of particles of various shapes [1]. BIE method avoids matching the complicated boundary conditions on the surfaces of the particles. Numerical solutions of the eigenvalue equation yield a dielectric dispersion spectrum through the spectral representation [2]. While BIE method is valid for arbitrary surfaces, we confirm it for two approaching cylinders and a concentric cylinder. In many typical cases, the numerical results are in excellent agreement with the exact analytic results. Moreover, BIE method offers a convenient way to compute the alternating current responses, and hence the dielectric dispersion of clustered cell suspensions.

12:39PM Z39.00008 Multi scale computer simulations of the self-assembly of block copolymeric beta-peptides , JAGANNATH MONDAL, ARUN YETHIRAJ, University of Wisconsin Madison — There is considerable interest in a class of molecules made from β-amino acids (which contain an additional backbone carbon atom when compared with natural amino acids). Block copolymers of β-peptides, where one block is hydrophobic and the other is hydrophilic, self-assemble into micelles. In this work we use computer simulations to provide insight into the self-assembly of these molecules. All-atom simulation results for the free energy of association of a pair of these block co polymeric β- peptides show that a $homochiral$ hydrophobic block promotes self assembly compared to a $heterochiral$ hydrophobic block, consistent with experiment. We have also developed a coarse-grained model for these block co-polymers and simulations using this model show that these molecules spontaneously forms micelles, and the morphology of these micelles is concentration dependent, with spherical micelles at low concentrations and worm-like micelles at high concentrations.

12:51PM Z39.00009 Ab initio Study of Structure and Hydrogen Bonding of Cellulose Crystals and Surfaces[1] , JAMES DAVENPORT, YAN LI, Brookhaven National Laboratory — We have studied the equilibrium structure and hydrogen bonding of cellulose crystals and surfaces using semi-empirical dispersion corrections to density functional theory (DFT+D)[1], which has been shown to be an efficient alternative to more advanced methods for weakly bound aromatic assemblies[2]. The predicted crystal structures for both I_α and I_β phases agree well with experiments. The cohesive energy was decomposed into interchain and intersheet interactions and analyzed in terms of hydrogen bonding and van der Waals dispersion forces. Both interactions were found to be responsible for holding cellulose sheets together. In particular, the dispersion corrections to DFT proved to be indispensable in reproducing the equilibrium intersheet distance and binding strength. Adsorption energy and configuration of water molecules on cellulose surfaces were found to depend sensitively on the surface orientation, adsorption site and contribution from vdW interactions.

1:03PM Z39.00010 Interfacial free energy and stiffness of the solid-melt interface of NaCl , TATYANA ZYKOVA-TIMAN, Chemistry Department, Cambridge Uni, ERIO TOSATTI, SISSA-ISAS, International School for Advanced Studies, DAAN FRENKEL, Chemistry Department, Cambridge Uni — The importance of the interfacial free energy for the equilibrium morphology of crystals is well understood. In contrast, much less is known about to the so-called "interfacial stiffness" that governs fluctuations of, e.g., solid-liquid interfaces. We carried out molecular dynamics simulations of capillary wave fluctuations on various faces of NaCl crystals in contact with its melt, that provides new information on the behaviour of this interface at the atomistic level. The capillary fluctuations connect directly with the interfacial stiffness, and indirectly also to the interface free energy. In our simulations we studied the (100)-liquid interface and adjacent vicinals. From the angular dependence of the surface stiffness, we deduce an estimate of NaCl(100)-melt interfacial free energy and discuss limitations of the fluctuation approach. Finally we compare this estimate of the surface free energy with values obtained through other methods [1,2,3] and discuss the differences [4].

1:15PM Z39.00011 Utilization of Metal Oxides and Chalcogenides Stabilized in Organic Solvents , LESTER LAMPERT, ROBBY FLAIG, JORGE CAMACHO, JAMES HAMILTON, University of Wisconsin-Platteville — Metal oxides and metal chalcogenides are important materials for a variety of applications including photocatalysis for decomposition of water, conductive and optical coatings, catalysts, photovoltaics, pryoelectrics, self-cleaning surfaces, pigments, and high efficiency Li-insertion materials in batteries among many other applications. Fundamental discoveries of surprising solubility of insoluble materials such as single and multi-walled carbon nanotubes and graphene has lead us to discover that certain metal oxides and metal chalcogenides such as TiO2 are soluble in certain solvents. Due to the industrial importance of TiO2, discovering stable pure solvent systems demonstrates a possibility to avoid surface modification of TiO2 nanoparticles by use materials such as of (3-methacryloxypropyl)-trimethoxysilane and various other methods of artificial stabilization. We have created thin films of TiO2, transparent ultraviolet (UV) –absorptive polymers, and Li-ion battery anodes with graphene-TiO2 hybrid materials.

1:27PM Z39.00012 EPR, Endor and DFT Studies on X-Irradiated Single Crystals of L-Lysine HCl $2H_2O$ and L-Arginine HCl H_2O , YIYING ZHOU, WILLIAM H. NELSON — When proteins and DNA interact, arginine and lysine are the two amino acids most often in close contact with the DNA. In order to understand the radiation damage to DNA in vivo, which is always associated with protein, it is important to learn the radiation chemistry of arginine and lysine independently, and then complexed to DNA. This work studied X-irradiated single crystals of L-lysine·HCl·$2H_2O$ and L-arginine·HCl·H_2O with EPR, ENDOR techniques and DFT calculations. In both crystal types irradiated at 66K, the carboxyl anion radical and the decarboxylation radical were identified. Specifically, the calculations performed on the cluster models for the carboxyl anion radicals reproduced the proton transfers to the carboxyl group from the neighboring molecules through the hydrogen bonds. Moreover, computations supported the identification of one radical type within irradiated arginine as the guanidyl radical anion with an electron trapped by the guanidyl group. Based on the radicals detected in the crystal irradiated at 66K and at 298K, and the annealing experiments from the irradiation at 66K, the mechanisms of the irradiation damage on lysine and arginine were proposed, and the possible effects of irradiated arginine and lysine to the DNA within chromatin were analyzed.

1:39PM Z39.00013 Detection of Nitro aromatics via fluorescence quenching of pegylated and siloxanated 4, 8-dimethylcoumarins[1] , ABHISHEK KUMAR, MUKESH PANDEY, JAYANT KUMAR, University of Massachusetts Lowell — There is considerable interest in developing chemical sensors for detection of trace explosives. Optical sensors, which rely on the change in optical properties of the material, proved to be very effective. Therefore, there is a need to develop materials for optical sensors which can interact specifically with analytes and detect them sensitively. Here, we report the synthesis of co-polymers of 4, 8-dimethylcoumarins with poly (ethylene glycol) (PEG) and polydimethylsiloxane (PDMS) using *Candida Antarctica lipase* as a catalyst under solvent-less condition. The low T_g of PEG and PDMS may facilitate porous structure in solid films which allows quencher molecules to easily diffuse in and out of these films. In addition, the co-polymers prevent aggregation and lend themselves easily for thin film fabrication which otherwise is difficult because of low molecular weight of coumarin. Fluorescence quenching of these co-polymer in presence of nitro aromatics, 2,4-dinitrotoulne and 2,4,6-trinitrotoluene, in solution and in vapor phase will be reported.

1:51PM Z39.00014 Correlated electrolyte solutions and ion-induced attractions between nanoparticles , JOS ZWANIKKEN, MONICA OLVERA DE LA CRUZ — Information about the degree of association can be obtained from a nonlinear Debye-Hueckel theory [1], in agreement with simulation and experimental results [2], in strong contrast with the widely applied (linear) Debye-Hueckel limiting law. The radial distribution functions calculated within this nonlinear theory are indistinguishable from molecular dynamics simulations of the restricted primitive model for divalent salts up to 0.1 molar concentrations. We apply the method to study the cohesive effects of strong couplings between ions on the effective interactions between nanoparticles, and the screening cloud around functionalized nanoparticles.

Session Z40 DPOLY: Semi Crystalline Polymers: Morphology and Electronics A122/123

11:15AM Z40.00001 Structure Evolution of Propylene-1-Butylene Random Copolymer under Uniaxial Stretching: from Unit Cells to Lamellae[1] , YIMIN MAO, Chemistry Department, Stony Brook University, Stony Brook, NY 11794-3400, CHRISTIAN BURGER, XIAOWEI LI, BENJAMIN HSIAO — Crystallization changes of propylene-1-butylene (P-H) random copolymer with low butylene content (5.7 mol%) under uniaxial tensile deformation at high temperature (100 °C) was investigated using time-resolved wide- and small-angle X-ray scattering (WAXS/SAXS) techniques. Structure and preferred orientation at length scales of crystal unit cell and lamellae were investigated explicitly using 2D whole pattern analysis. γ-phase was found to be the dominant initial modification which was transformed into α-phase during stretching, forming more stable parallel packed polymer chains in the unit cell. 2D WAXS analysis enabled us to identify three orientation modes from different crystal forms, i.e., γ-phase with tilted cross-β configuration, α-phase with parallel chain packing and *a*-axis orientation of α-form crystals in daughter lamellae. 2D SAXS analysis based on stacking model enabled us to understand the development of the four-point pattern under deformation.

[1]We thank National Science Foundation for financial support and Derek W. Thurman and Andy H. Tsou from ExxonMobil company for providing copolymer samples.

11:27AM Z40.00002 An In-Situ X-ray Scattering Study during Uniaxial Stretching of Ionic liquid/Ultra-High Molecular Weight Polyethylene Blend

, XIAOWEI LI, YIMIN MAO, HONGYANG MA, BENJAMIN S. HSIAO, Stony Brook University — The 1-docosanyl-3-methylimidazolium bromide ionic liquid (IL) was incorporated into ultra-high molecular weight polyethylene (UHMWPE) to form IL/UHWMPE blend by solution mixing. The structure evolution of this blend system during uniaxial stretching was followed by in-situ synchrotron wide-angle X-ray diffraction (WAXD) and small-angle X-ray scattering (SAXS) techniques. During deformation at room temperature, the elongation-to-break ratio of the IL/UHMWPE blend increased by 2 - 3 times compared with pure UHMWPE sample, where the blend did not lose the tensile strength. Deformation-induced phase transformation from orthorhombic to monoclinic phase was observed in both blend and neat UHMWPE. During deformation at high temperature (120 °C), no phase transformation was observed in both samples. However, the blend showed better toughness, higher crystal orientation, and tilted lamellar structure at high strains.

11:39AM Z40.00003 Microscopic kinetic model for polymer crystal growth[1]

, WENBING HU, Department of Polymer Science and Engineering,Stat Key Lab of Coordination Chemistry, School of Chemistry and Chemical Enginnering, Nanjing University — Linear crystal growth rates characterize the net result of competition between growth and melting at the liquid-solid interfaces. The rate equation for polymer crystal growth can be derived with a barrier term for crystal growth and with a driving force term of excess lamellar thickness, provided that growth and melting share the same rate-determining steps at the growth front. Such an ansatz can be verified by the kinetic symmetry between growth and melting around the melting point of lamellar crystals, as made in our recent dynamic Monte Carlo simulations. The profile of the growth/melting front appears as wedge-shaped, with the free energy barrier for intramolecular secondary crystal nucleation at its top, and with the driving force gained via instant thickening at its bottom. Such a scenario explains unique phenomena on polymer crystal growth, such as chain folding, regime transitions, molecular segregation of polydisperse polymers, self-poisoning with integer-number chain-folding of short chains, and colligative growth rates of binary mixtures of two chain lengths.

11:51AM Z40.00004 Polyethylene crystallization in compatibilized polyethylene/polyamide 6 blends

, SIMONA CECCIA, CNRS/Rhodia UMR5268, St.Fons (France), KATERINA HYNSTOVA[1], Institute of Materials Science, Faculty of Chemistry, Brno University of Technology (Czech Republic), ALEXANDRA FABRE, LISE TROUILLET-FONTI, DIDIER LONG, PAUL SOTTA, 1CNRS/Rhodia UMR5268, St.Fons (France) — Blends of semicrystalline polymers can exhibit much better properties than each of the pure polymers regarding e.g. impact/modulus compromise. Controlling the crystallization mechanisms (nucleation, kinetics) is a key factor to obtain the desired morphologies which lead to these unique properties. We have studied the crystallization of polyethylene (PE) in blends of PE and polyamide 6 (PA) compatibilized by PE functionalized with maleic anhydride (PE-g-MA, 1 wt% MA) obtained by reactive blending. Samples with different amounts of PA6 (0-60 %vol) have been investigated by polarized optical microscopy and Differential Scanning Calorimetry. The samples were heated at a temperature above the melting temperature of PE and below the melting temperature of PA, and then cooled at the selected crystallization temperature. We describe how the crystallization kinetics is modified by the presence of PA and MA.

12:03PM Z40.00005 Kinetic Partitioning of 1-Butene Defect in Random Propylene 1-Butene Copolymers by Time-Resolved FTIR

, CAROLINA RUIZ-ORTA, RUFINA G. ALAMO[1], FAMU-FSU College of Engineering Chemical and Biomedical Engineering Department, 2525 Pottsdamer St., Tallahassee, FL 32310 — Two different types of regularity bands are identified in a time-resolved FTIR crystallization of a series of random isotactic propylene 1-butene copolymers with a concentration of 1-butene from 2 to 19 mol%. The first type are bands associated with 31 helices of isotactic sequences of different n length (n, number of monomer units). The second are regularity bands at 830, 920, 1010 and 1240 cm-1 associated with continuous sequences of the chain that include the 1-butene comonomer. Conformational changes during the isothermal crystallization process were monitored with these regularity bands. The variation of the intensity of regularity band at 920 cm-1 with crystallinity content and a shift of the 841 cm-1 ($n = 12$) at lower frequencies correlate with the content of comonomer included in the crystal. Changes in frequency of the $n = 12$ band with varying crystallization temperature (Tc), and with crystallization time at a fixed Tc are associated with the kinetic partitioning of the comonomer units, that was quantified with data obtained from 13C NMR. The frequency shift is absent in copolymers with co-units that are excluded from the crystalline regions, such as the 1-octene comonomer.

12:15PM Z40.00006 Homogeneous bulk, surface, and edge nucleation in crystalline nanodroplets

, JESSICA L. CARVALHO, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada, L8S 4M1 — We present a study on the homogeneous nucleation of dewetted poly(ethylene oxide) droplets on a substrate that is itself crystallisable. While the chemical properties of the substrate prepared in either the amorphous or crystalline state are identical, the surface landscape varies widely. We observe a large difference in the substrate's nucleating ability depending on how it is prepared. Furthermore, the scaling dependence of the nucleation rate on the size of the droplets depends on the substrate surface properties. The birth of the crystalline state can be directed to originate predominantly within the bulk, at the substrate surface or at the droplet's edge depending on how we tune the substrate.

J.L. Carvalho and K. Dalnoki-Veress, Phys. Rev. Lett in press, 2010.

12:27PM Z40.00007 Molecular simulation of homogeneous crystal nucleation of n-alkane melts

, PENG YI, GREGORY RUTLEDGE, Massachusetts Institute of Technology — One of the most important phenomena in molecular systems is homogeneous nucleation of the crystal phase from a melt. This phenomenon is particularly interesting for chain molecules due to their strong anisotropy and their conformational flexibility. In this work we report the results of molecular simulations of homogeneous crystal nucleation of n-eicosane (C20) from the melt. A realistic united atom force field was employed. The crystal phase and melting behavior were first determined by ramping temperature in a set of MD simulations. The nucleation trajectory was then sampled using MD simulations at about 20% supercooling; and the nucleation free energy was sampled using Monte Carlo umbrella sampling method for three temperatures, ranging from 10% to 20% supercooling. A first-passage time technique was used to determine the critical nucleus and the nucleation rate. Detailed examination of the simulations reveals the critical nucleus to be a bundle of stretched segments about 8 CH2 groups long, organized into a cylindrical shape. The remaining CH2 groups form a disordered interfacial layer. By fitting the nucleation free energy curve to the cylindrical nucleus model, the crystal-melt interfacial free energies are calculated to be about 10 mJ/m2 for the side surface and 4 mJ/m2 for the end surface. We also discussed the effect of using different nucleus definitions

12:39PM Z40.00008 Hierarchal Ordered Structures in Hybrid Functional Supramolecules and Macromolecules[1] , STEPHEN CHENG, WEN-BIN ZHANG, CHIEN-LUNG WANG, XINFEI YU, YIWEN LI, XUEHUI DONG, RYAN VAN HORN — To create new functional materials for advanced technologies, control over their hierarchical structure and order is vital for obtaining the desired properties. We utilized and functionalized fullerene (C_{60}) and polyhedral oligomeric silsesquioxane (POSS), and assembled both of these particles with polymers to form those hierarchical structures. In order to do so, we have developed a novel way of attaching C_{60} and POSS onto other organic materials in a highly efficient and controlled manner via "click" chemistry. The structure of this assembly along with the resulting ordered structures were analyzed to determine their structure-property relationships. Examples are materials of POSS-[60]Fullerenoacetate conjugate crystals, giant surfactant of polystyrene-(carboxylic acid-functionalized polyhedral oligomeric silsesquioxane) amphiphile and porphyrin-C_{60} hybrids for intra- and inter-columnar in supramolecular double cable structures.

12:51PM Z40.00009 Nanoconfined Ferroelectricity in Polymers[1] , LEI ZHU, Department of Macromolecular Science and Engineering, Case Western Reserve University, FANGXIAO GUAN, JING WANG, Polymer Program, Institute of Materials Science and Department of Chemical, Materials and Biomolecular Engineering, University of Connecticut, QING WANG, Department of Materials Science and Engineering, Pennsylvania State University — In this presentation, a low loss polystyrene (PS) was grafted as side chains onto the P(VDF-CTFE) main chain. After PVDF crystallization, dielectric PS side chains were segregated to the crystalline-amorphous interface, forming a finite confinement layer for ferroelectric PVDF crystals. We speculated that less space charge was induced during electric poling because of the nanoscale confinement effect. Consequently, a fast discharge speed, relatively high energy density, and low losses were achieved.

[1]This work is supported by ONR (N00014-05-1-0338) and NSF (DMR-0907580).

1:03PM Z40.00010 Quantifying the rapid dynamics of polyelectrochromic switching in polymer acid-doped polyaniline , JACOB TARVER, YUEH-LIN LOO, Department of Chemical and Biological Engineering, Princeton University — Films cast from particles comprising polyaniline template synthesized on poly(2-acrylamido-2-methyl-1-propanesulfonic acid) exhibit polyelectrochromism and possess superior switching times ($<$10 s) and enhanced stability relative to other polymer acid-doped polyaniline systems. Solvent annealing in dichloroacetic acid induces polymer chain relaxation and further improves the speed ($\sim$1 s) and stability of electrochromic cycling. Electrochromic responses before and after solvent annealing can be described by Avrami kinetics that capture the influence of the film's mesoscale structural development and reveal variations in the dimensionality of reaction fronts when switching between the insulating and conducting states. Transitions from the conductive state are best fit by an Avrami exponent of 1.5 and are consistent with a reaction homogenously initiated throughout the film. Transitions to the conductive state require fits with exponents $\geq$2, suggesting nucleation and auto-accelerated propagation of conductive pathways away from the film/electrode interface in a manner analogous to polymer crystallization.

1:15PM Z40.00011 Enhanced RF Heating of Poly(N-Isopropylacrylamide) Gels by Utilization of Multiferroic Nanoparticles , EZEKIEL WALKER, University of North Texas, YUKIKUNI AKISHIGE, Shimane University, JAMES ROBERST, TONG CAI, ZHIBING HU, ARUP NEOGI, University of North Texas — Poly(N-Isoproylacrylamide) polymer hydrogels possess the special property of a discontinuous volumetric phase transition. This phase transition can be induced by external stimuli such as temperature, light, electric or magnetic fields, PH, and others. Of great interest is the functionalization of the gels to external stimuli for faster and more uniform spatial response. An efficient route to functionalization, specifically for termperature and light, is to utilize nanoparticles with EM resonances in the polymer network. The nanoparticles would be distributed throughout the gels, and an EM source resonant with the nanoparticle-gel structure would be used to induce a hysteresis-like effect to heat the gels, thereby, electromagnetically controlling the phase of the gel. KF-$BaTiO_3$ and $BiFeO_3$ are two sets of promising multiferroic nanoparticles that have exhibited resonances in the GHz region. Here, we present our findings for the functionalization and enhancement of the gels for radio-frequency light using KF-$BaTiO_3$ and $BiFeO_3$.

1:27PM Z40.00012 Manipulating functional properties at the interface of composite organic semiconductors , PANAGIOTIS MANIADIS, TURAB LOOKMAN, AVADH SAXENA, DARYL SMITH, Los Alamos National Laboratory — The formation of interfaces between different conjugated polymers is very important for the function of organic solar cells and other organic semiconductor devices. We propose a mechanism to control the properties of these interfaces with the addition of specially designed macro-molecules, with functional units. We develop the framework, using self consistent field theory (SCF), to study the concentration and the correlation function related to these functional units. When the functional units include a dipole moment, the average dipole moment and the standard deviation is expressed as a function of the SCF propagators. For electrostatic dipoles we also calculate the electric field difference created by the dipoles, as well as the charge distribution.

1:39PM Z40.00013 The Role of Exciton Dynamics in Photorefractivity in Organic Semiconductors , MOHAMMAD SAMIULLAH, Truman State University — A theory of the photorefractive effect in organic photorefractive materials based on formation, diffusion and dissociation of excitons in organic polymer semiconductors will be presented. A comparison with experimental results shows that the exciton dynamics plays an important role in the creation of the space charge field, and should be considered when selecting candidates for photorefractivity in organic systems.

1:51PM Z40.00014 Smart lens made of dielectric elastomer: simulation study , HONG TANG, Temple University — Electroactive Polymers (EAPs) are polymers that exhibit a change in size or shape when stimulated by an electric field. The common applications of this type of material are in actuators and sensors. A typical characteristic property of an EAP is that they will undergo a large amount of deformation while sustaining large forces. It has been demonstrated that EAPs can exhibit a strain from 10% to 300%. A dielectric elastomer (DEA) is a compliant capacitor, where a passive elastomer film is sandwiched between two compliant electrodes. When a voltage is applied, the electrostatic pressure arising from the Coulomb forces acting between the electrodes, therefore the electrodes squeeze the elastomer film. Based on the finite element analysis, we simulated the deformation of a polymer lens made of transparent dielectric elastomer materials under an application of electric field, which is provided by the transparent thin metal layers coated on the upper and lower surfaces of the lens. The focus of the lens can be adjusted by the applied electric field strength. By designing the electrode configuration on the lens surfaces, one can achieve both the positive and negative adjustment for the focus length.

Session Z42 DPOLY: Biopolymers: Molecules, Solutions, Networks, and Gels A302/303

11:15AM Z42.00001 How do polymers degrade? , SUPING LYU — Materials derived from agricultural products such as cellulose, starch, polylactide, etc. are more sustainable and environmentally benign than those derived from petroleum. However, applications of these polymers are limited by their processing properties, chemical and thermal stabilities. For example, polyethylene terephthalate fabrics last for many years under normal use conditions, but polylactide fabrics cannot due to chemical degradation. There are two primary mechanisms through which these polymers degrade: via hydrolysis and via oxidation. Both of these two mechanisms are related to combined factors such as monomer chemistry, chain configuration, chain mobility, crystallinity, and permeation to water and oxygen, and product geometry. In this talk, we will discuss how these materials degrade and how the degradation depends on these factors under application conditions. Both experimental studies and mathematical modeling will be presented.

11:51AM Z42.00002 Stretching semiflexible filaments with quenched disorder[1] , PANAYOTIS BENETATOS, EUGENE M. TERENTJEV, Cavendish Laboratory, University of Cambridge, UK — Many biopolymers, such as DNA, are characterized by sequence heterogeneity. At large scales, this heterogeneity may behave as a quenched random variable. We consider a wormlike chain with uncorrelated quenched disorder in its arc-length dependent spontaneous curvature. In the weakly bending approximation, we obtain analytic results for the elastic response to a stretching force applied at its end-points. We show that the effect of quenched disorder does not always reduce to a simple renormalization of the bending stiffness of the pure system. We also discuss a formally similar disordered system where a stretched wormlike chain is subject to random uncorrelated transverse forces.

[1] This work was supported by EPSRC via the TCM Programme Grant.

12:03PM Z42.00003 Chains Are More Flexible Under Tension[1] , ANDREY DOBRYNIN, JAN-MICHAEL CARRILLO, University of Connecticut, MICHAEL RUBINSTEIN, University of North Carolina — The mechanical response of networks, gels, and brush layers is a manifestation of the elastic properties of the individual macromolecules. The two main classes of models describing chain elasticity include the worm-like and freely jointed chain models. The selection between these two classes of models is based on the assumptions about chain flexibility. We are proposing a unified chain deformation model that describes the force deformation curve in terms of the chain bending constant, K, and bond length, b. This model demonstrates that the worm-like and freely jointed chain models correspond to two different regimes of polymer deformation, and the crossover between these two regimes depends on the chain bending rigidity and the magnitude of the applied force. Polymer chains with bending constant $K > 1$ behave as a worm-like chain under tension in the interval of the applied forces $f \leq KkT/b$ and as a freely jointed chain for $f \geq KkT/b$. (k is the Boltzmann constant and T is the absolute temperature.) The proposed crossover expression for chain deformation is in excellent agreement with the results of the molecular dynamics simulations of chain deformation and single molecule deformation experiments of biological and synthetic macromolecules.

12:15PM Z42.00004 Statistical Mechanics of Helical Wormlike Model[1] , YA LIU, TONI PEREZ, WEI LI, JAMES GUNTON, Lehigh University, AMANDA GREEN, Bucknell University — The bending and torsional elasticities are crucial in determining the static and dynamic properties of biopolymers such as dsDNA and sickle hemoglobin. We investigate the statistical mechanics of stiff polymers described by the helical wormlike model. We provide a numerical method to solve the model using a transfer matrix formulation. The correlation functions have been calculated and display rich profiles which are sensitive to the combination of the temperature and the equilibrium torsion. The asymptotic behavior at low temperature has been investigated theoretically and the predictions fit the numerical results very well. Our analysis could be used to understand the statics of dsDNA and other chiral polymers.

[1]This work is supported by grants from the NSF and Mathers Foundation.

12:27PM Z42.00005 DNA walks one step at a time in electrophoresis , JUAN GUAN, BO WANG, STEVE GRANICK, U of Illinois-Urbana Champaign — Testing the classical view that in DNA gel electrophoresis, long polymer chains navigate through their gel environment via reptation, we reach a different conclusion: this driven motion proceeds by stick-slip. Our single-molecule experiments visualize fluorescent-labeled lambda-DNA, whose intramolecular conformations are resolved with 30 ms resolution using home-written software. Combining hundreds to thousands of trajectories under amplitudes of electric field ranging from zero to large, we quantify the full statistical distribution of motion with unprecedented statistics. Pauses are seen between steps of driven motion, probably reflecting that the chain is trapped inside the gel matrix. The pausing time is exponentially distributed and decreases with increasing electric field strength, suggesting that the jerky behavior is an activated process, facilitated by electric field. We propose a stretch-assisted mechanism: that the energy barrier to move through the gel environment is first overcome by a leading segment, the ensuing intramolecular stress from stretching causing lagging segments to recoil and follow along.

12:39PM Z42.00006 The effects of end-interactions on semiflexible polymers looping , JAEOH SHIN, WOKYUNG SUNG, Pohang University of Science and Technology — Biopolymer looping is a ubiquitous dynamic process that occurs in cell, such as gene regulation and protein folding. We study the dynamics of looping for a variety of chain contour and persistence lengths via simulation and analytical theory. To speed up the looping time in simulation, which is very long for the short, rigid chains, we use the path integral hyperdynamics method. We analyze the effects of static and hydrodynamic interactions between the end beads on the looping time.

12:51PM Z42.00007 Modeling of biomimetic peptoid polymers , DINA MIRIJANIAN, STEVE WHITELAM, Lawrence Berkeley National Laboratory — Peptoids are sequence-specific, oligo-N-substituted glycine polymers that can mimic the structural motifs and functionalities of proteins. Recently, novel sheet-like nanostructured materials have been self-assembled from peptoids under physiological conditions. These structures are biocompatible and may be selectively functionalized. We have constructed atomistic models of peptoids using high level ab initio calculations to guide the parameterization of a classical force field based on the CHARMM22 peptide force field. Atomistic molecular dynamics simulations show the accessible configurations of peptoids in water to be markedly different from those of peptides. We have also used our parameterized force field to study the molecular structure of peptoid sheet-like nanostructures.

1:03PM Z42.00008 Periciliary Layer as a Protective Barrier of Human Airways[1] , LIHENG CAI, BRIAN BUTTON, RICHARD BOUCHER, MICHAEL RUBINSTEIN, University of North Carolina at Chapel Hill — The human airway surface layer consists of an overlaying gel-like mucus layer and a lower periciliary layer (PCL) protecting epithelial surface from mucus and the pathogens it contains. We investigated the permeability of the PCL using polymers that can readily penetrate through mucus. We found that in dilute solutions dextran larger than ~30 nm are excluded from the PCL, whereas dextran smaller than that can penetrate the PCL. The penetration depth increases (distance of dextran from epithelial surface decreases) as the dextran size decreases. We also found that the PCL can be compressed by semidilute solutions of dextran larger than 50 nm with concentration above a certain value, at which the solution correlation length (osmotic pressure) is about 30 nm (300 Pa). Above this concentration the height of the PCL decreases with the increasing concentration (osmotic pressure). The dependence of the PCL height on correlation length for semidilute solutions that compresses it is similar to the dependence of distance from cell surface on dextran size for the case of the PCL penetration by smaller polymers from dilute solutions. Our results suggest that the PCL protects the airways by limiting the penetration of inhaled infectious particles.

1:15PM Z42.00009 Cellulose aerogel from ionic liquid solution dried by silylation , DMITRY REIN, YACHIN COHEN, Technion — Aerogels are a class of materials characterised by a highly porous structure with low solids content. There is much interest in cellulose aerogel (aerocellulose) as a biodegradable and sustainable material. Cellulose lyogel can be fabricated from its solution in ionic liquids (IL) by coagulation with a nonsolvent such as water. However, subsequent drying capillary forces in the gel pores that result in severe shrinkage and pore closure. The use of supercritical fluids for drying or freeze-drying entails high equipment and energy requirements. We describe the fabrication and structure of aerocellulose fabricated from IL solution with a simple novel drying process: Addition of a compatible reactive agent (trimethylchlorosilane) and its diffusion into the water-swollen cellulose hydrogel pores results in a reaction with water as well as the pore surface hydroxyl groups. The remaining hydrophobic compound (hexamethyldisiloxane-HMDS), which fills the initially hydrophilic cellulose hydrogel pores, has a low intrinsic surface tension in the pores allowing easy drying with minimal shrinkage. Furthermore it allows modification of the pore surface and even fabrication of cellulose-polysiloxane composites. Relations between aerocellolose processing conditions and the resulting structural features will be discussed.

1:27PM Z42.00010 Macroscopic structure and properties of aqueous methylcellulose gels , TIRTHA CHATTERJEE, ROLAND ADDEN, MEINOLF BRACKHAGEN, ALAN I. NAKATANI, DAVID REDWINE, ROBERT L. SAMMLER, The Dow Chemical Company, DPCE TEAM — Cold semi-dilute aqueous methylcellulose (MC) solutions are known to undergo thermoreversible gelation when warmed. Here, studies on two MC materials, which contrast in thermal gelation performance (gel temperature, hot gel modulus etc.) even though they were prepared with similar methyl ether substitution levels and molecular weight distributions are presented. Small-angle neutron scattering (SANS)* measurements reveal differences in their gel structures which presumably are relevant to their thermal gelation performances. MC gel with higher gel temperature and lower hot gel modulus contains a single temperature invariant characteristic length ($\sim$ 1000 Å). However, besides this length scale, an additional and distinct smaller structure is also observed for the material with the lower gel temperature and the higher hot gel modulus. Further, in this case, the characteristic length scale decreases as temperature rises where as, the other length scale (smaller in size) remain almost temperature-invariant. The smaller domain size of the gel structure leads to the higher hot gel modulus for these methylcellulose materials. *Performed at NG3 beamline, NCNR, NIST.

1:39PM Z42.00011 Responsive Gelation in Physical Double Network Hydrogels from Artificial Protein Polymers , B.D. OLSEN, M.J. GLASSMAN, MIT — Artificial protein polymers with responsively associating groups on two different length scales are engineered in order to form physical double networks with potential application as shear-thinning hydrogels that may be toughened after injection. Gel-forming molecules are prepared by conjugating poly(N-isopropylacrylamide) (PNIPAM) at both ends of an artificial protein polymer to form PNIPAM-protein-PNIPAM triblock copolymers. Aggregation of the polymer endblocks forms a longer length scale network, while associating coiled-coil groups within the protein midblock form a shorter length scale network. At low temperatures where the coiled-coil domains are physically crosslinked but the copolymer endblocks are soluble, the materials form soft shear-thinning hydrogels. Elevating the temperature results in self-assembly of the second network, as manifest by stiffening of the gels. The structure of the materials is characterized using light scattering, X-ray scattering, and microscopy. Kinetics of the second network formation are characterized by linear oscillatory shear rheology, and nonlinear rheology is used to characterize the effect of the second network on the yield stress in these gels.

1:51PM Z42.00012 Universality in Nonlinear Elasticity of Biological and Polymeric Networks and Gels[1] , JAN-MICHAEL CARRILLO, ANDREY DOBRYNIN, Department of Physics, University of Connecticut — Networks and gels are part of our everyday experience starting from automotive tires and rubber bands to biological tissues and cells. Biological and polymeric networks show remarkably high deformability at relatively small stresses and can sustain reversible deformations up to ten times of their initial size. A distinctive feature of these materials is highly nonlinear stress-strain curves leading to material hardening with increasing deformation. This differentiates networks and gels from conventional materials, such as metals and glasses, showing linear stress-strain relationship in the reversible deformation regime. Using theoretical analysis and molecular dynamics simulations we propose and test a model that describes nonlinear mechanical properties of a broad variety of biological and polymeric networks and gels by relating their macroscopic strain hardening behavior with molecular parameters of the network strands. This model provides a universal relationship between the strain-dependent network modulus and the network deformation and explains strain-hardening of natural rubber, synthetic polymeric networks, and biopolymer networks of actin, collagen, fibrin, vimentin and neurofilaments.

2:03PM Z42.00013 Criticality and isostaticity in fiber networks[1] , XIAOMING MAO, OLAF STENULL, TOM C. LUBENSKY, University of Pennsylvania, CHASE P. BROEDERSZ, FRED C. MACKINTOSH, Vrije Universiteit — We investigated the elastic response of model semiflexible networks based on diluted periodic lattices, using a new effective medium theory and numerical simulations. In this model, central forces link nearest neighbor sites and bending forces link second neighbor sites along fibers. We found that by turning on fiber bending rigidity, the central force rigidity critical point became unstable, and the lattices lose rigidity at a lower threshold that is independent of fiber bending rigidity. We calculated scaling relations and exponents at both critical points. In addition to the bending and stretching dominated regimes, we identified a novel bend-stretch coupled regime in the vicinity of the central force critical point, in which the shear modulus exhibits a fractional power-law dependence on both the fiber bending and stretching rigidities.

Session Z43 DPOLY: Liquid Crystalline Order in Polymer and Complex Fluids A306/307

11:15AM Z43.00001 Nonlinear Dielectric Response of the Liquid Crystal 8CB near the phase transitions , HANNAH BUCHANAN, University of West Florida — The nonlinear dielectric response of the liquid crystal (LC) 8CB (4'-octyl-4-cyanobiphenyl) was measured near the smectic-nematic and nematic-isotropic phase transitions. The sample was filled in a commercially available LC capacitor cell of dimensions (1 cm $\times$ 1 cm $\times$ 9 μm). The cell was mounted in a temperature-controlled environment with a stability and resolution of 1 mK. The capacitance of the cell was measured at different temperatures in the range 25 – 45 $^\circ$C covering both phase transitions, and over a range of frequencies up to 100 kHz, and a signal level in the range of 0 – 5V, using a lock-in amplifier (SRS830) and LCR meter (Fluke PM6304). Nonlinear effects were observed in the capacitance even at a 200 mV signal level, and very large changes in the capacitance, both linear and nonlinear, were observed in the nematic phase, near each phase transition. *Undergraduate physics students **Recent physics graduates

11:27AM Z43.00002 A Novel Liquid Crystal Elastomer with Large Spontaneous Length Changes , PATRICIA CLADIS, ALCT, Inc., SIMON KRAUSE, YUSRIL YUSUF[1], Gadjah Mada University, Yogyakarta, 55281, Indonesia , SHOHEI HASHIMOTO[2], Kyushu University, Fukuoka 819-0395, Japan, LEONID FEL[3], Technion-IIT, 32000 Haifa, Israel, SHOICHI KAI[4], Kyushu University, Fukuoka 819-0395, Japan, HEINO FINKELMANN, Makromolekulare Chemie, Freiburg University, 79104 Freiburg, Germany — An order parameter describes an elastomer where a liquid crystal is cross linked at a temperature T_L far from its clearing temperature. At T_L, there is a first order constant density phase transition where the order parameter vanishes and the elastomer has cubic symmetry. Below T_L it is an icosahedral nematic and above a biaxial nematic. This theory quantitatively accounts for spontaneous shape change, nonlinear elasticity and gelation dynamics in a novel liquid crystal elastomer.

11:39AM Z43.00003 Magnetic field directed self-assembly of liquid crystalline block copolymers for membrane applications[1] , MANESH GOPINADHAN, PAWEL W. MAJEWSKI, CHINEDUM O. OSUJI, Yale University — The use of magnetic fields is presented as a facile approach to the control of long range order and alignment of block copolymers. Using SAXS we demonstrate the alignment of lamellar and hexagonally packed cylinder morphologies of a poly(ethylene oxide)-based LC diblock copolymer by slow cooling in the presence of the field through the order-disorder transition. Non-degenerate alignment of the lamellar system is enabled by sample rotation and alignment in the system is shown to be driven by the diamagnetic anisotropy of the LC mesogen, and not anisotropy resulting from crystallization of the PEO block. We consider the effects of lithium doping and field strength on the order-disorder transition of the system, and the effect of lithium content on the critical field required for attaining well aligned films. The controlled alignment of PEO channels over large areas offers a route to selective ion transport in solid state batteries.

11:51AM Z43.00004 Temperature Dependent Self-Assembly of Side-Group Liquid Crystalline Block Copolymers in LC Solvent , PAUL PIROGOVSKY, ZULEIKHA KURJI, ROHAN HULE, JULIA KORNFIELD, California Institute of Technology — Side Group Liquid Crystalline Polymers (SGLCPs) take on anisotropic conformations in a small molecule LC solvent. This conformation is affected by both the temperature and the sense of attachment of the mesogenic side group (either parallel or perpendicular to the backbone). Covalently linking the SGLCP with a random coil (PS) block leads to a block copolymer that self assembles into anisotropic micelles. Transmission Electron Microscopy was used to view these micelles in real space and determine their size and structure. Small Angle Neutron Scattering (SANS) was performed on dilute (1 wt%) solutions of a series of SGLCPs (homopolymers and block copolymers with a range of polystyrene block lengths) dissolved in deuterated 5CB. A rubbed alignment layer and a magnetic field were used to break symmetry and allow the ordered structure to be seen. PS-b-SGLCP block copolymers were seen to form self-assembled structures that changed qualitatively with the changing PS block length and the temperature. Most intriguingly, several polymers exhibit mutually orthogonal anisotropies at different length scales.

12:03PM Z43.00005 In-Situ X-Ray Diffraction Study of the Elongation Behavior of a Main Chain Liquid Crystal Elastomer[1] , SONAL DEY, D.M. AGRA-KOOIJMAN, LEELA JOSHI, SATYENDRA KUMAR, Kent State University, WANTING REN, WHITNEY M. KLINE, ANSELM C. GRRIFIN, Georgia Institute of Technology — We studied the structural evolution of a main chain smectic elastomer under uniaxial stress and during strain recovery. At low strains, both the alkyl chains and the smectic layers are oriented on average parallel to the strain direction. At higher strains, the development of layer undulations is observed at ∼50% which gradually evolve into chevron-like smectic structures as revealed by the four diffuse spots in small angle x-ray diffraction patterns. This is accompanied with an enhancement of the smectic order as inferred from higher intensity of small angle peaks and larger orientational order parameter, S [for example, $S(20\%) = 0.33$; $S(110\%) = 0.86$]. During strain recovery, two relaxation rates of 6.5 min and 38.5 min are observed which are associated with relaxations of the mesogenic part and the elastomer network, respectively.

12:15PM Z43.00006 Evaporative Self-Assembly and Formation of the Lyotropic Liquid Crystalline Phase of Poly(3-hexyl thiophene)[1] , MIN SANG PARK, AVISHEK AIYAR, JUNG OK PARK, ELSA REICHMANIS, MOHAN SRINIVASARAO, Georgia Institute of Technology — In this study, we electrically and optically interrogated the evolution of the thin film structure in conjugated systems using poly(3-hexylthiphene) (P3HT) as a model semiconducting polymer. In an effort to understand the electrical properties of the conducting channel in terms of polymer chain orientation and relaxation in solution, we performed in-situ micro-Raman measurements using polarized incident light. We measured the extent of molecular chain alignment during the process of film formation and showed the existence of a lyotropic liquid crystal phase at the three-phase contact line. The variation of frequency dispersion and the shift of position for Raman active mode, combined with the structural anisotropy of P3HT films, suggest a phase transition to the lyotropic liquid crystalline phase. The orientational order of P3HT chains in the liquid crystalline phase was quantified as a function of evaporation time using solidified solvent, 1,3,5-triclorobenzene (1,3,5-TCB).

12:27PM Z43.00007 Lyotropic nematic droplets of single-walled carbon nanotubes in super acids: equilibrium shape and dynamics , NATNAEL BEHABTU, BUDHADIPTA DAN, Rice University, LEE TAEWOO, IVAN SMALYUKH, University of Colorado , MATTEO PASQUALI, Rice University — The balance between surface tension, elastic energy and surface anchoring creates nematic droplets with elongated shape, called tactoids. Here we report equilibrium shape and coalescence dynamics of single-walled carbon nanotube (SWNT) nematic droplets in superacids. Surprisingly, we observe bipolar tactoids with uniform aspect ratio. The uniform aspect ratio is not expected based on theoretical arguments that indicated that aspect ratio should drop with domain volume. Bipolar order contrasts recent findings of uniform order in liquid crystalline tactoid droplets of aqueous SWNTs stabilized with bile salts. The coalescence dynamics is highly influenced by the drop elasticity. Coalescence pathways that lead to defect creation are not observed, unlike spherical nematic droplets. Instead coalescence proceeds by tangentially matching the nematic director of two drops.

12:39PM Z43.00008 The unique behavior of chiral templated polymers swollen with liquid crystals , MICHAEL MCCONNEY, JENNIFER HURTUBISE, VINCENT TONDIGLIA, TIMOTHY WHITE, TIMOTHY BUNNING, Materials and Manufacturing Directorate, Air Force Research Laboratory — Liquid crystals (LC) have the capability of impart a degree of order onto the molecular structure of polymers, essentially acting as "smart solvents." Furthermore, structured materials have the ability to force liquid crystals into structures that are far from the bulk LC structure. Our studies are aimed at exploring the interplay between LC templated polymers and polymer templated LCs. Specifically we investigated a unique swelling-deswelling phase transition involving an ordered liquid crystal solvent and a structured polymer. The polymer is formed through anisotropic photopolymerization of LC monomers in a chiral LC fluid, is only attached from one surface of a single cell, and only spans a fraction of the cell thickness. The details of the transition were studied with various techniques including DSC, confocal microscopy, polarized microscopy, and visible/near-IR spectrometry. The unusual thermally induced structural changes result in large changes to the reflection wavelength of the cholesteric LC cells.

12:51PM Z43.00009 The Shape of Structured Polymer Vesicles[1] , MARK BOWICK, Syracuse University, MIN-HUI LI, Institut Curie (Paris), HOMIN SHIN, UMass Amherst, XIANGJUN XING, Shanghai Jiao Tong University, ZHENWEI YAO, Syracuse University — Polymer vesicles are stable robust vesicles made from block copolymer amphiphiles. Recent progress in the chemical design of block copolymers has lead to the creation of a variety of polymer vesicles with varying internal structure, functionality and shape. By choosing suitable liquid-crystalline polymers for one of the copolymer components one can create vesicles with internal nematic or smectic order. This talk will address the possible shapes of these *structured* vesicles as well as their inherent topological defects.

[1]Supported by NSF grant DMR 0808812

1:03PM Z43.00010 Curvature-induced transitions in two-dimensional nematics , BADEL L. MBANGA, Department of Polymer Science and Engineering, University of Massachusetts, Amherst, Massachusetts 01003, USA, C.D. SANTANGELO, Department of Physics, University of Massachusetts, Amherst MA, 01003, G.M. GRASON, Department of Polymer Science and Engineering, University of Massachusetts, Amherst, Massachusetts 01003, USA — Anisotropic particles absorbed to a fluid interface are known to significantly alter the structure and mechanics of these surfaces, possibly even stabilizing surfaces of complex, bicontinuous topology, as in "bijels" formed from arrested spinodally- decomposing fluid mixtures. We study the intricate interplay between the morphology of these interfaces and the alignment of anisotropic elongated particles with nematic order. Here we present results from computer simulation of nematic order on hyperbolic surfaces using a model that accounts for the contribution of both the intrinsic and extrinsic curvatures to the energetics of topological defects defects.

1:15PM Z43.00011 Effect of chain stiffness on structural and thermodynamic properties of polymers , KIRAN KHANAL, JUTTA LUETTMER-STRATHMANN, Departments of Chemistry and Physics, The University of Akron — The stiffness of the chains affects many properties of polymers. We investigate structural and thermodynamic properties of a bond- fluctuation lattice model for semiflexible polymer chains. Monte Carlo simulations for polymer melts for a range of values of the bending penalty, density, and temperature show elongation of the polymer conformations with increasing chain stiffness but no transition to a nematic phase. Results for average bead-bead interaction energy and bending energy were studied separately and showed that the bending energy is almost independent of the filling fraction, suggesting that the stiffness of the chains can be treated as a single chain property. We calculated the bending energy from the partition function of a pair of neighboring bonds and find excellent agreement between theory and simulation. Equation of state properties of the lattice model were determined from insertion methods and thermodynamic integration. We develop a theoretical description of these properties and use it to determine model parameters for real polymer melts from a comparison with experimental data.

1:27PM Z43.00012 Symmetric reflection band broadening of weakly polymer stabilized cholesteric thin films using low DC electric fields , MADELINE DUNNING, CHRISTOPHER BAILEY, ANASTASIA VOEVODIN, VINCENT TONDIGLIA, LALGUDI NATARAJAN, TIMOTHY WHITE, TIMOTHY BUNNING — We report on a new, low field electro-optical effect in weakly polymer stabilized cholesteric liquid crystals with negative dielectric anisotropy. By applying low DC electric fields ($<3V/\mu m$), a symmetric broadening of the cholesteric reflection band can be seen, resulting in band width increases by factors of two or more. An intensive study of the various experimental parameters combined with numerical calculations of the transmission spectra, indicate that the polymer interacts with the electric fields resulting in an approximately constant pitch gradient across the cell thickness. Our results show that the maximum pitch distortions reach values of approximately 15% the zero voltage value for notches in the visible range (pitches of 300-400nm), but increase along with the pitch. Possible physical mechanisms will be explored and discussed that might explain this interesting electro-optical effect.

1:39PM Z43.00013 Structure of Rigid Hard-Ring Fluids , MARIAM NOURI, MARC ROBERT, Department of Chemical and Biomolecular Engineering, Rice University — Structure of fluids of molecules consisting of rigid rings of hard spheres is studied in two, quasi two, and three dimensions, using Monte Carlo computer simulations in the canonical ensemble. For rings of various size and for a wide range of densities, results are reported for the pair distribution function of the ring centers and for the pair distribution of the ring orientations. For dense fluids in two dimensions, a shoulder, precursor of the freezing transition, is observed in the second peak of the pair distribution function of the ring centers, as previously seen in the simple hard-sphere fluid. In quasi two dimensions, where the centers of the rings are confined to a plane but the rings themselves can wobble out of plane, a liquid crystalline nematic phase is observed at sufficiently high densities. Results are also presented for three dimensions.

1:51PM Z43.00014 Fast Off-Lattice Monte Carlo Simulations with a Novel Soft-Core Spherocylinder Model , JING ZONG, XINGHUA ZHANG, QIANG (DAVID) WANG, Colorado State University — Fast off-lattice Monte Carlo simulations with soft-core repulsive potentials that allow particle overlapping give orders of magnitude faster/better sampling of the configurational space than conventional molecular simulations with hard-core repulsions (such as in the Lennard-Jones potential).[1] Here we present our fast off-lattice Monte Carlo simulations on the structures and phase transitions of liquid crystals and rod-coil diblock copolymers based on a novel and computationally efficient anisotropic soft-core potential that gives exact treatment of the excluded-volume interactions between two spherocylinders (thus the orientational interaction between them favoring their parallel alignment). Our model further takes into account the degree of overlap of two spherocylinders, thus superior to other soft-core models that depend only on their shortest distance. It has great potential applications in the study of liquid crystals, block copolymers containing rod blocks, and liquid crystalline polymers.

2:03PM Z43.00015 Solvent involved self-crystallization of C_{70} molecules into high definition cube microstructure[1] , CHIBEOM PARK, HEE CHEUL CHOI, Department of Chemistry and Division of Advanced Materials Science, Pohang University of Science and Technology (POSTECH) — C_{70} molecules dissolved in mesitylene (good solvent) are self-crystallized into cube shape microstructure by the addition of isopropyl alcohol (poor solvent). Through control experiments attempted with different types of alcohols as well as in the replacement of mesitylene with other similar solvents, such as toluene, m-xylene, and m-dichlorobenzene, it is confirmed that mesitylene plays a critical role to guide C_{70} molecules to form cube microcrystal with high definition edges and surfaces. Thermal gravimetric and crystallographic analyses show that the crystal structure is simple cubic whose unit cell is composed of one C_{70} and two mesitylene molecules. The photoluminescence intensity from C_{70} cube crystals are enormously increased compared to C_{70} powder. Such abnormal photoluminescence increase is mainly attributed to the high crystallinity of C_{70} cubes as confirmed by time-resolved photoluminescence lifetime measurements.

Session Z44 DMP DPOLY: Focus Session: Organic Electronics and Photonics – New Materials and Applications A309

11:15AM Z44.00001 Ambipolar Electric Double Layer Transistors Using Organic Single Crystals , TAISHI TAKENOBU, Waseda University, PRESTO, DI WEN, Waseda University, HIDEKAZU SHIMOTANI, The University of Tokyo, SHIMPEI ONO, CRIEPI, YOSHIHIRO IWASA, The University of Tokyo, CREST — Among organic devices, ambipolar transistors are very unique device, in which both electrons and holes are equally mobile and we are able to observe light emission through the recombination of them. Progress in the applications of such light-emitting transistors (LETs) based on organic single crystals has provided possibilities in developing organic laser. However, in these LETs, the current density is still low for lasing, and, therefore, a different device structure is necessary to overcome this issue. Here we show the first demonstration of organic ambipolar electric double layer transistors (EDLTs), in which the gate dielectric is not a conventional insulator but an electrolyte. The peculiar merit of EDLT is extremely high conductivity due to the huge capacitance of the EDL formed at the organic/electrolyte interfaces. Consequently, we can increase current density. In this study, we used rubrene single crystal and ion-gel as the active material and electrolyte, respectively. These present results will provide a prospect for further development in LET operation.

11:27AM Z44.00002 Refractive Indices of Specific Nonconjugated Conductive Polymers: Organic Nanometallic Systems , PRASHANT DUBEY, SAPANA SHRIVASTAVA, MRINAL THAKUR, Photonic Materials Research Laboratory, Auburn University, AL 36849 — Exceptionally large quadratic electro-optic effect and two-photon absorption coefficients have been recently reported for nonconjugated conductive polymers after doping. These polymers include: cis- and trans- polyisoprene, poly(β-pinene) and others. The large optical nonlinearities observed in these materials have been attributed to the nanometallic state with subnanometer dimensions that is formed upon doping and charge-transfer. Measurement and calculation of linear refractive indices of these novel nonlinear optical systems before and after doping are important. Linear absorption coefficients (UV-Visible) of trans-1,4-polyisoprene have been measured for different doping levels of iodine. Refractive indices have been calculated using Kramers-Kronig transformation of absorption data for different doping levels. Numerical integration using MATLAB software was used for these calculations. Refractive indices at specific wavelengths have been determined by measuring reflectivity at normal incidence. The calculated and measured values of refractive indices have been compared. Results on calculations and measurements on these novel systems will be discussed.

11:39AM Z44.00003 ABSTRACT WITHDRAWN –

11:51AM Z44.00004 Sub-diffraction limited features in three-dimensional photopatterned, two-photon excimer-forming fluorescent dye-doped films , CHRISTOPHER RYAN, BRENT VALLE, JOSEPH LOTT, JACK R. JOHNSON, JIE SHAN, KENNETH D. SINGER, Case Western Reserve University, CHRISTOPH WEDER, University of Fribourg, DAVID A. SCHIRALDI, Case Western Reserve University — 3D Photopatterning is a key process in optical data storage, photolithography and other applications. Two photon active systems are a popular choice to pattern in 3D. The main challenges pertain to the contrast and density of the patterned features. By making use of a thermal threshold process which induces dye deaggregation, high contrast features are written with diameters smaller than the system's diffraction limit. A polymer film was doped with a two photon active dye that possesses two distinct fluorescence states in its monomer and excimer phases. The film's phases are stable at room temperature, and have a threshold response to heating. By selective exposure to a pulsed 675 nm source, the film is photopatterned in 3D as the focused pulses are absorbed and thus anneal the sample. Because the change is physical rather than chemical, the mechanism is shown to be a threshold process. As a result, sub diffraction limit photopatterns are demonstrated in the medium.

12:03PM Z44.00005 Low threshold conjugated polymer lasers by intrinsically directed resonator design , ALEXANDER KUEHNE, DAVID WEITZ, Harvard University — Creation of laser cavities requires external imposition of an optical feedback system onto the gain medium. By contrast, we use functional conjugated polymers that can be chemically or physically patterned from within to form diffractive laser resonators. One realization is based on a chemically-modified polyfluorene, which can be patterned into distributed feedback (DFB) resonators of any desired grating period. A different route is by physically pattering conjugated polymers into sub-micrometer colloids via microfluidics. These systems can be tuned with respect to particle size and their arrangement in the resulting laser structure. We show random lasing for a photonic-glass, self-assembled from monodisperse conjugated polymer particles.

12:15PM Z44.00006 Effects of polar analytes on the transport properties of organic semiconductor field-effect chemical sensors , DAVIANNE DUARTE, Univeristy of Texas at Austin, BRIAN COBB, ANANTH DODABALAPUR, University of Texas at Austin — Chemical recognition or sensing in organic thin film transistors (TFTs) can be achieved by direct analyte interaction or the inclusion of specific receptor molecules added to the semiconducting surface. Overall, sensing is dependent on the interactions occurring between the molecule and the OTFT active region, which includes the semiconductor and semiconductor-insulator interface. The magnitude of the interaction will depend on the molecules polarizability and the partition function of the analyte vapor. We employ a range of analytes (cyclohexane, ethanol, and styrene) with different solvations parameters (polarizability/dipolarity levels) to gain more clarity on their effects of the charge transport properties in OTFTs. Receptors are used to understand in more detail the physical and chemical interactions, which contribute to the sensor response. The receptors themselves have diverse polarizability/dipolarity parameters, which produce varying sensing behaviors dependent on the solvation parameters of the analytes.

12:27PM Z44.00007 Chemical vapor sensors using a poly(triarylamine) semiconductor modified through incorporation of organic receptors[1] , BRIAN COBB, DAVIANNE DUARTE, ANANTH DODABALAPUR, University of Texas at Austin — A poly(triarylamine) (PTAA) semiconducting active layer has been employed in order to produce OFET chemical sensors displaying excellent stability in air, with minimal bias stress effects. We propose a "chemical fingerprint" sensing array comprised of a single base polymer (PTAA), with the selectivity of individual devices modified through the incorporation of a variety of small molecule receptors. This allows for consistent device operation and optimization of the array. The effect of various receptors will be discussed, and reported while sensing alcohol vapors. Different methodologies will be proposed for incorporation of receptors into the device, including incorporation into the PTAA film and separate deposition on top of the PTAA film. The relative merits of each approach will be discussed, including the effect on both threshold voltage and carrier mobility.

[1]PTAA material supplied by Merck.

12:39PM Z44.00008 Nonadiabatic exciton dynamics in conjugated polymers , ADAM WILLARD, University of Texas, Austin, PETER ROSSKY — The results of mixed quantum/classical simulations of the nonadiabatic excited state dynamics of sexithiophene and the C60-sexithiophene interface are presented. The model is capable of describing the photogeneration and subsequent time-evolution of excitons in conjugated polymers at model bulk heterojunction interfaces. The effect of chain length and electric field on exciton mobility is discussed for both single-chain and π-stacked sexithiophene oligomer. In addition the dynamics of exciton dissociation at the C60-sexithiophene interface are described.

12:51PM Z44.00009 ABSTRACT WITHDRAWN –

1:03PM Z44.00010 Solution Processable Organic Solar Cell Microarrays for Use in MEMS[1] , JENNIFER TRINH, Swarthmore College, JASON LEWIS, PATRICK TOGLIA, XIAOMEI JIANG, University of South Florida — We have developed an innovative way to fabricate organic solar arrays for application as DC power supplies in electrostatic MEMS devices. The generation 1 microarray consists of 20 small (1 mm^2) solar cells connected in series (total device area of 2.2 cm^2). The device uses an active layer of poly(3-hexylthiophene) (P3HT) and [6,6]-phenyl-C61-butyric acid methyl ester ($PC_{61}BM$), which are mixed together (1:1 mass ratio) in appropriate solvent. We manipulated active layer nanomorphology by choice of solvents and annealing conditions. The optimized generation 1 device has an open-circuit voltage of 11.5V, short-circuit current density of 1 mA/cm^2, and a power conversion efficiency of 2% under simulated solar AM1.5 illumination. The generation 2 microarray has a new design with reduced series resistance and improved cell occupancy. The generation 2 arrays have demonstrated improved device efficiency and power output density. Detailed analysis of device physics in both generation microarrays will be presented. The procedure described has potential for producing microarrays as small as 0.01 mm^2.

[1]This work was supported by the NSF REU program (award No DMR-1004873). Authors at USF would like to thank New Energy Technology Inc. and Florida High Tech Corridor Matching Fund (FHT 09-18).

1:15PM Z44.00011 Synthesis and characterization of a new TPA-Thiophene based molecule for potential Organic PV applications , PRASHANT SARSWAT, University of Utah, Salt Lake City, Utah 84112, AMARCHAND SATHYAPALAN, MICHAEL FREE, University of Utah, Salt Lake City, Utah 84112 — Triphenylamine (TPA) containing molecules possess unique optical and photovoltaic properties. These molecules show very strong visible absorption due to unique electronic structure. Another class of molecules, thiophene derivatives and resulting polymers have higher hole mobility amongst other conjugate co-polymers. In view of these aspects, we have designed a new conjugated thiophene containing molecule with TPA. A solution processable technique is reported to synthesize this newly designed star shaped molecule with TPA derivative as its core and thiophene derivative as branches. The synthesized molecule is systematically characterized by studying Mass spectroscopy, Raman spectroscopy, UV-Vis spectroscopy, and cyclic voltammetry. This molecule shows solubility in various common organic solvents, broad absorption in spectral range of 300-650 nm, and good thermal stability. An atomistic simulations based on density functional theory was carried out to validate HOMO and LUMO levels. The cyclic voltammetry analysis is consistent with atomistic simulation results. A 3D simulated orbital image reveals that the HOMO level corresponds to oxygen as well as carbon in a benzene ring.

1:27PM Z44.00012 Quadratic Electro-optic Effect in the Nonconjugated Conductive Polymer Trans-1,4-polyisoprene Measured at 1.55 μm , SAPANA SHRIVASTAVA, MRINAL THAKUR, Photonic Mat. Res. Lab, Auburn University, AL 36849 — Quadratic electro-optic effect in the nonconjugated conductive polymer, iodine-doped trans-1,4-polyisoprene has been measured at a longer wavelength (1.55 μm) and x-ray diffraction of the polymer film has been studied. Optical absorption spectra of trans-1,4-polyisoprene (TPI) show two peaks after doping, one at 4.2eV (295 nm) due to radical cation and the other at 3.2eV (388 nm) due to charge-transfer from double to dopant. X-ray diffractometer scans show that the trans-1,4-polyisoprene film has γ-phase crystal structure. Upon doping intensities of two peaks were observed increase without significant changes in overall peak positions. Field induced birefringence technique has been used to measure quadratic electro optic effect at 1.55 μm (which is away from resonance) and an exceptionally large Kerr coefficient ($2.5x10^{-10}$ m/V^2) has been obtained. This large nonlinearity has been attributed to the subnanometer-size metallic quantum dot structure produced upon doping of this polymer.

1:39PM Z44.00013 Photo-active Silicon Containing Polymer Films; An Approach Towards All-Solution Processable Devices[1] , SCOTT LEFEVRE, XINXING LIU, LEONARD INTERRANTE, CHANG RYU, Rensselaer Polytechnic Institute — The continuous drive for smaller, cheaper electronic devices elucidates the necessity for the design and incorporation of materials with improved properties along with a greater ease of processability. Polycarbosilanes (PCSs) are a class of organic-inorganic hybrid materials which exhibit increased chemical and thermal stability, appreciable hydrophobicity, and significant mechanical robustness. Recently, we have developed UV-crosslinkable cyclolinear PCSs by the incorporation of aryl substituted disilacyclobutane (DSCB) rings into the backbone. This novel material exhibits a low dielectric constant (k), making it an attractive new material in the development of interlayer dielectrics. Preliminary data shows that there is a maximum UV-crosslinking depth of approximately 30 microns. Additionally we have successfully demonstrated the resist capabilities of this material by patterning micro-scale (about 10 microns) features with a surface roughness variation of approx. 1 percent. Finally, new approaches towards taking advantage of the reactivity of polysilanes and the effect of molecular weight and polydispersity will be discussed.

Session Z45 DAMOP: Bose-Einstein Condensates, Matter Optics, and Atomic Interferometry

11:15AM Z45.00001 New Facility to Probe Physics With Degenerate Bose and Fermi Gas , SUBHADEEP DE, Joint Quantum Institute, National Institute of Standard and Technology and University of Maryland, MD, USA, DANIEL L. CAMPBELL TEAM, ABIGAIL R. PERRY TEAM, RYAN PRICE TEAM, IAN B. SPIELMAN TEAM — A new facility to produce dual species degenerate Bose and Fermi gas is under construction at JQI. This apparatus is designed to create degnerate mixtures of bosonic rubidium (^{87}Rb) and fermionic lithium (^{6}Li). A degenerate Bose-Fermi mixture supports many quantum phase transitions, giving an experimental platform to study many-body statics, dynamics, and perhaps precision measurements. High T_c superconductivity could be probed, where fermions are bound into Cooper pairs by boson mediated interactions. Dual species heteronuclear molecules with large permanent electric dipole moment may lead to a system for implementing quantum bits. A spin-polarized, non-interacting, degenerate ^{6}Li gas coupled to ^{87}Rb atoms in an optical lattice will give rise to a long range, spin-dependent interactions to realize quantum magnetism and potentially supersolidity. Far red-detuned lattices are far weaker, in recoil units, for Li as compared to Rb. So, in the Mott phase of Rb - one atom per lattice site - the three body recombination of Li-Li-Rb is greatly suppressed. Thus the wide ^{87}Rb-^{6}Li Fesbach resonance at 1.1 kG is expected to effectively control fermion mediated interactions.

11:27AM Z45.00002 Solitons and Breathers in Strongly Repulsive Bose-Einstein Condensates , WILLIAM REINHARDT, University of Washington, Seattle, INDUBALA SATIJA, George Mason University, BRYCE ROBBINS, Colorado School of Mines, CHARLES CLARK, Joint Quantum Insititue, National Insitute of Standard and Technology — Collisional dynamics of solitary matter waves of hard core bosons, consisting of dark and bright waves as well as supersonic periodic trains, reveals remarkable richness and coherence, with the phase of the condensate playing a key role. Depending upon the condensate density, we see two distinctive effects in the collision of these waves: intuitively expected repulsive collision due to hard core boson constraint and also collisions in which they "pass through" each other without distortion. In addition to confirming the soliton status of the solitary waves, our studies reveal a variety of multi-solitons including a family of breathers, that can be demonstrated in an optical lattice with appropriate phase imprinting.

11:39AM Z45.00003 Macroscopic two-state systems in trapped atomic condensates , DMITRY MOZYRSKY, DMITRY SOLENOV, Los Alamos National Laboratory — We consider a macroscopic two-sate system based on persistent current states of a Bose-Einstein condensate (BEC) of interacting neutral atoms confined in a ring with a weak Josephson link [1]. We demonstrate that macroscopic superpositions of different BEC flows are energetically favorable in this system. Moreover, a macroscopic two-state dynamics emerges in the low energy limit. We also investigate fundamental limitations due to the noise inherent to the interacting BEC of Josephson-ring geometry. We show that the coherent macroscopic dynamics is readily measurable for an experimentally accessible range of parameters.

11:51AM Z45.00004 Analysis of a free oscillation atom interferometer , RUDRA KAFLE, Worcester Polytechnic Institute, DANA ANDERSON, JILA, NIST, and University of Colorado, Boulder, ALEX ZOZULYA, Worcester Polytechnic Institute — We analyze a Bose-Einstein condensate (BEC) - based free oscillation atom Michelson interferometer in a weakly confining harmonic magnetic trap. A BEC at the center of the trap is split into two harmonics by a laser standing wave. The harmonics move in opposite directions with equal speeds and return under the influence of the trapping potential at their classical turning points. The harmonics are allowed to pass through each other and a recombination pulse is applied when they overlap at the end of a cycle after their return at the second time. We derive an expression for the contrast of the interferometric fringes and obtain the fundamental limit of performance of the interferometer in the parameter space. The results are also compared and contrasted with the results of our previous work on a single- and double reflection atom Michelson interferometers.

12:03PM Z45.00005 Atomic population distribution in the output ports of a waveguide interferometer with optical splitting and recombination , EBUBECHUKWU ILO-OKEKE, ALEX ZOZULYA, Worcester Polytechnic Institute — Manipulation of atomic Bose-Einstein condensates (BECs) in an atom waveguide interferometer relies on the use of off-resonant laser pulses to split a cloud of BEC into two clouds that travel along different paths and are then recombined using the same laser pulses. During the evolution of the condensates, residual spatial-dependent phase is accumulated due to the confining potential and the inter-atomic interactions within the condensates. Additional phase is accumulated due to the mode-entangled state of the clouds after splitting that causes each atom in the condensate to evolve at a different rate. The recombination laser pulses are sensitive to these phases and the population of atoms in the atomic samples that emerge after recombination depends on them. We derive an expression for the probability density distribution of observing any number of atoms in the clouds after recombination and give a parameter space for optimum operation of the interferometer in the presence of phase due to mode-entangled state of BEC clouds and the residual spatial-dependent phase.

12:15PM Z45.00006 Momentum-space engineering of gaseous Bose-Einstein condensates[1] , BRANDON BENTON, JEFFREY HEWARD, Georgia Southern University, MARK EDWARDS, Georgia Southern University and NIST, CHARLES CLARK, NIST — We show how the momentum distribution of gaseous Bose–Einstein condensates can be shaped by applying a sequence of standing–wave laser pulses. We present a theory, whose validity was demonstrated in an earlier experiment,[2] of the effect of a two–pulse sequence on the condensate wavefunction in momentum space. We generalize the previous result to the case of N pulses having arbitrary pulse areas and separated by arbitrary time intervals and show how these parameters can be engineered to produce a desired final momentum distribution. We find that several momentum distributions, such as single–state distributions or a range of momentum states which are important in initial state selection in atom–interferometry applications, can be engineered with high fidelity with two or three pulses. We present several examples of such distributions and show how the fidelity improves as more pulses are added. We also give some ideas of how these momentum distributions can be applied to atom interferometry.

12:27PM Z45.00007 Enhanced atom interferometry through quantum information science[1] , MARK EDWARDS, Georgia Southern University and NIST, BRANDON BENTON, MICHAEL KRYGIER, Georgia Southern University, CHARLES W. CLARK, Joint Quantum Institute — New designs for atom interferometers can be inspired by quantum information science (QIS). QIS–inspired atom interferometer (AI) designs have the potential for producing AIs with enhanced sensitivity and robustness. We compare the sensitivity of a standard Mach–Zehnder (M–Z) Bragg AI with an AI whose design is based on the idea of decoherence–free subspaces (DFS).[2] We studied the performance of both atom interferometers using an enhanced version of a previously developed Bragg interferometer prototyping model.[3] This model approximates the effect on the condensate of multiple Bragg pulses separated by time delays using two elements: the effect of a single pulse and condensate evolution between pulses. The overall effect is rapidly approximated by following the steps of the interferometric process. We describe this model and then present the comparison of the performance of the M–Z interferometer with that of the DFS–inspired interferometer.

12:39PM Z45.00008 Eigenvalues of the linearized collision operator for a Bose-condensed gas , ERICH GUST, L.E. REICHL, University of Texas at Austin — Beginning from a Hamiltonian description, we have derived the kinetic equation for the elementary excitations of an interacting gas of bosons with and without a condensate. This kinetic equation is the quantum analog of the Boltzmann equation for a classical gas. Linearizing the kinetic equation about the equilibrium state allows us to treat it as a linear integral operator equation and find its eigenvalues. These eigenvalues give the rates at which different eigenmodes relax to equilibrium. They also provide a relationship between the microscopic properties of the interacting particles and the macroscopic properties of the gas.

12:51PM Z45.00009 Single-Particle Spectral Density of a Bose-Condensed Gas in the Two-Fluid Hydrodynamic Regime , EMIKO ARAHATA, NIKUNI TETSURO, Tokyo University of Science, ALLAN GRIFFIN, University of Toronto — In Bose supefluids, the single-particle Green's function can be directly related to the superfluid velocity-velocity correlation function in the hydrodynamic regime. An explicit expression for the single-particle spectral density was originally written down by Hohenberg and Martin in 1965, starting from the two-fluid equations for a superfluid. We give a new simple derivation of their results. Using these results, we calculate the relative weights of first and second sound modes in the single-particle spectral density as a function of temperature in a uniform Bose gas. We show that the second sound mode makes a dominant contribution to the single-particle spectrum in relatively high temperature region. We also discuss the possibility of experimental observation of the second sound mode In a Bose gas by photoemission spectroscopy.

1:03PM Z45.00010 A new self-consistent perturbation expansion for Bose-Einstein condensates satisfying conservation laws and Goldstone's theorem[1] , TAKAFUMI KITA, Department of Physics, Hokkaido University, Sapporo, Japan — Quantum-field-theoretic descriptions of Bose-Einstein condensates (BEC) have suffered from the lack of self-consistent approximation schemes satisfying Goldstone's theorem and dynamical conservation laws simultaneously. I will report on a new perturbation expansion of the kind developed recently and its predictions on the single-particle and two-particle excitations of BEC. It is shown that the single-particle Bogoliubov excitations are generally different from the two-particle density fluctuations in contradiction to the conclusion of previous studies. I will elucidate some properties of the two distinct modes in connection with Goldstone's theorem on spontaneously broken symmetries. References: T. Kita, Phys. Rev. B80, 214502 (2009); Phys. Rev. B81, 214513 (2010).

1:15PM Z45.00011 Hamiltonian monodromy in the spectrum and dynamics of a spin-1 Bose condensate , AUSTEN LAMACRAFT, University of Virginia — A spin-1 Bose condensate in a magnetic field in the single mode approximation – valid for sufficiently small condensates – represents a rather simple dynamical system. In this talk I will show that there is nevertheless scope for some rather unusual behavior. In particular, this system displays the phenomenon of *Hamiltonian monodromy*, a topological obstruction to the existence of global action-angle variables. I will discuss the signatures of this phenomenon in the classical dynamics and quantum spectrum

1:27PM Z45.00012 Ground States of a Mixture of Two Species of Spinor Bose Gases with Interspecies Spin Exchange , YU SHI, Fudan University — We consider a mixture of two species of spin-1 atoms with both interspecies and intraspecies spin exchanges, and find out the exact ground states in various parameter regimes. We describe the quantum phase diagrams in the space of parameters, including intraspecies and interspecies spin coupling strengths as well as the magnetic field. The boundaries where the ground states are either continuous or discontinuous are determined, with the latter identified as where quantum phase transitions take place. Interspecies spin exchange leads to features beyond the usual ones of a single species of spinor atoms.

1:39PM Z45.00013 Bound states of a localized magnetic impurity in a superfluid of paired ultracold fermions , DAVID PEKKER, Physics Department, Harvard University, Cambridge, Massachusetts 02138, USA, ERIC VERNIER, Departement de Physique, Ecole Normale Supe'rieure, Paris, France, MARTIN ZWIERLEIN, MIT-Harvard Center for Ultracold Atoms, Research Laboratory of Electronics, and Department of Physics, Cambridge, MA 02139, USA, EUGENE DEMLER, Physics Department, Harvard University, Cambridge, Massachusetts 02138, USA — The nature of states formed around localized impurities can be a valuable probe of the properties of a quantum many body system. We propose using a deep optical lattice to localize an impurity atoms. We show that such and impurity atom acts like a magnetic impurity and leads to the formation of a pair of Shiba bound states inside the superconducting gap as well as possible bound states below the Fermi. The properties of these localized bound states can be read out using RF spectroscopy.

1:51PM Z45.00014 Spectroscopy for cold atom gases in periodically modulated optical lattice potential[1] , AKIYUKI TOKUNO, THIERRY GIAMARCHI, DPMC-MaNEP, University of Geneva — Cold atoms in optical lattices are vigorously studied experimentally and theoretically as one of the candidates for a quantum simulator. At the same time, further development of probes to microscopic structure of systems is needed. We propose a novel spectroscopy in cold atom experiments by use of periodic phase-modulation of optical lattice potentials. Corresponding to the statistics of atoms, we formulate the different observables: The energy absorption rate for bosonic atom gases, and the doublon production rate for fermionic atom gases. These observables are formulated within the linear response theory. Interestingly they are given by the imaginary part of the retarded current-current correlation function which is familiar as a quantity corresponding to an optical conductivity. As an example, we discuss one-dimensional Mott insulating state, and also compare our spectroscopy with another known spectroscopy by amplitude-modulation of an optical lattice.

2:03PM Z45.00015 Subwavelength localization of a single atom via resonance fluorescence photon statistics , M. AL-AMRI, The National Center for Mathematics and Physics, KACST, P.O. Box 6086, Riyadh 11442, Saudi Arabia, SHUAI YANG, M. SUHAIL ZUBAIRY, Institute for Quantum Studies and Department of Physics, Texas A&M University, College Station, Texas 77843, USA — A subwavelength localization scheme of a single atom is investigated. The localization is based on the interaction of the two-level atom with a standing wave laser field. The photon statistics of resonant fluorescence depends on the Rabi frequency of the driving laser field and thus the position of the atom inside the standing wave. We show that this dependence can be used to localize the atom to a subwavelength accuracy.
